#### Abstract

We consider the problem of verifying the security of finitely many sessions of a protocol that tosses coins in addition to standard cryptographic primitives against a DolevYao adversary. Two properties are investigated here - secrecy, which asks if no adversary interacting with a protocol $P$ can determine a secret sec with probability $>1-p$; and indistinguishability, which asks if the probability observing any sequence $\bar{o}$ in $P_{1}$ is the same as that of observing $\bar{o}$ in $P_{2}$, under the same adversary. Both secrecy and indistinguishability are known to be coNP-complete for non-randomized protocols. In contrast, we show that, for randomized protocols, secrecy and indistinguishability are both decidable in coNEXPTIME. We also prove a matching lower bound for the secrecy problem by reducing the non-satisfiability problem of monadic first order logic without equality.

## 1. Introduction

Randomization is used in security protocols to achieve security guarantees such as anonymity (see for example dining cryptographers [11], Crowds [32] and onion routing [27]) and voter privacy in electronic voting (see for example [34]). Automated techniques to formally analyze security protocols are necessary because the design of such protocols is subtle and error-prone. While there has been a lot of work on understanding the computational difficulty of verifying security protocols that do not employ randomness, very little is known when it comes to randomized security protocols; this paper aims to address this void. We consider the problem of verifying security for randomized protocols with a bounded number of sessions. The reason for considering only bounded number of sessions is because it is well known that secrecy is undecidable for non-randomized protocols, in general [25], [23], [17].

The usefulness of a formal analysis crucially depends on a judicious delineation of the powers of an adversary. Given the success of the "Dolev-Yao" adversary model and perfect cryptography in non-probabilistic protocols, we make similar assumptions here. Thus protocol participants send and receive messages over public channel controlled by an omnipotent adversary who tosses coins, reads all messages sent on the channel, and can inject new messages into the network as well. The adversarial behavior can depend
on the entire communication transcript, but the adversary cannot decrypt messages whose key (s)he is not aware of. However, in the presence of coin tossing steps taken by the protocol, new subtleties need to be accounted for. As many researchers have recently observed [12], [7], [26], [10], [9], it is essential that the protocol coin tosses remain private to the protocol participants. In the absence of such guarantees, the analysis can reveal "flaws" where none exist (see examples in [12], [7], [26], [10], [9]).

In order to faithfully model private coin tosses, we follow [5] and our protocol semantics is described using (infinite-branching) partially observable Markov decision processes (POMDPs). POMDPs are often used as models of randomized, nondeterministic systems where some systems states are indistinguishable to a scheduler/adversary, who resolves the process nondeterminism. Indistinguishability among states is captured by an equivalence relation on states, and the assumption that the scheduler/adversary only observes the equivalence class of states, and not the actual states, during a computation. In our formalism, each state of the POMDP consists of the state of the protocol principals (that doesn't include the result of coin tosses) and the frame, the state of the adversary (i.e., the messages received by the adversary). The nondeterminism models the actions of an adversary who chooses both the next message and its recipient. For equivalence of states, we use static equivalence [2]. The adversary must take the same action in two executions with the same view. The view of an execution is the sequence of the equivalence classes of the states and the adversary actions in the execution. Our notion of indistinguishability of views coincides with the traceindistinguishability of applied-pi calculus processes [2].

Our Contributions. In this paper we establish the complexity of checking two properties of randomized protocols, namely, secrecy, and indistinguishability. The secrecy problem asks, given a bounded number of sessions of a randomized protocol, a secret name sec, and probability threshold $p$, is it the case that no adversary learns the secret sec with probability $>(1-p)$ ? Our first result is that this secrecy problem is decidable in coNEXPTIME for randomized protocols.

We outline the ideas behind establishing this decidability result. Recall that the secrecy problem for non-probabilistic
protocols with bounded sessions is coNP-complete [33], [23]. This result for non-probabilistic protocols is established by observing that in the "smallest" attack, any message sent by the adversary is either a subterm of a message received by the adversary (i.e., sent by a protocol participant), or is constructed by a composition of such subterms. Moreover, if the adversary ever composes subterms of messages (s)he sends, then the constructed message must match (ie, unify with) a non-variable subterm of the protocol of the protocol description. This results in observing that the sizes of messages (when encoded as dags), sent in a smallest attack, are linear in the protocol size and gives an NP algorithm to prove insecurity. Unfortunately, these observations no longer hold in the case of randomized protocols. In Example 5.1 on Page 10, we show that there are randomized protocols for which the adversary must send exponential-sized messages in order to break secrecy.

While the strong guarantees of message terseness that hold for non-probabilistic protocols are no longer true, we demonstrate that weaker properties do hold. We show that in the smallest attack, the adversary constructs a new composed message only if in an "equivalent" trace (from the perspective of the adversary's view), the corresponding composed message matches a subterm of the protocol description. This gives us an exponential upper bound on message sizes in the smallest attack, yielding an NEXPTIME algorithm to demonstrate insecurity.

Next we prove that this upper bound is optimal, i.e., we show that the secrecy problem is coNEXPTIME-hard. We establish this result by reducing the non-satisfiability problem for monadic first order logic without equality, which is known to be coNEXPTIME-complete [30]. There are three key ideas that play a role in establishing this result. The first is an observation due to Rusinowitch and Turuani [33] that shows how the satisfiability of propositional logic can be reduced to protocol insecurity. The second observation is that randomization can be used to simulate quantifier alternation, with the adversary making existential choices, and the protocol making universal choices by probabilistic steps. The last ingredient needed is the ability of a randomized protocol to "examine" the contents of an exponential sized message, which underlies the ideas in Example 5.1 on Page 10.

We also consider the problem of checking indistinguishability of two randomized protocols. We say that two protocols $P$ and $P^{\prime}$ are indistinguishable if for each adversary $\mathcal{A}$ and view $\bar{o}$, the sum of probability of executions of $P$ under $\mathcal{A}$ with the view $\bar{o}$ is the same as sum of probability of executions of $P^{\prime}$ under $\mathcal{A}$ with the view $\bar{o}$. We show that the indistinguishability problem for randomized protocols is decidable in coNEXPTIME for randomized protocols. This is achieved once again by bounding the size of the recipes in a bounded attack. We observe that the protocols in our formalism are simple; a protocol is said to be simple if there is no principal-level nondeterminism. As a consequence, our notion of indistinguishability coincides with the notion of trace-equivalence for simple non-probabilistic protocols [19]. This is because in a simple, non-probabilistic
protocol, for each view $\bar{o}$, there can be only one execution with the view $\bar{o}$.

Our last observation is a fixed-parameter complexity result for the secrecy and the indistinguishability problems: if we fix the number of coin tosses but not the number of protocol steps or the size of protocol terms, the secrecy and indistinguishability problems are coNPcomplete. This generalizes the results for checking secrecy of non-probabilistic security protocols, and for checking indistinguishability of simple non-probabilistic protocols [19], which are protocols that fix the number of coin tosses to 0 .

The rest of paper is organized as follows. The syntax of the protocols is presented in Section 2 and the semantics in Section 3. The upper bounds for complexity results are presented in Section 4 and lower bounds in Section 5. We conclude in Section 6.

Related Work. For (non-randomized) security protocols, secrecy was shown to be undecidable in [25], [23], [17], although decidability can be obtained for certain subclasses. For bounded number of sessions, secrecy was shown to be coNP-complete in [33], [23].

For indistinguishability (equivalence) properties of (nonrandomized) security protocols, undecidability is shown in [29]. For bounded number of sessions, decidability is established in [29], [4], [21], [35], [19], [13], [14], [15]. While [29], [35], [13], [14] allow only a limited set of cryptographic primitives (symmetric and asymmetric encryption and cryptographic hash), [21], [4], [35], [19], [15] allow cryptographic primitives modeled as subterm convergent rewrite systems [1]. Furthermore, if the protocols are determinate then the decision problem is also coNPcomplete. Determinate protocols are a generalization of simple protocols described above. [14] is the only decision procedure to consider negative tests, i.e., else branches and non-determinate processes. The complexity of the decision problem for non-determinate protocols remain open.

There are a number of tools that check for security in the non-randomized setting; examples include, MaudeNPA [24], ProverIf [6], AVISPA [3], APTE [13], [14], Scyther [20], Tamarin [31] and AKiSs [8].

## 2. Protocol syntax

We assume the reader is familiar with probability spaces. The set of all discrete measures on a set $S$ will be denoted by $\operatorname{Dist}(S)$. The support of a measure $\mu \in \operatorname{Dist}(S)$ is the set $\{s \in S \mid \mu(s)>0\}$. We will assume that for each $\mu \in$ $\operatorname{Dist}(S)$ the support of $\mu$ is finite. As usual, the set of finite sequences over $A$ will be denoted by $A^{*}$.

### 2.1. Terms, substitutions and frames

Terms. We assume a countable set Pub of public names, and a disjoint countable set Prv of private names that will model secret nonces and secret keys that a protocol participant may use. We assume that there is a countable subset PrivKeys $\subset$ Prv which will model private asymmetric
encryption keys. We assume that there is a countable set PublicKeys $\subset$ Pub which will model public asymmetric encryption keys. Furthermore, we assume that there is a bijection $^{-1}$ : PublicKeys $\rightarrow$ PrivKeys which maps public keys to their corresponding private decryption keys. We use $\mathrm{pk}, \mathrm{pk}_{1}, \ldots$ to range over public encryption keys. For a public encryption key pk , the corresponding private key will be denoted by $\mathrm{pk}^{-1}$. We also assume that the sets Prv $\backslash$ PrivKeys and Pub $\backslash$ PublicKeys are countably infinite.

We assume two sets of function symbols; a set $\mathcal{F}_{c}$ of constructor function symbols and a set $\mathcal{F}_{d}$ of destructor function symbols. The set $\mathcal{F}_{c}$ consists of binary function symbols senc, aenc and the pairing function $[\cdot, \cdot]$. The set $\mathcal{F}_{d}$ consists of binary function symbols sdec, adec and unary function symbols proj $_{1}$ and $\operatorname{proj}_{2}$. senc/sdec will model symmetric encryption/decryption and aenc/adec will model asymmetric encryption/decryption. We assume a countable set of protocol variables $\mathcal{X}$ and a disjoint countable set $\mathcal{X}_{w}$ of frame variables. $\mathcal{X}$ will be used as variables in the protocol description, while $\mathcal{X}_{w}$ will be used to refer to messages received by the adversary. We assume that there is a fixed enumeration $\left\{w_{1}, w_{2}, \ldots,\right\}$ of variables in $\mathcal{X}_{w}$.

Given a set of names $N \subseteq$ Pub $\cup$ Prv, a set of function symbols $F \subseteq \mathcal{F}_{c} \cup \mathcal{F}_{d}$ and a set of variables $X \subseteq \mathcal{X} \cup \mathcal{X}_{w}$, the set of terms built using $F, N$ and $X$ is defined as usual. The subterms of a term $t$ are defined as usual. We will say that a term $t$ is well-formed if for each term $t_{1}, t_{2}$, whenever aenc $\left(t_{1}, t_{2}\right)$ is a subterm of $t$ then $t_{1} \in$ PublicKeys. The set of well-formed terms built using $F, N$ and $X$ will be denoted by $\mathcal{T}(F, N, X)$. As is the case in [33], for the rest of the paper, we will assume that all terms are well-formed ${ }^{1}$. We use $S u b(t)$ to denote the set of subterms of $t$ and $S u b(T)$ to denote the set of subterms of a set of terms $T$. We will write $t \sqsubseteq t^{\prime}$ if $t$ is a subterm of $t^{\prime}$ and $t \sqsubset t^{\prime}$ if $t \sqsubseteq$ $t^{\prime}$ and $t \neq t^{\prime}$. The set of variables occurring in a term is denoted by $\operatorname{vars}(t)$. The set of names occurring in a term will be denoted by names $(t)$. A ground term is one that has no variables appearing in it. We identify the following abbreviations for sets of terms:

- The set of all terms $\mathcal{T}\left(\mathcal{F}_{c} \cup \mathcal{F}_{d}, \operatorname{Prv} \cup \operatorname{Pub}, \mathcal{X} \cup \mathcal{X}_{w}\right)$ will be denoted by Terms.
- The set $\mathcal{T}\left(\mathcal{F}_{c}\right.$, Pub $\left.\cup \operatorname{Prv}, \mathcal{X}\right)$ of constructor terms will be denoted by CTerms.
- The set $\mathcal{T}\left(\mathcal{F}_{c} \cup \mathcal{F}_{d}\right.$, Pub, $\left.\mathcal{X}_{w}\right)$ of recipes will be denoted by Recipes.

Any term $t$ can be viewed as a node-labeled and ordered finite tree, with nodes labeled by either a function symbol, or a name, or a variable. Leaves are labeled by either a name or a variable. Internal nodes are labeled by function symbols, with the number of children being determined by the arity of the function symbol. The edges from an internal node to its children are assumed to be numbered sequentially from

[^0]left to right starting from one; these numbers are considered as the labels of the edges. Now, the position of each node of $t$ can be uniquely represented by the sequence of the labels of the edges on the path from the root to the node, with the root node being represented by the empty sequence. We let $t \mid p$ denote the subterm of $t$ represented by the subtree of $t$ rooted at position $p$. We also let positions $(t)$ denote the set of positions of nodes of $t$. By the height of a term, denoted $\operatorname{height}(t)$, we mean the height of the tree representing $t$; the height of a tree with one node being taken to be 0 . Size of a term $t$ is defined to be the size of the tree representing $t$, i.e., the number of nodes in the tree representing $t$.

Any term $t$ can also be represented as a node-labeled directed acyclic graph (dag) $\operatorname{dag}(t)$ [33], [1]. Each node of $t$ is labeled by either a function symbol or a name or a variable. If a node is labeled by a name or a variable then its out-degree is 0 . If it is labeled by a function symbol $f$ then its out-degree is the arity of the function symbol $f$, and its outgoing edges are assumed to be numbered sequentially from 1 to the arity of the function symbol $f$. Every node $n$ of $\operatorname{dag}(t)$ represents a sub-term of $t$. If the node is labeled by a name (variable respectively) then it represents this name (variable respectively). If n is labeled by a function symbol $f$ of arity $n$ then it represents the term $f\left(t_{1}, \ldots, t_{n}\right)$ where $t_{i}$ is the term represented by the node $\mathrm{n}_{i}$ such that the edge from n to $\mathrm{n}_{i}$ is numbered $i$. Furthermore, we assume that the distinct nodes of $\operatorname{dag}(t)$ represent different subterms of $t$. The dag-size of $t$ is assumed to be the number of vertices of $\operatorname{dag}(t)$ and is the number of distinct subterms of $t$.

We assume that cryptographic operations are modeled via the means of a convergent rewriting system $\mathcal{R}$ on Terms. The set $\mathcal{R}$ consists of

| $\operatorname{adec}\left(\mathrm{pk}^{-1}, \operatorname{aenc}(\mathrm{pk}, y)\right)$ | $\rightarrow$ | $y$ |
| :--- | :--- | :--- |
| $\operatorname{sdec}(x, \operatorname{senc}(x, y))$ | $\rightarrow$ | $y$ |
| $\operatorname{proj}_{1}([x, y])$ | $\rightarrow$ | $x$ |
| $\operatorname{proj}_{2}([x, y])$ | $\rightarrow$ | $y$. |

For $t \in$ Terms, $\operatorname{nf}(t)$ denotes the normal form obtained by rewriting $t$ using $\mathcal{R}$. We write $t_{1}=\mathcal{R} t_{2}$ if $\operatorname{nf}\left(t_{1}\right)=$ $\mathrm{nf}\left(t_{2}\right)$. We also say that a term $t$ is valid, denoted $\operatorname{valid}(t)$, if $\mathrm{nf}(u) \in C$ Terms for any subterm $u$ of $t$.

Substitutions. A substitution $\sigma$ is a function that maps variables to terms. The set $\operatorname{dom}(\sigma)=\left\{x \in \mathcal{X} \cup \mathcal{X}_{w} \mid \sigma(x) \neq x\right\}$ is said to be the domain of the substitution $\sigma$. For the rest of the paper, each substitution will have a finite domain. A substitution $\sigma$ with domain $\left\{x_{1}, \ldots, x_{k}\right\}$ will be denoted as $\left\{x_{1} \mapsto t_{1}, \ldots, x_{k} \mapsto t_{k}\right\}$ if $\sigma\left(x_{i}\right)=t_{i}$. The set $\left\{t_{1}, . ., t_{k}\right\}$ will be denoted by $\operatorname{ran}(\sigma)$. A substitution $\sigma$ is said to be ground if every term in $\operatorname{ran}(\sigma)$ is ground and valid if every term in $\operatorname{ran}(\sigma)$ is valid. A substitution with empty domain will be denoted as $\emptyset$. A substitution can be extended to terms in the usual way. We write $t \sigma$ for the term obtained by applying the substitution $\sigma$ to the term $t$.

Two terms $t_{1}, t_{2}$ are said to be unifiable if there exists a substitution $\sigma$ such that $t_{1} \sigma=t_{2} \sigma$; here $\sigma$ is said to be the unifier of $t_{1}$ and $t_{2}$. We write $m g u\left(t_{1}, t_{2}\right)$ for the most general unifier for $t_{1}, t_{2}$. For the rest of the paper, we assume
that substitutions are in normal form, i.e., for each $x \in$ $\operatorname{dom}(\sigma), \operatorname{nf}(\sigma(x))=\sigma(x)$. Given two substitutions $\sigma_{1}$ and $\sigma_{2}$ such that $\operatorname{dom}\left(\sigma_{1}\right) \cap \operatorname{dom}\left(\sigma_{2}\right)=\emptyset$, we write $\sigma_{1} \cup \sigma_{2}$ as the unique substitution whose domain is $\operatorname{dom}\left(\sigma_{1}\right) \cup \operatorname{dom}\left(\sigma_{2}\right)$ and $\sigma(x)=\sigma_{1}(x)$ if $x \in \operatorname{dom}\left(\sigma_{1}\right)$ and $\sigma(x)=\sigma_{2}(x)$ if $x \in \operatorname{dom}\left(\sigma_{2}\right)$.

Frames. Intuitively, a frame represents the sequence of messages obtained by the adversary. Formally, a frame $\varphi$ is a ground and valid substitution such that $\operatorname{dom}(\varphi) \subseteq \mathcal{X}_{w}$ and $\operatorname{dom}(\varphi)=\left\{w_{1}, w_{2}, \ldots, w_{|\operatorname{dom}(\varphi)|}\right\}$. The set of frames will be denoted by Frames. $\varphi\left(w_{i}\right)$ denotes the $i$ th message received by the adversary. For a frame $\varphi$ with $\operatorname{dom}(\varphi)=$ $\left\{w_{1}, w_{2}, \ldots, w_{n}\right\}$ and a ground term $t$ in normal form, $\varphi \uplus t$ will denote the frame $\varphi^{\prime}$ such that $\left|\operatorname{dom}\left(\varphi^{\prime}\right)\right|=n+1$ and

$$
\varphi^{\prime}\left(w_{i}\right)= \begin{cases}\varphi\left(w_{i}\right) & \text { if } i \leq n \\ t & \text { otherwise }\end{cases}
$$

Intuitively, a term $t$ is deducible if the adversary can compute it using the messages it has received and public names. A valid ground term $t$ in normal form is deducible from a frame $\varphi$ with a recipe $r \in$ Recipes, denoted $\varphi \vdash^{r} t$ if $\operatorname{vars}(r) \subseteq \operatorname{dom}(\varphi), \operatorname{valid}(r \varphi)$ and $\operatorname{nf}(r \varphi)=t$.

Intuitively, two frames are considered statically equivalent if the adversary cannot distinguish them. An adversary tries to distinguish two frames by performing tests. There are two kinds of tests, one for validity of recipes and the second for equality of recipes. Formally, two frames $\varphi_{1}, \varphi_{2}$ are said to be statically equivalent, denoted $\varphi_{1} \sim \varphi_{2}$, if

- $\operatorname{dom}\left(\varphi_{1}\right)=\operatorname{dom}\left(\varphi_{2}\right)$,
- For each recipe $r$ with $\operatorname{vars}(r) \subseteq \operatorname{dom}\left(\varphi_{1}\right)$, $\operatorname{valid}\left(r \varphi_{1}\right)$ iff $\operatorname{valid}\left(r \varphi_{2}\right)$, and
- For each pair of recipes $r, r^{\prime}$ such that $\operatorname{vars}(r), \operatorname{vars}\left(r^{\prime}\right) \subseteq \operatorname{dom}\left(\varphi_{1}\right), \quad \operatorname{valid}\left(r \varphi_{1}\right)$, $\operatorname{valid}\left(r^{\prime} \varphi_{1}\right), r \varphi_{1}={ }_{\mathcal{R}} r^{\prime} \varphi_{1}$ iff $r \varphi_{2}=\mathcal{R}_{\mathcal{R}} r^{\prime} \varphi_{2}$.

Our definition is inspired from [2] and follows more recent definitions, for example [16].
Example 2.1. Let $k$ be a private name and let 0 and 1 be two distinct public names. Consider the two frames $\varphi=$ $\left\{w_{1} \mapsto \operatorname{senc}(k, \mathbf{0})\right\}$ and $\varphi^{\prime}=\left\{w_{1} \mapsto \operatorname{senc}(k, \mathbf{1})\right\}$. These two frames are statically equivalent even though the adversary has different terms. Intuitively, this is because the adversary cannot decrypt the ciphertext. On the other hand, the two frames $\varphi_{1}=\left\{w_{1} \mapsto \operatorname{senc}(k, \mathbf{0}), w_{2} \mapsto k\right\}$ and $\varphi_{1}^{\prime}=\left\{w_{1} \mapsto \operatorname{senc}(k, \mathbf{1}), w_{2} \mapsto k\right\}$ are not statically equivalent as $\operatorname{sdec}\left(w_{2}, w_{1}\right) \varphi_{1}={ }_{\mathcal{R}} \mathbf{0}={ }_{\mathcal{R}} \mathbf{0} \varphi_{1}$ but $\operatorname{sdec}\left(w_{2}, w_{1}\right) \varphi_{1}^{\prime}={ }_{\mathcal{R}} \mathbf{1} \neq \mathcal{R} \mathbf{0} \varphi_{1}^{\prime}$.

