Naito<sup>1</sup> and G. Ichihara<sup>1</sup>. <sup>1</sup>Department of Occupational & Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Japan; <sup>2</sup>Neuropsychopharmacology, Nagoya University Graduate School of Medicine, Nagoya, Japan; <sup>3</sup>Mie University Graduate School of Regional Innovation Studies, Tsu, Japan.

**Purpose:** People with 1-bromopropane (1-BP) intoxication show depression and reduction of cognitive function and memory. The present study tested the hypothesis that 1-BP suppresses neurogenesis in the dentate gyrus which is involved in higher cerebral function in adult rats.

**Methods:** Four groups of twelve male Wistar rats were exposed to 1-BP at 0, 400, 800 and 1000 ppm, 8 hrs/day for 7 days. Other four groups of six rats were exposed to 1-BP at 0, 400, 800 and 1000 ppm for two weeks and 0, 200, 400 and 800 ppm for another 2 weeks. The other four groups of six rats were exposed to 1-BP at 0, 200, 400 and 800ppm for 4 weeks. Rats were injected with 5-bromo-2'-deoxy-uridine (BrdU) after four-week exposure at 1000/800 ppm to examine neurogenesis in the dentate gyrus using immunostaining. Factors known to affect neurogenesis, including monoamine level in different brain regions, hippocampal brain-derived neurotrophic factor (BDNF) and glucocorticoid receptor (GR) mRNA expression levels were measured.

**Results:** BrdU positive cells decreased significantly at 800/1000 ppm after 4-week exposure to 1-BP. 1-week exposure to 1-BP at 800 and 1000 ppm significantly reduced noradrenalin level in the striatum. 4-week exposure to 1-BP decreased significantly noradrenalin level in the hippocampus, prefrontal cortex and striatum at 800 ppm. 1-BP also reduced hippocampal BDNF and GR mRNA levels.

**Conclusion:** Long-term exposure to 1-BP decreased neurogenesis in the dentate gyrus. Downregulation of mRNA expression of BDNF and GR and low hippocampal norepinephrine levels might partly contribute to the reduced neurogenesis.

## PS 911 Nitrosative Stress in Chemoconvulsant-Induced Epileptogenesis.

K. Ryan<sup>1,2</sup>, L. Liang<sup>1</sup> and M. Patel<sup>1</sup>. <sup>1</sup>Toxicology, Skaggs School of Pharmacy and Pharmaceutical Sciences; University of Colorado Anschutz Medical Campus, Aurora, CO; <sup>2</sup>NTP, NIEHS, Morrisville, NC.

Reactive oxygen and nitrogen species (ROS/RNS) are mediators of oxidative stress and are increased in the brain as a result of seizure activity and reactive gliosis; yet their contributing role in the process by which injury leads to epilepsy (i.e. epileptogenesis) is largely unknown. Our previous work in the kainate model of chemoconvulsant-induced epilepsy has confirmed significant oxidative macromolecular damage to hippocampal mitochondria (Ryan et al 2012). The primary goals of this study were to assess the consequences of nitrosative stress in cellular compartments to gain greater mechanistic insight into mitochondrial dysfunction during epileptogenesis. Rats were exposed to a single high dose of kainate (11mg/kg) or vehicle and monitored by video and/or EEG for seizure activity 6 wks. Nitrosative stress was measured in the susceptible hippocampal brain region acutely after kainate administration (8hr, 24hr, and 48hr), 1wk after kainate prior to development of epilepsy (latent period) and during the chronic stages of epilepsy (3wk and 6wk). Analysis from frozen hippocampal sections indicated global astrogliosis (GFAP) and microgliosis (Iba-1) after kainate. Hippocampal nitric oxide spiked 2-fold 8hr after kainate and remained elevated throughout epileptogenesis. Preliminary results suggest this could be associated with increased iNOS detected by immunohistochemical staining. Furthermore, cellular and mitochondrial 3-nitrotyrosine (3NT) progressively and significantly increased during epileptogenesis indicating protein nitration and subsequent immunofluorescent co-labeling showed that 3NT is localized to hippocampal neurons (NeuN). This study demonstrates a probable mechanism for gliosis-mediated nitric oxide production and downstream protein damage to hippocampal neurons in epileptogenesis. These studies propose a role for targeting oxidative and nitrosative species to delay or prevent disease progression by inhibiting detrimental protein nitration. NS039587 (M.P.) and NS R21 NS072099 (M.P.)

## PS 912 Ozone-Induced Changes in Oxidative Stress Parameters in Brains of Adult, Middle-Age, and Senescent Brown Norway Rats.

P. S. Kodavanti, J. E. Royland, J. E. Richards, D. I. Agina-Obu and R. C. MacPhail. NHEERL, US EPA, Research Triangle Park, NC.

Understanding life-stage susceptibility is a critical part of community based human health risk assessment following chemical exposure. Recently there is growing concern over a common air pollutant, ozone (O<sub>3</sub>), and adverse health effects including dysfunction of the pulmonary, cardiac, and nervous systems. Oxidative stress (OS) is a known contributor in multiple organ toxicities and plays an important role in age-related diseases. Growing evidence implicates OS in O<sub>3</sub> toxicity. The current study explored OS as a potential toxicity pathway for O<sub>3</sub> exposure and addressed whether these effects are life stage-dependent. OS-related measures included reactive oxygen species (ROS) production [NADPH Quinone oxidoreductase 1 (NQO1), NADH Ubiquinone reductase (UBIQ)], antioxidant homeostasis [total antioxidant substances (TA), superoxide dismutase (SOD), γ-glutamylcysteine synthetase (γ-GCS)], and oxidative damage (total aconitase). Male Brown Norway rats (4, 12, and 24 months) were exposed to O<sub>3</sub> (0, 0.25 or 1 ppm) via inhalation for 6 h/day, 2 days per week for 13 weeks. Frontal cortex (FC), cerebellum (CB), striatum (ST), and hippocampus (HP) were dissected 24 hours after last exposure, quick frozen, and stored at 80°C until analysis. Results indicated life stage-related increases in ROS production (~ 2x in UBIQ and > 1.5x in NQO1 in striatum), slight decreases in antioxidant homeostatic mechanisms (TAS, γ-GCS, and SOD), and a decrease in aconitase activity. The effects of O<sub>3</sub> exposure were brain area-specific, with the striatum being more sensitive than other brain regions. With regard to life stage, the effects of O<sub>3</sub> appeared to be greater in 4 month old than 12 or 24 month old rats. These results indicate OS could be a potential toxicity pathway for O<sub>3</sub>, but the complex interactions between age, exposure and brain region require further investigation. (This abstract does not necessarily reflect USEPA policy).

**PS 913 Protective Role of Carnosine Against Ischemic Brain Damage through Modulation of Mitochondrial Function and Autophagy.**

O. Bae<sup>1</sup>, S. Baek<sup>2</sup> and A. Majid<sup>3</sup>. <sup>1</sup>College of Pharmacy, Hanyang University, Ansan, Republic of Korea; <sup>2</sup>College of Pharmacy, Ajou University, Suwon, Republic of Korea; <sup>3</sup>Department of Neurology and Manchester Academic Health Sciences Centre, Salford Royal Hospital, Salford, United Kingdom.

We recently found that carnosine, an endogenous pleiotropic dipeptide, has a neuroprotective activity against ischemic stroke. To investigate the mechanism of carnosine neuroprotection, we examined the effect of carnosine on mitochondrial dysfunction and autophagic process in ischemic brain. In rat permanent middle cerebral artery occlusion models, intravenous treatment with carnosine exhibited robust neuroprotection. Carnosine treatment improved brain mitochondrial function as found in mitochondrial respiration, and fusion/fission signaling. Interestingly, autophagic pathways were activated in brain following ischemic insults, such as reduction of phosphorylated mTOR/p70S6K and the conversion of LC3 I to LC3 II, as found in western blot analysis of isolated brain homogenates. Treatment of carnosine attenuated the autophagic signaling in ischemic brain, while the change of ERK phosphorylation was not detected. Taken together, our data suggest that carnosine neuroprotection is mediated by mitochondrial protection, inhibiting excessive autophagic processes. We believe that our finding contributes to the development of carnosine as a strong candidate for stroke treatment, providing a new insight into the role of mitochondrial damage and autophagic pathways in ischemic brain damage.

**PS 914 The Neurotoxic Effects of Tributyltin on Tokai High Avoicer (THA) Rats Evaluated by the Sidman Electric Shock Avoidance Test.**

M. Tsunoda<sup>1</sup>, T. Kido<sup>2</sup>, M. Hosokawa<sup>3</sup>, C. Sugaya<sup>1</sup>, H. Endo<sup>4</sup>, T. Watanabe<sup>4</sup> and Y. Aizawa<sup>5</sup>. <sup>1</sup>Preventive Medicine, Kitasato University School of Medicine, Sagami-hara, Japan; <sup>2</sup>Public Health and Environmental Medicine, Jikei University School of Medicine, Tokyo, Japan; <sup>3</sup>Epidemiology and Environmental Health, Faculty of Medicine, Juntendo University, Tokyo, Japan; <sup>4</sup>Basic Clinical Science and Public Health, Tokai University School of Medicine, Isehara, Japan; <sup>5</sup>Kitasato University, Tokyo, Japan.

Tributyltin (TBT) compounds have been known as environmental pollutants. Although neurotoxicity is one of the major toxicities of TBT, the effects of TBT on learning ability have not yet been clearly demonstrated. Wistar-derived Tokai High Avoicer (THA) rats, which were developed at Tokai University, can achieve stable learning ability in the Sidman electric shock avoidance test because of their innate high-level avoidance ability and small individual differences. We evaluated the neurotoxicity of TBT in THA rats by Sidman electric shock avoidance test. The male and female THA rats were administered TBT in their food at 0 and 125 ppm after weaning (males, n = 5/group; females n = 4/group). From 6 weeks of age, the Sidman test sessions were performed for 60 min/day for 10 consecutive days. Rats can avoid electric shocks by pressing a lever. Avoidance rates for shock exposures were calculated for the first and second halves (30 minutes each) of each session. The mean values of the avoidance rates were compared between the control and TBT groups for each sex, and those of the TBT-exposed group were lower than those of the control for both sexes for all the sessions. Significantly lower mean values of the avoidance rates compared to the control were observed in the first 30 minutes of the sessions in male rats on days 2 and 5. It is suggested that learning ability was impaired in the THA rats exposed to TBT at 125 ppm. To detect the statistically significant differences in future studies, more THA rats should be used.

**PS 915 Protein Biomarker Panel of Cisplatin-Induced Neurotoxicity in a Preclinical Model.**

O. Y. Glushakova<sup>1</sup>, S. Mondello<sup>1</sup>, D. Johnson<sup>1</sup>, C. Heldermon<sup>2</sup>, J. Streeter<sup>1</sup> and R. L. Hayes<sup>1</sup>. <sup>1</sup>Banyan Biomarkers, Inc., Alachua, FL; <sup>2</sup>University of Florida, Gainesville, FL. Sponsor: C. Markgraf.

Background: Neurotoxic brain damage is a widely recognized adverse effect of chemotherapy affecting overall outcome and quality of life cancer survivors. Effective clinical monitoring of neurotoxicity using simple and reliable assays could provide timely information to clinicians allowing them to adjust treatment and reduce neurologic and cognitive side effects of chemotherapy. The goal of this study was to investigate spatiotemporal distributions in the brain, CSF and serum of glial, of neuronal and inflammatory biomarkers: ubiquitin C-terminal hydrolase-1 (UCH-L1), glial fibrillary acidic protein (GFAP),  $\alpha$ -spectrin break down products (SBDPs), microtubule-associated protein 2 (MAP2), myelin basic protein (MBP), MBP break down products (MBP-BDP), intercellular adhesion molecule (ICAM) and their relationships to cisplatin-induced neuropathology in rats.

Methods: Neurotoxicity in adult rats was induced by cisplatin (10 mg/kg, i.p.). The levels and localization of biomarkers in the brain were examined by immunohistochemistry (IHC) and their levels in CSF and serum were evaluated by ELISA. Results: IHC revealed that cisplatin caused abnormal changes in the brain starting at 6 h and increasing at 24 and 48 h including gliosis, determined by increased GFAP level, dendritic damage determined by decreased MAP2 level, neuronal demyelination determined by increased level of MBP-BDP, and inflammation determined by increased level of ICAM. Serum levels of UCHL-1, GFAP and SBDP150 were significantly increased at 24 h after cisplatin administration as compared to controls. The levels of these biomarkers were correlated with IHC brain pathologies and survival.

Conclusion: This study demonstrated the potential of using levels of glial and neuronal proteins in blood for assessment of cisplatin induced neurotoxicity. In addition, assessment of serum levels of biomarkers can provide information on underlying mechanisms of neurotoxicity and facilitate a personalized treatment to minimize side effects during and after chemotherapy.

**PS 916 Effects of a Smokeless Tobacco, Gutkha on Neurotransmitter Levels and Associated Parameters in the Mouse Brain.**

D. E. Lauterstein<sup>1</sup>, C. Hoffman<sup>1</sup>, M. M. Hossain<sup>3</sup>, J. Richardson<sup>3</sup>, F. Ganey<sup>2</sup> and J. T. Zelikoff<sup>1</sup>. <sup>1</sup>Environmental Medicine, New York University, Tuxedo, NY; <sup>2</sup>Memorial Sloan-Kettering Cancer Center, NY, NY; <sup>3</sup>Rutgers University, New Brunswick, NJ.

Many studies have been performed on the relationship between smoked tobacco and adverse effects on health. However, fewer data are available on the toxicity of smokeless tobacco. Gutkha, a smokeless tobacco (ST) product manufactured in India and readily available in the U.S. (used extensively by South Asian communities), is composed of powdered tobaccos, slake lime, and spices. To assess the effects of Gutkha usage on the brain, adult male mice (B6C3F1) were exposed daily via the oral mucosa to water (control), 50  $\mu$ L of a 21 mg water-soluble Gutkha solution or of a 8 mg/kg nicotine solution for 3 days and changes in brain levels of dopamine (DA), serotonin (5-HT), and norepinephrine (NE) were assessed in the striatum. Monoamine oxidase and tyrosine hydroxylase (enzymes important for neurotransmitter (NT) breakdown and synthesis, respectively) levels were assessed in the striatum, frontal cortex, and locus coeruleus. Serum cotinine levels for all the groups were analyzed upon sacrifice within 1 hr post-exposure; Gutkha- and nicotine-exposed mice had comparable cotinine levels ranging between 18-50 ng/mL and 20-60 ng/mL, respectively. HPLC studies measuring NT levels in the brain demonstrated that Gutkha-exposed mice had a significant increase in NE compared to those exposed to either nicotine or water. In contrast, Gutkha-exposed mice had a significant decrease in DA and 5-HT compared to the control and nicotine-exposed groups. The results here suggest that: effects of Gutkha on certain brain parameters may be due to Gutkha-associated toxicants other than nicotine; Gutkha may provide an additional biological stressor for the brain compared to nicotine alone; and, Gutkha may be more addictive than nicotine alone based on the rapid depletion rate of catecholamines in the brain. Studies supported by funds from the NYU Cancer Center and NYU NIEHS Center.

