Vlasov-Maxwell equilibria are described by the self-consistent solutions of the time-independent Maxwell equations for the real-space dynamics of electromagnetic fields, and the Vlasov equation for the phase-space dynamics of particle distribution functions (DFs) in a collisionless plasma. These two systems (macroscopic and microscopic) are coupled via the source terms in Maxwell's equations, which are sums of velocity-space 'moment' integrals of the particle DF. This paper considers a particular subset of solutions of the broad plasma physics problem: 'the inverse problem for collisionless equilibria' (IPCE), viz. *"given information regarding the macroscopic configuration of a collisionless plasma equilibrium, what self-consistent equilibrium DFs exist?"* We introduce the constants of motion approach to IPCE using the assumptions of a 'modified Maxwellian' DF, and a strictly neutral and spatially one-dimensional plasma, and this is consistent with 'Channell's method' (Channell, 1976). In such circumstances, IPCE formally reduces to the inversion of Weierstrass transformations (Bilodeau, 1962), such as those transformations that feature in the initial value problem for the heat/diffusion equation. We discuss the various mathematical conditions that a candidate solution of IPCE must satisfy. One method that can be used to invert the Weierstrass transform is expansions in Hermite polynomials. Building on the results of Allanson et al. (2016), we establish under what circumstances a solution obtained by these means converges, and allows velocity moments of all orders. Ever since the seminal work by Bernstein et al. (1957), on 'stationary' electrostatic plasma waves, the necessary quality of non-negativity has been noted as a feature that any candidate solution of IPCE will not *a priori* satisfy. We discuss this problem in the context of Channell equilibria, for magnetised plasmas.

1. Introduction

It is estimated that more than 99% of the observable matter in the universe is in the plasma state. These plasmas are frequently sufficiently hot and/or diffuse that the particles rarely collide, for example the collisional *mean free path* in the solar wind is approximately equal to the distance from the Sun to the Earth (e.g. see Marsch & Goldstein (1983); Marsch (2006)). In such circumstances, the plasma dynamics can be accurately modelled without including collisions (e.g. see Schindler (2007); Belmont et al. (2013)). Collisionless plasmas behave quite differently to collisional plasmas, and are best modelled using the Vlasov kinetic theory of particle distribution functions (DFs) in position-velocity phase space (e.g. see Krall & Trivelpiece (1973); Chen (2015)), rather than collisional fluid models that operate in position space only (e.g. see Kulsrud (1983); Freidberg (1987) for discussions of the Magnetohydrodynamic theory).

In nature, this difference is made manifest by the critical dependence of the macroscopic dynamics of collisionless plasmas on the velocity space structure of particle distributions (Gary, 2005), and on the short length and time scale physics of collisionless processes (e.g. see Lifshitz & Pitaevskiĭ (1981); Kulsrud (2005); Schindler (2007)). Modern instrumentation is now able to make observations of particle distributions with spatio-temporal resolution on kinetic scales, for example the NASA Multiscale Magnetospheric (MMS) mission (Hesse et al., 2016). As such, it is of interest and importance to plasma observers, modellers and theorists to better understand the micro-scale kinetic physics of collisionless plasmas, and in particular how this relates to the macroscopic dynamics, which are typically better understood.

Collisionless plasma dynamics are frequently modelled using self-consistent particle-in-cell (PIC) codes (e.g. see Birdsall & Langdon (2004)). In both PIC simulations and *ab initio* kinetic theory analyses, a very common approach that is used to model the dynamics is to first set up a Vlasov equilibrium state, then make a perturbation, and next track the subsequent kinetic evolution and the effect on the

macroscopic physics (e.g. see Drake & Lee (1977); Daughton (1999)). Due to the technical difficulty in calculating exact Vlasov equilibria, approximate solutions are often used as initial conditions instead of exact solutions (e.g. see Swisdak et al. (2003); Hesse et al. (2005); Pritchett (2008); Malakit et al. (2010); Aunai et al. (2013); Hesse et al. (2013); Guo et al. (2014); Hesse et al. (2014); Liu & Hesse (2016)), and it is not always known how far the approximate solution is from a true equilibrium. As such, it is of interest to modellers and theorists to better understand the equilibrium states of Vlasov plasmas. However, there is not a well-established 'user-friendly' theory that relates the equilibrium and stability properties of the macroscopic real-space description of the plasma to those of the microscopic phase-space description, in the sense of a 'one-to-one' correspondence, i.e. 'micro↔macro'. Calculating a kinetic equilibrium given some macroscopic conditions is an example of a non-unique inverse problem: 'the inverse problem in collisionless equilibria' (IPCE), viz. *"given information regarding the macroscopic configuration of a specific collisionless plasma equilibrium, what self-consistent equilibrium distributions exist?"* (e.g. see Channell (1976); Mynick et al. (1979); Harrison & Neukirch (2009b) for examples of IPCE solutions, and Allanson et al. (2016) for examples and discussion). This paper considers IPCE applied to spatially one-dimensional (1D) plasmas, and focuses in particular on the mathematical validity of 1D IPCE solutions.

This paper is structured as follows. In Section 2. we introduce the basic theory of the Vlasov equation and the equations of Vlasov-Maxwell equilibria. We discuss the two distinct approaches to calculating self-consistent collisionless plasma equilibria ('forward' and 'inverse'), and previous works on the non-negativity of DFs obtained in IPCE. Section 3. focusses on IPCE in spatially 1D plasmas; outlines parallels between the mathematical formalism of IPCE as presented, and the initial value problem for the heat equation; and introduces the Fourier transform method of formally inverting the equations in this formalism to obtain IPCE solutions. An alternative method to solve IPCE is to use expansions in Hermite polynomials, and this method is outlined in Section 4. One downfall of this method is that the non-negativity of expansions in Hermite polynomials is not *a priori* known. We present general results on the convergence of the Hermite polynomial expansions, and the existence of velocity moments of all orders, and we discuss the problem of non-negativity. In Section 5. we summarise the theory and results presented in this paper.

2. Basic Theory

2.1 *The Vlasov Equation*

The Vlasov equation (Vlasov, 1968) - also known as the collisionless Boltzmann equation - governs the evolution of the plasma DF for 'particle' species s, f_s, in six-dimensional phase-space, $(\boldsymbol{x}(t), \boldsymbol{v}(t))$. Here, $\boldsymbol{x}$ and $\boldsymbol{v} = d_t \boldsymbol{x}$ denote the particle position and velocity, respectively. The Vlasov equation can be used to model the statistical behaviour of collisionless particle distributions for rarefied gases and plasmas, or even to describe the distribution of stars (e.g. see Henon (1982); Pegoraro et al. (2015) for short introductions to some relevant literature and applications). The Vlasov equation is given in Cartesian geometry by

$$\frac{d}{dt} f_s(\boldsymbol{x}(t), \boldsymbol{v}(t); t) = \frac{\partial f_s}{\partial t} + \frac{d\boldsymbol{x}}{dt} \cdot \frac{\partial f_s}{\partial \boldsymbol{x}} + \frac{d\boldsymbol{v}}{dt} \cdot \frac{\partial f_s}{\partial \boldsymbol{v}} = 0. \tag{2.1}$$

Hence, the Vlasov equation states that the DF is conserved along the particle trajectories in phase-space, and we see that the closure of the system by Maxwell's equations (and the Lorentz force, introduced shortly) is necessary to define its characteristics.

One can construct 'macroscopic' quantities in real-space by taking velocity-space moments of the DF. For example, the number density (a scalar), bulk flow (a vector), and pressure tensor (of rank-2) for species s are given by

$$
\begin{aligned}
n_s(\boldsymbol{x};t) &= \int f_s\, d^3v, \\
\boldsymbol{V}_s(\boldsymbol{x};t) &= n_s^{-1} \int \boldsymbol{v} f_s\, d^3v, \\
P_{ij}(\boldsymbol{x};t) &= \sum_s m_s \int (v_i - V_{i,s})(v_j - V_{j,s}) f_s\, d^3v,
\end{aligned}
\tag{2.2}
$$

for m_s the mass of particle species s, and $\int d^3v$ the integral over all velocity space, i.e. $\mathbb{R}^3$. In order for the DF to be have physical meaning, one must be able to take at least as many velocity moments as a corresponding fluid theory requires, and the DF must be non-negative over all phase space. In this paper we define a physical DF as one which allows velocity-space moments of all orders, and so satisfies

$$
\left| \int v_x^i v_y^j v_z^k f_s\, d^3v \right| < \infty \, \forall i, j, k \in 0,1,2,\dots
\tag{2.3}
$$

$$
f_s(\boldsymbol{x},\boldsymbol{v},t) \geqslant 0 \,\forall\, (\boldsymbol{x},\boldsymbol{v},t).
\tag{2.4}
$$

