# sdg Interacting boson model : two nucleon transfer 

Y D Devi and V K B Kota<br>Physical Research Laboratory, Ahmedabad-380 009, Indıa

#### Abstract

A brief overview of the $s d g$ interacting boson model ( $s d g$ IBM) is given The two examples: (1) spectroscopic properties (spectra. $B(E 2)$ 's, $B(E 4)$ 's etc) of the rotor- $\gamma$ unstable transitional Os -Pt isotopes and (11) the analytical formulation of two nucleon transfer spectroscopic factors and sum-rule quantities are described in detail They demonstrate that  that large number of analytical formulas, which faciltate rapid analysis of data and provide a clear insight into the underlying structures, can be derived using sdgIBM dynamical symmetries respectuvely

## Keywords : Nuclear structure, interactung boson model

PACS No. : 21.10-k

## 1. Introduction

In the past few years considerable amount of experimental data on $E 4$ matrix elements, strength distributions and other observables that involve hexadecupole degree of freedom in nuclei has started accumulating and their theoretical understanding (using models or microscopic theories) is a challenging problem. This together with the microscopic theories of interacting boson model (IBM; which includes $l=0$ ( $s$-boson representing the pairing degree of freedom) and $l=2$ ( $d$-boson representing the quadrupole degree of freedom) bosorts) and several other indirect signatures indicating that $l=4$ ( $g$-boson representing the hexadecupole degree of freedom) bosons should be included in IBM. lead to the development of the extended $s d g$ interacting boson model ( $s d g$ IBM or simply $g$ IBM). The $s d g$ IBM is the only plausible model that allows one to systematically analyze hexadecupole data and understand the role of hexadecupole degree of freedom in nuclei (Devi and Kota 1992a).

Section 2 gives a brief overview of the various aspects of $s d g$ IBM including data analysis. The two specific examples of sdgIBM studies : (i) systematic analysis of
spectroscopic properties of $\mathrm{Pt}-\mathrm{Os}$ isotopes; (ii) the analytical formulation of two nucleon transfer spectroscopic factors and sum-rule quantities are described in detail in Sections 3 and 4 respectively. Finally Section 4 gives some concluding remarks.

## 2. $s d g$ IBM

In order to explore, understand and apply the salg interacting boson model which is ideally suited for the study of hexadecupole properties of atomic nuclei, we carried out large number of studes by exploiting the dynamical symnetres (analytical in nature) and their interpolations (numerical in nature) and it is established with good number of examples that sdg IBM is a viable and powerful tool for systematically analyzing $E 4$ propertics of nuclei. These studies and the contributions by various other research groups, to the development of this model are reviewed recently (Devi and Kota 1992a, Kota and Devi 1993). A schematic outline of all these studies is given in Figure I. In this article no attempt is made to describe all the developments in $s d g$ IBM as complete details are given emphasizing the sdg IBM analysis of hexadecupole observables in (Devi and Kota 1992a) and dynamical symmetry aspects of the sdg IBM in (Kota and Devi 1993). In the following two sections two specific studies are described in some detail, one emphasiang the numerical aspects and the other emphasizing the analytical aspects of $s d g$ IBM.

## 3. Spectroscopy of Pt -Os isotopes

Our purpose here is to show that a simple hamiltonan $H_{S Y M}$ (with 6-8 free parameters) defined in terms of Casimir operators of gIBM dynamical symmetries and a truncated space with no more than $g$-bosons (the resulting hamiltonian matrix dimensions being ~ 100) describes the spectroscopic properties of a cham of isotopes. To this end we choose the rotor $\gamma$ unstable transitional $\mathrm{Pt}=\mathrm{Os}$ s.sotopes: ${ }^{198} \mathrm{Pt},{ }^{196} \mathrm{Pt}{ }^{194} \mathrm{Pt}$ and ${ }^{192} \mathrm{Os}$. For these isotopes, recently the $E 4$ matrix elements for the decay of the first few $4^{+}$levels to the ground state (GS) are deduced from the inelastic scattering of polarized protons ( $\bar{p}, p^{\prime}$ ) (Todd Baker et al 1989; Sethı et al 199(), 1991). The falure of attempts to describe this data within $s d$ IBM and $s d$ IBM $\oplus \mid g$ models lead to the present study with two $g$-bosons.

