#### Abstract

The $O$-alkylation of dihydroxo(tetraarylporphyrinato)phosphorus $(\mathrm{V})$ complexes with several kinds of alkyl bromide in MeCN in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and 18-crown-6 ether produced dialkoxo(tetraarylporphyrinato)phosphorus(V) complexes in-moderate-good yields. Similar $O$-alkylation was applied to dihydroxo(tetraarylporphyrinato)antimony(V) complexes. The $O$-alkylation proceeded by the occurrence of an $\mathrm{S}_{\mathrm{N}} 2$ attack of the alkoxide anion of the complexes at the carbon substituted with halides.

Porphyrinatometal complexes are chemically and biologically important molecules that have versatile catalytic capabilities in an electron-transfer reaction or energy transfer. ${ }^{1}$ Therefore, a number of porphyrinatometal complexes have been synthesized. ${ }^{2}$ Our interests have been paid to high-valent porphyrinatophosphorus $(\mathrm{V})$ and antimony $(\mathrm{V})$ complexes having a variety of axial ligands from the standpoints of the photoelectronic properties, redox electrochemistry, and catalytic activities. ${ }^{3,4}$ However, convenient methods to introduce axial ligands to the porphyrinatoantimony or phosphorus complexes have rarely been reported.

The synthesis of dialkoxo-coordinated tetraarylporphyrinatophosphorus(V) and antimony(V) complexes ([M(TAP)$\left.(\mathrm{OR})_{2}\right] ; \mathrm{M}=\mathrm{P}$ and $\mathrm{Sb}, \mathrm{TAP}=$ tetraarylporphyrinato group) can be achieved by a substitution reaction of $\left[\mathrm{M}(\mathrm{TAP}) \mathrm{Br}_{2}\right]$ with ROH or an alkylation reaction of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]$ with RX ( $\mathrm{X}=$ halide, tosylate etc.). However, the yields of the reaction of $\left[\mathrm{M}(\mathrm{TAP}) \mathrm{Br}_{2}\right.$ ] with ROH have usually been low. Segawa and Shimidzu have preliminarily reported the $O$-alkylation of dihydroxo(tetraphenylporphyrinato)phosphorus ([P(TPP) $\left.(\mathrm{OH})_{2}\right] ;$ TPP $=$ tetraphenylporphyrinato group) with
alkyl halides (RX). ${ }^{5}$ In order to develop a convenient and efficient method to prepare $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OR})_{2}\right](\mathrm{M}=\mathrm{P}$ and Sb$)$, we investigated the scope and limitation of the $O$-alkylation of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]$ complexes with RX.

## Result and Discussion

As the starting materials, we used dihydroxo(tetraarylporphrinato)phosphorus( V ) and antimony $(\mathrm{V})$ hexafluorophosphate complex $\left(\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right]\right.$ and $\left[\mathrm{M}(\mathrm{TPP})(\mathrm{OH})_{2}\right] ; \mathrm{M}=\mathrm{P}$ and Sb , TMP $=$ tetra( $p$-methoxyphenyl)porphyrinato group, see Scheme 1), which could be easily prepared by the hydrolysis of $\left[\mathrm{P}(\mathrm{TMP}) \mathrm{Cl}_{2}\right],\left[\mathrm{P}(\mathrm{TPP}) \mathrm{Cl}_{2}\right]$ and $\left[\mathrm{Sb}(\mathrm{TPP}) \mathrm{Br}_{2}\right]$, respectively. ${ }^{5,6}$ Shimidzu and co-workers' method involved the $O$-alkylation of $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ with $\mathrm{RX}(\mathrm{R}=\mathrm{Me}, \mathrm{Et})$, having good leaving groups ( $\mathrm{X}=\mathrm{I}, \mathrm{OSO}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}, \mathrm{OSO}_{2} \mathrm{CF}_{3}$ ), which occurred in DMF in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}$ at room temperature. ${ }^{5}$ We investigated the $O$-alkylations of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right](\mathrm{M}=\mathrm{P}$ and Sb$)$ using $\mathrm{RX}(\mathrm{X}=\mathrm{Br}$ and Cl$)$, which are the more available alkyl reagents.

