

1 **1 Introduction**

2 As a developing country, fossil fuels dominate energy consumption in China.

3 Smog, which results from fossil fuel combustion, is frequently an issue for major

4 cities in China and has attracted attention from all over the world. At the 21st

5 Conference of the Parties to the UN Framework Convention on Climate Change

6 (COP21), China pledged that CO₂ emissions would peak by around 2030 or sooner.

7 Carbon dioxide Capture and Storage (CCS), a highly effective technology capable of

8 large-scale reduction of emissions from fossil fuels, will be essential in reducing CO₂

9 emissions¹. According to the new Five-Year Plan (2016-2020) of the Ministry of

10 Industry and Information Technology of the People's Republic of China, the Chinese

11 government will develop CCUS (Carbon dioxide Capture, Utilisation and Storage)

12 demonstration plants in high-emission industries (chemical, cement, steel etc.) and

13 reduce the CO₂ emissions per unit of industrial added value by 22% within the next

14 five years.

15 Chinese researchers have carried out many case studies of CO₂ storage in

16 important hydrocarbon-bearing basins of China²⁻¹⁰. However, few assessments

17 consider the Jiyang Depression. This structure is one of the most important

18 sedimentary basins in China as it is geographically large with multiple potential

19 reservoir and seal formations and the Shengli Oilfield (the third largest oil field in

20 China) is located here. After more than 50 years of hydrocarbon exploration and

21 development, the Jiyang Depression is deemed to have CO₂ storage potential, as

22 depleted hydrocarbon reservoirs and deep saline formations offer potential CO₂

1 storage options that are widely considered in similar assessments **in a number of**
2 **countries** ¹¹.

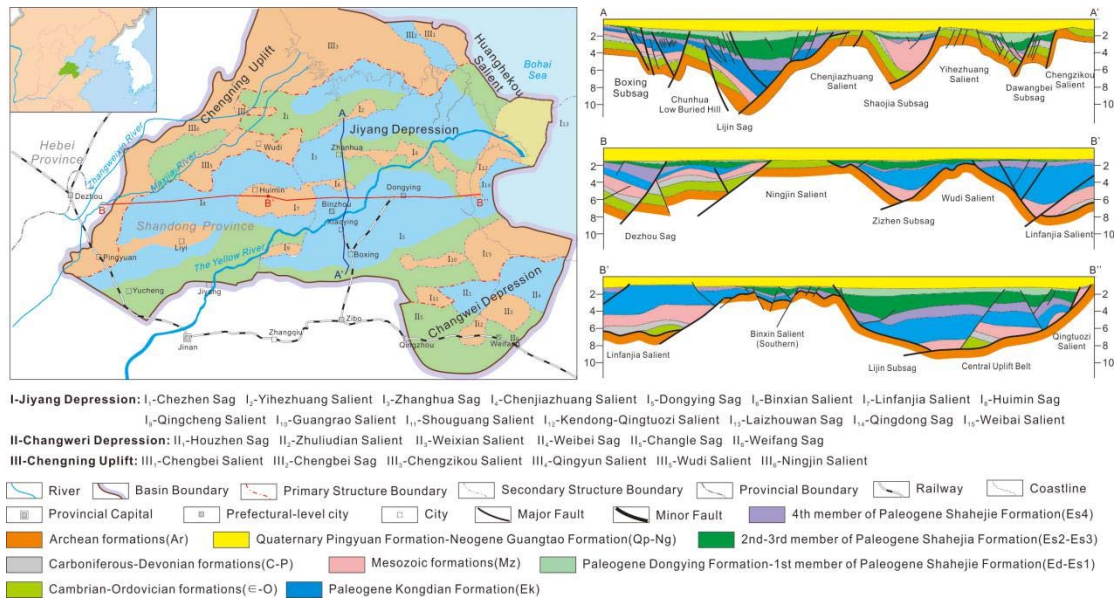

3 The geological **setting**, including reservoir properties, potential seals,
4 hydrogeology, formation temperature and pressure conditions, and regional crustal
5 stability were analysed in this study. **The scoring system uses** 43 weighted criteria.
6 The results of this storage site evaluation are presented here.

7 **2 Geological Setting**

8 **2.1 Regional geology**

9 The Jiyang Depression lies at latitude 37° to 38°, and longitude 116°40' to 119°;
10 **and has** an area of 26,500 km². It **lies in the south of the** Bohai Bay Basin and is
11 surrounded by several geological uplifts and depressions. The metamorphic basement
12 of the Jiyang Depression **formed** during the Archeozoic Eon (Fig. 1).

13 The depression itself is a fault-bounded basin, developed through several stages:
14 slow uplift during the Paleozoic Era, strong folding during the Permian to Triassic
15 periods, rifting during Jurassic to Cretaceous times, syn-rift extension and subsidence
16 during the Paleogene Era and post-rift subsidence during **the Neogene and Quaternary**
17 **Eras** ^{12, 13}.

1
 2 Figure 1. Geological structure of the Jiyang Depression (The map and cross sections
 3 were modified from Li, Gy et al (2002) ¹⁴.)

4 **2.2 Sedimentary geology**

5 Based on available core, seismic and geophysical log data, the Cenozoic strata
 6 have a thickness of more than 10,000 m in the Jiyang Depression. The thickness of
 7 Paleogene sediments is greatest in the center of the depression, reaching about 7,000
 8 m and decreasing towards the edges. In some areas, Paleogene sediments are entirely
 9 missing due to erosion. The Quaternary and upper Neogene sediments are 1,000 to
 10 2,000 m thick and are present across the whole depression. Cenozoic strata contain
 11 mature source rocks and ideal seals and reservoirs for hydrocarbons, which has
 12 enabled the formation of large oilfields (Fig. 2).

Figure 2. Stratigraphic column of the Jiyang Depression. (The sizes of red/green circles under column ‘seal’ indicate the **expected** ability of seals to trap hydrocarbon or injected CO₂; the sizes of red/green circles under column ‘reservoir’ indicate the **assessed** suitability and potential for hydrocarbon accumulation or CO₂ storage; **please see section 3.2 and 3.3 for detail**)

3 Potential storage area in Jiyang Depression

3.1 Candidate formations

In general, 800m is considered the shallowest depth suitable for CO₂ storage as CO₂ should be in a **dense state**^{15, 16}. Based on geophysical log data, the Neogene

1 Guantao Formation (Ng) is present across the whole depression at depths greater than
2 800 m, with a few exceptions at the southeast edge. The base of the Guantao
3 Formation is the seismic reflection T1 and second-order sequence boundary Tsb1¹⁷ in
4 Figure 2. The base of this formation is also important in terms of structure and
5 hydrogeology; across this boundary, hydrodynamic conditions, regional structural
6 characteristics and tectonic stress field clearly change. The base of the Guantao
7 Formation seems a reasonable upper limit for candidate formations for CO₂ storage in
8 the Jiyang Depression.