A simple hamiltonian $H_{S Y M}$ interpolating sdgIBM dynamical symmetries and $E 2$ and $E 4$ transition operators interpolating the group generators are employed in the calculations. The $H_{S Y M}$ is

$$
\begin{aligned}
H_{S Y N} & =\varepsilon_{d} \hat{n}_{d}+\varepsilon_{g} \hat{n}_{g}+\alpha_{1}\left[H\left(S U_{v d g}(3)\right)\right]+\alpha_{2}\left[H\left(S U_{v d g}(5)\right)\right] \\
& +\alpha_{3}\left[H\left(S U_{s d g}(6)\right)\right]+\alpha_{4}\left[H\left(O_{s d k}(15)\right)\right]+\alpha_{5}\left[H\left(O_{v d}(6)\right)\right] \\
& +\alpha_{6}[H(O(3))] H\left(S U_{v d g}(3)\right)=-\frac{3}{4} Q^{2}(s) \cdot Q^{2}(s)
\end{aligned}
$$

Figure 1. Schematic overview of various evelopments in sdgIBM

$$
\begin{align*}
& Q_{\mu}^{2}(s)=4 \sqrt{\frac{7}{15}}\left(s^{\dagger} \tilde{d}+d^{+} \tilde{s}\right)_{\mu}^{2}-11 \sqrt{\frac{2}{21}}\left(d^{\dagger} \tilde{d}\right)_{\mu}^{2}+\frac{36}{\sqrt{105}}\left(d^{\dagger} \tilde{g}+g^{\dagger} \tilde{d}\right)_{\mu}^{2} \\
& -2 \sqrt{\frac{33}{7}\left(g^{+} \tilde{g}\right)_{\mu}^{2}} ; H\left(S U_{\mathrm{sdg}}(5)\right)=-4\left\{G^{2} \cdot G^{2}+G^{4} \cdot G^{4}\right\} ; \\
& G_{\mu}^{2}=\frac{1}{\sqrt{5}}\left(\left(s^{\dagger} \tilde{d}+d^{\dagger} \tilde{s}\right)_{\mu}^{2}-\sqrt{\frac{3}{14}}\left(d^{\dagger} \tilde{d}\right)_{\mu}^{2}+\frac{6}{\sqrt{245}}\left(d^{\dagger} \tilde{g}+g^{\dagger} \tilde{d}\right)_{\mu}^{2}\right. \\
& +\frac{\sqrt{198}}{14}\left(g^{\dagger} \tilde{g}\right)_{\mu}^{2} G_{\mu}^{4}=\frac{1}{\sqrt{5}}\left(\left(s^{\dagger} \tilde{g}+g^{\dagger} \tilde{s}\right)_{\mu}^{4}+\frac{2}{7}\left(d^{\dagger} \tilde{d}\right)_{\mu}^{4}\right. \\
& +\sqrt{\frac{55}{98}}\left(d^{\dagger} \tilde{g}+g^{\dagger} \tilde{d}\right)_{\mu}^{4}+\sqrt{\frac{143}{980}}\left(g^{\dagger} \tilde{g}\right)_{\mu}^{4} ; H\left(S U_{s d g}(6)\right) \\
& =-4\left\{h^{2} \cdot h^{2}+h^{4} \cdot h^{4}\right\} ; \\
& h_{\mu}^{2}=-\frac{1}{\sqrt{6}}\left(s^{+} \tilde{d}+d^{+} \tilde{s}\right)_{\mu}^{2}+\frac{5}{7 \sqrt{6}}\left(d^{+} \tilde{d}\right)_{\mu}^{2}-\frac{9}{14 \sqrt{2}}\left(d^{+} \tilde{g}+g^{+} \tilde{d}\right)_{\mu}^{2} \\
& -\frac{\sqrt{33}}{14}\left(g^{+} \tilde{g}\right)_{\mu}^{2} \\
& h_{\mu}^{4}=-\frac{1}{\sqrt{6}}\left(s^{\dagger} \tilde{g}+g^{\dagger} \tilde{s}\right)_{\mu}^{4}-\frac{3}{14} \sqrt{\frac{5}{2}}\left(d^{\dagger} \tilde{d}\right)_{\mu}^{4}-\frac{1}{14} \sqrt{\frac{55}{3}}\left(d^{\dagger} \tilde{g}+g^{\dagger} \tilde{d}\right)_{\mu}^{4} \\
& +\frac{1}{14} \sqrt{\frac{143}{2}}\left(g^{\dagger} \tilde{g}\right)_{\mu}^{4} ; \\
& H\left(O_{s d g}(15)\right)=I^{2 \cdot 2}+I^{4} \cdot I^{4} ; I_{\mu}^{2}=\left(s^{\dagger} \tilde{d}+d^{\dagger} \tilde{s}\right)_{\mu}^{2}, I_{\mu}^{4}=\left(s^{\dagger} \tilde{g}+g^{1} \tilde{s}\right)_{\mu}^{4} ; \\
& H\left(O_{s d}(6)\right)=I^{2} \cdot I^{2} \\
& H(O(3))=\mathbf{L} . \mathbf{L} ; \mathbf{L}_{\mu}^{1}=\sqrt{10}\left\{\left(d^{+} \tilde{d}\right)_{\mu}^{1}+\sqrt{6}\left(g^{+} \tilde{g}\right)_{\mu}^{1}\right\} \tag{1}
\end{align*}
$$

