Dataset Documentation for the ERTMS-Oriented Signalling Maintenance in the Danish Railway System

Shahrzad M. Pour

This documentation provides information about the dataset generated as part of a PhD thesis (*Towards Signalling Maintenance Scheduling Problem for European Railway Traffic Management System*) for the signaling maintenance of the Danish railway system. The data instances (M. Pour 2017a; M. Pour 2017b) have been created for the purpose of adaptation to the newest railway signalling standard which is so called European Railway Traffic Management System (ERTMS). The data instances are used particularly in the following research papers:

Clustering of Maintenance Tasks for the Danish Railway System. Published in proceeding of *International Conference on Intelligent Systems Design and Applications*. (Pour and Benlic 2016)

A Choice Function Hyper-heuristic Framework for the Allocation of Maintenance Tasks in Danish Railways. Published in *Journal of Computer & Operations Research*. (M. Pour, Drake, and Burke 2017)

A Constructive Framework to the Preventive signalling Maintenance Crew Scheduling Problem for the Danish Railway systems. Shahrzad M. Pour, Kourosch Marjani Rasmussen, John H. Drake and Edmund K. Burke. Submitted to *Journal of the Operational Research Society*.

Dataset Documentation for The ERTMS-Oriented Signalling Maintenance in the Danish Railway System

The chapter provides explanation of the different types of maintenance tasks in the ERTMS, followed by data definition. Furthermore, it presents information on how the dataset is created and how the software application generates each data file. Data generation is explained through a step by step procedure along with snapshots.

1.1 Signaling maintenance tasks in ERTMS

Signaling maintenance is an essential requirement for the ERTMS implementation. This means that it is necessary to maintain all signaling equipments required for the ERTMS implementation, proportional to any type of railway networks. Overall, there are three different types of signaling equipments for the current ETRMS, including on-board signaling, track-related and pre-installed equipments. Accordingly, three different maintenance tasks are defined, depending on the position of each of these equipments in the system. On-board signaling equipments are the most important components of ERTMS. For installation of such equipments, a complete renewal of the existing system is needed. This can be done by implementation of the European Train Control System (ETCS) which will innately facilitate the maintenance of on-borad equipments through enhancing the accessibility/portability of these devices for the maintenance purpose. This means that the equipments can be transferred directly to the workshop for maintenance which is much easier than the maintenance of the signaling equipment installed along the track, positioned far from the maintenance location. Using this way, we can ensure that the related tasks such as on-site maintenance / inspection of the equipments, installed on the railway tracks, are no longer required.

The second type of tasks contains track-related equipment like balises and point machine for which the crew/engineer is needed for doing the maintenance at the track position. Tasks related to the tracking equipments such as balises and point machines need the crew/engineer support for maintaining the equipments at the the track position. Other than the aforementioned tasks, there are maintenance tasks which need to be handled in the installation points, regardless of whether they are track-related or signaling-related. Examples of such tasks that are required to be performed on-site (in the geographical position of the track) include maintenance of driver screen in the train, the antenna mounted on the top of train and the equipments installed in the radio block center. According to the above categorization, we designed three different set of problems. Each of these sets is different from the other sets according to the location of the maintenance tasks. Each sets of data instances are geographical data indicating tasks and crew locations, task duration, and positioning of the time windows.

1.2 Dataset

Each dataset consists of a set of geographical points, demand, time window constraint, duration and type as below. All the geographical points are located inside the biggest region of Denmark, Jutland. To standardize our dataset, we follow the file format from standard benchmark test-sets for Vehicle Routing Problem Time Windows (VRPTW), introduced by Solomon in 1987 (<http://w.cba.neu.edu/~msolomon/problems.htm>). Since the maintenance planning in Denmark has a decentralized maintenance structure, the crew are located in different locations in the Jutland, meaning that they start their daily tasks from their home location rather than a single depot/station. According to this, the locations of the crew are different from each other in the dataset. We have two sets of rows in each dataset, indicating the number of crew, the number of tasks and their specifications, respectively. The first set of rows is related to the crew which are located in different geographical locations over the region and are distinguished by setting the demand and the duration of the row by zero. In summary, in this set of rows we have the below information:

- Index
- Crew geographical coordination
- Demand = 0,
- time window $[e_0, l_0]$
- Duration = 0,
- Type = 0,

The time window for each crew is used for working hours of the related crew. In this way, we can differentiate between full time and half time crew.

The second set of rows belongs to the maintenance tasks consisting (or including) of the geographical coordination, and the demand of the tasks, used for the synchronization tasks. If a demand of task is one, it means that the task should be done by one crew, if it is two, it means that they should jointly do the task and so on.