### 2.2. Protocols

We define protocols as a finite set of communicating roles. A role models the actions of one participant in one instance of the protocol and all communication is assumed to be mediated by the adversary. Each role performs a finite number of actions. In each action of the protocol participant, the participant receives a message, tosses coins and sends
out a message. We will assume that each protocol role itself is deterministic. Before giving the formal definition, we give an example of a protocol that will be used to illustrate the protocol syntax and semantics.
Example 2.2. We model a simple electronic voting protocol in our formalism. The electronic voting protocol will have 2 voters $A$ and $B$ with public keys $\mathrm{pk}_{\mathrm{A}}$ and $\mathrm{pk}_{\mathrm{B}}$ respectively and an election authority (EA) with public key $\mathrm{pk}_{\mathrm{EA}}$. The two voters will choose amongst two candidates who will be modeled as public names $\mathbf{0}$ and 1 in the set Pub $\backslash$ PublicKeys. The protocol will proceed as follows. Initially, the election authority will generate two private tokens $\mathrm{tk}_{\mathrm{A}}$ and $\mathrm{tk}_{\mathrm{B}}$ and send them to $A$ and $B$ encrypted under their respective public keys. These tokens will be used by the voters as proofs of their eligibility. A voter after receiving its token will send its choice to the EA along with its proof of eligibility encrypted under $\mathrm{pk}_{\text {EA }}$. The EA, after receiving both the votes and checking their validity, tosses a fair coin. If tails turns up then it outputs $A$ 's vote first and then $B^{\prime} s$ vote. The order is reversed if head turns up. The security property that we are interested is that the protocol must respect privacy of votes, i.e., an adversary should not be able to deduce from the results how each voter voted.
Defintion 2.3. A protocol role $R$ is a tuple $\left(S, s_{0}, \prec, \Delta\right)$ where

- $S$ is a finite set of states,
- $s_{0}$ is the initial state,
- $\prec$ is a strict partial order on $S$,
- $\Delta \subseteq S \times C$ Terms $\times \operatorname{Dist}(S \times C$ Terms $)$ is a finite set of transitions such that
- If $(s, t, \mu) \in \Delta$ then $s \prec s^{\prime}$ whenever $\exists t^{\prime} \cdot \mu\left(\left(s^{\prime}, t^{\prime}\right)\right)>0$.
- If $(s, t, \mu)$ and $\left(s, t_{1}, \mu_{1}\right)$ are distinct elements of $\Delta$ then $t$ and $t_{1}$ are not unifiable.
- If $(s, t, \mu) \in \Delta$ then the support of $\mu$ is finite.

Remark: The condition that if $(s, t, \mu)$ and $\left(s, t_{1}, \mu_{1}\right)$ are elements of $\Delta$ then $t$ and $t_{1}$ are not unifiable ensures that a role is deterministic.
Notation: For a transition $\operatorname{tr}=(s, t, \mu) \in \Delta$ we denote $t$ as $l h t(t r)$ (left-hand term of $t r$ ). If the support of $\mu$ is $\left(s_{1}, t_{1}\right), \ldots,\left(s_{n}, t_{n}\right)$ and $p_{i}=\mu\left(\left(s_{i}, t_{i}\right)\right)$ for each $i=1, \ldots, n$, then we write $t r$ as

$$
s: t \Rightarrow\left[s_{1}: t_{1}\right]^{p_{1}} \oplus \cdots \oplus\left[s_{n}: t_{n}\right]^{p_{n}} .
$$

If the $p_{i}=\frac{1}{n}$ for each $i$, we will ignore the superscripts and just write

$$
s: t \Rightarrow\left[s_{1}: t_{1}\right] \oplus \cdots \oplus\left[s_{n}: t_{n}\right]
$$

We use $\operatorname{vars}(\operatorname{tr})$ for $\operatorname{vars}(t) \bigcup \cup_{1 \leq i \leq n} \operatorname{vars}\left(t_{i}\right)$. For the role $R$, we write $\operatorname{vars}(R)=\cup_{t r \in \Delta} \operatorname{vars}(\operatorname{tr})$. Similarly, we use $\operatorname{terms}(\operatorname{tr})=\left\{t, t_{1}, \ldots, t_{n}\right\}$ and $\operatorname{terms}(R)=$ $\cup_{t r \in \Delta} \operatorname{terms}(t r)$. We take $\operatorname{span}(t r)=n$ and $\operatorname{span}(R)=$ $\max _{t r \in \Delta} \operatorname{span}(t r)$. The size of $t r$ is the sum of the sizes of
each term $t, t_{i} \in \operatorname{terms}(t r)$ and the sizes of the numerator and denominator of each $p_{i}$ written in binary.

Example 2.4. We show how EA in Example 2.2 can be specified as a role $R_{E A}$. $R_{E A}$ will have 3 states $s_{0} \prec$ $s_{w} \prec s_{f} . s_{0}$ is the initial state of the protocol, $s_{w}$ is the state in which EA has sent the eligibility token and is waiting for the votes, and $s_{f}$ is the final state of the protocol. There are two protocol transitions:

$$
\begin{aligned}
s_{0}: o k \Rightarrow\left[s_{w}:\right. & {\left.\left[\operatorname{aenc}\left(\mathrm{pk}_{\mathrm{A}}, \mathrm{tk}_{\mathrm{A}}\right), \operatorname{aenc}\left(\mathrm{pk}_{\mathrm{B}}, \mathrm{tk}_{\mathrm{B}}\right)\right]\right] } \\
s_{w}:\left[\operatorname { a e n c } \left(\mathrm{pk}_{\mathrm{EA}},\right.\right. & {\left.\left[\mathrm{tk}_{\mathrm{A}},\left[x, z_{1}\right]\right]\right), \operatorname{aenc}\left(\mathrm{pk}_{\mathrm{EA}},\left[\mathrm{tk}_{\mathrm{B}},\left[y, z_{2}\right]\right]\right] } \\
& \Rightarrow\left[s_{f}:[x, y]\right] \oplus\left[s_{f}:[y, x]\right]
\end{aligned}
$$

Here $o k$ is a public name, $\mathrm{tk}_{\mathrm{A}}, \mathrm{tk}_{\mathrm{B}}$ are private names and $x, z_{1}, y, z_{2}$ are variables. Intuitively, $x$ and $y$ are the votes of $A$ and $B$ respectively, and $z_{1}$ and $z_{2}$ are the nonces used by $A$ and $B$ when sending their votes to the EA. The importance of these nonces will be explained later.

Defintion 2.5. A protocol $P$ with $n$ roles is a tuple $\left(\varphi_{0}, R_{1}, \ldots, R_{n}\right)$ such that $\varphi_{0}$ is a frame and $R_{1}, \ldots, R_{n}$ are roles such that $\operatorname{vars}\left(R_{i}\right) \cap \operatorname{vars}\left(R_{j}\right)=\emptyset$ for $i \neq j$.

In a protocol $P=\left(\varphi_{0}, R_{1}, \ldots, R_{n}\right), \varphi_{0}$ models the initial knowledge the adversary has and $R_{1}, \ldots, R_{n}$ model the different roles executing the protocol $P$.
Example 2.6. Consider the voting protocol given in Example 2.2. We have already described the role $R_{E A}$ in Example 2.4. Now for a voter $v \in\{A, B\}$ and a choice vote $\in\{\mathbf{0}, \mathbf{1}\}, R_{v}$ (vote) will denote the role in which $v$ votes for choice vote. We now describe the role $R_{0}^{A}$ when $A$ votes for candidate $\mathbf{0}$. $A$ has two states $s_{0}^{A} \prec s_{1}^{A}$. Intuitively $s_{0}^{A}$ is the initial state where $A$ is waiting for the token from EA and $s_{1}^{A}$ is the final state for $A$. There is only one transition:

$$
s_{0}^{A}: \operatorname{aenc}\left(\mathrm{pk}_{\mathrm{A}}, t k\right) \Rightarrow\left[s_{1}^{A}: \operatorname{aenc}\left(\mathrm{pk}_{\mathrm{EA}},\left[t k,\left[\mathbf{0}, n_{A}\right]\right]\right] .\right.
$$

Here $t k$ is a variable and $n_{A}$ is a private name used by $A$. We can similarly define the roles $R_{1}^{A}, R_{0}^{B}$ and $R_{1}^{B}$. We assume that the attacker has a private/public key pair, sko ${ }_{0}$ pko. The scenario when $A$ votes for $v_{A}$ and $B$ votes for $v_{B}$ can be described as a protocol $P_{v_{A}, v_{B}}=$ $\left(\left\{w_{1} \mapsto \mathrm{sk}_{\mathrm{O}}\right\}, R_{E A}, R_{v_{A}}^{A}, R_{v_{B}}^{B}\right)$ with three roles and the initial frame containing the knowledge sko.

Remark: In order to model multiple sessions of the same protocol, we will model a principal's action in one session as a separate role.

## 3. Protocol semantics

The semantics of a protocol will be defined using Partially Observable Markov Decision Processes (POMDP)s. We begin by recalling some standard notions from Markov Chains and POMDPs.

### 3.1. Discrete-time Markov Chains (DTMCs)

A DTMC is used to model systems which exhibit probabilistic behavior. Formally, a DTMC is a tuple $\mathcal{M}=$ $\left(Z, z_{s}, \Delta\right)$ where $Z$ is a countable set of states, $z_{s}$ the initial state and $\Delta: Z \hookrightarrow \operatorname{Dist}(Z)$ is a (partial) function which is called the transition function and which maps $Z$ to a (discrete) probability distribution over $Z$. We say that enabled $(z)$ is true iff $\Delta(z)$ is defined. Informally, the process modeled by $\mathcal{M}$ evolves as follows. The process starts in the state $z_{s}$. After $i$ execution steps, if the process is in the state $z$, the process moves to state $z^{\prime}$ at execution step $(i+1)$ with probability $\Delta(z)\left(z^{\prime}\right)$.

An execution $\rho$ of $\mathcal{M}$ of length $m$ is a sequence $z_{0} \rightarrow$ $z_{1} \rightarrow \cdots \rightarrow z_{m}$ such that $z_{0}=z_{s}$ and for each $i \geq 0$, $\Delta\left(z_{i}\right)\left(z_{i+1}\right)>0$. For an execution $\rho$, as given above, we say $\operatorname{last}(\rho)=z_{m}$. The measure of the execution $\rho$ is said to be the product $\prod_{i=0}^{m-1} \Delta\left(z_{i}\right)\left(z_{i+1}\right)$. The set of all executions of $\mathcal{M}$ will be denoted by $\operatorname{Exec}(\mathcal{M})$. For each Markov chain $\mathcal{M}$ that we will construct, there is a bound $L_{\mathcal{M}}$ such that the length of each execution in $\operatorname{Exec}(\mathcal{M})$ is $\leq L_{\mathcal{M}}$.

An execution $\rho_{1}$ is said to be a one-step extension of the execution $\rho=z_{0} \rightarrow z_{1} \rightarrow z_{2} \cdots \rightarrow z_{m}$ if there exists $z_{m+1}$ such that $\rho_{1}=z_{0} \rightarrow z_{1} \rightarrow z_{2} \cdots \rightarrow z_{m} \rightarrow z_{m+1}$. In this case, we say that $\rho_{1}$ extends $\rho$ by $z_{m+1}$. We will say that an execution $\rho$ is maximal if $\rho$ does not have any one-step extension. Notice that the set of all executions of $\mathcal{M}$ forms a labeled tree $\mathcal{T}_{\mathcal{M}}$ whose root node is $z_{s}$. Each node in this tree is an execution of $\mathcal{M}$. For the tree $\mathcal{T}_{\mathcal{M}}$, we take the label of a node $\rho$ to be $\operatorname{last}(\rho)$.

### 3.2. Partially Observable Markov Decision Processes (POMDPs)

POMDPs are used to model processes which exhibit both probabilistic and non-deterministic behavior, where the states of the system are only partially observable. Formally, a POMDP is a tuple $\mathcal{M}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$ where $Z$ is a countable set of states, $z_{s} \in Z$ is the initial state, Act is a (countable) set of actions, $\Delta: Z \times \operatorname{Act} \hookrightarrow \operatorname{Dist}(Z)$ is a partial function called the probabilistic transition relation, $\mathcal{O}$ is a set of observations and $O b s: Z \rightarrow \mathcal{O}$ is a function called the observation function that maps each state to an observation. As a matter of notation, we will write $z \xrightarrow{\alpha} \mu$ whenever $\Delta(z, \alpha)=\mu$. Furthermore, we say that enabled $(z, \alpha)$ is true iff $\Delta(z, \alpha)$ is defined. A POMDP is like a Markov Chain except that at each state $z$, there is a choice amongst several possible probabilistic transitions. The choice of which probabilistic transition to trigger is resolved by an adversary. Informally, the process modeled by $\mathcal{M}$ evolves as follows. The process starts in the state $z_{s}$. After $i$ execution steps, if the process is in the state $z$, then the adversary chooses an action $\alpha$ with probability $p_{\alpha}$ such that $z \xrightarrow{\alpha} \mu$ and the process moves to state $z^{\prime}$ at the $(i+1)$-st execution step with probability $\mu\left(z^{\prime}\right) p_{\alpha}$.

An execution $\rho$ of length $m$ in the POMDP $\mathcal{M}$ is a finite sequence $z_{0} \xrightarrow{\alpha_{0}} z_{1} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ such that $z_{0}=z_{s}$,
and for each $i \geq 0$, there exists $\mu_{i+1}$ with $z_{i} \xrightarrow{\alpha_{i}} \mu_{i+1}$ and $\mu_{i+1}\left(z_{i+1}\right)>0$; the length of an execution will be denoted as length $(\rho)$. The set of all finite executions of $\mathcal{M}$ will be denoted by $\operatorname{Exec}(\mathcal{M})$. For $\rho=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}} z_{2} \cdots \xrightarrow{\alpha_{m-1}}$ $z_{m}$, we write last $(\rho)=z_{m}$ and last_action $(\rho)=\alpha_{m-1}$ if $m>0$. An execution $\rho_{1}$ is said to be a one-step extension of the execution $\rho=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}} z_{2} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ if there exists $\alpha_{m}$ and $z_{m+1}$ such that $\rho_{1}=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}}$ $z_{2} \cdots \xrightarrow{\alpha_{m-1}} z_{m} \xrightarrow{\alpha_{m}} z_{m+1}$. In this case, we say that $\rho_{1}$ extends $\rho$ by $\left(\alpha_{m}, z_{m+1}\right)$. In the rest of the paper we only consider POMDPs $\mathcal{M}$ with the property that there is a bound $L_{\mathcal{M}}$ such that all executions in $\operatorname{Exec}(\mathcal{M})$ have length $\leq$ $L_{\mathcal{M}}$.

Given an execution $\rho=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}} z_{2} \cdots \xrightarrow{\alpha_{m-1}}$ $z_{m}$, the view of $\rho$, written $\operatorname{view}(\rho)$, is the sequence $\operatorname{Obs}\left(z_{0}\right) \alpha_{0} \operatorname{Obs}\left(z_{1}\right) \alpha_{1} \cdots \alpha_{m-1} \operatorname{Obs}\left(z_{m}\right)$. Let $\mathcal{V}$ be the set $(\mathcal{O} \cdot A c t)^{*} \cdot \mathcal{O}$. Observe that $\operatorname{view}(\rho)$ is an element of $\mathcal{V}$. As discussed above, the choice of which transition to take in an execution is resolved by an adversary. Formally, an adversary is a function $\mathcal{A}: \mathcal{V} \rightarrow \operatorname{Dist}(A c t)$. An adversary $\mathcal{A}$ resolves all non-determinism and the resulting behavior can be described by a DTMC $\mathcal{M}^{\mathcal{A}}=(\operatorname{Exec}(\mathcal{M}) \cup($ Act $\times$ $\{\diamond\}), z_{s}, \Delta^{\mathcal{A}}$ ) where $\diamond$ is a special symbol. $\Delta^{\mathcal{A}}((\alpha, \diamond))$ is undefined for each $\alpha \in$ Act. For each $\rho \in \operatorname{Exec}(\mathcal{M}), \Delta^{\mathcal{A}}(\rho)$ is the unique discrete distribution that satisfies the following:

- For each $\rho_{1} \in \operatorname{Exec}(\mathcal{M}), z \in Z, \alpha \in \operatorname{Act}$ such that $z=\operatorname{last}\left(\rho_{1}\right)$ and $\rho_{1}$ extends $\rho$ by $(\alpha, z)$, $\Delta^{\mathcal{A}}(\rho)\left(\rho_{1}\right)=\mathcal{A}(\operatorname{view}(\rho))(\alpha) \cdot \Delta(\operatorname{last}(\rho), \alpha)(z)$,
- $\Delta^{\mathcal{A}}(\rho)((\alpha, \diamond))=\mathcal{A}(\operatorname{view}(\rho))(\alpha)$ if and only if $\operatorname{enabled}(\operatorname{last}(\rho), \alpha)$ is false.

Observe that an execution $\kappa=\zeta_{0} \rightarrow \zeta_{1} \rightarrow \ldots \rightarrow \zeta_{m} \in$ $\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ is such that $\zeta_{i} \in \operatorname{Exec}(\mathcal{M})$ for each $i<m$. $\zeta_{m}$ is either an element in $\operatorname{Exec}(\mathcal{M})$ or a state $(\alpha, \diamond)$ for some $\alpha \in A c t$. Furthermore $\kappa$ is maximal if and only if $\zeta_{m}$ is $(\alpha, \diamond)$ for some $\alpha \in$ Act.
State-Based Safety properties. Given a POMDP $\mathcal{M}=$ $\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$, a set $\Psi \subseteq Z$ is said to be a statebased safety property. An execution $\rho=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}}$ $z_{2} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ of $\mathcal{M}$ is said to satisfy $\Psi$ if $z_{j} \in \Psi$ for all $0 \leq j \leq m$. An execution $\kappa=\zeta_{0} \rightarrow \zeta_{1} \rightarrow \ldots \rightarrow \zeta_{n} \in$ $\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ is said to satisfy $\Psi$, denoted $\kappa \models \Psi$, if whenever $\zeta_{i} \in \operatorname{Exec}(\mathcal{M})$ then $\zeta_{i}$ satisfies $\Psi^{2}$. We say $\mathcal{M}$ satisfies $\Psi$ with probability $\geq p$ against the adversary $\mathcal{A}$ (written $\left.\mathcal{M}^{\mathcal{A}} \models_{p} \Psi\right)$ if the sum of the measures of executions in the set $\left\{\kappa \in\left(\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)\right) \mid \kappa\right.$ is maximal and $\left.\kappa \models \Psi\right\}$ in the DTMC $\mathcal{M}^{\mathcal{A}}$ is $\geq p$. We say that $\mathcal{M}$ satisfies $\Psi$ with probability $\geq p\left(\right.$ written $\left.\mathcal{M}=_{p} \Psi\right)$ if for all adversaries $\mathcal{A}$, $\mathcal{M}^{\mathcal{A}} \models_{p} \Psi$.
Indistinguishability. Recall that $\kappa=\zeta_{0} \rightarrow \zeta_{1} \rightarrow \ldots \rightarrow$ $\zeta_{m} \in \operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ is such that $\zeta_{i} \in \operatorname{Exec}(\mathcal{M})$ for each $i<m$. We will write that $\operatorname{view}(\kappa)$ is $\operatorname{view}\left(\zeta_{m}\right)$ if $\zeta_{m} \in \operatorname{Exec}(\mathcal{M})$ and $\operatorname{view}\left(\zeta_{m-1}\right) \cdot \zeta_{m}$ otherwise. Given a POMDP $\mathcal{M}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$, a sequence $\bar{o} \in$
2. This definition means that we are treating $(\alpha, \diamond)$ as safe iff $\alpha$ is safe for our purposes.
$\mathcal{V} \cup(\mathcal{V} \cdot(A c t \times\{\diamond\}))$ and an adversary $\mathcal{A}$, the probability of $\mathcal{A}$ observing $\bar{o}$, written $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A})$, is the sum of the measures of executions in the set $\left\{\kappa \in\left(\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)\right) \mid \operatorname{view}(\kappa)=\bar{o}\right\}$.

Given two POMDPs $\mathcal{M}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$ and $\mathcal{M}^{\prime}=\left(Z^{\prime}, z_{s}^{\prime}, A c t, \Delta^{\prime}, \mathcal{O}, O b s^{\prime}\right)$ with the same set of actions and observations, we say that $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are distinguishable by an adversary $\mathcal{A}$ if there is an $\bar{o} \in \mathcal{V} \cup(\mathcal{V} \cdot(\operatorname{Act} \times$ $\{\diamond\})$ ) such that $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A}) \neq p r_{\mathcal{M}^{\prime}}(\bar{o}, \mathcal{A})$. We say that $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are indistinguishable if they cannot be distinguished by any attacker. The following proposition states that it suffices to consider only $\bar{o} \in \mathcal{V}$ for indistinguishability (see Appendix B for the proof).
Proposition 3.1. Let $\mathcal{M}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right), \mathcal{M}^{\prime}=$ $\left(Z^{\prime}, z_{s}^{\prime}, A c t, \Delta^{\prime}, \mathcal{O}, O b s^{\prime}\right)$ and $\mathcal{A}$ be an adversary. If there is a $\bar{o} \in \mathcal{V} \cdot($ Act $\times\{\diamond\})$ such that $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A}) \neq$ $\operatorname{pr}_{\mathcal{M}^{\prime}}(\bar{o}, \mathcal{A})$ then there is a $\bar{o}_{1} \in \mathcal{V}$ such that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}\right)$.
Pure Adversaries. An adversary $\mathcal{A}: \mathcal{V} \rightarrow \operatorname{Dist}($ Act $)$ is said to be pure if for each $\bar{o} \in \mathcal{V}, \mathcal{A}(\bar{o})(\alpha)$ is non-zero for exactly one $\alpha \in$ Act. It turns out that it suffices to consider only pure adversaries for safety and indistinguishability properties. Intuitively, an adversary does not gain by tossing coins as it can always choose to do the worst-possible action.
Proposition 3.2. If $\mathcal{M}^{\mathcal{A}} \forall_{p} \Psi$ then there is a pure adversary $\mathcal{A}_{0}$ such that $\mathcal{M}^{\mathcal{A}_{0}} \forall_{p} \Psi$. If $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are distinguishable then they are distinguishable by a pure adversary.
Remark: For a POMDP $\mathcal{M}$ and adversary $\mathcal{A}$ let $\mathcal{M}_{\text {alive }}^{\mathcal{A}}$ be the DTMC obtained from $\mathcal{M}^{\mathcal{A}}$ by removing the set of states $A c t \times\{\diamond\}$. Observe that if $\mathcal{A}$ is a pure adversary then for any execution $\rho$, the transition probability of going from $\rho$ to a state $(\alpha, \diamond)$ in $\mathcal{M}^{\mathcal{A}}$ is either 0 and 1 . An execution $\kappa$ in $\operatorname{Exec}\left(\mathcal{M}_{\text {alive }}^{\mathcal{A}}\right)$ is maximal iff the execution $\kappa \cdot(\alpha, \diamond)$ is maximal in $\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ where $\alpha=\mathcal{A}(\operatorname{view}(\operatorname{last}(\kappa)))$. These facts imply that it suffices to consider $\mathcal{M}_{\text {alive }}^{\mathcal{A}}$ for pure adversaries $\mathcal{A}$ when considering the probability of satisfying a safety property. Similarly, Proposition 3.1 implies that it suffices to consider $\mathcal{M}_{\text {alive }}^{\mathcal{A}}$ and $\left(\mathcal{M}^{\prime}\right)_{\text {alive }}^{\mathcal{A}}$ when distinguishing $\mathcal{M}$ and $\mathcal{M}^{\prime}$.