In (1) $\left\{Q^{2}(s)\right\},\left\{U^{2}, G^{4}\right\},\left\{h^{2}, h^{4}\right\}$ and $\left\{R^{2}, I^{4}\right\}$ are generators of $S U_{v d g}(3), S U_{\text {sdg }}(5)$, $S U_{s d g}(6)$ and $O_{s d g}(15)$ respectively ( $I^{2}$ is also a generator of $O_{s d}(6)$ ). The E2 and E4 transition operators are chosen keeping in mind that $S U_{\mathrm{sdg}}(3)$ and $O_{\mathrm{vdg}}(15)$ symmetries are relevent for the nuclei in $\mathrm{Os}-\mathrm{Pt}$ region. In terms of $S U_{\mathrm{sdg}}$ (3) quadrupole generator $Q_{\mu}^{2}(s)$ and the $O_{\text {sdg }}(15)$ (or $O_{s d}(6)$ ) quardrupole generator $I_{\mu}^{2}$ of eq. (1), the $E 2$ operator is $T^{E 2}=\alpha\left[Q_{\mu}^{2}(s)+\beta I_{\mu}^{2}\right]$. Similarly the $E 4$ transition operator is chosen to be a linear combination on the $Q_{o s c}^{4}$,

$$
\begin{align*}
Q_{\text {osc. } \mu}^{4} & =\left[\left(s^{\dagger} \tilde{g}+g^{+} \tilde{s}\right)_{\mu}^{4}+\frac{19 \sqrt{5}}{28}\left(d^{+} \tilde{d}\right)_{\mu}^{4}-\frac{5 \sqrt{11}}{14}\left(d^{+} \tilde{g}+g^{4} \tilde{d}\right)_{\mu}^{4}\right. \\
& +\frac{3 \sqrt{143}}{28}\left(g^{+} \tilde{g}\right)_{\mu}^{4} \tag{2}
\end{align*}
$$

and the $O_{\text {sdg }}(15)$ rank-4 generator $I_{\mu}^{4}$ defined in (1), $T^{E 4}=\xi\left[I_{\mu}^{4}+\eta Q_{N, x}^{4} \mu\right]$. It should be noted that although $Q_{o s c}^{4}$ is not a generator of any of the gIBM dynamical symmetries, it can be viewed as a close analogue of $Q^{2}(s)$ but of rank-4, as the factors multyplying the terms in the $Q_{\text {osc }}^{4}$ are obtained by evaluating the matrix elements of $r^{4} Y^{4}$ operator in the $s d g$ harmonic oscillator basis and it is successfully used in earlier studies describing data relating to E4 observables (Devi and Kota 1992b).

