33

34 **Abstract**

35

36 BACKGROUND: A major objective of the IFCC Committee on Education and Use of
37 Biomarkers in Diabetes is to generate awareness and improvement of HbA1c assays
38 through evaluation of the performance in countries and manufacturers.

39

40 METHODS: Fresh whole blood and lyophilized hemolysate specimens manufactured
41 from the same pool were used by 17 EQA organizers to evaluate analytical
42 performance of 2166 laboratories. Results were evaluated per country, per
43 manufacturer, and per manufacturer and country combined according to criteria of
44 the IFCC model for Quality targets.

45

46 RESULTS: At the country level with fresh whole blood specimens, 6 countries met
47 the IFCC criterion, 2 did not, and 2 were borderline. With lyophilized hemolysates, 5
48 countries met the criterion, 2 did not, and 3 were borderline. At the manufacturer level
49 using fresh whole blood specimens, 13 manufacturers met the criterion, 8 did not,
50 and 3 were borderline. Using lyophilized hemolysates, 7 manufacturers met the
51 criterion, 6 did not, and 3 were borderline. In both country and manufacturer groups
52 the major contribution to total error derived from between laboratory variation. There
53 were no substantial differences in performance between groups using fresh whole
54 blood or lyophilized hemolysate samples.

55

56 CONCLUSION: The state of the art is that 1 out of 20 laboratories does not meet the
57 IFCC criterion but there are substantial differences between country and between
58 manufacturer groups. Efforts to further improve quality should focus on reducing

59 between laboratory variation. With some limitations, fresh whole blood and well-
60 defined lyophilized specimens are suitable for purpose.

61

62

63 **Introduction**

64

65 HbA1c is a key parameter in the monitoring of diabetic control as well as in the
66 screening and diagnosis of Type 2 diabetes (1,2). The high clinical relevance of
67 HbA1c testing necessitates high quality measurement. This is well recognized by the
68 International Federation of Clinical Chemistry and Laboratory Medicine (IFCC), which
69 has a long standing program to improve HbA1c testing:

- 70 • The development of the IFCC Reference Measurement Procedure (RMP) by the
71 IFCC Working Group on Standardization of HbA1c (3). The working group
72 embedded the RMP in a sustainable global network of 15 approved network
73 laboratories (4).
- 74 • A consensus statement from the International Diabetes Federation (IDF),
75 European Association for the Study of Diabetes (EASD), American Diabetes
76 Association (ADA) and the IFCC which recognized the RMP as the only valid
77 analytical anchor to standardize HbA1c (5).
- 78 • Subsequent to the working group an IFCC Task Force on Implementation of
79 HbA1c Standardization developed a model for Quality Targets (QTmodel) (6).
- 80 • More recently the IFCC Committee on Education and Use of Biomarkers in
81 Diabetes (C-EUBD) has a focus on education around the use of biomarkers for
82 diabetes, encompassing both the analytical and clinical utility of HbA1c (7).

83 External Quality Assessment (EQA)/Proficiency Testing (PT) is a powerful
84 educational tool to monitor quality which, by identifying poor performing laboratories
85 and test systems, can be used as a tool to improve quality. Smaller scale studies
86 initially in Italy and later in a multinational project in Germany, Belgium and the
87 Netherlands were used as a basis for the design of the current study by the C-EUDB
88 (8,9). 17 EQA organizers in Europe agreed to participate in the European HbA1c
89 Trial (EurA1c). Half of the EQA organizers preferred to use fresh whole blood
90 samples (WB) and the other half lyophilized hemolysates (LH). This paper relates to
91 the EQA results in both matrices and are considered per country, per manufacturer
92 and per manufacturer and country combined.

93

94

95 **Materials and Methods**

96

97 *Study Design*

98 The EurA1c study design is shown in Fig.1. From two pools of fresh whole blood
99 (yellow), batches of WB (green) and LH EQA specimens were prepared. Specimens
100 were shipped in bulk to the EQA organizers who forwarded them to their participants.
101 Results were collected and evaluated (blue). The study also included frozen whole
102 blood specimens (the common sample in IFCC and NGSP certification).
103 Homogeneity and stability were tested according to ISO 13528 and results met the
104 criteria. Frozen samples, homogeneity, stability and targeting (all grey) were beyond
105 the scope of this paper and will not be addressed.