**PS 917 3, 4-Methylenedioxymethamphetamine (Ecstasy)-Mediated Acute and Long-Term Effects Are Reduced in SERT-Knockout Rats.**

L. E. Lizarraga, A. B. Cholanians, J. M. Herndon, S. S. Lau and T. J. Monks. Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

3,4-Methylenedioxymethamphetamine (MDMA, Ecstasy) is a ring-substituted amphetamine derivative structurally related to the psychomotor stimulant amphetamines and the hallucinogen mescaline. The neuropharmacological effects of MDMA are biphasic in nature. MDMA initially causes synaptic monoamine release, primarily of serotonin (5-HT), producing hyperthermia and hyperactivity (5-HT syndrome). The long-term effects of MDMA manifest as a prolonged depletion in 5-HT, and structural damage to 5-HT nerve terminals. The effects of MDMA are in part mediated by an ability to inhibit the presynaptic 5-HT reuptake transporter (SERT). Using a SERT-knockout (SERT-KO) rat model, we determined the effects of SERT deficiency on MDMA (10mg/kg, sc, X 4 at 12h intervals)-mediated hyperthermia, locomotor activity, and neurotoxicity in SERT-KO or Wistar-based wild-type (WT) rats. Open-field activity cages equipped with photo-beam sensor rings revealed that WT rats were 2.4-fold more active (displaying higher horizontal movement distance and mean velocity) than their SERT deficient counterparts. Exposure to MDMA stimulated total movement by 4.2-fold in both WT and SERT-KO rats. Although the peak hyperthermic response in SERT-KO (38.9C & 38.4C) and WT animals (39.1C & 38.8C) were similar after the first and third doses of MDMA, the response was delayed and prolonged in WT animals. Thus the cumulative (temp X time) elevation in temperature was significantly

( $p < 0.01$ ) higher in the WT rats. Finally, SERT KO animals were insensitive to MDMA-mediated long-term (7 days) depletions in 5-HT and its metabolite, 5-hydroxyindoleacetic acid (5-HIAA), in both cortex and striatum. In conclusion, SERT deficiency in KO animals attenuated MDMA-induced hyperthermia and neurotoxicity but not locomotor activity. The data confirm that SERT is essential for the manifestation of the acute and long-term effects of MDMA (NIH R01 DA023525, P30ES006694, and T32ES007091).

**PS 918 Structurally-Distinct Dopaminergic Neurotoxins Acutely Decrease ATP-Dependent Calcium Signaling in Astrocytes by Inhibiting TRPC3.**

K. Streifel, A. Gonzales, B. Trout, B. Mohl, S. Earley and R. B. Tjalkens. *Environmental and Radiological Health Science, Colorado State University, Fort Collins, CO.*

Dopaminergic nuclei within the basal ganglia are important for control of motor function but are highly sensitive to damage from oxidative stress, inflammation, and environmental neurotoxins. Here we propose that inhibition of transmitter-evoked calcium ( $Ca^{2+}$ ) signaling in astrocytes may contribute to this sensitivity because ATP-dependent  $Ca^{2+}$  waves in these cells modulate diverse trophic functions in the CNS, including metabolism, synaptic activity, and regional cerebral blood flow. To examine mechanisms underlying alterations in  $Ca^{2+}$  signaling in astrocytes, we postulated that cationic neurotoxins of the basal midbrain would acutely inhibit ATP-induced  $Ca^{2+}$  signals in astrocytes through a common channel. To test this hypothesis, we examined the capacity of MPP<sup>+</sup> and 6-Hydroxydopamine (6-OHDA) to block ATP-dependent  $Ca^{2+}$  waves and transients in primary striatal astrocytes. Calcium imaging studies revealed a dose-dependent decrease in ATP-induced intracellular  $Ca^{2+}$  transients and mechanically stimulated  $Ca^{2+}$  waves following acute application of both MPP<sup>+</sup> and 6-OHDA. These compounds also acutely inhibited OAG-induced  $Ca^{2+}$  influx, suggesting the transient receptor potential channel, TRPC3, as a probable target. MPP<sup>+</sup> inhibited OAG-induced intracellular  $Ca^{2+}$  transients similarly to the TRPC3 channel antagonist, pyrazole-3, whereas 6-OHDA only partly suppressed OAG-induced  $Ca^{2+}$  transients. In whole cell patch clamp experiments conducted in TRPC3-overexpressing cells, acute application of MPP<sup>+</sup> completely blocked TRPC3-like currents, whereas only partial inhibition was detected in the presence of 6-OHDA. These findings indicate that dopaminergic neurotoxins that have cationic properties differentially inhibit TRPC3 in astrocytes, thereby diminishing the amplitude of ATP-induced  $Ca^{2+}$  transients. These compounds may therefore share a common mechanism of neurotoxicity in their capacity to acutely disrupt astrocytic trophic functions reliant on this signaling mechanism.

**PS 919 Comparative Toxicity of Amphotericin B and Amphotericin B Methyl Ester in Oligodendrocytes *In Vitro* and *In Vivo*.**

O. U. Nnodi<sup>1</sup>, C. P. Schaffner<sup>2</sup> and K. R. Reuhl<sup>1</sup>. <sup>1</sup>*Pharmacology & Toxicology, Rutgers University, Piscataway, NJ;* <sup>2</sup>*Waksman Institute, Rutgers University, Piscataway, NJ.*

Amphotericin B methyl ester (AME) is a polyene macrolide antibiotic highly effective against systemic fungal infections. Introduced more than 40 years ago, AME is less toxic than the commonly used Amphotericin B (AMB), which has serious dose-limiting nephrotoxicity. Nevertheless, reports of neurotoxicity led to cessation of its clinical use. Research in our lab using pure AME suggest that the reported myelin toxicity was due to contamination by AMB which injures myelin-producing oligodendrocytes in the CNS. To test this hypothesis, adult female Balb/c mice were administered to AMB or AME (5 mg/kg, ip) or vehicle for 28 days and 54 days. Histopathologic analysis of mice using Fluoromyelin dyes demonstrated white matter vacuolation and demyelination, with accumulation of myelin debris within macrophages. AMB also induced apoptosis of glial cells. AME-treated mice were normal. Quantitative dose-response assessment using an immortalized human oligodendroglial cell line (MO3.13) exposed to 0.5-30  $\mu$ g/ml AMB or AME demonstrated that AME was at least 10-fold less toxic than AMB as measured by dye exclusion. The lowest concentration of AMB to induce cell membrane injury in MO3.13 cells was 1  $\mu$ g/ml. AMB induced an apoptotic phenotype at concentrations ten times lower than AME as determined by nuclear area factor assessment. AMB induces the mitochondrial intrinsic apoptotic pathway in the MO3.13 cells. A direct effect of AMB on the mitochondrial membrane was confirmed by labeling with JC-1, a fluorescent marker of mitochondrial membrane potential ( $\Delta\Psi_m$ ), which revealed diminished intensity following AMB treatment at 1  $\mu$ g/ml. Changes in  $\Delta\Psi_m$  were not rescued by Trolox, a mitochondrial membrane pore inhibitor. AME concentrations below 10  $\mu$ g/ml did not alter  $\Delta\Psi_m$ . These data suggest that AMB, but not pure AME, causes potentially lethal injury to oligodendrocytes by inducing plasma membrane permeability and mitochondrial perturbation, with consequent apoptosis. (Supported by ES005022 and ES07148).

**PS 920 Effects of "Uptake 2" Blockade and/or Risperidone on Murine 5-HT Uptake, Social and Repetitive Behavior.**

C. Smolik<sup>1,2</sup>, M. Javors<sup>1</sup>, J. Hensler<sup>1</sup>, W. Koek<sup>1</sup>, L. C. Daws<sup>1</sup> and G. G. Gould<sup>1</sup>. <sup>1</sup>*CBN, UTHSCSA, San Antonio, TX;* <sup>2</sup>*Biology, UTSA, San Antonio, TX*

Uptake 2 mechanisms in the brain such as organic cation transporters (OCTs) may play a major role in the modulation of monoamine neurotransmission. OCTs have affinity for and/or transport many endogenous and xenobiotic compounds. Their blockade produces similar effects to selective serotonin (5-HT) reuptake inhibitors. The pseudoisocyanine 1,1'-diethyl-2,2'-cyanine iodide (decynium-22 or D-22) blocks 5-HT uptake in vivo and produces antidepressant-like effects in mice. Administration of D-22 (0.01-0.1 mg/kg) or diazepam (1 mg/kg) increased social approach in BTBR mice 50 min afterward ( $p < 0.05$ ,  $N=6$ ), in contrast to risperidone (0.1 mg/kg). Unlike diazepam or risperidone, D-22 failed to reduce BTBR marble burying. D-22 (0.01 mg/kg) increased social sniffing of stranger mice by SERT -/- mice ( $p < 0.05$ ,  $N=12$ ), with a similar lack of effect on marble burying. We hypothesized that D-22 produces its effects on social behavior by blocking OCTs or other uptake-2 sites in the mouse brain. Saturation binding of [<sup>3</sup>H] D-22 in mouse hippocampal homogenates revealed a  $K_D$  of  $\approx 3-4$  nM, and a  $B_{max}$  of  $700 \pm 167$  fmol/mg protein ( $N=3$ ). Binding of [<sup>3</sup>H] D-22 is partially blocked by the neurotoxin 1-methyl-4-phenylpyridinium (MPP<sup>+</sup>), a substrate of OCTs. We confirmed that [<sup>3</sup>H] MPP<sup>+</sup> uptake by hOCT expressing HEK cells was blocked by D-22 with IC50 values ranging from 3-8  $\mu$ M ( $N=5$ ). We also found that D-22 blocks hippocampal 5-HT uptake (IC50=197 nM), albeit more weakly than striatal DA uptake (IC50=35 nM), in synaptosomes from mice ( $N=4-7$ ). Through HPLC measurements D-22 was detectable in the brain when administered by intraperitoneal (i.p.) injection at 10 mg/kg, but not at lower doses. D-22 has a serum clearance half-life of 30 min in BTBR mice. OCT3 blockade appears to be a promising therapeutic strategy for social interaction deficiencies. Research was supported by NIH-NINDS #R25NS080684 START-UP Program, NIH-NIMH #R03MH086708 and DOD AR110109.

**PS 921 Social Behaviors, Monoamine Transporter Function, and Brain Mitochondrial Efficiency in Insulin-Resistant Mice.**

R. Lozano<sup>1,2</sup>, W. Q. Zhang<sup>1</sup>, C. Smolik<sup>1</sup>, P. A. Barba-Escobedo<sup>1</sup>, M. Gamez<sup>1</sup>, H. Van Remmen<sup>3</sup>, L. C. Daws<sup>1</sup> and G. G. Gould<sup>1</sup>. <sup>1</sup>*Physiology, UTHSCSA, San Antonio, TX;* <sup>2</sup>*Psychology, Texas A&M University, College Station, TX;* <sup>3</sup>*Barshop Center, UTHSCSA, San Antonio, TX.*

Insulin resistance and elevated blood glucocorticoids are key components of the metabolic syndrome that often comes before type 2 diabetes. Use of atypical antipsychotics can increase the risk for developing metabolic syndrome, yet the impact of elevated insulin on drug response, monoamine systems and behavior is poorly understood. In streptozotocin-treated rats and in type 1 diabetes, insulin production is suppressed and dopamine transporter function is impaired. Conversely, we hypothesized that high circulating insulin and corticosteroid levels, as seen in type 2 diabetes, may instead enhance monoamine transporter function and impair sociability. We tested this hypothesis using BTBR x C57BL/6 (BL6) F1 male mice, which exhibit insulin resistance as adults, and their parent strains. BTBRxBL6 F1 mice had increased abdominal adiposity, but their serum levels of corticosterone were intermediate ( $89 \pm 8$  ng/ml) to higher BTBR and low BL6 levels ( $N=5-8$ ). Their social behavior in three chambered tests and marble burying was similar to that of socially-deficient BTBR mice. Yet BTBRxBL6 F1 were more impulsive than either parent strain in the tube test for social dominance. Brain tissue from BTBR and BTBRxBL6 F1 mice had lower  $H_2O_2$  production from mitochondrial electron transport than BL6 mice ( $P < 0.05$ ,  $N=5$ ). Binding of [<sup>3</sup>H] citalopram to serotonin transporters in hippocampal synaptosomes was reduced in BTBR and BTBRxBL6 mice, but [<sup>3</sup>H] 5-HT uptake was similar to BL6 mice ( $N=4-6$ ). In contrast, [<sup>3</sup>H] WIN 35,428 binding to dopamine transporters in striatal synaptosomes was similar among strains, but [<sup>3</sup>H] dopamine uptake was significantly increased in BTBR mice ( $N=4-6$ ). Based on [<sup>3</sup>H] domperidone binding in cortical synaptosomes, dopamine receptor density may be increased in BTBR and BTBRxBL6 F1 mice. Hence dopamine transmission could be suppressed in these insulin-resistant mice, which may alter their responsiveness to antipsychotics.

**PS 922 Impact of Pair Housing and Selection of Photobeam-Based Motor Activity Parameters for Neurobehavioral Evaluation.**

P. Mukerji, S. S. Anand, L. A. Malley, N. P. Betts and S. E. Loveless. *DuPont Haskell Global Centers for Health & Environmental Sciences, Newark, DE.*

Social housing is widely considered to be beneficial to the welfare of laboratory animals, compared with single housing, and is recommended by the Guide for the Care and Use of Laboratory Animals. Therefore, the impact of social housing on

measurable neurobehavioral endpoints was evaluated. Socially defeated or submissive rats exhibit body weight loss and decreased exploratory behavior relative to socially dominant rats. It was hypothesized that any impact of social dominance on a neurobehavioral endpoint (e.g., motor activity) would correlate with a difference in bodyweight gain between the two pair-housed rats. However, the control data from five 90-day studies (N=114) indicated no significant correlation between the difference in bodyweight gain within each cage and the difference in motor activity, grip strength, hindlimb splay, or body temperature values within the same cages. Our second objective was to optimize the use of a photobeam-based system which computes multiple parameters for motor activity assessment and is widely used in the industry. We evaluated baseline data from eight studies (N=816), to select two representative motor activity parameters from a list of multiple options. Duration of movement and number of ambulatory movements offered the greatest unique value (lowest correlation coefficients) and were the best predictors (highest R-squared values) of the remaining motor activity parameters. A positive control study conducted with carbaryl and amphetamine using pair housing conditions demonstrated neurobehavioral effects that were consistent with previously published literature. Based on the analysis of data from multiple studies including a positive control, we concluded that pair housing does not interfere with neurobehavioral evaluations and that motor activity can be characterized effectively using duration of movement and number of ambulatory movements in a photobeam-based system.

