Abstract

Background In this short report, we use data from a previous cohort study to explore the relationship between five out of eight consensus indicators for successful transition and patient-reported outcomes in young adulthood.

Methods Data came from a 6-year cohort study that consisted of a survey among 518 young adults with various chronic conditions and a review of their electronic patient records. Associations between five indicators for successful transition and background variables and patient-reported outcomes were explored with Spearman's r . Significant variables were included in stepwise (logistic) regression analyses with transition outcomes as dependent variables.

Results The indicators relate to some extent to better healthcare-related transition outcomes, but not to autonomy in participation. The explained variance of the models varied from 9.7% to 26.4%. The change in explained variance after adding indicators varied from 2% to 16%.

Conclusions The challenge of translating the definition of transition into holistic indicators remains. The current consensus indicators are a good start, but there is more to transition than transfer.

Keywords

indicators, transfer, transition, transition outcomes, young adults

Introduction

Over two decades ago, Blum *et al.* (1993) defined transition in health care as 'a multifaceted, active process that attends to the medical, psychosocial, and educational/vocational needs of adolescents as they move from the child-focused to the adult-focused health-care system', while emphasizing that this 'implies an increase in independent behavior and personal autonomy'. Since then, numerous research articles have been discussing aspects such as transfer readiness of adolescents and the need to improve paediatric practices to support them during their transition and transfer. In the past decade, more attention was paid to collaboration with and practices in adult care and to the study of transition outcomes in young adulthood. More specifically, the question of what constitutes a successful transition has been posed. Recently, Suris and Akre

(2015) conducted a Delphi study to reach international consensus on key elements of transitions programmes and indicators that could serve to assess the success of such programmes.

Given the holistic definition provided by Blum *et al.* (1993), transition programmes and indicators are expected to relate to the medical, psychosocial and educational/vocational outcomes in young people. In this short report, we use data from a previous cohort study (Sattoe *et al.* 2014; van Staa & Sattoe 2014) to explore the relationship between some of the consensus indicators for successful transition and patient-reported outcomes in young adulthood. These include outcomes in the medical, psychosocial and educational/vocational areas, independent behaviour and autonomy in participation. As such, insight could be gained into how current consensus on transition in the international literature

relates to transition outcomes in the light of the holistic definition of transition (Blum *et al.* 1993).

Methods

Study design and participants

The cohort study included a questionnaire among 518 young adults (YAs; aged 18–25 years) with various chronic conditions and a review of their medical files. Participants of a web-based survey in 2006 (T0) were re-invited for a similar survey 6 years later (T1). In 2006, they were adolescents aged 12 to 18 years and had been undergoing treatment in the Erasmus Medical Center – Sophia's Children's Hospital Rotterdam for more than 3 years. In 2012, death notices and contact information were retrieved from the hospital's electronic patient registry. Eligible YAs were invited through a letter that explained our study and provided a unique password to log in on a secured website. Reminders were carried out by mail after 1 month and by phone after another month. Respondents were entered in a lottery for 25 cookbooks, 2 smart phones and 1 iPad. The Medical Ethical Committee of the Erasmus Medical Center approved the study (MEC-2012-022).

Of the 1039 participants in the original study, 13 had died and 25 could not be traced. In 2012, 1001 YAs were invited to participate. Of these, 606 responded (60.5%) while 88 declined to participate. Consequently, 518 YAs submitted the survey (net response rate 51.8%). Thirty respondents did not mention their current healthcare provision, 48 were still in paediatric care and five did not provide all necessary information for the current analysis. Hence, the current study sample numbered 433 YAs.