106

107 *Sample preparation and assigned values*

108 250 mL donations of whole blood were collected into EDTA from diabetic and non-
109 diabetic volunteers and used to make two pools (EurA1c-1 and EurA1c-2). Target
110 values were assigned with the RMP by 5 approved network laboratories; each
111 laboratory measured the samples in fourfold. The assigned value for EurA1c-1 was
112 42.3 (6.02%) with an expanded uncertainty of 0.7 mmol/mol (0.06%). The assigned
113 value for EurA1c-2 was 57.9 mmol/mol (7.45%) with an expanded uncertainty of 0.9
114 mmol/mol (0.08%). From each pool WB and LH specimens were made. Throughout
115 the paper IFCC- and National Glycohemoglobin Standardization Program (NGSP)
116 units will be referred to with results in NGSP units in brackets.

117

118 *Logistics*

119 In order to process the samples in a timely manner, donations were collected on day
120 one, on day two the WB samples were shipped by courier to the respective EQA
121 organizers at ambient temperature. On day three the EQA organizers distributed the
122 samples to participants, again at ambient temperature, who analyzed the samples on
123 day four or five. An exception to this was the samples for Italy which were shipped
124 direct to the participating laboratories on cool packs. LH samples were manufactured
125 the day after blood donation; shipment and analysis was between November 2016
126 and April 2017.

127

128 *Data Collection and Evaluation*

129 EQA organizers collated the results from their participants and forwarded them to the
130 IFCC network coordinator. The number of laboratories (2166) is the number of
131 submitted datasets. The number of manufacturers (24) is the number of platforms
132 that could be evaluated reasonably ($N > 5$) according to the QTmodel. Mean values,

133 between laboratory CVs and bias were calculated, after removal of outliers, defined
134 as a value outside the target $\pm 25\%$. Outliers amounted to 1% of all results.

135 Commonly these outliers were due to mix-up of samples or decimal errors. IFCC
136 results were converted to NGSP units with the Master Equation (NGSP =
137 $0.0915\text{IFCC} + 2.15$). (10)

138 The bias is defined as $\{(M1-T1) + (M2 -T2)\}/2$ in which M1 and M2 are the mean
139 measured HbA1c concentrations in samples 1 and 2, and T1 and T2 are the target
140 values of samples 1 and 2 assigned with the RMP. The between laboratory CV
141 (BLCV) is defined as the mean of the BLCV in samples 1 and 2. Note that the BLCV
142 in IFCC and NGSP units differs substantially; for explanation see Ref 11.

143

144 *Manufacturers/Instruments*

145 The study aimed to capture all manufacturer details but unfortunately registration was
146 different per EQA organizer. For Siemens point-of-care users the DCA 2000 and
147 Vantage instruments were combined to one group. The Menarini/ARKRAY 8160 VP
148 and TP instruments formed a single group as did the various types of Bio-Rad
149 Variant. There was a considerable variation in reporting method type for Roche
150 methods, therefore these were combined into one group as they all used the same
151 method principle. 137 laboratories did not report their instrument at all; results of this
152 group were included in the calculation per country and in the result per manufacturer
153 they are considered as a separate group.

154

155 *IFCC Model for Quality Targets*

156 EurA1c results were evaluated according to the criteria of the QTmodel. Although
157 previously described in the literature a short explanation of the model follows to

158 facilitate the reader in understanding the Figures (6,12).The QTmodel is based on the
159 concept of total error which takes into account the principal sources of analytical
160 error: bias and imprecision. Performance criteria are derived from sigma metrics.
161 Bias is plotted on the vertical axis with scaling in IFCC units (mmol/mol) and NGSP
162 units (% in parentheses). Imprecision, expressed as the Coefficient of Variation (CV)
163 is plotted on the horizontal axis. The criterion was set at 5 mmol/mol (0.46%) at the 2
164 sigma level and applies to HbA1c concentrations around 50 mmol/mol (6.7%). In the
165 graph this criterion is shown as the line drawn from 5 mmol/mol (0.46%) on the
166 vertical axis to 5.0% (3.4%) on the horizontal axis. A performance within the triangle
167 meets the criterion. When HbA1c is used for diagnosis more stringent criteria might
168 be desirable. Therefore more challenging criteria are defined at total allowable errors
169 of 3.3, 2.2 and 1.1 mmol/mol (0.3-0.2 and 0.1%), represented by the bronze, silver
170 and gold triangles in the QTmodel. The QTmodel can be applied at the level of a
171 single laboratory (precision is the within laboratory CV) or for groups of laboratories
172 (precision is the between laboratory CV). The latter is used in this paper to evaluate
173 the performance of specific country/manufacturer groups.