9 Due to large-scale hydrocarbon exploration and development, formations above
10 4000 m depth have been studied and described fully in previous studies. However,
11 since reservoirs are absent below 4000 m, detailed data of formations below this depth
12 are not available. Therefore, the authors used 4000 m as the lower limit of candidate
13 CO₂ storage formations for the purposes of this study. Between these two limits, the
14 Dongying Formation (Ed) and the Shahejie Formation (Es) were chosen for
15 assessment.

16 **3.2 Reservoirs**

17 There are several sedimentary facies present in the Jiyang Depression. For the
18 candidate formations identified above, the depositional facies are mainly nearshore
19 subaqueous fan, turbidite fan, fan delta, shallow lake, lake shore and beach-barrier
20 deposits¹⁸. The lithology of the Dongying and Shahejie formations is mainly
21 sandstone with medium grain sorting and sphericity, and low maturity.

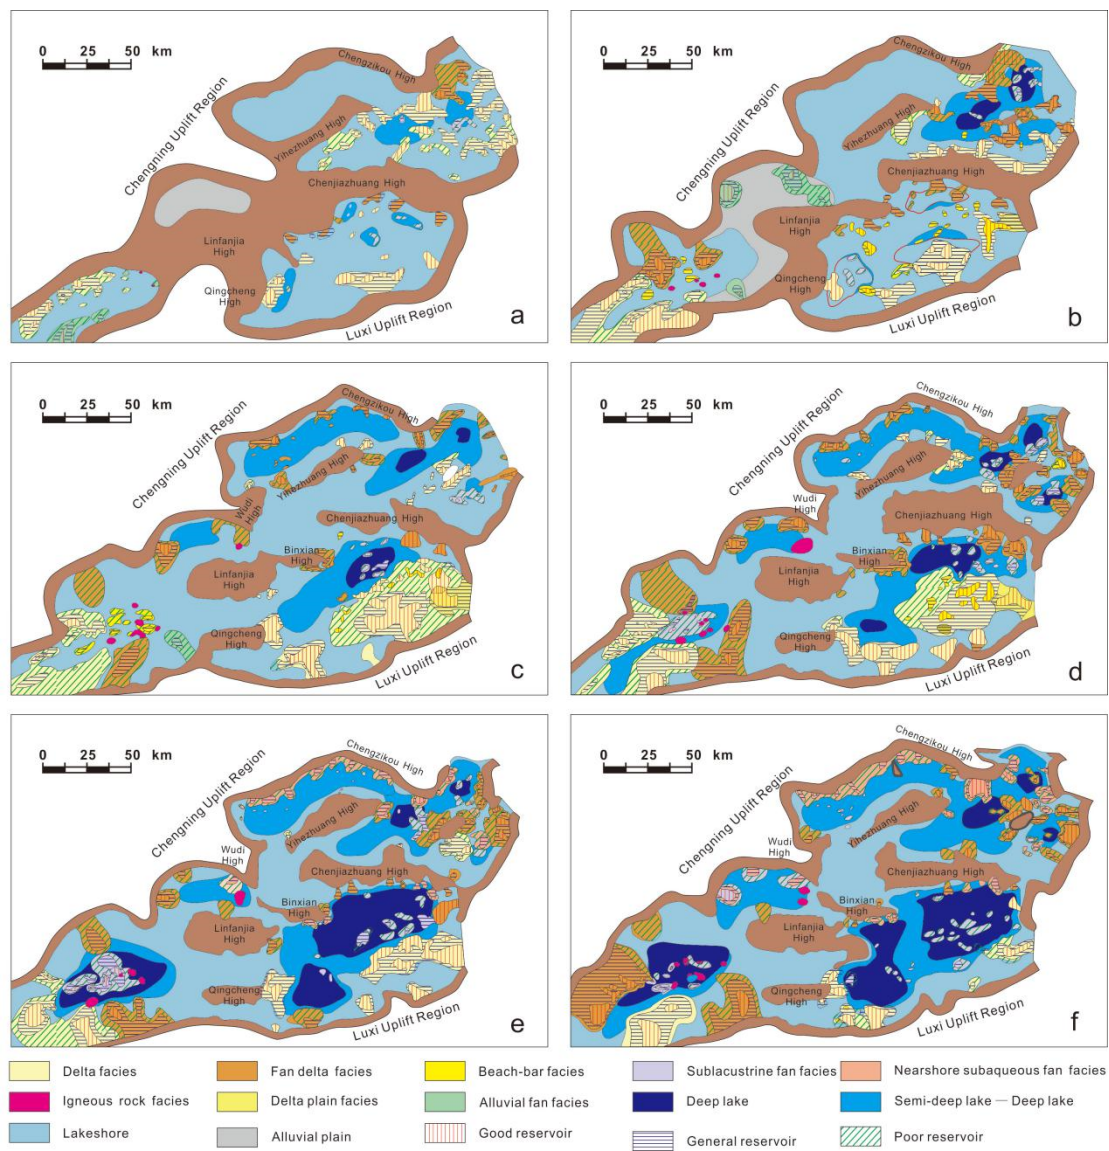

1 Several reservoirs are present in the Dongying and Shahejie formations (Fig. 3).
2 For the reservoirs in the same formation but different parts of the depression, the
3 physical properties, such as porosity and permeability are usually variable, which
4 needs to be taken into consideration when selecting potential storage sites. The most
5 promising reservoir is located in the 2nd member of the Shahejie Formation (Es2).
6 Across the depression this formation has a maximum thickness of 500 m, porosity of
7 13.3~33.7%, permeability of 13.3~32000mD and depth of about 2000 m. The
8 formation mainly comprises multiple sandstone layers and sandy mudstone strata.

9 The physical properties of the 3rd member of Shahejie Formation (Es3) vary
10 with depth. Minimum porosity and permeability in the formation are 12.4% and 4 mD
11 respectively, while the maximum are 35.35% and 11000 mD. The lithology of the
12 formation comprises pebbly sandstone, siltstone, sandstone intercalated with
13 mudstone, and oil shale. The 3rd member of the Shahejie Formation generally has a
14 total thickness of 250 - 1500m; but in some parts of the depression, this formation is
15 absent or classic reservoirs are not developed (Fig. 3).