Consensus indicators for successful transition

Our data allowed for the operationalization of five of the eight indicators (Suris & Akre, 2015):

- Indicator 1 – patient not lost to follow-up: It is recorded whether a patient is transferred and to where, and/or a note or letter of transfer of the patient to adult care is found in the electronic patient record (EPR) (yes/no). Those who score 'no' are no longer seen in pediatric care, but it is not clear whether and where they receive adult care treatment.
- Indicator 2 – attending scheduled visits in adult care: The patient has not missed any consultations in the 3 years after transfer (yes/no), as reported in the EPR.
- Indicator 3 – patient building a trusting relationship with adult provider: The patient trusts the current adult care provider as indicated by a score >15 on a scale of 5–20 (yes/no) in the survey. A five-item 4-point Likert scale (from 1 = "never" to 4 = "always"; $\alpha=0.90$) was used. This was measured in the questionnaire with a validated Dutch adaptation of one scale from the American Consumer Assessment of Health Plan Surveys questionnaire (Delnoij *et al.* 2006).
- Indicator 4 – continuing attention for self-management: The patient reports that professionals give ample attention to self-management topics (including non-medical issues) as indicated by a mean rating on all topics of ≥ 3 on a Likert scale of 1–5 (yes/no) in the survey. The topics included relationships and sexuality and subjects related to the prospects like family planning, further education, jobs and the chronic condition (Van Staa *et al.* 2015).
- Indicator 5 – patient and family satisfaction with transfer of care: The patient is satisfied with the process of transfer as indicated by a score of ≥ 7 on a 1–10 numeric scale (yes/no). No information on family satisfaction was available.

Background variables

Patient characteristics were age, gender, age at transfer, educational level (low/medium vs. high) and presence of a physical limitation (yes/no) (Sattoe *et al.* 2014; van Staa & Sattoe 2014).

Patient-reported transition outcomes

Transition outcomes were

- Adherence to therapeutic regimen, measured with the five-item Medication Adherence Report Scale [5-point Likert scales (from 1 = "never" to 5 = "always"; $\alpha=0.75$)] (Horne & Hankins, unpubl. observ.).
- Disease-related self-efficacy, measured with the 16-item On Your Own Feet Self-efficacy Scale [4-point Likert scales (from 1 = "no, definitely not" to 4 = "yes, certainly"; $\alpha=0.87$)] (van Staa 2012).
- Independence during consultations, self-rated on a 1–10 numeric scale.
- Actual independent behaviours during consultations, measured with the seven-item Independent Behaviors During Consultations Scale [5-point Likert scales (from 1 = "never" to 5 = "always"; $\alpha=0.79$)] (van Staa & Sattoe 2014).
- Health-related quality of life (HRQoL), measured with the 37-item DISABKIDS questionnaire [5-point Likert scales (from 1 = "often" to 5 = "never"; $\alpha=0.95$)] (Simeoni *et al.* 2007).

- Perceived impact of the chronic condition on vocational functioning, measured with a five-item scale (5-point Likert scales [from 1 = “totally disagree” to 5 = “totally agree”; $\alpha = 0.89$]) (Sattoe *et al.* 2014).
- Autonomy in social participation in seven life areas; measured with the Rotterdam Transition Profile (Donkervoort *et al.* 2009). The Rotterdam Transition Profile describes participation in seven life areas defined in the International Classification of Functioning, Disability, and Health: finances, employment and education, housing, intimate relationships, sexuality, transportation and leisure. We dichotomized the outcomes, a score of 1 indicated full autonomy in participation.

Analysis

Associations between indicators for successful transition and background variables and patient-reported outcomes were explored with Spearman's r . Significant variables were included in stepwise (logistic) regression analyses with the transition outcomes as dependent variables. The first step included background variables; the second step added the indicators. Backward logistic analysis was used to test if background and outcome variables were associated with being included in the regression analysis or not. Data were analysed with SPSS 20.