2.2 *Vlasov-Maxwell equilibria*

This paper will focus on the application to a fully ionised and non-relativistic ion-electron plasma, for which the electromagnetic forces dominate the collective behaviour of the plasma. We shall also ignore gravitational effects. In such circumstances, an individual particle of charge q_s and mass m_s is subject to the Lorentz force,

$$
m_s \frac{d\boldsymbol{v}}{dt} = q_s(\boldsymbol{E} + \boldsymbol{v} \times \boldsymbol{B}),
\tag{2.5}
$$

for $\boldsymbol{E}$ and $\boldsymbol{B}$ the self-consistent electric and magnetic fields respectively. A Vlasov equilibrium corresponds to a statistically steady-state of the particle distribution, and is mathematically described by $\partial_t f_s = 0$. Therefore, we see from equations (2.1) and (2.5) that a collisionless plasma equilibrium DFs obeys by the steady-state *Vlasov-Maxwell* equation,

$$
\boldsymbol{v} \cdot \frac{\partial f_s}{\partial \boldsymbol{x}} + \frac{q_s}{m_s}(\boldsymbol{E} + \boldsymbol{v} \times \boldsymbol{B}) \cdot \frac{\partial f_s}{\partial \boldsymbol{v}} = 0.
\tag{2.6}
$$

Most typically (e.g. see Schindler (2007)), analytical equilibrium solutions of the Vlasov equation are constructed using a theorem attributed to Jeans (Jeans, 1915; Lynden-Bell, 1962). 'Jeans' theorem' states that f_s is a solution of the Vlasov equation if it is a function of a subset of the k known constants of motion for particle species s,

$$
\{C_{n,s}(\boldsymbol{x}(t),\boldsymbol{v}(t)) : d_t C_{n,s} = 0, n = 1,\dots,k\}.
$$

Since $d_t C_{n,s} = \partial_t C_{n,s} = 0$, we see that any such function will *also be* a Vlasov equilibrium ($\partial_t f_s = 0$). We should mention another (numerical) method to solve the Vlasov equation based on the notion of 'particle accessibility' (Whipple et al., 1984), that exploits the fact that whilst the DF must be a single-valued function over phase-space, $(\boldsymbol{x},\boldsymbol{v})$, it need not necessarily be a single-valued as a function of the

constants of motion, $C_{n,s}(\boldsymbol{x}, \boldsymbol{v})$, since $C_{n,s}$ may not be monotonic functions of $(\boldsymbol{x}, \boldsymbol{v})$ (e.g. see Belmont et al. (2012); Dorville et al. (2015) and references therein).

Whilst the steady-state Vlasov-Maxwell equation (equation 2.6) can trivially be solved by any function of the constants of motion (that also obeys equations (2.3) and (2.4)), the challenge lies in the fact that the DF must also be self-consistent with the time-independent Maxwell equations,

$$\nabla \cdot \boldsymbol{E} = \frac{\sigma}{\varepsilon_0}, \tag{2.7}$$

$$\nabla \times \boldsymbol{E} = \boldsymbol{0}, \tag{2.8}$$

$$\nabla \cdot \boldsymbol{B} = 0, \tag{2.9}$$

$$\nabla \times \boldsymbol{B} = \mu_0 \boldsymbol{j}, \tag{2.10}$$

for the speed of light $c = (\mu_0 \varepsilon_0)^{-1/2}$, ε_0 the vacuum permittivity, μ_0 the vacuum permeability, σ the charge density, and $\boldsymbol{j}$ the current density. Maxwell's equations couple to the Vlasov-Maxwell equation through the source terms on the right-hand side (RHS) of Gauss' law, and Ampère's Law (equations (2.7) and (2.10) respectively):

$$\sigma(\boldsymbol{x}) = \sum_s q_s n_s = \sum_s q_s \int f_s \, d^3 v, \tag{2.11}$$

$$\boldsymbol{j}(\boldsymbol{x}) = \sum_s q_s n_s \boldsymbol{V}_s = \sum_s q_s \int \boldsymbol{v} f_s \, d^3 v. \tag{2.12}$$

Note that equations (2.8) and (2.9) are automatically satisfied for the electric field $\boldsymbol{E} = -\nabla \phi$ defined as the (negative) gradient of the scalar potential $\phi(\boldsymbol{x})$, and $\boldsymbol{B} = \nabla \times \boldsymbol{A}$ the curl of the vector potential $\boldsymbol{A}(\boldsymbol{x})$.

An equilibrium solution of the *Vlasov-Maxwell system* is therefore characterised by a self-consistent set of DFs and potential functions,

$$\{f_s : s = i, e\}, \boldsymbol{\phi}(\boldsymbol{x}), \boldsymbol{A}(\boldsymbol{x}),$$

such that equations (2.6), (2.7) and (2.10) are satisfied, with the subscripts i and e corresponding to ions and electrons respectively (e.g. see Mynick et al. (1979); Greene (1993); Schindler (2007)).

2.3 *The forward and inverse approaches*

The Vlasov-Maxwell system is an integro-differential set of equations, and there are two different approaches that could be made to solve it. The one most typically seen is the 'forward' approach, in which one specifies the DFs, proceeds to calculate the source terms via the integrals in equations (2.11) and (2.12), and then attempts to solve the differential equations (2.7) and (2.10) for ϕ and $\boldsymbol{A}$ (e.g. see discussions in Bennett (1934); Grad (1961); Harris (1962); Sestero (1964, 1965); Lee & Kan (1979); Schindler (2007); Kocharovsky et al. (2010); Vasko et al. (2013)). In this approach ('micro'→'macro'), one typically assumes a form of the equilibrium DF that is thought to be mathematically/physically reasonable, and frequently one of Maxwellian form,

$$f_{\mathrm{Maxw},s} = \frac{n_s(\boldsymbol{x})}{(\sqrt{2\pi} v_{\mathrm{th},s})^3} e^{-(\boldsymbol{v} - \boldsymbol{V}_s(\boldsymbol{x}))^2 / (2 v_{\mathrm{th},s}^2)},$$

for $v_{\mathrm{th},s}$ a positive constant (the *thermal velocity*). Then, given some conditions on certain elements of the macroscopic description (e.g. boundary conditions for the electromagnetic potentials), one is hopefully able to solve differential equations and calculate the macroscopic quantities $\boldsymbol{E}$ and $\boldsymbol{B}$, as well as

$n_s, \boldsymbol{V}_s, \boldsymbol{j}, P_{ij}$ etc (e.g. see Harris (1962); Schindler (2007); Vasko et al. (2013)). Whilst this approach is typically easier than the one that we are about to introduce, it has one significant drawback. In contrast to collisional plasmas for which there is in principle a unique equilibrium solution of the corresponding kinetic equation: the Maxwellian DF (Grad, 1949b), collisionless plasmas admit an infinity of possible equilibrium DFs (i.e. any function of the constants of motion). Hence, for the many man-made, terrestrial, space, solar and astrophysical plasmas in which the collisionality is insufficient to drive the DF to a thermal equilibrium Maxwellian DF, one does not *a priori* know what form of the DF on which to base their calculation.

The 'inverse' approach is the method that we shall focus on in this paper ('macro'→'micro'). In the 'inverse problem for collisionless equilibria' (IPCE), one specifies certain features of the macroscopic equilibrium configuration, e.g. $\boldsymbol{B}$ and $\boldsymbol{E}$, and attempts to find a self-consistent DF (e.g. see discussions in Alpers (1969); Channell (1976); Mynick et al. (1979); Greene (1993); Harrison & Neukirch (2009b); Belmont et al. (2012); Allanson et al. (2016)). This approach involves the inversion of integral equations, and has two potential drawbacks. The first is that there are in principle infinitely many solutions to IPCE, and so one has to question whether the DF obtained by the chosen method is physically realistic, or just a mathematical curiosity. The second is that the equilibrium DF may not be able to be expressed in closed form, and the necessary conditions of equations (2.3) and (2.4) may be in question.

2.4 *Previous work on non-negativity*

The first body of works on IPCE (Bernstein et al., 1957; Montgomery & Joyce, 1969; Tasso, 1969; Schamel, 1971) mainly focussed on electrostatic configurations, i.e. $\boldsymbol{E} \neq \boldsymbol{0}$ and $\boldsymbol{B} = \boldsymbol{0}$ (the *Vlasov-Poisson* system). In Bernstein et al. (1957), an inductive integral equation method is developed that calculates the DF of trapped electrons in a nonlinear travelling electrostatic wave (*Bernstein-Greene-Kruskal (BGK) waves*), for a given 1D scalar potential, ϕ, in the wave frame. Whilst Bernstein et al. (1957) recognised that equation (2.4) must be satisfied for the DF to be physically meaningful, they did not formally explore this feature. Montgomery & Joyce (1969), Tasso (1969) and Schamel (1971) demonstrated that it is indeed possible to obtain non-negative trapped DFs for the trapped electron population, and this is relevant to the physics of nonlinear plasma waves (e.g. see Schamel (1972, 1986)) and collisionless shocks (e.g. see Burgess & Scholer (2015)).