For the rest of the paper, we will assume that all of our adversaries are pure and we will confuse $\mathcal{M}^{\mathcal{A}}$ by $\mathcal{M}_{\text {alive }}^{\mathcal{A}}$. Note that a pure adversary $\mathcal{A}$ can also be uniquely identified by the function $\mathcal{A}_{\text {pure }}$ from $\mathcal{V}$ to Act such that for each $\bar{o}, \mathcal{A}_{\text {pure }}(\bar{o})=\alpha$ where $\alpha$ is the action such that $\mathcal{A}(\bar{o})(\alpha)=1$. Thus, in the rest of the paper, we will consider a pure adversary to be a function from $\mathcal{V}$ to Act. Also observe that as defined above, the measure of an execution $\kappa \in \operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ is exactly the measure of the execution last $(\kappa) \in \operatorname{Exec}(\mathcal{M})$ where the measure of the execution $\rho=z_{0} \xrightarrow{\alpha_{0}} z_{1} \xrightarrow{\alpha_{1}} z_{2} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ is said to be the product $\prod_{i=0}^{m-1} \Delta\left(z_{i}, \alpha_{i}\right)\left(z_{i+1}\right)$.

### 3.3. Semantics

The semantics of the protocol $P$ is given in terms of a POMDP $\mathcal{M}_{P}$. A state of the POMDP $\mathcal{M}_{P}$ consists of
a state $s_{i}$ of each role, a ground substitution $\sigma$ that maps variables in the protocol to ground terms, the frame $\varphi$ that models the messages that have been received by the adversary, the message received from the adversary before the current state was entered, and the message sent out by the protocol role just before transitioning to the current state. The actions of the POMDP $\mathcal{M}_{P}$ model the actions of the adversary. In an action, the adversary chooses which role will move next and also constructs (using its frame) the message that is sent to that role. The role accepts a message from the adversary only if the message is valid and matches one of the left hand sides of one of its rules.
Defintion 3.3. The semantics of the protocol $P=$ $\left(\varphi_{0}, R_{1}, R_{2}, \ldots R_{n}\right)$ with $s_{i}^{0}$ as the initial state of $R_{i}$ is given in terms of a POMDP $\mathcal{M}_{P}=$ $\left(Z, z_{s}\right.$, Act,$\Delta$, Frames $\left./ \sim, O b s\right)$ where

- $\quad Z=\left\{\left(\left(s_{1}, s_{2}, \ldots s_{n}\right), \sigma, \varphi, \ell\right) \mid s_{i}\right.$ is a state of $R_{i}, \sigma$ a ground substitution, $\varphi$ a frame and $\ell$ is an element in the set $\{\star\} \cup(C$ Terms $\times C$ Terms $)\}$.
- Act $=\{1,2, \ldots, n\} \times$ Recipes .
- $z_{s}=\left(\left(s_{1}^{0}, s_{2}^{0}, \ldots, s_{n}^{0}\right), \emptyset, \varphi_{0}, \star\right)$.
- For a state $z=\left(\left(s_{1}, s_{2}, \ldots s_{n}\right), \sigma, \varphi, \ell\right) \in Z$ and an action $\alpha=(i, r)$, the transition $\Delta(z,(i, r))$ is defined iff there is a transition $t r$ given as

$$
s_{i}: t_{i} \Rightarrow\left[s_{1}^{\prime}: t_{1}^{\prime}\right]^{p_{1}} \oplus \cdots \oplus\left[s_{n}^{\prime}: t_{n}^{\prime}\right]^{p_{n}}
$$

of $R_{i}$ and a ground term $t$ such that

$$
\begin{aligned}
& \mathbf{-} \quad \operatorname{vars}(\operatorname{tr}) \backslash \operatorname{vars}(\operatorname{lh} t(t r)) \subseteq \operatorname{dom}(\sigma), \\
& \mathbf{-} \quad \varphi \vdash^{r} t \text { and } \\
& \mathbf{-} \quad t \text { is valid and unifiable with } t_{i} \sigma .
\end{aligned}
$$

If defined, let $t r$ be the unique transition as given above (uniqueness follows from the fact that $R_{i}$ is deterministic) and $t$ be the term as given above. Let $\sigma^{\prime}=\sigma \cup m g u\left(t, t_{i} \sigma\right)$.
$\Delta(z, \alpha)$ is the unique probability distribution such that for a state $z^{\prime}=$ $\left(\left(s_{1}, s_{2}, \ldots, s_{i-1}, s_{j}^{\prime}, s_{i+1}, \ldots s_{n}\right), \sigma^{\prime}, \varphi \quad \uplus\right.$ $\operatorname{nf}\left(t_{j}^{\prime} \sigma^{\prime}\right),\left(t_{i}, t_{j}^{\prime}\right)$ ), (where $\left[s_{j}^{\prime}: t_{j}^{\prime}\right]$ is one of the options on the right hand side of $t r$ )
$\Delta(z, \alpha)\left(z^{\prime}\right)=p_{j}$ (where $p_{j}$ is the probability for option $\left[s_{j}^{\prime}: t_{j}^{\prime}\right]$ in $\left.t r\right)$.

- The set of observations is Frames $/ \sim$, the set of equivalence classes of the set of frames under static equivalence.
- $\quad \operatorname{Obs}\left(\left(\left(s_{1}, s_{2}, \ldots s_{n}\right), \sigma, \varphi, \ell\right)\right)=\varphi / \sim$.

Remark: Since all our substitutions are in normal form and $t$ is a valid ground term, it follows that $\sigma^{\prime}$ is also a valid substitution in the above definition.
We now define the secrecy and indistinguishability decision problems. For a protocol $P$ with $n$ roles, the size of $P$ is defined to be the sum of sizes of each term in the initial frame, the number of states in each role and the sizes of each transition $t r$ of $P$.
Defintion 3.4. Given a protocol $P$, a name sec $\in \operatorname{Prv}$ and a state $z=\left(\left(s_{1}, s_{2}, \ldots s_{n}\right), \sigma, \varphi, \ell\right)$ of $\mathcal{M}_{P}$, consider
the state-based secrecy property Secret(sec) defined as follows: $z \models$ Secret(sec) iff there is no recipe $r$ such that $\varphi \vdash^{r} \mathrm{sec}$.
Given a rational threshold $p$, a protocol $P$, a name sec $\in \operatorname{Prv}, P$ keeps sec secret with probability at least $p$ (written $P \models_{p} \operatorname{Secret}(\mathrm{sec})$ ) if $\mathcal{M}_{P} \models_{p} \operatorname{Secret}(\mathrm{sec})$.
The secrecy problem is, given a protocol $P$, a secret sec $\in \operatorname{Prv}$ and a probability value $p$, determine if $\mathcal{M}_{P} \models_{p} \operatorname{Secret}(\mathrm{sec})$.
Defintion 3.5. Given protocols $P$ and $P^{\prime}$ with $n$ roles each, $P$ and $P^{\prime}$ are said to be indistinguishable if the POMDPs $\mathcal{M}_{P}$ and $\mathcal{M}_{P^{\prime}}$ are indistinguishable.
The indistinguishability problem is, given two protocol $P$ and $P^{\prime}$, determine if $P$ and $P^{\prime}$ are indistinguishable.

Example 3.6. We continue Example 2.6 on Page 5. Privacy of votes can be modeled as an indistinguishability property [22] as follows. The protocol satisfies privacy of votes if the adversary cannot distinguish the scenario in which $A$ votes for $\mathbf{0}$ and $B$ votes for $\mathbf{1}$ from the scenario in which $A$ votes for 1 and $B$ votes for $\mathbf{0}$, i.e., $P(\mathbf{0}, \mathbf{1})$ is indistinguishable from $P(\mathbf{1}, \mathbf{0})$. This property is true for the electronic voting protocol in Example 2.6. Privacy can also be modeled as secrecy property (see Appendix A). We highlight two things.
First, observe that if the result of coin tosses was made public then $P(\mathbf{0}, \mathbf{1})$ will be distinguishable from $P(\mathbf{1}, \mathbf{0})$. Essentially, if the coin toss had resulted in tails then the attacker will distinguish the two protocols by test whether the first vote output is 0 . This test will succeed in the protocol $P(\mathbf{0}, \mathbf{1})$ and fail in the protocol $P(\mathbf{1}, \mathbf{0})$, revealing $A$ 's vote.
Second, attaching secret names to votes protects vote privacy even if the eligibility tokens are made public after the protocol finishes. For example, if the adversary learns $t k_{A}$ and votes did not have nonces then the adversary will be able to check whether aenc $\left(\mathrm{pk}_{\mathrm{A}},\left[\mathrm{tk}_{\mathrm{A}}, \mathbf{0}\right]\right)$ matches the vote sent by $A$ to reveal the vote of $A$.

### 3.4. Simple adversaries

In order to establish the decidability results, we show that if a protocol is not secure then there is an attack of bounded size. The bounded attack that we construct is going to be a simple attack, which is an adaptation of the notion of simple attacks in non-randomized protocols [18] to our formalism. In order to define a simple attack, we first define simple executions. An execution is simple if for each term $t$, the adversary always uses the same recipe whenever it has to construct $t$.
Defintion 3.7. Given a protocol $P$ and an execution $\rho=$ $\left(g_{0}, \sigma_{0}, \varphi_{0}, \ell_{0}\right) \xrightarrow{\left(i_{0}, r_{0}\right)}\left(g_{1}, \sigma_{1}, \varphi_{1}, \ell_{1}\right) \cdots \xrightarrow{\left(i_{m-1}, r_{m-1}\right)}$ $\left(g_{m}, \sigma_{m}, \varphi_{m}, \ell_{m}\right)$ of the POMDP $\mathcal{M}_{P}$, we say that $\rho$ is simple if for any two recipes $r$ and $r^{\prime}$ such that $r$ is a subterm of $r_{i}$ for some $0 \leq i \leq m-1$ and $r^{\prime}$ is a subterm of $r_{j}$ for some $0 \leq j \leq m-1, r \varphi_{i}=\mathcal{R} r^{\prime} \varphi_{j} \Rightarrow r=r^{\prime}$.

An adversary $\mathcal{A}$ is simple if every reachable state of the DTMC $\mathcal{M}_{P}^{\mathcal{A}}$ is a simple execution.
Defintion 3.8. An adversary $\mathcal{A}$ for a protocol $P$ is said to be a simple adversary if for each execution $\rho_{1} \rho_{2} \ldots \rho_{m}$ of the DTMC $\mathcal{M}_{P}^{\mathcal{A}}, \rho_{i}$ is simple for each $0 \leq i \leq m$.
We have the following:
Proposition 3.9. For a protocol $P$, a name sec $\in \operatorname{Prv}$ and a number $p$, if there is an adversary $\mathcal{A}$ such that $\mathcal{M}_{P}^{\mathcal{A}} \not \vDash_{p}$ Secret (sec) then there is simple adversary $\mathcal{B}$ such that $\mathcal{M}_{P}^{\mathcal{B}} \not \vDash_{p}$ Secret(sec).
Furthermore, if $P$ and $P^{\prime}$ are two protocols such that $P$ and $P^{\prime}$ are distinguishable then there is an adversary $\mathcal{A}$, simple for both $P$ and $P^{\prime}$, such that the POMDPs $\mathcal{M}_{P}$ and $\mathcal{M}_{P^{\prime}}$ are distinguishable by $\mathcal{A}$.

## 4. Decidability proof

We now establish that the secrecy and indistinguishability problems are decidable in coNEXPTIME. We start by showing that the secrecy problem is decidable in coNEXPTIME by proving that the non-secrecy problem is in NEXPTIME; the non-secrecy problem is the one where one needs to determine that $P$ does not keep the secret sec with probability at least $p$. This is done showing the boundedness property: if $P$ does not keep the secret with probability at least $p$ then there is a bound $b$, exponential in the size of the protocol, and a simple adversary $\mathcal{A}$ such that $\mathcal{M}_{P}^{\mathcal{A}} \not \vDash_{p}$ sec and $\mathcal{A}$ only uses recipes whose dag-size is bounded by $b$.

Proof strategy. We recall the strategy used in [33] to prove that the non-secrecy problem in non-randomized protocols is decidable in NP. The proof proceeds by bounding the size of the smallest attack, if one exists. In case of a nonrandomized protocol $P$, the tree $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ for an adversary $\mathcal{A}$ has a single branch. Thus, there is at most one value assigned to each variable $x$ in $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. Let $\sigma$ denote the substitution that maps each variable to the value assigned to it. We say that $t$ is a subterm of $P$ if it occurs either in the initial frame or the lefthand side or the right hand side of a transition or if it is a public name. The proof in [33] relies on the key observation that in the smallest attack, for each variable $x$ there is a $t \in$ $C T e r m s \backslash \mathcal{X}$ which is a subterm of $P$ such that $\sigma(x)=t \sigma$. As the number of subterms of a protocol $P$ is polynomial, this implies that the messages sent by the adversary and the recipes used by the adversary to construct those messages have a polynomial dag-size. Thus, the whole attack can be represented by the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ which is polynomial in the size of the protocol. The NP procedure then guesses this attack.

A natural extension of this strategy for randomized protocols would be to show that the value of a variable $x$ at some node of $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ is the same as the value of a nonvariable subterm $t$ of $P$ at some other node (note that values of variables and terms can be different in different branches). We show that this observation fails for randomized protocols due to the fact that the adversary has to use the same recipe in executions that have the same view.

Example 4.1. Consider a protocol $P$ which has one role $R$. The role $R$ itself has 4 states $s_{0}, s_{1}, s_{2}, s_{3}$ and the following 3 transitions.

$$
\begin{aligned}
& s_{0}: m_{0} \Rightarrow\left[s_{1}: \operatorname{senc}\left(\text { key, } m_{1}\right)\right] \oplus\left[s_{2}: \operatorname{senc}\left(\text { key }, m_{2}\right)\right] \\
& s_{1}:\left[\operatorname{senc}(\operatorname{key}, x), \operatorname{senc}\left(\operatorname{key}, m_{1}\right)\right] \Rightarrow\left[s_{3}: \sec \right] \\
& s_{2}: z \Rightarrow\left[s_{3}: \sec \right] .
\end{aligned}
$$

Here $m_{0}, m_{1}$ and $m_{2}$ are pairwise distinct public names and key, sec are private names. There is a (unique) attack on $P$ that reveals the secret sec with probability 1. The attack initially sends the public name $m_{0}$. As a result, the role $R$ may land in two different states each with probability $\frac{1}{2}$. Note that these two states are indistinguishable. Hence the adversary has to use the same recipe in both branches to send the next message. The adversary uses the recipe $\left[w_{1}, w_{1}\right]$ to send the next message. The secret sec is now revealed with probability $1, x$ gets the value $m_{1}$ in one branch and $z$ gets the value $\left[\operatorname{senc}\left(\right.\right.$ key,$\left.m_{2}\right)$, senc $\left(\right.$ key, $\left.\left.m_{2}\right)\right]$ in the other branch. Observe that the value of the variable $z$ is not the value of a non-variable subterm of $P$.

In our strategy for randomized protocols detailed below, we show that there is a simple attack such that if the adversary uses a recipe $r$ to send a message in an execution $\rho$ then for any $r_{1} \sqsubset r$ such that $r_{1}$ is not a public name or a variable, there must be an execution $\rho^{\prime}$ in which the term deduced by $r_{1}$ matches the value of a term $t \in C$ Terms $\backslash \mathcal{X}$ of the protocol in some branch of the attack tree. This is achieved by showing that if there is a recipe $r_{1}$ which does not satisfy this property then we can replace $r_{1}$ with a fresh public name new and get a new attack. A combinatorial argument is then used to establish that this implies that the dag-size of $r$ must be exponentially bounded.

Boundedness Result. We first define the notion of a recipe size of an adversary $\mathcal{A}$.
Defintion 4.2. The recipe-size of a recipe $r$, denoted $r \operatorname{size}(r)$, is the dag-size of $r$. Given a protocol $P$ and adversary $\mathcal{A}$ for $P$, we say that a recipe $r$ is used by $\mathcal{A}$ if there is an execution $\rho$ of the DTMC $\mathcal{M}_{P}^{\mathcal{A}}$ such that last_action $(\operatorname{last}(\rho))=(i, r)$ for some role name $i$. The recipe-size of $\mathcal{A}, \operatorname{rsize}(\mathcal{A})$ is defined to be the quantity $\max \{r \operatorname{size}(r) \mid r$ is used by $\mathcal{A}\}$.

Theorem 4.3. Let $P=\left(\varphi_{0}, R_{1}, R_{2}, \ldots R_{n}\right)$ and let sec $\in$ Prv. Let $\lambda$ be the total number of transitions in the protocol. Let $\gamma$ be the total number of transitions in the protocol whose span is $>1$. Let $\eta=\max \left\{\operatorname{span}\left(R_{i}\right) \mid 1 \leq i \leq\right.$ $n\}$. Let $\theta$ be the cardinality of the set $\operatorname{subterms}(P)=$ $\operatorname{Sub}(\operatorname{ran}(\varphi)) \cup\left(\cup_{1 \leq i \leq n} \operatorname{Sub}\left(\operatorname{terms}\left(R_{i}\right)\right)\right)$. If $P \quad \not{ }_{p}$ Secret(sec) then there is a simple adversary $\mathcal{A}$ such that $\mathcal{M}_{P}^{\mathcal{A}} \not \models_{p} \operatorname{Secret}(\mathrm{sec})$ and such that $r \operatorname{size}(\mathcal{A}) \leq 3 \theta \lambda \eta^{2 \gamma}$.

Proof: Recall that the POMDP $\mathcal{M}_{P}$ denotes the semantics of the protocol $P$. For a given adversary $\mathcal{A}$, the behavior of the protocol $P$ with respect to the adversary is given by the DTMC $\mathcal{M}_{P}^{\mathcal{A}}$. The actions of the adversary $\mathcal{A}$ are pairs of the form $(i, r)$ where $1 \leq i \leq n$ is a role
name and $r$ is a recipe. The nodes/states of the DTMC are executions of $\mathcal{M}_{P}$ and its transitions are one-step extensions obtained by using the action specified by the $\mathcal{A}$. Every transition advances the state of a role. So a transition cannot be triggered twice in the same execution. As a consequence, the DTMC is a finite tree whose height is bounded by, $\lambda$, the total number of transitions in the protocol. Any path in the tree has at most $\gamma$ nodes who have more than one child. Furthermore, each such node has at most $\eta$ children where $\eta$ be the maximum of spans of each role $R_{i}$. Thus, the total number of branches in the tree is bounded by $\eta^{\gamma}$ and hence the size of the tree is bounded by $\lambda \eta^{\gamma}$.

Assume now that $P$ does not keep sec secret with probability at least $p$. Let $\mathcal{M}_{P}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$ where its components $Z, z_{s}$, Act, $\Delta, \mathcal{O}, O b s$ are as given in Section 2 . This means that there is a simple adversary $\mathcal{A}$ such that $\mathcal{M}_{P}^{\mathcal{A}} \not \models_{p}$ sec. Now consider the DTMC $\mathcal{M}_{P}^{\mathcal{A}}$. Recall that each state of $\mathcal{M}_{P}^{\mathcal{A}}$ is a simple execution $\rho$ of $\mathcal{M}_{P}$ which is a finite sequence $z_{0} \xrightarrow{\alpha_{0}} z_{1} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ such that $z_{0}=z_{s}$, and for each $j \geq 0, z_{j} \xrightarrow{\alpha_{j}} \mu_{j}$ and $\mu_{j}\left(z_{j+1}\right)>0$; here, $\alpha_{j}=\mathcal{A}\left(\operatorname{view}\left(\rho_{j}\right)\right)$ where $\rho_{j}=z_{0} \xrightarrow{\alpha_{1}} z_{1} \cdots \xrightarrow{\alpha_{j-1}} z_{j}$ and $\mu_{j}=\Delta\left(z_{j}, \alpha_{j}\right)$. We view $\mathcal{M}_{P}^{\mathcal{A}}$ as a finite tree $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ where each node is uniquely labeled by a simple execution of $\mathcal{M}_{P}$. For a node n labeled by $\rho$, as given above, its children are all labeled one step extensions $z_{0} \xrightarrow{\alpha_{0}} z_{1} \cdots \xrightarrow{\alpha_{m}} z_{m+1}$ of $\rho$ such that $\alpha_{m}=\mathcal{A}(\operatorname{view}(\rho))$. Observe that $\rho_{m}=\rho$. Furthermore, we will say $\operatorname{prev}(\rho)$ is the execution $\rho_{m-1}$. Observe that the execution $\operatorname{prev}(\rho)$ is the label of the parent of n . Also, recall that, for $\rho$ as given above, $\operatorname{last}(\rho)$ is defined as the state $z_{m}$.

For the execution $\rho$ as given above, let $\alpha_{i}=\left(k_{i}, r_{i}\right)$ for each $0 \leq i \leq m-1$. We say that $\operatorname{Recipes}(\rho)=\left\{r_{i} \mid\right.$ $0 \leq i \leq m-1\}$. We will say that a recipe $r$ originates at $\rho$ if $r \sqsubseteq r_{m-1}$ and $r \nsubseteq r_{i}$ for any $0 \leq i<m-1$. Observe that if $r$ originates at $\rho$ then it does not originate at a state that labels a proper ancestor or proper descendant of $n$. Furthermore, if $r$ originates at $\rho$ then it also originates at any execution $\rho^{\prime}$ such that $\operatorname{view}\left(\operatorname{prev}\left(\rho^{\prime}\right)\right)=\operatorname{view}(\operatorname{prev}(\rho))$ and $\rho^{\prime}$ labels some node in the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$.