Results

Characteristics of the current study sample and scores per indicator are presented in Table 1. In the study sample, 73.7% of the YAs were not lost to follow-up after transfer (indicator 1; i.e. a transfer note was available in the chart) and 87.4% attended all scheduled visits in adult care in the 3 years after transfer (indicator 2). Less than half of the YAs (45.2%) reported continuing attention for self-management after transfer (indicator 3), 66.2% built a trusting relationship with their adult care provider (indicator 4), and 64.5% were satisfied with the transfer of care (indicator 5) (Table 1). In bivariate correlation analysis, the indicators were not associated with educational level, self-reported adherence and autonomy in social participation on all life areas except the financial domain. Associations with the latter were non-significant in the regression analysis. Because of the large number of missing data in indicators 2 and 4, the multivariate models included 178 cases. Backward logistic regression showed that the YAs without any missing data were older

Table 1. Characteristics of the study sample and scores per indicator ($n = 433$)

Characteristics	
Age [mean \pm SD]	20.76 \pm 1.88
Gender (male) [n (%)]	161 (37.2)
Level of education (high) [n (%)] ^a	192 (45.4)
Age at transfer [mean \pm SD] ^b	17.45 \pm 2.00
Physical limitation (yes) [n (%)] ^c	124 (28.8)
Consensus indicators	
Indicator 1 – patient not lost to follow-up (yes) [n (%)]	319 (73.7)
Indicator 2 – attending scheduled visits in adult care (yes) [n (%)] ^d	216 (87.4)
Indicator 3 – patient building a trusting relationship with adult provider (yes) [n (%)] ^e	215 (66.2)
Indicator 4 – continuing attention for self-management after transfer (yes) [n (%)] ^e	147 (45.2)
Indicator 5 – patient satisfaction with transfer of care (yes) [n (%)] ^f	267 (64.5)

^a $n = 10$ missing;

^b $n = 30$ missing;

^c $n = 3$ missing;

^d $n = 186$ missing (because only young people who transferred 3 years or longer ago at time of the chart review were included, and these data were only available for patients transferred within the same hospital);

^e $n = 108$ missing;

^f $n = 19$ missing.

and were transferred at younger age compared with YAs with missing data, but no associations with any transition outcomes appeared.

Not being lost to follow-up (indicator 1) was negatively associated with disease-related self-efficacy, while building a trusting relationship with the adult provider and patient satisfaction with the transfer of care (indicators 3 and 5) had positive associations with self-efficacy. Not attending all scheduled visits in adult care (indicator 2) was negatively associated with disease-related self-efficacy and self-rated independence and independent behaviours during consultations. Continuing attention for self-management in adult care (indicator 4) was positively associated with HRQoL and negatively with perceived impact of the chronic condition on vocational functioning (i.e. with less impact). The explained variance of the models varied from 9.7% to 26.4%. The change in explained variance after adding indicators in step 2 varied from 2% to 16% (Table 2).

Discussion

Continuing attention for self-management in adult care (indicator 4) was the only indicator associated with higher HRQoL and less perceived impact on vocational functioning. HRQoL is considered an important patient-reported outcome

Table 2. Results of regression analyses ($n = 178$)

Model	Standardized betas (β) of step 2	P value
Disease-related self-efficacy		
Step 1: explained variance $R^2 = 0.10$; F value (d.f.): 4.78 (4, 173); $P = 0.001$

Continues

Table 2. (Continued)

Model	Standardized betas (β) of step 2	P value
Indicator 2 – attending scheduled visits in adult care	–0.11	0.16
Indicator 3 – patient building a trusting relationship with adult provider	–0.03	0.66
Indicator 4 – continuing attention for self-management	–0.22	0.004
Indicator 5 – patient and family satisfaction with transfer of care	–0.06	0.42
Autonomy in social participation, financial domain	Odds ratio (CI) of step 2	P value
Step 1: explained variance $R^2 = 0.21$; $\chi^2 = 31.33$, d.f. = 4; $P < 0.001$		
Age	1.67 (1.22–2.29)	0.001
Gender (male)	0.77 (0.37–1.60)	0.48
Age at transfer	0.95 (0.69–1.31)	0.75
Physical limitation (yes)	2.78 (1.36–5.71)	0.005
Step 2: explained variance: $R^2 = 0.23$; $\chi^2 = 33.93$, d.f. = 9; $P < 0.001$		
Indicator 1 – patient not lost to follow-up	1.26 (0.52–3.03)	0.60
Indicator 2 – attending scheduled visits in adult care	0.80 (0.31–2.07)	0.65
Indicator 3 – patient building a trusting relationship with adult provider	0.73 (0.35–1.51)	0.39
Indicator 4 – continuing attention for self-management	1.32 (0.67–2.57)	0.42
Indicator 5 – patient satisfaction with transfer of care	1.48 (0.74–2.98)	0.27

