

HEURISTIC ALGORITHMS FOR THE TRAVELLING SALESMAN PROBLEM

Given a DIRECTED GRAPH $G = (V, A)$ with

- $V = \{1, \dots, n\}$ vertex set
 - $A = \{(i, j) : i \in V, j \in V\}$ arc set (complete digraph)
 - c_{ij} = cost associated with arc $(i, j) \in A$ ($c_{ii} = \infty, i \in V$)
(the costs can take any value)
- Find a HAMILTONIAN CIRCUIT (Tour) whose global cost is minimum (Asymmetric Travelling Salesman Problem: ATSP).

Maximization version

- ATSP is \mathcal{NP} -Hard in the strong sense.
- If G is complete the “feasibility problem” is polynomial ($\{(1, 2), (2, 3), \dots, (n-1, n), (n, 1)\}$ is a feasible tour).
 - * If G is sparse the “feasibility problem” is \mathcal{NP} -Hard
- If G is an undirected graph: Symmetric TSP (STSP)
 - $(c_{ij} = c_{ji} \text{ for each } (i, j) \in A)$
- If $G = (V, A)$ is a sparse graph: $c_{ij} = \infty$ for each $(i, j) \notin A$.
- If the “Triangle Inequality” holds:

$$c_{ij} \leq c_{ik} + c_{kj} \text{ for each } i, j, k \in V.$$

Example 1 (STSP: undirected graph)

$$n = |V| = 8$$

Optimal solution

Optimal solution cost: $Opt = 27$

Example A (ATSP)

Optimal solution

Optimal solution Cost = 16

Applications

- **Vehicle Routing** (sequencing the customers in each route in an urban area calls for the optimal solution of the ATSP corresponding to the depot and the customers in the route).
- **Scheduling** (optimal sequencing of jobs on a machine when the set-up costs depend on the sequence in which the jobs are processed).
- **Picking in an Inventory System** (sequence of movements of a crane to pick-up a set of items stored on shelves).
- ...

INTEGER LINEAR PROGRAMMING FORMULATION

$$x_{ij} = \begin{cases} 1 & \text{if arc } (i, j) \text{ is in the optimal tour} \\ 0 & \text{otherwise} \end{cases} \quad i \in V, j \in V$$

$$\min \sum_{i \in V} \sum_{j \in V} c_{ij} x_{ij}$$

s.t.

$$\begin{matrix} \circlearrowright i \\ \sum_{j \in V} x_{ij} = 1 \end{matrix} \quad i \in V$$

$$\begin{matrix} \circlearrowleft j \\ \sum_{i \in V} x_{ij} = 1 \end{matrix} \quad j \in V$$

$$\sum_{i \in S} \sum_{j \in S} x_{ij} \leq |S| - 1 \quad S \subset V, |S| \geq 2$$

$$x_{ij} \in \{0, 1\} \quad i \in V, j \in V$$

**SUBTOUR ELIMINATION
CONSTRAINTS**
(impose the connectivity
of the solution; $O(2^n)$)

ASSIGNMENT PROBLEM (AP) RELAXATION ($O(n^3)$ time)

$$\min \sum_{i \in V} \sum_{j \in V} c_{ij} x_{ij}$$

s.t.