Consider the execution $\rho$ labeling ${ }^{P}$ node n as above and let $r$ be a recipe originating at $\rho$. Given a term $t \in \operatorname{subterms}(P) \backslash \mathcal{X}$ and executions $\rho^{1}, \rho^{2}$ such that $\rho^{1}$ and $\rho^{2}$ label some nodes in $\mathcal{T}_{\mathcal{M}_{P}^{A}}, \operatorname{view}(\operatorname{prev}(\rho))=\operatorname{view}\left(\rho^{1}\right)$, $\operatorname{enabled}\left(\rho^{1}, \alpha_{m-1}\right)$ and $\operatorname{last}\left(\rho^{j}\right)=\left(g^{j}, \sigma^{j}, \varphi^{j},\left(t_{i n}^{j}, t_{\text {out }}^{j}\right)\right)$ for $j=1,2$, we say that the recipe $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match if $r$ is not a public name or recipe variable, ie, $r \notin \operatorname{Pub} \cup \mathcal{X}_{w}$ and one of the following hold:

1) $\rho^{2}$ is the initial state of $\mathcal{M}_{P}^{\mathcal{A}}, t$ is a subterm of $\operatorname{ran}\left(\varphi_{0}\right)$ and $\mathrm{nf}\left(r \varphi^{1}\right)=\mathrm{nf}\left(t \sigma^{2}\right)$. In this case, $\mathrm{nf}\left(t \sigma^{2}\right)=t$ as $t$ is a subterm of initial frame.
2) $\rho^{2}$ is not the initial state of $\mathcal{M}_{P}^{A}, t$ is a subterm of either $t_{\text {in }}^{2}$ or $t_{\text {out }}^{2}$ and $\operatorname{nf}\left(r \varphi^{1}\right)=\operatorname{nf}\left(t \sigma^{2}\right)$.
We say that the execution $\rho$ is an $\mathcal{A}$-match if for every recipe $r$ originating at $\rho$, either $r \in \operatorname{Pub} \cup \mathcal{X}_{w}$ or there is a term $t$ and executions $\rho^{1}, \rho^{2}$ such that $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match. We say that a simple adversary $\mathcal{A}$ is small if every execution $\rho$
labeling a node in $\mathcal{T}_{\mathcal{M}^{A}}$, is an $\mathcal{A}$-match. The following is proved in Appendix D.1.
Lemma 4.4. If a simple adversary $\mathcal{A}$ is small then rsize $(\mathcal{A}) \leq 3 \theta \lambda \eta^{2 \gamma}$.
Essentially, the proof of the Lemma constructs a one-toone function that maps a recipe $r$ used in the protocol to a triple $\left(\rho^{1}, t, \rho^{2}\right)$ such that $r$ is $\left(\rho^{1}, t, \rho^{2}\right)$-match. A straightforward counting argument is then used to count the number of elements in the co-domain of this function. Thus, the Theorem will follow if we can establish that there is a small adversary.
Lemma 4.5. For a protocol $P$, a name sec $\in \operatorname{Prv}$ and a number $p$, if there is a simple adversary $\mathcal{A}$ such that $\mathcal{M}_{P}^{\mathcal{A}} \not \models_{p} \operatorname{Secret}(\mathrm{sec})$ then there is a small adversary $\mathcal{B}$ such that $\mathcal{M}_{P}^{\mathcal{B}} \not \models_{p} \operatorname{Secret}(\mathrm{sec})$.

Proof: For recipes $r, r_{1}, r_{2}$, let $r\left[r_{1} \mapsto r_{2}\right]$ be the recipe obtained by replacing every occurrence of the recipe $r_{1}$ as a subterm in $r$ by $r_{2}$. For a substitution $\sigma$ and terms $t, t_{2} \in C$ Terms, let $\sigma\left[t \mapsto t_{2}\right]$ be the substitution obtained by replacing every occurrence of $t$ as subterm in $\operatorname{ran}(\sigma)$ by $t_{2}$.

Let $\mathcal{A}$ be a simple adversary which is not small. Consider the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. For a node n of this tree labeled $\rho$, we define nsize of n to be 0 if n is the root and the size of the recipe $r$ such that last_action $(\rho)=(k, r)$ for some $k$ otherwise. The nsize of the tree will be defined as the sum of sizes of all nodes.

Since $\mathcal{A}$ is not small, there must be a non-atomic recipe $r_{0}$, an execution $\rho_{0}$ labeling a node $n_{0}$ in the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ such that $r_{0}$ originates at $\rho_{0}$ and is not a $\left(\rho, t, \rho^{\prime}\right)$-match for any $\rho, \rho^{\prime}, t$. Fix $\mathrm{r}_{0}, \mathrm{n}_{0}$ and $\rho_{0}$. Let $\rho^{1}$ be $\operatorname{prev}\left(\rho_{0}\right)$ and let $\mathcal{S}$ be the set $\left\{\rho^{\prime} \mid\right.$ $\operatorname{view}\left(\rho^{\prime}\right)=\operatorname{view}\left(\rho^{1}\right)$ and $\rho^{\prime}$ labels a node of $\left.\mathcal{T}_{\mathcal{M}_{P}^{A}}\right\}$. Let $\mathcal{S}=\left\{\rho^{1}, \rho^{2}, \ldots, \rho^{N}\right\}$. Let $\operatorname{Nodes}(\mathcal{S})$ be the sets of nodes labeled by an execution in $\mathcal{S}$. For $1 \leq j \leq N$, let $\operatorname{last}\left(\rho^{j}\right)=\left(g^{j}, \sigma^{j}, \varphi^{j}, \ell^{j}\right)$ and $t^{j}=\operatorname{nf}\left(\mathrm{r}_{0} \varphi^{j}\right)$. Let new $\in$ Pub $\backslash$ PublicKeys be a fresh public name that does not occur anywhere in the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$.

Now, we will construct a new tree $\mathcal{T}^{\text {new }}$ by relabeling the nodes of the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ as follows. Consider a node $n$ of the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ and let this be labeled by the execution $\rho$. The new label of the n in $\mathcal{T}^{\text {new }}$ will be denoted as $\rho^{\text {new }}$ and is constructed as follows.

- If n is not a descendant of a node in the set $\operatorname{Nodes}(\mathcal{S})$ then $\rho^{\text {new }}=\rho$.
- Otherwise let $\rho$ be the execution $\left(z_{0} \xrightarrow{\alpha_{0}}\right.$ $\left.z_{1} \cdots \xrightarrow{\alpha_{m-1}} z_{m}\right)$ and let $\rho$ extend an execution $\rho^{j} \in \mathcal{S}$. For each $0<i \leq m$, let $z_{i}=\left(g_{i}, \sigma_{i}, \varphi_{i}, \ell_{i}\right)$ and let $\alpha_{i-1}=\left(k_{i-1}, r_{i-1}\right) \cdot \rho^{\text {new }}$ is the execution $\left(z_{0}^{\text {new }} \xrightarrow{\alpha_{0}^{\text {new }}} z_{1}^{\text {new }} \cdots \xrightarrow{\alpha_{m-1}^{\text {new }}} z_{m}^{\text {new }}\right)$ where
- $\alpha_{i}^{\text {new }}=\alpha_{i}$ for each $i<\operatorname{length}\left(\rho^{j}\right)$ and is $\left(k_{i}, r_{i}\left[\mathrm{r}_{0} \mapsto \mathrm{new}\right]\right)$ otherwise.
- $\quad z_{i}^{\text {new }}=z_{i}$ for each $i \leq \operatorname{length}\left(\rho^{j}\right)$ and is $\left(g_{i}, \sigma_{i}\left[t^{j} \mapsto\right.\right.$ new $], \varphi_{i}\left[t^{\bar{j}} \mapsto\right.$ new $\left.], \ell_{i}\right)$ otherwise.

We have the following claim which is proved in the Appendix D.2.
Claim 1. For each execution $\rho$ labeling a node of $\mathcal{T}_{\mathcal{M}_{P}^{A}}$, $\rho^{\text {new }}$ is a simple execution of the POMDP $\mathcal{M}_{P}$. The measure of the execution $\rho^{\text {new }}$ is the measure of the execution $\rho$. Furthermore, if $\rho$ is either an execution in $\mathcal{S}$ or a descendant of an execution in $\rho^{j} \in \mathcal{S}$ then for each recipe $r$, if $\operatorname{enabled}\left(\rho^{\text {new }},\left(k, r\left[\mathrm{r}_{0} \mapsto\right.\right.\right.$ new $\left.\left.]\right)\right)$ then enabled $(\rho,(k, r))$ also. Furthermore, $\rho \not \vDash \operatorname{Secret}(\mathrm{sec})$ iff $\rho^{\text {new }} \not \vDash \operatorname{Secret}(\mathrm{sec})$.
We also have the following claim which says that two distinguishable executions continue to remain distinguishable in the new tree. The claim is proved in the Appendix D.
Claim 2. If $\rho_{1}$ and $\rho_{2}$ are two executions labeling nodes of $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ such that $\operatorname{view}\left(\rho_{1}\right) \neq \operatorname{view}\left(\rho_{2}\right)$ then $\operatorname{view}\left(\rho_{1}^{\text {new }}\right) \neq \operatorname{view}\left(\rho_{2}^{\text {new }}\right)$.
Consider the partial function $\mathcal{A}^{\text {new }}$ that maps an execution $\operatorname{prev}\left(\rho^{\text {new }}\right)$ in $\mathcal{T}^{\text {new }}$ to the action last_action $\left(\rho^{\text {new }}\right)$. The above two claims imply that $\mathcal{A}^{\text {new }}$ can be extended to the set of all executions such that $\mathcal{A}^{\text {new }}$ is a simple adversary, the attack tree of $\mathcal{A}^{\text {new }}$ is $\mathcal{T}^{\text {new }}$ and $\mathcal{M}_{P}^{\mathcal{A}^{\text {new }}} \not \vDash_{p}$ Secret(sec). Observe that the nsize of the tree $\mathcal{T}^{\text {new }}$ is strictly less than the nsize of the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. Now, if $\mathcal{A}^{\text {new }}$ is small then we are done. Otherwise, we can construct another simple adversary $\mathcal{A}^{\prime}$ such that the size of the tree $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}^{\prime}}}$ is strictly less than the size of the tree $\mathcal{T}^{\text {new }}$. Since the size of the tree is $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ is finite, repeating this process eventually leads to a small adversary.
This completes the proof of the Theorem.
Using similar ideas, we can show that we need to only consider bounded size recipes for indistinguishability (see Appendix E for the proof).
Theorem 4.6. Let $P$ and $P^{\prime}$ be two protocols with $n$ roles. Let $\lambda$ be the total number of transitions in $P$ and $P^{\prime}$ and $\gamma$ be the total number of transitions in $P$ and $P^{\prime}$ whose span is $>1$. Let $\eta$ be the maximum span of the transitions of $P$ and $P^{\prime}$ and $\theta$ be the total number of subterms of $P$ and $P^{\prime}$. If $P$ and $P^{\prime}$ are distinguishable then there is a simple adversary $\mathcal{A}$ such that $\mathcal{M}_{P}$ and $\mathcal{M}_{P^{\prime}}$ are distinguishable by $\mathcal{A}$ and such that $\operatorname{rsize}(\mathcal{A}) \leq$ $12 \theta \lambda \eta^{2 \gamma}$.

Complexity results. Thanks to the boundedness property and the fact that static equivalence and deducibility can be checked in polynomial time [1], [15], we get that the secrecy and indistinguishability problems are in coNEXPTIME for randomized protocols. Essentially, the coNEXPTIME decision procedure guesses a simple attack of bounded size, and checks that this attack violates secrecy/indistiguishability. The proof of the following theorem can be found in Appendix F.
Theorem 4.7. Secrecy and Indistinguishability problems are in coNEXPTIME.

We say that a protocol $P$ has bounded randomness $k$ if there are at most $k$ transitions of $P$ whose span is greater
than one. For each constant $k$, we define $\operatorname{Secrecy}(k)$ to be the decision problem that given a protocol $P$ with bounded randomness $k$, secret sec and rational number $p$ checks if $P \models_{p}$ Secret(sec). Similarly, Indistinguishability $(k)$ problem is the decision problem that given two protocols $P$ and $P^{\prime}$ with bounded randomness $k$ each checks if $P$ and $P^{\prime}$ are indistinguishable. Observe that for each constant $k$, the number of branches in an attack tree $\mathcal{T}_{\mathcal{M}_{A}^{A}}$ for a protocol $P$ with bounded randomness $k$ is bounded by a polynomial $\eta^{k}$ and hence the number of nodes of $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ is polynomial in the size of $P$. Theorems 4.3 and 4.3 then imply that the adversary only need to use recipes of polynomial size. This yields the following:
Corollary 4.8. For each constant $k$, $\operatorname{Secrecy}(k)$ and Indistinguishability $(k)$ are in coNP.

## 5. Lower Bound for Secrecy

One of the key ideas used in establishing the complexity of non-probabilistic protocols, is the observation that if there is an attack that breaches security, then there is one where the adversary is only required to send messages whose size is bounded by a polynomial in the size of the protocol. However, this observation no longer holds for randomized protocols. We illustrate this through the next example.
Example 5.1. Consider a protocol $P$ with one role $R=$ $\left(S, s_{0}, \prec, \delta\right)$, with the states $S=\left\{s_{0}, s_{1}, s_{2}, s_{\top}\right\}$ and ordering $s_{0} \prec s_{1} \prec s_{2} \prec s_{\top}$. We assume that the initial frame $\varphi_{0}$ is $\emptyset$. We assume that $k_{1}, k_{2} \in \operatorname{Prv}$ are secret keys unknown to the adversary, and sec $\in \operatorname{Prv}$ is the secret message that the adversary is trying to discover. We assume that $\mathbf{0}, \mathbf{1} \in \mathrm{Pub}$ are public names. The transitions in $\delta$ are as follows.

$$
\begin{gathered}
s_{0}:\left[y_{0}, y_{1}\right] \Rightarrow\left[s_{1}: \operatorname{senc}\left(k_{1},\left[y_{0}, \mathbf{0}\right]\right)\right] \oplus \\
{\left[s_{1}: \operatorname{senc}\left(k_{1},\left[y_{1}, \mathbf{1}\right]\right)\right]} \\
s_{1}: \operatorname{senc}\left(k_{1},\left[\left[x_{0}^{1}, x_{1}^{1}\right], g\right]\right) \Rightarrow \\
{\left[s_{2}: \operatorname{senc}\left(k_{2},\left[x_{0}^{1},[g, \mathbf{0}]\right]\right)\right] \oplus} \\
{\left[s_{2}: \operatorname{senc}\left(k_{2},\left[x_{1}^{1},[g, \mathbf{1}]\right]\right)\right]} \\
s_{2}: \operatorname{senc}\left(k_{2},[z, z]\right) \Rightarrow\left[s_{\top}: \sec \right]
\end{gathered}
$$

In order for the adversary to get the secret message sec with probability $>\frac{3}{4}$ (which will imply that $P \quad \not \models_{\frac{1}{4}}$ Secret(sec)), in the first step, the adversary has to send the message

$$
[[[\mathbf{0}, \mathbf{0}],[\mathbf{0}, \mathbf{1}]],[[\mathbf{1}, \mathbf{0}],[\mathbf{1}, \mathbf{1}]]] .
$$

In this case the adversary succeeds with probability 1. Notice that this message is nothing but a full binary tree of height 2 , where each leaf contains a different pair of the public names $\mathbf{0}, \mathbf{1}$. Thus, the size of this message (even in a dag representation) is the size of the binary tree.
The above example can be generalized to force the adversary to send a full binary tree of height linear in the size of the protocol. Once again the protocol has only one role $R=\left(S, s_{0}, \prec, \delta\right)$, where $S=$ $\left\{s_{0}, s_{1}, \ldots s_{n}, s_{\top}\right\}$ with the ordering $s_{i} \prec s_{j}$ if $i<j$
and $s_{i} \prec s_{\top}$ for all $i \in\{0,1, \ldots n\}$. We assume $k_{1}, \ldots k_{n} \in \operatorname{Prv}$ are secret keys, and transitions are given as follows.

$$
\begin{aligned}
& s_{0}:\left[y_{0}, y_{1}\right] \Rightarrow\left[s_{1}: \operatorname{senc}\left(k_{1},\left[y_{0}, \mathbf{0}\right]\right)\right] \oplus \\
& \quad\left[s_{1}: \operatorname{senc}\left(k_{1},\left[y_{1}, \mathbf{1}\right]\right)\right] \\
& s_{i}: \operatorname{senc}\left(k_{i},\left[\left[x_{0}^{i}, x_{1}^{i}\right], g\right]\right) \Rightarrow \\
& \quad\left[s_{i+1}: \operatorname{senc}\left(k_{i+1},\left[x_{0}^{i},[g, \mathbf{0}]\right]\right)\right] \oplus \\
& \quad\left[s_{i+1}: \operatorname{senc}\left(k_{i+1},\left[x_{1}^{i},[g, \mathbf{1}]\right]\right)\right] \text { for } 1 \leq i<n \\
& s_{n}: \operatorname{senc}\left(k_{n},[z, z]\right) \Rightarrow\left[s_{\top}: \sec \right]
\end{aligned}
$$

The secret sec is revealed with probability 1 if and only if the adversary sends, as the first message, a full binary tree of height $n$, where each leaf has different strings (over $\mathbf{0}, \mathbf{1}$ ). The size of this message as a dag is $2^{n}$, which is exponential in the size of the protocol.
Before concluding this example, we would like to observe that even though the protocol (as described above) keeps its coin tosses private, this is not essential to ensure the need for exponential sized messages. The same initial message would need to be sent even if we considered a modified protocol where in each step the protocol reveals the result of its coin toss in plaintext to the adversary.
We will show that the problem of checking if the security of a randomized protocol can be breached with probability greater than some threshold $p$, is NEXPTIME-hard. The hardness proof is shown by reducing the satisfiability problem of first-order logic with monadic predicates [30]. Before presenting the reduction, we first introduce the logic.
Defintion 5.2. A monadic signature $\tau$ is a set of relation symbols of arity one. First order formulas over a monadic signature $\tau$ is given by the grammar

$$
\varphi::=R x|\neg \varphi| \varphi \vee \varphi|\varphi \wedge \varphi| \exists x . \varphi \mid \forall x . \varphi
$$

where $R$ is a relation symbol in $\tau$ and $x$ is a first-order variable.

Notice that $=$ is not allowed in this logic and there are no constant symbols. The satisfiability problem for this logic is known to be NEXPTIME-complete [30] ${ }^{3}$. We will reduce the satisfiability problem of this logic to the nonsecrecy problem as follows.
Theorem 5.3. The secrecy problem is coNEXPTIMEhard.

Proof: It suffices to show that given a protocol $P$, secret sec $\in \operatorname{Prv}, p>0$, the problem of checking if $P \not \models_{p}$ Secret(sec) is NEXPTIME-hard.

There are 3 key ideas that play a role in establishing this result. The first is an observation due to Rusinowitch and Turuani [33] that shows how the satisfiability of propositional logic can be reduced to protocol insecurity. Given a 3 CNF formula $\varphi$, Rusinowitch-Turuani construct a protocol that proceeds in two phases. First, the adversary guesses a satisfying truth assignment, and sends this to the protocol.

[^1]The protocol ensures the commitment of the adversary to this assignment for the rest of the execution by encrypting the assignment using a key that is secret. After this phase, the adversary demonstrates the satisfaction of each clause by revealing a relevant portion of the assignment that (s)he committed to in the first step. If all clauses are satisfied, the secret is revealed.

The second observation is that randomization can be used to simulate quantifier alternation, with the adversary making existential choices, and the protocol making universal choices by probabilistic steps. Before presenting the NEXPTIME-hardness result, we show a PSPACE-hardness result that shows how these two observations can be combined to reduce QSAT to protocol insecurity of randomized protocols. Consider a QBF $\varphi=Q_{1} x_{1} . Q_{2} x_{2} \ldots Q_{n} x_{n} . \psi$, where $Q_{i} \in\{\exists, \forall\}, x_{i}$ is a propositional variable and $\psi=\wedge_{j=1}^{m} C_{j}$ is a 3CNF formula with clauses $C_{j}$. The satisfiability of $\varphi$ can be reduced to the insecurity of a protocol $P$ with only one role $R$. We assume that $\top, \perp$ are public names in Pub standing for true and false, respectively. Keys $\left\{k_{1}, \ldots k_{n}\right\}$ (one for each propositional variable) are secret names in Prv. For each variable $x_{i}$, the protocol $P$ has a state $g_{i}$ and for each clause $C_{j}, P$ has a state $c_{j} . P$ has one additional state $s_{\text {T }} . P$ proceeds in phases. First, a truth assignment for the variables is chosen. The value for variable $x_{i}$ is picked in state $g_{i}$; if $x_{i}$ is existentially quantified then the adversary picks the value for $x_{i}$, and if $x_{i}$ is universally quantified then the protocol picks the value for $x_{i}$. The transition rules capturing these steps are as follows (with the understanding that $g_{n+1}=c_{1}$ ).

$$
\begin{aligned}
g_{i}: t \Rightarrow & {\left[g_{i+1}: \operatorname{senc}\left(k_{i}, t\right)\right] \text { if } Q_{i}=\exists } \\
g_{i}: \top \Rightarrow & {\left[g_{i+1}:\left[\operatorname{senc}\left(k_{i}, \perp\right), \perp\right]\right] \oplus } \\
& {\left[g_{i+1}:\left[\operatorname{senc}\left(k_{i}, \top\right), \top\right]\right] \text { if } Q_{i}=\forall }
\end{aligned}
$$

Notice, that when the value of a universally quantified variable is picked, the result of the coin toss is made public so that the adversary's choice for future existential variables may depend on this value. Also, the variables are chosen in the order in which they are quantified in $\varphi$ by the use of states $g_{i}$. After all variables have been assigned truth values, the clauses in $\psi$ are evaluated in sequence, using states $\left\{c_{1}, \ldots c_{m}\right\}$. In each state $c_{j}$, the adversary sends a (encrypted) truth value of a variable that makes one of the literals in $C_{j}$ true. The rules capturing these steps are as follows (with the understanding that $c_{m+1}=s_{T}$ ).

$$
\begin{array}{ll}
c_{j}: \operatorname{senc}\left(k_{i}, \perp\right) \Rightarrow\left[c_{j+1}: \top\right] & \text { if } \neg x_{i} \in C_{j} \\
c_{j}: \operatorname{senc}\left(k_{i}, \top\right) \Rightarrow\left[c_{j+1}: \top\right] & \text { if } x_{i} \in C_{j}
\end{array}
$$

Observe that the only way the protocol can reach state $c_{m}$ is if all clause $C_{1} \ldots C_{m-1}$ are satisfied by the truth assignment picked initially. In the state $c_{m}$, if the adversary sends a truth value that satisfies a literal in $C_{m}$, the protocol moves to state $r$ ("reveal"). Here the secret message sec is revealed, moving to the terminal state $s T$.

$$
r: \top \Rightarrow\left[s_{\top}: \mathrm{sec}\right]
$$

TABLE 1. COMPLEXITY OF VERIFYING SECURITY PROTOCOLS. WE ONLY CONSIDER SIMPLE PROTOCOLS. THERE IS NO DIFFERENCE IN COMPLEXITY FOR PUBLIC AND PRIVATE COIN TOSSES WHEN THE NUMBER OF COIN TOSSES ARE FIXED.

|  | Non-randomized Protocols | Coin tosses are private | Coin tosses are public | Fixed number of coin tosses |
| :---: | :---: | :---: | :---: | :---: |
| Secrecy | coNP-complete $([33],[23])$ | coNEXPTIME-complete | coNEXPTIME-complete | coNP-complete |
| Indistinguishability | coNP-complete $([19])$ | coNEXPTIME | coNP-complete | coNP-complete |

Observe that, under the assumption that the keys $\left\{k_{i}\right\}_{i}$ are not known to the adversary, $\varphi$ is satisfiable iff sec is obtained with probability 1 . If $\varphi$ is not satisfiable then the protocol keeps sec secret with probability at least $\frac{1}{2^{n_{1}}}$ where $n_{1}$ is the number of universal quantifications.

The last ingredient needed in order to prove NEXPTIME-hardness, is the ability of a randomized protocol to "examine" the contents of an exponential sized message. This is accomplished using ideas in the protocol described in Example 5.1. Details of how we combine all these ideas to reduce the satisfaction problem of monadic first-order formulas to the insecurity problem of randomized protocols is given in Appendix G. One particular feature of the proof is that all coin tosses in the reduction are public. Thus, the NEXPTIME-hardness result holds even for checking the insecurity of randomized protocols where all coin tosses are public.