16 Potential storage reservoirs are also found in the Dongying Formation and the
17 4th member of Shahejie Formation (Es4). Across the Jiyang Depression, the
18 Dongying Formation contains alternating beds of sandstone and mudstone, with a
19 porosity 17.59~35.2% and permeability 192~5500 mD. Although the maximum
20 thickness is more than 600 m, in some parts of the depression, the formation is absent
21 due to erosion at relatively shallow depths (Fig. 3). The upper part of the 4th member
22 of the Shahejie Formation contains limestone and bioclastic limestone, providing an

1 additional opportunity to store CO₂. In the uplifted part of the Jiyang Depression, the
2 depth of the 4th member of the Shahejie Formation is greater than 2500 m, while in
3 the sag part of the depression it usually lies at depths greater than 3000 m or even
4 5000 m, so in some places it is below the lower depth limit suggested for CO₂ storage
5 in the Jiyang Depression.

6 Across the Jiyang Depression, the 1st member of the Shahejie Formation (Es1) is
7 dominated by mudstone. Only scattered reservoirs are found amongst continuous
8 mudstones, these reservoirs have average porosity of 14.9-35.9% and permeability of
9 16.05-5500 mD. This member is not considered ideal for CO₂ storage since the
10 reservoirs are small and scattered.

Figure 3. The distribution of sedimentary facies and reservoirs in the Jiyang

Depression (a. Lower Es3 formations; b. Middle Es3 formations; c. Upper Es3 formations-Lower Es2 formations; d. Upper Es2 formations-Es1 formations; e. Ed3 formations-Ed2 formations; f. Ed1 formations) ¹⁷

3.3 Seals

As the Dongying Formation (Ed) and the Shahejie Formation (Es) were chosen for assessment, the seals under consideration in the Jiyang Depression comprise thick mudstone layers in the upper Guantao Formation (Ng), mudstone and shale layers in

1 the 1st member of the Shahejie Formation; and mudstone and gypsum layers in the
2 3rd and 4th members of the Shahejie Formation.

3 The mudstones of the Guantao Formation are **present** across the whole Jiyang
4 Depression, without absence or breaks and thus constitute the regional seal that **covers**
5 all the **underlying** formations. Although the porosity is relatively high (>20% in some
6 areas), the net thickness of mudstone layers is quite large (Table 1). With increasing
7 formation depth, the disconnection of mudstone seals begins to appear in the uplifted
8 parts of the depression; while in the sag parts the mudstone is continuous (Fig. 4),
9 where the porosity of seals is low (5-20%) and ultra-low (<5%). The measurement of
10 displacement pressure and sealed gas column height also indicate that all the seals
11 have sufficient **sealing ability** for gas (Table 1). Moreover, the 2nd and 3rd members
12 of the Shahejiang Formation contain the most important natural gas reservoirs of the
13 Jiyang Depression, and also some **natural** CO₂ reservoirs^{21,22}, which **offers**
14 supplementary evidence that these seals would be expected to prevent **gases from**
15 **escaping**, including CO₂.

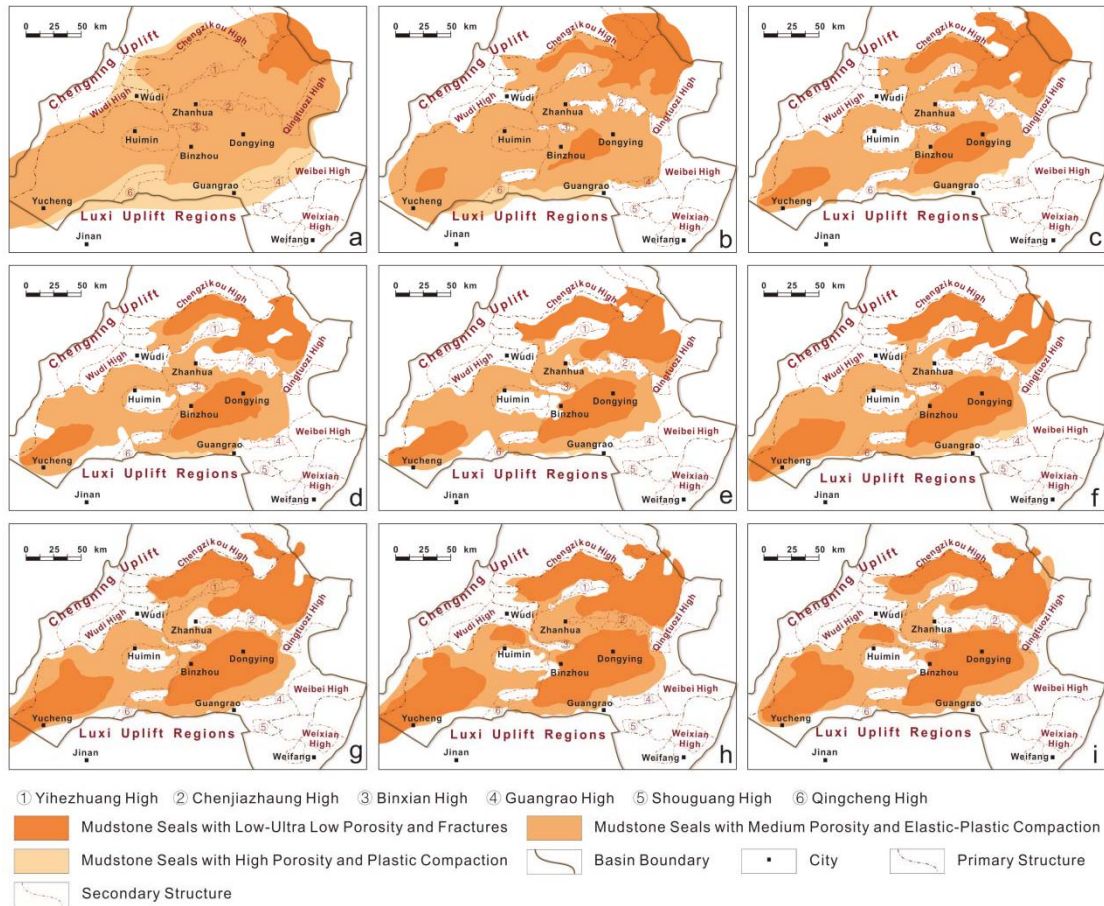

Figure 4. Distribution and classification of mudstone seals in the Jiyang Depression (modified from Wang YJ(2002)²³; a. Ng formations; b. Ed formations; c. Es1 formations; d. Upper Es2 formations; e. Lower Es2 formations; f. Upper Es3 formations; g. Middle Es3 formations; h. Lower Es3 formations; i. Upper Es4 formations)