In attempts to find the optimum conditions, control experiments were performed for the $O$-alkylation of $\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right]$

Scheme 1.
( 0.02 mmol ) with $n-\operatorname{PrX}(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}$, and $\mathrm{I} ; 10-100 \mathrm{mmol})$ in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3}(0.06 \mathrm{mmol})$ and 18-crown-6 ether $(0.03 \mathrm{mmol})$ in the solvent $(50 \mathrm{~mL})$ under refluxing conditions. As alkylating agents, although $n-\mathrm{PrBr}$ and $n-\mathrm{PrI}$ were effective, $n-\mathrm{PrCl}$ was ineffective. Therefore, we used RBr as alkyl reagents because of easy handling and more available reagents. $O$-alkylation at room temperature required a longer reaction time. $\mathrm{K}_{2} \mathrm{CO}_{3} / 18$-crown- 6 was used as a base, because of the occurrence of a relatively clean reaction compared with the cases of other bases (e.g. pyridine, $\mathrm{Et}_{3} \mathrm{~N}$, and NaH ). It was found that MeCN and THF were better solvents, since $O$-alkylation with $n-\mathrm{PrBr}$ proceeded effectively. DMF was a poor solvent because of the occurrence of demetallation from the porphyrin complex, although Segawa et al. succeeded to carry out $O$-alkylation in DMF at room temperature. ${ }^{5}$ Probably $\mathrm{K}_{2} \mathrm{CO}_{3}$ served as a stronger base under refluxing conditions to lead the demetallation. Therefore, $O$-alkylations were performed in MeCN in the presence of $\mathrm{K}_{2} \mathrm{CO}_{3} / 18$-crown- 6 under refluxing conditions throughout the present investigation.

The reaction progress from $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]$ to $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OR})_{2}\right](\mathbf{1}(\mathrm{M}=\mathrm{P})$ and $\mathbf{2}(\mathrm{M}=\mathrm{Sb}))$ was followed by spectral changes of a Soret band of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]: \lambda_{\text {max }}=$ 440 nm for $\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right], 424 \mathrm{~nm}$ for $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$, and 417 nm for $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$. The structures of $\mathbf{1}$ and $\mathbf{2}$ were certainly confirmed by observing common up-field shifts of all protons on the alkyl group in the ${ }^{1} \mathrm{H}$ NMR spectra.

Although the $O$-alkylation of $\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right]$ with $i-\mathrm{PrBr}$ gave 1b, that with $i$-PrI did not at all, probably because an elimination of HI from $i$-PrI occurred predominantly. RCl were unreactive, except for the case of $\mathrm{PhCH}_{2} \mathrm{Cl}$. In the cases of $\mathrm{RBr}\left(\mathrm{R}=\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CH}_{2}-, \mathrm{Br}\left(\mathrm{CH}_{2}\right)_{3}{ }^{-}\right.$, and $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{3}-$ ) and $\mathrm{PhCH}_{2} \mathrm{Cl}$, the $O$-alkylation products ( $\mathbf{1 c - e}$ and $\mathbf{1 f}$ ) were obtained. A small amount of free base porphyrin ( $\mathrm{H}_{2}$ TMP) was formed as a by-product, except for the case of entry 9 . The $O$-alkylation of $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ with $\mathrm{RBr}(\mathrm{R}=\mathrm{Et}, n-\mathrm{Pr}$, and $\left.\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CH}_{2}-\right)$ and $\mathrm{PhCH}_{2} \mathrm{Cl}$ gave $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OR})_{2}\right](\mathbf{1 g - i}$ and $\mathbf{1 m}$ ) in moderate-to-good yields. The $O$-alkylation of $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right.$ ] with $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{Br}(n=5,7,9)$ smoothly gave $\mathbf{1} \mathbf{j} \mathbf{- I}$ irrespective of the long alkyl chain. No O -alkylation with $t$ - $\mathrm{BuBr}, \mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{Br}, \mathrm{NCCH}_{2} \mathrm{CH}_{2} \mathrm{Br}$, and $\mathrm{CF}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Br}$ occurred at all. The present method was applied to the $O$-alkylation of $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ with $\mathrm{RBr}\left(\mathrm{R}=n-\mathrm{Bu}, i-\mathrm{Pr}, \mathrm{CH}_{2}=\mathrm{CH}-\right.$ $\mathrm{CH}_{2}-, \mathrm{Br}\left(\mathrm{CH}_{2}\right)_{3}-$ ) and $\mathrm{PhCH}_{2} \mathrm{Cl}$, which gave $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OR})_{2}\right]$ (2a-d) in moderate-to-good yields, except for entry 24. In the case of $i-\mathrm{PrBr}$ (entry 24), a mono-alkylated complex, $[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})(\mathrm{O}-i-\mathrm{Pr})](3)$, was formed without the formation of $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{O}-i-\mathrm{Pr})_{2}\right]$. The $O$-alkylation of $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ with $i$-PrI, $t$ - $\mathrm{BuBr}, \quad \mathrm{BrCH}_{2} \mathrm{CH}_{2} \mathrm{Br}, \quad \mathrm{NCCH}_{2} \mathrm{CH}_{2} \mathrm{Br}$, and $\mathrm{CF}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Br}$ gave little or no products. The results are summarized in Table 1.