## 6. Conclusions

We have shown that the problem of checking secrecy of randomized security protocols is coNEXPTIMEcomplete, and the problem of checking indistinguishability of two randomized security protocols is in coNEXPTIME. The hardness results for secrecy hold even if we assume that the results of the coin tosses are public. In contrast, it can be shown that for public coin tosses, the indistinguishability problem is coNP-complete. Our results also show that, when the number of coin tosses are bounded, i.e., the number of probabilistic transitions are bounded, both secrecy and indistinguishability are coNPcomplete. Our results are summarized in Table 1. The model of protocols we considered, allow the cryptographic primitives corresponding to symmetric as well as asymmetric encryption and decryption. It can easily be shown that our results extend to the case when digital signatures and hash functions are also allowed in the protocols. Obtaining tight bounds for the indistinguishability problem needs to be explored as part of future work. The decidability and complexity of the above problems also needs to be investigated for the case when we allow conditional statements in the protocols and for other cryptographic primitives that can be modeled as subterm convergent rewrite systems.

## Appendix A. <br> Privacy of votes as secrecy property

We modeled privacy of votes as an indistinguishability property in Example 2.6. The same property can modeled as secrecy. We explain the modeling informally here. Essentially, in the modeling, the two voters $A$ and $B$ first toss a fair coin each to decide which candidate. After EA publishes the votes, the adversary sends a message to $A$ which is its guess of the candidate chosen by $A$. If the guess is correct then $A$ outputs a secret sec. Now, privacy of votes can be modeled as secrecy of the secret sec. Observe that if both $A$ and $B$ choose the same candidate (which happens with probability $\frac{1}{2}$ ), the attacker knows how $A$ voted and hence can get sec. If $A$ and $B$ both choose different candidates then thanks to the mixing of the votes by EA, the best the attacker can do is to guess randomly. Thus, the protocol will keep the votes private if sec is kept secret with probability at least $\frac{1}{4}$. The modeling of privacy as secrecy allows us to model and reason about deviations from ideal behavior. If the coin tosses used by the protocol are biased then the protocol will only be able to guarantee probable privacy, namely, that sec is kept secret with probability $>0$.

## Appendix B. Proof of Proposition 3.1

Fix $\bar{o} \in \mathcal{V} \cdot(\operatorname{Act} \times\{\diamond\})$ such that $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A}) \neq$ $p r_{\mathcal{M}^{\prime}}(\bar{o}, \mathcal{A})$. Let $\bar{o}=\bar{o}_{0} \cdot(\alpha, \diamond)$. It can be shown that
$p r_{\mathcal{M}}\left(\bar{o}_{0}, \mathcal{A}\right) \mathcal{A}\left(\bar{o}_{0}\right)(\alpha)=p r_{\mathcal{M}}(\bar{o}, \mathcal{A})+\sum_{o \in \mathcal{O}} p r_{\mathcal{M}}\left(\bar{o}_{0} \cdot \alpha \cdot o, \mathcal{A}\right)$
and
$\operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{0}, \mathcal{A}\right) \mathcal{A}\left(\bar{o}_{0}\right)(\alpha)=\operatorname{pr}_{\mathcal{M}^{\prime}}(\bar{o}, \mathcal{A})+\sum_{o \in \mathcal{O}} p r_{\mathcal{M}^{\prime}}\left(\bar{o}_{0} \cdot \alpha \cdot o, \mathcal{A}\right)$.
As $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A}) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}(\bar{o}, \mathcal{A})$, the above two equations imply that either $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{0}, \mathcal{A}\right) \neq p r_{\mathcal{M}^{\prime}}\left(\bar{o}_{0}, \mathcal{A}\right)$ or there is an $o \in \mathcal{O}$ such that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{0} \cdot \alpha \cdot o, \mathcal{A}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{0} \cdot \alpha \cdot o, \mathcal{A}\right)$.

## Appendix C. <br> Proof of proposition 3.2

Let $\mathcal{M}=\left(Z, z_{s}, A c t, \Delta, \mathcal{O}, O b s\right)$ be a POMDP and $\Psi \subseteq Z$ a safety property.. Fix an adversary $\mathcal{A}: \mathcal{V} \rightarrow$ $\operatorname{Dist}(A c t)$. We will say that $\bar{o} \in \mathcal{V}$ is $\mathcal{A}$-interesting for $\mathcal{M}$ if $\operatorname{pr}_{\mathcal{M}}(\bar{o}, \mathcal{A})>0$ and the set $\{\alpha \mid \mathcal{A}(\bar{o})(\alpha>0)\}$ has at least two elements. Let Interesting $(\mathcal{M}, \mathcal{A})=\{\bar{o} \mid$ $\bar{o}$ is $\mathcal{A}$-interesting for $\mathcal{M}\}$. Note that $\operatorname{Interesting}(\mathcal{M}, \mathcal{A})$ is finite. For an execution $\kappa \in \operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$, we will write $\operatorname{pr}_{\mathcal{M}}(\kappa, \mathcal{A})$ to be the measure of the execution $\kappa$. If $\kappa$ is not an execution but a sequence of states of $\operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$ then we will write $p r_{\mathcal{M}}(\kappa, \mathcal{A})=0$. For a set $W \subseteq \operatorname{Exec}\left(\mathcal{M}^{\mathcal{A}}\right)$, we will write $p r_{\mathcal{M}}(W, \mathcal{A})$ for $\sum_{\kappa \in \mathrm{W}} p r_{\mathcal{M}}(\kappa, \mathcal{A})$.

We first consider consider safety properties. It suffices to show that the following claim:

Claim 3. For each adversary $\mathcal{A}$, if $\mathcal{M}^{\mathcal{A}} \not \vDash_{p} \Psi$ then there is an $\mathcal{A}^{\prime}$ such that Interesting $\left(\mathcal{M}, \mathcal{A}^{\prime}\right)=\emptyset$ and $\mathcal{M}^{\mathcal{A}^{\prime}} \not \models_{p}$ $\Psi$.

Proof: The proof is by induction on the cardinality of the set Interesting $(\mathcal{M}, \mathcal{A})$. The claim is trivially true if the cardinality is 0 . Now, suppose that the claim is true for all adversaries $\mathcal{A}$ such that Interesting $(\mathcal{M}, \mathcal{A})$ has at most $k$ elements.

Now, consider an adversary $\mathcal{A}_{0}$ such that Interesting $\left(\mathcal{M}, \mathcal{A}_{0}\right)$ has $k+1$ elements and such that $\mathcal{M}^{\mathcal{A}_{0}} \quad \not \vDash_{p} \Psi$. Fix $\bar{o} \in \operatorname{Interesting}\left(\mathcal{M}, \mathcal{A}_{0}\right)$. Fix an enumeration $\alpha_{1}, \alpha_{2}, \ldots, \alpha_{m}$ of actions $\alpha$ such $\mathcal{A}_{0}(\bar{o})(\alpha)>0$. For each $1 \leq i \leq m$, let $p_{i}=\mathcal{A}_{0}(\bar{o})\left(\alpha_{i}\right)$ and $\mathcal{A}_{i}: \mathcal{V} \rightarrow \operatorname{Dist}(A c t)$ to be the adversary such that $\mathcal{A}_{i}(\bar{o})\left(\alpha_{i}\right)=1$ and $\mathcal{A}_{i}\left(\bar{o}^{\prime}\right)=\mathcal{A}\left(\bar{o}^{\prime}\right)$ for $\bar{o}^{\prime} \neq \bar{o}$. It is easy to see Interesting $\left(\mathcal{M}, \mathcal{A}_{i}\right)$ has at most $k$ elements for each $1 \leq i \leq m$.

Now, let $W$ be the set $\{\kappa$ | $\kappa$ is a maximal execution of $\mathcal{M}^{\mathcal{A}}$ and $\left.\kappa \quad \not \vDash \Psi\right\}$. Now, we have that

$$
\operatorname{pr}_{\mathcal{M}}(\mathrm{W}, \mathcal{A})>1-p
$$

Let $W_{\bar{o}}$ be the set $\{\kappa \in \mathrm{W} \mid \bar{o}$ is a prefix of $\operatorname{view}(\kappa)\}$.
It is easy to see that
$\left.\operatorname{pr}_{\mathcal{M}}\left(\mathrm{W}, \mathcal{A}_{0}\right)=\operatorname{pr}_{\mathcal{M}}\left(\mathrm{W} \backslash \mathrm{W}_{\bar{o}}, \mathcal{A}_{0}\right)+\sum_{1 \leq i \leq m} p_{i} \cdot p r_{\mathcal{M}}\left(\mathrm{W}_{\bar{o}}, \mathcal{A}_{i}\right)\right)$
and that

$$
p r_{\mathcal{M}}\left(\mathrm{W} \backslash \mathrm{~W}_{\bar{o}}, \mathcal{A}_{0}\right)=p r_{\mathcal{M}}\left(\mathrm{W} \backslash \mathrm{~W}_{\bar{o}}, \mathcal{A}_{i}\right)
$$

for each $1 \leq i \leq m$. Now, since $\sum_{1 \leq i \leq m} p_{i}=1$, the above two observations imply that

$$
\begin{aligned}
& \operatorname{pr}_{\mathcal{M}}\left(\mathrm{W}, \mathcal{A}_{0}\right)= \sum_{1 \leq i \leq m} p_{i} \cdot\left(\operatorname{pr}_{\mathcal{M}}\left(\mathrm{W} \backslash \mathrm{~W}_{\bar{o}}, \mathcal{A}_{0}\right)\right. \\
&\left.+\quad+r_{\mathcal{M}}\left(\mathrm{W}_{\bar{\sigma}}, \mathcal{A}_{i}\right)\right) \\
&= \sum_{1 \leq i \leq m} p_{i} \cdot\left(\operatorname{pr}_{\mathcal{M}}\left(\mathrm{W} \backslash \mathrm{~W}_{\bar{o}}, \mathcal{A}_{i}\right)\right. \\
&\left.+\operatorname{pr} r_{\mathcal{M}}\left(\mathrm{W}_{\bar{\sigma}}, \mathcal{A}_{i}\right)\right) \\
&= \sum_{1 \leq i \leq m} p_{i} \cdot p r_{\mathcal{M}}\left(\mathrm{W}, \mathcal{A}_{i}\right) .
\end{aligned}
$$

The above equation implies that there must an $i$ such that $\operatorname{prob}_{\mathcal{M}}\left(\mathrm{W}, \mathcal{A}_{i}\right) \geq \operatorname{pr}_{\mathcal{M}}\left(\mathrm{W}, \mathcal{A}_{0}\right)>1-p$. This implies that there must be an $i$ such that $\mathcal{M}^{\mathcal{A}_{i}} \not \vDash_{p} \Psi$. The claim follows.

The proof for indistinguishability properties is similar.
Claim 4. If $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are POMDPs with the same set of actions and observations, then $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are distinguishable by an adversary $\mathcal{A}$, then an $\mathcal{A}^{\prime}$ such that Interesting $\left(\mathcal{M}, \mathcal{A}^{\prime}\right)=\operatorname{Interesting}\left(\mathcal{M}^{\prime}, \mathcal{A}^{\prime}\right)=\emptyset$ and $\mathcal{M}$ and $\mathcal{M}^{\prime}$ are distinguishable by an adversary $\mathcal{A}^{\prime}$.

Proof: The proof is by induction on the cardinality of the set Interesting $(\mathcal{M}, \mathcal{A}) \cup \operatorname{Interesting}\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$. The claim is trivially true if the cardinality is 0 . Now, suppose that the claim is true for all adversaries $\mathcal{A}$ such that Interesting $(\mathcal{M}, \mathcal{A}) \cup$ Interesting $\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$ has at most $k$ elements.

Now, consider an adversary $\mathcal{A}_{0}$ such that Interesting $\left(\mathcal{M}, \mathcal{A}_{0}\right) \cup \operatorname{Interesting}\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$ has $k+1$
elements and $\mathcal{A}_{0}$ distinguishes $\mathcal{M}$ and $\mathcal{M}^{\prime}$. Fix $\bar{o} \in \operatorname{Interesting}\left(\mathcal{M}, \mathcal{A}_{0}\right) \cup$ Interesting $\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$. Fix $\bar{o}_{1} \in \mathcal{V}$ such that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)$. We haver two possible cases.

1) The first case is that $\bar{o}$ is a strict prefix of $\bar{o}_{1}$. Thus, $\bar{o}_{1}=\bar{o}_{1} \alpha \bar{o}_{0}$ for some $\alpha \in$ Act and $\bar{o}_{0} \in \mathcal{V}$. As either $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right) \neq 0$ or $\operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right) \neq 0$, it means that $\mathcal{A}_{0}(\bar{o})(\alpha) \neq 0$. Consider the adversary $\mathcal{A}_{\alpha}$ such that $\mathcal{A}_{\alpha}(\bar{o})(\alpha)=$ 1 and $\mathcal{A}_{\alpha}\left(\bar{o}_{2}\right)=\mathcal{A}_{0}\left(\bar{o}_{2}\right)$ for each $\bar{o}_{2} \neq \bar{o}$. Clearly, Interesting $\left(\mathcal{M}, \mathcal{A}_{0}\right) \cup$ Interesting $\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$ has at most $k$ elements. It is easy to see that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)=\mathcal{A}_{0}(\bar{o})(\alpha) \cdot \operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)$ and that $\operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)=\mathcal{A}_{0}(\bar{o})(\alpha) \cdot \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)$. Since $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)$, we get that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right) \neq \operatorname{pr} \mathcal{M}^{\prime}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)$. The claim follows in this case.
2) The second case is when $\bar{o}$ is not a strict prefix of $\bar{o}_{1}$. Fix $\alpha$ such that $\mathcal{A}_{0}(\bar{o})(\alpha)>0$. Consider the adversary $\mathcal{A}_{\alpha}$ such that $\mathcal{A}_{\alpha}(\bar{o})(\alpha)=1$ and $\mathcal{A}_{\alpha}\left(\bar{o}_{2}\right)=\mathcal{A}_{0}\left(\bar{o}_{2}\right)$ for each $\bar{o}_{2} \neq \bar{o}$. Clearly, Interesting $\left(\mathcal{M}, \mathcal{A}_{0}\right) \cup$ Interesting $\left(\mathcal{M}^{\prime}, \mathcal{A}\right)$ has at most $k$ elements. It is easy to see that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)=\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)$ and that $\operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)=\operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)$. Since $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{0}\right)$, we get that $\operatorname{pr}_{\mathcal{M}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right) \neq \operatorname{pr}_{\mathcal{M}^{\prime}}\left(\bar{o}_{1}, \mathcal{A}_{\alpha}\right)$. The claim follows in this case also.

## Appendix D. <br> Proof of Theorem 4.3

## D.1. Proof of Lemma 4.4

Let n be a node of the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. Let $\rho=z_{0} \xrightarrow{\alpha_{0}}$ $z_{1} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ be the label of n and let $\alpha_{i}=\left(k_{i}, r_{i}\right)$ for each $0 \leq i<m$. It suffices to show that $\operatorname{rsize}\left(r_{m-1}\right) \leq$ $3 \theta \eta^{2 \gamma} \lambda$. In order to establish the latter, it suffices to show that the cardinality of the set $S R\left(r_{m-1}\right)=\left\{r^{1} \mid r^{1} \notin\right.$ Pub $\cup$ $\left.\mathcal{X}_{w}, r^{1} \sqsubseteq r_{m-1}\right\}$ is less than or equal to $\theta \eta^{2 \gamma} \lambda$. This is because every node in the dag-representation of $r_{m-1}$ has at most 2 outgoing edges. If $S R\left(r_{m-1}\right) \leq \theta \eta^{2 \gamma} \lambda$ then there are at most $\theta \eta^{2 \gamma} \lambda$ nodes which have outgoing edges, and thus, the total number of nodes is bounded by $3 \theta \eta^{2 \gamma} \lambda$.

Pick $r \in S R\left(r_{m-1}\right)$. Observe that either $r$ originates in $\rho$ or in an execution labeling some ancestor of n . Let $\rho_{r}$ be $\rho$ if $r$ originates in $\rho$ else $\rho_{r}$ is the execution labeling the ancestor of n such that $r$ originates in $\rho_{r}$. Since $\mathcal{A}$ is a small attack, there must be executions $\rho^{1}, \rho^{2}$ and a term $t$ such that $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match. Observe that $\operatorname{view}\left(\operatorname{prev}\left(\rho_{r}\right)\right)=\operatorname{view}\left(\rho^{1}\right)$. Let Nodes be the set of nodes of the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. Thus, we can define a function map : $S R\left(r_{m-1}\right) \rightarrow$ Nodes $\times$ terms $(P) \times$ Nodes such that if $\operatorname{map}(r)=\left(\mathrm{n}_{1}, t, \mathrm{n}_{2}\right)$ then $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match where $\rho^{i}$
is the execution labeling the node $\mathrm{n}_{i}$ for $i \in\{1,2\}$. As observed above, there are at most $\eta^{\gamma} \lambda$ nodes in the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$. Thus, the cardinality of the set Nodes $\times \operatorname{terms}(P) \times$ Nodes is less than or equal to $\theta \eta^{2 \gamma} \lambda$. Thus, the result will follow if we can show that map is a one-to-one function.

We now establish that map is a one-to-one function. We proceed by contradiction. Fix $r, r^{\prime} \in S R\left(r_{m-1}\right)$ such that $r \neq r^{\prime}$ and $\operatorname{map}(r)=\operatorname{map}\left(r^{\prime}\right)=\left(\mathrm{n}_{1}, t, \mathrm{n}_{2}\right)$. Let $\rho_{r}, \rho_{r^{\prime}}$ be the executions in which $r$ and $r^{\prime}$ originate as given above. For $i \in\{1,2\}$, let $\rho^{i}$ be the execution labeling the node $\mathrm{n}_{i}$. Either $\rho_{r}=\rho_{r^{\prime}}$ or one of $\rho_{r}, \rho_{r^{\prime}}$ labels a node which is an ancestor of a node labeling the other. In particular, it means that either $\rho_{r}=\rho_{r^{\prime}}$ or $\operatorname{view}\left(\operatorname{prev}\left(\rho_{r}\right)\right) \neq \operatorname{view}\left(\operatorname{prev}\left(\rho_{r^{\prime}}\right)\right)$. In the latter case, we immediately get a contradiction as $\operatorname{map}(r)=\operatorname{map}\left(r^{\prime}\right)$ implies that $\operatorname{view}\left(\operatorname{prev}\left(\rho_{r}\right)\right)=\operatorname{view}\left(\rho^{1}\right)=\operatorname{view}\left(\operatorname{prev}\left(\rho_{r^{\prime}}\right)\right)$ by definition of map. Hence it must be the case that $\rho_{r}=\rho_{r^{\prime}}$. Let $\operatorname{last}\left(\rho^{i}\right)=\left(g^{i}, \sigma^{i}, \varphi^{i}, \ell^{i}\right)$ for $i \in\{1,2\}$. By definition of map, we have that $\mathrm{nf}\left(r \varphi^{1}\right)=\mathrm{nf}\left(t \sigma^{2}\right)$ and $\mathrm{nf}\left(r^{\prime} \varphi^{1}\right)=\mathrm{nf}\left(t \sigma^{2}\right)$. Hence $\mathrm{nf}\left(r \varphi^{1}\right)=\mathrm{nf}\left(r^{\prime} \varphi^{1}\right)$. Since $\mathcal{A}$ is a simple adversary, we have $r=r^{\prime}$. This contradicts our assumption that $r \neq r^{\prime}$.

## D.2. Proof of Lemma 4.5

We say that a recipe $r$ is a constructive recipe if the root of $r$ is a constructor function symbol. We say that $r$ is a destructive recipe if the root of $r$ is a destructor function symbol. We say that the recipe $r$ is $\left(r_{1}, \varphi\right)$-simple for a frame $\varphi$ and a recipe $r_{1}$ if $\operatorname{vars}(r), \operatorname{vars}\left(r_{1}\right) \subseteq \operatorname{dom}(\varphi)$, $\operatorname{valid}(r \varphi)$, $\operatorname{valid}\left(r_{1} \varphi\right)$, and for every recipe $r_{2} \sqsubseteq r$ and recipe $r_{3} \sqsubseteq r_{1}$ such that $r_{2} \varphi={ }_{\mathcal{R}} r_{3} \varphi$, we have that $r_{2}=r_{3}$. Observe that if $r$ is $\left(r_{1}, \varphi\right)$-simple then so is every subterm of $r$. We say that the recipe $r$ is $\varphi$-simple for a frame $\varphi$ if $r$ is $(r, \varphi)$-simple. When the frame $\varphi$ is clear from the context, we will abuse terminology and say that "recipe $r$ is simple" to mean "recipe $r$ is $\varphi$-simple". Observe that every recipe used by a simple adversary is simple and that every subterm of a simple recipe is simple. We say that a term $t$ is away from a public name new $\in \mathrm{Pub} \backslash$ PublicKeys if new $\notin S u b(t)$. We say that a substitution $\sigma$ is away from a public name new if new $\notin \operatorname{Sub}(\operatorname{ran}(\sigma))$.

We first show that if a recipe is simple and destructive, then it computes a subterm of the frame.
Proposition D.1. Given a destructive recipe $r$, a frame $\varphi$ such that $r$ is $\varphi$-simple, $\operatorname{nf}(r \varphi) \in \operatorname{Sub}(\operatorname{ran}(\varphi))$.

Proof: Proof is by induction on the height of $r$. The proposition is trivially true for a recipe of height 0 as $r$ cannot be destructive. Assume now that the proposition is true for every $\varphi$-recipe $r^{\prime}$ such that the height of $r^{\prime}$ is $\leq k$. Now fix a recipe $r$ of height $k+1$. The root of $r$ must be in the set $\left\{\operatorname{proj}_{1}, \operatorname{proj}_{2}\right.$, sdec, adec $\}$. We show that $n f(r \varphi)$ must be a subterm of $\operatorname{ran}(\varphi)$ for the case that the root of $r$ is sdec. The other cases are similar. Assume that $r=\operatorname{sdec}\left(r_{1}, r_{2}\right)$. As $r$ such that $\operatorname{valid}(r \varphi)$, it follows that $r_{2}$ is either a variable $w_{j} \in \operatorname{dom}(\varphi)$ or is a destructive recipe or is a encrypted recipe $\operatorname{senc}\left(r_{1}^{\prime}, r_{2}^{\prime}\right)$. If $r_{2}$ is a
variable $w_{j} \in \operatorname{dom}(\varphi)$, the proposition follows immediately from definition. If $r_{2}$ is a destructive recipe, the proposition follows from inductive hypothesis. If $r_{2}$ is $\operatorname{senc}\left(r_{1}^{\prime}, r_{2}^{\prime}\right)$ then as $\operatorname{valid}(r \varphi), r \varphi={ }_{\mathcal{R}} r_{2}^{\prime} \varphi$. This contradicts the fact that $r$ is $\varphi$-simple. The proposition follows in this case as well.