174

175

176 **Results**

177

178 *Preamble*

179 The EurA1c Trial revealed many data: results of 2166 laboratories provided by 17
180 EQA organizers and measured with assays of 41 different manufacturers. In addition
181 there were two matrices and according to the consensus statement results have to
182 be reported in IFCC- and NGSP units. The multiple and detailed data necessitated

183 choices on what and how to present results. Condensed EQA results in WB and LH
184 are included in the main body of the paper and the detailed data are systematically
185 presented in the supplemental data section.

186

187 *Results by Country*

188 Table 1 shows the results ranked alphabetically by country. The first two columns
189 show the names and countries of the EQA organizers. Then there are sections with
190 results in WB and LH. For each matrix there are columns for the number of
191 laboratories (n), bias and between laboratory CV in IFCC- and NGSP units
192 respectively. Results are the mean of both samples EurA1c-1 and EurA1c-2.

193

194 *Results by Manufacturer*

195 Table 2 shows the results ranked alphabetically by manufacturer. The first column
196 shows the manufacturer. Then there are sections with results in WB and LH. For
197 each matrix there are columns for the number of laboratories (n), bias and between
198 laboratory CV in IFCC- and NGSP units. Results are the mean of both samples
199 EurA1c-1 and EurA1c-2.

200

201 *Performance of each Country in the QTmodel*

202 Fig. 2A and B show the performances by country in WB and LH in the framework of
203 the criteria of the QTmodel. The plotted bias and BLCV were taken from table 1.

204

205 *Performance of each Manufacturer in the QTmodel*

206 Fig. 2C and D show the performance of each manufacturer in WB and LH in the
207 framework of the criteria of the QT model. The plotted bias and BLCV were taken
208 from table 2.

209

210 *Manufacturer performance by Country in the QTmodel*

211 Fig. 3 shows the performance of each manufacturer by country within the framework
212 of the QTmodel. Scaling is omitted to simplify. There were more than 200
213 manufacturer/country combinations, therefore only data for combinations with at least
214 5 laboratories per manufacturer in a country are calculated. This resulted in 79 such
215 combinations (data in tables 4,8,12,16 of the supplemental data). Fig. 3 shows the
216 QTmodel plots for manufacturers with at least 6 laboratories using their test in at
217 least 4 countries. Four manufacturers are included for both WB and LH and three for
218 WB only.

219

220 *Detailed results in supplemental data*

221 Detailed results are provided in the supplemental data. Table 3 shows how the data
222 are systematically differentiated and organized in the 16 supplemental tables. For
223 example: Supplemental table 2 shows the results per sample in IFCC units in WB for
224 manufacturers with more than 5 laboratories using their assay.

225

226

227 **Discussion**

228

229 *Overall performance*

230 The last line of table 1 shows the overall performance of all participating laboratories.
231 In the group of laboratories that used WB the mean overall bias of 1517 laboratories
232 was +0.2 mmol/mol (+0.02%) and the BLCV was 4.4% (3.0%). In the group of
233 laboratories that used LH the mean bias of 649 laboratories was -0.5 mmol/mol (-
234 0.05%) and the BLCV was 4.9% (3.2%). These data are plotted in the QTmodel in
235 Fig. 2 A and B (black stars). It can be seen that the performance in WB is borderline
236 within and in LH borderline outside the criterion. The overall performance data can be
237 interpreted as, in both matrices, approximately 95% of the laboratories meet the
238 criterion of a total allowable error below 5 mmol/mol (0.46%). The position of the
239 black stars is close to the horizontal and not to the vertical axis, implying that the
240 major contribution to the total error is derived from the BLCV rather than bias. A
241 similar performance pattern has been reported by the College of American
242 pathologists (CAP) survey in the US (13).

