# THE GENETIC CHARACTERISTICS OF CEPHALIC ABNORMALITY AND ITS AQUACULTURE IMPLICATION IN CLARIAS GARIEPINUS (BURCHELL 1822) 

Aremu, A; Aboh. A.A.Woru. D and Isa Shuaibu<br>National Institute for fresh water fisheries Research<br>Aquaculture Biotech Department.<br>P.M.B 6006, New Bussa

#### Abstract

S Cephalic abnormality in nine mating groups involving Clarias gariepinus with cephalic abnormality, non Cephalic and Maiduguri origin were investigated to determine the level and the genetic basis of the occurrences and its aquaculture implication. The highest mean percentage survival in a Cephalic crossed with non cephalic group was $68.6 \%$ whereas the last mean percentage survival was $25.7 \%$ in the group of Maiduguri cross with Maiduguri parent. Cephalic abnormality was observed in the crosses with both female and male cephalic with a total frequency ranging from $0 \%$ to $70.8 . \%$. The least number of cephalic abnormality was $18.5 \%$ which involved a cross of non cephalic with cephalic, and the highest was $70.8 \%$. This level of cephalic abnormality shows that the defect was hereditary. This result implies that, the genetic factor is a major contributor in the feature of cephalic abnormality in clarias gariepinus.

Keywords cephalic, Non-cephalic, abnormality cephalic hereditary.

## INTRODUCTION:

The African Clariid catfish, especially the species of clarias and Heterobranchus, are candidates for commercial aquaculture in African, they are mostly used under controlled condition in fish hatcheries.
In addition, hatchery operators hardly have room for exchange of genes with collections from the wild or other hatcheries, thus encouraging morphological abnormalities in hatchery breed catfish (Aluko et al 2001). Some of the most important problems in fish culture is high rate of body deformation and abnormalities. Deformities represent a considerable problem since the injury may reduce product quality and lead to economic losses for the fish farming industry. Communications describing the incidence and inheritance of morphological trait in commercial valuable fish are increasingly being documented. A lot of studies have been carried out among Cyprinids, Salmonids, Casostomils, percids, Silurids as well as in aquarium fish such as the cepridontidae and the peocilidae (Kirpichnikov, 1987). Aberrations commonly described include; scaling pattern, fin shape, skeletal deformity, eye abnormality and colour differences. Morphological abnormalities affecting pectoral and ventral fins have been reported in some second generation backross hybrids of clarias and Heterobranchus species (Aluko, 1998). Other aberrations that affect the dorsal, adipose, caudal and anal fins as well as the cephalic region and the shape of the abdominal region have been observed in hatchery breed African catfish, clariid species (Aluko et al. 2001).

The reasons for this deformation in fishes are barely understood. There is evidence of both environmental and genetic causes. Blaxter et al (1974) induce skeletal abnormalitic: with nutritional deficiencies experimentally. Environmental factors may affect egg during vitellogenesis or incubation, or hatched larvae in rearing tanks. Malformation is induced when eggs are incubated in excessive densities or exposed to mechanical shock (Porhmaranz 1974). Other environmental factors such as density of eggs, mechanical or thermal shocks, presence of pollutants in the water, radiation, salinity, oxygen depletion and light intensity have also been reported to cause aberration in development Caris and Rice, 1990).
Van valen (1962) considered that the presence of asymmetrical abnormalities is an external symptum of a weakness in the buffering power of the polygenetic systems under unfavourable environmental conditions. In some natural populations of fish, frequency of abnormalities has been shown to increase with age. This suggests that unfavourable environmental factor notably toxin pesticides and other polluting agents may induce abnormalities of any stages of the fish life (Valentine, 1975). Finally, the genetic basis of the ceplalic abnormality of African catfish; clarias gariepinus and its aquaculture implication has not been reported before in the literature.

The aim of this study was therefore designed to determine whether environmental or genetic factor is responsible for cephalic abnormality in clarias gariepinus and the implication of cephalic abnormality to aquaculture.

