

## Preparation and magnetic properties of Ni-Cr doped strontium hexaferrite

### ABSTRACT

The Ni-Cr-substituted M-type Strontium Hexaferrite such as  $\text{SrFe}_{12-2x}\text{Ni}_x\text{Cr}_x\text{O}_{19}$ , with  $x = 0.2, 0.4, 0.6, 0.8$  mol% has been successfully prepared by the sol-gel process. The ferrites were systematically investigated by using powder X-Ray diffractometer (XRD), High Resolution Scanning Electron Microscope (HR-SEM) and Vibrating Sample Magnetometer (VSM). The XRD analysis confirms the single phase and lattice constants ( $a$  and  $c$ ), have been calculated from the XRD data using powderX software. The lattice parameter was found to increase with increasing nickel-chromium concentration. Values of coercivity are found to increase up to the substitution level of  $x = 0.0-0.2$  and then decrease slightly while that of saturation decrease continuously with increase in Ni-Cr concentration.