243

244 *Per Country*

245 In table 1 the performance data is split by country. In WB blood the bias ranges from
246 0.0 mmol/mol (0.0%) in Sweden and Turkey to +0.8 mmol/mol (+0.08%) in Italy. The
247 BLCV ranges from 3.0% (2.0%) in Ireland to 7.2% (4.8%) in Turkey. In LH bias
248 ranges from 0.0 mmol/mol (0.0%) in Greece to -1.2 mmol/mol (-0.11%) in South
249 Africa (2 laboratories). The between laboratory CV ranges from 3.1% (2.1%) in Italy
250 to 6.4% (4.2%) in Greece. The data are plotted in the QTmodel in Fig 2 A and B.
251 There are substantial differences in performance per country. The best performing
252 countries are approaching the bronze performance criterion line (Ireland in WB; Italy
253 in LH) whereas other countries are outside the 2 sigma criterion (Turkey and
254 Switzerland in WB; Greece and Austria in LH). In other words: the total error in the

255 best performing countries (approximately 3 mmol/mol; 0.27%) is half of the total error
256 in countries with the poorest performance.

257

258 A remarkable phenomenon was observed in Austria: the 11 laboratories using the
259 Abbott enzymatic test had an excellent BLCV of 2.6% (1.8%) but a high bias of -5.8
260 mmol/mol (-0.53%; tables 8 and 16 supplemental data). This led to suspicion of a
261 matrix effect with the LH samples. However no difference in results with WB or LH
262 was seen when samples were measured with the Abbott enzymatic test at the IFCC
263 Reference laboratory (results not shown). This suggests a specific standardization
264 issue with the Abbott assay in Austria. When the results of the 11 labs were omitted
265 from of the calculations for Austria, bias and BLCV dropped substantially and the
266 overall Austrian performance moved from outside the criterion (AT in Fig. 2B) to
267 within the criterion (A* in Fig. 2B).

268 The data points representing the respective countries are all close to the horizontal
269 and distant from the vertical axis. Thus, like for the overall performance, traceability
270 to the IFCC RMP is achieved in all countries and remaining total error stems mainly
271 from between laboratory variation.

272

273 *Per Manufacturer*

274 Detailed results per manufacturer are in the supplemental data and divided into
275 results of manufacturers with 6 or more laboratories (n = 40; tables 2,6,10,14) and
276 manufacturers with less than 6 laboratories (n = 29; tables 3,7,11,15). In the small
277 groups relevant conclusions can not be made and therefore only the condensed data
278 of manufacturers with 6 or more laboratories are shown in Table 2 and Fig. 2. Fig. 2
279 C and D show that there are substantial differences between manufacturers.

280 Excellent performance is seen with WB (A) and LH (H) but there are also poor
281 performers (S and K in WB; T and A in LH). In general the data points for the
282 manufacturers are quite close to the horizontal and distant from the vertical axis.
283 From this it can be concluded that the majority of manufacturers achieved traceability
284 to the IFCC RMP. Total error at the manufacturer level mainly came from between
285 laboratory variation.

286

287 *By Manufacturer and by Country*

288 Fig. 3 shows the performance per manufacturer per country for manufacturers with at
289 least 6 laboratories using their test in at least 4 countries. For some manufacturers
290 the data points are close to each other which implies that performance in the
291 countries is similar (Fig. 3G and 3F). However for Roche using WB there are
292 differences between the countries: good results in Sweden, the Netherlands and UK
293 and quite poor in Switzerland and Turkey (Fig. 3C2). Differences between countries
294 for the assay of a manufacturer can be laboratory based and be related to
295 maintenance, rigidity of quality management or training/motivation of the staff. They
296 can also be manufacturer based and be related to training and education of the
297 customers and batch-to-batch management of calibrators and reagents. Like in the
298 previous sections the major contribution to total error derived from between
299 laboratory variation.

300

301 *Fresh Whole Blood and Lyophilized Hemolysate*

302 In the EurA1c trial both WB and LH were used. In principle WB is the ideal sample: it
303 is patient material and thus commutable per definition, but sample stability limits its
304 use. General ageing causes lysis, glucose consumption by erythrocytes (formation of

