ABSTRACT

Eurocode 4, part 1.2 (CEN, 2005a), proposes the assessment of the cross section using the method of the four components (flanges, web, reinforcement and concrete) to determine the resistance and stiffness under fire conditions. This simple calculation method (informative annex G) should be validated by numerical simulation. This numerical study aims to validate new simple formulae with respect to the calculation of the plastic resistance to axial compression and the effective flexural stiffness of the cross section with respect to the weak axis. New simple formulas will be proposed to determine the flange average temperature, the residual height and average temperature of the web, the residual cross section and average temperature of concrete and also the reduced stiffness and strength of reinforcement. This new formulae agrees with the numerical results and increases safety level of the fire resistance of partially encased sections.

Keywords: Partially Encased Sections, Numerical simulation, Simple calculation model, Fire, Composite Steel and Concrete.

INTRODUCTION

Partially encased section members are usually made of hot rolled steel profiles, reinforced with concrete between the flanges. The composite section is responsible for increasing the torsional and bending stiffness when compared to the same section of the steel profile. In addition to these advantages, the reinforced concrete is responsible for increasing the fire resistance. The fire resistance of partially encased sections depends on the temperature effect in each component. According to Eurocode 4, Part 1.2 (CEN, 2005a), the fire resistance can be evaluated by the four components method (the flanges of steel profile, the web of steel profile, concrete and reinforcement) when submitted to standard fire and for different fire resistance classes (R30, R60, R90 and R120). This study aims to assess the parameters of Annex G: average temperature of the flange, part of the web to be neglected, residual area and average temperature of the concrete and the reduction of reinforcement mechanical properties. To study the effect of fire, two types of cross section were selected, corresponding to a set of cross section geometry: IPE ranging from 200 to 500 and HEB ranging from 160 to 500. Fig. 1 represents the generic partially encased section, identifying the four components and showing the finite element mesh used. The nonlinear solution method (ANSYS) was used to evaluate the temperature field. The finite element method requires the solution of Eq. 1 in the cross section domain and Eq. 2 in the boundary. In these equations: T represents the temperature of each material; ρ defines specific mass; $C_{p(T)}$ defines the specific heat; $\lambda_{(T)}$

defines the thermal conductivity; α_c specifies the convection coefficient; T_g represents the gas temperature of the fire compartment; Φ specifies the view factor; ε_m represents the emissivity of each material; ε_f specifies the emissivity of the fire; σ specifies the Stefan-Boltzmann constant. It is assumed the use of standard fire curve ISO 834 (ISO, 1999) around the cross section (4 exposed sides).

$$\nabla \cdot (\lambda_{(T)} \cdot \nabla T) = \rho_{(T)} \cdot C_{p(T)} \cdot \partial T / \partial t \quad (\Omega) \tag{1}$$

$$\left(\lambda_{(T)} \cdot \nabla T\right) \cdot \vec{n} = \alpha_c (T_g - T) + \Phi \cdot \varepsilon_m \varepsilon_f \cdot \sigma \cdot (T_g^4 - T^4) \quad (\partial\Omega) \tag{2}$$

Fig. 1 - Partially encased section: Model, parameters and approximation.

PARTIALLY ENCASED SECTIONS

The cross sections were designed according to the tabulated method applied to column design in fire conditions (CEN, 2005a), considering the minimum reinforcement ratio $A_s/(A_s + A_c)$, the minimum concrete cover dimensions (u) and the minimum cross section dimensions (b, h).Table 1 presents the main dimensions, in particular the number of rebars, the diameter of each rebar Φ and the concrete cover dimensions in both principal directions, u_1, u_2.

Table 1 - Section properties.