The $\mathrm{p} K_{\mathrm{a}}$ values of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]$ were determined based on the spectral change by the addition of KOH: $\mathrm{p} K_{\mathrm{a}}=10.0$ for $\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right], \mathrm{p} K_{\mathrm{a}}=9.5$ for $\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$, and $\mathrm{p} K_{\mathrm{a}}=$ 10.3 for $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$. Therefore, the axial hydroxy group of $\left[\mathrm{P}(\mathrm{TMP})(\mathrm{OH})_{2}\right],\left[\mathrm{P}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$, and $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ can be readily dissociated by $\mathrm{K}_{2} \mathrm{CO}_{3}$. O-Alkylation proceeded by the occurrence of an $\mathrm{S}_{\mathrm{N}} 2$ attack of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH}) \mathrm{O}^{-}\right.$] at the carbon substituted with halides. In the case of a secondary RX (e.g. $i-\mathrm{PrBr}$ ), the $\mathrm{S}_{\mathrm{N}} 2$ attack would be slow to give a mono-
alkoxo complex, $[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})(\mathrm{OR})]$. The $O$-alkylation of $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OH})_{2}\right]$ with tertiary RX (e.g. $\left.t-\mathrm{BuBr}\right)$ did not occur due to the steric hindrance.

An alternative synthetic method ${ }^{7}$ of $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OR})_{2}\right]$ was attempted by the reaction of $\left[\mathrm{Sb}(\mathrm{TPP}) \mathrm{Br}_{2}\right]$ with ROH . However, the reaction of $\left[\mathrm{Sb}(\mathrm{TPP}) \mathrm{Br}_{2}\right]$ with ROH under refluxing conditions gave a mono-alkoxo complex, $[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OR}) \mathrm{Br}]$. For example, the reaction of $\left[\mathrm{Sb}(\mathrm{TPP}) \mathrm{Br}_{2}\right]^{+} \mathrm{Br}^{-}$with EtOH gave $\left[\mathrm{Sb}(\mathrm{TPP})(\mathrm{OEt}) \mathrm{Br}^{+} \mathrm{Br}^{-}(4 ; 95 \%)\right.$.

In conclusion, the optimum route to $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OR})_{2}\right](\mathrm{M}=$ P and Sb$)$ is the double $O$-alkylation of $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right](\mathrm{M}=$ P and Sb ) with RBr under basic conditions. The present method will be applied to porphyrinatophosphorus and antimony complexes having various functionalized axial ligands.

## Experimental

${ }^{1} \mathrm{H}$ NMR spectra were taken in $\mathrm{CDCl}_{3}$ using tetramethylsilane as an internal standard on a Bruker AC 250P spectrometer at 250 MHz. UV spectra were measured on a Hitachi U2001 spectrometer. SIMS were obtained on a Hitachi M2000A spectrometer. High-resolution FAB-MS were obtained on a JEOL JMS-HX 110A spectrometer using $m$-nitrobenzyl alcohol as a matrix agent.

Materials. Reagents were obtained from the following sources: antimony(III) bromide, chloroform, acetonitrile, potassium carbonate, propyl bromide, isopropyl bromide, and butyl bromide from Nacalai Tesque; anhydrous pyridine, dichloromethane, hexane, methanol, hydrobromic acid, tetrahydrofurane, 18-crown-6 ether, butyl chloride, butyl iodide, propyl iodide, and 1,4-dibromobutane from Wako Pure Chemical Industries; tetraphenylporphyrin, $t$-butyl bromide, 3-bromo-1,1,1-trifluoropropane, benzyl bromide, and 1,3-dibromopropane from Tokyo Kasei; $N, N$-dimethylformamide from Katayama Kagaku; silver hexafluorophosphate, phosphoryl chloride, and tetra(4-methoxyphenyl)porphyrin from Aldrich.

General Procedure of $\boldsymbol{O}$-Alkylation. A dry MeCN solution $(50 \mathrm{~mL})$ containing RX $(1 \mathrm{~mL} ; 10-100 \mathrm{mmol}),\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OH})_{2}\right]$ ( $\mathrm{M}=\mathrm{P}$ or $\mathrm{Sb} ; 0.02 \mathrm{mmol}$ ), ${ }^{5,6} \mathrm{~K}_{2} \mathrm{CO}_{3}(0.06 \mathrm{mmol})$, and 18 -crown$6(0.03 \mathrm{mmol})$ was refluxed at $85^{\circ} \mathrm{C}$ under a nitrogen atmosphere. The mixture was cooled, filtered, and concentrated in vacuo. A dichloromethane solution of the crude product was added into hexane to form the precipitate. The dichloromethane solution of the precipitate was washed three times with 50 mL portions of $\mathrm{H}_{2} \mathrm{O}$. After removing the solvent, the crude product was subjected to the column chromatography on silica gel (Fuji-Silysia FL60D) to give $\left[\mathrm{M}(\mathrm{TAP})(\mathrm{OR})_{2}\right]$.