## PS 923 Feasibility Study of EEG Measurements in Chair Restrained Cynomolgus Monkeys.

C. B. Rose, S. H. Korte and B. Niggemann. *Covance Laboratories GmbH, Muenster, Germany*. Sponsor: G. Weinbauer.

Quantitative EEG is one of the most sensitive non-invasive approaches for the detection of drug effects on the brain. Therefore, a validation study was performed using 4 male and 4 female cynomolgus monkeys. Two electrodes each were placed on the frontal, central and occipital cortex, with the reference electrode either placed at CZ (central region) or the mastoid. The electrode positions were calculated and marked with a tattoo on the head of the sedated animal 1-3 weeks before start of EEG measurements to guarantee exact electrode placement over the course of the study. The animals were habituated to the primate chair before start of the study. At the day of EEG recordings, the animals were habituated to the room approximately 5-10 minutes prior to EEG recordings. Subcutaneous steel needle electrodes as well as a reference electrode were fixed on the primate head and connected to the EEG system (EEG Kit for Neuropack S1, MEB-9400, Nihon Kohden). For determination of artefacts, ECG recordings were simultaneously performed. Sedating effects were shown using the drug lorazepam. An intermittent slowing of Delta- and/or Theta- waves was observed for all animals dosed intravenously with 0.2 mg/kg lorazepam, however the expected increase in frontal beta-activity was only recorded after a lorazepam dose of 0.4 mg/kg. For the 0.4 mg/kg dose level, an antidote was applied after sedating effects were observed in the EEG. To demonstrate seizure-inducing effects, female animals of an inhouse project were treated with pentylenetetrazole (PTZ) under anesthesia until seizures were visible. Anesthesia was induced with ketamine, the animals were ventilated and anesthesia was maintained with a mixture of oxygen and nitrous oxide. To avoid muscle artefacts in the EEG recordings, rocuronium was used as peripheral muscle relaxant. Seizures were observed at a single intravenous dose of 20 mg/kg PTZ at a dose volume of 0.2 mL/kg. In conclusion, this validation study demonstrated the feasibility of EEG recordings in chair-restrained cynomolgus monkeys since sedating as well as seizure-inducing effects could be demonstrated.

## PS 924 Characterization of Urinary microRNA in Cisplatin-Induced Nephrotoxicity in Rats.

M. Kanki<sup>1</sup>, A. Moriguchi<sup>1</sup>, D. Sasaki<sup>1</sup>, H. Mitori<sup>1</sup>, A. Yamada<sup>2</sup>, R. Hirota<sup>1</sup> and Y. Miyamae<sup>1</sup>. <sup>1</sup>Astellas Pharma Inc., Osaka, Japan; <sup>2</sup>Astellas Research Technologies Co., Ltd., Osaka, Japan.

Recent studies with urinary microRNA (miRNA) report that some urinary miRNAs detect renal dysfunction and histopathological damages. The purpose of this study is to find urinary miRNAs that can detect the drug-induced nephrotoxicity in rat as one of novel biomarkers.

Male Sprague-Dawley rats were given a single intraperitoneal injection of saline (10 animals) or cisplatin (6 mg/kg, 20 animals) and the urine was collected from 4 to 5 days (17hr) after administration. To examine the effects of feeding condition, half of animals in each group were fed and the others were fasted during urine collection. The kidney and serum were collected at 5 days after administration. Eighteen

protein biomarkers of nephrotoxicity in the urine were also measured. Urinary miRNAs were individually isolated from 5 animals in each group and miRNA expression data was obtained by TaqMan® rodent microRNA array cards.

In cisplatin-treated groups, moderate or marked proximal tubular necrosis was observed in the kidney and blood urea nitrogen and creatinine were significantly increased in the serum. Furthermore, most of protein biomarkers were significantly increased in the urine. There were no noteworthy differences in these items due to the feeding conditions. Regarding miRNAs, approximately 80 miRNAs showed statistically significant difference in the expression levels between fed and fasted condition. These miRNAs might be affected by feeding condition and were excluded when we explore changed miRNAs in cisplatin-treated groups. Approximately 30 miRNAs were found to be up- or down-regulated in cisplatin-treated group regardless of feeding condition during urine collection. Some of up-regulated urinary miRNAs, such as miR-192, were reported their expression in the rat kidney, so that these miRNAs might be derived from the injured kidney tissue. In conclusion, the feeding condition during urine collection affects the urinary miRNA profiles and we could identify some of urinary miRNAs that can detect the cisplatin-induced nephrotoxicity in rats.

## PS 925 Circulating miR-208a As Potential Cardiac Toxicity Biomarker.

J. Wang, L. Ling, S. Aquirre, W. W. Collette, M. Ko, F. Sace, Q. Peng, R. L. Yafawi, Q. Zong and A. John-Baptiste. *Drug Safety Research and Development, Pfizer, La Jolla, San Diego, CA*.

Literature is rife with information about several potential miRNAs that are involved in acute cardiac injury. In this dose finding study, we evaluated miR-1, -133a, -208a and -499-5p as potential biomarkers for cardiac injury in an oxidative stress mouse model and compared them alongside Troponin I.

Isoproterenol Hydrochloride (80, 160 or 320 mg/kg) was administered to female SOD2 +/- mice intraperitoneally once daily for one day to induce cardiac injury. EDTA plasma samples were collected at 6 and 24 hours for assessing miR-1, -133a, -208a, and -499-5p by Taqman real time PCR and Troponin I, the current golden standard for detecting early cardiac injury via MSD® ELISA kit. Cardiac damage was confirmed microscopically in heart tissues collected at day 10 and by measuring conventional serum biomarkers ALT, AST, ALP and GLDH at day 10.

Treatment related findings at doses  $\geq 80$  mg/kg at 6 and 24 h consisted of increased of cTn I in a dose-response fashion. Levels of cTn I declined after 6 hours. Concordant with cTn I results, miR-208a was elevated significantly. A similar, yet smaller, magnitude of response was noted for miR-499-5p while miR-1 and miR-133a appeared to be the least sensitive. Microscopically, mild myocardial inflammation and fibrosis at the heart base was observed in some mice given 160 mg/kg while ALT, AST, ALP and GLDH were not changed.

In conclusion, the release profile of miR-208a is comparable to cTn I suggests its utility as a putative cardiac injury biomarker. A dose level of 160 mg/kg caused significant elevations in cTn I and miR-208a which correlated with histopathologic findings in the heart.

## PS 926 Evaluation of the Pancreas-Specific microRNAs, miR-216a, and miR-217 As Biomarkers of Acute Pancreatitis.

D. G. Goodwin, J. Zhang, S. R. Stewart, L. Xu, B. A. Rosenzweig, K. L. Thompson and R. L. Rouse. *CDER, US FDA, Silver Spring, MD*.

Pancreatitis is a serious side effect associated with nearly half of the 100 most prescribed medications that is often under- or misdiagnosed because of its non-specific symptoms and the relative insensitivity of the clinical biomarkers, serum amylase and lipase. MicroRNAs (miRs) are short, non-coding RNA sequences involved in the regulation of gene expression. Serum miR-216a has been reported as a potential biomarker of acute pancreatitis, and our results suggest that miR-217 may also serve that purpose. miR-216a and miR-217 are selectively expressed in pancreatic acinar cells and are present at very low or undetectable levels in serum under normal conditions. To further evaluate the possible utility of miR-216a and miR-217 as serum biomarkers of pancreatitis, we investigated their performance in models of acute pancreatitis induced by caerulein, L-arginine, and ductile ligation in both rats and mice. Liver and acute kidney injury models were used to demonstrate the specificity of miR-216a and miR-217 for pancreatic injury. Both miR-216a and miR-217 showed a time and dose dependent correlation with the severity of pancreatitis in each of the pancreatic injury models and with amylase and lipase levels. The preliminary data suggest that miR-216a and miR-217 may be more sensitive and specific indicators of pancreatic injury than amylase and lipase in mice and rats and useful in pre-clinical drug development. Given the highly conserved nature of these microRNAs, a translation to clinical use would be also anticipated.

**PS 927 Multilaboratory Assessment of Best Practices for Quantification of microRNAs Associated with Isoproterenol-Induced Myocardial Injury in the Urine and Plasma of Rats.**

K. Thompson<sup>1</sup>, S. J. Nielsen<sup>2</sup>, T. Chen<sup>3</sup>, P. Coutter<sup>4</sup>, H. Ellinger-Ziegelbauer<sup>5</sup>, M. Kanki<sup>6</sup>, J. Kelsall<sup>7</sup>, E. Boitier<sup>8</sup>, R. Nassirpour<sup>9</sup>, G. Searfoss<sup>10</sup>, C. Spire<sup>11</sup>, P. Yuen<sup>12</sup> and R. O'Lone<sup>13</sup>. <sup>1</sup>CDER, Silver Spring, MD; <sup>2</sup>Exiqon, Vedbæk, Denmark; <sup>3</sup>NCTR, Jefferson, AR; <sup>4</sup>Novartis Pharma AG, Basel, Switzerland; <sup>5</sup>Bayer Pharma AG, Wuppertal, Germany; <sup>6</sup>Astellas Pharma Inc, Osaka, Japan; <sup>7</sup>AstraZeneca, Macclesfield, United Kingdom; <sup>8</sup>Sanofi, Vitry-sur-Seine, France; <sup>9</sup>Pfizer, Andover, MA; <sup>10</sup>Lilly, Indianapolis, IN; <sup>11</sup>Servier, Gidy, France; <sup>12</sup>NIDDK, NIH, Bethesda, MD; <sup>13</sup>ILSI Health and Environmental Sciences Institute, Washington DC.

MicroRNAs are promising noninvasive biomarkers of drug-induced toxicities due to their tissue-selective expression, rapid release post-injury, and stability in biofluids, but their low levels in biofluids present challenges to their reliable quantification. The HESI Genomics committee initiated a collaborative study to assess best practices for measuring injury-related microRNAs in biofluids. Samples were derived from a model of acute cardiotoxicity in male Wistar rats induced by a single s.c. injection of 0.5 mg/kg isoproterenol. The heart-enriched microRNAs miR-208, miR-499, and miR-1 increased by approximately 10-fold in serum and plasma 4 hr after treatment. In a follow-up study using the same model system, urine was collected overnight and plasma at 24 hr post-injection. Biofluids were pooled from 5 rats per group and aliquots were sent to 10 laboratories for analysis of levels of the 3 heart-enriched microRNAs. At each site, samples were assayed using a standard protocol and the data normalized to levels of a spiked-in ath-miR159a control. The results from this interlaboratory analysis of multiple preanalytical and technical issues provide guidelines for the accurate measurement and reporting of injury-related microRNAs in biofluids.

**PS 928 Circulating miR-9\* and miR-384-5p As Potential Indicators for Trimethyltin-Induced Neurotoxicity.**

K. Ogata<sup>1,2</sup>, K. Sumida<sup>1</sup>, K. Miyata<sup>1</sup>, M. Kushida<sup>1</sup>, M. Kuwamura<sup>2</sup> and J. Yamate<sup>2</sup>. <sup>1</sup>Environmental Health Science Laboratory, Sumitomo Chemical Co., Ltd., Osaka, Japan; <sup>2</sup>Laboratory of Veterinary Pathology, Division of Veterinary Sciences, Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Izumisano, Japan. Sponsor: T. Yamada.

MicroRNAs (miRNAs) are believed to be promising biomarkers due to their tissue-specific expression and high stability in blood. Our study was conducted to determine nervous system-specific miRNAs in blood as potential indicators for neurotoxicity. Using trimethyltin (TMT)-induced neurotoxicity model, we analyzed serum miR-9\* and miR-384-5p which were reported to be highly or specifically expressed in the nervous system, and compared the sensitivity as neurotoxicity parameters with nervous symptoms and histopathology.

Seven-week-old SD rats were orally given a single dose of 6, 9 and 12 mg/kg of TMT. Nervous tissues (brain, spinal cord and sciatic nerve) and blood were collected 1, 4 and 7 days after administration (D1, 4 and 7). Daily observation of symptoms and histopathology were conducted. Immunohistochemistry (PCNA, GFAP, Iba1) and TUNEL method were performed on brain. Expressions of miR-9\* and miR-384-5p in serum and hippocampus were analyzed by RT-PCR.

TMT induced tremor, hypersensitivity and decreased auditory response after D2 at 12 mg/kg and after D4 at 9 mg/kg. Neural cell death including apoptosis and glial reaction in cerebrum (mainly hippocampus) and cerebellum was observed after D1 at 12 mg/kg and after D4 at 6 and 9 mg/kg, and the severities increased in a dose- and time-dependent manner.

Expression levels of miR-9\* (D4 and 7 at 12 mg/kg and D7 at 6, 9 mg/kg) and miR-384-5p (D4 at 9 mg/kg, D7 at 12mg/kg) in serum were significantly higher than the vehicle control, but not changed in hippocampus. Increased serum level of these miRNAs might be due to leakage from damaged nervous tissue.

The detection sensitivity of neurotoxicity of serum miR-9\* miR-384-5p was similar to observation of nervous symptoms, therefore they were considered possible novel indicators of neurotoxicity.

**PS 929 Assessment of microRNA 122 As a Preclinical and Clinical Biomarker of Hepatotoxicity Utilizing Affymetrix QuantiGene Technology.**

S. J. Schomaker<sup>1</sup>, D. Burt<sup>1</sup>, R. Warner<sup>2</sup>, K. Johnson<sup>2</sup> and J. Aubrecht<sup>1</sup>. <sup>1</sup>Safety Sciences, Pfizer Inc, Groton, CT; <sup>2</sup>Department of Pathology, University of Michigan Medical School, Ann Arbor, MI.

Hepatotoxicity is major challenge in drug development. While alanine aminotransferase (ALT) remains the gold standard biomarker of liver injury, the availability of alternative biomarkers to better predict the potential for drug induced liver injury is essential. In this study we evaluated the utility of miRNA122 as a biomarker of liver

injury in both preclinical and clinical serum samples utilizing Affymetrix QuantiGene Technology. The Affymetrix system is a 96-well plate based assay that uses a sandwich nucleic acid hybridization platform to detect miRNA directly without a reverse transcription step followed by signal amplification via a branched DNA amplifier and chemiluminescence signal generation. In this study, male Sprague-Dawley rats were treated with a single dose of 1400mg/kg acetaminophen (APAP), 100mg/kg naphthylisothiocyanate (ANIT), or 0.2mg/kg microcystin-LR (MC) to induce hepatocellular necrosis which was confirmed by histopathological examination. Statistically significant increases ( $p < 0.01$ ) in miRNA122 were observed after treatment with all three of the model hepatotoxins. miRNA122 was also assessed in cohorts of human subjects including 27 healthy subjects, 31 patients with a variety of liver impairments, and 7 cases of APAP poisoning collected from the University of Michigan health care system under an approved IRB. In the absence of histopathologic evaluation that was not feasible due to ethical and practical reasons, miRNA122 values were correlated with ALT levels as an indicator of liver injury. A Spearman's rank correlation analysis between miRNA122 and ALT of the 65 human samples yielded a correlation coefficient of  $r_s = 0.88$ . Analysis of miRNA122 in the APAP poisoned subjects resulted in increases of 13-95 fold when compared to miRNA122 levels from healthy subjects. This study demonstrates the utility of miRNA122 as a preclinical and clinical biomarker of liver injury utilizing Affymetrix QuantiGene Technology.

**PS 930 Urinary microRNA Profiles After Glomerular vs Proximal Tubular Injury.**

B. Riefke<sup>2</sup>, M. Pavkovic<sup>1</sup>, I. Groetcke<sup>1</sup>, A. Frisk<sup>2</sup>, F. McDonald<sup>2</sup> and H. Ellinger-Ziegelbauer<sup>2</sup>. <sup>1</sup>Bayer Pharma AG, Wuppertal, Germany; <sup>2</sup>Bayer Pharma AG, Berlin, Germany.

MicroRNAs (miRNAs) are small, conserved, non-coding RNAs that modulate gene expression post-transcriptionally. They are remarkably stable in various body fluids like urine and thus suggested as new non-invasive biomarkers (BM) of tissue injury, especially since some miRNAs are produced in cell- or tissue specific manners offering the possibility to identify the site of injury. Furthermore, their tissue expression profiles may be used for investigation of the mechanistic details of compound-induced toxicities.