BALANCED SUMMATION METHOD

Eurocode 4 part 1.2 (CEN, 2005a) enables the calculation of the effective flexural stiffness of the cross section around the weak axis and the plastic resistance to axial compression, considering the contribution of the four components, assuming the section exposed to standard fire by four sides. Each component should be assessed by temperature evolution in each component, affecting the resistance of the cross section. The design value of the plastic resistance to axial compression, $N_{fi,pl,Rd}$ and the effective flexural stiffness of the cross-section, $(EI)_{fi,eff,z}$ may be obtained by a balanced summation model, according to Eq. 3.

$$N_{fi,pl,Rd} = N_{fi,pl,Rd,f} + N_{fi,pl,Rd,w} + N_{fi,pl,Rd,c} + N_{fi,pl,Rd,s}$$
$$(EI)_{fi,eff,z} = \varphi_{f,\theta}(EI)_{fi,f,z} + \varphi_{w,\theta}(EI)_{fi,w,z} + \varphi_{c,\theta}(EI)_{fi,c,z} + \varphi_{s,\theta}(EI)_{fi,s,z}$$
(3)

The weighting parameters $\varphi_{i,\theta}$ depend on the effect of thermal stresses. The values are given in table 2. The contribution of each component depends on the temperature effect. This simple calculation method allows the fire design of partially encased columns.

Table 2 - Reduction coefficients for bending stiffness around week axis.

Standard Fire resistance	$\varphi_{f,\theta}$	$\varphi_{w,\theta}$	$\varphi_{c,\theta}$	$\varphi_{s,\theta}$
R30	1,0	1,0	0,8	1,0
R60	0,9	1,0	0,8	0,9
R90	0,8	1,0	0,8	0,8
R120	1,0	1,0	0,8	1,0

Flange Component

The average temperature of the flange, $\theta_{f,t}$ may be approximated by Eq. 4, assuming the empirical coefficients k_t and the reference value $\theta_{0,t}$ (CEN, 2005a).

$$\theta_{f,t} = \theta_{0,t} + k_t(A_m/V)$$
(4)

Web Component

The effect of fire affects the resistance of the web, by heat conduction. The reduction of the height of the web in Fig. 1b), $h_{w,fi}$, part to be neglected in fire design, may be calculated according to Eq. 5. The parameter H_t is also defined accordingly (CEN, 2005a).

$$h_{w,fi} = 0.5(h - 2t_f)(1 - \sqrt{1 - 0.16(H_t/h)})$$
(5)

Concrete Component

The direct effect of the fire on both sides of the section and the indirect effect by heat conduction allow to specify the isothermal limit to the load bearing capacity of concrete. This 500 ºC isothermal defines the extension of concrete to be neglected, $b_{c,fi}$ in both principal directions (y,z). The thickness reduction of concrete should be calculated according to table 3.

The average temperature in concrete $\theta_{c,t}$ may be calculated (CEN, 2005a), depending on the section factor A_m/V of the e cross-section and on standard fire resistance classes.

Table 3 - Thickness reduction of the concrete.

Standard fire resistance	$b_{c,fi}$[mm]
R30	4.0
R60	15.0
R90	0.5(Am/V)+22.5
R120	2.0(Am/V)+24.0

Reinforcement Component

The temperature effect in steel reinforcement considers the reduction of the elastic modulus and yield stress. Both reduction factors are determined according to standard fire resistance and the average value of the concrete cover dimensions, u, see Eqs. 6-8 and table 4.

$$u = \sqrt{u_1 \cdot u_2} \tag{6}$$

$$u = \sqrt{u_2 \cdot (u_2 + 10)} \quad ,(u_1 - u_2) > 10 \left[mm\right] \tag{7}$$

$$u = \sqrt{u_1 \cdot (u_1 + 10)} \quad ,(u_2 - u_1) > 10 \left[mm\right] \tag{8}$$

Table 4 - Reduction factors $k_{y,t}$ and $k_{E,t}$ for reinforcement.