$$\sum_{j \in V} x_{ij} = 1 \quad i \in V$$

$$\sum_{i \in V} x_{ij} = 1 \quad j \in V$$

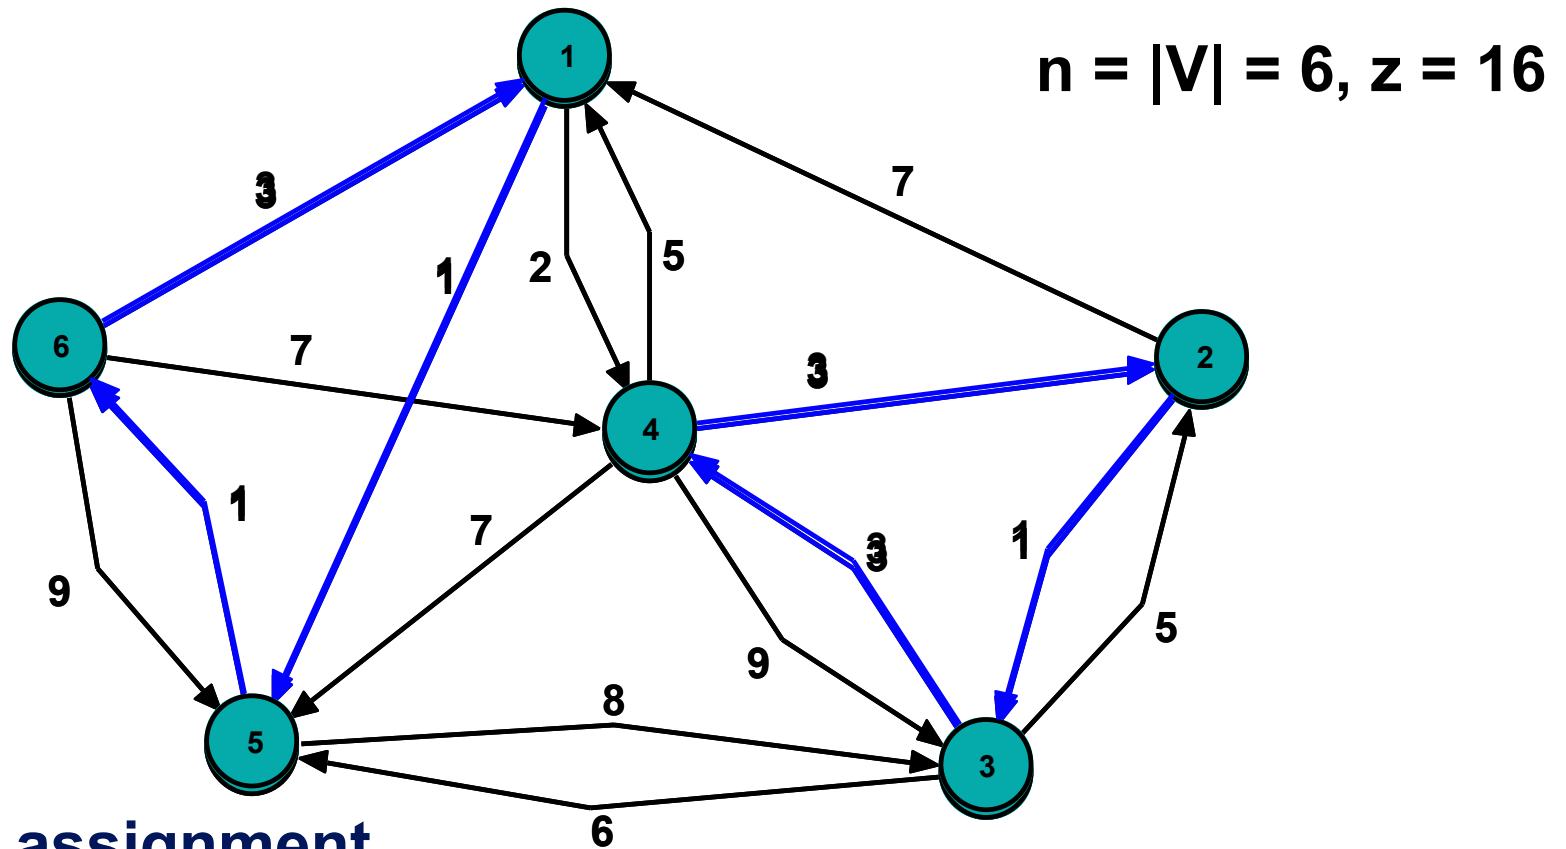

$$\sum_{i \in S} \sum_{j \in S} x_{ij} \leq |S| - 1 \quad S \subset V, |S| \geq 2$$

$$x_{ij} \in \{0, 1\} \quad i \in V, j \in V$$

$$x_{ij} \geq 0 \text{ (LP Relaxation)} \quad i \in V, j \in V$$

* The AP solution is given by a family of “*subtours*” (partial circuits)