However, the work in this paper will focus on IPCE applied to 'strictly neutral' magnetised plasma configurations ($\phi = |\boldsymbol{E}| = \sigma = 0$ and $\boldsymbol{B} \neq \boldsymbol{0}$), as used in Vlasov-Maxwell equilibrium studies by Grad (1961); Hurley (1963); Nicholson (1963); Schmid-Burgk (1965); Moratz & Richter (1966); Lerche (1967); Alpers (1969); Channell (1976); Bobrova & Syrovatskiǐ (1979); Lakhina & Schindler (1983); Attico & Pegoraro (1999); Bobrova et al. (2001); Fu & Hau (2005); Yoon & Lui (2005); Harrison & Neukirch (2009a); Neukirch et al. (2009); Panov et al. (2011); Wilson & Neukirch (2011); Belmont et al. (2012); Janaki & Dasgupta (2012); Abraham-Shrauner (2013); Ghosh et al. (2014); Kolotkov et al. (2015); Allanson et al. (2015, 2016). This approach is somewhat stricter than imposing quasineutrality. Quasineutrality (typically taken to mean that $\sigma = 0$) is satisfied when typical spatial variations, L, are much larger than a quantity known as the *Debye radius*, λ_D,

$$\frac{\lambda_D}{L} \ll 1, \quad \text{s.t.} \quad \lambda_D = \sqrt{\frac{\varepsilon_0 k_B T_e}{n_e e^2}},$$

for k_B Boltzmann's constant, T_e the electron temperature, and e the fundamental charge (Schindler, 2007).

Questions regarding the non-negativity of IPCE solutions for magnetised plasmas arise in the works

by Abraham-Shrauner (1968); Alpers (1969); Channell (1976); Hewett et al. (1976); Suzuki & Shigeyama (2008); Allanson et al. (2015, 2016). All of these works, except Suzuki & Shigeyama (2008), consider equilibria that are 1D in space, and use (possibly infinite) expansions in Hermite polynomials (Arfken & Weber, 2001) to represent the DF, i.e. a non-closed form. In the following section, we proceed to develop the basic formalism required for IPCE with 1D neutral Vlasov-Maxwell equilibria, using the constants of motion approach.

3. One-dimensional strictly neutral Vlasov-Maxwell equilibria

Without loss of generality, we take the z coordinate as the one spatial coordinate on which the 1D system dynamics depend. There are numerous environments and phenomena in which this approximation is justifiable (based on a separation of scales), with examples including current sheets (e.g. see Schindler (2007); Fruit et al. (2002); Yamada et al. (2010); Beidler & Cassak (2011); Zelenyi et al. (2011); DeVore et al. (2015)); nonlinear waves (e.g. see Bernstein et al. (1957); Ng et al. (2012)); electron holes, ion holes and double layers (e.g. see Schamel (1986)); and colllisionless shock fronts (e.g. see Montgomery & Joyce (1969); Burgess & Scholer (2015)). As a result of this 1D assumption, the magnetic field and current density are written as

$$\boldsymbol{B} = \left(-\frac{dA_y}{dz}, \frac{dA_x}{dz}, 0 \right),$$

$$\boldsymbol{j} = \frac{1}{\mu_0} \left(-\frac{dB_y}{dz}, \frac{dB_x}{dz}, 0 \right),$$

respectively. Furthermore, the classical action (for a particle of species s),

$$S = \int_{t_1}^{t_2} L \, dt = \int_{t_1}^{t_2} (m_s v^2/2 + q_s \boldsymbol{v} \cdot \boldsymbol{A}) \, dt,$$

for $t_1, t_2, t \in \mathbb{R}$, is invariant ($\delta S = 0$) under infinitesimal continuous transformations in t, x and y (e.g. see Landau & Lifshitz (2013)). Since the system is invariant in both time and two spatial dimensions, we have – by Noether's theorem (e.g. see Weinberg (2005)) – three known constants of motion for a particle in an electromagnetic field,

$$
\begin{aligned}
H_s &= m_s v^2/2, \\
p_{x,s} &= m_s v_x + q_s A_x, \\
p_{y,s} &= m_s v_y + q_s A_y,,
\end{aligned}
$$

the Hamiltonian, and canonical momenta in the x and y directions respectively. We shall now make one broad assumption on the functional form of the DF, namely that – as a function of the constants of motion – it is written as,

$$f_s = f_s(H_s, p_{x,s}, p_{y,s}) = \frac{n_0}{(\sqrt{2\pi} v_{\text{th},s})^3} e^{-\beta_s H_s} g_s(p_{x,s}, p_{y,s}), \tag{3.1}$$

for $n_0, v_{\text{th},s}$, and $\beta_s = (m_s v_{\text{th},s}^2)^{-1}$ positive constants/parameters, with dimensions of number density, velocity and energy-1 respectively; and g_s an unknown function to be determined. This assumption has a long history in the literature (e.g. see first use in Alpers (1969); Channell (1976)), and is chosen for both mathematical reasons (integrability), and physical ones (the DF reduces to a 'stationary'

Maxwellian when $g_s = 1$). Hence, the task of IPCE has been reduced to finding g_s functions that are self-consistent with the prescribed macroscopic conditions. As written, it is the g_s function that potentially encodes the interesting non-Maxwellian phase-space structure, only permitted for collisionless plasma equilibria.

One immediate consequence of the ansatz in equation (3.1) is that $V_{z,s} = 0$, since the DF is an even function of v_z. As such, the zz component of the pressure tensor (equation 2.2) is written as

$$P_{zz} = \sum_s m_s \int v_z^2 f_s d^3 v. \tag{3.2}$$

Many authors have noted the pivotal role that P_{zz} plays in the Vlasov-Maxwell equilibrium system for 1D plasmas (e.g. see Grad (1961); Channell (1976); Mynick et al. (1979); Greene (1993); Tassi et al. (2008); Harrison & Neukirch (2009b)), and the following discussion shall make use of results from these works.

The zz component of P_{ij} is not the only non-zero component for our problem, but it is the only one that plays a role in macroscopic force balance, given for a neutral plasma as

$$\sum_{i=1}^{3} \frac{\partial}{\partial x_i} P_{ij} = (\boldsymbol{j} \times \boldsymbol{B})_j,$$

$$\implies \frac{d}{dz} P_{zz} = j_x B_y - j_y B_x = -\frac{1}{2\mu_0} \frac{d}{dz} B^2. \tag{3.3}$$

Equation (3.3) is the statement of pressure balance, $P_{zz} + B^2/(2\mu_0) = P_{\text{total}}$, for $B^2/(2\mu_0)$ the magnetic energy density (pressure), and P_{total} the total pressure (thermal plus magnetic). Furthermore, the existence of a neutral Vlasov-Maxwell equilibrium can be shown to imply that $P_{zz} = P_{zz}(A_x(z), A_y(z))$ (Channell, 1976), and hence the chain rule gives

$$\frac{d}{dz} P_{zz} = \frac{\partial P_{zz}}{\partial A_x} \frac{dA_x}{dz} + \frac{\partial P_{zz}}{\partial A_y} \frac{dA_y}{dz}. \tag{3.4}$$

By comparing terms in the first equality of equation (3.3), and equation (3.4), we see that P_{zz} plays the role of a potential function in this problem, from which the sources of Ampère's Law (equation (2.10)) can be derived

$$-\frac{1}{\mu_0} \frac{d^2 A_x}{dz^2} = j_x(z) = \frac{\partial P_{zz}}{\partial A_x}, \tag{3.5}$$

$$-\frac{1}{\mu_0} \frac{d^2 A_y}{dz^2} = j_y(z) = \frac{\partial P_{zz}}{\partial A_y}. \tag{3.6}$$

These equations are analogous to the equations of motion ($\boldsymbol{F} = -\nabla U = m d^2 \mathbf{x}/dt^2$, for a particle at position $\boldsymbol{x} = \boldsymbol{x}(t)$ under the influence of a potential U) for a particle at 'position' (A_x, A_y) and 'time' z, under the influence of a 'potential', P_{zz}. Equations (3.2), (3.5) and (3.6) neatly summarise the task for a self-consistent solution of the neutral Vlasov-Maxwell equilibrium system.