We investigated miRNAs in urine of male Crl:WI (Han) rats treated with nephrotoxics: Cisplatin (Cp), to specifically elicit proximal tubular injury; and male Wistar Kyoto rats treated with a nephrotoxic serum (NTS) containing antibodies against the glomerular basement membrane to induce glomerular damage. The expected tissue injury was confirmed by histopathology. Total RNA including small RNAs was isolated from urine on day 3, 5, 8, 15 and 26 after a single dose of Cp (0, 1 and 3 mg/kg) and on day 8 and 14 after NTS injection (0.1, 0.25 and 0.5 mL/100g bw). Urinary miRNA profiles were measured with TaqMan® MicroRNA Cards (TLDA). MiRNA levels were normalized to a non-endogenous spiked-in control miRNA and to urinary creatinine. Comparing Cp-high dose vs. control samples and NTS-high dose vs. control samples we identified 131 and 68 miRNA, respectively, with significantly increased urinary levels. About 65 miRNAs were affected by both treatments, whereas app. 10 and 35 urinary miRNAs were exclusively affected by NTS and Cp treatment, respectively. Furthermore, TLDA analysis of kidneys from NTS-treated rats showed deregulation of many miRNAs upon glomerular injury.

Our results suggest that urinary miRNAs may be used as promising new and site-specific BMs for nephrotoxicity and encourage further investigations of their role in different types of kidney injury.

**PS 931 Proposed Workflow for microRNA Analysis in Urine.**

H. Ellinger-Ziegelbauer<sup>1</sup>, M. Pavkovic<sup>1</sup>, B. Riefke<sup>2</sup> and R. Khan-Malek<sup>3</sup>. <sup>1</sup>Bayer Pharma AG, Wuppertal, Germany; <sup>2</sup>Bayer Pharma AG, Berlin, Germany; <sup>3</sup>Sanofi-Aventis, Bridgewater, NJ.

MicroRNAs (miRNAs) have emerged as new non-invasive biomarkers (BM) for various diseases and tissue injuries due to their release into body fluids upon tissue damage. At least some of these miRNAs are produced in a cell- or tissue specific manner.

For evaluation of miRNAs, urine was collected from male Wistar rats treated with the nephrotoxicant Cisplatin (Cp). Tissue injury was confirmed by histopathology. Total RNA was isolated from urine on days 3, 5, 8, 15 and 26 after a single dose of Cp (0, 1 and 3 mg/kg). Using TaqMan® MicroRNA Cards (TLDA) urinary miRNA profiles were measured. Since currently a commonly accepted endogenous control miRNA is not available, and since we could not identify invariant miRNAs in our study, we describe here a normalization procedure based on the spiked-in control miRNA (ath-miR159a) and urinary creatinine (uCreat). For other urinary BMs uCreat is commonly used to account for different urine volumes.

For the TLDA- derived PCR data, a modified  $\Delta\Delta C_t$  method was applied: delta-Ct values obtained by subtracting ath-miR-159a Cts from target miRNA Cts were de-logarithmized and divided by the corresponding uCrea value. This normalization reduced the variation of the delta-Ct values for miRNAs across samples. Then ratios were calculated between treated and time-matched control groups. With this method we identified 131 miRNAs with significantly increased urinary levels on days 3 and 5. Twenty miRNAs with distinct time-dependent profiles were then measured using TaqMan® MicroRNA Assays. The data were analysed either with the modified  $\Delta\Delta C_t$  method, or absolutely quantified using synthetic miRNA standard curves run in parallel. With both methods we obtained comparable results with respect to observed direction of changes and time course of affected urinary miRNAs.

Our results indicate that urinary miRNAs may be used as BMs for nephrotoxicity in rats.

Furthermore, normalization to uCrea, which is recommended for urinary BMs, appears feasible for analysis based either on the PCR-generated Ct values only, or including absolute quantification.

### PS 932 **MiR-122 Is a Sensitive Indicator of Stem Cell-Derived Hepatocyte-Like Cell Maturity with Utility in Hepatotoxicity Screening.**

C. Rowe, C. Goldring, L. Kelly, N. Hanley, H. Z. Malik, R. Jones, D. Tosh, R. Kia, N. R. Kitteringham and B. Park. *MRC Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom.* Sponsor: *D. Mendrick.*

Consistent differentiation of embryonic, or induced pluripotent, stem cells into functional hepatocyte-like cells available on demand for hepatotoxicity screening would be a valuable resource for drug development programs. Assessments of stem cell-derived hepatocyte-like cell maturity often lack quantitative comparisons with primary human hepatocytes and the presumed fetal-like phenotype currently achieved is concluded from observations of cell morphology and the detection of a small number of proteins such as albumin, alpha fetoprotein and alpha 1 antitrypsin. The identification of a hepatocyte-specific marker that can be quantified absolutely would aid the assessment of cells and be useful for inter-laboratory comparisons. miRNA-122 is a micro-RNA species that is very highly enriched in hepatocytes. We hypothesised that this molecule would be a useful biomarker of differentiation and could also serve as a more sensitive indicator of hepatocyte-specific injury. Our study demonstrates that miR-122 is a specific and sensitive marker of hepatocyte phenotype, present at high levels in primary human hepatocytes and in fetal liver samples but of low abundance or absent in hepatoma and non-hepatic human cell lines. Expression of miR-122 was greatly elevated in stem cell-derived hepatocyte-like cells compared to the undifferentiated stem cell lines. Furthermore we demonstrate miR-122's utility as a sensitive marker of hepatotoxicity in primary hepatocytes and a potential adjunct to screens such as lactate dehydrogenase release and ATP depletion. We conclude that quantitative measurement of miR-122 may be used as sensitive and specific marker during the hepatocyte differentiation process or to confirm the hepatocyte-like status of stem cell-derived material following hepatotoxicity screening assays.

### PS 933 **Potential Utilization of microRNA As Circulating Biomarkers in Th2-Mediated Disorders Such As Asthma and Ulcerative Colitis.**

H. Lin<sup>1</sup>, M. Kasaian<sup>2</sup>, A. Brennan<sup>2</sup> and S. Ramaiah<sup>1</sup>. <sup>1</sup>DSRD, Pfizer Inc., Andover, MA; <sup>2</sup>Immunology & Autoimmunity, Pfizer Inc., Cambridge, MA.

MicroRNAs (miRNAs) are single-stranded RNAs which constitute a class of non-coding RNAs which have emerged as key regulators of gene expression. They are generally thought to inhibit translational activities or promote degradation of mRNA targets. miRNA profiles have been proposed as a diagnostic tool to predict survival and relapse in lung and colon cancer patients. Moreover, circulating miRNAs have been proposed as a new class of biomarker of human diseases and toxicities. IL-4 and IL-13 are central Th2 cytokines in the immune system and potent activators of inflammatory responses during Th2-mediated inflammation. In particular, an essential role for Th2-mediated immune response has been demonstrated in animal models of allergic asthma and experimental colitis. We hypothesized that miRNAs may be involved in the homeostatic regulation of IL-4/-13 expression in disease, or may be modulated during the course of therapeutic antagonism of IL-4/-13 in order to maintain homeostasis of IL-4/-13 expression. Using web based databases that provide literature information on the predicted mRNA targets of miRNAs related to the Th2 immune response, distinct subsets of miRNAs were selected and used to construct a Taqman miRNA assay panel for miRNA screening of sera from asthmatic and ulcerative colitis patients. We found that the profile of circulating miRNAs is capable of distinguishing healthy volunteers from patients with asthma or ulcerative colitis. The results described here have

implications for the use of serum or plasma miRNA profiles as biomarkers for Th2-associated diseases. The overlap with tissue miRNA expression as described in the literature suggests that circulating miRNA expression may be a sensitive indicator of disease activity in the target organ.

### PS 934 **Circulating Nucleic Acids As Lead Exposure Biomarkers in a Mammalian Model System.**

S. Lee and M. E. Gillespie. *Pharmaceutical Sciences, St. John's University, Queens, NY.*

Exposure to lead (Pb) causes numerous deleterious health effects including developmental and cognitive abnormalities in children. Early detection of lead exposure is critical to reduce serious health problems arising from chronic lead toxicity. Circulating nucleic acid based biomarkers are present in various bodily fluids such as blood, serum, and urine. A number of studies have reported the use of circulating nucleic acids as biomarkers for pathological conditions and developmental stages. In this study, a Long Evans rat model system is used to identify lead exposure-induced circulating nucleic acid biological markers in peripheral blood. Two different groups of animals are used, females and time-pregnant Long Evans rats. Females are exposed to 112 parts per million (ppm) Pb (lead acetate) via drinking water ad libitum for 5 days then switched to 19 ppm Pb treatment for an additional 15 days. Dams are exposed to 112 ppm Pb (lead acetate) via drinking water ad libitum from gestation day 16 through 21 then switched to 19 ppm Pb treatment on postnatal day 1 through 15. Animals are euthanized at the conclusion of treatment and blood and brain tissue are collected for analysis. Inductively coupled plasma optical emission spectrometry (ICP-OES) is used to determine blood lead levels of all samples. A microarray approach was initially used to identify differentially expressed circulating nucleic acid sequences only present in animals exposed to Pb. This data highlighted 3 genes of interest: Nt5c3, Skap1, and Coq7. Circulating nucleic acid expression levels in blood samples will be quantified using real-time RT-PCR analysis. Comparison between lead exposed females and pregnant females will identify unique genes as biomarkers of lead exposure and confirm the origin of the circulating nucleic acids.

### PS 935 **Examination of Oxidative Stress As a Possible Risk Factor for Colorectal Cancer Susceptibility.**

R. Sellamuth, S. Dickinson, Z. Wang, S. Zhou and J. E. Klaunig. *Indiana University, Bloomington, IN.*

The present study investigated the role of oxidative stress as a possible risk factor for colorectal cancer in humans. Blood samples were collected from 232 subjects including 102 healthy controls, 90 patients with polyps, 39 patients diagnosed with colorectal cancer. We measured both direct and oxidative DNA damage in peripheral white blood cells (WBCs) using alkaline (direct DNA damage) and formamidopyrimidine DNA glycosylase modified (oxidative DNA damage) Comet assay. Trolox equivalent total antioxidant capacity (TEAC) in plasma was also determined spectrophotometrically. Results showed that Oxidative Stress induced DNA damage was associated with a significantly higher probability of colorectal cancer in males ( $p = 0.008$ ) but not in females ( $p = 0.675$ ) compared to healthy controls. Direct DNA damage also showed a marginally significant effect on colorectal cancer ( $p = 0.071$ ). Results from the TEAC assay showed a positive trend on colorectal cancer, but was not statistically significant ( $p = 0.230$ ). Oxidative stress induced DNA damage, TEAC, and direct DNA damage did not show significant relationships with probability of polyps. Females showed significantly higher probability of developing polyps ( $p < 0.01$ ); and older patients showed significantly lower probability of polyps in this study ( $p < 0.001$ ). Further, these results were not affected by life-style related oxidative stress such as smoking and alcohol. Selected SNPs for oxidative damage, detoxification and DNA repair were examined. Initial results suggested a correlation between SNPs in hOGG and GSTM and colorectal cancer. The results of this study suggest that high level of oxidative stress induced DNA damage is associated with increased risk of colorectal cancer in males, not in females.

### PS 936 **Circulating mRNA Changes in Rat Serum Associated with Drug-Induced Vascular Injury.**

M. Scicchitano, D. Dalmás, K. Roland and H. Thomas. *GlaxoSmithKline, King of Prussia, PA.*

Drug-induced vascular injury (DIVI) continues to be an obstacle to early drug-development due to the lack of biomarkers and by a limited understanding of the pathologic mechanism/s. Recently, a novel gene panel has been developed, for use in rat mesenteric arteries, which can potentially be used to identify and/or predict

the occurrence of drug-induced medial arterial necrosis (MAN) in rats; however, a non-invasive method for detecting this type of injury is currently lacking. To determine whether these genes regulated in mesenteric arteries have the potential to be utilized as circulating serum genomic biomarkers, the gene panel was assessed in mRNA isolated from the serum of rats given a vasotoxic dose of Fenoldopam or Dopamine and compared to mRNA data obtained from serum of rats given Yohimbine, a vasoactive compound which does not cause histologic evidence of vascular injury. Out of the 69 potential circulating biomarkers, 10 genes, including *Lrrc59*, *Tubb6*, *Kpna2*, *Abca8a*, *Prosl*, *S100a11*, *IL-8R*, *CTGF*, *Nfkbiz*, and *Daf1*, were observed to be upregulated (5 fold or greater) and correlated with histologic evidence of MAN following treatment with a vasotoxic dose of Fenoldopam. Six of the 10 genes including *Lrrc59*, *Abca8a*, *S100a11*, *IL-8R*, *Nfkbiz* and *Daf1*, were also upregulated (4 fold or greater), in the serum of rats given Dopamine. With exception of *S100a11*, these genes were not regulated in the serum of rats given Yohimbine thereby, providing further evidence of their association with vascular injury, namely mesenteric MAN. Although further studies are required to fully assess the utility of these serum-derived mRNAs as biomarkers of DIVI, they have the potential to help improve the characterization of DIVI in rats for early safety assessment in drug development.

**PS 937 Identification and Quantitative Evaluation of Novel Circulating Liver-Specific mRNAs in Rats Treated with Various Hepatotoxic Compounds: Validation for Biomarkers of Drug-Induced Liver Injury.**

S. Okubo<sup>1,2</sup>, M. Miyamoto<sup>1,2</sup>, K. Takami<sup>1,2</sup>, M. Kanki<sup>2,3</sup>, A. Ono<sup>2,4</sup>, N. Nakatsu<sup>2</sup>, H. Yamada<sup>2</sup>, Y. Ohno<sup>4</sup> and T. Urushidani<sup>2,5</sup>. <sup>1</sup>Drug Safety Research Laboratories, Takeda Pharmaceutical Company Limited, Kanagawa, Japan; <sup>2</sup>Toxicogenomics Informatics Project, National Institute of Biomedical Innovation, Osaka, Japan; <sup>3</sup>Astellas Pharmaceutical Incorporated, Osaka, Japan; <sup>4</sup>National Institute of Health Sciences, Tokyo, Japan; <sup>5</sup>Doshisha Women's College of Liberal Arts, Kyoto, Japan.

In our previous report, circulating liver-specific albumin (Alb) and  $\alpha$ -1 microglobulin/bikunin precursor (Ambp) mRNAs have been shown to be potential biomarkers for drug-induced liver injury (DILI). We identified apolipoprotein h (ApoH) and group specific component (Gc) mRNAs as additional biomarkers, and quantified total of four mRNAs in plasma from rats treated with wide variety of hepatotoxicants to validate circulating liver-specific mRNAs as biomarkers for DILI. Bioinformatic and molecular biological analyses revealed the high liver-specificity of ApoH and Gc mRNAs, and increased plasma levels of these mRNAs were confirmed by real-time quantitative RT-PCR in rats treated with thioacetamide (TAA). To examine the characters of the four circulating liver-specific mRNAs, seven hepatotoxicants were administered to rats. The severities of liver injury were variable among individuals and compounds. At 24 hr after single dosing, parallel increases of the four circulating liver-specific mRNAs were noted and the levels correlated with changes in the ALT values and hepatocellular necrosis scores. In addition, all the four mRNAs increased with greater magnitude than the ALT values. Time course analysis within 24 hr after single dosing of TAA showed that the plasma levels of Alb and Gc mRNAs increased remarkably before the ALT elevations and the timing of the increase was different among mRNA species, indicating that circulating liver-specific mRNAs may predict the beginning of liver damage and enable us to know the stages of injury. This validation study clearly demonstrated that the four circulating liver-specific mRNAs would be reliable and useful biomarkers for DILI.