## MATERIALAND METHODS

Induced spawning and incubation: The brood stock of clarias gariepinus were obtained from Fish Genetic Experimental tanks (NIFFR), which can be described as cephalic abnormality (CP), Non-cephalic (NC) and Maiduguri Origin (Mai) were selected. Induced Spawning were carried out by injecting only the females of each combinations with ovaprim hormone at a single dosage of $0.5 \mathrm{ml} / \mathrm{kg}$ body weight.
After latency period of 12 hrs the males of each combination were sacrificed and their tastes were removed, cleaned and kept in a covered Petri-dishes. Slight-pressure were applied to the abdomen of the females to release their eggs into separate Petri-dishes. These tastes were cut opened with a sterilized razor blade and the spermatozoa were diluted with saline. The eggs were then fertilized by mixing them with spermatozoa with the aid of sterilized dry feather.
From those combinations, nine generic groups were formed;
Ceplalic (F) $\times$ Cepjalic (m) (CP x CP)
Non cephalic (f) $x$ Non Cephalic (m) (NCP $\times N C P$ )
Maiduguri (f) $\times$ Maiduguri (m) (Mai x Mai)
Cephalic (f) $\times$ Non Cephalic (m) (CP $\times N C P$ )
Cephalic (f) $\times$ Maiduguri (m) (CP $\times$ Mai)
Non Cephalic (f) $x$ Cephalic (m) ( $\mathrm{NCP} \times \mathrm{CP}$ )
Non Cephalic (f) $x$ Maiduguri (m) (NCP x Mai)
Maiduguri (f) $\mathrm{xCephalic}(\mathrm{m})(\mathrm{NCP} \times \mathrm{CP})$
Maiduguri ( f ) $\times$ Non cephalic ( m ) (Mai X Cp )
All these series of combinations were carefully transferred into well aerated glass aquarian of $60 \mathrm{~cm} \times 30 \mathrm{~cm}$ size tanks immediately after fertilization with the following water quality parameters, dissolved oxygen 5 mg $/ 1, \mathrm{pH} 7.4$, and temperature $26.1^{\circ} \mathrm{C}$.
Within the 24 hrs , the hatchings were observed swimming around the base of aquaria. The percentage hatchability of each the combinations were taken.

## REARINGINDOOR

Immediately after completion of hatchlings, one hundred numbers (100) of hatchlings were randomly picked out from each combination and stocked in each aquarium with duplication making total of 18 aquaria. The aquaria was filled with water to the depth of $2 / 3$ of the containers. During the indoor rearing for a period of 11 days, these fry were fed once daily with live mixed 200 plankton till the time of stocking out door. Daily survivals were monitored by individual counting of the fry.

At the age of 1 day, 70 numbers from each replicates of the combination were re-selected and stocked in $2 \mathrm{~m} \times 2 \mathrm{~m} \times 2 \mathrm{~m}$ concrete tanks, the mean initial weight and length were taken at stocking. During the rearing out-door, the fry were fed with compounded $45 \%$ crude protein.

## DATACOLLECTION

Data collections were made by taken weight and length on weekly basis for a period of 3 weeks. The length measurements were carried out with the aid of metric ruler while the weight measurements were carried out with Acculab 333 of 0.1 g sensitivity.

[^0]value. Group 2 NCP x NCP gave 71.0\% in door survival and $37.1 \%$ outdoor survival value. In group 3 MAI x MAI gave $80 \%$ indoor survival and $25.7 \%$ outdoor survival value. The group 4 gave $88 \%$ indoor survival and $68.6 \%$ outdoor survival value, which is the highest percentage survival value recorded. From group 5 CPx MAI gave $81 \%$ indoor survival value and $54.3 \%$ survival value $56 \%$ while outdoor percentage survival value was $38.6 \%$. From 7 NCP x MAI gave $63 \%$ for indoor survival value and $47.2 \%$ gave outdoor survival value. From group 8 the indoor value and outdoor survival value read $71 \%$ and $30 \%$ respectively. Group 9, the indoor percentage survival value $62 \%$ while outdoor survival value was $30 \%$.
Table 1 figure 3 shows the percentage of cephalic abnormality value among the mating groups. The cephalic abnormality recorded in the group involving CP x CP gave $38.5 \%$ of cephalic abnormality.