Example A: AP relaxation of ATSP

Optimal assignment

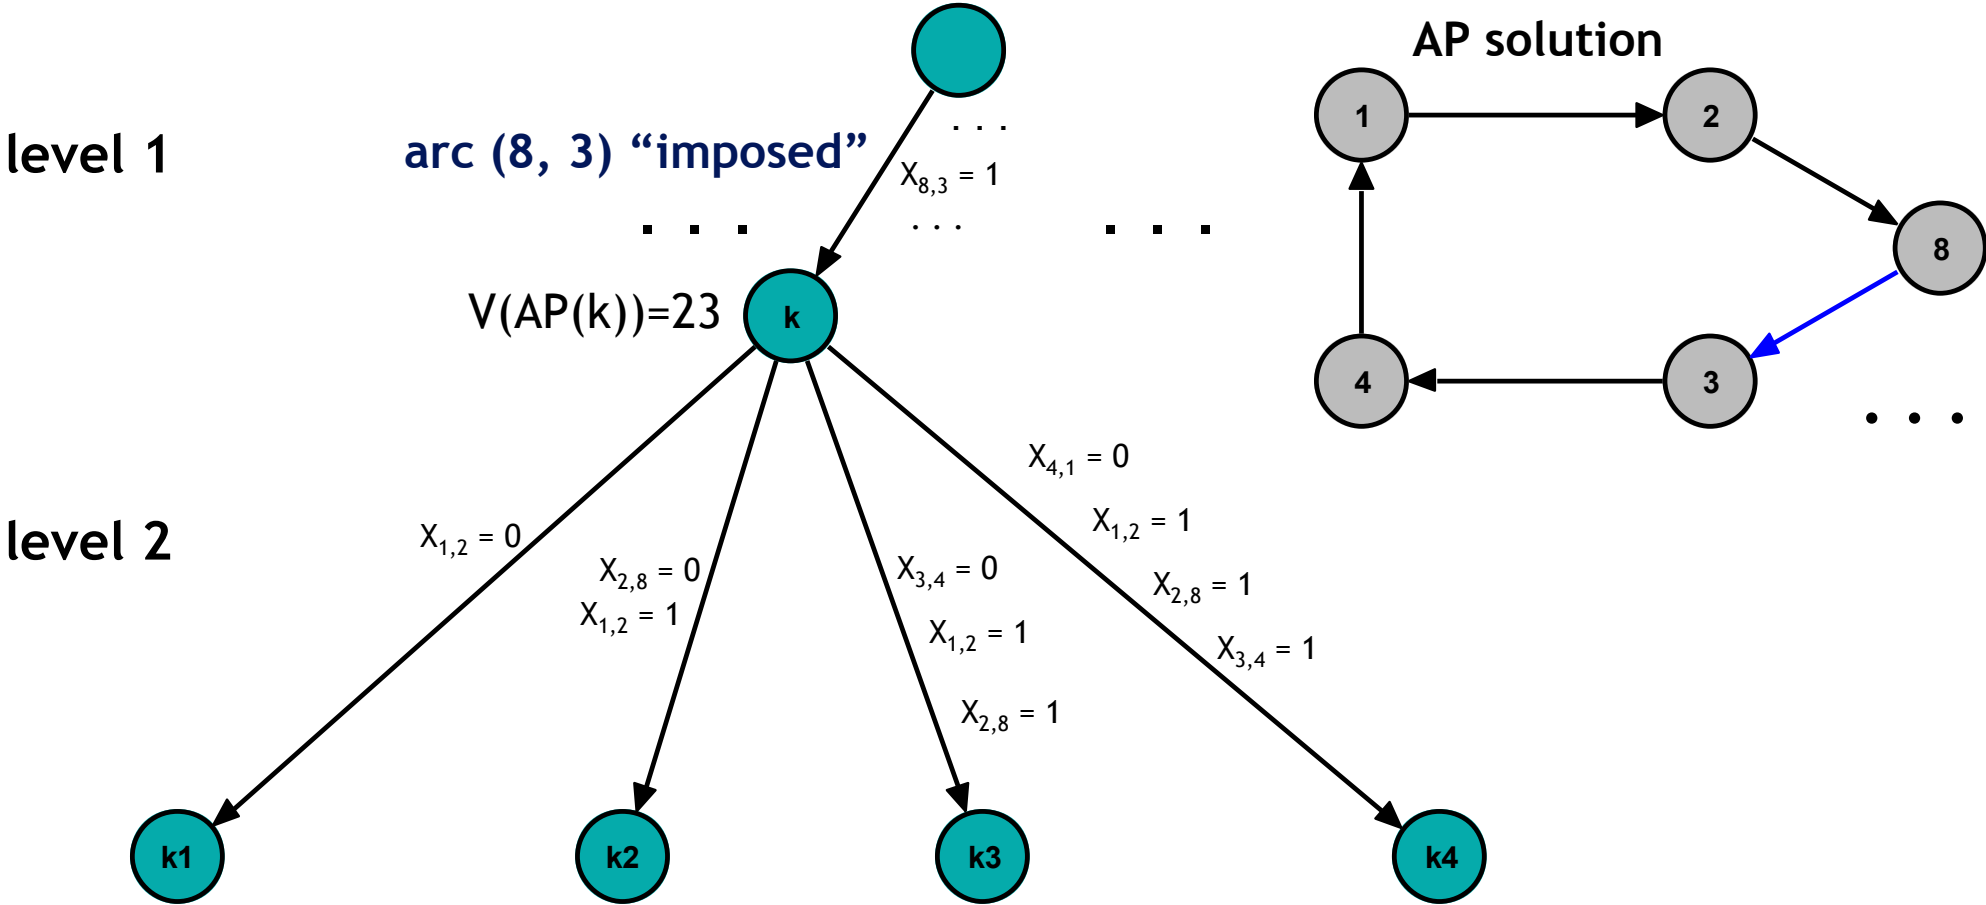

$v(\text{AP}) = 12$ (lower bound)

Optimal solution Cost = 16

BRANCH-AND-BOUND ALGORITHM FOR ATSP

- At each node of the decision tree solve the **AP-RELAXATION** of the corresponding subproblem.
- If the AP solution contains no subtour (feasible solution), “fathom” the node (possible updating of the best solution so far)
- Otherwise: **SUBTOUR-ELIMINATION BRANCHING SCHEME:**
 - Select the subtour S with the minimum number h of not imposed arcs.
 - Generate h descendent nodes so as to forbid subtour S for each of them (by “imposing” and “excluding” proper arc subsets).

BRANCHING TREE FOR ATSP

TWO CLASSES OF HEURISTIC ALGORITHMS FOR TSP

1) CONSTRUCTIVE ALGORITHMS

build a Hamiltonian circuit starting from the input data of the original problem (i.e. n , cost matrix c_{ij}).

2) LOCAL SEARCH ALGORITHMS (tour improvement)

starting from an initial feasible Hamiltonian circuit (tour), try to find a tour with a lower cost through a sequence of “moves” corresponding to “arc exchanges” or “vertex exchanges”.

CONSTRUCTIVE ALGORITHMS (iterative algorithms)

Main ingredients

- a) choice of the “initial partial circuit” (subtour) or of the “initial vertex”;
- b) choice of the vertex to be inserted, at each iteration, into the current subtour (or into the current “path”);
- c) choice of the position of the selected vertex in the current solution.

GREEDY ALGORITHM “NEAREST NEIGHBOUR”

Version for STSP

1. Choose any vertex h as “initial vertex” of the current “path”.
Set $i := h$ (last visited vertex),
 $V' := V \setminus \{i\}$ (set of the “unvisited” vertices).
2. Determine the “unvisited” vertex k “nearest” to vertex i
($k : c_{ik} = \min \{c_{ij} : j \in V'\}$).
3. Insert vertex k just after vertex i in the current path ($V' := V' \setminus \{k\}$);
set $i := k$;
If $V' \neq \emptyset$ (at least one vertex is unvisited) return to STEP 2.
4. Complete the Hamiltonian circuit with arc (i, h) ;
STOP.

