18	Running Head: Dietary shift in Japanese scallop

## **Abstract**

- Ontogenetic niche shifts in diet are a consequence of changes in body size or resource 20 partitioning between age classes. To better resolve the feeding patterns of the Japanese 21 scallop Mizuhopecten yessoensis, we examined the relative importance of age and size 22 in the diet of this species using stable isotope ratios of carbon ( $\delta^{13}$ C) and nitrogen ( $\delta^{15}$ N) 23 from 2006 to 2009. Contribution of food sources was quantified using an isotope 24 mixing model by comparing the muscle tissue isotope ratios to those of suspended 25 particulate organic matter (SPOM) and their zooplankton prey (e.g. micro- and meso-26 zooplankton). Unlike the  $\delta^{13}$ C values which remained constant with age and size, 27 muscle  $\delta^{15}$ N values were more positively correlated with age accounting for 69% of 28 variations than size with only 46%. Increasing <sup>15</sup>N values with age suggested that shifts 29 in diet from SPOM to micro- and meso-zooplankton occurred during ontogeny in M. 30 yessoensis. Results of the isotope mixing model indicated that SPOM contribution to 31 scallop's diet decreased from 68% to 8% while those of zooplankton increased from 15 32 to 50% with increasing age. This study concludes that age-related dietary shift explains 33 the enrichment of <sup>15</sup>N, as a result of predation on zooplankton by M. yessoensis. 34

### Introduction

Ontogenetic diet shifts are common among invertebrates, as a direct consequence of increase in body size [1] or resource partitioning between age classes. Body size is one of the most fundamental traits that affect individual characteristics determining food acquisition [2]. The age of the individuals however, is related with resource use capability [3]. Age-related shifts in diet composition lead to decreased potential intraspecific competition for resources [4,5]. As a predator ages, it will feed on larger and high quality food sources to meet the required energy for growth and reproductive functions [6] and an ontogenetic change in diet is expected to occur [7,8].

For a long time, scallops feed mainly on phytoplankton [9] and sinking particles [10,11], even though other larger zooplankton has been found in the guts of marine bivalves [9]. It has been shown that bivalves are not only herbivores, but omnivores that feed on bacteria, nano-zooplankton and micro-zooplankton [12–14]. In fact, mussels are reported to have assimilated about 37 to 54% of meso-zooplankton, an evidence of a strong trophic link between mussels and zooplankton [14]. Scallops reared at Lake Saroma, Hokkaido, Japan feed not only on suspended particulate organic matter (SPOM) but also on zooplankton [15].

Stable isotope analysis of carbon ( $\delta^{13}$ C) and nitrogen ( $\delta^{15}$ N) are now 54 increasingly used to estimate trophic position and the food sources of marine organisms 55 [16–18]. The  $\delta^{15}$ N of an animal tissue is enriched by 3-4% relative to its diet [19] while 56  $\delta^{13}$ C is less, about 1‰ [20]. Several studies have shown that factors such as age or size 57 are known to influence the isotopic composition of bivalve tissues. For instance, large 58 differences in  $\delta^{15}$ N occur with size, particularly in mussels and fishes than with age 59 [19,21] but not in walleye [22]. Hence, it is necessary to re-examine the importance of 60 these factors as determinants of ontogenetic niche shifts in diet of many bivalve species. 61 The Japanese scallop Mizuhopecten yessoensis (Jay, 1857) is a commercially 62 important temperate scallop reared in the coastal waters of northern Japan. It is 63 cultivated using the "rotational" harvesting system, where a particular culture zone is 64 seeded with juveniles after the adult-sized individuals are harvested [23]. Previous 65 studies have analyzed some aspects of Mizuhopecten yessoensis biology and ecology, 66 including distribution and abundance [24], recruitment [23], and feeding rates [25,26]. 67 However, information concerning the ontogenetic dietary changes of this species is not 68 known. 69 Therefore, this study aimed (1) to examine age and size-specific shifts in the diet 70

of Japanese scallop; and (2) to estimate the contribution of suspended particulate

organic matter (SPOM) and zooplankton prey in the scallop's diet using stable isotopes of  $\delta^{13}$ C and  $\delta^{15}$ N. We hypothesized that if the ingestion of  $^{15}$ N-rich larger zooplankton is responsible for the heavy nitrogen found in adult scallops, then it follows that juvenile individuals should have a lighter nitrogen isotope ratio, similar to that of phytoplankton-derived organic matter.

