**Abstract :** The mahseer, an Indian carp (*Tor species*) known as 'Sport fish' continues to be decimated by the large scale natural and anthropogenic factors and categorized as threatened fishes in India. The present research data revealed that total species richness of 33 and 24 number of fish species were identified in river Ganga and Yamuna respectively. The size group of mahseer (400-460mm) recorded as a dominant size of catch composition and contributed about 36.8% and 42.6% based on different sampling sites in river Yamuna and Ganga respectively. The populations of *Tor tor*, *T. putitora* have shown a decreasing trend at very alarming rate and influenced the sex ratio, maturity size and natural breeding condition. Only 12.5 to 14.8% mahseer female brooders have shown maturity phase or emenable to release ova during particular breeding seasons. The fecundity of mature female fish brooders ranged from 2500-4500 no. of eggs during July-August. The current status of mahseer fishery may be attributed to the over exploitative nature in riverine system. '*In situ* and *Ex-situ*' breeding techniques should be practiced for enhancement of viable population size of mahseer species to restore the genetic loss under mahseer conservation programme in aquatic ecosystem of Himalayan region.

**Keywords:** Mahseer fish, *Tor species*, Population dynamics, Fish conservation, Riverine ecosystem

### INTRODUCTION

India is one of the Megabiodiversity countries in the world and occupies ninth position in terms of fresh water mega biodiversity (Mittermeier and Mittermeier, 1997). In India, there are 2500 species of fishes, of which 930 inhabited in fresh water (Kar, 2003 and Jayaram, 1999). The principal endemic and exotic fishes occurring in the natural upland waters of the Himalaya are about 225 species and contributed approximately 9.32% of the fish germplasm resources of India (Das, 1994). In Uttarakhand, the Himalayan mahseer (*Tor species*) is largely confined to the lotic and lentic habitats e.g. streams, rivers and lakes. It is a fresh water largest scale carp belonging to the family cyprinidae having a wide distribution occurring all along the foot hills of Himalaya (Day, 1878, and Singh *et al.*, 1987). Fishery resource of the Yamuna river in Garhwal Himalaya is not well known except some contributions (Nath *et al.*, 1994, Soni 1998 and Moza *et al.*, 2005), but the report on the status of fish diversity and biomass in Yamuna river at the foot hills of Garhwal Himalaya is scanty, as while, the foot hill region of lesser Himalayan zone at Doon valley formed a unique transition zone and reflected the rich fish diversity in the Yamuna river and its tributaries. The mahseer has been categorized as one of the threatened fish species of the

Himalayan region (NCA, 1976) and has necessity for conservation of mahseer resources in riverine system of Garhwal Himalaya. The ecological stress on the mahseer population occurred due to many natural and anthropogenic activities specially developing hydro-electrical projects. The artificial propagation or induced breeding programme has played a major role to maintaining endemic fish species diversity in aquatic system of Himalayan region. '*In situ*' conservation programme would be more dynamic steps for enhancing the natural stocks of mahseer species in riverine system of Garhwal region at Uttarakhand. The present study provided an existed fish diversity, population status of mahseer and an induced breeding practice was tried to enhance the mahseer fish seeds for stocking in Ganga and Yamuna rivers.

### MATERIALS AND METHODS

**Study sites:** Garhwal Himalaya lies in between the latitudes 29° 26' to 31° 28' N and longitude 77° 49' to 80° 06' E, as almost central position in the long Himalayan sweep. The main stream of river Ganga originates from the confluence point of river Bhagirathi and river Alaknanda at Devprayag. The combined river flow down through Byasghat, Byasi, Gular, Laxmanjhula and Rishikesh to Hardwar and Yamuna river system extends from Yamunotri

\* Above fish species not found in Yamuna river.

to Hathnikund barrage at Tajewallah in Garhwal region. **Collection of samples:** The fish samples were obtained from upstream sites as in-between from Devprayag to Byasi Ghat and downstream sites of Veerbhadra barrage and Bhimgoda barrage located at Ganga river. In Yamuna river, the fish samples were collected from upstream sites in-between Kalsi and Dakpathar barrage and downstream sites in-between Dakpathar barrage to Asan barrage. Most of the fish samples were collected from the local fishermen, anglers from the river sites or fish landing sites. The fishermen were landed using gill nets and cast nets, the size of gill nets varied from 10 x 5 and 5 x 2.5 meters with mesh size of 8 – 10 cm respectively. The fishes were identified according to Talwar and Jhingran (1991) and Day (2007). The status of fish species in both rivers were categorized according to CAMP report (1998). The experimental fishing was done during April - May and July –September during 2007-08 with collaboration of Uttarakhand state fisheries to analyze the maturity stages of mahseer species and semi-intensive induced breeding programme. The hatching processes were done in regulated flow water hatchery of state fish farm situated

at Dhakrani near the Yamuna river. Several breeding measures for experimental seed production and stock enhancement methods have been adopted by Sehgal and Malik (1991) and Ogale (2000).