	$k_{y,t}$	$k_{y,t}$	$k_{y,t}$	$k_{y,t}$	$k_{E,t}$	$k_{E,t}$	$k_{E,t}$	$k_{E,t}$
u [mm]	R30	R60	R90	R120	R30	R60	R90	R120
40	1,000	0,789	0,314	0,170	0,830	0,604	0,193	0,110
45	1,000	0,883	0,434	0,223	0,865	0,647	0,283	0,128
50	1,000	0,976	0,572	0,288	0,888	0,689	0,406	0,173

60	1,000	1,000	0,822	0,436	0,935	0,763	0,619	0,285

ADVANCED CALCULATION METHOD

The most important parameter to validate the simple calculation method is the temperature field in the cross section. The temperature field was determined by the finite element method (ANSYS). The plane element "PLANE55" was selected to perform a nonlinear transient thermal analysis. This element uses linear interpolation functions and 4 integration points to determine the conductivity matrix, see Fig. 2. The model used 4, 6 and 8 elements in the web thickness, flange thickness and in both directions of reinforcement, respectively. Perfect contact between materials or components was considered. Standard fire boundary conditions were applied in the exposed surface, according to EN1991-1-2 (CEN, 2002). Material properties were defined according to the corresponding Eurocode for steel EN1993-1-2 (CEN, 2005b) and concrete EN1992-1-2 (CEN, 2004), whereas with 3% water content by weight and a thermal conductivity corresponding to the upper limit.

The advanced calculation method used the following criteria to define the effect of fire in each component: The temperature of the flange, $\theta_{f,t}$ was determined by the arithmetic average of nodal temperature. The reduction of the web height, $h_{w,fi}$ was determined according to the 400 °C isothermal (Cajot et al., 2012)). The residual cross section of concrete depends on the extension of concrete to be neglected, $b_{c,fi}$, being determined according to the

500 °C isothermal limit (CEN, 2004), while the temperature effect on steel reinforcement was calculated by the arithmetic average temperature of this component, see Fig. 2.

Fig. 2 - Criteria and Finite element "PLANE55".

Fig. 3 shows several temperature field examples corresponding to different fire resistance classes.

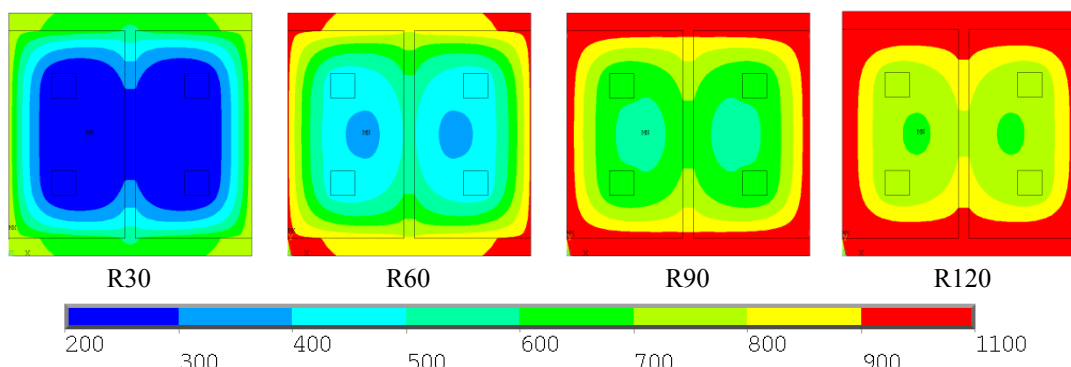

Fig. 3 - Numerical results for section HEB 200 for different fire ratings.

COMPARISON AND NEW FORMULAE

The effect of fire was determined for each component in 24 different cross sections. The numerical results were compared to the existing formulas of Eurocode (CEN, 2005a) and also to the new formulae.