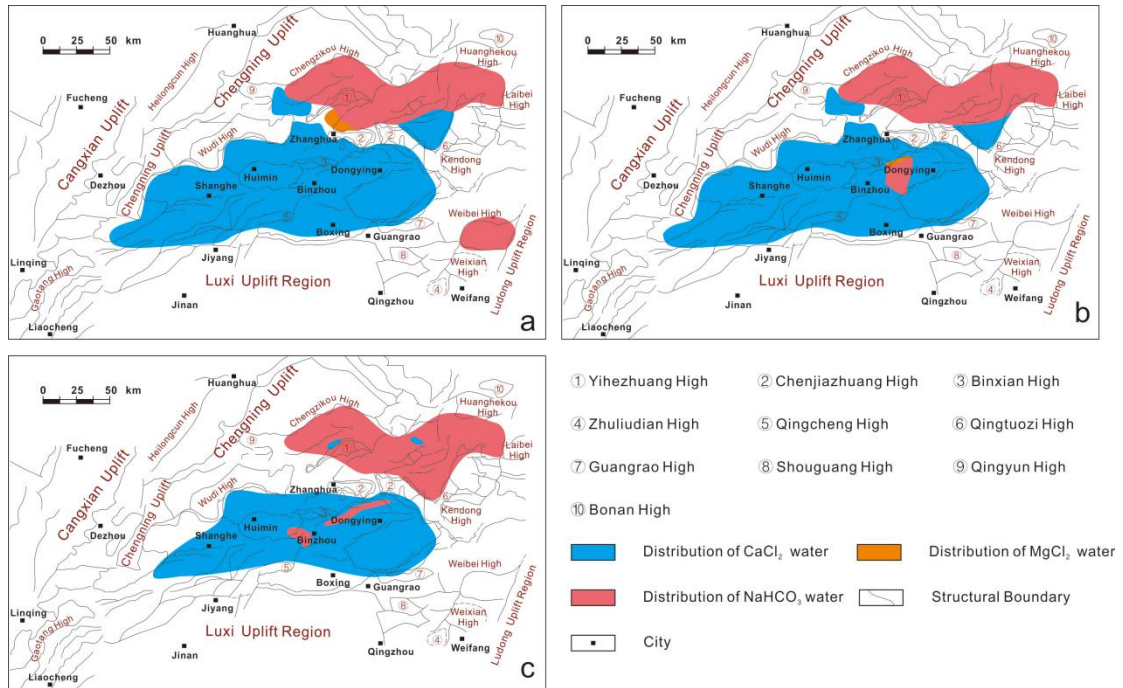

3.4 Hydrogeology

According to the classification of salinity of groundwater in China²⁶, over 50% of the aquifers in the Dongying and Shahejie formations are saline, while the proportion of aquifers with highly brackish water and brine are 10-30% and 5-25% respectively. Water with high salinity cannot be used as drinking or irrigation water,

1 which means there is **currently no** conflict of interest with water supply in considering
2 these formations for CO₂ storage.

3 The overall salinity of aquifers in the southern part of the Jiyang Depression
4 (Dongying Sag and Huimin Sag), is usually more than 40 g/L (even reaching up to
5 350 g/L), which is much higher than the observed salinity of 10-20 g/L in the northern
6 part of the depression (Chezhen Sag and Zhanhua Sag). The Na⁺/Cl⁻ ratio of aquifers
7 in the southern part of the depression is usually lower than in the northern part
8 (Na⁺/Cl⁻ ratio is the ratio of the concentrations of sodium and chloride ions, which is
9 an important indicator of formations tightness and groundwater activity; the higher
10 the value is, the greater the impact of infiltration water on groundwater). Analysis
11 shows that the minimum Na⁺/Cl⁻ ratio in the Jiyang Depression is 0.6, which appears
12 in the middle of the Doingying Sag, while the maximum **ratio** of 1.3 is found in the
13 Chezhen Sag²⁷. These **data indicate that** meteoric water infiltrate the groundwater
14 from the northern part of Jiyang **Depression**. According to V. A. SuLing's theory^{28, 29},
15 the type of groundwater in the southern part of the depression is completely different
16 from that found in the northern part of the depression (Fig. 5), which also suggests
17 that in the southern Jiyang Depression, the formations are more isolated with weaker
18 groundwater activity compared with the northern part. In addition, hydrodynamic
19 studies show that although each sag in the Jiyang Depression has its own
20 hydrodynamic system, the phreatic water head of the Quaternary strata **has overall**
21 **control**, which is the cause of the stagnant state of groundwater in the Jiyang
22 Depression as a whole³⁰⁻³⁸. Good sealing conditions and low groundwater activity

- 1 will reduce the risk of CO₂ leakage caused by groundwater flow and so these
- 2 indicators are also seen a positive factor for CO₂ storage in this region.