The above proposition immediately implies that if $r$ is a $\varphi$-simple recipe and $t$ is a subterm of $\operatorname{nf}(r \varphi)$ then either $t$ is a subterm of $\operatorname{ran}(\varphi)$ or $t$ is constructed explicitly by $r$ using a constructive recipe.
Proposition D.2. Given a recipe $r$, a frame $\varphi$ such that $r$ is $\varphi$-simple, and a term $t$ such that $t \notin \operatorname{Sub}(\operatorname{ran}(\varphi))$. If $\mathrm{nf}(r \varphi)$ contains $t$ as a subterm then there is a constructive $r^{\prime} \sqsubseteq r$ such that $\operatorname{nf}\left(r^{\prime} \varphi\right)=t$.

If a recipe $r$ is simple then a constructive recipe is never destructed in $r$. This intuition is captured in the following proposition.
Proposition D.3. Let $r, r^{\prime}$ be recipes and $\varphi$ be a frame such that $\operatorname{valid}(r \varphi), r^{\prime}$ is a constructive recipe and $r$ is $\left(r^{\prime}, \varphi\right)$-simple. Let new be a public name such that $r, r^{\prime}, \varphi$ are away from new. Let $t=\mathrm{nf}(r \varphi)$ and $t^{\prime}=\operatorname{nf}\left(r^{\prime} \varphi\right)$. Then

- $\operatorname{valid}\left(r^{\text {new }} \varphi^{\text {new }}\right)$, and
- $\operatorname{nf}\left(r^{\text {new }} \varphi^{\text {new }}\right)=t^{\text {new }}$ where
$r^{\text {new }}=r\left[r^{\prime} \mapsto\right.$ new $], t^{\text {new }}=t\left[t^{\prime} \mapsto\right.$ new $]$ and $\varphi^{\text {new }}=\varphi\left[t^{\prime} \mapsto\right.$ new].

Proof: Proof is by induction on $r$. The proposition is trivially true if $r$ is a public name. If $r$ is a variable $w_{j} \in \operatorname{dom}(\varphi)$ then $w_{j}$ is not the recipe $r^{\prime}$ as the latter is a constructive recipe. Hence the proposition is trivially true in this case also.

Now, suppose $r$ is constructive. Thus, the root of $r$ is a function symbol in the set $\{[\cdot, \cdot]$, aenc, senc $\}$. We consider the case when the root of $r$ is the function symbol $[\cdot, \cdot]$. The other cases are similar. Thus, $r=\left[r_{1}, r_{2}\right]$ for some $r_{1}, r_{2}$. Now, either $r=r^{\prime}$ or $r \neq r^{\prime}$. In the former case, the proposition follows trivially since $r^{\text {new }}=$ new and $t^{\text {new }}=$ new. In the latter case, the proposition is immediate from induction hypothesis.

Now, suppose $r$ is a destructive. Thus, the root of $r$ is a function symbol in the set $\left\{\right.$ proj $_{1}, \operatorname{proj}_{2}$, sdec, aenc $\}$. We consider the case when the root of $r$ is the function symbol sdec. The other cases are similar. Thus, $r=\operatorname{sdec}\left(r_{1}, r_{2}\right)$ for some $r_{1}, r_{2}$. Now, $r$ cannot be the recipe $r^{\prime}$ as $r^{\prime}$ is a constructive recipe. Thus $r^{\text {new }}=\operatorname{sdec}\left(r_{1}^{\text {new }}, r_{2}^{\text {new }}\right)$. By induction hypothesis we have that $\operatorname{valid}\left(r_{1}^{\text {new }} \varphi^{\text {new }}\right)$ and $\operatorname{valid}\left(r_{2}^{\text {new }} \varphi^{\text {new }}\right)$. Thus, we will have that $\operatorname{valid}\left(r^{\text {new }} \varphi^{\text {new }}\right)$ if we can show that the term $\operatorname{sdec}\left(r_{1}^{\text {new }}, r_{2}^{\text {new }}\right) \varphi^{\text {new }} \in C$ Terms. Observe also that since valid $(r \varphi), r_{2}$ must be a variable or a destructive recipe or an encryption recipe $\operatorname{senc}\left(r_{3}, r_{4}\right)$ for some $r_{3}, r_{4}$.

If $r_{2}$ is a variable $w_{j}$ or a destructive recipe, then $\operatorname{nf}\left(r_{2} \varphi\right)=\operatorname{senc}\left(t_{1}, t_{2}\right), \operatorname{nf}\left(r_{1} \varphi\right)=t_{1}$ and $\operatorname{nf}(r \varphi)=t_{2}$ for some $t_{1}, t_{2} \in C$ Terms. Furthermore, as $r$ is $\left(r^{\prime}, \varphi\right)$ simple and $r^{\prime}$ is constructive, it follows that $r_{2} \neq r^{\prime}$ and that $\operatorname{nf}\left(r_{2} \varphi\right) \neq t^{\prime}$. Thus, by inductive hypothesis,
$\operatorname{nf}\left(r_{2}^{\text {new }} \varphi^{\text {new }}\right)=\operatorname{senc}\left(t_{1}^{\text {new }}, t_{2}^{\text {new }}\right)$ where $t_{i}^{\text {new }}=t_{i}\left[t^{\prime} \mapsto\right.$ new $]$ for each $i=1,2$. By induction hypothesis, we have that $\operatorname{nf}\left(r_{1}^{\text {new }} \varphi^{\text {new }}\right)=t_{1}^{\text {new }}$. Since $t_{1}$ is a constructor term, so is $t_{1}^{\text {new }}$. Thus, the proposition follows in this case.

Now, suppose that $r_{2}$ is $\operatorname{senc}\left(r_{3}, r_{4}\right)$ for some $r_{3}, r_{4}$. As valid $(r \varphi), \operatorname{nf}(r \varphi)=t_{4}, \operatorname{nf}\left(r_{1} \varphi\right)=\operatorname{nf}\left(r_{3} \varphi\right)=t_{1}$ and $\operatorname{nf}\left(r_{4} \varphi\right)=t_{4}$ for some $t_{1}, t_{4} \in C$ Terms. Thus, we have that $r \varphi={ }_{\mathcal{R}} r_{4} \varphi$ and hence $r_{4}$ cannot be a subterm of $r^{\prime}$ since $r$ is $\left(r^{\prime}, \varphi\right)$-simple. Thus $r_{2} \neq r^{\prime}$, and by induction hypothesis $\operatorname{valid}\left(\operatorname{nf}\left(r_{2}^{\text {new }} \varphi^{\text {new }}\right)\right), \operatorname{nf}\left(r_{2}^{\text {new }} \varphi^{\text {new }}\right)=\operatorname{senc}\left(t_{1}^{\text {new }}, t_{4}^{\text {new }}\right)$. We also have that $\operatorname{valid}\left(r_{1}^{\text {new }} \varphi^{\text {new }}\right)$ and $\operatorname{nf}\left(r_{1}^{\text {new }} \varphi^{\text {new }}\right)=t_{1}^{\text {new }}$ by induction hypothesis. As $r$ is different from $r^{\prime}$, we get that $r^{\text {new }}=\operatorname{sdec}\left(r_{1}^{\text {new }}, r_{2}^{\text {new }}\right)$. Thus, $r^{\text {new }} \varphi^{\text {new }}=t_{4}^{\text {new }}$. As $t_{4}$ is a constructor term, so is $t_{4}^{\text {new }}$. The proposition follows. The following proposition can also be proved using induction.

Proposition D.4. Let $r, r^{\prime}$ be recipes and $\varphi$ be a frame such that $\operatorname{vars}(r), \operatorname{vars}\left(r^{\prime}\right) \subseteq \operatorname{dom}(\varphi), \operatorname{valid}\left(r^{\prime} \varphi\right)$ and $r^{\prime}, \varphi$ are away from new. Let $\varphi^{\text {new }}=\varphi\left[\operatorname{nf}\left(r^{\prime} \varphi\right) \mapsto\right.$ new]. If $\operatorname{valid}\left(r \varphi^{\text {new }}\right)$ and $\operatorname{nf}\left(r \varphi^{\text {new }}\right)=t$ then $\operatorname{valid}(r[$ new $\mapsto$ $\left.\left.r^{\prime}\right] \varphi\right)$ and $\operatorname{nf}\left(r\left[\right.\right.$ new $\left.\left.\mapsto r^{\prime}\right] \varphi\right)=t\left[\right.$ new $\left.\mapsto \operatorname{nf}\left(r^{\prime} \varphi\right)\right]$.

Proof of Claim 1. Now going back to the proof of the lemma, let $\rho$ be an execution which is a descendant of some execution $\rho^{j}$ in the set $\mathcal{S}$. Let $\rho$ be the execution $z_{0} \xrightarrow{\alpha_{0}}$ $z_{1} \cdots \xrightarrow{\alpha_{m-1}} z_{m}$ where each $1 \leq i \leq m, z_{i}=\left(g_{i}, \sigma_{i}, \varphi_{i}, \ell_{i}\right)$ and $\alpha_{i}=\left(k_{i}, r_{i}\right)$. Let $m_{0}=\operatorname{length}\left(\rho^{j}\right)$. Recall that $t^{j}=$ $\operatorname{nf}\left(r_{0} \varphi_{m_{0}}\right)$. We first show that $t^{j}$ does not occur in $\rho^{j}$.
Proposition D.5. For each $0 \leq i \leq m_{0}, t^{j} \nsubseteq \operatorname{ran}\left(\sigma_{i}\right) \cup$ $\operatorname{ran}\left(\varphi_{i}\right)$.

Proof: The proof is by induction on $i$. Since the recipe $r_{0}$ originating at $\rho_{0}$ is not a $\left(\rho^{\prime}, t, \rho^{\prime \prime}\right)$-match for any $\rho^{\prime}, t, \rho^{\prime \prime}$, it follows that $t^{j}$ is not a subterm of any term in the initial frame $\varphi_{0}$. Thus, the proposition is true for $i=0$.

Now, assume that the proposition has been proved for all $i \leq i^{\prime}$. Now, we first claim that $t^{j} \nsubseteq \operatorname{nf}\left(r_{i} \varphi_{i}\right)$ for each $i \leq i^{\prime}$. Indeed, if $t^{j} \sqsubseteq \mathrm{nf}\left(r_{i} \varphi_{i}\right)$ then thanks to Proposition D. 2 above and induction hypothesis, it follows that there is a subrecipe $r^{\prime} \sqsubseteq r_{i}$ such that $t^{j}=\operatorname{nf}\left(r^{\prime} \varphi_{i}\right)$. Since $\rho$ is simple, this means that $r^{\prime}=r_{0}$. But this contradicts the fact that $r_{0}$ originates in the execution $\rho_{0}$. Therefore $t^{j} \nsubseteq \operatorname{nf}\left(r_{i} \varphi_{i}\right)$.

Now, let $\ell_{i^{\prime}+1}=\left(t_{\text {in }}, t_{\text {out }}\right)$. By definition of the semantics, we have that $\operatorname{nf}\left(r_{i} \varphi_{i}\right)=t_{i n} \sigma_{i^{\prime}+1}$. Since $t^{j}$ is not a subterm of $\operatorname{nf}\left(r_{i} \varphi_{i}\right)$, we get immediately that $\operatorname{ran}\left(\sigma_{i^{\prime}+1}\right)$ cannot contain $t^{j}$ as a subterm. Also, $\varphi_{i^{\prime}+1}=\varphi_{i} \uplus t_{\text {out }} \sigma_{i^{\prime}+1}$. By induction hypothesis, we have that $t^{j}$ is not a subterm of $\operatorname{ran}\left(\varphi_{i}\right)$. Observe also that we have already shown that $t^{j}$ is not a subterm of $\operatorname{ran}\left(\sigma_{i^{\prime}+1}\right)$. Therefore if $t^{j}$ is a subterm of $t_{\text {out }} \sigma_{i^{\prime}+1}$ then it must be the case that there is a subterm $t^{\prime}$ of $t_{\text {out }}$ such that $t^{\prime}$ is not a variable and $t^{j}=t^{\prime} \sigma_{i^{\prime}+1}$. Now this contradicts the fact that $\mathrm{r}_{0}$ is not a $\left(\rho^{\prime}, t, \rho^{\prime \prime}\right)$-match for any $\rho^{\prime}, t, \rho^{\prime \prime}$. Thus, $t^{j} \nsubseteq \operatorname{ran}\left(\varphi_{i^{\prime}+1}\right)$ as well. The proposition follows.

We get as a consequence of Proposition D. 5 that $r_{0}$ is a constructive recipe.
Corollary D.6. $r_{0}$ is a constructive recipe.

Proof: Observe that Proposition D. 5 implies that $t^{j}=\operatorname{nf}\left(\mathrm{r}_{0} \varphi_{m_{0}}\right)$ is not a subterm of $\varphi_{m_{0}}$. Proposition D. 1 immediately implies that $r_{0}$ cannot be a destructor recipe or a subterm of a destructive recipe. Thus, $r_{0}$ must be a constructive recipe.

For, $1 \leq i \leq m$, let $\rho[0: i]$ be the execution $z_{0} \xrightarrow{\alpha_{0}}$ $z_{1} \cdots \xrightarrow{\alpha_{i-1}} z_{i}$ and $\rho^{\text {new }}[0: i]$ be $z_{0}^{\text {new }} \xrightarrow{\alpha_{0}^{\text {new }}} z_{1}^{\text {new }} \cdots \xrightarrow{\alpha_{i-1}^{\text {new }}}$ $z_{i}^{\text {new }}$.
Proposition D.7. For each $0<i \leq m, \alpha_{i-1}^{\text {new }}$ is enabled in $z_{i-1}^{\text {new }}, \rho^{\text {new }}[0: i]$ is a simple execution of $\mathcal{M}_{P}$ and the measure of the execution $\rho^{\text {new }}$ is the same as the measure of execution $\rho$. Furthermore, $\rho[0: i] \not \vDash \operatorname{Secret}(\mathrm{sec})$ iff $\rho^{\text {new }}[0: i] \not \models \operatorname{Secret}(\mathrm{sec})$.

Proof: We first show that $\rho^{\text {new }}[0: i]$ is an execution of $\mathcal{M}_{P}$ and the measure of the execution $\rho^{\text {new }}$ is the same as the measure of execution $\rho$. It suffices to show that $z_{i-1}^{\text {new }} \xrightarrow{\text { new }_{i-1}^{\text {new }}} \mu_{i}^{\text {new }}$ and $\mu_{i}^{\text {new }}\left(z_{i}^{\text {new }}\right)=\mu_{i}\left(z_{i}\right)$ where $\mu_{i}$ is such that $z_{i-1} \xrightarrow{\alpha_{i-1}} \mu_{i}$.

Fix $m_{0}<i \leq m$ and let $\ell_{i}=\left(t_{\text {in }}, t_{\text {out }}\right)$. Note that $r_{0}$ is a constructive recipe. Since $\rho$ is a simple execution, $r_{i-1}$ is also $\left(r_{0}, \varphi_{i-1}\right)$-simple. Proposition D. 3 implies that $\operatorname{valid}\left(r_{i-1}^{\text {new }} \varphi_{i-1}^{\text {new }}\right)$. Furthermore, if $t_{i-1}=\operatorname{nf}\left(r_{i-1} \varphi_{i-1}\right)$ then $r_{i-1}^{\text {new }} \varphi_{i-1}^{\text {new }}=t_{i-1}\left[t^{j} \mapsto\right.$ new $]$.

Now, by definition, we also have that $r_{i-1} \varphi_{i-1}=t_{i n} \sigma_{i}$. Consider the term $t_{i n}$ as a tree. Let $\operatorname{Vpositions}\left(t_{i n}\right) \subseteq$ positions $\left(t_{i n}\right)$ be the set $\left\{p \mid\left(t_{i n} \mid p\right) \in \mathcal{X}\right\}$. Observe that the tree representation of $t_{i n} \sigma_{i}$ is the obtained from $t_{i n}$ by replacing the variable $x$ at position $p \in \operatorname{Vpositions}\left(t_{i n}\right)$ by $\sigma_{i}(x)$. Now, it is easy to see that if $t^{j}$ is a subterm of $t_{i n} \sigma_{i}$ then $t_{j}$ cannot be a term at a position $\operatorname{position}\left(t_{i n}\right) \backslash$ $\operatorname{Vpositions}\left(t_{i n}\right)$ as $r_{0}$ is not a $\left(\rho^{\prime \prime}, t, \rho^{\prime \prime}\right)$-match for any $\rho^{\prime \prime}, t, \rho^{\prime \prime}$. Thus, it is easy to see that $\left(t_{i n} \sigma_{i}\right)\left[t^{j} \mapsto\right.$ new $]=$ $t_{i n}\left(\sigma_{i}\left[t^{j} \mapsto\right.\right.$ new $\left.]\right)=t_{i n} \sigma_{i}^{\text {new }}$. Thus, $r_{i-1}^{\text {new }} \varphi_{i-1}^{\text {new }}=t_{i n} \sigma_{i}^{\text {new }}$. Hence, $\alpha_{i-1}^{\text {new }}$ is enabled in $z_{i-1}^{\text {new }}$.

As in the case of $t_{i n}$ above, we can show that $\left(t_{\text {out }} \sigma_{i}\right)\left[t^{j} \mapsto\right.$ new $]=t_{\text {out }}\left(\sigma_{i}\left[t^{j} \mapsto\right.\right.$ new $\left.]\right)$. Thus $\varphi_{i-1}^{\text {new }} \uplus$ $t_{\text {out }}\left(\sigma_{i}\left[t^{j} \mapsto\right.\right.$ new $\left.] \varphi_{i-1}^{\text {new }}\right)=\varphi_{i}^{\text {new }}$. Observe that this implies that $z_{i-1}^{\text {new }} \xrightarrow{\alpha_{i-1}^{\text {new }}} \mu_{i}^{\text {new }}$.

If $\rho[0: i] \not \models \operatorname{Secret}(\mathrm{sec})$ then there is a recipe $r$ such that $r \varphi_{i} \vdash \mathrm{sec}$. Without loss of generality, we can assume that $r$ is away from new and that $r$ is $\left(r_{0}, \varphi_{i}\right)$-simple. Proposition D. 3 implies that $r^{\text {new }} \varphi_{i}^{\text {new }} \vdash$ sec.

If $\rho^{\text {new }}[0: i] \not \vDash \operatorname{Secret}(\mathrm{sec})$ then there is a recipe $r$ such that $r \varphi_{i}^{\text {new }} \vdash$ sec. Using Proposition D.4, we have that $\operatorname{valid}\left(r\left[\right.\right.$ new $\left.\left.\mapsto \mathrm{r}_{0}\right] \varphi_{i}\right)$ and that $\operatorname{nf}\left(r\left[\right.\right.$ new $\left.\left.\mapsto \mathrm{r}_{0}\right] \varphi_{i}\right)=$ $\operatorname{nf}\left(r \varphi_{i}^{\text {new }}\right)\left[\right.$ new $\left.\mapsto t^{j}\right]=$ sec.

The fact that $\rho^{\text {new }}[0: i]$ is simple can be easily shown from the fact that $\mathcal{A}$ is simple. The proposition follows. This completes the proof of Claim 1.
Proof of Claim 2. It suffices to consider $\rho_{1}$ and $\rho_{2}$ such that $\rho_{1}$ and $\rho_{2}$ label nodes that are descendants of nodes labeling $\rho^{j_{1}}$ and $\rho^{j_{2}}$ respectively for some $\rho^{j_{1}}, \rho^{j_{2}} \in \mathcal{S}$. We proceed by contradiction.

Fix $\rho_{1}, \rho_{2}, \rho^{j_{1}}, \rho^{j_{2}}$ which contradict the claim. So, we have that $\operatorname{view}\left(\rho_{1}\right) \neq \operatorname{view}\left(\rho_{2}\right)$ but $\operatorname{view}\left(\rho_{1}^{\text {new }}\right)=$
$\operatorname{view}\left(\rho_{2}^{\text {new }}\right)$. Thus, the lengths of $\rho_{1}, \rho_{2}, \rho_{1}^{\text {new }}, \rho_{2}^{\text {new }}$ must be equal. Let $\operatorname{last}\left(\rho_{i}\right)=\left(g_{i}, \sigma_{i}, \varphi_{i}, \ell_{i}\right)$ for $i \in\{1,2\}$ and let $\operatorname{last}\left(\rho_{i}^{\text {new }}\right)=\left(g_{i}, \sigma_{i}^{\text {new }}, \varphi_{i}^{\text {new }}, \ell_{i}\right)$. Let $\operatorname{last}\left(\rho^{j_{i}}\right)=$ $\left(g^{i}, \sigma^{i}, \varphi^{i}, \ell^{i}\right)$ for $i \in\{1,2\}$. Recall that $t^{j_{i}}=\operatorname{nf}\left(r_{0} \varphi^{j_{i}}\right)$ for $i \in\{1,2\}$. For the rest of the proof, for each recipe $r$, by $r^{\text {new }}$ we mean the recipe $r\left[\mathrm{r}_{0} \rightarrow\right.$ new $]$.

Claim 5. For each recipe $r, r_{\text {sub }}$ and $i \in\{1,2\}$ such that $r$ is away from new and $r_{s u b} \sqsubseteq r_{0}$ if $\operatorname{valid}\left(r \varphi_{i}\right)$ and $r \varphi_{i}=\mathcal{R}$ $\mathrm{r}_{s u b} \varphi_{i}$ then $\operatorname{valid}\left(r \varphi_{3-i}\right)$ and $r \varphi_{3-i}=\mathcal{R} \mathrm{r}_{s u b} \varphi_{3-i}$.

Proof: The proof is by induction on the height of the recipe $r$. The base case when $r$ is a public name is immediate from definition.

If $r$ is a variable $w$ then $r$ cannot be $r_{0}$ as $r_{0}$ is a constructive recipe. Thus we have that $r^{\text {new }}=w$ and hence $\operatorname{valid}\left(r^{\text {new }} \varphi_{i}^{\text {new }}\right)$ for each $i \in\{1,2\}$. Fix $i$ and $\mathrm{r}_{\text {sub }} \sqsubseteq \mathrm{r}_{0}$. Assume that $\operatorname{valid}\left(r \varphi_{i}\right)$ and $r \varphi_{i}=\mathcal{R}^{\mathrm{R}} \mathrm{r}_{\text {sub }} \varphi_{i}$. Let $t=w \varphi_{i}=r \varphi_{i}=r_{\text {sub }} \varphi_{i}$. By definition, we have that $r^{\text {new }} \varphi_{i}^{\text {new }}=w \varphi_{i}^{\text {new }}=t\left[t^{j_{i}} \mapsto\right.$ new $]$. We also have $\mathrm{r}_{\text {sub }}$ is $\left(r_{0}, \varphi_{i}\right)$-simple. Hence by Proposition D.3, $r_{s u b}^{\text {new }} \varphi_{i}^{\text {new }}=$ $t\left[t^{j_{i}} \mapsto\right.$ new $]$. Thus, we get that $r^{\text {new }} \varphi_{i}^{\text {new }}=\mathrm{r}_{s u b}^{\text {new }} \varphi_{i}^{\text {new }}$. Thanks to the assumption that $\operatorname{view}\left(\rho_{1}^{\text {new }}\right)=\operatorname{view}\left(\rho_{2}^{\text {new }}\right)$ we get that $r^{\text {new }} \varphi_{3-i}^{\text {new }}=\mathcal{R} \mathrm{r}_{s u b}^{\text {new }} \varphi_{3-i}^{\text {new }}$ also. Now, $\mathrm{r}_{s u b}^{\text {new }}$ is new (if $\mathrm{r}_{\text {sub }}=\mathrm{r}_{0}$ ) or $\mathrm{r}_{\text {sub }}$ (if $\mathrm{r}_{\text {sub }} \sqsubset \mathrm{r}_{0}$ ). In the latter case, $\mathrm{r}_{0}$ not occur as a subterm of $r_{0}$. Thus, by Proposition D.4, we have that $r \varphi_{3-i}=\mathcal{R} \mathrm{r}_{\text {sub }} \varphi_{3-i}$.