**PS 938 Metabolomics and Transcriptomics Evaluation of Preclinical Biomarkers of Hepatotoxicity: An Update.**

R. D. Beger<sup>1</sup>, L. K. Schnackenberg<sup>1</sup>, S. Jinchun<sup>1</sup>, L. Pence<sup>1</sup>, T. Schmitt<sup>1</sup>, Y. Ando<sup>2</sup>, X. Yang<sup>1</sup>, J. Greenhaw<sup>1</sup>, S. Slavov<sup>1</sup>, S. Bhattacharyya<sup>1,3</sup>, W. E. Salminen<sup>1</sup> and D. L. Mendrick<sup>1</sup>. <sup>1</sup>NCTR, US FDA, Jefferson, AR; <sup>2</sup>Daiichi Sankyo Co. Ltd., Tokyo, Japan; <sup>3</sup>Arkansas Children's Hospital Research Institute, Little Rock, AR.

Drug-induced hepatotoxicity represents a major reason that drugs are recalled post market. Furthermore, it has been estimated that 10% of acute liver failure is due to idiosyncratic events. While there is no standard definition for "idiosyncratic," the term is generally applied to compounds that induce a relatively low incidence of hepatotoxicity in humans and fail to exert liver damage using classical toxicity endpoints in commonly used preclinical testing species such as rats and dogs. The inability to identify such compounds with classical preclinical markers of

hepatotoxicity has necessitated the need to discover new biomarkers. In order to identify biomarkers of idiosyncratic toxicity, a systems biology study was initiated to evaluate omics endpoints in urine, blood and liver tissue from rats dosed with compounds that have been shown to be overt hepatotoxicants, idiosyncratic hepatotoxicants, and negative hepatotoxicants. The two overt hepatotoxicants were acetaminophen (APAP) and carbon tetrachloride (CCl<sub>4</sub>). Three additional compounds have been studied; one is generally classified as idiosyncratic in nature, felbatol (FEL), while the other two are considered to not cause liver injury, meloxicam (MEX) and penicillin (PEN). Since idiosyncratic and non-hepatotoxicant drugs do not cause overt hepatotoxicity, doses were used to induce some adverse effect (e.g., a decrease in body weight) to provide a phenotypic anchor. Early results show that increases in blood levels of multiple acyl carnitines could be an indication of hepatic mitochondrial injury and altered levels of bile acids may be related to drug-induced hepatotoxicity, activation of liver transporters or due to effects on gut microflora. Blood levels of lysoPCs were decreased in the rats treated with a high dose of APAP, CCl<sub>4</sub> and FEB at 6 and/or 24 hr.

**PS 939 Whole Transcriptome RNA-Seq of FFPE Liver.**

S. S. Auerbach<sup>1</sup>, B. A. Merrick<sup>1</sup>, R. R. Shah<sup>2</sup>, D. Phadk<sup>2</sup>, B. Xie<sup>3</sup>, J. Shin<sup>3</sup>, Y. Gao<sup>3</sup> and R. R. Tice<sup>1</sup>. <sup>1</sup>Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>SRA International, Durham, NC; <sup>3</sup>Lieber Institute for Brain Development, Johns Hopkins University, Baltimore, MD.

Formalin fixed, paraffin embedded (FFPE) pathology specimens represent a potentially rich resource for transcriptomic-based biomarker discovery. While a number of approaches have been developed that employed targeted, amplification dependent microarray analysis, no one has employed the agnostic approach of whole transcriptome RNA-seq to the analysis of RNA extracted from FFPE samples. Here, we compare whole transcriptome using RNA-seq performed on fresh frozen (FF) and FFPE RNA samples obtained from Fischer F344 rats exposed to Aflatoxin B1 (AFB1) at 1 ppm in feed for 90d and paired control animals. ~70% of reads generated from each FFPE sample aligned to Rn4and mapping corresponded well with defined transcription boundaries for most RefSeq genes. Whole transcriptome PCA indicated clear distinction between FFPE and FF however robust, parallel differentiation between AFB1 and control samples was obvious in both data sets. A rank based comparison of global transcript abundance was strongly correlated between FF and FFPE, suggesting the global liver biology at the transcript level remained intact in the FFPE samples. Differential expression analysis indicated that of the 405 RefSeq genes altered by AFB1 in FF samples, 288 (of 487 showing differential expression) were also differentially expressed in FFPE samples. Expression of selected genotoxic carcinogenicity biomarker genes (e.g., Adam8, Mybl2, Cdh13, Cngl1, Ddit4l, Cdkn1c) were concordantly up-regulated in FF and FFPE by AFB1 treatment. Comparison of the genomic response to AFB1 in FF and FFPE at a pathway level using GSEA found concordant regulation of cell cycle, autophagy, xenobiotic metabolism, and p53 signaling and discordant regulation of proteasome and NOD-like signaling pathways. We have demonstrated that accurate whole transcriptome profiling is possible with RNA extracted from FFPE samples. The success of this approach opens up new avenues for performing signature-based biomarker discovery.

**PS 940 Hepatic Hemangiosarcoma Due to Occupational Vinyl Chloride Exposure Generates a Distinct Plasma Metabolite Profile.**

M. Cave<sup>1,2</sup>, B. Wheeler<sup>1</sup>, K. Falkner<sup>1</sup> and C. McClain<sup>1,2</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY.

Occupational vinyl chloride (VC) exposure has been associated with the development of hepatic hemangiosarcoma (HS), an extremely aggressive and otherwise unusual form of liver cancer. Routine liver biochemistries are typically normal even in advanced hemangiosarcoma. The purpose of this study is to determine if VC-related hemangiosarcoma alters the plasma metabolome. Plasma samples from 16 highly-exposed VC workers with hemangiosarcoma (VC+/HS+), 17 highly-exposed VC workers without hemangiosarcoma (VC+/HS-), and 27 unexposed healthy volunteers (VC-/HS-) were obtained from a specimen bank. GC/MS and LC/MS2 were performed following metabolite extraction. Software was used to match ions to a library of standards for metabolite identification and quantitation by peak area integration. Random Forest analysis was performed. Welch's Two Sample t-test comparisons were made between the means of each biochemical. Results of Random Forest analyses of all 613 named and 518 unnamed biochemicals observed in plasma yielded an overall predictive accuracy of 82% for classifying

samples within each group, strongly indicating that hemangiosarcoma generates a distinct global metabolic profile in plasma from those that were exposed but failed to develop the disease. When comparing VC+/HS+ vs. VC+/HS-, 65 named biochemicals were up-regulated while 50 were down-regulated. Likewise, 43 unnamed biochemicals were up-regulated and 27 were down-regulated. Four key metabolite subclasses containing named biochemical were identified. Hemangiosarcoma increased metabolite levels in these classes accordingly: Class A (8/10 metabolites, up to 6 fold increase); Class B (5/7 metabolites, up to 121 fold increase); Class C (3/3 metabolites, up to 84 fold increase); Class D (9/15 metabolites, up to 92 fold increase). In chemical workers with high-level vinyl chloride exposures, hemangiosarcoma generates a distinct plasma global metabolic profile from those that were exposed but failed to develop the disease.

#### PS 941 **Metabolomic Biomarkers in Long-Term Smokers and Moist Snuff Consumers.**

G. L. Prasad<sup>1</sup>, B. A. Jones<sup>1</sup>, P. Chen<sup>1</sup> and A. D. Kennedy<sup>2</sup>. <sup>1</sup>R & D, RJ Reynolds Tobacco Co., Winston-Salem, NC; <sup>2</sup>Metabolon Inc, Durham, NC. Sponsor: G. Krautter.

The long-term health effects associated with cigarette smoking have been shown to be more harmful compared to those associated with the use of non-combustible tobacco products, such as moist snuff. To investigate the long-term effects of tobacco exposure, we evaluated the biochemical profiles of 40 smokers, 40 moist snuff consumers (MSC), and 40 non-tobacco consumers (NTC) using UHPLC-mass-spectrometry based global metabolomics. Matching twenty-four-hour urine and plasma samples were collected from study subjects to generate metabolomic profiles. In this global profiling study, a total of 511 biochemicals (290 known and 221 unknown metabolites) were detected in the plasma, whereas 972 biochemicals (396 known and 596 unknown) were found in urine. The "named" metabolites could be grouped into diverse physiological pathways such as glucose, lipid, bile acid and amino acid metabolism.

Based on the differential levels of metabolites, random forest analyses separated non-tobacco consumers (NTC), smokers, and MSC with high accuracy (96%) when all metabolites were included. On the other hand, MSC showed more subtle changes in metabolomic profiles, and were more difficult to separate from NTC when nicotine metabolites were excluded from the analyses. The metabolomic changes suggest that smokers exhibited exacerbated oxidative stress and inflammatory pathways relative to MSC and NTC cohorts. Biochemical changes in glucose, lipid amino acid and xenobiotic metabolism were also noted in the study cohorts. These metabolites could be used as potential biomarkers of effect, pending further validation. In summary, global metabolomic profiles and panels of selected biomarkers could potentially be used to assess the effects of tobacco use.

#### PS 942 **Effect of Benzo(a)pyrene Exposure Dose on Levels of Exposure Biomarkers, DNA Adducts, and Gene Expression in Rats.**

M. Moreau<sup>1</sup>, P. Ayotte<sup>2</sup> and M. Bouchard<sup>1</sup>. <sup>1</sup>Department Environmental and Occupational Health, University of Montréal, Montréal, QC, Canada; <sup>2</sup>Institut national de santé publique du Québec, Québec, QC, Canada.

The effect of benzo(a)pyrene (BaP) doses on levels of several biomarkers of exposure and early effects was studied in rats intravenously injected with 0.4, 4, 10 and 40 µmol/kg of BaP. Blood, tissues and excreta were collected 8 h and 24 h post-treatment. BaP and several of its metabolites, 3- and 7-OHBP, 4,5- and 7,8-BaPdiols, tetrol, 1,6-, 3,6- and 7,8-BaP-diones, were simultaneously measured in blood, tissues and excreta by UHPLC/fluorescence. BaPDE-DNA adducts in lungs were quantified in parallel using an ultrasensitive immunoassay with chemiluminescence detection. Expression of various genes in lungs of treated rats (lung RNA) compared to control rats was also assessed by qRT-PCR. There was a dose-dependent increase in blood and tissue levels as well as excretion of BaP metabolites. At 8 h and 24 h postinjection, BaP and 3-OHBP were found in higher concentrations in blood and tissues compared to the other analytes. However, BaPdiols were excreted in greater amounts in urine and apparently more quickly than hydroxyBaP. Mean percentages (± SD) of injected dose excreted in urine as 4,5-diol-BaP during the 0-8 and 0-24-h period post-treatment were 0.16 ± 0.03% and 0.14 ± 0.08%, respectively. Corresponding values for 3-OHBP were 0.004 ± 0.001% and 0.026 ± 0.014%. Diones were not detectable in blood, tissues and excreta using the developed method and BaP-7,8-diol and 7-OHBP were found to be more minor metabolites. There was also a dose-dependent increase in DNA adduct formation. Analysis of gene expression further showed a modulation of cyp1a1, cyp1b1, nqo1, nrf2, fos and Ahr expression at the 10 and 40 µmol/kg doses, but not at the lower

doses. This study confirms the interest of measuring multiple metabolites in combination with DNA adducts and alteration of gene expression for a more comprehensive assessment of links between biomarkers of BaP exposure and early effects.

#### PS 943 **Biomarker Discovery for Early Detection of Hepatocellular Carcinoma (HCC) in Hepatitis C (HCV) Infected Patients.**

G. M. Mustafa<sup>1</sup>, J. R. Petersen<sup>1</sup>, J. Hyunsu<sup>1</sup>, L. Cicalese<sup>1</sup>, N. Snyder<sup>2</sup>, S. J. Haidacher<sup>1</sup>, L. Denner<sup>1</sup> and C. Elferink<sup>1</sup>. <sup>1</sup>University of Texas Medical Branch, Galveston, Galveston, TX; <sup>2</sup>Kelsey Seybold Clinic, Galveston, TX.

The projected rise in HCC (the most common primary liver cancer) cases in the US is mainly due to HCV infections with onset of HCC coming several decades after initial infection. However, additional environmental risk factors including alcohol, tobacco and other dietary insults that induce liver injury also increase the incidence of HCC. The poor prognosis for HCC is largely due to late stage diagnosis making successful intervention difficult. Existing biomarkers for early HCC detection lack the specificity and sensitivity to be very effective. Our aim is to develop serum-based biomarkers suitable for early HCC detection that will provide a sensitive yet specific screen. Serum was obtained from individuals positive for HCV who were clinically diagnosed with liver disease (pre-HCC) or HCC. Serum was pre-fractionated using an aptamer-based technology and further fractionated using 2D-Difference In Gel Electrophoresis. Pre-HCC and HCC profiles were compared and the peptides located in 24 different 2D-DIGE spots exhibiting a statistically significant ≥1.5-fold change between pre-HCC and HCC samples were identified by mass spectrometry (MS). Stable isotope O18/O16 labeling was used to verify the identity of proteins identified by 2D-DIGE and to aid in development of Selected Reaction Monitoring (SRM) assays. ApoA1 was selected to develop an SRM as proof of concept in this biomarker discovery protocol. Using a Triple Quadrupole MS (Agilent), Optimizer (Agilent) and skyline (MacCoss) to assist in the design we developed an SRM assay to quantify this candidate biomarker using labeled internal standards (AQUA peptides). The SRM is capable of reliably detecting a >30% reduction in ApoA1 in HCC serum samples relative to the pre-HCC samples. Future multiplexing of SRM assays for other candidate biomarkers is envisioned to develop a biomarker panel for subsequent verification and validation studies.

#### PS 944 **Effects of Acrylamide Exposure on Gene Expression in the Thyroid of Male and Female RccHan Wistar Rats.**

R. C. Colli-Dula<sup>1</sup>, M. A. Friedman<sup>2</sup> and N. Denslow<sup>1</sup>. <sup>1</sup>CEHT, University of Florida, Gainesville, FL; <sup>2</sup>TR Services, Oviedo, FL.

Acrylamide is a chemical commonly utilized to make polymers used in industry including waste water treatment, mining, among other uses. It became a public health concern when it was detected in food products. Daily exposure to acrylamide has been associated with neurological toxicity in different animal species and with tumors in the mammary gland, testicular tunica vaginalis, and thyroid. In relation to its potential for forming tumors, it is important to distinguish its ability to act as genotoxin from a hormone mimic. The goal of this study was to use microarray analysis to determine changes in gene expression in the thyroid gland of male and female RccHan Wistar rats treated at 3 mg/kg in drinking water from gestational day 6 to pnd (post natal day) 30. Thyroid glands were collected from rats at 10 PM to reflect non-quietest thyroid activity. The transcriptome analysis showed that acrylamide caused a significant alteration in the expression of genes related to phase II detoxifying enzymes and oxidative stress, neurotoxicity, apoptosis, and tumorigenesis. Results from enrichment and pathway analysis showed that in both genders, acrylamide caused differential regulation of genes associated with cell processes of protein folding, microtubule cytoskeleton assembly, DNA replication, DNA repair and ROS generation. These data suggest a potential involvement of this chemical in cell processes other than mutagenicity which may be associated with tumorigenesis. Furthermore, our study, by identifying affected gene ontologies and pathways, provides insight into a potential mechanism of action and may have substantial impact on risk assessment.