With the transition operators given in (2) and (3), $B(E 2)$ values,

$$
B\left(E 2 ; L_{t} \rightarrow L_{t}\right)=\begin{gathered}
\left|\left\langle L_{f}\left\|T^{E 2}\right\|_{L_{t}}\right\rangle\right|^{2} \\
\left(2 L_{t}+1\right)
\end{gathered}
$$

and the absolute $E 2$ and $E 4$ reduced matrix elements

$$
M\left(E \lambda ; L_{t} \rightarrow L_{f}\right)=\mid<L_{f}\left\|T^{E \lambda}\right\| L_{t} \quad ; \lambda=2,4
$$

are calculated and compared with data.
The boson number $N=5,6,7$ and 8 for ${ }^{198} \mathrm{Pt},{ }^{196} \mathrm{Pt},{ }^{194} \mathrm{Pt}$ and ${ }^{192} \mathrm{Os}$ and based on occupation numbers one sees that one can safely use a truncated space $n_{1} \geq 1,2,2$ and 2 respectively. The successful calculations for Sm isotopes (Devi and Kota 1992b) lead to the restriction $n_{g} \leq 2$. With these truncations (the maximum hamiltonian matrix dimensions being 27, 27, 53 and 95 respectively) and with the parameters given in Table 1. The spectra

Figure 2. Experimental and calculated (sdgIBM) spectra for Os -pt isotopes.
occupation numbers and from them one can inier the hexadecupole content in the wavefunctions. It is seen from the figures that the quality of agreements in the sdgIBM (2g) calculations is much better than in $s d \times 1 g$ and as good as $g I B M$ (fult) results. Thine quality
of agreements extends to $E 2$ and $E 4$ transition matrix elements; the results are given in Tables $2 a-d$ and Table 3 respectively. Thus the consistently good description of spectra,

$E 2$ and $E 4$ properties with a $2 g$-boson truncation establishes that the present truncation scheme is meaningful for $\mathrm{Pt}-\mathrm{Os}$ isotopes.

## 4. Two nucleon transfer

Two nucleon transfer (TNT) cross sections and the corresponding spectroscopic factors (or strengths) are one of the most valuable observables in nuclear structure and they provide deeper insights into effects due to pairing degrees of freedom, single particle aspects etc. The IBM provides a natural frame work for a unified and analytical description of TNT strengths and cross sections. This analytical feature of IBM together with the rich dynamical symmetry structures in $s d g$ IBM make TNT studies in $s d g$ IBM an ideal probe to infer the structure of the excited rotational bands (two phonon quadrupole, one phonon
hexadecupole vibrational, two quasi particle) and also about shapes and shape phase transitions.

In sdgIBM the TNT operators for $l=0,2,4$ transfers, ignoring cut-off factors (Devi and Kota 1991) that depend on boson numbers, are

$$
\begin{array}{lll}
P^{l=0} & =\eta+{ }_{0} s^{+} & P_{-}^{l=0}=\eta-{ }_{0} \tilde{s} \\
P_{+}^{l=2} & =\eta+{ }_{2} d^{\dagger} & P^{l=2}=\eta-2 \tilde{d} \\
P_{+}^{l=4} & =\eta+{ }_{4} g^{+} & P_{-}^{l=4}=\eta-{ }_{4} \tilde{g}
\end{array}
$$

where ( + ) is for particle addition and $(-)$ is for particle removal and $\eta$ 's are free parameters. Employing these operators analytical expressions for TNT strengths

$$
\begin{equation*}
S_{l}^{( \pm)}\left(N ; 0_{G S}^{+} \rightarrow N \pm 1 ; L_{f}^{+}\right)=(\eta \pm l)^{2}\left|\left\langle N \pm 1 ; L_{f}^{+}\left\|P_{( \pm)}^{l}\right\| N ; 0_{G S}^{+}\right\rangle\right\rangle^{2} \delta_{l u . f} \tag{3}
\end{equation*}
$$

in the $S U_{\text {adg }}(3)$ limit are reported by Devi and Kota (1991) and for the $S U_{\text {, }}(3) \times 1 \mathrm{~g}$ limit the results are reported here.