Flange Component

Fig. 4 represents the average temperature of the flange, depending on the section factor and on the standard fire resistance class. Each graph depicts the results of the simplified calculation method (CEN, 2005a), the results of the advanced calculation method (ANSYS) and the results of the new formulae (New proposal). Eurocode 4 Part 1.2 (CEN, 2005a) presents conservative values for some sections factors and unsafe values to others. The average temperature of the flange of HEB and IPE sections is safe for standard fire R30, partially safe for R60 and unsafe for the remaining classes.
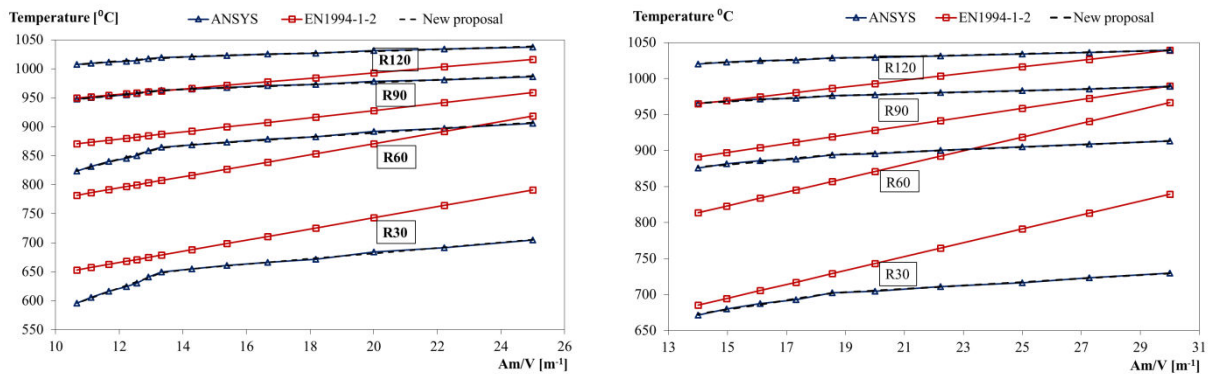

Fig. 4 - Average temperature of the flange. HEB sections (left). IPE Sections (right).

The new proposal is based on the same formulae of Eurocode 4 (CEN, 2005a), Eq. 4, but using a bilinear approximation for temperature, using a new empirical coefficient k_t and a new reference value $\theta_{0,t}$, see table 5.

Table 5 - Parameters to determine flange temperature (Section HEB and IPE).

Sections	10<Am/V<14		14<=Am/V<25		10<Am/V<19		19<=Am/V<30	
Standard	HEB		HEB		IPE		IPE	
Fire	$\theta_{0,t}$ [^{0}C]	k_t [m^{0}C]	$\theta_{0,t}$ [^{0}C]	k_t [m^{0}C]	$\theta_{0,t}$ [^{0}C]	k_t [m^{0}C]	$\theta_{0,t}$ [^{0}C]	k_t [m^{0}C]
R30	387	19,55	588	4,69	582	6,45	656	2,45
R60	665	14,93	819	3,54	824	3,75	862	1,72
R90	887	5,67	936	2,04	935	2,20	956	1,09
R120	961	4,29	998	1,62	997	1,68	1010	0,96

Web Component

The effect of fire on the web of the cross section was determined by the 400 °C isothermal criterion. This procedure defines the affected zone of the web and predict the web height reduction, see Fig. 5. The numerical results demonstrate a strong dependence on the section factor, regardless of the fire resistance class, unlike the simplified method of EN1994-1-2 (CEN, 2005a). The results of EN1994-1-2 are unsafe for all fire resistance classes and for all section factors. The new proposal presents a parametric expression that depends on section factor and standard fire resistance class, Eqs. 9-10. Both equations have the application limits defined in table 6.