3.1 *The inverse problem for one-dimensional Vlasov-Maxwell equilibria*

In the context of IPCE, after one has first specified the macroscopic equilibrium, i.e. (in our case) given $(A_x(z), A_y(z))$, the first step is to calculate a P_{zz} function that satisfies equations (3.5) and (3.6). For

example, in the case of 'force-free' magnetic fields (Marsh, 1996), there is an algorithmic path that takes $(A_x(z), A_y(z))$ as input, and gives $P_{zz}(A_x, A_y)$ as output (e.g. see Harrison & Neukirch (2009a); Neukirch et al. (2009); Wilson & Neukirch (2011); Abraham-Shrauner (2013); Kolotkov et al. (2015); Allanson et al. (2015, 2016)).

The next task is to invert equation (3.2) for a known left-hand side (LHS), and the unknown function f_s. The details of this step are summarised in Channell (1976). Channell's method is characterised by the inversion of the following equation for g_s,

$$P_{zz}(A_x, A_y) = \frac{\beta_e + \beta_i}{\beta_e \beta_i} \frac{n_0}{2\pi m_s^2 v_{\text{th},s}^2} \int \int e^{-\beta_s \left((p_{x,s} - q_s A_x)^2 + (p_{y,s} - q_s A_y)^2 \right)/(2m_s)} g_s(p_{x,s}, p_{y,s}) dp_{x,s} dp_{y,s}, \quad (3.7)$$

which is a re-expression of equation (3.2) (after one layer of integration over v_z, with the functional form of the DF given by the ansatz in equation (3.1), and the integral taken over $\mathbb{R}^2$). Note that P_{zz} is formally defined as a sum (over species) of integrals, whereas the RHS of equation (3.7) has only one integral, indexed by a generic species s, i.e. the RHS must yield the same result for $s = i$ as for $s = e$. This requirement is shown by Channell to be equivalent to that imposed by exact charge neutrality,

$$n_i(A_x, A_y) = n_e(A_x, A_y).$$

After some consideration, we should be convinced that the species-independent result of the RHS of equation (3.7) implies that the g_s function must itself depend on species-dependent parameters. Using this fact, and after making some substitutions, equation (3.7) can be re-written according to

$$\mathscr{P}(A_{x,s}, A_{y,s}) = \frac{1}{4\pi \varepsilon_s} \int \int e^{-\left((p_{x,s} - A_{x,s})^2 + (p_{y,s} - A_{y,s})^2 \right)/(4\varepsilon_s)} g_s(p_{x,s}, p_{y,s}; \varepsilon_s) dp_{x,s} dp_{y,s}, \quad (3.8)$$

with $\varepsilon_s = m_s^2 v_{\text{th},s}^2/2$, $\boldsymbol{A}_s = q_s \boldsymbol{A}$, $g_s = g_s(p_{x,s}, p_{y,s}; \varepsilon_s)$, and with $\mathscr{P}$ defined according to

$$\mathscr{P}(A_{x,s}, A_{y,s}) = \frac{\beta_e \beta_i}{(\beta_e + \beta_i) n_0} P_{zz}(A_x, A_y). \quad (3.9)$$

3.2 *The Weierstrass transform*

Equations (3.7) and (3.8) express P_{zz} (or $\mathscr{P}_s$) as two-dimensional (2D) integral transforms of the g_s function. As discussed in Allanson et al. (2015, 2016), the integral transform in equation (3.8) is a 2D generalisation of the 1D Weierstrass transform (Widder, 1951, 1954; Bilodeau, 1962; Zayed, 1996). The Weierstrass transform, $u(x,t)$, of $u_0(y)$ is defined by

$$u(x,t) := \mathscr{W}[u_0](x,t) = \frac{1}{\sqrt{4\pi t}} \int e^{-(x-y)^2/(4t)} u_0(y) \, dy, \quad (3.10)$$

for $x, y, t \in \mathbb{R}$ and $t > 0$. This is also known as the Gauss transform, Gauss-Weiertrass transform or the Hille transform (Widder, 1951). As the Green's function solution to the 1D heat/diffusion equation on an infinite domain,

$$\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = 0,$$

with initial data $u_0(x)$, $u(x,t)$ represents the temperature/density profile on an infinite rod, t seconds after it was $u_0(x)$ (e.g. see Widder (1951)). Note that equation (3.10) is only a meaningful representation of the function $u(x,t)$ (i.e. the Weierstrass transform exists) if $u_0(x)$ is locally integrable, and such that

$$|u_0(x)| \leqslant M e^{\alpha x^2},$$

for $M < \infty$ and $0 < t < 1/(4\alpha)$ (e.g. see Widder (1951); Zayed (1996)). One can immediately see from equation (3.10) that the Weierstrass transform of an everywhere non-negative function is itself a non-negative function, and furthermore that the transform of an everywhere negative function is an everywhere negative function. However, it is possible for the Weierstrass transform of a function that is somewhere negative (i.e. a candidate g_s function), to be a function that is everywhere non-negative (i.e. the P_{zz} function). This case is potentially very troubling for a meaningful solution of IPCE, and is discussed in Allanson et al. (2016), and later on in this paper.

Motivated by the appearance of the Weierstrass transform in IPCE, and for completeness, we now introduce some basic properties of the initial value problem (IVP) for the heat equation.

3.3 *Initial value problems for the heat equation*

The n-dimensional (nD) heat equation models the temperature distribution, $u(\boldsymbol{x},t)$, on an infinite nD spatial domain, and is given by

$$\frac{\partial u}{\partial t} - \nabla^2 u = 0,$$

for $\nabla^2 = \sum_{i=1}^{n} \partial_{x_i}^2$. We define the IVP for the nD heat equation on the unbounded spatial domain $\mathbb{R}^n$, according to

$$u = u(\boldsymbol{x},t) \in C^2(\mathbb{R}^n \times \Omega_T) \cap C^0(\mathbb{R}^n \times \overline{\Omega_T}),$$

$$\frac{\partial u}{\partial t} - \nabla^2 u = 0 \quad \text{in} \quad \mathbb{R}^n \times \Omega_T,$$

$$u(\boldsymbol{x},0) = u_0(\boldsymbol{x}), \quad \boldsymbol{x} \in \mathbb{R}^n,$$

$$\sup_{(\boldsymbol{x},t) \in \mathbb{R}^n \times \Omega_T} |u(\boldsymbol{x},t)| = u_{\mathrm{B}}(\boldsymbol{x}),$$

for the as yet unspecified temporal domain Ω_T, for $\overline{\Omega_T}$ the closure of Ω_T, and for $u_{\mathrm{B}}(\boldsymbol{x})$ the as yet unspecified supremum of $u(\boldsymbol{x},t)$. There are some standard results regarding bounded, unbounded, and non-negative solutions of the IVP respectively, and we shall briefly detail these.

There is a unique bounded solution of the IVP for bounded and continuous initial data, u_0, i.e. $\Omega_T = (0,\infty)$ and $u_{\mathrm{B}}(\boldsymbol{x}) = C < \infty$ (e.g. see Sauvigny (2012)). This unique solution is defined by the nD integral transform (a generalisation of the Weierstrass transform) given by

$$u(\boldsymbol{x},t) = (4\pi t)^{-n/2} \int e^{-(\boldsymbol{x}-\boldsymbol{y})^2/(4t)} u_0(\boldsymbol{y}) \, d\boldsymbol{y}, \tag{3.11}$$

and belongs to C^∞ for $\boldsymbol{x} \in \mathbb{R}^n$, $t > 0$. Moreover, u has the initial values u_0, in the sense that when we extend u by $u(\boldsymbol{x},0) = u_0(\boldsymbol{x})$ to $t = 0$, then u is continuous for $\boldsymbol{x} \in \mathbb{R}^n$, $t \geqslant 0$.

It is also possible to obtain unbounded solutions of the heat equation, using equation (3.11). In fact, there is a unique solution to the IVP on the bounded temporal domain $\Omega_T = (0,T)$, with $u_{\mathrm{B}}(\boldsymbol{x}) = Me^{\alpha \boldsymbol{x}^2}$, and such that $4\alpha T < 1$ (e.g. see John (1991)). Unbounded solutions are of interest to IPCE, since - for example in our problem - the g_s function need not be bounded from above.

Of clear interest to the work in this paper, are solutions to the IVP for non-negative functions. It is a standard result that there is a unique solution to the IVP on $\Omega_T = (0,T)$ using equation (3.11), with the condition that $u(\boldsymbol{x},t)$ is non-negative on $\mathbb{R}^n \times [0,T)$ (e.g. see John (1991)).