Materials and Methods

79 Study area

The study was carried out in Tokoro, Sea of Okhotsk (44°13'N, 143°55'E), where there is an extensive culture of Japanese scallops on the seabed (**Figure 1**). It measures a maximum depth of 40–65 m. The sediments are mainly coarse sand or pebbles [27]. In the spring and autumn 2007, surface salinity ranges from 32.3 to 34.1. The fishing ground is divided into four culture zones (Zone A to D), where each zone contains different age class at a given time [24].

86

87

Sampling and analyses

Suspended particulate organic matter (SPOM) was sampled at Station S-O (44°10′N and 143°58.9′E) between May and November 2007, July 2008, and July 2009. Depth-

integrated water samples for SPOM were collected with a 10–L Niskin bottle attached to a Kevlar wire from 0, 10, 20, 30 and 40 m depths. SPOM (1 to 2 L) samples were filtered onto pre-combusted (450°C for 5 h) Whatman GF/F (25 mm) glass fiber filters immediately after collection.

Zooplankton samples were collected with vertical net tows from bottom to surface at Station S-0 with NORPAC nets of 100 and 330  $\mu$ m mesh sizes during the same collection dates with SPOM and stored either in a 125 or 250 mL wide-mouth polyethylene (PE) bottle. Zooplankton fractions (100–330  $\mu$ m and >330  $\mu$ m) were filtered onto pre-weighed, pre-combusted (450°C for 5 h) Whatman GF/F glass fiber (25 mm) filters.

Scallop individuals in four age classes (1<sup>+</sup>- to 4<sup>+</sup>-year-old) from six cohorts were obtained monthly either from April or July to December in three seasons (2006–2008) and May 2009, except during the winter months. Shell height was measured to the nearest 0.1 mm using a vernier caliper. Soft tissues were dissected and muscle samples were removed, washed with Milli-Q water and weighed.

All samples were stored at -30°C until analysis. Small portion of muscle samples were freeze-dried and ground with mortar and pestle. Lipids were extracted from muscle tissues using the modified "Folch" extraction method [28]. SPOM and

zooplankton filters were freeze-dried and exposed to HCl fumes for 4 h to eliminate inorganic carbon.

All samples were measured for elemental and stable isotopes. About 1 mg of 110 two to three muscle samples were weighed with a microbalance and packed in tin 111 capsules for analysis. SPOM filters were put in tin capsules and fashioned into a tablet 112 using a hand compressor. Zooplankton that was retained on the filters (1 to 1.5 mg for 113 100–330 μm and 1.5 to 2 mg for >330 μm fractions) were scraped carefully, prepared in 114 duplicate and placed in tin capsules and folded. Stable isotope ratios of carbon and 115 nitrogen were measured with a Thermo Electron Delta V Plus Continuous Flow IRMS 116 (Bremen, Germany) attached to a Thermo Electron Flash Elemental Analyzer 1112 117 Series (Milan, Italy). Precision was better than 0.2% for both  $\delta^{13}$ C and  $\delta^{15}$ N estimated 118 119 with alanine and tyrosine as internal standards (Kyoto University, Kyoto, Japan). Stable isotope ratios are expressed in delta notation ( $\delta^{13}$ C or  $\delta^{15}$ N) and are reported in per mil 120 (‰) using the equation:  $\delta^{13}C_{\text{sample}}$  or  $\delta^{15}N_{\text{sample}} = (R_{\text{sample}}/R_{\text{standard}} - 1)$ , where R 121 = <sup>13</sup>C/<sup>12</sup>C or <sup>15</sup>N/<sup>14</sup>N with Vienna Pee Dee Belemnite (VPDB) and atmospheric nitrogen 122 as international reference standards for  $\delta^{13}$ C and  $\delta^{15}$ N, respectively. Delta  $\delta^{13}$ C 123 values are normalized using VPDB-LSVEC calibration curve. 124

126 Data analyses

All statistical analyses were done using the Number Cruncher Statistical System (NCSS, 07.1.4 version) 2007 software [29]. We applied one-way analyses of variance (ANOVA) to test significant differences in  $\delta^{13}$ C and  $\delta^{15}$ N values among scallop populations and post hoc Tukey's-Kramer test was used when significant differences were detected. Linear regression analysis was performed to examine relationships between muscle tissue  $\delta^{13}$ C and  $\delta^{15}$ N values, and their age and size. Prior to regression analysis, the actual age of scallops was recalculated from the difference between sampling dates and seeding time (3<sup>rd</sup> week of May until 1<sup>st</sup> week of June) and expressed as fractions of a year.