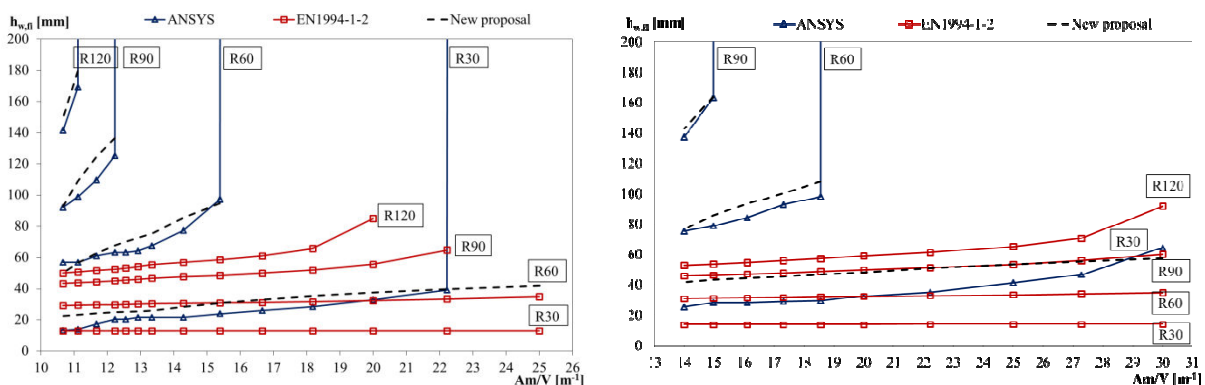

Fig. 5 - Web height reduction. HEB sections (left). IPE Sections (right).

$$2h_{w,fi} / h_i \times 100 = 0.0035 \times t^2 \times (A_m/V) - 0.03 \times t^{2.02} + (A_m/V)/2 \quad ,(HEB) \tag{9}$$

$$2h_{w,fi} / h_i \times 100 = 0.002 \times t^2 \times (A_m/V) - 0.03 \times t^{1.933} + (A_m/V) \quad ,(IPE) \tag{10}$$

Table 6 - Application limits for HEB and IPE cross sections

Standard fire resistance	Section factor (HEB)	Section factor (IPE)
R30	Am/V <22.22	Am/V <30.00
R60	Am/V <15.38	Am/V <18.56
R90	Am/V <12.22	Am/V <14.97
R120	Am/V <11.11	-

The arithmetic average temperature $\theta_{w,t}$ of the effective web section was defined by the nodes under the limiting condition and plotted in Fig. 6 (ANSYS). Temperature results of EN1994-1-2 (CEN, 2005a) were determined by the inverse method, using the reduction factor of the yielding stress $\sqrt{1 - 0.16(H_t/h)}$. The new proposal was adjusted to numerical results.

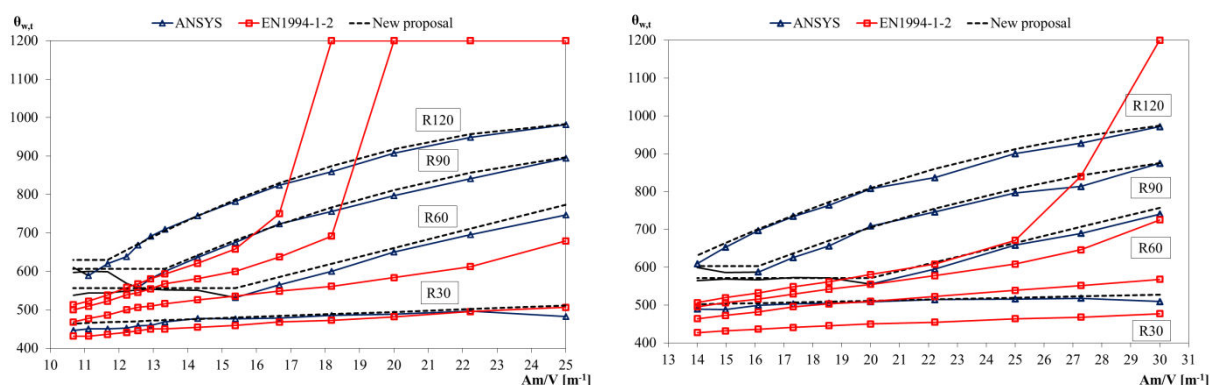

Fig. 6 - Average web temperature for different standard fire resistance classes and sections. HEB sections (left). IPE Sections (right)