- Index
- Maintenance task geographical coordination
- Demand $q_i > 0$,
- Time window $[e_i, l_i]$,
- Duration = 0,
- Type = 0,

Dataset Documentation for the ERTMS-Oriented Signalling Maintenance in the Danish Railway System

The locations of the crew are identical for all problems, while the set of the maintenance tasks have been randomly generated by utilizing Google Map API in the following categories:

- Random points on whole Jutland area
- points on the railway's lines in Jutland
- Mixed of random points and the exact points on the railways

In order to test the scheduler on different time-horizons, each set of problems has four different numbers of tasks which should be done by a certain number of crews: 100, 500, 1000, and 5000. These numbers are chosen respectively for the number of maintenance tasks needed to be done on daily, weekly, monthly, and half yearly basis according to the current scale of maintenance planning in Denmark. In addition to different maintenance task locations, this helps us to evaluate our approach on clustering the maintenance tasks in different situations when the coordination of the tasks are randomly scattered through the area, are densely located in the railway lines and are a mixture of scattered and on-track points. Figure 1.1 is a snapshot of the text file of one of data instances.

Figure 1.1: Snapshot of the text file for one data instance

1.3 Data Generation

We have generated our dataset through three following steps:

1. Finding the Jutland boundary
2. Finding the geographical points on the rail track
3. Generating random points for each dataset

1.3.1 Finding the boundary of Jutland

We have used a drawing application for polyline, polygon, a polygon with holes, rectangle, circle, marker(icon), and direction(route, path). This application uses the Google Maps API Version 3 (V3). It has all the features of Google Maps MyMaps and has direct access to the code for the shapes (overlays). While we drew and created a map of the region (Jutland), KML or Javascript code was presented in the text-area. We copied KML code and pasted it into a text editor. Then we had a KML file including all of the geographical points of the boundary.

Figure 1.2 shows the interface of the Google Maps API v3 Tool and the created boundary of Jutland through this application. For more information, the reader is referred to <http://www.birdtheme.org/useful/v3tool.html>

Dataset Documentation for the ERTMS-Oriented Signalling Maintenance in the Danish Railway System

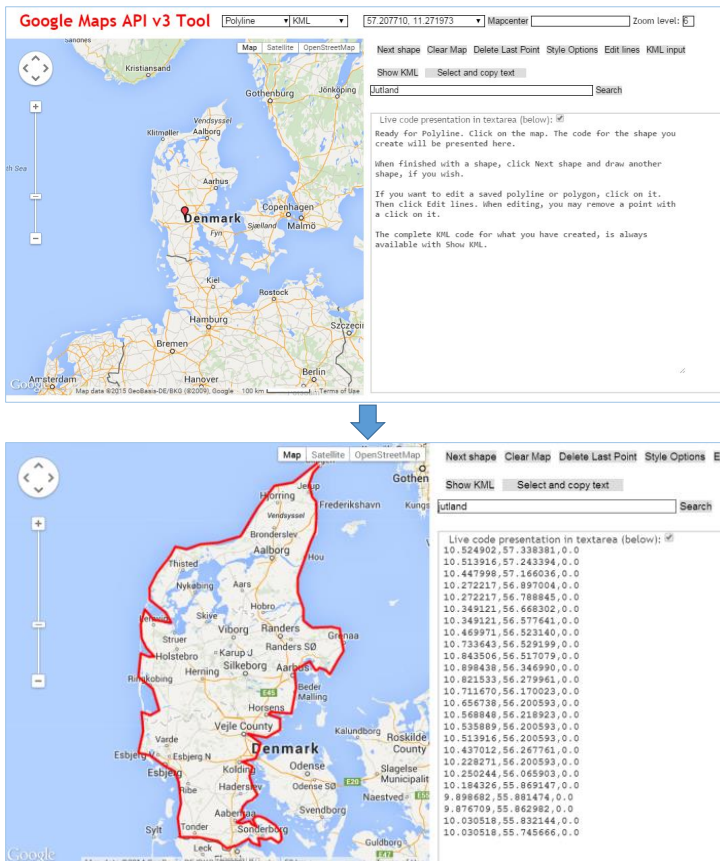

Figure 1.2: Interface of the Google Maps API v3 Tool and the created boundary of Jutland through this application

1.3.2 Finding the geographical points on the rail track

In order to generate random points, particularly on the rail track, we prepared a list of routes from different Origins and Destinations. The list covers the whole track routes on the Jutland region. Figure 1.3 shows some of the routes included in the whole set of routes.