Now, assume that for each $r^{\prime}$ such that height of $r^{\prime}$ is $\leq j$, each $\mathrm{r}_{\text {sub }}$ such that $\mathrm{r}_{\text {sub }} \sqsubseteq \mathrm{r}_{0}$ and for each $i \in\{1,2\}$, $\operatorname{valid}\left(r^{\prime} \varphi_{i}\right), r^{\prime} \varphi_{i}=\mathcal{R} r_{s u b} \varphi_{i} \Rightarrow \operatorname{valid}\left(r^{\prime} \varphi_{3-i}\right), r^{\prime} \varphi_{3-i}=_{\mathcal{R}}$ $\mathrm{r}_{\text {sub }} \varphi_{3-i}$.

Now consider a recipe $r$ whose height is $j+1$. The root of the tree representing $r$ must be in the set $\left\{[\cdot, \cdot]\right.$, senc, aenc, $\operatorname{proj}_{1}, \operatorname{proj}_{2}$, sdec, adec $\}$. We show that the inductive step holds when the root is $[\cdot, \cdot]$ or sdec. The other cases are similar.

1) Assume that $r=\left[r_{1}, r_{2}\right]$. Let $P_{1}$ be the set of positions $p$ of $r_{1}$ different from the root such that there is a recipe $\mathrm{r}_{\text {sub }} \sqsubseteq \mathrm{r}_{0}$ and either $\operatorname{valid}\left(\left(r_{1} \mid p\right) \varphi_{1}\right),\left(r_{1} \mid p\right) \varphi_{1}={ }_{\mathcal{R}} \mathrm{r}_{\text {sub }} \varphi_{1}$ or $\operatorname{valid}\left(\left(r_{2} \mid p\right) \varphi_{2}\right),\left(r_{2} \mid p\right) \varphi_{2}={ }_{\mathcal{R}} \mathrm{r}_{s u b} \varphi_{2}$. Now let $P_{\text {fix }}$ be the subset of positions of $P_{1}$ such that if $p \in P_{\text {fix }}$ then no strict prefix of $p$ is in $P_{1}$. Let rfix ${ }_{1}$ be the recipe obtained from $r_{1}$ by replacing the term $r_{1} \mid p$ by $r_{s u b}^{p}$ for each position $p \in P_{\text {fix }}$ where $\mathrm{r}_{\text {sub }}^{p} \sqsubseteq \mathrm{r}_{0}$ is the (unique) recipe such that either $\left(r_{1} \mid p\right) \varphi_{1}=\mathcal{R} \mathrm{r}_{s u b}^{p} \varphi_{1}$ or $\left(r_{2} \mid p\right) \varphi_{2}=\mathcal{R} \mathrm{r}_{\text {sub }} \varphi_{2}$. The uniqueness of $r_{\text {sub }}^{p}$ follows from induction hypothesis.
Thanks to induction hypothesis, for each $p \in$ $P_{\text {fix }}$, if $r^{\prime}=r_{1} \mid p$ then $\operatorname{valid}\left(r^{\prime} \varphi_{1}\right), r^{\prime} \varphi_{1}={ }_{\mathcal{R}}$ $\mathrm{r}_{\text {sub }}^{p} \varphi_{1}, \operatorname{valid}\left(r^{\prime} \varphi_{2}\right)$ and $r^{\prime} \varphi_{2}=\mathcal{R} \mathrm{r}_{\text {sub }}^{p} \varphi_{2}$. Therefore, for each $i \in\{1,2\} \operatorname{valid}\left(\operatorname{rfix}_{1} \varphi_{i}\right) \Leftrightarrow \operatorname{valid}\left(r_{1} \varphi_{i}\right)$ and $\operatorname{rfix}_{1} \varphi_{i}={ }_{\mathcal{R}} r_{1} \varphi_{i} \Leftrightarrow \operatorname{rfix}_{1} \varphi_{3-i}={ }_{\mathcal{R}} r_{1} \varphi_{3-i}$. We can define rfix 2 similarly. Let $\mathrm{rfix}=\left[\mathrm{rfix}_{1}, \text { rfix }\right]_{2}$. By construction, we have that for each $i \in\{1,2\}$, $\operatorname{valid}\left(\operatorname{rfix} \varphi_{i}\right) \Leftrightarrow \operatorname{valid}\left(r \varphi_{i}\right)$ and $\operatorname{rfix} \varphi_{i}=\mathcal{R} r \varphi_{i} \Leftrightarrow$ $\operatorname{rfix} \varphi_{3-i}=\mathcal{R} r \varphi_{3-i}$.

Fix $i$. Assume that $\operatorname{valid}\left(r \varphi_{i}\right)$ and $r \varphi_{i}=\mathcal{R} \mathrm{r}_{\text {sub }} \varphi$ for some $r s u b \sqsubseteq \mathrm{r}_{0}$. Then we have $\operatorname{valid}\left(\operatorname{rfix} \varphi_{i}\right)$ and $\mathrm{rfix} \varphi_{i}={ }_{\mathcal{R}} \mathrm{r}_{\text {sub }} \varphi_{i}$. Observe that the construction of $\mathrm{rfix}_{1}$, rfix ${ }_{2}$ also imply that $\mathrm{rfix}{ }_{1}$, $\mathrm{rfix}_{2}$ are $\left(\mathrm{r}_{0}, \varphi_{i}\right)$ simple. We have two cases. Either $r_{\text {sub }} \sqsubset r_{0}$ or $r_{\text {sub }}=r_{0}$.
First assume that $\mathrm{r}_{\text {sub }} \sqsubset \mathrm{r}_{0}$. If $t_{1}=\mathrm{nf}\left(r_{1} \varphi_{i}\right)$ and $t_{2}=\operatorname{nf}\left(r_{2} \varphi_{i}\right)$, it follows that $\operatorname{nf}\left(\operatorname{rfix} \varphi_{i}\right)=$ $\left[t_{1}, t_{2}\right]=\operatorname{nf}\left(\mathrm{r}_{\text {sub }} \varphi_{i}\right)$. Note that as $\mathrm{r}_{\text {sub }}$ only contains frame variables in $\operatorname{dom}\left(\varphi^{j_{i}}\right)$, we get that $\left[t_{1}, t_{2}\right]=\operatorname{nf}\left(\mathrm{r}_{\text {sub }} \varphi^{j_{i}}\right)$. Now, we already established in the proof of Claim 1 that $t^{j_{i}}$ is not a subterm of $\operatorname{ran}\left(\varphi^{j_{i}}\right)$ (see Proposition D.5). Thanks to Proposition D.2, the only way that $t^{j_{i}}$ is a subterm of $t_{1}$ or $t_{2}$ is if $r_{s u b}$ has a sub-recipe $r_{\text {sub }}^{\prime}$ such that $\mathrm{r}_{s u b}^{\prime} \varphi_{i}=t^{j_{i}}$. This contradicts the fact that $\mathrm{r}_{0}$ is a simple recipe. It follows that $t^{j_{1}} \nsubseteq t_{1}, t_{2}$.
Thus, $t_{1}\left[t^{j_{1}} \mapsto\right.$ new $]=t_{1}$ and $t_{2}\left[t^{j_{2}} \mapsto\right.$ new $]=t_{2}$. Observe that rfix $\neq r_{0}$ and hence $r$ rix ${ }^{\text {new }}=\left[\operatorname{rfix}_{1}^{\text {new }}\right.$, rfix $\left._{2}^{\text {new }}\right]$. Thus, $\operatorname{rfix}^{\text {new }} \varphi_{i}^{\text {new }}=$ $\left[\mathrm{rfix}_{1}^{\text {new }} \varphi_{i}^{\text {new }}, \mathrm{rfix}_{2}^{\text {new }} \varphi_{i}^{\text {new }}\right]$. Since $\mathrm{rfix}_{1}$ and $\mathrm{rfix}_{2}$ are $\left(r_{0}, \varphi_{i}\right)$-simple, we get by Proposition D. 3 that $\mathrm{nf}\left(\operatorname{rfix} 1_{1}^{\text {new }} \varphi_{i}^{\text {new }}\right)=t_{1}\left[t^{j_{i}} \mapsto\right.$ new $]=t_{1}$ and $\mathrm{nf}\left(\mathrm{rfix}_{2}^{\text {new }} \varphi_{i}^{\text {new }}\right)=t_{2}\left[t^{j_{i}} \mapsto\right.$ new $]=t_{2}$. Thus, $\mathrm{nf}\left(\operatorname{rfix}{ }^{\text {new }} \varphi_{i}^{\text {new }}\right)=\left[t_{1}, t_{2}\right]=\operatorname{nf}\left(\mathrm{r}_{\text {sub }} \varphi_{i}\right)$. Since $\mathrm{r}_{\text {sub }}$ only contains frame variables in $\operatorname{dom}\left(\varphi^{j_{1}}\right)$, it follows that $\operatorname{nf}\left(\mathrm{rfix}^{\text {new }} \varphi_{i}^{\text {new }}\right)=\operatorname{nf}\left(\mathrm{r}_{\text {sub }} \varphi_{i}^{\text {new }}\right)$. As, we have that $\operatorname{view}\left(\rho_{1}^{\text {new }}\right)=\operatorname{view}\left(\rho_{2}^{\text {new }}\right)$, we get that $\operatorname{valid}\left(\right.$ rfix $\left.^{\text {new }} \varphi_{3-i}^{\text {new }}\right)$ and $\operatorname{nf}\left(\operatorname{rfix}^{\text {new }} \varphi_{3-i}^{\text {new }}\right)=$ $\mathrm{nf}\left(\mathrm{r}_{\text {sub }} \varphi_{3-i}^{\text {new }}\right)$. The proposition now follows from Proposition D.4.
Now assume that $r_{s u b}=r_{0}$. Now, as $r_{0}$ is a constructive recipe and $\operatorname{nf}\left(r_{0} \varphi_{i}\right)=\left[\operatorname{nf}\left(r_{1} \varphi_{i}\right), \operatorname{nf}\left(r_{2} \varphi_{i}\right)\right]$, it follows that $\mathrm{r}_{0}=\left[r_{0}^{1}, r_{0}^{2}\right]$ for some recipes $r_{0}^{1}, r_{0}^{2}$. Furthermore, $\mathrm{nf}\left(r_{1} \varphi_{i}\right)=\operatorname{nf}\left(r_{0}^{1} \varphi_{i}\right)$ and $\operatorname{nf}\left(r_{2} \varphi_{i}\right)=\operatorname{nf}\left(r_{0}^{2} \varphi_{i}\right)$. Observe that $r_{0}^{1}, r_{0}^{2}$ are subrecipes of $r_{0}$. Hence, the proposition immediately follows from induction hypothesis in this case.
2) Now assume that $r=\operatorname{sdec}\left(r_{1}, r_{2}\right)$. Now, as in the case of pairing above, construct rfix, $\mathrm{rfix}_{1}, \mathrm{rfix}_{2}$. Fix $i$ and $\mathrm{r}_{\text {sub }} \sqsubseteq \mathrm{r}_{0}$. Suppose now that $\operatorname{valid}\left(r \varphi_{i}\right)$ and $r \varphi_{i}=\mathcal{R} r_{\text {sub }} \varphi_{i}$. Thanks to the construction of rfix, we have that $\operatorname{valid}\left(\operatorname{rfix} \varphi_{i}\right)$ and $\operatorname{rfix} \varphi_{i}=\mathcal{R}$ $\mathrm{r}_{\text {sub }} \varphi_{i}$. Thanks to the construction of rfix , it suffices to show that valid $\left(\operatorname{rfix} \varphi_{3-i}\right)$ and $\operatorname{rfix} \varphi_{3-i}=\mathcal{R}$ $\mathrm{r}_{\text {sub }} \varphi_{3-i}$. Observe also that $\mathrm{rfix}_{1}, \mathrm{rfix}_{2}$ are $\left(r_{0}, \varphi_{i}\right)$ simple recipes.
Observe that as $\operatorname{valid}\left(\operatorname{rfix} \varphi_{i}\right), r \operatorname{rfix}_{2}$ can be either a constructor recipe or a frame variable or a destructive recipe.
If $\mathrm{rfix}_{2}$ is a constructive recipe, it must be the case rfix ${ }_{2}=\operatorname{senc}\left(r_{3}, r_{4}\right)$ where $r_{3}$ and $r_{4}$ are recipes such that $\mathrm{rfix}_{1} \varphi_{i}={ }_{\mathcal{R}} r_{3} \varphi_{i}$ and $\operatorname{rfix} \varphi_{i}={ }_{\mathcal{R}} \quad r_{4} \varphi_{i}==_{\mathcal{R}} \quad r_{s u b} \varphi_{i}$. By construction of $\mathrm{rfix}_{2}, r_{4}$ must be $\mathrm{r}_{\text {sub }}$. Furthermore, as $\operatorname{rfix}_{1} \varphi_{i}=r_{3} \varphi_{i}$ and $\mathrm{rfix}_{1}, r_{3}, \mathrm{r}_{\text {sub }}$ are $\left(r_{0}, \varphi_{i}\right)$ simple recipes, we get using Proposition D. 3 that
$\operatorname{valid}\left(\mathrm{rfix}{ }_{1}^{\text {new }} \varphi_{i}^{\text {new }}\right), \operatorname{valid}\left(r_{3}^{\text {new }} \varphi_{i}^{\text {new }}\right), \operatorname{valid}\left(\mathrm{r}_{\operatorname{sub}}^{\text {new }} \varphi_{i}^{\text {new }}\right)$ and that $\operatorname{rfix}_{1}^{\text {new }} \varphi_{i}^{\text {new }}=r_{3}^{\text {new }} \varphi_{i}^{\text {new }}$. Let $r_{\text {final }}=\operatorname{sdec}\left(\operatorname{rfix}{ }_{1}^{\text {new }}, \operatorname{senc}\left(r_{3}^{\text {new }}, r_{\text {sub }}^{\text {new }}\right)\right)$. We have that $\operatorname{valid}\left(r_{\text {final }} \varphi_{i}^{\text {new }}\right)$ and that $\operatorname{nf}\left(r_{\text {final }} \varphi_{i}^{\text {new }}\right)=\mathrm{nf}_{\mathrm{n}}\left(\mathrm{r}_{\text {suw }}^{\text {new }} \varphi_{i}^{\text {new }}\right)$. Since $\operatorname{view}\left(\varphi_{1}^{\text {new }}\right)=\operatorname{view}\left(\varphi_{2}^{\text {new }}\right)$, we get that $\operatorname{valid}\left(r_{\text {final }} \varphi_{3-i)}^{\text {new }}\right.$ and that $\operatorname{nf}\left(r_{\text {final }} \varphi_{3-i}^{\text {new }}\right)=$ $\mathrm{nf}\left(\mathrm{r}_{s u b}^{\mathrm{new}} \varphi_{3-i}^{\text {new }}\right)$. Proposition D. 4 implies that $\operatorname{valid}\left(\mathrm{rfix} \varphi_{3-i}\right)$ and that $\operatorname{nf}\left(\operatorname{rfix} \varphi_{3-i}=\mathrm{r}_{s u b} \varphi_{3-i}\right)$. If $\mathrm{rfix}_{2}$ is a frame variable or a destructive recipe then $r$ fix ${ }_{2}$ cannot be $r_{0}$ as $r_{0}$ is a constructive recipe. By construction of $\mathrm{rfix}_{2}$, we have that $\operatorname{nf}\left(\operatorname{rfix}_{2} \varphi_{i}\right) \neq$ $t^{j_{i}}$. Now as valid $\left(\operatorname{rfix} \varphi_{i}\right)$, we get that $\operatorname{nf}\left(\operatorname{rfix}_{1} \varphi_{i}\right)=$ $t_{1}, \operatorname{nf}\left(\operatorname{rfix}_{2} \varphi_{i}\right)=\operatorname{senc}\left(t_{1}, t_{2}\right)$ and that $\operatorname{rfix} \varphi_{i}=$ $\mathrm{r}_{\text {sub }} \varphi_{i}=t_{2}$ for some $t_{1}, t_{2} \in$ CTerms. As, $\mathrm{rfix}_{1}$, $\mathrm{rfix}{ }_{2}$ are $\left(r_{0}, \varphi_{i}\right)$-simple recipes, we get by Proposition D. 3 that $\operatorname{nf}\left(\mathrm{rfix}_{1}^{\text {new }} \varphi_{i}^{\text {new }}\right)=t_{1}\left[t^{j_{i}} \mapsto\right.$ new $]$ and that $\operatorname{nf}\left(\operatorname{rfix}_{2}^{\text {new }} \varphi_{i}^{\text {new }}\right)=\operatorname{senc}\left(t_{1}\left[t^{j_{i}} \mapsto\right.\right.$ new $], t_{2}\left[t^{j_{i}} \mapsto\right.$ new $\left.]\right)$. From this it is easy to see that the recipe valid (sdec (rfix ${ }_{1}^{\text {new }}$, rfix $\left.{ }_{2}^{\text {new }}\right) \varphi_{i}^{\text {new }}$ ) and that $\operatorname{nf}\left(\operatorname{sdec}\left(\right.\right.$ rfix $\left.\left._{1}^{\text {new }}, \operatorname{rfix}_{2}^{\text {new }}\right) \varphi_{i}^{\text {new }}\right)=t_{2}\left[t^{j_{i}} \mapsto\right.$ new]). Now, thanks to Proposition D. 3 again, we have that $\operatorname{valid}\left(\mathrm{r}_{s u b}^{\text {new }} \varphi_{i}^{\text {new }}\right)$ and that $\operatorname{nf}\left(\mathrm{r}_{s u b}^{\text {new }} \varphi_{i}^{\text {new }}\right)=$ $t_{2}\left[t^{j_{i}} \mapsto\right.$ new $] \stackrel{\text { nf }}{=} \operatorname{nf}\left(\operatorname{sdec}\left(\right.\right.$ rfix $\left.\left._{1}^{\text {new }}, \operatorname{rfix}_{2}^{\text {new }}\right) \varphi_{i}^{\text {new }}\right)$. Now we can conclude that $\operatorname{valid}\left(\operatorname{rfix} \varphi_{3-i}\right)$ and that $\operatorname{nf}\left(\operatorname{rfix} \varphi_{3-i}\right)=\operatorname{nf}\left(\mathrm{r}_{\text {sub }} \varphi_{3-i}\right)$ as in the above case. Therefore, $\operatorname{nf}\left(r \varphi_{3-i}\right)=\operatorname{nf}\left(\mathrm{r}_{s u b} \varphi_{3-i}\right)$, and the proposition follows.

Claim 6. For any $i \in\{1,2\}$ and recipe $r$ away from new, if $\operatorname{valid}(r \varphi)$ then $\operatorname{valid}\left(r \varphi_{3-i}\right)$.

Proof: First consider the case when $r$ is $\left(r_{0}, \varphi_{i}\right)$ simple. Now, $r_{0}$ is a constructive recipe. Thanks to Proposition D.3, we have that $\operatorname{valid}\left(\left(r\left[\mathrm{r}_{0} \quad \mapsto\right.\right.\right.$ new] $\left.) \varphi_{i}^{\text {new }}\right)$. Since $\operatorname{view}\left(\rho_{1}^{\text {new }}\right)=\operatorname{view}\left(\rho_{2}^{\text {new }}\right)$, we get that $\operatorname{valid}\left(\left(r\left[\mathrm{r}_{0} \mapsto \mathrm{new}\right]\right) \varphi_{3-i}^{\text {new }}\right)$ as well. Proposition D. 4 implies that $\operatorname{valid}\left(r \varphi_{3-i}\right)$.

Now suppose $r$ is not $\left(r_{0}, \varphi_{i}\right)$-simple. Let $P_{1}$ be the set of positions $p$ of $r$ such that there is a recipe $\mathbf{r}_{\text {sub }} \sqsubseteq \mathrm{r}_{0}$ and either $\operatorname{valid}\left((r \mid p) \varphi_{1}\right),(r \mid p) \varphi_{1}=\mathcal{R} \mathbf{r}_{\text {sub }} \varphi_{1}$ or $\operatorname{valid}\left((r \mid p) \varphi_{2}\right),(r \mid p) \varphi_{2}=\mathcal{R}^{\mathcal{R}} \mathrm{r}_{\text {sub }} \varphi_{2}$. Let $P_{\text {fix }}$ be the largest subset of positions of $P_{1}$ such that if $p \in P_{\text {fix }}$ then no strict prefix of $p$ is in $P_{1}$. Let rfix be the recipe obtained from $r$ by replacing the term $r \mid p$ by $\mathrm{r}_{\text {sub }}^{p}$ for each position $p \in P_{\text {fix }}$ where $r_{s u b}^{p} \sqsubseteq r_{0}$ is the (unique) recipe such that either $\left(r_{1} \mid p\right) \varphi_{1}=\mathcal{R} \mathrm{r}_{s u b}^{p} \varphi_{1}$ or $\left(r_{2} \mid p\right) \varphi_{2}=\mathcal{R} \mathrm{r}_{s u b} \varphi_{2}$. The uniqueness follows from the fact that $r_{0}$ is simple and Claim 5. It is easy to see by Claim 5 that rfix is $\left(\mathrm{r}_{0}, \varphi_{i}\right)$ simple and that $\operatorname{valid}\left(r \varphi_{j}\right)$ iff $\operatorname{valid}\left(\operatorname{rfix} \varphi_{j}\right)$ for $j \in\{1,2\}$. The above case implies that $\operatorname{valid}\left(\operatorname{rfix} \varphi_{3-i}\right)$ if $\operatorname{valid}\left(r \varphi_{i}\right)$. Hence, $\operatorname{valid}\left(r \varphi_{3-i}\right)$ as well.
Claim 7. For any $i \in\{1,2\}$ and recipes $r, r^{\prime}$ away from new such that $\operatorname{valid}\left(r \varphi_{i}\right), \operatorname{valid}\left(r^{\prime} \varphi_{i}\right)$, if $r \varphi_{i}=\mathcal{R} r^{\prime} \varphi_{i}$ then $r \varphi_{3-i}=\mathcal{R} r^{\prime} \varphi_{3-i}$ also.