Scallop's trophic position (TP) was estimated based on a 3-year average  $\delta^{15}N$  isotope ratio of SPOM (5.3  $\pm 0.8\%$ ; F. Aya, unpubl. data) and using the average trophic fractionation of 1.7% [16, F. Aya, unpubl. data] where the average trophic level of the Japanese scallop can be calculated as [30]:

 $TP = 1 + (scallop \ \delta^{15}N - SPOM \ \delta^{15}N) \ / \ 1.7 \ using SPOM \ as the basal level of the$ 142 food web

To account for the trophic increases among the populations, the percentage  $\delta^{13}$ C and  $\delta^{15}$ N contributions of micro- (PL100–330), mesozooplankton (PL>330) and SPOM to scallops' diet were estimated with an isotope mixing model [31]. The isotopic values of SPOM during 2007 and 2008 at Station S-0 were reported elsewhere [11]. Application of the mixing model required correction of consumer  $\delta^{13}$ C and  $\delta^{15}$ N values using tissue-diet isotopic fractionation values. The difference between isotopic ratios of gut content and that of muscle tissue was used as representation of tissue-diet isotopic fractionation [11, F. Aya, unpubl. data]. Muscle  $\delta^{13}$ C and  $\delta^{15}$ N values were corrected for 3.4‰ and 1.7‰ isotopic fractionation, respectively, prior to analysis [16, F. Aya, unpubl. data]. The contribution is calculated as follows:

155 
$$\operatorname{Mix} \delta^{13}C = f_{\text{SPOM}} * \delta^{13}C_{\text{SPOM}} + f_{\text{PL}100-330} * \delta^{13}C_{\text{PL}100-330} * f_{\text{PL}>330} * \delta^{13}C_{\text{PL}>330};$$

**and** 

157 Mix 
$$\delta^{15}N = f_{\text{SPOM}} * \delta^{15}N_{\text{SPOM}} + f_{\text{PL}100-330} * \delta^{15}N_{\text{PL}100-330} + f_{\text{PL}>330} * \delta^{15}N_{\text{PL}>330};$$

**with** 

$$f_{\text{SPOM}} + f_{\text{PL}100-330} + f_{\text{PL}>330} = 1$$

where the  $\delta^{13}$ C and  $\delta^{15}$ N isotope values of the consumer is the combination of the  $\delta^{13}$ C and  $\delta^{15}$ N isotope values of potential food sources (SPOM, micro- and mesozooplankton) and f is the fractional contribution of a source [31]. The last equation specifies that the fractions must equal to 1.

# **Results**

Suspended particulate organic matter (SPOM) and zooplankton showed no significant differences in  $\delta^{13}$ C (P < 0.05) (Table 1). C/N molar ratios in SPOM and zooplankton were between 6.1 and 6.8, indicating phytoplankton-derived organic material. However, zooplankton, composed of micro- and meso-zooplankton, was 1.2 to 1.5‰ more enriched in  $^{15}$ N than SPOM, suggesting different trophic position between primary producers and zooplankton.

Muscle  $\delta^{15}$ N values significantly increased from 7.2 to 8.3% with age (P < 0.01; Table 2), indicating differences in food preferences and trophic position. The  $\delta^{15}$ N values of age-3<sup>+</sup> and 4<sup>+</sup> scallops were similar and significantly higher than those of age-1<sup>+</sup> and 2<sup>+</sup> individuals (P < 0.05). Muscle  $\delta^{15}$ N were independent of location or site with values ranging from 7.6 to 8.1% (mean = 7.9%). Ontogenetic changes in stable isotope ratios were found for all the cohorts examined, showing significant positive trends of

increasing  $\delta^{15}$ N values with age  $(n = 83, r^2 = 0.69, P < 0.001)$ :  $\delta^{15}$ N = 6.7 + 0.35 (age) (in years) and size  $(n = 83, r^2 = 0.46, P < 0.001)$ :  $\delta^{15}N = 5.3 + 0.02$  (S<sub>H</sub>) (in mm) (**Figures 2a,b**). However, muscle  $\delta^{15}$ N values were highly correlated with age than with size among cohorts, indicating greater influence of age on  $\delta^{15}$ N. On the contrary, the  $\delta^{13}$ C values did not vary significantly among the four age classes (Table 2), although age-1<sup>+</sup> individuals had less depleted  $^{13}$ C. Moreover,  $\delta^{13}$ C values remained constant on average among parameters age and size, in which the  $\delta^{13}$ C values were neither correlated with age nor size (Figures 2c,d). On the average, M. yessoensis occupied a trophic position between 2.3 to 2.7 (Table 3). 