In informal terms, we see that a non-negative initial condition (or history) for the heat distribution implies a non-negative distribution in the present and in the future. However, the converse is not necessarily true. The extent to which we can be sure of a non-negative 'past', given a non-negative 'present',

2D Heat Eq. Green's function (Equation (3.11))	1D strictly neutral IPCE: (Equation (3.8))	Caveat?
Primary space variable: $\boldsymbol{x}$	Vector potential: $\boldsymbol{A}_s = q_s \boldsymbol{A}$	Exact analogy.
Conjugate space variable: $\boldsymbol{y}$	Canonical momenta: $\boldsymbol{p}_s$	Exact analogy.
Time: t	('thermal momentum')^2: $\varepsilon_s = m_s^2 v_{th,s}^2/2$	Exact analogy.
Temp. distribution at time t: $u(\boldsymbol{x},t)$	Pressure: $\mathscr{P}(A_{x,s}, A_{y,s})$	$\mathscr{P}_s$ fixed at 'time' $\varepsilon_s = (eB_0 L)^2 \delta_s^2/2$ (micro-macro parameter conditions).
(Fixed) Initial temp. distribution: $u_0(\boldsymbol{y})$	Momentum-dependent part of DF: $g_s(p_{x,s}, p_{y,s}; \varepsilon_s)$	g_s is a function of 'time' ε_s, it represents the 'temperature' ε_s 'seconds' ago.

Table 1. The analogy between 1D strictly neutral IPCE and the Green's function for the 2D heat equation

is the question we consider. Tackling this inverse problem, in the context of equation (3.8), is perhaps the main mathematical challenge for validity of solutions obtained in IPCE, and is akin to going backwards in time (see Evans (2010) for a brief discussion on 'backwards solutions of the heat equation'). Our known and non-negative 'present distribution' is defined by $\mathscr{P}(A_{x,s}, A_{y,s})$, and the 'past distribution', with questionable sign, is defined by $g_s(p_{x,s}, p_{y,s}; \varepsilon_s)$.

3.4 *Implications and interpretation for IPCE*

Equation (3.8) casts the inverse problem in direct comparison with the Weiertrass transform, thus making a correspondence between space and time in the heat equation, (x,t), to $(\boldsymbol{A}, \varepsilon_s)$ in our inverse problem. However, one difference is that the g_s function must - at least parametrically - depend on 'time', ε_s, in contrast to the initial condition (i.e. a time-independent function) that is part of the integrand in Equation (3.10). We know that g_s must depend on ε_s, since the result of the integral (the LHS) must be independent of ε_s, as mentioned in Section 3.1. Hence, it is not immediately clear how 'far' the analogy applies, e.g. is there a differential equation (the heat equation or similar) that g_s and/or P_{zz} obey?

On this subject, and in contrast to the IVP, the approach of IPCE casts the P_{zz} function as the given/fixed quantity, i.e. the *final condition*. In tackling IPCE, we look for non-negative *'initial conditions'*, g_s, that will produce the correct P_{zz}. Hence, it is reasonable that the 'initial condition' should be 'time-dependent'. That is to say, *"given a $P_{zz}(A_x, A_y)$ function, we calculate the self-consistent g_s function 'ε_s seconds ago' by inverting equation (3.8), the integral transform that 'evolves' the $g_s(p_{x,s}, p_{y,s}; \varepsilon_s)$ function by 'ε_s seconds'* ". We summarise the analogy between 1D strictly neutral IPCE, and the 2D Green's function solution of the Heat equation in Table 1.

There is one more conceptual hurdle to overcome, that has its origins in a physical problem rather than a mathematical one. Properly considered, the LHS of equation (3.7) is a function of the (macroscopic) vector potential, which is typically normalised using the macroscopic parameters B_0 and L ($\tilde{\boldsymbol{A}} = \boldsymbol{A}/(B_0 L)$): constants with dimensions of magnetic field and length respectively. In contrast, the integral on the RHS is in (microscopic) momentum space, which is typically normalised using the

microscopic parameters m_s and $v_{\text{th},s}$ ($\tilde{\boldsymbol{p}}_s = \boldsymbol{p}_s/(m_s v_{\text{th},s}) = \boldsymbol{p}_s/(\sqrt{2\varepsilon_s})$). Whenever we solve the Vlasov-Maxwell system, much of the hard work is in actually fixing all of the micro-macro parameter relationships (e.g. see Neukirch et al. (2009); Wilson & Neukirch (2011); Kolotkov et al. (2015); Allanson et al. (2015, 2017); Wilson et al. (2017); Neukirch et al. (2018) for practical examples). For given values of the macroscopic parameters (B_0, L), the one parameter than characterises the micro-macro parameter relationships is

$$\delta_s = \frac{r_{L,s}}{L} = \frac{m_s v_{\text{th},s}}{eB_0 L},$$

for e the fundamental charge. δ_s is the dimensionless and species-dependent *magnetisation parameter* (e.g. see Fitzpatrick (2014)). It is the ratio of the thermal Larmor radius, $r_{Ls} = v_{\text{th},s}/|\Omega_s|$, to the characteristic length scale of the system, L (the gyrofrequency of particle species s is $\Omega_s = q_s B_0/m_s$). By fixing δ_s we also fix ε_s, according to

$$\left(\frac{m_s^2 v_{\text{th},s}^2}{2} =:\right) \varepsilon_s := \frac{(eB_0 L)^2 \delta_s^2}{2}, \tag{3.12}$$

which is analogous to fixing the 'time' in the heat equation analogy.

3.5 *Using Fourier transforms to solve IPCE*

As written, Equation (3.8) defines $\mathscr{P}(A_{x,s}, A_{y,s})$ as a 2D *convolution* of the functions $G_s = e^{-(p_{x,s}^2 + p_{y,s}^2)/4\varepsilon_s}$ and $g_s(p_{x,s}, p_{y,s})$] As such, and using the convolution theorem, g_s can - at least formally - be written

$$g_s(p_{xs}, p_{ys}; \varepsilon_s) = 4\pi\varepsilon_s \text{IFT}\left[\tilde{P}_{zz}/\tilde{G}_s\right], \tag{3.13}$$

for IFT the 2D inverse Fourier transform, and $\tilde{P}_{zz}$, $\tilde{G}_s$ denoting the 2D Fourier transforms of P_{zz} and G_s respectively. This Fourier transform method has been used by authors to solve IPCE (e.g. see Channell (1976); Harrison & Neukirch (2009a). Indeed, at first glance, it would seem that using equation (3.13) is the general solution to our IPCE problem. However, the solution defined is only formal, without further investigation. It is not of use when either the Fourier transform of the g_s or $\mathscr{P}$ functions cannot be evaluated, or when the inverse Fourier transform expression on the RHS of equation (3.13) cannot be evaluated. It may be the case that these transforms cannot be evaluated either in the sense that there exists no exact analytic answer in closed form, or that they are divergent (e.g. see Channell (1976); Allanson et al. (2016) for examples and discussion).

The subsequent work in this paper makes use of, and develops, the theory of solutions to IPCE with the use of Hermite polynomial expansions. This technique is to be seen as an alternative method to Fourier transforms.

3.6 *Summary*

In this section we have demonstrated that for neutral equilibria, IPCE in 1D can be reduced to the inversion of Weierstrass transforms once the expression for the pressure tensor component P_{zz} is known. The problem is therefore succinctly described by equations (3.5), (3.6) and (3.8). We have discussed the parallels between the integral equations to be inverted, and the Green's function solutions of the heat equation. Whilst there are many standard results regarding the IVP for the heat equation, the problem that we face with IPCE is more related to 'backwards solutions': *'for a given distribution that is everywhere non-negative heat distribution at time t_1, was there a everywhere non-negative distribution at time t_0, in the past?'*.

4. Expansions in Hermite polynomials

4.1 *Hermite polynomials*

The use of Hermite polynomials in kinetic theory dates back, at least, to Grad (1949b) in the study of rarefied collisional gases, in which non-equilibrium DFs are represented by shifted Maxwellians multiplied by an expansion in "n-dimensional" Hermite polynomials (Grad, 1949a). However, the most typical approach in collisionless and weakly collisional plasma kinetic theory is to use expansions in 'scalar' Hermite polynomials (Zayed, 1996), defined by

$$H_n(p) \quad = \quad (-1)^n e^{p^2} \frac{d^n}{dp^n} e^{-p^2}, \qquad (4.1)$$

$$\int_{-\infty}^{\infty} H_m(p) H_n(p) e^{-p^2} dp \quad = \quad \delta_{m,n} 2^n n! \sqrt{\pi}, \qquad (4.2)$$

for $\delta_{m,n}$ the Kronecker delta, and $p \in \mathbb{R}$. Hermite polynomials are a complete orthogonal set of polynomials for $g(p) \in L^2(\mathbb{R}, e^{-p^2} dp)$ (Sansone, 1959; Arfken & Weber, 2001). That is to say that for any piecewise continuous $g(p)$, such that

$$\int_{-\infty}^{\infty} |g(p)|^2 e^{-p^2} dp < \infty, \qquad (4.3)$$

then there exists an (infinite) expansion in Hermite polynomials, $\sum_{n=0}^{\infty} c_n H_n(p)$, such that

$$\lim_{k \to \infty} \int_{-\infty}^{\infty} \left| g(p) - \sum_{n=0}^{k} c_n H_n(p) \right|^2 e^{-p^2} dp = 0. \qquad (4.4)$$

Hermite polynomials have a long history in kinetic theory precisely due to equation (4.2): they are a natural orthogonal basis with which to use when also considering Gaussian/Maxwellian/normal profiles $\sim e^{-\tilde{p}^2} \sim e^{-\tilde{v}^2}$, for some appropriately normalised momenta or velocity ($\tilde{p}$ or $\tilde{v}$).