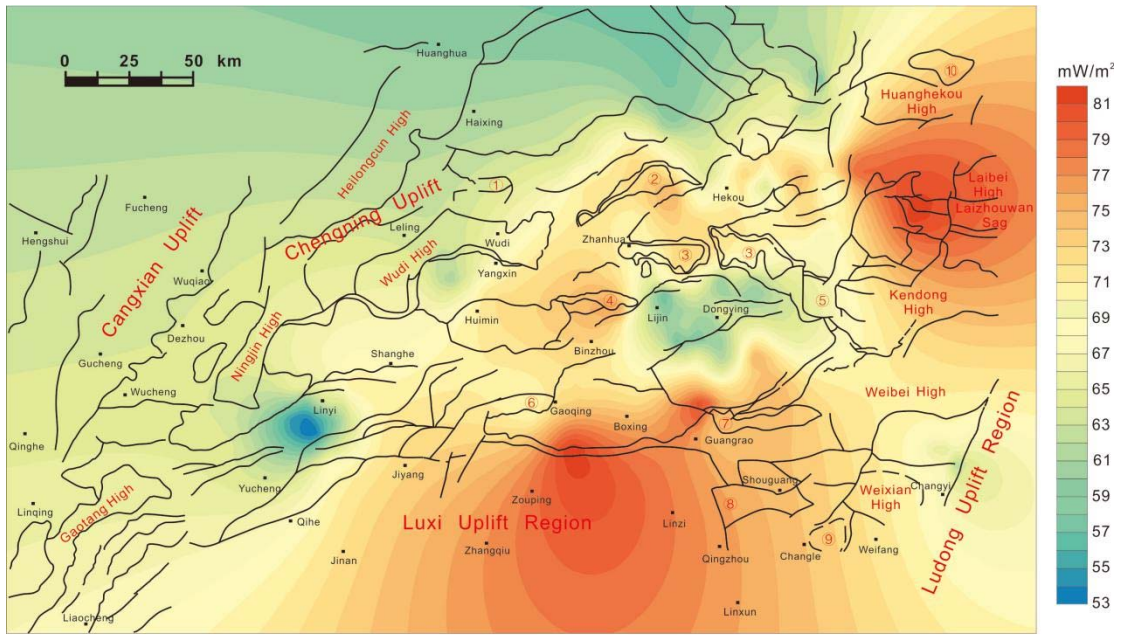

3
4 Figure 5. Classification of water type in the Jiyang Depression (a. Ek-Es4 formations;
5 b. Es3 formations; c. Es2-Es1 formations)

6 3.5 Underground pressure and temperature

7 Most of formations in the Jiyang Depression have a pressure gradient of 0.9~1.1
8 MPa per 100 m. Due to the thermal anomaly caused by lithospheric thinning and
9 asthenospheric upwelling during the evolution of the Bohai Bay Basin, the Jiyang
10 Depression has a high geothermal gradient³⁹. The thermal field of the Jiyang
11 Depression is asymmetrical: The heat flow in the southern part of the depression is
12 lower, with an average value of 50-80 mW/m² in the Dongying Sag and 50-70
13 mW/m² in the Huimin Sag. In the Chezhen Sag, the heat flow increases to 60-

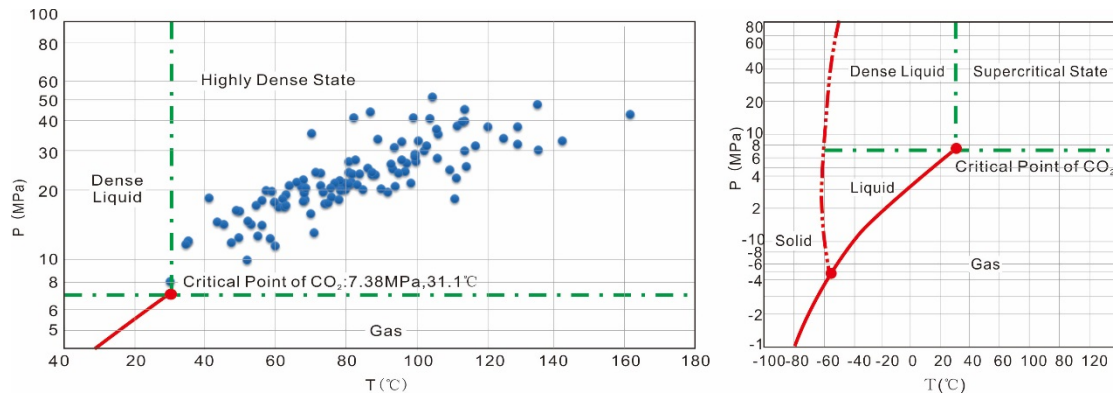

1 70 mW/m², and the highest heat flow value of 60-80 mW/m² is observed in the
 2 Zhanhua Sag (Fig. 6).

3 ① Qingyun High ② Yihezhuang High ③ Chenjiazhuang High ④ Binxian High ⑤ Qingtuozi High ⑥ Qingcheng High ⑦ Guangrao High
 8 ⑧ Shouguang High ⑨ Zhuliudian High ⑩ Bonan High

4 Figure 6. Heat flow distribution in the Jiyang Depression (Heat flow data is from
 5 Gong Y L et al (2003) ⁴⁰)

6 Under such thermal conditions, the temperature gradient is higher than average
 7 for China. In most formations, the temperature gradients are between 3 and 3.5°C per
 8 100 m, while others are between 3.5 and 4°C per 100 m. Irrespective of the higher
 9 temperature geothermal regime, the injected CO₂ would remain in a favorable highly
 10 dense state in almost all the formations under current temperature and pressure
 11 conditions (Fig. 7).

1

2 Figure 7. The formation temperature-pressure conditions in the Jiyang Depression

3 **3.6 Stability**

4 Neotectonism could potentially increase the risk of CO₂ leakage. The Jiyang
 5 Depression is located on the Tancheng-Lujiang fault zone, with scattered faults. Based
 6 on research into fault activity in this area, only a few faults on the boundary of
 7 tectonic units are still active and influence the occurrence of earthquakes, including
 8 the Wudi-yidu Fault, Guangrao-qihe Fault and Chengzikou Fault. Other faults, which
 9 are categorised as basement faults and superficial faults, appear to have been inactive
 10 since the Quaternary Period and current geological conditions suggest a low
 11 probability of future moderate or strong earthquakes influenced by these faults due to
 12 their current geological conditions⁴¹. No strong earthquakes have occurred in the
 13 depression during recorded history. The strongest recorded event is 5.0 on the Richter
 14 Scale (M5), which occurred in Kenli Country, AD 1588⁴². According to studies
 15 characterising seismicity in this area, earthquake activity in this region is in a stage of
 16 releasing the remaining energy following a seismically active period. Multiple M4 - 5
 17 earthquakes may occur in this stage, but the possibility that an earthquake over M6
 18 could occur is very small⁴³. Further study on crustal stability of this region and the

1 adjacent coastal area also indicated that most of the onshore and offshore areas are in
2 a relatively stable state; only submarine areas far from land are unstable. In the last
3 100 years, only two earthquakes over M5 (both in 1969) happened in the nearby
4 coastal area, with no obvious damage to the depression and the Shenli Oilfield.
5 Research also shows that the possibility of suffering a destructive tsunami in the
6 nearby coastal area is relatively small in the future⁴⁴. In summary, the Jiyang
7 Depression seems quite stable for deep geological storage of CO₂.

8 **4 Assessment of CO₂ storage suitability**

9 **4.1 Selected regions**

10 The areas with the most advantageous characteristics for CO₂ storage in the
11 Jiyang Depression were delimited based on the geological conditions described in the
12 previous sections.