## RESULTS AND DISCUSSION

The fast changing ecology of upland waters seems to have primarily affected the well being of the fish species inhabiting in cold water aquatic bodies. The principal endemic and exotic fish species occurring in natural waters of Garhwal and Kumaon region are about 225 species (Sehgal, 1991). Among these, more than 100 endemic fish species occurred in aquatic system of Garhwal region. Fish fauna occurring in the Ganga river in the foothills of Garhwal Himalaya is quite rich and diversified. The fish species richness as 33 species belonging to 9 families, 7 sub families and 21 genera were observed in Ganga river. The fresh water fish diversity as 24 fish species belonging to 18 genera, 7 sub families and 8 families occurred in Yamuna river. The Cyprinids fishes exist in highest endemic fish species in both the rivers. The distribution pattern of fish species revealed

**Table 2.** Experimental induced breeding (*In Situ*) of mahseer during, 2007 - 08.

Breeding months	No. of female brooder	Size range of female brooders		Fecundity	Hatching rate (%)	Fry survival rate (%)
		Length(mm)	Weight( gm)			
April	3 + 4	425 – 500	650 – 1250	2400 – 3000	85.0 – 87.5	75.0 – 78.5
May	4 + 6	420 – 550	650 – 1400	2000 – 2750	82.0 – 85.4	77.0 – 80.0
July	3 + 2	400 – 600	600 - 1550	2000 – 3000	90.0 – 92.4	78.0 – 82.4
August	8 + 8	410 – 620	600 – 1600	3250 – 4500	90.0 – 94.0	80.0 – 90.0
September	6 + 4	400 – 650	600 - 1600	2500 – 3500	92.0 – 95.5	80.0 – 90.0

that two species are endangered, 11 species are vulnerable and one species endangered, 9 fish species vulnerable in Ganga and Yamuna river respectively (Table 1). Jhingran (1990) also reported the population status of fresh water fishes in river of Himalayan region and mentioned one species was extinct, five were endangered and 22 fish species were rare in Ganga river. Khanna *et al.* (1998) mentioned about 35 fish species inhabited in Ganga river. Malik *et al.* (1998) recorded the fish diversity in relation to their ecological status in upland water of Himalayan regions. The present distributional pattern of fishes in downstream of both the rivers have shown drastic ecological changes and ultimately affected the fish species richness due to non-maintenance of the minimum water requirements and alteration of ecological characteristics for the maintaining endemic fish diversity. The fish catch composition studies revealed that the mahseer were contributed about 32.5% in upstream and 25.6% in downstream stretches of Yamuna river as while, 38.6% in upstream and 28.2% in downstream in Ganga river. The size of the fish as 350-450mm was recorded as a dominant and maximum density of mahseer was recorded in the size ranging from 400-450mm in length. The maximum size (600mm-700mm) fishes showed their minimum percentage (Fig.1). The present data indicated a sharp decline in size range as well as abundance of mahseer. Thus the mahseer fish species could be categorized as vulnerable or threatened fish species in Garhwal region at Uttarakhand. The decline trend of mahseer population in riverine system of Garhwal region

**Fig.1.** Average percentage of different size group of mahseer species in rivers.

may be due to altering ecological characteristics by many anthropogenic factors as also described by Bhatt *et al.* (2000).

The male species of mahseer had maximum density in size range from 300-550 mm in both the rivers. The maximum percentages of female species of mahseer were recorded in the size ranging from 400 mm-450 mm as 15.8% and 11.2% in Ganga and Yamuna river respectively (Fig. 2 and 3). The sex ratios of male and female species of the fish were recorded about 6:1 and 4:1 in size range (300-350mm) were recorded but in the higher size range, the sex ratio about 3:1 was recorded in both the rivers. The seasonal sex ratio of mahseer showed that more males were present in upstream sites of river than females. Chaturvedi (1976) recorded the sex ratio of male and female to be 1:2 in *T. tor* while, Pathani (1978) observed sex ratio 1:1.33 for *T. tor* and 1: 1.56 for *T. putitora* in Bhimtal lake. The different sex ratios of female and male mahseer in the upstream and downstream of Ganga and Yamuna river may be due to population drift by the existing barrages on both rivers.

A trend of multiple spawning was observed in mahseer (*T. tor* and *T. putitora*) in Ganga and Yamuna rivers. The present observations revealed that matured mahseer fishes spawned in two seasons dominantly during April – May as the first set, while the second set being in July-September. The similar seasonal breeding spawning periodicity pattern have also been described by Khan (1939) and Sehgal (1974 and 1992) in mahseer. In the present study, the regular field observations were showed

**Fig. 2.** Percentage of male and female mahseer in Ganga river.

Fig. 3. Percentage of male and female mahseer in Yamuna river.