Concrete Component

The numerical result of the third component was determined by the 500 ºC isothermal. The external layer of concrete to be neglected was measured in both principal directions, defining $b_{c,fi,vertical}$ and $b_{c,fi,horizontal}$. According to EN1994-1-2 (CEN, 2005a), the thickness of concrete to be neglected depends on section factor for standard fire resistance of R90 and R120. The numerical results demonstrates a strong dependence on section factors for all standard fire resistance classes. Fig. 7 presents the new proposal for $b_{c,fi,vertical}$ and $b_{c,fi,horizontal}$ for HEB sections. Similar results were obtained to IPE sections. Tables 7-8 provide the new formulae to determine the thickness of concrete to be neglected in fire design, based on the new Eq. 11, which applies to both cross section types (HEB and IPE) and directions (horizontal and vertical).

$$b_{c,fi} = a \times (A_m/V)^2 + b \times (A_m/V) + c \tag{11}$$

a) Horizontal reduction on HEB section.

b) Vertical reduction on HEB section.

c) Horizontal reduction on IPE section.

d) Vertical reduction on IPE section.

Fig. 7 - Thickness reduction of the concrete area for HEB and IPE sections.

The average temperature of the residual concrete section is represented in Fig. 8. The new proposal introduces a parametric approximation, based on the standard fire resistance and section factor, Eqs. 12-13.

$$\theta_{c,t} = +3.1 \times t^{0.5} \times (A_m/V) + 0.003 \times t^{1.95} \quad , (HEB) \tag{12}$$

$$\theta_{c,t} = +2.67 \times t^{0.5} \times (A_m/V) + 3.4 \times t^{0.61} \quad , (IPE) \tag{13}$$
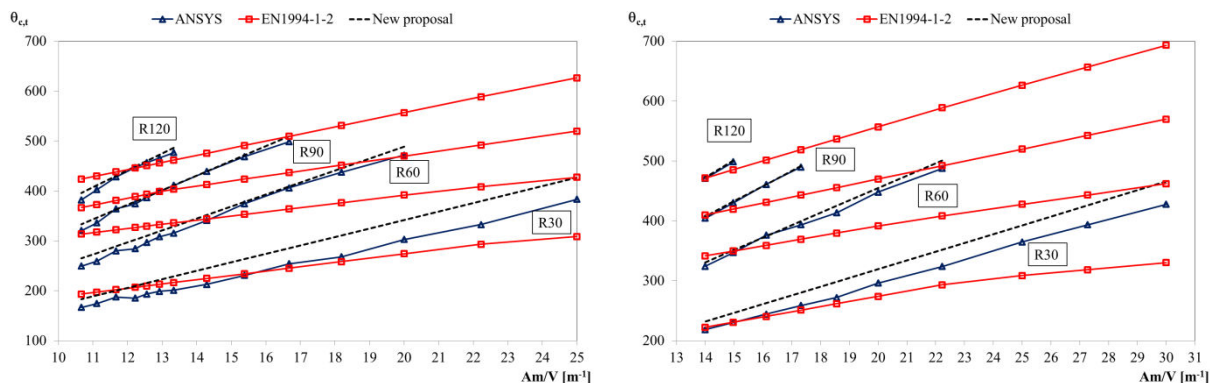

Fig. 8 - Average temperature of residual concrete. HEB sections (left). IPE Sections (right).

Reinforcement Component

Fig. 9 depicts the average temperature of rebars determined by the numerical results. The results of EN1994-1-2 (CEN, 2005a) were indirectly determined through the most critical reduction factor. Alternatively, the new parametric formula is presented for the calculation of the average temperature of rebars. Eqs. 14-15 were developed to the new proposal, based on the distance of rebars to fire exposed surface.