GREEDY ALGORITHM “NEAREST NEIGHBOUR” (2)

- ❖ Time complexity: $O(n^2)$.
- ❖ Different choices of the “initial vertex” lead to different solutions.

The same algorithm can be used for ATSP

Example 1 (Alg. Nearest Neighbour)

Initial vertex: 1

Solution cost: 32

Example 1 (Alg. Nearest Neighbour)

Initial vertex: 6

Example 1 (Alg. Nearest Neighbour)

Initial vertex: 7 (second vertex: 6)

Opt = 27

Solution cost: 29

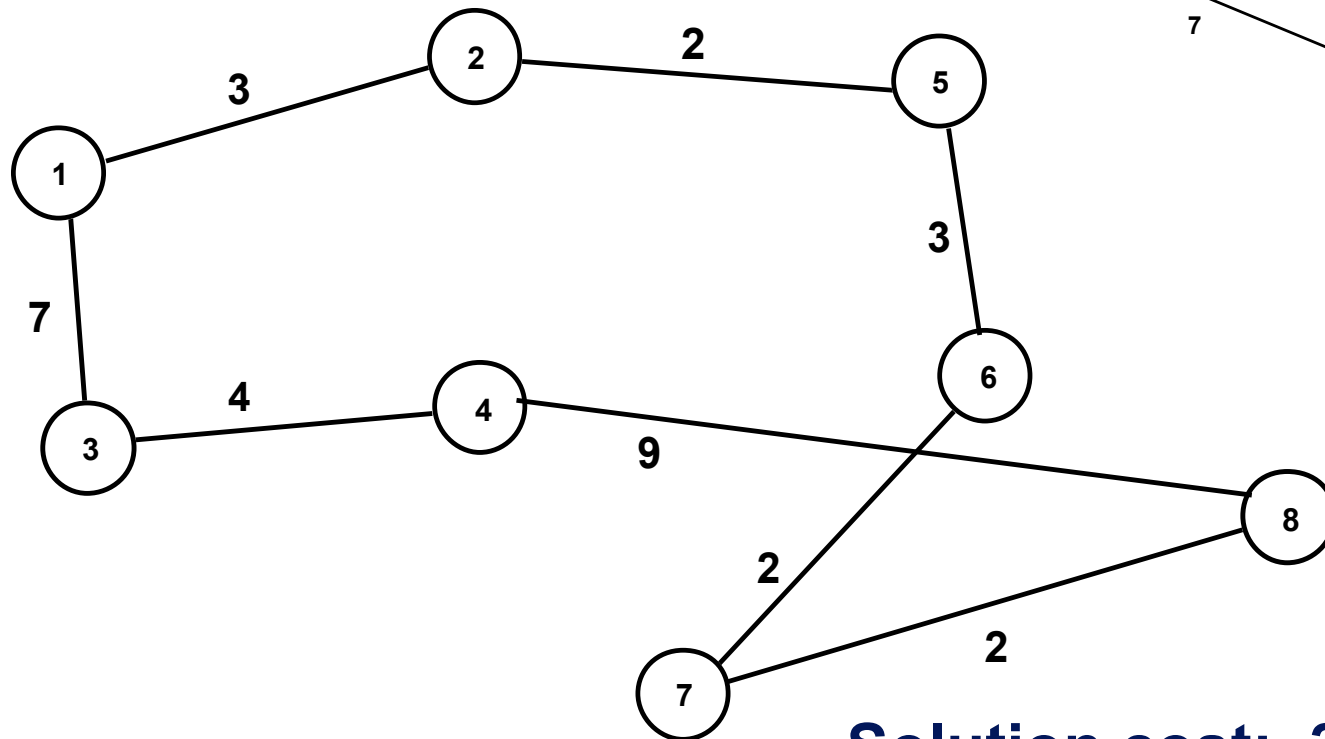

Example 1 (Alg. Nearest Neighbour)

Initial vertex: 7 (second vertex: 8)

Example 1 (Alg. Nearest Neighbour)

Initial vertex: 8

Solution cost: 32

(same solution as that found with
"Initial vertex": 1)

Opt = 27

Example 2

$n = 6$

Optimal solution X

Optimal solution cost: Opt = 33

Example 2 (Alg. Nearest Neighbour)