#### PS 945 **Development of a Quantitative Proteomics Multiplexed Assay for the Predictive Assessment of Drug-Induced Organ Toxicity in the Preclinical Setting.**

M. Gharib<sup>1,2</sup>, P. Thibault<sup>2</sup>, A. Nelson<sup>3</sup>, D. Chelsky<sup>1</sup>, L. Di Donato<sup>1</sup> and L. McIntosh<sup>1</sup>. <sup>1</sup>Caprion Proteome Inc, Montréal, QC, Canada; <sup>2</sup>Université de Montréal, Montréal, QC, Canada; <sup>3</sup>ITR Canada, Baie d'Urfé, QC, Canada. Sponsor: W. Lee.

Drug-induced organ toxicity is the primary reason for the withdrawal of drugs from the market and the failure of lead compounds during drug development. Detection of organ toxicity early in the development pipeline would not only reduce the cost

of drug development but also prevent injuries to patients in the clinic. Limitations of traditional approaches highlight the need for more sensitive and specific tools to predict drug toxicity. With the recent regulatory qualification of seven renal safety biomarker for use during drug development, biomarkers are increasingly viewed as potential means for providing toxicity assessments. Here, we have employed a targeted mass spectrometry (MS) approach, known as multiple reaction monitoring (MRM) to quantitatively measure changes in organ-specific toxicity biomarkers in rats. A highly multiplexed MRM assay, targeting 192 candidate protein biomarkers of hepatotoxicity, nephrotoxicity, cardiotoxicity as well as muscle, vascular and neurotoxicity, was developed. Results show that markers for all organs covered in our toxicity biomarker panel are detectable in serum and urine under normal conditions. Significantly, GGT5 and MDH-1, important liver injury biomarkers currently under investigation as well as qualified kidney injury biomarkers cystatin-C, clusterin and  $\beta$ -2-microglobulin and albumin were successfully detected in serum and urine, respectively. We tested the predictive value of our panel on cyclophosphamide treated rat blood samples. In agreement with the literature, we found that serum biomarkers for the kidney, the vascular system and the liver were markedly increased following toxicity. The present MRM assay has the potential to become standard practice for pre-clinical drug safety assessments. Further studies will be centered on applying this assay to monitor urinary kidney injury biomarkers following cisplatin-induced nephrotoxicity of rats.

**PS 946 Development of a LC/MS Serum Bile Acid Profiling Method for Sensitive Detection of Biliary Injury in Dogs.**

J. M. Maher, T. Sharapova, R. Yeager, E. Blomme and S. Cepa. *R45M, Abbott Laboratories, Abbott Park, IL.*

Currently there are many non-invasive methods for assessing hepatic toxicity in large animal species, but biliary injury is often difficult to detect in lieu of histopathology. Notably hepatobiliary biomarkers such as liver transaminases, alkaline phosphatase, gamma glutamyl transferase, and total bilirubin suffer from poor specificity or sensitivity in detection of biliary injury. Quantification of serum bile acids has been utilized in veterinary medicine in the diagnosis of biliary disease with success, but the current methods of quantification suffer from technical hurdles and lack robustness. Thus the purpose of the current study was to develop a method for detection of serum bile acids in dogs using liquid chromatography-mass spectrometry (LC/MS) for sensitive and rapid detection of hepatobiliary injury by quantifying the individual bile acid species in tandem. Twenty bile acids species were assessed with the current LC/MS method, including primary cholic and chenodeoxycholic bile acids and secondary bile deoxycholic and lithocholic bile acids, including the glycine- and taurine-conjugated forms. A diagnostic reference range was established from more than 50 untreated, fasted beagles of both genders to assess normal variability with benchmarked clinical pathology. These individual serum bile acid levels ranged from approximately 900 pmol/ml to levels below the limits of detection, with all taurine-conjugated species notably detected in serum. The applications of this method in assessing the sensitivity and specificity of serum bile acids versus existing methods will be discussed in the early detection of drug-induced hepatobiliary injury.

**PS 947 Lack of Concordance in Microarray Gene Expression Responses to Phenobarbital in Companion-Aged FFPE and Frozen Liver Samples.**

S. Hester, G. Carswell, B. Vallanat, A. B. DeAngelo and C. E. Wood. *US EPA, Durham, NC.*

Despite the immense potential value of public and private biorepositories, direct utilization of archival tissues for molecular profiling has been limited. A major reason for this limited use is the difficulty in obtaining reliable transcriptomic profiles from formalin-fixed paraffin-embedded (FFPE) tissue samples with highly fragmented nucleic acid. The goal of this study was to evaluate transcriptional responses in 16 year-old FFPE and companion frozen (FROZ) liver samples from F344 rats treated for 2 yrs with control water or water with 0.06% Phenobarbital (PB), a known CAR/PXR inducer and rodent liver mitogen. RNA isolation and gene expression was performed using the Rat Illumina Bead Array® for 16 samples, paired FFPE and FROZ. The RNA integrity numbers (RINs) ranged from 2-3 for FFPE and 3-5 for FROZ, and RNA yield for both FFPE (2 10 $\mu$ m sections) and FROZ (20 mg) samples was 2-4 micrograms. Nugen Ovation® and Encore® reagents optimized for FFPE tissues were used to amplify and label the RNA followed by hybridization to arrays. We selected 12 of 16 samples based on successful hybridization performance for analysis. Differential gene expression was assessed using Rank Products followed by pathway mapping. Results showed only 10 significantly altered PB-responsive genes in common between paired FFPE (n=1373) and FROZ (n=721) samples whereas pathway analysis identified only a 10% overlap in pathways significantly altered by PB between FFPE and FROZ samples. Pathway profiles for both FFPE and FROZ samples were unique to their respective

sample type. The lack of concordance in genomic responses to PB suggests that traditional microarray platforms are inadequate for genomic profiling of aged FFPE samples, despite improved RNA isolation and labeling methods. Further work will evaluate more recent next-generation sequencing (NGS) technologies for transcriptomic analysis of archival specimens. This abstract does not reflect EPA policy.

**PS 948 Formaldehyde-Induced Changes in microRNA Signaling.**

J. E. Rager<sup>1</sup>, B. C. Moeller<sup>2</sup>, M. Doyle-Eisele<sup>3</sup>, J. A. Swenberg<sup>1,2</sup> and R. C. Fry<sup>1,2</sup>. <sup>1</sup>Environmental Sciences and Engineering, The University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Curriculum in Toxicology, The University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Lovelace Respiratory Research Institute, Albuquerque, NM.

MicroRNAs (miRNAs) are critical regulators of gene expression, yet much remains unknown regarding miRNA changes resulting from environmental exposures and whether they influence pathway signaling across various cell types and time. To gain knowledge on these novel topics, we set out to investigate in vivo miRNA responses to inhaled formaldehyde, an important air pollutant known to disrupt miRNA expression profiles. Rats were exposed by inhalation to either 0 or 2 ppm formaldehyde (6 hours/day) for 7 days, 28 days, or 28 days followed by a 7 day recovery. Genome-wide miRNA expression profiles and associated signaling pathways were assessed within the nasal respiratory mucosa, circulating mononuclear white blood cells (WBC), and bone marrow (BM). We found that miRNAs were responsive to formaldehyde exposure in the nose and WBC, but not the BM. A transcriptomics-based analysis was performed in the nose and WBC of the rats exposed for 28 days. In the nose, formaldehyde altered the expression of 42 transcripts; of these, 15 (36%) were computationally predicted to be regulated by formaldehyde-responsive miRNAs. Conversely, in the WBC, formaldehyde altered the expression of 130 transcripts; of these, 18 (14%) were predicted to be regulated by miRNAs. Systems-level analyses revealed that the transcripts regulated by miRNAs play diverse roles in cell signaling. Key players include dosage suppressor of mck1 homolog, meiosis-specific homologous recombination (Dmcl1) and secreted frizzled-related protein 4 (Sfrp4) within the nose, involved in cell death signaling. In WBC, key players were v-akt murine thymoma viral oncogene homolog 3 (protein kinase B, gamma) (Akt3) and integrin, alpha 2 (Itga2), involved in inflammation signaling. Our study informs critical knowledge towards the biological consequences of inhaled formaldehyde exposure.

**PS 949 Dermal Sensitization to Toluene Diisocyanate in Mice Is Manifested by Early Changes in the Proteome of Auricular Lymph Nodes and Serum.**

S. Haenen<sup>1,3</sup>, E. Clynen<sup>2</sup>, V. De Vooght<sup>1</sup>, L. Schoofs<sup>3</sup>, B. Nemery<sup>1</sup>, P. Hoet<sup>1</sup> and J. Vanoirbeek<sup>1</sup>. <sup>1</sup>Occupational, Environmental and Insurance medicine, KU Leuven, Leuven, Belgium; <sup>2</sup>Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium; <sup>3</sup>Research Group of Functional Genomics and Proteomics, KU Leuven, Leuven, Belgium.

**Introduction.**

Diisocyanates are capable of initiating an allergic response, which can lead to occupational asthma after a latency period. Clinical symptoms such as cough, wheezing and dyspnea occur only late, making it difficult to intervene at an early stage.

We explored proteome changes, before asthma is apparent, in the local draining lymph nodes and serum of mice dermally sensitized once or twice with toluene diisocyanate (TDI) to explore biomarkers of sensitization.

**Methods.**

The proteomes of male BALB/c mice (6 weeks old, 20g), sensitized once (n=12) or twice (n=12) with 0.3% TDI, were individually compared with control mice (n=12) using two-dimensional difference gel electrophoresis (2D-DIGE). A level of p<0.01 (Student's t-test) was considered significant.

Western blot or ELISA was used to verify a subset of the differential proteins. A level of p<0.05 (unpaired t-test) was considered significant.

**Results.**

In the lymph nodes, we found between TDI-treated and control mice 38 and 58 differential proteins after one and two treatments, respectively. In serum, 7 and 16 differential proteins were detected after one and two treatments, respectively. We identified 80-85% of these proteins by mass spectrometry. Among them, lymphocyte specific protein-1, coronin 1a and hemopexin were verified in an independent group of mice by Western blot or ELISA.

**Conclusion.**

Our study revealed, in a mouse model, alterations in the proteome during sensitization. If validated in humans, these changes could lead to earlier diagnosis of exposed workers.

All animal experiments were approved by the Local Ethical Committee for animal experiments of the KU Leuven.

## PS 950 Smoking-Induced microRNA Changes in Human Sperm.

E. L. Marczylo<sup>1</sup>, J. Janus<sup>3</sup>, A. A. Amoako<sup>2</sup>, J. C. Konje<sup>2</sup>, T. H. Marczylo<sup>1</sup> and T. W. Gant<sup>1</sup>. <sup>1</sup>CRCE, Health Protection Agency, Didcot, United Kingdom; <sup>2</sup>Reproductive Sciences, Leicester Royal Infirmary, Leicester, United Kingdom; <sup>3</sup>Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom.

Recent work has suggested that some of the constituents of cigarette smoke, along with other environmental chemicals, can have adverse effects not just on the exposed individuals, but also on their progeny. Although the mechanisms underlying multigenerational toxicity are not well understood, a number of studies have implicated heritable microRNA-mediated epigenetic modifications. Using microarray profiling and pathway analysis, we have shown that cigarette smoke induces specific differences in the spermatozoa microRNA content of human smokers compared with non-smokers, and that these altered microRNAs appear to predominantly mediate pathways vital for healthy sperm and normal embryo development, particularly cell death and apoptosis. MicroRNA-mediated perturbation of such pathways may explain how harmful phenotypes can be induced in the progeny of smokers. Consequently, we have also been developing an *in vitro* system for investigating the potential roles of microRNAs in toxicology. By differentiating embryonic stem cells into embryoid bodies we have been able to generate and subsequently isolate sets of clonal primordial germ cell lines. These cell lines can be produced in the presence and absence of environmental chemicals (for example 17 $\beta$ -estradiol and di-butyl-phthalate), and exhibit chemically-induced differential microRNA expression. This model (including both the embryoid bodies and the resulting primordial germ cell lines) shows promise for further investigating the mechanisms of microRNA-mediated toxicity induced by environmental chemicals, including cigarette smoke. All work was approved by the Leicestershire, Rutland and Northamptonshire Ethics (Institutional Ethics) Committee and written informed consent to partake in the study was obtained from all volunteers.

## PS 951 New Data from Old Studies: Development of qRT-PCR Signature Assays for Assessment of Mode-of-Action from Formalin Fixed Paraffin Embedded Archival Tissues.

S. Phillips<sup>2,1</sup>, L. Recio<sup>1,2</sup>, T. Maynor<sup>1</sup> and M. D. Waters<sup>1</sup>. <sup>1</sup>ILS, Research Triangle Park, NC; <sup>2</sup>ILS Genomics, Morrisville, NC.

Archival formalin fixed paraffin embedded (FFPE) tissue samples collected over decades from toxicological studies represent a rich source of biological materials with detailed pathological evaluations from the testing of numerous substances. Until recently, the application of 'omics technologies to toxicology studies has been primarily limited to fresh frozen tissue samples collected at necropsy. Archival FFPE tissues represent a rich and largely untapped resource of invaluable information. There is a clear need to develop methods to apply 'omics based technologies to FFPE tissue banks. ILS and ILS Genomics have developed a systematic approach using bioinformatics and laboratory testing for the de novo design of gene specific qRT-PCR assays for use on FFPE archival tissue samples. For these studies, mouse liver carcinogen furan was administered by oral gavage at 0.0, 2.0, 4.0 and 8.0 mg/kg with 5 animals per group for three weeks. Animals were necropsied at 4 hrs after the final administration, liver sections were flash frozen in liquid nitrogen and stored at -80°C. Other liver sections were fixed in formalin for 18-24 hrs, transferred to ethanol for 2 days and then processed into FFPE tissue blocks. Total RNA was extracted from paired frozen and FFPE tissues (10  $\mu$ m sections) for subsequent qRT-PCR analysis. Custom designed qRT-PCR assays using TaqMan technology with amplicons of approximately 70 bp were tested to demonstrate equal primer efficiencies between frozen and FFPE tissue RNA isolations. Using this strategy we have validated a set of 8 genes and 2 lncRNAs (Chek1, Cyp4a14, Egr1, Ephx2, Cdkn1a, Xrcc1, Dppa5a, Gsta1 lncRNA-p21 and lncRNA-Chr9: 78107225-78118850) and normalization gene Actb to quantify mRNA levels in liver RNA isolated from FFPE compared to frozen tissues. These studies demonstrate that quantitative analysis of mRNA levels from FFPE tissue samples can be done using highly specific mRNA qRT-PCR assays.

## PS 952 Identification of Novel Biomarkers for Drug-Induced Renal Papillary Necrosis in Rats by Toxicoproteomic Techniques.

D. Sasaki<sup>1,2</sup>, M. Kanki<sup>1</sup>, K. Nishihara<sup>1</sup>, M. Hiramoto<sup>1</sup>, M. Yuri<sup>1</sup>, H. Umeno<sup>1</sup>, A. Moriguchi<sup>1</sup>, H. Mitori<sup>1</sup>, R. Hirota<sup>1</sup>, J. Seki<sup>1</sup>, Y. Miyamae<sup>1</sup>, G. Hwang<sup>2</sup> and A. Naganuma<sup>2</sup>. <sup>1</sup>Astellas Pharma Inc., Osaka and Tsukuba, Japan; <sup>2</sup>Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.