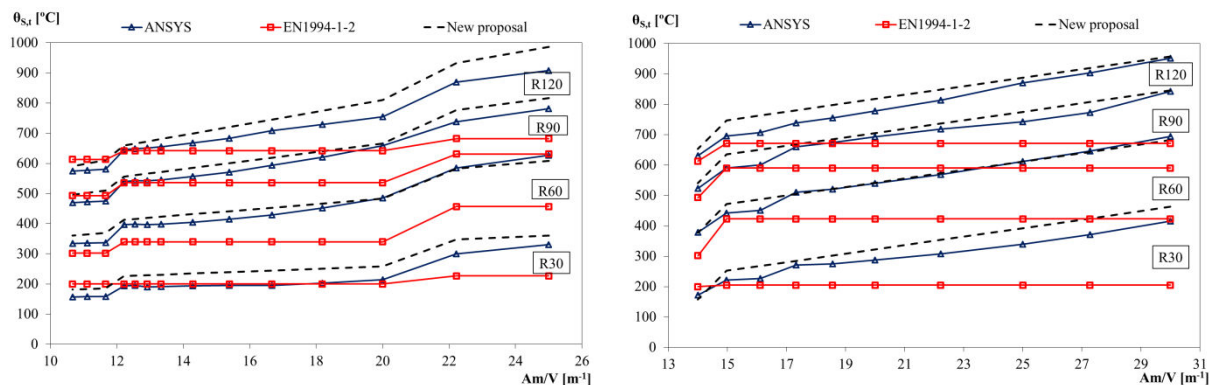

Fig. 9 - Average temperature of rebars. HEB sections (left). IPE Sections (right).

$$\theta_{s,t} = 0.1 \times t^{1.1} \times (A_m/V) + 7.5 \times t - 0.1 \times t^{1.765} - 8 \times u + 390 \quad ,(HEB) \tag{14}$$

$$\theta_{s,t} = 14.0 \times (A_m/V) + 11.0 \times t - 0.1 \times t^{1.795} - 8 \times u + 115 \quad ,(IPE) \tag{15}$$

FIRE RESISTANCE ACCORDING TO NEW PROPOSAL

Fig. 10 and Fig. 11 present the margin of safety of the new proposal for the plastic resistance to axial compression and for the effective flexural stiffness around the weak axis.

CONCLUSION

24 simulations were developed to assess the fire behaviour of Partially Encased Sections, in particular the new proposals to annex G of EN1994-1-2 (CEN, 2005a). This numerical simulations were developed by finite plane elements, and are only valid to standard fire exposure, running with ISO834 (ISO, 1999).
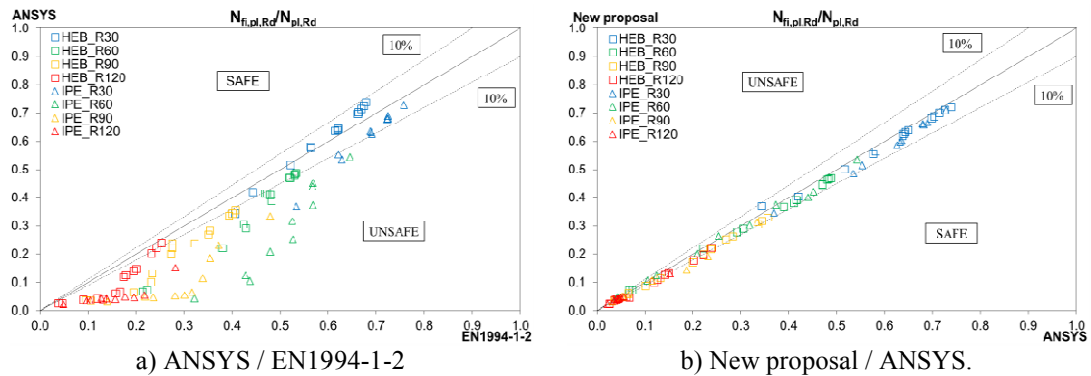

Fig. 10 - Comparison results for plastic resistance to axial compression.

Fig. 11 - Comparison results for the effective flexural stiffness around the weak axis.

The simplified method proposed in Annex EN1994-1-2 G is unsafe for certain classes of fire resistance compared to numerical results. This paper presented new formulae, with safety guarantee to the calculation of plastic resistance to axial compression and effective flexural stiffness of the cross-section with respect to the week axis, under fire conditions.