In the $S U_{\text {sdg }}(3)$ limit as shown in Figure 3, in addition to the usual ground, beta and gamma bands generated by the $S U(3)$ irreducible representations (irreps) $(4 N, 0) K^{\pi}=0$, $(4 N-4,2) K^{\pi}=0$ and $(4 N-4,2) K^{\pi}=2$ respectively, there are two new features: (i) odd $K$ bands arising due to the irrep $(4 N-6,3) K^{\pi}=1,3$; (ii) two types of $4^{+}$(also $0^{+}$and $2^{+}$bands)

Figure 3. Analytical expressions for TNT strengths in the $\mathrm{SU}_{\text {sdg }}($ (3) limit.
arising from the two $(4 N-8,4)$ irreps labeled $\alpha=0,1$. From the structure of the intrinsic states shown in the inset to Figure 3, the $\alpha=0$ bands are two phonon in nature and the $\alpha=$

1 bands are one phonon hexadecupole in nature. The analytical expressions (functions of $N$ the boson number) given in Figure 3 allow the rapid analysis of data and makes transparent the structure of rotational bands as the selection rule forbidding (indicated by dashed lines in the figure) the excitation of two phonon bands. In fact the branching/selection rules provided by these analytical expressions explain the observed TNT strengths in the ${ }^{166} \mathrm{Er}(t, p){ }^{168} \mathrm{Er}$ data; details of this data analysis are given ahead.

In the $S U_{s d}(3) \times 1 \mathrm{~g}$ limit the coupling of a $g$-boson to the core described by the $S U_{s d}(3)$ limit gives rise to $K^{\pi}=0,1,2,3,4$ bands in addition to the ground, beta and gamma bands generated by the $(2 N, 0) K^{\pi}=0,(2 N-4,2) K^{\pi}=0$ and $(2 N-4,2) K^{\pi}=2$ irreps of $S U_{s d}(3)$ limit respectively and the two phonon quadrupole bands arising due to $(2 N-8,4)$ irrep with $K^{\pi}=0,2,4$. The analytical expressions for TNT strengths are shown in Figure 4.

Figure 4. Analytical expressions for TNT strengths in the $\mathrm{SU}_{s d}(3) \times 1 \mathrm{~g}$ limit.
These results establish that TNT studies clearly determine the appropriateness of $S U_{s d g}(3)$ limit and the $S U_{s d}(3) \times 1 \mathrm{~g}$ limit descriptions as in the example of ${ }^{166} \mathrm{Er}(t, p){ }^{168} \mathrm{Er}$ data described below;