13 The reservoirs in the 2nd member of the Shahejie Formation (ES2) combined
14 with overlying regional mudstone seals in the 1st member of the Shahejie Formation
15 (ES1) and mudstone layers in 2nd member of Shahejie Formation (Es2) constitute the
16 most favorable reservoir-seal assemblages.

17 The assemblage of reservoirs in the 3rd member of the Shahejie Formation
18 (ES3), mudstones seals of the 3rd member of the Shahejie Formation (ES3), and both
19 mudstones and gypsum layers in the 4th member of the Shahejie Formation (ES4)
20 also have potential to trap CO₂. The reservoirs combined with overlying and
21 underlying mudstones and gypsum in the 4th member of the Shahejie Formation
22 (Es4), and the reservoirs in the Dongying Formation (Ed) combined with seals of the

1 uppermost Dongying Formation and the Guantao Formation (Ng) could together be
2 considered depending on the site specific geological conditions.

3 In terms of geographical distribution, the recommended assemblage of reservoirs
4 and seals occur more frequently in the Dongying Sag and Huimin Sag. In addition, in
5 these areas the subsurface temperatures are relatively low and the hydrodynamic
6 characteristics are more stable compared with the rest of the depression. Therefore,
7 **the authors believe that** the southern part of the depression (Dongying Sag and
8 Huimin Sag) **is more suitable** for CO₂ storage, compared with the northern part of the
9 depression (Chezhen Sag and Zhanhua Sag). **Therefore, the authors identified the**
10 **southern part as the most promising region for further investigation.**

11 **4.2 Detailed Assessment of Potential Storage Areas in saline aquifers and** 12 **oilfields**

13 A successful CO₂ storage project needs to satisfy three **key** requirements:
14 adequate capacity, good injectivity and safe storage. **Thus, detailed assessments are**
15 **required to further evaluate potential storage sites in promising areas.**

16 **Bachu (2003)⁴⁵ defined basin-scale criteria for CO₂ storage. The criteria were**
17 **used for the ranking and selection of sedimentary basins for CO₂ injection. Chadwick**
18 **et al. (2008)⁴⁶ proposed a number of quantitative criteria for reservoir suitability for**
19 **storage. In this paper, a new scoring system was developed for the ranking of**
20 **localized areas in terms of their suitability for CO₂ storage. The system considers**
21 **units in more detail than the system used by Bachu (2003) and builds on the criteria**
22 **recommended by Chadwick et al., (2008). The criteria developed for this study**

1 consider the complex geological nature of onshore geological basins in China where
2 deposition occurred in continental environments, resulting in heterogeneous storage
3 formations, with multiple sandstone and mudstone layers within each geological unit.

4 The system is divided into four categories: safety, feasibility, economics and
5 acceptability. Each category contained several criteria. The safety category considered
6 the conditions of CO₂ injection and storage security. Criteria were selected based on
7 the possibility of creating CO₂ leakage pathways, including seal quality, faults, legacy
8 well bores and crustal stability. The feasibility category considered the suitability and
9 capacity of a CO₂ storage site and criteria included scale, properties and conditions of
10 potential reservoirs. The economic category focused on the CO₂ storage costs, criteria
11 included capital costs for establishing a storage site and costs for operation and
12 maintenance. The acceptability category considered the potential effects of CO₂
13 storage on local populations including potential effects on human societies and effects
14 on the environment. In total, 43 criteria with weightings determined by the analytic
15 hierarchy process (AHP)⁴⁷⁻⁵⁰, were selected for the evaluation (Table 2). In order to
16 make the system user-friendly, criteria have a detailed description and are quantified
17 wherever possible. For each criterion, a score (1, 3 or 5) was given according to
18 detailed data analysis of each candidate CO₂ storage site in the selected region. The
19 final score of the site was the weighted mean value of all the scores used to rank and
20 screen the recommended CO₂ storage sites. By using the scoring system, it is
21 relatively easy to make an initial judgement on suitability of CO₂ storage at a local
22 scale. The design of the system fully considered the characteristics of oilfields in

1 China. The criteria and corresponding weight **would need** to be redesigned for other
2 situations.

3 The scoring system was applied in the candidate storage units in Jiyang
4 Depression (**a storage** unit is defined as the combination of reservoirs integrated with
5 seals above and below). 147 candidate storage units (including oil reservoirs and
6 saline aquifers) were finally identified in the depression. The final scores of candidate
7 storage units are all between 6.8 and 8.6. Amongst these units, the authors identified
8 55 storage units with scores over 8.0 as the primary recommended units, and 62 with
9 scores between 7.5 and 8.0 as the secondary recommended units, representing about
10 37.41% and 42.18% of all studied units respectively. The recommended storage units
11 are mainly concentrated in the **2nd and 3rd** member of the Shahejie Formation mainly
12 within the Dongying Sag and the Linyi-Shanghe areas of the central Huimin Sag (Fig.
13 8).