Application of the mixing model to muscle  $\delta^{15}N$  values indicated that SPOM contribution to scallop's diet decreased from 68% to 8%, being the highest in age- $1^+$  and  $2^+$ , and lowest for age- $3^+$  and  $4^+$  individuals (Figure 3, Table 4). However, consumption of zooplankton increased from 15 to 50% as scallop aged (Figure 3, Table 4). These results indicated that *M. yessoensis* to some degree shift their diet from SPOM to zooplankton, potentially influencing the  $\delta^{15}N$  values of this species. However, application of the mixing model to muscle  $\delta^{13}C$  values did not agree well with the isotope values of their presumed potential food sources (Figure 3), indicating that

scallops were preferentially assimilating highly enriched component (i.e. sinking particles [11]) in the suspended organic matter pool.

### **Discussion**

Our study provides information on the relative importance of age as an indicative of dietary change in *Mizuhopecten yessoensis*. It also uncovers an ontogenetic shift in diet wherein juvenile scallops mainly depend on suspended particulate organic matter (SPOM), whereas adult individuals forage on zooplankton as the most important dietary component. We indeed observed with our isotopic dataset that juveniles and adult scallops, independent of age and size, exhibited similar  $\delta^{13}$ C values indicative of similar quality of food sources. This is also evident from the lack of significant relationship between the  $\delta^{13}$ C values for muscle and age or size because of the small variability in the  $\delta^{13}$ C isotopic values. These results however are not supported by previous dietary studies using bivalves [31,32], where carbon isotope ratios showed greater differences than nitrogen isotope ratios. The large differences in  $\delta^{15}N$  between young and adult scallops may suggest that they preferred different food sources but to some extent, scallops still occupied the same trophic position (2.3–2.7). Our estimates of scallop's trophic position supported the results of [33] confirming the herbivorous and detrivorous nature of M. yessoensis. Bivalve species, scallops in particular, are feeding on a mixed diet sources but mainly on phytoplankton [9] or sinking particles in their natural habitats [10,11]. The increase in  $^{15}$ N values with age may result from foraging on zooplankton, which supports the observed enrichment in  $^{15}$ N. The  $\delta^{15}$ N isotope ratios could be expected to increase with age if nitrogen undergoes fractionation during the transamination or deamination process where the lighter  $\delta^{14}$ N is excreted at a faster rate than  $\delta^{15}$ N from the body of some animals [19]. The isotope fractionation, with the lighter isotope reacting faster in each direction of the reversible reactions has been determined to occur during transamination reactions [34]. We may interpret that age is a stronger determinant of the diet of M. yessoensis and the increase of  $^{15}$ N values with age as indicative of the ontogenetic foraging shift from SPOM to zooplankton.

Mizuhopecten yessoensis, as they age and grow, gradually shift their diet from SPOM to zooplankton, and through assimilation, the isotopic ratios of their food sources were reflected in the scallop muscle tissues. Our study indicated significant discrepancy in the isotopic composition between SPOM and zooplankton which may have a large impact on the  $\delta^{15}N$  values observed in the different age classes of M. yessoensis. In fact, a significant increase in  $\delta^{15}N$  values with age in the present study suggests ontogenetic shifts similar to that of freshwater mussels [35] and walleye [22]

and shows that age is a stronger determinant of dietary change than size. However, previous studies on mussels [19] and rainbow smelts [21] failed to identify any significant change of  $\delta^{15}N$  with age. The percentage of the total variation in  $\delta^{15}N$  as explained by size (46%) was lower than those accounted for by age (69%), possibly due to constant growth among adult scallops. Indeed, *M. yessoensis* reached an asymptote size of 126 mm between age-3<sup>+</sup> and 4<sup>+</sup>, the difference in growth rate between these age classes was not significant [F. Aya, unpubl. data].

