Lightning Talk: Making It Easier To Understand Research Software Impact

Abstract— How can we make it easier to understand research software impact? Is it easy for new researchers to start research in this area? In particular, are the tools available that would let them generate the research that we as the research software community require to convince our funders, fellow researchers and the public at large that having sustainable, open-use research software is important?

Index Terms — software, research software, software metrics, software impact.

I. BACKGROUND

In this lightning talk I will pitch the idea of the WSSSPE community working together to define a conceptual framework and architecture for the tools that are useful to measure research software impact for instance:

- mining scholarly literature for mentions of software
- identifying the linkages between pieces of software
- visualising dependencies between pieces of software or between software and other artefacts

There are already a number of tools that have been developed by others. Depsy¹ is a tool which mines papers to find fulltext mentions of software (currently only those written in Python and R) and analyses GitHub repositories to see where software is being used, thus giving a measure of the impact of a piece of research software or library. The Software Discovery Dashboard² aims to search multiple code hosting services, such as Zenodo, Figshare, and GitHub, for scientific software and undertake analysis of it, utilising the Codemeta³ metadata standards for describing scientific software and building on previous work by Mozilla Science Lab, Github and Figshare on Code as a Research Object⁴. ContentMine⁵ provides a platform

for machine mining academic papers. ScholarNinja⁶ provided a way of scraping software metadata. Lagatto⁷ is a tool for tracking analysing article level events in scholarly content which has been used to identify GitHub repositories in scientific papers. Libraries.io⁸ provides a way identifying open source library dependencies and discovering alternative software. SciCrunch⁹ is developing ways of allocating resource identifiers to software using Research Resource Identifiers (RRIDs)¹⁰ to improve citation and discovery.

What I propose is a working group in WSSSPE to:

- Collectively capture all the useful tools that the community is aware of
- Summarise the use cases for tools in this area
- Define a conceptual framework / architecture
- Identify any areas of functionality which are missing
- Determine what we should work on first
- Run hackathons / sprints to address low-hanging fruit

As researchers, we use evidence and experiences to test our hypotheses and inform our work. However we are lacking the tools to make this easy in the area of research software. By working together, we can ensure that our efforts are aligned.

ACKNOWLEDGMENT

The Software Sustainability Institute is supported by the EPSRC, ESRC and BBSRC through grant EP/N006410/1. This paper is based on input from many members of the Software Sustainability Institute team, Fellows, and collaborators including the participants of the CodeMeta workshop¹¹, especially Abigail Cabunoc-Reyes, James Howison and Daniel S. Katz.