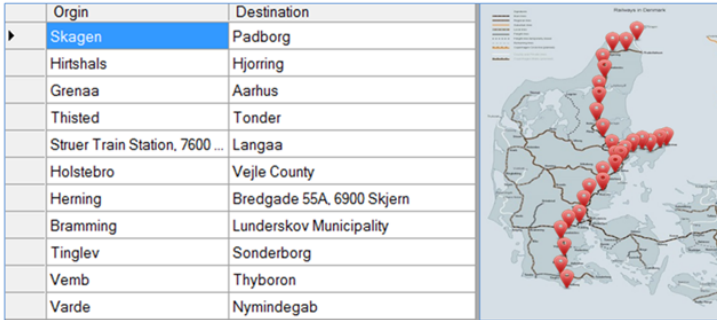

Figure 1.3: *The included routes*

1.3.3 Generating random points for each dataset

For generating random points inside the boundary, we have used the JavaScript (or a JavaScript code) from (shivrajawat 2014). The boundary of the region is given as an input to the script. The script, in turn, generates a number of desired points inside the boundary.

For creating a random set of problems, we have generated a maximum set of random points through the JavaScript (or the aforementioned JavaScript code). Accordingly, we have chosen the number of requested tasks for each problem randomly through a C# random generator function. Similarly, for the problems with tasks on the track, we have chosen the number of tasks required from the collected points on different track routes using the same random function in C#. Figure 1.4 represents the schematic picture of the chosen random tasks after applying the procedure discussed above.

Dataset Documentation for the ERTMS-Oriented Signalling Maintenance in the Danish Railway System

Figure 1.4: The schematic picture of the chosen random tasks

1.3.4 Software Application

To generate each data file, we have developed a software using Microsoft Visual Studio C#.Net. Figure 1.5 represents the user interface of our application. The input contains the number of the tasks and the mode of geographical locations. The output is a text file with the Solomon dataset format. The other parameters in each data have been considered as constant values in the code. For example, the number of the crew has the constant value of 8 in all data instances. However, the software can be updated to get every parameter as input, later on.

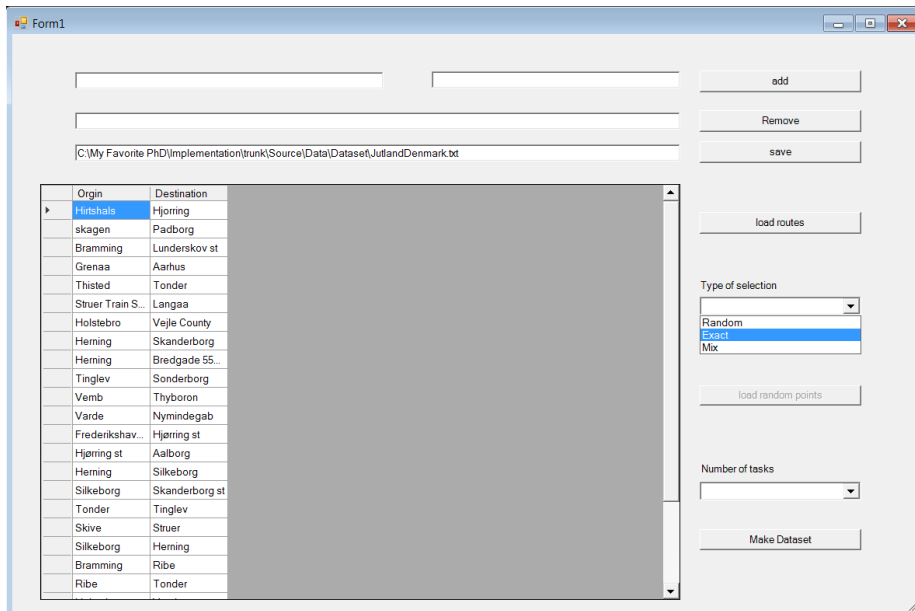

Figure 1.5: *The user interface of the application*

In order to generate the geographical coordinations exactly on the railway tracks, the software makes use of previously added routes on the rail track of Jutland. However, the software gives possibilities to add additional routes, including more regions into the dataset. Accordingly, to generate the geographical coordination, randomly scattered all over the network, the software loads a pool of generated random points in Jutland by the JavaScript and randomly chooses the number of needed points depending on the size of the dataset. Finally, for generating a mixture of points, the software randomly generates points (By the `Random.Next()` function in C#) for our two sets of mentioned geographical sources.

1.4 Adopted Java Script code

```
// source: https://github.com/shivrajawat/chicagogit/blob/
// master/locationselector.php
var map;
var boundaryPolygon;
function initialize() {