4.2 *Hermite polynomials for exact VM equilibria*

In the work by Abraham-Shrauner (1968), expansions in Hermite polynomials of the canonical momentum are used to solve the VM system for the case of 'stationary waves' in a manner similar to that to be described in this section. In the laboratory frame, these nonlinear waves are not Vlasov equilibria, however they are equivalent to Vlasov equilibria once a transformation is made to a frame co-moving with the wave. Abraham-Shrauner considers a 1D plasma with only one component of current density, first in a general sense, and then considers three different magnetic field configurations. Alpers (1969) also presents a somewhat general discussion on the use of Hermite polynomials for 1D VM equilibria, and proceeds to consider models suitable for the magnetopause, with both one component of the current density, and with two. In the work by Channell (1976), two methods are presented for the solution of the inverse problem with neutral VM equilibria, by means of example. These two methods are inversion by Fourier transforms and – once again – expansion over Hermite polynomials respectively. Channell uses Hermite polynomials in the canonical momenta, but this time with two components of the current density, for the specific case of a magnetic field that is especially suitable to be considered as a stationary wave solution.

In contrast to Abraham-Shrauner (1968); Alpers (1969); Channell (1976), the works by Hewett et al. (1976); Suzuki & Shigeyama (2008) both consider the forwards problem in VM equilibria, and

use Hermite polynomial expansions in velocity space, for 1D and 2D plasmas respectively. Hewett et al. (1976) assume a representation for the DF using expansions in velocity space, but with only one current density component, and ensure self-consistency with Maxwell's equations numerically, whereas Suzuki & Shigeyama (2008) use an analytical approach, e.g. demonstrating that the Hermite polynomial approach can reproduce known equilibria such as the Harris sheet (Harris, 1962), and the Bennett Pinch (Bennett, 1934).

Crucially, none of the above references sytematically tackled the necessary mathematical conditions of convergence and non-negativity in a rigorous way. Motivated by new exact Vlasov-Maxwell solutions involving expansions in Hermite polynomials in Allanson et al. (2015), the work in Allanson et al. (2016) formally treated the use of Hermite polynomials in IPCE, and tackled the problems of convergence, boundedness and non-negativity of the resultant DF. This work will be discussed, and built upon, in the following sections.

To give a subset of (modern) examples outside the realm of equilibrium studies *per se*, Hermite polynomial expansions are used by Daughton (1999) to assess the linear stability of a Harris current sheet; by Camporeale et al. (2006) also on the linear stability problem, using a truncation method somewhat like that of Grad (1949b), and managing to bypass the traditional approach of integrating over the 'unperturbed orbits' (Coppi et al., 1966; Drake & Lee, 1977; Quest & Coroniti, 1981; Daughton, 1999); by Zocco (2015) on linear collisionless Landau damping (Landau, 1946; Mouhot & Villani, 2011); by Schekochihin et al. (2016); Adkins & Schekochihin (2018) on the problem of the free-energy associated with velocity-space moments of the DF, in the context of plasma turbulence; and by Servidio et al. (2017) in the analysis of the plasma velocity-space cascade observed by the MMS mission in the Earth's magnetosheath.

4.3 *Formal solutions to 1D IPCE using Hermite polynomials*

Whereas Equations (4.1) and (4.3) are the standard 'physicists' definitions of Hermite polynomials, it will be of use in this work, as in Alpers (1969); Channell (1976); Allanson et al. (2015, 2016) to consider the scaled function $H_n(p/(2\sqrt{\varepsilon_s}))$. This slight modification results in changes to Equations (4.1), (4.2), (4.3) and (4.4), easily achieved by substitution.

In fact, we see that expansions in Hermite polynomials $H_n(p/(2\sqrt{\varepsilon_s}))$ are a complete orthogonal set for $f \in L^2(\mathbb{R}, e^{-p^2/(4\varepsilon_s)}dp)$. By equation (4.3), we see that this means that expansions in Hermite polynomials, $H_n(p/(2\sqrt{\varepsilon_s}))$, are valid representations for piecewise-continuous functions g, such that $|g| \leqslant Me^{p^2/(8\varepsilon_s)}$, for $M < \infty$. This condition is more strict than that for the existence of the integrals in equations (3.8) and (3.10), i.e. the validity of the Weierstrass transform representation (equivalent to $|g| \leqslant Me^{p^2/(4\varepsilon_s)}$).

Expansions in Hermite polynmials are of particular interest when the Fourier transform inversion technique detailed in Section (3.5) is intractable, and/or when $P_{zz}(A_x, A_y)$ is not given in closed form. In Allanson et al. (2016), IPCE was solved using Hermite polynomial expansion, and the assumption was made that the Maclaurin expansion of $P_{zz}(A_x, A_y)$ was either 'summatively' or 'multiplicatively' separable in it's indices, i.e. of the form

$$P_{zz} \propto P_1(A_x) + P_2(A_y), \quad \text{or} \quad P_{zz} \propto P_1(A_x)P_2(A_y). \tag{4.5}$$

Here we generalise the work presented in Allanson et al. (2016) to an arbitrarily indexed 2D sum, we

suppose that $P_{zz}(A_x, A_y)$ is given as a 2D sum of the most general form,

$$P_{zz}(A_x, A_y) = n_0 \frac{\beta_e + \beta_i}{\beta_e \beta_i} \sum_{m,n} c_{m,n} \left(\frac{A_x}{B_0 L} \right)^m \left(\frac{A_y}{B_0 L} \right)^n, \qquad (4.6)$$

with the RHS a convergent Maclaurin expansion with infinite radius of convergence in both of its arguments. The indices $m, n \in \{0, 1, 2, ...\}$, and the coefficient $c_{m,n} \in \mathbb{R}$. (Note that convergence of the Maclaurin expansion of P_{zz}, and hence the convergence of the sum of derivatives, implies that $P_{zz} \in C^\infty(\mathbb{R}^2)$, e.g. see Bartle & Sherbert (2000)).

Using theory as in Bilodeau (1962); Allanson et al. (2016), it can be shown that the following expansion in Hermite polynomials

$$g_s(p_{x,s}, p_{y,s}; \varepsilon_s) = \sum_{m,n} c_{m,n} \mathrm{sgn}(q_s)^{m+n} \left(\frac{\delta_s}{\sqrt{2}} \right)^{m+n} H_m \left(\frac{p_{x,s}}{2\sqrt{\varepsilon_s}} \right) H_n \left(\frac{p_{y,s}}{2\sqrt{\varepsilon_s}} \right), \qquad (4.7)$$

is, formally speaking, an exact inverse solution of equation (3.7), for P_{zz} given by equation (4.6). The only change in this calculation, as compared to those thoroughly detailed in Allanson et al. (2015, 2016), is that the once 'separable' index $c_{m,n}$ (i.e. 'additively' separable, $c_{m,n} = a_m + b_n$; or 'multiplicatively' separable, $c_{m,n} = a_m b_n$), is now not assumed to be separable. However, this constant index/coefficient falls outside of any integrals, and has no effect on the main outcome.

4.4 *Mathematical criteria*

Since a g_s function found using the Hermite polynomial method - as in equation (4.7) - could be an infinite series of polynomials that does not represent a known function in closed form, it is by no means clear if g_s is everywhere non-negative. This issue is recognised by Abraham-Shrauner (1968); Hewett et al. (1976). Not only is the non-negativity in question, but it is not obvious whether a given expansion in Hermite polynomials even converges, and this question was also raised by Hewett et al. (1976). Finally, even if the Hermite expansion converges, it must -when multiplied by the Maxwellian factor (equation (3.1)) - produce a DF for which velocity moments of all order exist, as discussed in Section 2. In order to have full confidence in the Hermite polynomial method we need to address these issues of non-negativity, convergence, and the existence of moments.