305 lactic acid lowers pH), spectral changes (browning) and additional hemoglobin
306 fractions. Glycation (HbA1c formation) may proceed during storage. Ageing
307 processes mean that WB is a dynamic specimen that may change characteristics
308 over time depending on shipment time and temperature, resulting in different
309 properties from laboratory to laboratory over wide geographical areas with differing
310 infrastructures and thus different HbA1c results. Results of Italian laboratories in WB
311 are slightly higher than in other countries. This may reflect differences in shipment
312 temperature (Italian samples were shipped on cool packs). It is not clear if the
313 difference is significant at all, and if yes, if there is a negative impact on shipment on
314 cool packs (increased lysis) or at ambient temperature (ageing). LH does not have
315 stability problems but may have commutability issues. Before lysis plasma is
316 removed and cell-debris is removed. The reconstitution volume is such as that the
317 hemoglobin concentration is equal to WB but matrix changes may have an impact. It
318 is assumed that LH may not be commutable with the Roche assays. However,
319 EurA1c results (bias in WB -0.9 mmol/mol/0.08%; bias in LH -0.1 mmol/mol/0.01%)
320 show only a small difference between the matrices and it is not clear whether this
321 difference derives from non-commutability of LH or from instability of WB blood.
322 Lyophilized material is not suitable for (point of care) methods that can only work with
323 whole blood. Inappropriate reconstitution may also cause complications. It must be
324 taken into account that the manufacture of LH, in general, – and thus the
325 commutability- varies widely per manufacturer (use of cryolyoprotectants and
326 native/artificial HbA1c). In summary: with WB samples there is doubt around sample
327 stability and with LH there is doubt around commutability. The EurA1c trial showed
328 that bias and BLCV are comparable for both matrices. Probably the impact of
329 instability of WB and non-commutability of LH is low but it should be stressed that this

330 is only true for the specimens and test conditions in this study. With knowledge of the
331 limitations and in the proper setting, both WB and LH are suitable for EQA purposes.
332 EQA organizers balance the advantages and disadvantages of both sample types. In
333 countries with fast and reliable communication links where the whole logistic chain of
334 blood donation, dispensing/packaging of the samples, shipment and measurement in
335 the laboratories is feasible within one working week WB is the specimen of choice. In
336 countries where this is not possible, LH will be used.

337

338 *State of the art*

339 The EurA1c results show that the present state of art of HbA1c measurement in
340 relation to quality targets can be summarized in one number: a total error of
341 approximately 5 mmol/mol (0.46%). In words: if HbA1c of a patient is measured in
342 one of the 2166 laboratories that participated in the EurA1c trial, it can be expected
343 that 1 out of 20 laboratories will report a result that will differ 5 mmol/mol (0.46%) or
344 more from the true value.

345 Results have shown that the major contribution to total error was derived from the
346 between laboratory variation. The low bias observed suggests that the main
347 manufacturers have made significant improvements in the calibration of their
348 instruments to align with the consensus statement, which dictates the use of the
349 IFCC RMP. To achieve further improvement, the focus should be on reducing the
350 between laboratory variation. A starting point for such improvement is knowledge of
351 the causes. The EurA1c trial attempted to elicit some of these causes by
352 investigation of a number of factors. Figures 2 and 3 show that there are substantial
353 differences: between countries and between manufacturers. In addition the
354 performance of laboratories using the test of the same manufacturer can be (but is

355 not always) quite different per country. The data do not allow a clear conclusion on
356 the cause of poor performance. One can speculate that it is a combination of factors.
357 Due to e.g. financial pressure, quality may have a different priority. In case of low
358 priority, the attitude of the laboratories towards quality will be lower.

359

360 *Clinical considerations*

361 The quality target in the QTmodel is a total allowable error of 5 mmol/mol (0.46%).
362 Thus if the true value is 43 mmol/mol (6.1%) results between 38 and 48 mmol/mol
363 (5.6 to 6.5%) are acceptable. One can argue that an error of 5 mmol/mol (0.46%) is
364 good enough for monitoring of diabetic control, but questionable for diagnosis: the
365 clinical interpretation of 38 or 48 mmol/mol (5.6/6.5%) is quite different. The
366 community of laboratory medicine should aim for a tighter quality goal, closer to the
367 “bronze” target of 3.3 mmol/mol (0.30%) in the QTmodel.