Renal papillary necrosis (RPN) is a type of kidney injury that is often observed in diabetics and patients taking nonsteroidal anti-inflammatory or anticancer drugs. However, no prognostic biomarkers (BMs) for RPN in humans have been identified. Here, we searched for novel BMs suitable for early RPN detection using toxicoproteomic techniques.

Urine from rats with RPN induced by a single injection of 2-bromoethylamine hydrobromide (BEA; 0, 3, 10, 30, and 100 mg/kg) was pooled into 4 groups. Urinary proteins in each group were analyzed by 2-dimensional LC-MS/MS coupled with isobaric tags (iTRAQ) to identify BM candidates. The urinary levels of BM candidates were quantified in individual rats after BEA treatment to assess the ability of these markers to detect RPN in comparison with FDA- and/or EMA-approved BMs for assessing preclinical kidney injury. The identified BM candidates were also measured in the urine of rats with glomerular- or proximal tubular (PT)-injury induced by puromycin, cisplatin, or gentamicin to verify the site specificity of the kidney lesions. In BEA-treated rats, 75 proteins with >2-fold increases in urinary concentrations compared with those in control rats were identified. Among these proteins, the selectivity and sensitivity of Es2, fetuin-A, and fibrinogen for RPN were evaluated. Es2 levels in urine were elevated rapidly after BEA treatment compared to those of serum BUN, creatinine, urinary clusterin, KIM-1, and RPA-1, and were also increased in glomerular- or PT-injury rats, suggesting that Es2 is a highly sensitive, but nonselective for RPN. In contrast, fetuin-A and fibrinogen were selective for RPN, as no marked changes in their urinary concentrations were observed in glomerular or PT-injury rats, but had low sensitivity for RPN detection. In conclusion, we identified three BM candidates for RPN with kidney lesion-site specificity and different sensitivities.

## PS 953 Determination of Formaldehyde Specific DNA-Protein-Crosslinks.

B. C. Moeller<sup>1</sup>, W. M. Bodnar<sup>2</sup> and J. A. Swenberg<sup>1,2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Formaldehyde (FA) is classified as a known human and animal carcinogen. It is a ubiquitous environmental pollutant and is used in a number of consumer products or industrial applications. FA is also endogenously produced as part of normal cellular metabolism. FA is a genotoxic agent, causing a number of effects on cells including DNA monoadducts, DNA-DNA crosslinks and DNA-protein-crosslinks (DPC). DPCs are believed to be one of the critical lesions involved in FA induced carcinogenesis and is thought to provide a key initiating step in the Mode-of-Action. Currently, there are no available methods to distinguish between endogenous and exogenous FA induced DPCs. To investigate the possible link between inhaled FA and the formation of both endogenous and exogenous DPCs, several analytical techniques are being developed. *O*-Alkylguanine-DNA alkyltransferase (AGT) is a DNA repair enzyme that is known to form DPCs with FA and other crosslinking agents at the active Cys145 residue. Using AGT as a model protein, a series of experiments were undertaken to understand the formation, stability and degradation of the DNA-protein-crosslink at the reactive cysteine and the *N*<sup>2</sup> position of deoxyguanosine. Digestion conditions for both DNA and protein cleavage were investigated to determine approaches that would allow for the isolation and identification of either cysteine-CH<sub>2</sub>-dG or AGT peptide-CH<sub>2</sub>-dG crosslinks using sensitive and selective Liquid Chromatography – Mass Spectrometry. Further experiments investigating the ability to distinguish between crosslinks formed by both [<sup>13</sup>CD<sub>2</sub>]-FA and unlabeled FA were accomplished. Further validation and development of these approaches may allow for accurate and quantitative determination of endogenous and exogenous FA specific DPCs in cell culture and animal models. This information will be critical in advancing the understanding of the risks associated with inhaled FA and its role as a human carcinogen.

## PS 954 Pulmonary Toxicity and Global Gene Expression Profile in Response to Crystalline Silica Exposure in Rats.

R. Sellamuthu, C. Umbright, J. R. Roberts, S. Young, D. Richardson, W. McKinney, B. T. Chen, D. Frazer, S. Li, M. L. Kashon and P. Joseph. National Institute for Occupational Safety and Health (NIOSH), Morgantown, WV.

The ability to detect target organ toxicity as well as to determine the molecular mechanisms underlying such toxicity by employing surrogate biospecimens that can be obtained either by a non-invasive or minimally invasive procedure has significant advantage in toxicology. Pulmonary toxicity and global gene expression profiles in the lungs, blood and bronchoalveolar lavage (BAL) cells were determined in rats 44-weeks following inhalation exposure to crystalline silica (15 mg/m<sup>3</sup>, 6-hours/day, 5 days). A significant elevation in lactate dehydrogenase activity and albumin content in the BAL fluid as well as histological alterations, mainly type II pneumocyte hyperplasia and fibrosis, observed in the lungs suggested silica-induced pulmonary toxicity in the rats. A significant increase in the number of neutrophils and elevated monocyte chemotactic protein 1 in the BAL fluid indicated silica-induced pulmonary inflammation in the rats. Determination of global gene expression profiles in the lungs, BAL cells, and blood of the silica exposed rats identified 175, 273, and 59 significantly differentially expressed genes (SDEGs) (FDR <0.05 and >1.5 fold change in expression), respectively, compared with the corre-

sponding control samples. Bioinformatics analysis of the SDEGs demonstrated a remarkable similarity in the biological functions, molecular networks and canonical pathways that were significantly affected by silica exposure in the lungs, BAL cells and blood of the rats. Induction of inflammation was identified as the major molecular mechanism underlying the silica-induced pulmonary toxicity. These findings demonstrated the potential application of global gene expression profiling of blood and BAL cells as a valuable minimally invasive approach to study silica-induced pulmonary toxicity.

**PS 955 Comparison of a New Skin Penetration System Containing an Automated Toxicokinetic Modul with Franz Diffusion Cells.**

A. G. Schepky, I. Herberz, M. Akhiani, S. Müller, H. Wenck and D. Gerstel.  
4218-Research Toxicology, Beiersdorf AG, Hamburg, Germany.

Critical endpoints in in vitro testing of cosmetic ingredients are the determination of the bioavailability of test substances in different skin layers and the examination of the toxicokinetic profile. Skin penetration studies are so far performed in Franz diffusion cells using pig skin. Unfortunately with these cells an automated toxicokinetic determination of percutaneously penetrated substance is not receivable.

To perform toxicokinetic studies, we developed a new Vitrocell systems skin penetration system (SPS) with eight parallel running diffusion cells, which is able to take samples from the receptor fluid automatically. To substitute the Franz diffusion cells with the SPS it is important to compare both systems in terms of performance and reproducibility. Therefore we compared the penetration of caffeine through full thickness pig skin in Franz diffusion cells with manual sampling from the receptor fluid with the prototype of the SPS that provides automated sampling from the receptor fluid.

We could show toxicokinetic profiles for manual and automated samples with comparable lag times and recovery rates. Furthermore we could even show lower standard deviations using the SPS.

In conclusion, the new SPS is highly comparable to the Franz diffusion cell with the additional advantage to allow the automated detection of toxicokinetic profiles from the receptor fluid.

**PS 956 Risk Assessment for Cosmetic Ingredients Using Alternative Methods—Skin Sensitization.**

T. Atobe<sup>1</sup>, K. Tsujita<sup>1</sup>, S. Oeda<sup>1</sup>, M. Hirota<sup>1</sup>, T. Ashikaga<sup>1</sup>, H. Kouzuki<sup>1</sup>, T. Yoshida<sup>2</sup> and S. Aiba<sup>3</sup>. <sup>1</sup>Safety Technology Development Group, Shiseido Research Center, Yokohama, Japan; <sup>2</sup>Department of Biochemical Toxicology, Showa University School of Pharmacy, Tokyo, Japan; <sup>3</sup>Department of Dermatology, Tohoku University Graduate School of Medicine, Sendai, Japan.

Development of non-animal safety evaluation methods for chemicals is necessary from the viewpoint of animal welfare and to meet the 7th amendment of the European cosmetics directive. As an in vitro skin sensitization test, we have established two methods. One was the human cell line activation test (h-CLAT) detecting augmentation of CD86 and CD54 expression in THP-1 cells exposed by skin sensitizers. The other was the SH test taking advantage of changing cell-surface thiols on THP-1 cells induced by skin sensitizers. Recently the Antioxidant Response Element (ARE) assay measuring oxidative stress caused by skin sensitizers have been attracted attention. However, hazard assessment of skin sensitization has been unable to predict by only one test in vitro yet. Furthermore, non-animal methodologies in risk assessment how much a chemical has skin sensitization potency has just started in earnest. This study attempted to verify how to combine tests in vitro or in silico to assess chemical skin sensitizers. EC3 values from LLNA were accumulated by non-linear analysis using each endpoint from in vitro skin sensitization test and then some descriptors suggesting correlation to LLNA threshold values were selected. Correlation between the descriptors and EC3 values were analyzed by Artificial Neural Network (QwikNet Ver. 2.23). Molecular orbital of the three-dimensional chemical structures was also used in silico. As a result, the model obtained from tests in vitro or in silico reveals good correlation to in vivo data, thus the combination of in vitro and in silico method could be a sophisticated non-animal testing for risk assessment in skin sensitization.

**PS 957 Application of a Modified Keratinsens Assay to Predict Sensitization Hazard for Botanical Extracts.**

D. Gan<sup>1</sup>, K. Norman<sup>2</sup>, N. Barnes<sup>2</sup>, H. Raabe<sup>2</sup>, C. Gomez<sup>1</sup> and J. W. Harbell<sup>1</sup>.  
<sup>1</sup>Mary Kay Inc., Addison, TX; <sup>2</sup>IIVS, Gaitersburg, MD.

An essential step in the safety review of cosmetic/personal care ingredients is hazard assessment, including dermal sensitization potential. In vitro methods to identify allergic (haptenic) potential are based on electrophilic interaction with marker pep-

tides or cellular target systems. These assays use a specific molar ratio of the test chemical to the test system. Botanical extract ingredients, as mixtures, preclude specific molar ratio determination. Often, the botanical extract portion is a small fraction of the complete ingredient. To assess these mixtures, the KeratinoSens assay was selected because it operates over a wide dose range and sets cytotoxicity limits on doses used to measure marker gene expression (Emter et al, 2010). Induction of a luciferase gene, under the control of the antioxidant response element (ARE), was measured. Cytotoxicity was assessed by both NRU and MTT assays. Concentrations up to 1 mg/mL (of complete ingredient) were tested and a test dose was considered positive if the fold induction of luciferase was 1.5x (EC1.5) and viability  $\geq 70\%$  relative to the solvent controls. The goal of the study was to measure the activity of 3 known sensitizers (gluteraldehyde (GA) [strong], dimethyl maleate (DM) [moderate] and cinnamic aldehyde (CA) [moderate] spiked into four different botanical ingredients (with different excipient solvent systems). Activity was measured, relative to the EC1.5 of the neat sensitizer, as a function of sensitizer concentration and ingredient composition. Three independent trials were performed. No appreciable cytotoxicity was observed. The recovery of the GA spike required at least a 3-fold increase in concentration relative to the chemical alone and one extract reduced the activity below detection. The DM and CA showed activity at about the same effective concentrations as the neat chemicals although the DM showed reduced activity in one extract as well. These data suggest that the KeratinoSens assay has the potential to identify electrophile allergens within a botanical extract ingredient matrix.

**PS 958 Development of a Highly Reproducible Three-Dimensional Chinese Skin Reconstructed Model for Evaluating Drug and Cosmetic Skin Irritation.**

J. Wang<sup>1</sup>, Z. Du<sup>1</sup>, Z. Wang<sup>2</sup> and X. Zhang<sup>1</sup>. <sup>1</sup>Foreland Biopharma Co. Ltd., Beijing, China; <sup>2</sup>Boston University, Boston, MA. Sponsor: J. Wang.

In vitro models to study irritation, corrosivity and phototoxicity are important tools for research and development in the pharmaceuticals and cosmetic industries. Human skin is the best possible model for such in vitro studies. The commercially reconstructed human epidermis models are similar to the morphology, lipid composition and biomarkers of native human tissue and have been approved by European Centre for the Validation of Alternative Methods (ECVAM) for the validation of cosmetics. The models are available in many countries but not in China. Here, we describe the development of a constructed three-dimensional (3D) model using Chinese human skin, which consists of a "dermis" with fibroblasts embedded in rat collagen matrix and an "epidermis" comprised of differentiated keratinocytes. The fibroblasts and keratinocytes were first separated from foreskins of Chinese adults after incubating in dispase and collagenase solutions. Then, rat type I collagen was constructed onto the polycarbonate membrane of a culture insert. After gels solidified at room temperature, a collagen matrix with Chinese dermal fibroblasts was constructed above the acellular collagen layer. Keratinocytes were added to the surface of the contracted collagen gels and allowed to attach to the matrix to generate a confluent cellular monolayer. The reconstructed tissues were raised to an air-liquid interface to enable complete stratification and differentiation. After exposure and incubation, MTT assay was performed for cell viability. Nine well-known irritants or corrosive chemicals caused cell viability rates less than 50%. Cosmetics both from Western nations and China were also tested in the model. We found the Western cosmetics did not influence the cell viability compared to some of Chinese cosmetics which dramatically decreased cell viability 1 hour after exposure. Our data indicate that the reconstructed 3D Chinese skin model is highly reproducible and sensitive to assess skin irritation to chemicals and cosmetics.

**PS 959 Incorporation of Reconstructed Human Epidermal Tissues into a Corporate Toxicology Laboratory: Use of In Vitro Test Data for Diverse Safety and Risk Assessment Applications.**

L. M. Milchak, D. H. Brandwein and J. Zappia. Corporate Medical Department, 3M, St. Paul, MN.

The 3M Strategic Toxicology Laboratory (STL) is an internal corporate resource providing toxicology support to 3M businesses. An objective in the STL is to routinely incorporate *in vitro* test methods, with a recent focus on the use of reconstructed human epidermis tissues. The first model utilized has been EpiDerm™, which is currently validated for classification of chemicals for dermal irritation in OECD 439, and also dermal corrosion in OECD 431. Following the process outlined in the standard protocols for demonstration of technical proficiency, both test methods have been validated and used to assist with classification of chemistries for consumer and industrial use, utilizing the standardized MTT based cell viability assay. In addition, custom protocols have been performed using the tissues in time course irritation studies to evaluate the release of the inflammatory marker cytokine

IL-1 $\alpha$ . This approach has been advantageous for the simultaneous screening of multiple formulations for irritation potential during research and development for new products. Other customized studies have evaluated the efficacy of various skin washing agents at removal of a viscous coating from the skin tissues, in a simulated washing study to help formulate occupational health recommendations for workers. These studies evaluated irritation potential using MTT, IL-1 $\alpha$  and LDH release, and also analyzed the dermal penetration of an amine component in the coating. In summary, incorporation of these test methods has been very useful for the evaluation of a multitude of dermal exposure scenarios. The tissues have been used in standardized irritation and corrosion assays, as well as custom protocols utilizing additional markers of cell damage, and also specialized skin washing and dermal penetration studies. The results of these studies have provided valuable information for safety and risk assessment purposes, particularly during the product development phases, and have permitted these evaluations without animal use.