- The strength to $I K^{\pi}=44^{+}$at 2.06 MeV is observed to be rather weak. In the $S U_{s d g}(3)$ limit this level belongs to $(4 N-4,4)_{\alpha=0}$ which is two-phonon in nature and the selection rule then explains the data. In the $S U_{s d}(3) \times 1 \mathrm{~g}$ limit this level belongs to $(2 N-6,4)$ irrep as shown in Figure 4 which then also explains the selection rule.
- In $S u_{s d}(3)$ and $S U_{s d}(3) \times 1 \mathrm{~g}$ limits $K^{\pi}=0_{3}^{+}, 0_{4}^{+}$and $2_{2}^{+}$cannot be excited. These forbidden levels are observed experimentally. The strengths to $0_{1}^{+}, 0_{2}^{+}$( 1.217 $\mathrm{MeV}), 0_{3}^{+}(1.422 \mathrm{MeV})$ and $\mathrm{O}_{4}^{+}(1.833 \mathrm{MeV})$ are $(100,15,10,2.4)$ and ( $100,8.4$, $15.2,0)$ in experiment and $S U_{\text {sdg }}(3)$ limit respectively.
- The strength to $I K^{\pi}=22_{2}^{+}$is 6 times the strength to $22_{1}^{+}$in $S U_{, d g}(3)$ limit and the data value is $5 ; 22_{2}^{+}$belongs to $(4 N-8,4)_{\alpha=0}$. In the $S U_{s d}(3) \times 1 g$ limit the value of this ratio is zero.
- The $4_{5}^{+}(1.737 \mathrm{MeV})$ level is strongly populated in experiments. In $S U_{s d g}(3)$ limit this level belongs $43_{1}^{+}$and then single step excitation to this level is possible which then explains the data. This is a forbidden transition in the $S U_{\text {, }}(3) \times 1 \mathrm{~g}$ limit.

Thus TNT studies in $S U_{s d}(3) \times 1 \mathrm{~g}$ and $S U_{\text {sdg }}(3)$ limits clearly establish that ${ }^{168} \mathrm{Er}$ is a good $S U_{v d_{k}}(3)$ nucleus.

In general going beyond dynamical symmetries TNT studies can still have analytical formulation by considering the ratio $R_{ \pm}$(the advantage in dealing with this ratio is that it makes it a good approximation to deal with spectroscopic factors in place of cross sections) proposed by Grarrett et al (1990) which results in a sum-rule quantity in sdgIBM,

$$
\begin{align*}
R_{ \pm} & =\frac{\sum_{f \neq G S} S_{(l=0)}^{( \pm)}\left(N ; 0_{G S}^{+} \rightarrow N \pm 1 ; 0_{f}^{+}\right)}{S_{(l=0)}^{( \pm)}\left(N ; 0_{G S}^{+} \rightarrow N \pm 1 ; 0_{G S}^{+}\right)} \\
R_{+} & =\frac{1+\left\langle N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right| s^{\dagger} s\left|N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right\rangle}{\left.\left|\left\langle N+1 ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right| s^{\dagger}\right| N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right\rangle\left.\right|^{2}}-1 \\
& =\frac{\left(\beta_{2}^{0}\right)^{2}+\left(\beta_{4}^{0}\right)^{2}}{N}+O\left(1 / N^{2}\right)  \tag{4}\\
R_{-} & =\frac{\left\langle N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right| s^{\dagger} s\left|N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right\rangle}{\left.\left|\left\langle N-1 ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right| s\right| N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right\rangle\left.\right|^{2}}-1 \\
& =0 \text { in all cases } \tag{5}
\end{align*}
$$

The equilibrium coherent states $\left|N ; \beta_{2}^{0}, \beta_{4}^{0}, \gamma^{0}\right\rangle$ are determined for all the dynamical symmetries of sdg IBM by Devi and Kota (1990). The analytical results in eqs. $(4,5)$ are used in analyzing the data (data is due to D.G.Burke; private communication) for the ratio $R$ in rare-earth nuclei and the results are shown in Figure 5. Due to particle-hole symmetry in determining the boson number $N$, both the $(t, p)$ data shown in the Figure 5 correspond to $R$ $=R_{+}$. The analysis clearly brings out the regions of applicability of sdg dynamical symmetries (the ratio $R$ is same for both $S U_{s d g}(3)$ and $S U_{s d g}(5)$ limits) and they are consistant with the conclusions drawn from coherent state studies (Devi and Kota 1990).

Although the average trend in data is well explained by symmetry limits, there are peaks observed (for example in the neutron number 90 region) and they correspond to shapephase transitions. To describe the peaks a hamiltonian interpolating shperical-deformed

Figure 5. Experimental data for the ratio $R$ in rare-earth nuclet and the corresponding sdgIBM results
shapes is employed in a detailed $s d g$ IBM numerical calculations (Devi and Kota 1992b) and the peak is well described by the calculations (big circles in Figure 5). Thus the analysis of the ratio $R$ gives information on the regions of relevance of $s d g$ IBM dynamical symmetries ((i.e.) about shapes) and also about shape phase transitions.