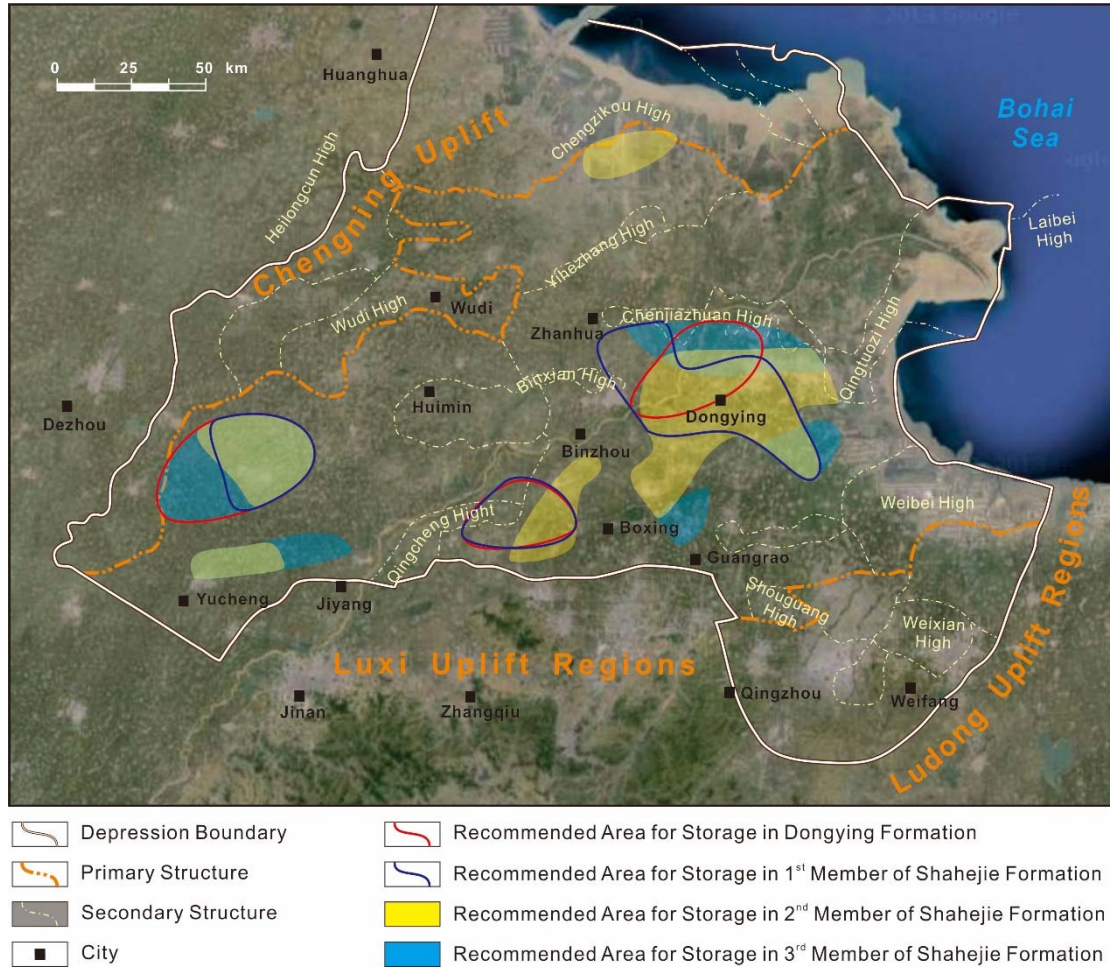

Figure 8. Distribution of recommended CO₂ storage units in the Jiyang

Depression

5 Additional screening of candidate oil reservoirs

Amongst all the primary and secondary recommended storage units, 77 candidate oil reservoirs were identified for further evaluation. These units were then further screened with an additional two sets of criteria to determine if they were suitable for CO₂ EOR (Enhanced Oil Recovery) (Table 3). After this screening, 34 depleted oil reservoirs were considered only suitable for storage, and an additional 11 oil reservoirs were potentially suitable for both CO₂ EOR and storage.

6 Potential for CO₂ storage in oil reservoirs and saline aquifers

1 The theoretical storage capacity of saline aquifers in the primary and secondary
2 recommended storage units was calculated using the method of Wang et al (2014)⁵³,
3 which was modified based on the methods presented by USDOE⁵⁴ and CSLF⁵⁵.

$$M_{CO_2} = A \times H \times \phi \times \rho_{CO_2a} \times [1 - S_{wirr} \times (1 - s_{CO_2})] \quad (1)$$

$$M_{CO_2e} = M_{CO_2} \times E \quad (2)$$

6 where, M_{CO_2} is theoretical CO₂ storage capacity (t); A is area of aquifer, (m³);
7 H is thickness of aquifer (m); ϕ is porosity of aquifer; S_{wirr} is irreducible water
8 saturation; ρ_{CO_2a} is density of CO₂ in the aquifer(t/m³); s_{CO_2} is solubility of CO₂ in
9 the aquifer fluid (t/m³); M_{CO_2e} is effective CO₂ storage capacity (t); E is efficiency
10 factor. The efficiency factor used in the calculation was based on IEA GHG, 2009)⁵⁶,
11 which, for clastic reservoirs, gave P10 as 1.86%, P50 as 2.70% and P90 as 6.00%.
12 This report assumes that for 10% of cases, E would be 1.86% or lower, for 50% of
13 cases, E would be 2.70% or lower and for 90% of cases, E would be 6.00% or lower.

14 Mineral trapping was excluded from the capacity calculation because the chemical
15 reaction between CO₂ and rocks is a relatively slow process and the amount of chemically
16 trapped CO₂ is not expected to be significant over the injection lifetime. The capacity would
17 be larger if CO₂ storage capacity by mineral trapping was taken into account, but the
18 complexity of the calculation and the demand for data would increase several-fold and it is
19 unlikely much of this potential could be realised during injection.

20 Based on the calculations carried out for this study, the total capacity of saline
21 aquifers in primary recommended storage units is 2.49×10^8 t CO₂ respectively using
22 the P50 storage coefficient given above. For secondary recommended storage units,

1 the calculated CO₂ storage potential is 2.07×10^8 t CO₂ using the P50 storage
2 coefficient given above.

3 The method put forward by Ecofys⁵⁷ was used to calculate the CO₂ storage
4 capacity and CO₂ EOR potential of oil reservoirs in the recommended storage units of
5 the Jiyang Depression.

$$6 \quad M_{CO_2e} = E_R \times OOIP \times C \times \rho_{CO_2r} \times R_{CO_2} \quad \text{for CO}_2 \text{ EOR reservoirs} \quad (3)$$

$$7 \quad M_{CO_2e} = N_p \times \rho_{CO_2r} \times R_{CO_2} \times \frac{B_o}{\rho_o} \quad \text{for depleted oil reservoirs} \quad (4)$$

8 where, E_R is enhanced oil recovery after CO₂ EOR, obtained by empirical statistics;
9 $OOIP$ is original oil in place, (m³); C is contact coefficient of CO₂ with oil, usually
10 0.75; ρ_{CO_2r} is density of CO₂ in the oil reservoir (t/m³); R_{CO_2} is ratio for net CO₂
11 injection to oil production (t/m³), usually between 0.9 and 5, average value 2.8 is
12 used in this paper; N_p is accumulative oil production (m³); B_o is oil volume
13 factor; ρ_o is oil density (t/m³).

14 The total storage capacity of the selected 34 depleted oil reservoirs is 41.83×10^6 t.
15 For the additional 11 oil reservoirs with CO₂ EOR potential, the total storage capacity
16 is 5.06×10^6 tCO₂, and the calculated additional oil production through CO₂ EOR is
17 15.02×10^6 t.