368

369 *Strengths and Weaknesses*

370 The strengths of EurA1c include the scale, rigour and quality of the study with
371 international oversight from the C-EUBD resulting in an overview of the state of the
372 art of HbA1c measurement with comparisons between countries and manufacturers.
373 However there are also weaknesses. A weak point is that a number of laboratories
374 did not report their method (group “unknown”) and that EQA organizers have different
375 definitions of the same method. Striking examples are the tests of Roche: definitions
376 are “instrument type”, “generation 2 or 3 reagent”, “whole blood/hemolysate mode” or
377 simply “Roche Tina-quant”. The approach of the EurA1c evaluation was to consider
378 all Roche results as one group, whilst not ideal the differentiation into all variables
379 would reveal 16 Roche methods which is not ideal either.

380

381

382 **Conclusions**

383 A trial like EurA1c with collaboration of many EQA organizers was possible. With
384 some limitations, WB specimens and well-defined LH appeared suitable for purpose.

385 The state of the art was a total error of 5 mmol/mol at the 2 sigma level.

386 Differentiation of the results showed substantial differences between countries and
387 between manufacturers. Traceability to the IFCC RMP was a minor issue; total error
388 derived mainly from between laboratory variation. International studies like EurA1c
389 trigger all parties involved in HbA1c measurement to consider and improve quality
390 and thus to work on better patient care. Therefore the IFCC C-EUBD will continue to
391 organize the trial yearly. EurA1c has Eurocentric roots but participation is open to
392 non-European countries.

527

528 **Figure Legends**

529

530 **Fig.1. Design of the European HbA1c Trial**

531 Donation (yellow) from which fresh whole blood (green) and lyophilized hemolysate
532 (pink) samples are prepared and used in the respective countries (blue). Supporting
533 tests (grey). Countries: Austria (AT), Belgium (BE), Switzerland (CH), Czech
534 Republic (CZ), Germany (DE), Spain (ES), France (FR), Greece (GR), group of
535 individual laboratories in multiple countries (I), Ireland (IE), Italy (IT), the Netherlands
536 (NL), Portugal (PT), Sweden (SE), Turkey (TR), United Kingdom (UK), South Africa
537 (ZA).

538

539 **Fig 2. Performance per Country (A,B) and per Manufacturer (C,D)**

540 Mean between laboratory CV is on the horizontal axis; mean absolute bias on the
541 vertical axis. The black star represents the overall performance of all laboratories. In
542 Fig. A and B the circles and squares represent the countries (for abbreviations see
543 legend of Fig. 1; A* is Austria without Abbott enzymatic Test users). In Fig. C and D
544 the circles and squares represent the manufacturers: Abbott Architect Enzymatic test
545 (A), Abbott Architect Immunochemical test (B), Abbott test not specified (C), Alere
546 Afinion (D), Beckman Coulter AU systems (E), Beckman Coulter Unicell DxC
547 systems (F), Bio-Rad D10 (G), Bio-Rad D100 (H), Bio-Rad Variant II (J), Medinor (K),
548 Menarini-ARKRAY HA-8160 (L), Menarini-ARKRAY HA-8180 (M), not-specified
549 methods (N), Roche (O), Sebia Capillarys 2 Flex Piercing (P), Sebia Capillarys 3
550 Tera (Q), Sebia MiniCap (R), Siemens Advia (S), Siemens DCA/Vantage (T),
551 Siemens Dimension (U), Siemens not specified (V), Tosoh G7 (W), Tosoh G8 (X),
552 Trinity Biotech Premier Hb9210 (Z). The bias on the y-axis is absolute; to differentiate

553 between positive and negative bias, circles represent positive and squares negative
554 bias.