that mahseer fishes laid their eggs in two phases as in April-May and secondly in July-September, indicated two main natural breeding seasons i.e. pre-summer and rainy season in the riverine system of Garhwal region. Welcomme (1985) reported different ways of habitat restoration and fish conservation for endemic fishes and emphasized to declare fish sanctuaries in the selected upland water bodies as protected areas for preservation of endemic fishery resources, especially those endemic

fishes, which are categorized as endangered, vulnerable, rare and intermediate. These natural protected riverine habitats would be contributing for development of brood fishes and growth of juveniles of endemic fishes. Artificial propagation or induced breeding project for intensive production of stocking of fish seed of mahseer fish species in the upland water bodies are the only solution to save the threatened fish species of mahseer. Induced breeding is an important method of mahseer aquaculture including hatchery practice and nursery management effort made by Sehgal and Kumar (1977). Sehgal and Malik (1996) have tremendously introduced dry stripping method for induced breeding practices of mahseer in aquatic ecosystem at Uttarakhand. A flow model diagram has shown the complete process of induced breeding as 'In situ' conservation steps to replenish the fingerlings of the mahseer in the natural water bodies of Garhwal Himalaya (Fig.4). The present study of matured female brooders of mahseer indicated that only 12.5 to 14.8% mahseer female brooders showed the maturity phase or emenable to release ova during particular breeding seasons in river Ganga and Yamuna. The fecundity of mature female fish brooder ranged 2500- 4500 no. of eggs during breeding seasons i.e. April-May and July to September. The percentage of hatching and rate of cumulative survival of fry ranged as 82.0-95.5 and 75.0 -

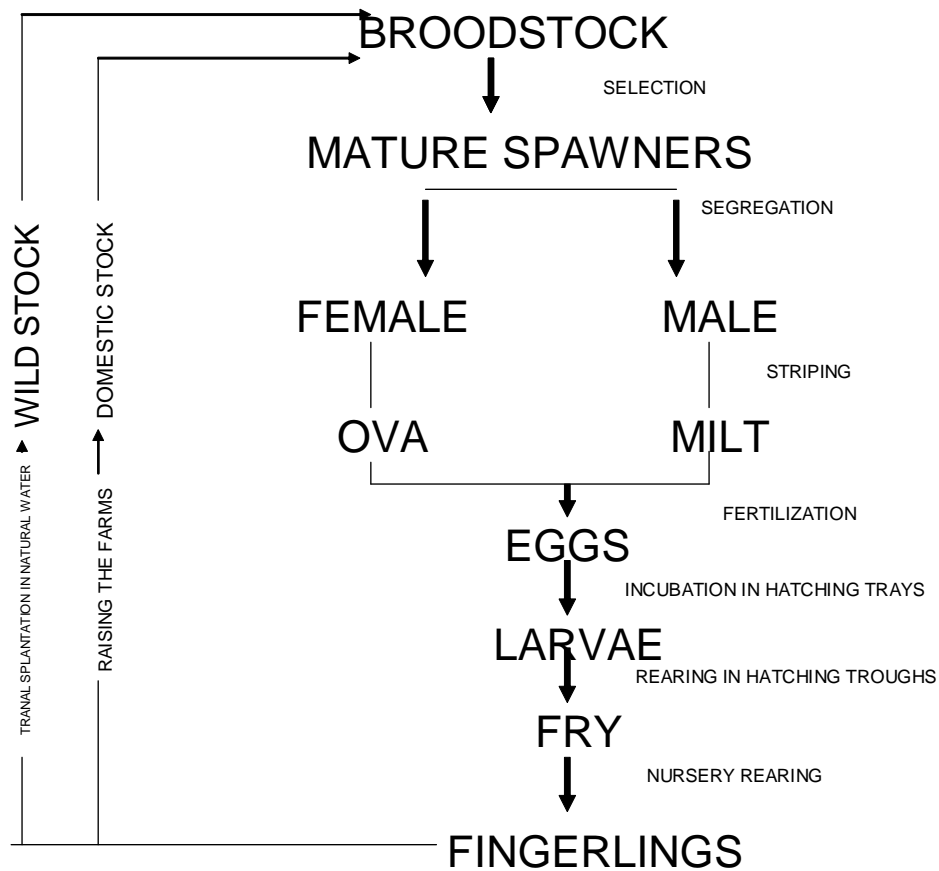

Fig. 4. Induced breeding operation ('In situ' conservation) of Mahseer.

90.0 respectively depending upon the physico-chemical characteristics of water in hatching troughs and produced maximum fish seed quantity in relation to used number of female brooders in comparison to natural breeding of mahseer species that occurred in Ganga and Yamuna river (Table 2). By using breeding techniques such as induced or striping method, the intensive mahseer seed production could be maximum for the subsequent transplantation in the Ganga and Yamuna rivers. About one lakh mahseer fingerlings sizes 25-35mm were stocked to replenish mahseer population in these rivers. The mahseer seed stocking programme can significantly improve the status of mahseer fishery in lentic and lotic aquatic ecosystem of Garhwal Himalaya. It could be therefore, concluded that conservation and management of aquatic natural habitat should be protected for enhancement of viable population size of mahseer species and restore the genetic loss under mahseer conservation programme in aquatic ecosystem of Himalayan region.

### ACKNOWLEDGEMENTS

The author is highly thankful to Joint Director, Uttarakhand State Fisheries Department, Dehradun (U.K.) for providing all the necessary facilities of fishing and collection of mahseer specimen and hatchery to carry out the research work.