We should mention that the *reverse* questions are well established, i.e. if one *a priori* knows the DF in closed form, or at least if Equation (4.3) is satisfied. In such circumstances, one can represent a given non-negative DF as a Maxwellian multiplied by an expansion in Hermite polynomials, $H_n(p/(2\sqrt{\varepsilon_s}))$, provided the g_s function grows at a rate below $e^{p^2/(8\varepsilon_s)} \sim e^{v^2/4v_{\mathrm{th},s}^2}$ (Grad, 1949b; Widder, 1951).

In Allanson et al. (2016), sufficient conditions on the $c_{m,n}$ coefficients were found that when satisfied, guaranteed the convergence of the Hermite expansion in the case of additive or multiplicative separability. The resultant DFs were also demonstrated to be bounded over all velocity/momentum space. Furthermore, it was proven for certain g_s function classes that the derived Hermite polynomial expansion will correspond to a non-negative DF, for at least some finite range of values of $0 < \delta_s < \delta_{c,s}$.

4.5 *Convergence for separable indices*

In Allanson et al. (2016), it was proven that for g_s functions compatible with P_{zz} as in equation (4.5),

$$g_s \propto g_{x,s}(p_{x,s}; \varepsilon_s) + g_{y,s}(p_{y,s}; \varepsilon_s), \quad \text{or} \quad g_s \propto g_{x,s}(p_{x,s}; \varepsilon_s) g_{y,s}(p_{y,s}; \varepsilon_s),$$

the corresponding Hermite expansions of the form

$$g_{js}(p_{js}; \varepsilon_s) = \sum_{m=0}^{\infty} a_m \operatorname{sgn}(q_s)^m \left(\frac{\delta_s}{\sqrt{2}}\right)^m H_m\left(\frac{p_{js}}{2\sqrt{\varepsilon_s}}\right) \tag{4.8}$$

for $j = x, y$, converge for all p_{js}, provided

$$\lim_{m \to \infty} \sqrt{m} \left|\frac{a_{m+1}}{a_m}\right| < 1/\delta_s, \tag{4.9}$$

in the case of a series composed of both even- and odd-order terms, or

$$\lim_{m \to \infty} m \left|\frac{a_{2m+2}}{a_{2m}}\right| < 1/(2\delta_s^2), \quad \lim_{m \to \infty} m \left|\frac{a_{2m+3}}{a_{2m+1}}\right| < 1/(2\delta_s^2), \tag{4.10}$$

in the case of a series composed only of even-, or odd-order terms, respectively. In order to get a better understanding of the meaning of this theorem, it is instructive to recapitulate the results in a continuous setting. One could imagine the modulus of the coefficients, $|a_m|$, as a subset of the range of a continuous function of the independent variable m,

$$|a_m|, m = 0, 1, 2, ...$$
$$\to \quad a = a(m), m \in [0, \infty), \quad \text{s.t.} \quad a(0) = |a_0|, a(1) = |a_1|....$$

In this case, we require

$$a(m) = O(a_u(m)), \quad \text{s.t.} \quad a_u(m) = (\delta_s^2 m)^{-m/2},$$

since the function a_u defines the limiting behaviour of a_m, according to the restrictions of Equations (4.9) and (4.10), i.e

$$\left|\frac{a_u(m+1)}{a_u(m)}\right| = \frac{1}{\delta_s\sqrt{m}},$$
$$\left|\frac{a_u(2m+2)}{a_u(2m)}\right| = \frac{1}{2\delta_s^2 m},$$
$$\left|\frac{a_u(2m+3)}{a_u(2m+1)}\right| = \frac{1}{2\delta_s^2 m}.$$

Hence the modulus of the coefficients, $|a_m|$ must 'fall below' the graph of $(\delta_s^2 m)^{-m/2}$ for large m, depicted in Figure 1.

4.6 *Convergence for non-separable indices*

Here we generalise the results of Allanson et al. (2016), as detailed in Section 4.5, for the convergence of a Hermite expansion representation for g_s that is indexed by a non-separable index, $c_{m,n}$ (i.e. the general solution that corresponds to the pressure function in equation (4.6)).

Essentially, the argument rests on applying the conditions for 1D indices of equations (4.9) and (4.10), to the case of 2D indices. Formally speaking, we know that g_s defined by equation (4.7), and
FIG. 1. If the modulus of the coefficients, $|a_m|$, 'fall below' the graph of $(\delta_s^2 m)^{-m/2}$ as $m \to \infty$, then the Hermite series will converge.

indexed by the 2D index $c_{m,n}$, is the IPCE solution for P_{zz} defined by equation (4.6). Now, let d_m and e_n be 1D indices fixed by the following conditions,

$$d_m \in D \quad := \quad \left\{ |c_{m,n^\star}| \, : \, \lim_{m \to \infty} |c_{m+1,n^\star}/c_{m,n^\star}| = \max_n \left(\lim_{m \to \infty} |c_{m+1,n}/c_{m,n}| \right), m = 0,1,2,... \right\}, \quad (4.11)$$

$$e_n \in E \quad := \quad \left\{ |c_{m^\star,n}| \, : \, \lim_{n \to \infty} |c_{m^\star,n+1}/c_{m^\star,n}| = \max_m \left(\lim_{n \to \infty} |c_{m,n+1}/c_{m,n}| \right), n = 0,1,2,.. \right\}. \quad (4.12)$$

In $row - column$ matrix terminology, that is to say that d_m is a 1D index that identifies the (not necessarily unique) column, $n = n^\star$, for which the $c_{m,n}$ indices decay most slowly as $m \to \infty$. Likewise, e_n identify the (not necessarily unique) row, $m = m^\star$, for which the $c_{m,n}$ indices decay most slowly as $n \to \infty$.

Once d_m and e_n are identified, we can - for sufficently large m and n - formally bound the summand of the general solution (equation (4.7)),

$$c_{m,n} \operatorname{sgn}(q_s)^{m+n} \left(\frac{\delta_s}{\sqrt{2}} \right)^{m+n} H_m \left(\frac{p_{x,s}}{2\sqrt{\varepsilon_s}} \right) H_n \left(\frac{p_{y,s}}{2\sqrt{\varepsilon_s}} \right) < d_m e_n \left(\frac{\delta_s}{\sqrt{2}} \right)^{m+n} \left| H_m \left(\frac{p_{x,s}}{2\sqrt{\varepsilon_s}} \right) \right| \left| H_n \left(\frac{p_{y,s}}{2\sqrt{\varepsilon_s}} \right) \right|,$$

and construct a sum composed of these upper bounds, according to

$$g_{s,\text{bound}} = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} d_m e_n \left(\frac{\delta_s}{\sqrt{2}} \right)^{m+n} \left| H_m \left(\frac{p_{x,s}}{2\sqrt{\varepsilon_s}} \right) \right| \left| H_n \left(\frac{p_{y,s}}{2\sqrt{\varepsilon_s}} \right) \right|. \quad (4.13)$$

The RHS of this equation is now of separable form. If each individual sum (over both m and n) is convergent, then the expression on the RHS is convergent. Then, by using the comparison test (e.g. see Bartle & Sherbert (2000)), convergence of the 2D series, $g_{s,\text{upper}}$, guarantees convergence of the series representation of g_s in equation (4.7).

One can now treat equation (4.13) in the same manner as in Allanson et al. (2016), and derive conditions on the d_m and e_n coefficients for convergence of the general solution, exactly analogous to those of equations (4.9) and (4.10), and by using an upper bound on Hermite polynomials (e.g. see Sansone (1959))

$$|H_j(x)| < k\sqrt{j!} 2^{j/2} \exp \left(x^2/2 \right) \text{ s.t. } k = 1.086435. \quad (4.14)$$

As a result, a sufficient condition for the Hermite series representation of g_s in equation (4.7) to converge is given by

$$\lim_{m \to \infty} \sqrt{m} \left| \frac{d_{m+1}}{d_m} \right| < 1/\delta_s,$$

in the case of a series composed of both even- and odd-order terms, or

$$\lim_{m \to \infty} m \left| \frac{d_{2m+2}}{d_{2m}} \right| < 1/(2\delta_s^2), \quad \lim_{m \to \infty} m \left| \frac{d_{2m+3}}{d_{2m+1}} \right| < 1/(2\delta_s^2),$$

and analogously for e_n, with d_m and e_n defined by equations (4.11) and (4.12).

4.7 *The existence of all velocity moments*

Once the convergence of the Hermite polynomial expansion is established, then one can begin to consider the boundedness of the DF, and the existence of velocity moments. In Allanson et al. (2016), it was shown that DFs of the form in equation (4.7) were bounded over all velocity space, but this does not guarantee that the DF has velocity space moments of all orders. For the DF to be physically meaningful, equation (2.3) must be satisfied.