Proof: As in the proof of Claim 6, it suffices to consider the case when $r, r^{\prime}$ are $\left(r_{0}, \varphi_{j}\right)$-simple for $j \in\{1,2\}$.

Now, $r_{0}$ is a constructive recipe. Thanks to Proposition D.3, we have that $\left(r\left[r_{0} \mapsto\right.\right.$ new $\left.]\right) \varphi_{i}^{\text {new }}={ }_{\mathcal{R}}\left(r^{\prime}\left[r_{0} \mapsto\right.\right.$ new $\left.]\right) \varphi_{i}^{\text {new }}$. Since $\operatorname{view}\left(\rho_{1}^{\text {new }}\right)=\operatorname{view}\left(\rho_{2}^{\text {new }}\right)$, we get that $\left(r\left[\mathrm{r}_{0} \mapsto\right.\right.$ new $]) \varphi_{3-i}^{\text {new }}=\mathcal{R}\left(r^{\prime}\left[\mathrm{r}_{0} \mapsto\right.\right.$ new $\left.]\right) \varphi_{3-i}^{\text {new }}$. Proposition D. 4 implies that $r \varphi_{3-i}=r^{\prime} \varphi_{3-i}$.

Claim 6 and Claim 7 contradict the fact that $\operatorname{view}\left(\rho_{1}\right) \neq$ $\operatorname{view}\left(\rho_{2}\right)$. This completes the proof of the claim.

## Appendix E. Proof of Theorem 4.6

The proof of the theorem is similar to the proof of Theorem 4.3. Let $\mathcal{A}$ be a simple adversary that distinguishes $\mathcal{M}_{P}$ and $\mathcal{M}_{P^{\prime}}$. As in the case of the proof of Theorem 4.3, we can view the DTMCs $\mathcal{M}_{P}^{\mathcal{A}}$ and $\mathcal{M}_{P^{\prime}}^{\mathcal{A}}$ as trees $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ and $\mathcal{T}_{\mathcal{M}_{P^{\prime}}^{\mathcal{A}}}$ respectively. The nodes of $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ and $\mathcal{T}_{\mathcal{M}_{P^{\prime}}^{A}}$ are labeled by executions of $\mathcal{M}_{P}$ and $\mathcal{M}_{P^{\prime}}$ respectively. Observe that the total number of nodes in either of these two trees is $\leq \lambda \eta^{\gamma}$.

As in the case of proof of Theorem 4.3, we can again define the notion of a recipe $r$ originating at an execution labeling a node of $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}^{\mathcal{A}}$ or $\mathcal{T}_{\mathcal{M}_{P^{\prime}}^{\mathcal{A}}}$. Analogous to the notion of a match defined in the proof of Theorem 4.3, we can also define the notion of a small adversary. Consider a recipe $r$ originating at execution $\rho$. Given a term $t \in \operatorname{subterms}\left(P, P^{\prime}\right) \backslash \mathcal{X}$ and executions $\rho^{1}, \rho^{2}$ such that $\rho^{1}$ and $\rho^{2}$ label some nodes in $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ or in $\mathcal{T}_{\mathcal{M}_{P^{\prime}}^{\mathcal{A}}}, \operatorname{view}(\operatorname{prev}(\rho))=\operatorname{view}\left(\rho^{1}\right), \operatorname{enabled}\left(\rho^{1}, \alpha_{m-1}\right)$ and $\operatorname{last}\left(\rho^{j}\right)=\left(g^{j}, \sigma^{j}, \varphi^{j},\left(t_{\text {in }}^{j}, t_{\text {out }}^{j}\right)\right)$ for $j=1,2$, we say that the recipe $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match if $r$ is not a public name or recipe variable, ie, $r \notin \operatorname{Pub} \cup \mathcal{X}_{w}$ and one of the following hold:

1) $\quad \rho^{2}$ is the initial state of $\mathcal{M}_{P}^{\mathcal{A}}$ or of $\mathcal{M}_{P^{\prime}}^{\mathcal{A}}, t$ is a subterm of $\operatorname{ran}\left(\varphi_{0}\right)$ and $\operatorname{nf}\left(r \varphi^{1}\right)=n f\left(t \sigma^{2}\right)$.
2) $\rho^{2}$ is not the initial state of $\mathcal{M}_{P}^{\mathcal{A}}$ or of $\mathcal{M}_{P^{\prime}}^{\mathcal{A}}, t$ is a subterm of either $t_{\text {in }}^{2}$ or $t_{\text {out }}^{2}$ and $\operatorname{nf}\left(r \varphi^{1}\right)=$ $n f\left(t \sigma^{2}\right)$.
We say that the execution $\rho$ is an $\mathcal{A}$-match if for every recipe $r$ originating at $\rho$, either $r \in \operatorname{Pub} \cup \mathcal{X}_{w}$ or there is a term $t$ and executions $\rho^{1}, \rho^{2}$ such that $r$ is a $\left(\rho^{1}, t, \rho^{2}\right)$-match. We say that a simple adversary $\mathcal{A}$ is small if every execution $\rho$ labeling a node in $\mathcal{T}_{\mathcal{M}_{P}^{\mathcal{A}}}$ or a node in $\mathcal{T}_{\mathcal{M}_{\mathcal{P}^{\prime}}^{\mathcal{A}}}$, is an $\mathcal{A}$-match.

An argument similar to the proof of Lemma 4.4 then shows that if a simple adversary $\mathcal{A}$ is small then $\operatorname{rsize}(\mathcal{A}) \leq$ $12 \theta \lambda \eta^{2 \gamma}$. A factor of 4 arises because the total number of nodes in the two trees is at most $2 \lambda \eta^{\gamma}$.

We proceed once again as in the proof of Theorem 4.3 by showing that if $P$ and $P^{\prime}$ are distinguishable by an adversary $\mathcal{A}$ then they are distinguishable by a small adversary as follows.

Fix a simple adversary $\mathcal{A}$ that distinguishes $P$ and $P^{\prime}$. As in the proof of Lemma 4.5 , if $\mathcal{A}$ is not small then we can construct a new adversary $\mathcal{A}_{\text {small }}$ by iteratively replacing recipes that witness the fact $\mathcal{A}$ is not small by fresh public names. The main obligation that we have to show is that $\mathcal{A}_{\text {small }}$ distinguishes $P$ and $P^{\prime}$.

Let $\mathcal{E}$ be the set of executions of the DTMCs $\mathcal{M}_{P}^{\mathcal{A}}$ and $\mathcal{M}_{P^{\prime}}^{\mathcal{A}}$. Let $\mathcal{E}_{\text {small }}$ be the set of executions of the DTMCs $\mathcal{M}_{P}^{\mathcal{A}_{\text {small }}}$ and $\mathcal{M}_{P^{\prime}}^{\mathcal{A}_{\text {small }}}$. The proof of Lemma 4.5 implies that there is a bijection $s m: \mathcal{E} \rightarrow \mathcal{E}_{\text {small }}$ such that

1) The measure of execution $\kappa \in \mathcal{E}$ is exactly the measure of the execution $\operatorname{sm}(\kappa)$.
2) If $\operatorname{view}(\operatorname{last}(\kappa)) \neq \operatorname{view}\left(\operatorname{last}\left(\kappa^{\prime}\right)\right.$ for $\kappa, \kappa^{\prime} \in \mathcal{E}$ then $\operatorname{view}(\operatorname{last}(\operatorname{sm}(\kappa))) \neq \operatorname{view}\left(\operatorname{last}\left(\operatorname{sm}\left(\kappa^{\prime}\right)\right)\right)$.
As $\mathcal{A}$ distinguishes $P$ and $P^{\prime}$ there must be a sequence $\bar{o} \in(\text { Frames } / \sim)^{*} \times(\{1,2, \ldots, n\} \times$ Recipes $)$ such that $\operatorname{pr}_{\mathcal{M}_{P}}(\bar{o}, \mathcal{A}) \neq \operatorname{pr}_{\mathcal{M}_{P^{\prime}}}(\bar{o}, \mathcal{A})$. Fix $\bar{o}$. Let $\mathcal{E}_{\bar{o}}$ be the set $\{\kappa \mid \operatorname{view}(\operatorname{last}(\kappa))=\bar{o}\}$. Let $\bar{O}_{\text {small }}$ be the set $\left\{\bar{o}_{s m} \mid \bar{o}_{s m}=\operatorname{view}(\operatorname{last}(\operatorname{sm}(\kappa)))\right.$ for some $\left.\kappa \in \mathcal{E}_{\bar{o}}\right\}$. The above two conditions imply that

$$
\operatorname{pr}_{\mathcal{M}_{P}}(\bar{o}, \mathcal{A})=\sum_{\bar{o}_{s m} \in \bar{O}_{\text {small }}} p r_{\mathcal{M}_{P}}\left(\bar{o}_{s m}, \mathcal{A}_{\text {small }}\right)
$$

and

$$
\operatorname{pr}_{\mathcal{M}_{P^{\prime}}}(\bar{o}, \mathcal{A})=\sum_{\bar{o}_{s m} \in \bar{O}_{s m a l l}} p r_{\mathcal{M}_{P^{\prime}}}\left(\bar{o}_{s m}, \mathcal{A}_{\text {small }}\right) .
$$

Since $p r_{\mathcal{M}_{P}}(\bar{o}, \mathcal{A}) \neq p r_{\mathcal{M}_{P^{\prime}}}(\bar{o}, \mathcal{A})$, we get immediately that there must be an $\bar{o}_{s m} \in \bar{O}_{\text {small }}$ such that

$$
p r_{\mathcal{M}_{P}}\left(\bar{o}_{s m}, \mathcal{A}_{\text {small }}\right) \neq p r_{\mathcal{M}_{P^{\prime}}}\left(\bar{o}_{s m}, \mathcal{A}_{\text {small }}\right)
$$

Thus, $\mathcal{A}_{\text {small }}$ also distinguishes $P$ and $P^{\prime}$. The theorem follows.

## Appendix F.

## Proof of Theorem 4.7

We first consider the secrecy problem and show that the non-secrecy problem can be decided in NEXPTIME. The NEXPTIME time procedure for deciding the nonsecrecy problem non-deterministically constructs the tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ which corresponds to a simple adversary $\mathcal{A}$ such that $\operatorname{rsize}(\mathcal{A}) \leq 3 \theta \lambda \eta^{2 \gamma}$ where $\theta, \eta, \gamma$, and $\lambda$ are as defined in the statement of Theorem 4.3. The tree $\mathcal{T}_{\mathcal{M}_{P}^{A}}$ is constructed incrementally. Initially all children of the root are guessed by guessing the initial recipe used by the adversary, the role the first message is sent to and the transition of the role that is triggered. The recipe is guessed in its dag form and is of size $\leq 3 \theta \lambda \eta^{2 \gamma}$. The procedure checks that the recipe chosen is valid, message computed by the recipe chosen unifies with the left-hand size of the transition chosen and computes the unifier. These steps can be performed in time polynomial in the size of the recipe. Then the children of the root are computed, making sure that the terms in the labels of the children are also kept in dag form. We also label the edge from the root to its child by the probability of making that transition. The procedure then guesses the children of each of nodes at level 1 in a similar fashion except that the adversary has to perform some additional tests. These tests are done to make sure that if the adversary uses different recipes for two executions at level 1 then
these two executions are distinguishable. In order to check if two executions are distinguishable, the procedure checks that the last states in the executions of these two nodes are distinguishable. The latter is achieved by guessing the test which distinguishes the frames at these states. The results of [1], [15] imply that this test must be of size polynomial in the size of the frames. The subsequent levels of the tree are guessed incrementally in a similar fashion. The resulting tree has most $\lambda \eta^{\gamma}$ nodes. It is easy to show that the dagsize of terms in each state is exponential in the size of the protocol. After guessing the tree, the procedure marks the leaf nodes such that the secret sec is revealed in the last state of executions labeling these nodes. Finally, the procedure checks that the measure of the paths from the root to the marked nodes is $>p$.

Now, indistinguishability of two protocols can be shown to be in coNEXPTIME along similar lines using Theorem 4.6.

## Appendix G. <br> Proof of Theorem 5.3

Before proving the hardness result, we state the precise pair of results about the monadic logic in Definition 5.2 that we will exploit in our proof.
Theorem G. 1 (Theorem 5.1 in [30]). Given a monadic formula $\varphi, \varphi$ is satisfiable if and only if $\varphi$ has a model of size $\leq 2^{k}$, where $k$ is the number of monadic relation symbols appearing in $\varphi$.
Theorem G. 2 (Theorem 4.1 in [30]). Let $\varphi$ be a monadic formula of the form

$$
\exists z \cdot F_{1}(z) \wedge \forall y \exists x \cdot F_{2}(y, x) \wedge \forall y_{1} \forall y_{2} \cdot F_{3}\left(y_{1}, y_{2}\right)
$$

where $F_{1}, F_{2}$, and $F_{3}$ are quantifier-free $3-\mathrm{CNF}$ formulas. The problem of checking if $\varphi$ is satisfiable is NEXPTIME-hard.

We are now ready to prove Theorem 5.3. Given a monadic formula $\varphi$, we will construct (in polynomial time) a protocol $P$ such that the secret is revealed in $P$ with probability 1 iff $\varphi$ is satisfiable. First, recall that from Theorem G.2, we can assume that $\varphi$ is of the form $\exists z . F_{1}(z) \wedge$ $\forall y \exists x . F_{2}(y, x) \wedge \forall y_{1} \forall y_{2} . F_{3}\left(y_{1}, y_{2}\right)$, where $F_{1}, F_{2}$, and $F_{3}$ are quantifier-free 3-CNF formulas. Second, we know that if $\varphi$ is satisfiable, it has a model of size at most $2^{k}$, where $k$ is the number of predicate symbols appearing in $\varphi$ (Theorem G.1). In fact, without loss of generality, we can take the model to have size exactly $2^{k}$. This is because we can construct a formula $T(\varphi)$ with one additional monadic predicate inUniv such that $T(\varphi)$ has a model of size $2^{k}$ iff $\varphi$ is satisfiable. In $T(\varphi)$, inUniv determines if an element of the universe is a "valid" element of the universe. The formula $T(\varphi)$ is constructed inductively, with $T(\exists x \cdot \psi)=\exists x \cdot \operatorname{inUniv}(x) \wedge T(\psi)$ and $T(\forall x . \psi)=\forall x \cdot \operatorname{inUniv}(x) \rightarrow T(\psi)$. Notice, $T(\varphi)$ has the same pattern of quantifiers as $\varphi$, and hence is of the same "form" as $\varphi$.

The protocol $P$ will have one role $R$ and proceeds as follows. In the first step, the adversary guesses a model for the formula $\varphi$ and sends this to the protocol. In order to ensure that the adversary cannot change this model at a later step, this model is encrypted by the protocol using a secret key. This very much like what happens in the reduction from 3SAT [33] or QSAT. From Theorem G. 1 and the observations in the previous paragraph, we can assume that the size of the model constructed by the adversary is $2^{k}$ where $k$ is the number of predicate symbols in $\varphi$; we will assume that the $k$ predicate symbols in $\varphi$ are $\left\{P_{0}, \ldots P_{k-1}\right\}$. The protocol assumes that the model sent by the adversary is encoded as a full binary tree of height $k$, with leaves of the tree corresponding to the elements of the universe. Each leaf in the tree is labeled by a tuple of size $k$ of the form $\left[b_{1},\left[b_{2}, \cdots\left[b_{k-1}, b_{k}\right]\right]\right]$, where $b_{i} \in\{\top, \perp\}$ encodes if the $i$ th predicate is true at this element. Thus, the first step in the protocol is a rule as follows.

$$
s_{0}: m \Rightarrow\left[g_{z 0}: \operatorname{senc}(M, m)\right]
$$

Here $s_{0}$ is the initial state, $M$ is a secret key, and $g_{z 0}$ is the state in the next phase of the protocol where the variable $z$ (see format of $\varphi$ ) is assigned an element of the universe.

The next phase of the protocol is one where the variables in the formula are instantiated to a specific element in the model. Like in the QSAT case, existential variables are chosen by the adversary, and universal variables are picked stochastically by the protocol. Picking the value of a variable takes $k$ steps of the protocol, where in each step you walk through the binary tree representation of the model until a leaf (i.e., an element of the universe) is reached. After this, the protocol takes another $k$ steps to send to the adversary the truth of each predicate at the chosen element, in an encrypted form; encryption is again used so that the adversary does not cheat during the formula evaluation phase. Here we show the rules that are used for $\forall y \exists x$; the other variables are handled similarly. Here $g_{y 0}$ is the state where the first bit of $y$ is picked, and the keys $\left\{y^{i} \mid i \leq 2 k\right\} \cup\left\{x^{i} \mid i \leq 2 k\right\} \cup\left\{P_{i}(y) \mid i \leq k\right\} \cup\left\{P_{i}(x) \mid i \leq\right.$ $k\} \subseteq \operatorname{Prv}$ are assumed to be unknown to the adversary. We begin with the rules for picking $y$.

$$
\begin{gathered}
g_{y 0}: \operatorname{senc}\left(M,\left[u_{0}^{0}, u_{1}^{0}\right]\right) \Rightarrow\left[g_{y 1}:\left[\operatorname{senc}\left(y^{1}, u_{0}^{0}\right), \mathbf{0}\right]\right] \oplus \\
{\left[g_{y 1}:\left[\operatorname{senc}\left(y^{1}, u_{1}^{0}\right), \mathbf{1}\right]\right]} \\
g_{y i}: \operatorname{senc}\left(y^{i},\left[u_{0}^{i}, u_{1}^{i}\right]\right) \Rightarrow \\
{\left[g_{y(i+1)}:\left[\operatorname{senc}\left(y^{i+1}, u_{0}^{i+1}\right), \mathbf{0}\right]\right] \oplus} \\
\quad\left[g_{y(i+1)}:\left[\operatorname{senc}\left(y^{i+1}, u_{1}^{i+1}\right), \mathbf{1}\right]\right] \text { for } 1 \leq i<k \\
g_{y j}: \operatorname{senc}\left(y^{j},\left[t_{j}^{y}, r_{j}^{y}\right]\right) \Rightarrow \\
{\left[g_{y(j+1)}:\left[\operatorname{senc}\left(P_{j-k}(y), t_{j}^{y}\right), \operatorname{senc}\left(y^{j}, r_{j}^{y}\right)\right]\right]} \\
\quad \text { for } k \leq j<2 k-2 \\
g_{y(2 k-2)}: \operatorname{senc}\left(y^{2 k-2},\left[t_{2 k-2}^{y}, t_{2 k-1}^{y}\right]\right) \Rightarrow \\
{\left[g_{x 0}:\left[\operatorname{senc}\left(P_{k-2}(y), t_{2 k-2}^{y_{2}}\right), \operatorname{senc}\left(P_{k-1}(y), t_{2 k-1}^{y}\right)\right]\right]}
\end{gathered}
$$

Notice that the coin tosses in the first $k$ steps (choosing the bits of $y$ ) are made public. Also at the end, the adversary has messages of the form $\operatorname{senc}\left(P_{i}(y), b_{i}\right)$ where $b_{i}$ is the truth of predicate $P_{i}$ at the chosen $y$ in the model. The steps for
$\exists x$ are similar, except that the adversary chooses the bits of $x$.

$$
\left.\begin{array}{c}
g_{x 0}:\left[\operatorname{senc}\left(M,\left[v_{0}^{0}, v_{1}^{0}\right]\right), \mathbf{0}\right] \Rightarrow\left[g_{x 1}: \operatorname{senc}\left(x^{1}, v_{0}^{0}\right)\right] \\
g_{x 0}:\left[\operatorname{senc}\left(M,\left[v_{0}^{0}, v_{1}^{0}\right]\right), \mathbf{1}\right] \Rightarrow\left[g_{x 1}: \operatorname{senc}\left(x^{1}, v_{1}^{0}\right)\right] \\
g_{x i}:\left[\operatorname{senc}\left(x^{i},\left[v_{0}^{i}, v_{1}^{i}\right]\right), \mathbf{0}\right] \Rightarrow\left[g_{x(i+1)}: \operatorname{senc}\left(x^{i+1}, v_{0}^{i}\right)\right] \\
\text { for } 1 \leq i<k \\
g_{x i}:\left[\operatorname{senc}\left(x^{i},\left[v_{0}^{i}, v_{1}^{i}\right]\right), \mathbf{1}\right] \Rightarrow\left[g_{x(i+1)}: \operatorname{senc}\left(x^{i+1}, v_{1}^{i}\right)\right] \\
\text { for } 1 \leq i<k \\
g_{x j}: \operatorname{senc}\left(x^{j},\left[t_{j}^{x}, r_{j}^{x}\right]\right) \Rightarrow\left[g_{x(j+1)}:\left[\operatorname{senc}\left(P_{j-k}(x), t_{j}^{x}\right),\right.\right. \\
\left.\left.\operatorname{senc}\left(x^{j}, r_{j}^{x}\right)\right]\right] \\
\text { for } k \leq j<2 k-2
\end{array}\right] \begin{gathered}
\\
g_{x(2 k-2)}: \operatorname{senc}\left(x^{2 k-2},\left[t_{2 k-2}^{x}, t_{2 k-1}^{x}\right]\right) \Rightarrow\left[g_{y 10}^{x}:\right. \\
\left.\left[\operatorname{senc}\left(P_{k-2}(x), t_{2 k-2}^{x}\right), \operatorname{senc}\left(P_{k-1}(x), t_{2 k-1}^{x}\right)\right]\right]
\end{gathered}
$$

After all the variables are chosen, the adversary has encrypted values of the truth of each predicate symbol at each of the values chosen. The protocol now moves to the phase where the 3CNF formulas $F_{1}(z), F_{2}(y, x)$, and $F_{3}\left(y_{1}, y_{2}\right)$ are evaluated. The rules for this are very similar to the evaluation of QSAT formulas after the truth assignment is picked. We, therefore, skip describing these rules. Like in the QSAT case, it is easy to see that sec is revealed with probability 1 if and only if $\varphi$ is satisfiable. The protocol keeps sec secret with probability at least $\frac{1}{2^{3 k}}$ if $\varphi$ is not satisfiable.

We conclude the proof by observing that all coin tosses in the above reduction are public. Thus, the NEXPTIMEhardness result holds even for checking the insecurity of randomized protocols where all coin tosses are public.

[^0]:    1. This definition of well-formed terms does not restrict the adversary's power. Protocol specifications in our formalism assume that each (sent or received) message encrypted using asymmetric encryption is encrypted with a public key. An attacker sending a message that will be received by a protocol role can always use the expected public key.
[^1]:    3. Strictly speaking, [30] shows that the satisfiability problem is NEcomplete, where $\mathbf{N E}=\cup_{c} \mathbf{N T I M E}\left(2^{c n}\right)$. From the results of [28], it also follows that satisfiability is NEXP-complete.