Our analysis of the isotope mixing model supports the hypothesis that juveniles (age-1<sup>+</sup> and 2<sup>+</sup>) exploit higher proportion of SPOM than adults (age-3<sup>+</sup> and 4<sup>+</sup>), possibly due to difference in foraging capabilities. Juveniles have small mouth gape which limits their consumption to SPOM, whereas adult individuals, with larger mouth gape size, can feed on a wider range of prey including SPOM to large-sized food sources such as zooplankton. Previous work on the same species showed that for juveniles, sinking particles, composed of aggregated fresh microalgae, are considered more important energy source although they also consumed SPOM [11]. This explains the higher contributions of SPOM for the age-1<sup>+</sup> and 2<sup>+</sup> scallops, while zooplankton was significantly important for the age-3<sup>+</sup> and 4<sup>+</sup> individuals. Feeding studies analyzing stomach contents of other bivalve species have observed shifts from planktivorous to

piscivorous diets in different size classes [31]. In other studies, zooplankton is considered a potential food source for zebra mussels [14], while larger zebra mussels have been reported to suppress zooplankton abundance [36]. Also, [35] reported that the stomach contents of fan shell *Pinna nobilis* consist of water column calanoid copepods, an indication of exploitation on zooplankton by this species. Older and larger mussel individuals, with larger inhalant siphons, may eat drifting invertebrates or other organisms that feed higher on the food chain [35]. These age-related dietary resource partitioning is consistent with physiological differences arising with age [37]. **However**, the large discrepancy between the diet  $\delta^{13}$ C values and those of scallop muscle tissues could be attributed to the low assimilation of low amount of carbon from ingested material [11].

In summary, the present study demonstrates the greater influence of age than size on  $\delta^{15}N$  isotope ratios of M. yessoensis. Results of the isotope mixing model suggest unequal contributions of SPOM and zooplankton to scallops' diet, indicating gradual shift in prey consumption. These findings explain the potential accumulation of  $^{15}N$  with age, as suggested by a strong nutritional dependence of M. yessoensis on zooplankton.

Figure legends

Figure 1. Sampling stations and culture zones for scallops in the Sea of Okhotsk.

Figure 2. Relationship between muscle  $\delta^{15}N$  and (a) age and (b) size, and between muscle  $\delta^{13}C$  and (c) age and (d) size (as shell height,  $S_H$ ) from different cohorts of *Mizuhopecten yessoensis*.

Figure 3. Dual isotope plots showing the natural  $\delta^{13}$ C and  $\delta^{15}$ N isotope values (mean  $\pm$  SD) of scallop muscle tissues in different age classes and potential food sources (PL100–330, micro-zooplankton; PL>330, meso-zooplankton; SPOM, suspended particulate organic matter). Scallop age classes are denoted by open symbols, with expected diet values after trophic correction of 3.4% and 1.7% for muscle  $\delta^{13}$ C and  $\delta^{15}$ N isotope values, respectively, indicated by solid symbols.