as well as a relevant transition outcome (Fair *et al.* 2016). Still, receiving continuing attention for self-management was reported by less than half of the sample. This finding highlights the challenge for adult care to incorporate a more holistic approach to care delivery for YAs with chronic conditions. Moreover, the international transition community seems to be facing this challenge, too, because all other consensus indicators concern continuity of care and healthcare-related outcomes (Suris & Akre, 2015). It therefore comes as no surprise that the indicators explained some of the variance of healthcare-related outcomes and none of the variance in social participation. Thus, when using these indicators to define successful transition, most emphasis will be placed on the medical aspect, i.e. the transfer of care, and much less on young people's successful transition to adulthood (i.e. reaching their full potential). This narrow focus does not seem to be justified, because the transfer of care is influenced by the transition to adulthood (Sattoe 2015). Moreover, young people themselves repeatedly stress the importance of non-medical themes when asked about their lived experiences (Taylor *et al.* 2008). The results suggest that the consensus indicators cover the medical aspects of transition, but do not address the psychosocial and participation outcomes. So, although the holistic definition of transition seems to be leading for over 20 years, the challenge of translating it into holistic indicators and practice remains. The current consensus indicators are a good start, but there is more to transition than transfer.

Two limitations of this study must be considered. First, loss to follow-up (indicator 1) can be operationalized in different ways. We used data from the EPR, whether the transfer to adult care was recorded and where young people were transferred to. It cannot be ruled out that YAs, classified as 'lost to follow-up', are

seen in adult care without knowledge of their paediatric care provider. Still, a comparison of the EPR data about referrals with patient-reported data (from the questionnaire) on current providers confirmed that a quarter of young people were not in regular (specialist) care anymore ($n = 125$; 25.6%). Agreement on the current provider between EPR and patient-reported data was only found in 293 out of 488 cases (60.0%). Kappa was 0.40 (95% CI, 0.34–0.46), indicating 'fair' agreement. Most disagreement was found in the group of YAs stating they are 'not in active treatment anymore'.

Finally, indicator 4 had many missing values on the scale measuring continuing attention for self-management. As this is the only indicator related to HRQoL and vocational functioning, we compared the cases with missing values with those without missing values on these outcome measures. Our additional analysis showed that the group without missing values reported lower HRQoL and more perceived impact on vocational functioning. This might have influenced the score of the study sample on indicator 4, but we think the associations found still emphasize the need for a broader view on transition.

Key messages

- The indicators relate to some extent to better healthcare-related transition outcomes, but not to more autonomy in participation. Additional indicators are needed to encourage healthcare services to cover both the medical and non-medical challenges that adolescents and YAs face and to assess the success of more holistic transition programmes.

Funding

The On Your Own Feet programme (2004–2008) was funded by ZonMw, The Netherlands Organization for Health Research and Development (grant 32560005) and the Dutch charity foundation Kinderpostzegels (grant 23674/1/4). The follow-up study was performed in the framework of the Self-management and Participation Innovation Lab, supported by SIA-RAAK, the Foundation Innovation Alliance with funding from the Dutch Ministry of Education, Culture and Science (OCW) (PRO-02-025).

Conflict of interests

The funding sources had no role in the design and conduct of the study; collection, management, analysis and interpretation of the data; preparation, review or approval of the manuscript; and decision to submit the manuscript for publication.

Acknowledgements

The authors thank the other members of the On Your Own Feet Research Group, Jos Latour, Susan Jedeloo and Linda van der Knaap, for their support in the design and execution of the study. Laila Oumansour, Wendy de Boer, Marjolijn Bal and Mariëlle Peeters are thanked for their assistance in collecting data.