555

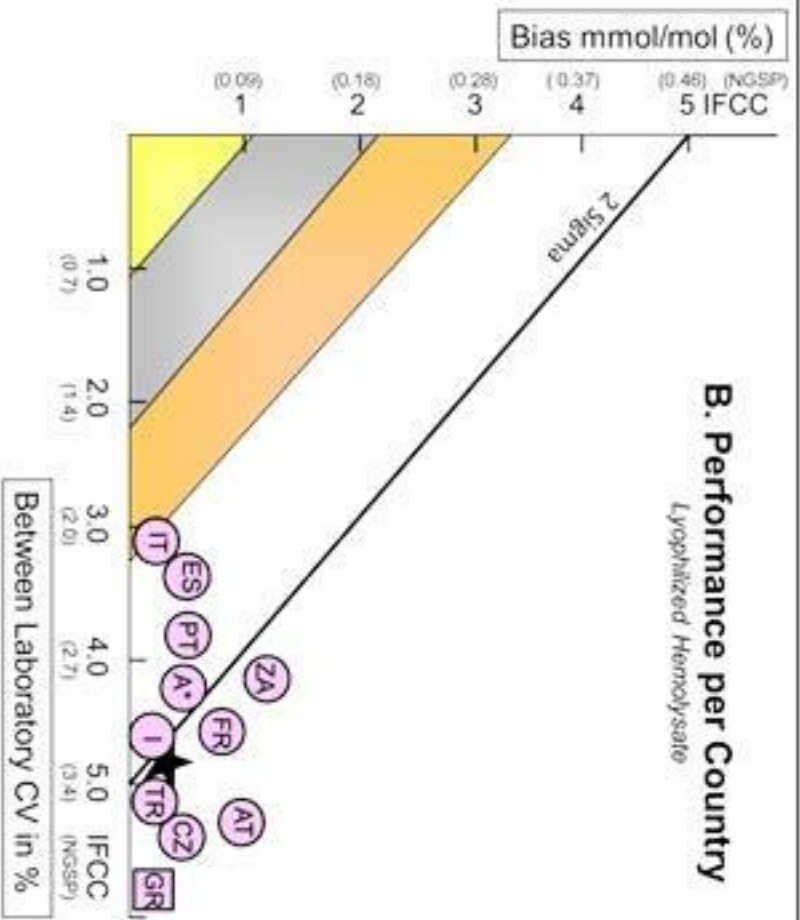

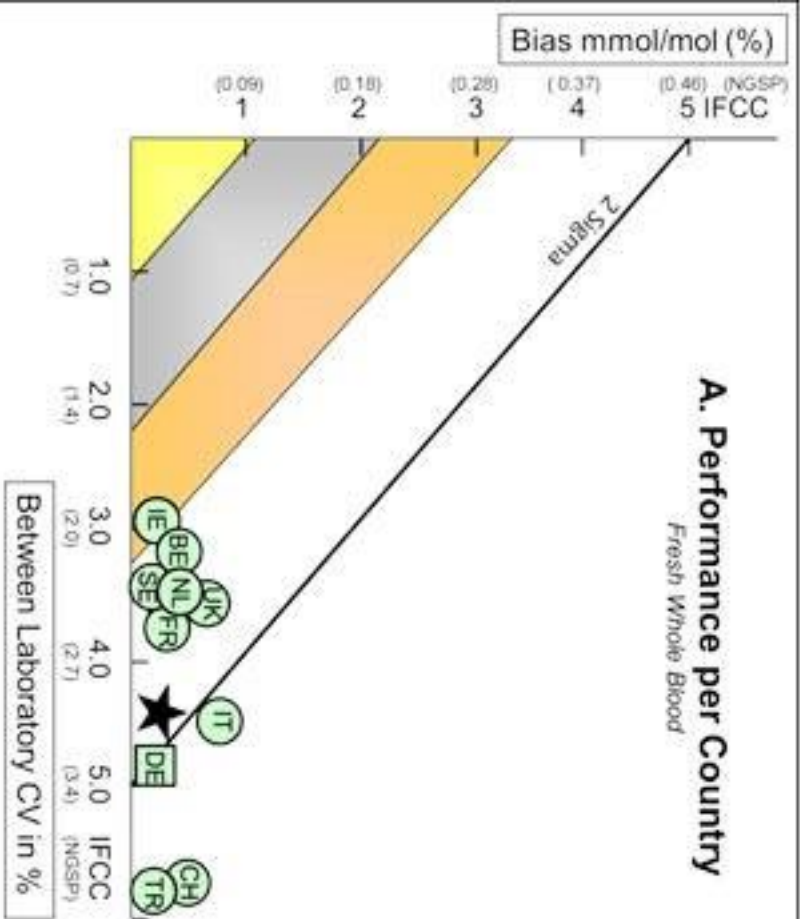

556 **Fig. 3. Performance per Manufacturer per Country**

557 Performance per manufacturer per country in lyophilized and fresh whole blood for a
558 selection of major manufacturers. The black star represents the overall performance
559 of all laboratories in the groups. The circles and squares show the performances per
560 country within the respective manufacturer groups. The bias on the y-axis is
561 absolute; to differentiate between positive and negative bias, circles represent
562 positive and squares negative bias. For scaling, see legend of Fig. 2. For country
563 abbreviations see legend of Fig 1.