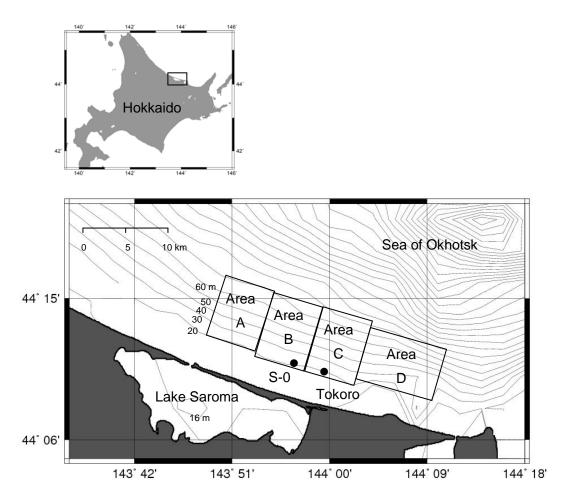

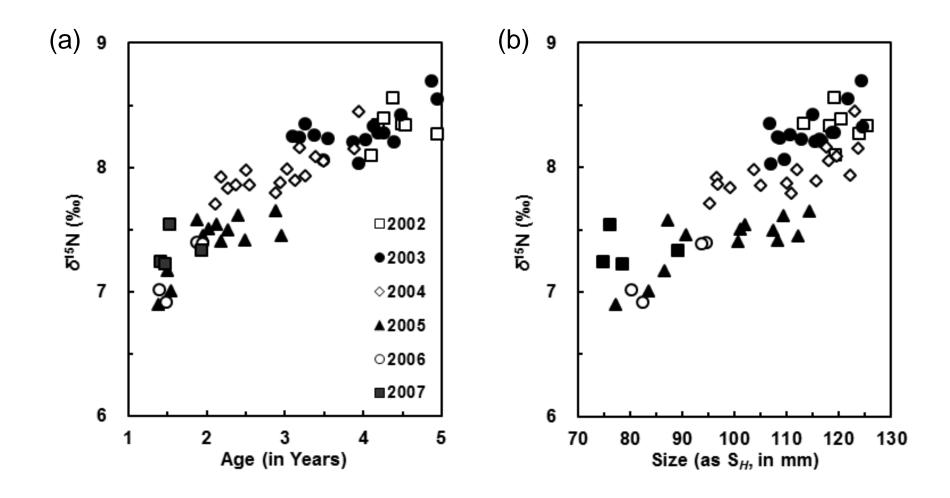

Figure 1

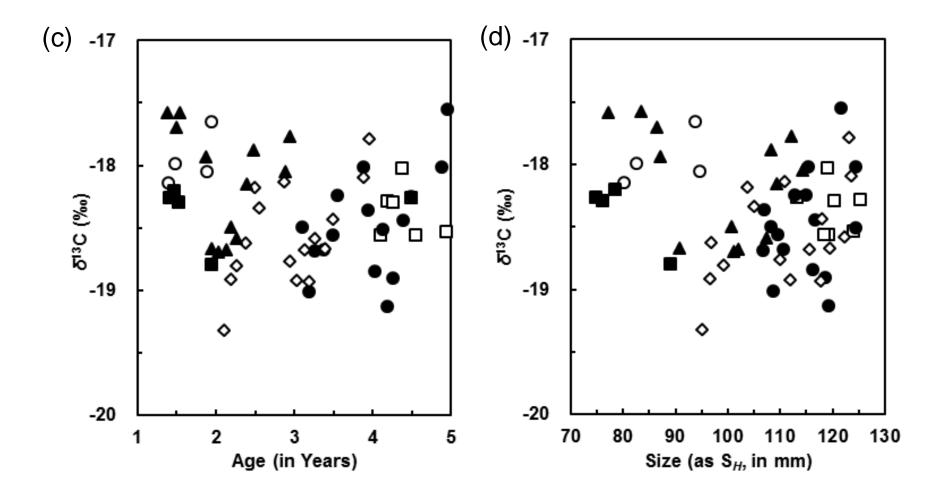

Figure 2

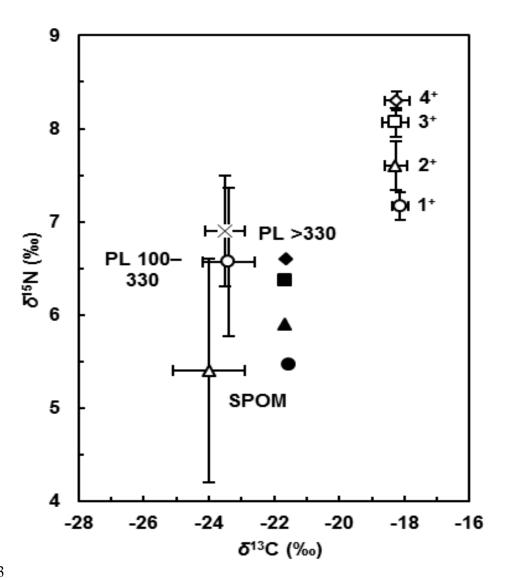

Fig. 3

Table 1 Stable isotopes ( $\delta^{13}$ C and  $\delta^{15}$ N) and carbon to nitrogen (C/N) molar ratios of potential food sources collected at Station S-0, Sea of Okhotsk

Food source	$\delta^{13}$ C (‰)	$\delta^{15}$ N (‰)	C/N molar ratios
SPOM	$-24.0 \pm 1.1 (25)^{a}$	$5.4 \pm 1.2 (24)^a$	$6.1 \pm 1.4^{a}$
Zooplankton			
100–330 μm	$-23.4 \pm 0.8 (8)^{a}$	$6.6 \pm 0.8 (8)^{b}$	$6.7 \pm 1.4^{a}$
>330 µm	$-23.5 \pm 0.6 (8)^{a}$	$6.9 \pm 0.6 (8)^{b}$	$6.8 \pm 0.9^{a}$