If the Hermite representation of g_s is a convergent series, then by using Equation (4.14) we deduce that

$$|g_s(p_{x,s}, p_{y,s}; \varepsilon_s)| < \mathscr{L}_{x,s}(\varepsilon_s) \mathscr{L}_{y,s}(\varepsilon_s) \exp\left(\frac{p_{x,s}^2 + p_{y,s}^2}{8\varepsilon_s^2} \right) \quad \forall p_{x,s}, p_{y,s}$$

and for $\mathscr{L}_{x,s}(\varepsilon_s), \mathscr{L}_{y,s}(\varepsilon_s)$ finite positive constants, independent of space and momentum, but dependent on ε_s. Now, by using the form of the DF from equation (3.1) we see that

$$\begin{aligned}
|f_s| < n_0 &\left(\frac{m_s}{\pi\sqrt{8\varepsilon_s}} \right)^{3/2} \left(\mathscr{L}_{xs}(\varepsilon_s) \mathscr{L}_{ys}(\varepsilon_s) e^{p_{xs}^2/(8\varepsilon_s^2)} e^{p_{ys}^2/(8\varepsilon_s^2)} \right) \\
&\times \exp\left[-(p_{xs} - q_s A_x)^2/(4\varepsilon_s^2) - (p_{ys} - q_s A_y)^2/(4\varepsilon_s^2) - v_z^2/(2v_{\text{th},s}^2) \right],
\end{aligned} \quad (4.15)$$

and we see that boundedness in momentum space (and hence velocity space) is guaranteed. The reasoning is as follows. Since $p_{js} = m_s v_j + q_s A_j$, the arguments of the exponentials scale like

$$\exp\left(-\frac{v_j^2}{4v_{\text{th},s}^2} \right), \quad (4.16)$$

in v_j velocity space. There is also a spatial dependence in the argument of the exponential, through $A_j(z)$, but this does not affect the value of f_s at a given z value. The scaling described by Expression (4.16) not only ensures boundedness, but guarantees that velocity moments of all order exist, since

$$\left| \int_{-\infty}^{\infty} v^k e^{-v^2/(4v_{\text{th},s}^2)} dv \right| < \infty \, \forall k \in 0, 1, 2, \ldots$$

Hence, a convergent Hermite series representation for the g_s function, will guarantee that the DF in equation (3.1) allows velocity moments of all orders.

4.8   *Non-negativity of the Hermite polynomial solution*

The sign of the DF as written in equation (3.1) is identified with the sign of g_s, and hence non-negativity of the DF depends entirely on the non-negativity of the g_s function. It was demonstrated in e.g. Channell (1976); Allanson et al. (2016), that the non-negativity of the P_{zz} function does not necessarily guarantee non-negativity of the g_s function. For example, consider the pressure function originally studied by Channell (1976),

$$P_{zz} \propto \frac{1}{2}\left(a_0 + a_2\left(\frac{A_x}{B_0 L}\right)^2\right) + \frac{1}{2}\left(a_0 + a_2\left(\frac{A_y}{B_0 L}\right)^2\right),$$

with $a_0, a_2 > 0$. This pressure function is positive for all (A_x, A_y). However, the corresponding g_s function is of the form

$$g_s \propto \frac{1}{2}\left[a_0 + a_2\left(\frac{\delta_s}{\sqrt{2}}\right)^2 H_2\left(\frac{p_{xs}}{2\sqrt{\varepsilon_s}}\right)\right] + \frac{1}{2}\left[a_0 + a_2\left(\frac{\delta_s}{\sqrt{2}}\right)^2 H_2\left(\frac{p_{ys}}{2\sqrt{\varepsilon_s}}\right)\right].$$

By substituting $p_{xs} = p_{ys} = 0$, we see that positivity of g_s is – for given values of a_0 and a_2 – dependent on the size of ε_s,

$$g_s(0,0) = a_0 - a_2 \delta_s^2,$$
$$\therefore g_s(0,0) \geqslant 0 \implies \delta_s^2 \leqslant \frac{a_0}{a_2}.$$

The dependence of the sign of g_s on δ_s, seems to be a rather general principle. In Allanson et al. (2016) it was proven that for a smooth P_{zz} function (either summatively or multiplicatively separable), and under the *a priori* assumption of a continuous g_s function that is uniformly bounded from below in momentum space, the corresponding g_s function is non-negative for at least a finite range of δ_s values, i.e. for all $\delta_s \leqslant \delta_{c,s}$, for $\delta_{c,s} \in (0, \infty)$ some critical value of δ_s, and as yet undetermined. Here we generalise this result for the arbitrarily indexed general solution of the form in equation (4.7)

4.9   *The limit as $\delta_s \to 0$, $B_0 L \to \infty$ and fixed ε_s*

First suppose that for a given value of δ_s, that there exists some regions in $(p_{x,s}, p_{y,s})$ space where $g_s < 0$. Then, the *priori* assumption that g_s is uniformly bounded from below, combined with the expression in Equation (4.7) implies that the g_s function is bounded below according to

$$g_s(p_{x,s}, p_{y,s}; \varepsilon_s) > c_{0,0} + \delta_s \mathscr{M}$$

with $\mathscr{M}$ a finite constant,

$$\mathscr{M} = \frac{1}{\sqrt{2}} \inf_{(p_{x,s}, p_{y,s})} \sum_{n=1}^{\infty}\sum_{m=1}^{\infty} c_{m,n} \mathrm{sgn}(q_s)^{m+n}\left(\frac{\delta_s}{\sqrt{2}}\right)^{m+n-1} H_m\left(\frac{p_{x,s}}{2\sqrt{\varepsilon_s}}\right) H_n\left(\frac{p_{y,s}}{2\sqrt{\varepsilon_s}}\right),$$

i.e. the greatest lower bound of all terms in g_s above zeroth order. In Allanson et al. (2016), the next step in the (similar) argument was to let $\delta_s \to 0$, independently of ε_s (from equation (3.12), we see that this is equivalent to sending $B_0 L \to \infty$). We see that by letting $\delta_s \to 0$ whilst keeping ε_s fixed, that $\delta_s \mathscr{M} \to 0$, and so

$$\lim_{\delta_s \to 0} g_s = c_{0,0} = \lim_{B_0 L \to \infty} P_{zz} \geqslant 0, \quad \text{for fixed } \varepsilon_s > 0,$$

since $P_{zz} \geqslant 0 \forall (A_x, A_y)$. Therefore, there must exist some critical value of $\delta_s = \delta_{s,c}$, such that for all $\delta_s < \delta_c$, g_s is non-negative. Note that if the negative patches of g_{js} do not exist for any δ_s, then trivially $\delta_{s,c} = \infty$ as a special case.

5. Discussion & Conclusions

This paper has introduced and reviewed the theory first of collisionless plasma equilibria (Vlasov-Maxwell equilibria), and then of the inverse problem in collisionless plasma equilibria (IPCE) in a general sense. Then we have applied this theory to equlibrium distribution functions that are single valued functions of the constants of motion, and are self-consistent with spatially one-dimensional and strictly neutral magnetised plasmas. We have demonstrated that in this context, IPCE can reduce to the inversion of Weierstrass transforms, and discussed the parallels between IPCE and 'backwards solutions of the heat equation'. It will be a very interesting topic for future investigation to see if this analogy can bring further useful insight and results.

The main theoretical developments of this paper have focussed on the mathematical criteria that a candidate solution of IPCE must satisfy, and in particular for those solutions obtained by use of a Hermite polynomial expansion. We have reviewed the recent works by Allanson et al. (2015, 2016) on this topic and placed them in context with existing works using Hermite polynomials in Vlasov-Maxwell equilibria. We have derived new results relating to convergence and non-negativity of a candidate solution for IPCE, as well as the existence of velocity moments of all orders, for distribution functions that are consistent with an arbitrarily indexed 2D Maclaurin expansion of the pressure function. In particular, we have proven that non-negative solutions of IPCE will exist over all momentum space, and for some sections of parameter space, for candidate solutions belonging to a certain class. Future work should focus on extending the results regarding non-negativity to a broader class of solutions, since at present we have *a priori* assumed that the momentum-dependent part of the naive/formal solution to IPCE (the g_s function) is uniformly bounded from below, over all parameter and momentum space. It would be useful to understand to what extent this condition can be relaxed, and whether the aforementioned analogy with the heat equation can be brought to bear on this problem. Furthermore, we would like to establish precisely over which values of parameter space the candidate solution is non-negative, i.e. extend the results from being purely *existence* results, to something more concrete.

The other obvious generalisation is to relax earlier assumptions relating to the macroscopic nature of the plasma. For example, to what extent does IPCE change when applied to spatially 2D plasmas, non-strictly-neutral or even non-neutral, non-planar (e.g. cylindrical) geometries, or even the inclusion of gravitational effects? Future work could be directed in these directions, motivated by the many possible applications in plasma physics.