In the group 3 involving MAI x MAI has zero \% cephalic abnormality was as high as $70.8 \%$ which was the highest number of abnormality occurrence. In group $5 \mathrm{CP} \times$ Mai gave $34.2 \%$ as cephalic occurrence. The cross involving NCP x CP (group 6) gave $18.5 \%$ as the lowest cephalic abnormality. Group $7 \mathrm{NCP} \times$ MAI gave $36.4 \%$ cephalic abnormality. From group 8 involving MAI $x$ CP give $47.6 \%$ cephalic abnormality. From group 9, MAIX NCP has no record of any abnormality.
Statistical Analysis
Student T-test was used to test whether there is significant difference in the indoor and outdoor survival, cephalic and non cephalic. It was observed that there is significant different. The mean is $p>0.05$ level of significant which implies that there is no significant different between cephalic and non cephalic frequencies.

Fig.2: Final percentage survival of outdoor Cephalic tish

Fig. 3: Percentage survival of Cephalic abnormality and weight (g)

Fig. 4: Percentage survival of Cephalic abnormality and

From this studies the hatchability percentages of these series of combinations, Its ranges from $67.484 .6 \%$ which the average was $76 \%$, this records is still acceptable aqua culturally.

In table 1, the combinations that involves cephalic parents did well with the records of more than $70 \%$ hatchlings, likewise the other combinations that involves parental female; NCP performed well, but the MAI combines with others did not performed well like when MAI x MAI because from the hatchability results it has the highest percentage of $84.6 \%$.

As regardš to heritability of cephalic abnormality, it can not be established at this level or to conclude that the cephalic abnormality does not affect the hatchlings capabilities of each of those combinations that
involves.
After the hatching, the hatchings were decentralized for proper monitoring and rapid growth in the laboratory at the rate of 100 fry pen tank of $60 \mathrm{~cm} \times 30 \mathrm{~cm} \times 30 \mathrm{~cm}^{3}$ in replicates from table 2, as regards to indoor survival which lasted for 1 week and 4 days, from the combination of $\mathrm{CP} \times \mathrm{NCP}, 88 \%$ was recorded as the survival percentages and the lowest percentage was $62 \%$ for MAI x NCP. From the assessment, it was observed that all the combinations that has female Contribution of CP has a better growth performance; the parental CP has $70 \%$, CP x NCP $88 \%$ while the last combination with CP female has $81 \%$ hatchability percentage. This result show that cephalic female favors both better growth and higher survival in door. The average weight gains in all the combinations that involves female CP was 0.2 g per day. The outdoor survival also a range from $25.7 \%$. to $68.6 \%$ this record is not good enough for aquiculture practices. The combination $\mathrm{CP} \times \mathrm{NCP}$ has the highest survival value while MAI x MAI has the lowest survival value. This information clearly shown that cephalic defect does not affect growth and survival at early stage of their lives.
The heritability of cephalic defect might not yet reach lethal level, in another hand the genetic code (DNA) is yet to be decoded before it will start to have negative effect on the survival especially. This was also in accordance with the work of Berra and AU , (1981), where he stated that, anomalies caused by genetic ulteration result from mutation or recombination's on DNA and these alterations are heritable unless they are lethal. That is; as long as there are genetic mutation which has already affected the phenotypes structurally of the fish will one time or the other affect the genotype or vice versa. But with this records CP and NCP were batter than the rest of the combinations
Couch et al (1977) conducted an experiment by inducing vertebral deformities, which wash to confirm that, environment and genetic factors can all cause abnormality, but in this case such environmental deformities will never be transferred to an offspring from such animal.
During the out-door management, from the first to fourth week, it was impossible to detect any form of abnormalities, but on the fifth week, were able to see those with cephalic defect and those without and their frequencies were taken.
Schapsenduns (1992) agreed that there are many factors that can cause abnormalities which heredity is one of them. Any mutation is a change in the DNA, resulting from exposure to mutagens e.g. (Radiation and chemical) or an error in replication during cell division
Recombination created new combinations of allelies for genes on the same chromosome (crevasses. 1983) This cephalic information in this fish has been coded in the genes, which gave it an enablement to be transferred to their offspring. All the combination with cephalic defect has highest frequencies of cephalic inheritance especially those with CPX CP and those with CP XNCP. This Non cephalic parents but having Cephalic traits were never totally free from cephalic abnormality but also such information with it from the level of cephalic inheritance in the combination of $\mathrm{CP} \& N C P$ which is $70.8 \%$ as it is between $\mathrm{CP} \times \mathrm{NCP}$ shows that there were genetic information in stock which causes the abnormalities, also such information by DNA recombination according to (Chevassus 1983) are in stock within the genetic locus of Non cephalic which one of it parents was cephalic, and that is why their offering were not void of cephalic abnormality.