## 5. Conclusions

The two specific examples: (i) the spectroscopy of a chain of isotopes (i.e.) the rotor- $\gamma$ unstable transitional $\mathrm{Pt}-\mathrm{Os}$ isotopes; (ii) the analytical formulation of two nucleon transfer strength in $S U_{s d g}(3), S U_{s d}(3) \times 1 g$ limits and the ratio $R$, demonstrate that $s d g$ IBM is a powerful and viable tool in analyzing collective spectroscopic properties of heavy nuclei. In order to include the description of single particle aspects one has to extend sdgIBM to include a few (1-4) quasi particle excitations and this project is in progress (Devi and Kota 1993).

## Note added in proof :

In Figure $4 S_{(1)}^{(+)}\left(N ;(2 N, 9) 0_{G S}^{+} \rightarrow N+1 ;(2 N-2,2) K_{f}=0^{+}, L_{f}=\mathrm{C}_{f}^{+}\right)$should be $2 / 3$ but not $(2 / 3)(1+1 / N)$. The $S_{l}^{+}$strengths shown in Figures 3,4 satisfy some important sum rules. For example $\sum_{L_{f}} S_{(1)}^{(+)}\left(N ;(\eta N, 0) 0_{G i}^{+} \rightarrow N+1 ;\left(\lambda_{f} \mu_{f}\right) K_{f} L_{t}\right)$ is $\left(2-\delta_{K_{t}}, 0\right)$ for the ground and one phonon bands while it is zero for the two phonon bands; $\eta=4$ for $\mathrm{SU}_{\mathrm{sdg}}(3)$ and 2 for $\mathrm{SU}_{s d}(3) \times 1 \mathrm{~g}$. Note that the sum rule is inciependent of $\eta$. Another sum rule (called $S\left(\lambda_{f} \mu_{f}\right)$ ) is

$$
\begin{aligned}
& \sum_{K_{r}, L_{f}} S_{(l)}^{(+)}\left(N ;(\eta N, 0) 0_{G S}^{+} \rightarrow N+1 ;\left(\lambda_{f} \mu_{f}\right) K_{f} L_{f}\right)=1<\quad>1^{2} \\
& \quad \times d\left(\lambda_{f} \mu_{f}\right) / d(\eta N .0)
\end{aligned}
$$

where the triple barred matrix element < III III > is the SU(3) CFP defined in (Devi and Kota 1991, 1992a) and $d\left(\lambda_{\mu}\right)$ is $\operatorname{SU}(3)$ dimension. We derived explicitly that $S\left(\lambda_{f} \mu_{f}\right)=$ $N\left(1+\frac{3}{N}\right)$ for $\left(\lambda_{f} \mu_{f}\right)=(4 N+4,0)$ and $3\left(1+\frac{5}{4 N}\right)$ for (4N,2) irrep in $S U_{s d g}(3)$ case. Similarly, in the $S U_{s d}(3) \times 1 g$ case $S\left(\lambda_{f} \mu_{f}\right)$ takes values $N\left(1+\frac{3}{N}\right)$ and $3\left(1-\frac{1}{2 N}\right)$
for ( $2 N+2,0$ ) and ( $2 N-2,2$ ) irreps respectively. The expressions given in Figures 3, 4 satisfy both the above sum rules. The sum rules show that there is a one to one correspondence between the low-lying irreps of $\mathrm{SU}_{s d g}(3)$ and $\mathrm{SU}_{s d}(3) \times I g$ limits and one difference hetwcen the two limits is in the nature of fragmentation of TNT strength. In data analysis, the sum rules can be used to distinguish between the $S U_{s d g}(3)$ and $S U_{s d}(3) \times 1 g$ descriptions.