18 The current annual emissions of the 11 large-scale CO₂ sources (emission >20 ×
19 10⁴t/a) in the Jiyang Depression are about 14.5×10^6 t⁵⁸. Therefore, the total CO₂
20 storage capacity of saline aquifers and oil reservoirs in the primary and secondary
21 recommended storage units (5.03×10^8 t at P50 for saline aquifers) is equal to about 30

1 years of emissions from the large-scale sources in the area of the Jiyang Depression
2 (if emissions were to remain at present levels).

3 **7 Conclusions**

4 Criteria designed to evaluate geological and societal aspects of CO₂ storage in
5 the Jiyang Depression were used to assess the most promising storage options in
6 terms of geological suitability (capacity and safety), economic viability and potential
7 conflicts of interest, in order to identify the most promising storage options. The
8 storage **capacities** of these recommended storage units were then calculated. In the
9 Jiyang Depression, the 2nd and 3rd members of the Shahejie Formation **appear**
10 favourable for CO₂ storage. The recommended storage units are mainly concentrated
11 in these two members over most of the area of the Dongying Sag and the Linyi-
12 Shanghe area of the central Huimin Sag.

13 The calculated storage capacity of the saline aquifers in **these** recommended
14 storage units is 4.56×10^8 tCO₂ **using a storage efficiency factor of 2.7%; whilst** for
15 oil reservoirs in **the** recommended storage units, the **calculated** capacity is 46.89×10^6 t
16 CO₂. Theoretically, these recommended storage units offer a combined **volume** that
17 could store the CO₂ emitted from large-scale sources in the Jiyang Depression for
18 more than 30 years at current emission rates. In addition, an estimated 15.02×10^6 t
19 extra oil could be produced through CO₂ EOR from **the identified** 11 suitable
20 reservoirs in the recommended storage units.

Table 2. Scoring system for suitability of CO₂ storage in localized areas

category	Criterion	Good (10)	Intermediate (5)	Poor (1)	Weight
safety	Continuity of top seal	Cover most of the whole basin or depression	Cover secondary tectonic structure or several reservoirs	Cover some part of secondary tectonic structure or single reservoir	0.15182
	Shale volume fraction of seal	>70%	50-70%	<50%	0.07213
	Seal thickness	>100m	50-100m	<50m	0.07213
	Number of overlying seals*	several	single	None	0.03402
	Sealing gas thickness by pressure	>100m	50-100m	<50m	0.01271
	Number of faults	<2/km ²	2-5/km ²	>5/km ²	0.11365
	Sealing capability	closed	Semi-open	open	0.03790
	Earthquake intensity	<6Ms	6-8Ms	>8Ms	0.00550
	Earthquake frequency(>6Ms, within 50 km of the candidate site)	<1/100a	1-3/100a	>3/100a	0.00550
	Volcanicity (within 50 km of the candidate site)	dormant	extinct	active	0.00205
	Hydrodynamic	Stagnant flow	Slow flow	Rapid flow	0.01487
	Well spacing density	<20/km ²	20-30/km ²	>30/km ²	0.04743
	feasibility	Well completion	Cased and cemented	Cased but not cemented	Open hole
Reservoir thickness		>80m	50-80m	<50m	0.01423
Reservoir area		>30km ²	10-30km ²	<10km ²	0.01423
Reservoir permeability		>500mD	100-500mD	<100mD	0.01423
Reservoir porosity		>0.2	0.1-0.2	<0.1	0.01423
Reservoir lithology		Gritstone and more porous rocks	Medium-fine sandstone	Siltstone-shaley sandstone	0.00445
Depositional environment		Fluvial	Deltaic	Lacustrine	0.01014
Net/gross ratio		>0.5	0.2-0.5	<0.2	0.00186
Salinity		>6g/L	3~6g/L	<3g/L	0.00083
Reservoir depth		800 ~ 3000m	3000 ~ 4000m	<800m , >4000 m	0.10805

	Pressure gradient	0.9 ~ 1.1MPa/100m	<0.9MPa/100m	>1.1MPa/100m	0.04777	
	Geothermal gradient	<3°C/100m	3-4°C/100m	>4°C/100m	0.01995	
	Heat flow	<50mW/m ²	50-70 mW/m ²	>70 mW/m ²	0.00880	
economic	Source scale (larger sources are more economic)	>25×10 ⁴ t/Y	10-25×10 ⁴ t/Y	<10×10 ⁴ t/Y	0.05691	
	Cost of transport	Pipeline	Road transport	Ship	0.01050	
	Infrastructures	Can use directly	Need reconstruction	None	0.00464	
	Site location	Onshore		Offshore	0.02515	
	Cost of mitigating geological hazard	None	Low	High	0.00243	
	Surface temperature	<10°C	10-20°C	>20°C	0.00027	
	Typhoon	None	Affected, but no severe damage	Affected and devastated	0.00027	
	Topography	Easy (e.g. plane)	Normal (e.g. hills, wash)	Difficult (e.g. Plateau, mountain area)	0.00027	
	Area prone to storm surge	No		Yes	0.00243	
	Area prone to ice flooding	No		Yes	0.00243	
	Area prone to flooding	No		Yes	0.00243	
	Annual precipitation	<500mm	500-700mm	>700mm	0.00027	
	acceptability	Usable groundwater	Without usable groundwater	Usable groundwater with good seals	Usable groundwater with poor seals	0.00215
		Usable surface water	No rivers or reservoirs	Rivers or reservoirs with distance>150km	Rivers or reservoirs with distance <150km	0.00215
Distance from nature reserve		>15km	5-15km	<5km	0.00024	
Vegetation coverage		<30%	30-60%	<60%	0.00024	
Population density		<25 persons/km ²	25-200 persons/km ²	>200 persons/km ²	0.03864	
Public acceptance		>70%	30-70%	<30%	0.00429	

- 1 *overlying seals: all the impermeable seals located above reservoir, regardless
- 2 local or regional seal.

1 Table 3. Criteria for screening depleted oil reservoirs and CO₂ EOR reservoirs

Items	Units	Criteria
Depleted oil reservoirs(Modified from Zeng SP et al, 2005) ⁵¹		
Recovery percent of recoverable reserves	-	>85%
Recovery percent of geological reserves	-	>30%
Effective porosity	-	>15%
Effective permeability	μm ²	>50×10 ⁻³
Geological reserves	t	>400×10 ⁴
CO ₂ EOR reservoirs ⁵²		
API gravity	°API	>22
Viscosity	mPa.s	<10
Oil saturation	%	>0.20

2