Comparing this result with Maiduguri origin the level of cephalic abnormalities were reduced. From the combination that involves MAI and CP, it has $47.6 \%$ cephalic occurrence which is in agreement with Mendel's experiment.

## CONCLUSION

This work shows the comprehensive effect of cephalic abnormality on Africa catfish Claria ganiepinus and the possible ways of eradicating it without the use of prophylaxis medication. The aquacultural implication of whatever breeding programme we are carrying out is very important. In this case, in our world today we are so much careful on what we consumes, why because its side effect. Like it is generally believe that diseases are rarely transferred from fish to man, but when the deformity is glaring, everybody will like to run away from it. And let assume that more than $70 \%$ of table size fish from a particular fish farm are cephalic, there is a tendency that many of those fish will not be sold, and some of it will still die due to that cephalic abnormality defects. All these will amount to aquaculture loss. In another hands if such fish farm deals in fingerlings productions, there will be reduction in there patronage, because the moment their customer discovered that the fish bought from them are not acceptable and it also goes with mortalities which are all due to cephalic defects, in no time if correction is not done, such fish farm may fold up, which can also leads
cephalic abnormality can be eradicated and this can be achieved by proper breeding programme couple with understanding of genetic of selective breeding. Crossing the parent cephalic with other parent that does not have a sign of cephalic traces in their generation will reduces cephalic problem, but for total eradication, to break the heritability you dare not cross any fish with cephalic defects together but rather culled them.

 IVlew bris of stueeg on boens

[^0]:    RESULTS
    Table 1 and Appendix 1 shows the percentage hatchability of eggs for nine generic groups. Among these crosses (group 1) which involves CP x MAI CP gave $82.5 \%$ hatchability. The cross involving NCP x NCP (group 2) gave 67.4\% hatchability. The percentage hatchability in + Mai O Mai (group (3) gave 84.6\%, which is the highest percentage of the hatchability. The cross involving CPx NCP (group 4) gave $73.8 \%$ hatchability. The cross involving Cp $\times \mathrm{MAI}$ (group gave $76.3 \%$ hatchability. From (group 6) $\mathrm{NCP} \times \mathrm{CP}$ gave $75.4 \%$. Group 7 involving NCP $\times$ MAI gave $73.5 \%$ while that of group 8 and 9 involving MAI $\times \quad$ CP and MAIx NCP gave $70.1 \%, 72.2 \%$ respectively.
    Table 1, figure 1, Appendix 2 and 3 shows the indoor and outdoor daily survival and percentage survival of fry for each day for nine generic groups. Group $1 \quad \mathrm{CP} \times \mathrm{CP}$ gave survival of $70 \%$ and $35.7 \%$ outdoor survival