Initial vertex: 1

Same solution found with "Initial vertex": 2

Opt = 33

Solution cost: 35

Example 2 (Alg. Nearest Neighbour)

Initial vertex: 5

No feasible solution found
(with alternative choices as well)

Opt = 33

Example 2 (Alg. Nearest Neighbour)

Initial vertex: 3

Opt = 33

Solution cost: 33
(Optimal solution)

Same solution found with "Initial vertex": 4, 6

Example B

$n = 8$

Optimal solution

Optimal solution cost: $Opt = 30$

Example B (Alg. Nearest Neighbour)

Initial vertex: 1

Opt = 30

Solution cost: 35

No better solution found with "Initial vertex": 2, 3, 4, 5, 6, 7, 8

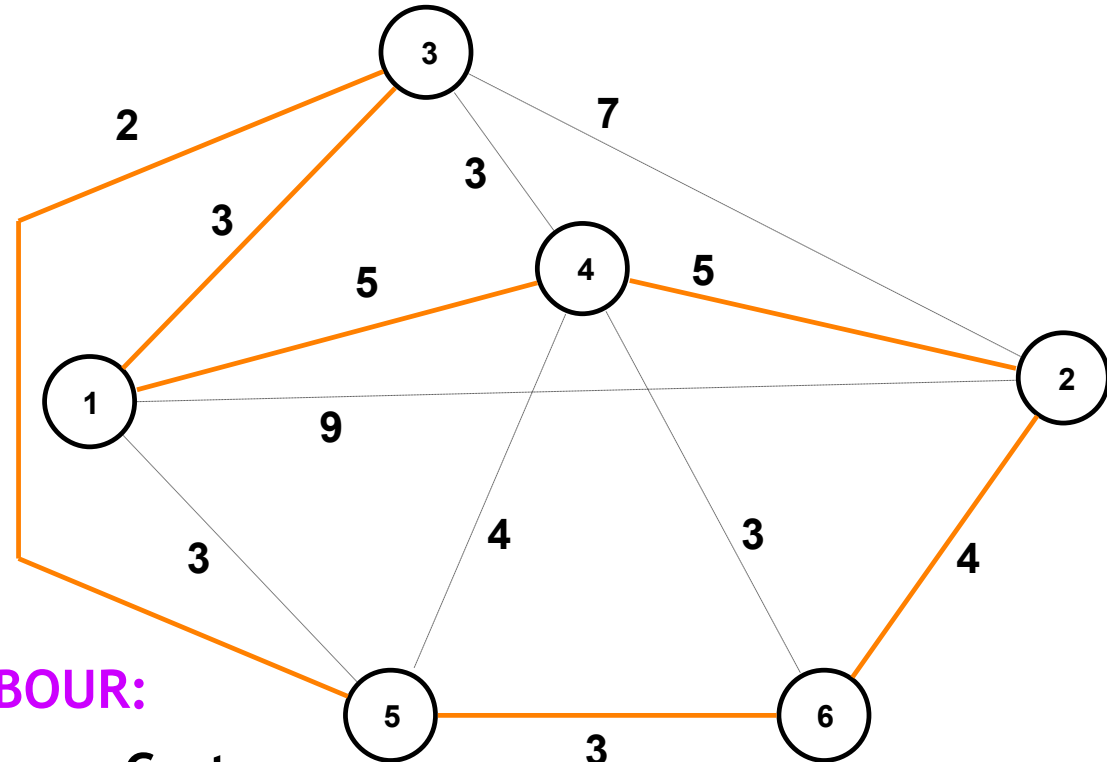

Example 3

when ties are present one can construct alternative solutions

$n = 6$

Optimal solution

Optimal solution cost = 21

ALGORITHM NEAREST NEIGHBOUR:

Initial vertex	Solution	Cost	
1	■	25	(■ 24)
2	■	24	(■ 22, ■ 26)
3	■	24	(■ 25, ■ 29)
4	■	24	(■ 25)
5	■	24	(■ no feasible sol. found)
6	■	22	(... ≥ 24)