SPOM, suspended particulate organic matter. Values in parenthesis represent the number of samples analyzed. Column means followed by a different letter superscript are significantly different at P < 0.05

Table 2 Stable isotope ratios ( $\delta^{13}$ C and  $\delta^{15}$ N) of muscle tissues in different age classes and sizes

Age class	Shell height	N	$\delta^{13}$ C	$\delta^{15}$ N
(in Years)	(mm)		(‰)	(‰)
1+	65-95	13	$-18.1 \pm 0.3^{a}$	$7.2 \pm 0.2^{a}$
$2^{+}$	95-116	24	$-18.3 \pm 0.4^{a}$	$7.6 \pm 0.3^{a}$
3+	108-125	24	$-18.3 \pm 0.4^{a}$	$8.1 \pm 0.2^{b}$
4 <sup>+</sup>	116-127	22	$-18.2 \pm 0.4^{a}$	$8.3 \pm 0.1^{b}$

Column means followed by a different letter superscript are significantly different at P < 0.05

Table 3

Mean trophic position of scallops grouped by age

Age class	N	Mean $\pm$ SD	Range
(in Years)			
1+	13	$2.5 \pm 0.3$	2.1-3.2
$2^{+}$	24	$2.3 \pm 0.1$	2.1-2.4
$3^+$	24	$2.5 \pm 0.2$	2.2-2.9
4+	22	$2.7 \pm 0.2$	2.4–3.0

Table 4 Percentage  $\delta^{13}C$  and  $\delta^{15}N$  contributions of micro- (100–330  $\mu$ m), meso-zooplankton (>330  $\mu$ m) and suspended particulate organic matter (SPOM) to scallops' diet in different age classes. Values represent mean (range).

Age class	Food sources			
(in Years)	SPOM	Zooplankton		
		100–330 μm	>330 µm	
1+	68 (65-70)	18 (0-35)	15 (0-30)	
$2^+$	46 (41-50)	30 (0-59)	25 (0-50)	
3 <sup>+</sup>	19 (12-25)	44 (0-88)	38 (0-75)	
4 <sup>+</sup>	8 (0-15)	50 (0-100)	43 (0-85)	

Table S1 Summary table showing the mean  $\delta^{13}$ C and  $\delta^{15}$ N (‰) values of suspended particulate organic matter (SPOM) sampled from 2007 to 2009 at Tokoro seabed, Okhotsk Sea

Date	δ <sup>13</sup> C (‰)	$\delta^{15}$ N (‰)
2007 ( <i>n</i> = 18)	$-24.7 \pm 0.8$	$5.4 \pm 1.7$
2008 (n = 24)	$-24.0 \pm 0.9$	$4.4 \pm 1.3$
2009 (n = 12)	$-22.7 \pm 0.5$	$6.0 \pm 1.0$
Mean	-23.8	5.3
SD	1.0	0.8

Table S2 Summary table showing the tissue-diet isotopic fractionation values ( $\Delta \delta^{13}$ C and  $\Delta \delta^{15}$ N) among ages of *Mizuhopecten yessoensis* grown at Tokoro seabed, Okhotsk Sea. The difference between isotopic ratios of gut content and that of muscle tissue was used as representation of tissue-diet isotopic fractionation.

Age (in Years)	$\Delta \delta^{13}$ C	$\Delta\delta^{15}{ m N}$
$1^{+}$ ( $n = 12$ )	$3.3 \pm 0.7$	$1.6 \pm 1.0$
$2^{+}$ ( $n = 12$ )	$3.3 \pm 0.9$	$1.3 \pm 0.8$
$3^+$ ( $n = 12$ )	$3.4 \pm 0.7$	$1.6 \pm 1.3$
$4^{+}$ ( $n = 12$ )	$3.7 \pm 0.6$	$2.3 \pm 1.2$
Mean	3.4	1.7
SD	0.2	0.4

Table S3 Mean  $\delta^{13}$ C and  $\delta^{15}$ N (‰) values of muscle tissues from different cohorts of *Mizuhopecten yessoensis* grown at Tokoro seabed, Okhotsk Sea