**PS 960 Intralaboratory Reproducibility of the Direct Peptide Reactivity Assay (DPRA) to Assess the Robustness of the Current Prediction Model.**

L. Foertsch and F. Gerberick. *Central Product Safety, Procter & Gamble Company, Cincinnati, OH.*

One characteristic of a chemical allergen is its ability to react with proteins prior to the induction of skin sensitization. The majority of chemical allergens is electrophilic and reacts with nucleophilic amino acids such as cysteine or lysine. In the DPRA, test chemicals are incubated for 24 hours with two synthetic peptides containing a cysteine or lysine residue, and the reactions are analyzed by HPLC to measure peptide depletion. We have previously demonstrated that reactivity correlates with sensitization potential and have developed a prediction model to assign a reactivity category for each material tested in the assay (Gerberick et al. *Tox Sci* 2007; 97:417-427). In order to assess the robustness of this prediction model and its ability to distinguish reactive skin sensitizers from minimally reactive non-sensitizers, a historical DPRA dataset of 133 chemicals was analyzed retrospectively with a modified prediction in which the cut-off between minimal and low reactivity was changed from 6.38% to 8% depletion. Regardless of cut-off, the accuracy of the prediction model remained at 86% with little to no change in sensitivity, specificity, and positive and negative productivity. To further investigate the robustness and reproducibility of the prediction model, a small intra-laboratory study was conducted. In this study, 9 chemicals were tested blindly in three independent runs. The depletion data was analyzed using the current prediction model as well as the described modified prediction model. In both cases, 7 out of 9 chemicals showed the same reactivity prediction in all 3 runs. Neither the retrospective analysis nor the intra-laboratory study provided any compelling evidence to adjust this cut-off value from the current model. Taken together, these studies further display the reproducibility and robustness of the DPRA and its prediction model.

**PS 961 A Novel Animal-Free Approach to Dermal Sensitization Hazard Identification and Potency Assessment.**

J. McCauley. *Toxicology Assessment & Compliance Assurance, 3M, St. Paul, MN.*  
Sponsor: D. Luebker.

International regulatory efforts have played a major role in advocating for the Three R's of animals used in safety evaluations for toxicological endpoints. These efforts support a movement away from the current in vivo-dependent toxicity testing state, to an animal-free toxicity testing state that includes in vitro human biology and a computational systems approach. To accomplish this goal, key stakeholders have proposed an ITS methodology to assess the skin-sensitizing potential of test chemicals to facilitate safety evaluation decision-making. The use of this ITS model integrated both novel and literature-reported data on 116 chemicals of known skin-sensitizing potential. Two in vitro assays and one in silico prediction model were used to cover four key sources of toxicological information: peptide reactivity; induction of ARE dependent luciferase activity; calculated octanol-water partition coefficient; and TIMES-SS model in silico prediction. The results from the in vitro assays were scaled into five classes from 0 to 4 and then compared with the LLNA data, which were also scaled from 0 to 4. Using an optimized model, an 87.9% overall accuracy was obtained for predicting sensitizers with a linear relationship between the LLNA scores and the in vitro scores. The use of clogP to account for potential differences in the bioavailability of the test chemicals did not reduce the correlation. With the increasing number of large-scale toxicology risk assessment programs for chemicals and emerging or expanding areas of chemical use, the development and acceptance of an ITS model appears to be the solution needed to strike a balance between safety, speed, cost and animal welfare. Along with ITS data refinements and the inclusion of other in vitro assays and in silico models accompanied by larger data sets, consideration should be given to defining a validation strategy focused on regulatory acceptance of an ITS model for skin sensitization.

**PS 962 Development of a Compromised Skin Model In Vitro Using a Tape Stripping Method.**

J. Heylings<sup>2</sup>, D. Davies<sup>2</sup>, M. C. Correa<sup>1</sup> and T. J. McCarthy<sup>1</sup>. <sup>1</sup>Johnson & Johnson, Skillman, NJ; <sup>2</sup>Dermal Technology Laboratory Ltd., Keele, United Kingdom.

Dermal absorption of chemicals from topically applied products is studied in a variety of *in vitro* and *in vivo* models. Skin barrier function may be impaired due to intrinsic or extrinsic factors. To our knowledge there is not a standardized model for evaluation of dermal absorption in compromised skin barrier conditions. Our objective was to validate an *in vitro* model of altered barrier function generalizable across compromised skin states. To investigate the permeability properties of compromised skin compared to normal skin, we explored the relationship between non-invasive (Trans Epidermal Water Loss, TEWL) and invasive (Electrical Resistance, ER; Tritiated Water Flux, TWF) markers of barrier function in slaughterhouse pig skin before and after tape stripping. Skin samples were randomly divided into groups and subjected to a standardized tape stripping procedure. The pre-and post-values for the 3 measures of skin integrity were recorded for 0, 5, 10, 15 and 20 tape strips. A full analysis of the distribution of TEWL, ER and TWF for 70 separate skin samples revealed that only ER was robust enough to discriminate between the barrier property changes effected by sequential tape stripping. The measurement of water flux through the skin (TEWL, TWF) required a long period of stabilization and proved to be unsuitable as a short term test. However, a significant difference could be observed with ER between control and each group of 5-20 tape strips ( $p < 0.01$ ,  $n = 53$ ). Further analysis of the data revealed that removal of 10 tape strips provided a loss of barrier function approximately equivalent to a 3-4 fold increase in TEWL, which approximates the altered barrier function clinically observed in atopic dermatitis, psoriasis, and diaper dermatitis. In conclusion, we have developed an *in vitro* model of compromised skin barrier function that is simple and robust and can be used to study the dermal absorption of chemicals that may come in contact with skin with impaired barrier properties.

**PS 963 A Predictive High-Content Imaging Cell-Based Assay As an Alternative to the Local Lymph Node Assay for Skin Sensitization.**

R. N. Ghosh, M. J. Tomaszewski, M. L. Pietila and J. R. Haskins. *ThermoFisher Scientific, Pittsburgh, PA.*

Allergic contact dermatitis (ACD) is a health effect that can develop in those exposed to skin sensitizing chemicals. To decrease the occurrence of this adverse reaction, regulations require that testing be performed to identify which chemicals are responsible for this effect, and be labeled accordingly. The current standard for ACD measurement is the Local Lymph Node Assay (LLNA), which is both animal and labor intensive. The LLNA testing procedure is based upon enumerating the responding cells in the draining lymph nodes of the mouse after treatment. Alternatives for this assay have depended on the measurement of phenotypic changes of a defined cell line, which would be analogous to a prior step in the pathway of induction of sensitization than that of the LLNA endpoint. To the end of developing an assay that more comprehensively mimics the role of the immune system during ACD *in vitro*, we describe a phenotypic and functional cell based assay that can be used to predict the sensitizing potential of compounds. The prediction method of this assay is based upon the up-regulation of cell surface molecules and proliferation indicative of the induced maturation of the cell line after compound treatment, and also a functional response whereby the treated cells are exposed to chemotaxis inducing reagents and migration measured. These features can easily be captured and measured via an automated fluorescent imaging and analysis platform. The measurement of these features when combined allow for prediction of sensitizing potential, but also provide toxicity data which allows for compounds to be easily re-screened at lower concentrations. Tested compounds ( $n=24$ ) yielded a high sensitivity rate (100%) and a high concordance (82%) to the LLNA. In summary, this assay shows promise in its ability to predict in vivo responses and may offer a viable alternative to traditional animal studies. In addition, it could provide a valuable first level triage for chemicals entering the consumer and industrial products pipeline.

**PS 964 Performance Standards and Alternative Assays: Practical Insights from Skin Sensitization.**

D. Basketter<sup>2</sup>, S. N. Kolle<sup>1</sup>, S. Casati<sup>3</sup>, W. S. Stokes<sup>4</sup>, J. Strickland<sup>6</sup>, H. Vohr<sup>5</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>DABMEB Consultancy Ltd., Sharnbrook, United Kingdom; <sup>3</sup>ECVAM, European Commission, Ispra, Italy; <sup>4</sup>Interagency Center for the Evaluation of Alternative Toxicological Methods, National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>5</sup>Bayer Health Care, Wuppertal, Germany; <sup>6</sup>Integrated Laboratory Systems, Inc, Research Triangle Park, NC.

To encourage the development and validation of alternative toxicity test methods, the effort required for validation of test methods proposed for regulatory purposes should be minimised. Performance standards (PS) facilitate efficient validation by requiring limited testing. Based on the validated method, PS define accuracy and reliability values that must be met by the new similar test method. The OECD adopted internationally harmonized PS for evaluating new endpoint versions of the local lymph node assay (LLNA). However, in the process of evaluating a lymph node cell count alternative, the LNCC, simultaneous conduct of the regulatory LLNA showed that this standard test may not always perform in perfect accord with its own PS. The LNCC results were similar to the concurrent LLNA; discrepancies between PS, LLNA and LNCC were largely associated with "borderline" substances and the variability of both endpoints. Two key lessons were learned: firstly, the understandable focus on substances close to the hazard classification borderline are more likely to emphasise issues of biological variability, which should be taken into account during the evaluation of results; secondly, variability in the results for the standard assay should be considered when selecting reference chemicals for PS.

**PS 965 Alternative Method in Practice: Postvalidation Experience of the Skin Sensitization *In Vitro* Test Strategy.**

S. N. Kolle, B. van Ravenzwaay and R. Landsiedel. *Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany.*

Several *in vitro* methods including dendritic cell line activation (e.g. MUSST and h-CLAT), keratinocyte activation (e.g. LuSens and KeratinoSens) and *in chemico* (e.g. DPRA) assays have been described as promising animal-free tools to qualitatively predict skin sensitizing potential. While these methods are currently undergoing evaluations in the different stages of formal validation, testing strategies have been proposed based on the combination of these assays. Yet to use suggested methods and prediction models for the diverse industrial sectors, such as the cosmetic, industrial chemical, pharmaceutical and maybe even the agrochemical sector, the scope of the substance classes tested as part of the initial validation exercise needs to be extended. Typically in a first validation phase novel alternative methods are evaluated against their gold standard *in vivo* assays using model substances selected from literature for their well described toxicological endpoint effects. The substances tested in the first validation phase, do, however, usually not reflect the typical test substance portfolio of the different industrial sectors. Therefore in this study we present the post-validation evaluation of 40 additional substances with available *in vivo* skin sensitization data from various substance classes including acrylates, surfactants, isocyanates, plant extracts, and agrochemical formulations in state of the art *in vitro* methods to assess skin sensitization. This additional data provides valuable information to understand the predictive capacity in terms of the applicability domains and may also help to manage expectations what can be achieved with those assays.

**PS 966 Alternative Methods in Practice: Testing of Acrylate and Methacrylate Esters with the Skin Sensitization *In Vitro* Test Strategy.**

K. Wiench<sup>2</sup>, S. N. Kolle<sup>1</sup>, H. Müllerschön<sup>3</sup>, M. Pemberton<sup>5</sup>, L. Andrews<sup>4</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Chemicals Management, Evonik Industries, Darmstadt, Germany; <sup>4</sup>The Dow Chemical Company, Midland, MI; <sup>5</sup>Systox Ltd., Wilmslow, United Kingdom.

Allergic contact dermatitis is a common skin disease and is elicited by repeated skin contact with an allergen. In the regulatory context, up to now only data from animal experiments have been accepted to assess the skin sensitizing potential of substances. Animal welfare concerns and the EU Cosmetic Directive/Regulation call for the implementation of animal-free alternatives for safety assessments. The mechanisms that trigger skin sensitization are complex and various steps are involved. Therefore, a single *in vitro* method may not be able to accurately assess this

endpoint. An *in vitro* testing battery that addresses different stages of the sensitization process was developed based on protein reactivity (direct peptide reactivity assay, DPRA), activation of the Keap-1/Nrf2 signaling pathway (LuSens and KeratinoSensTM) and dendritic cell activation assays (MUSST and h-CLAT). Based on an in-house validation this *in vitro* test strategy for the identification of skin sensitizers showed an accuracy comparable to that of the LLNA assay (94% compared to 89% for the LLNA). In this in-house validation, model substances selected from literature for their well characterized sensitizing potential were selected but did not necessarily reflect to typical testing portfolio. Therefore in this study, the in-house validation was extended by acrylates and methacrylate esters with available *in vivo* skin sensitization data. Further, the *in vitro* test battery has been used as a replacement for more than a dozen acrylates and methacrylate esters.

**PS 967 IVSA: *In Vitro* Sensitization Assay.**

M. Troese, L. F. Pratt, D. R. Cerven and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

Regulatory agencies worldwide are seeking non-animal or *in vitro* testing methods that embrace the 3Rs philosophy. Strong support now exists in the consumer products, pharmaceutical and cosmetics industries to develop and validate alternative assays for use in preclinical safety testing programs. Our group has adapted the Sensitization *in vitro* sensitization NCTC2594 IL-18 response assay of Corsini, et al. (Toxicol In Vitro 23 (5):789-796, 2009) for use in the MatTek EpiDerm™ model, measuring IL-18 secretion into the media to identify dermal sensitizers. In intra-lab validation tests, IL-18 release was measured after a 24-hour topical exposure using twelve sensitizers and five irritants/non-sensitizers. Either distilled water or EtOH was used as solvent vehicles. A Stimulation Index (SI) was calculated relative to the solvent vehicle for each test material. An SI > 1.6 result was considered biologically significant and best fit the data for identification of a positive sensitizer using a 2x2 contingency table and Cooper statistics. The overall Accuracy of the assay was 94%, with no false positives. The Sensitivity, Specificity, Positive and Negative Predictivity were 92%, 100%, 100% and 83%, respectively. The *In Vitro* Sensitization Assay (IVSA) produced a dose-dependent release of IL-18 upon treatment with increasing concentrations of 4-nitrobenzyl bromide. In addition, IVSA correctly identified two photosensitizers (+UVA): chlorpromazine and olaquinoxid. Thus, in this initial evaluation, IVSA has proven to be a useful and highly predictive tool for identifying dermal sensitizers without the use of animals.

**PS 968 Evaluation of Skin Irritation for Household Products Using a Reconstructed Human Epidermis Model.**

F. Yamaguchi, N. Takebuchi and J. Sato. *Lion Corporation, Odawara-shi, Japan.*  
Sponsor: H. Kojima.

Classification for irritation using reconstructed epidermis test methods have been developed. These test methods have been validated with the ability of dividing chemicals into skin irritants or non-irritants, in accordance with the UN Globally Harmonized System of Classification and Labeling (GHS). Application of these models to dermal safety evaluation of household products, which are consisted of several chemical substances, is of highly importance from the point of view to ensure product safety.

The aim of this research is to estimate skin irritation potential of household products comparing cell viability patterns on reconstructed epidermis when household products are applied.

We select LabCyte EPI-MODEL24 (Japan Tissue Engineering Co., Ltd) model with JACVAM validated protocol for GHS classification of chemical substances. Twenty five commercial household detergents in Japan including laundry detergents, dishwashing detergents, fabric softeners and household cleaners were tested. It appeared that the cell viability becomes comparable in some product categories. The products which contains highly anionic surfactants tends to show low cell viability. Fabric softeners which were based on cationic surfactants showed no cytotoxicity in this model. Powder laundry detergents tend to show low cytotoxicity. Liquid laundry detergents, dishwashing detergents and household cleaners shows various cell viability. It seemed that category and/or its concentrations of contained surfactants might be affected the results.

These results suggested that reconstructed epidermis test methods useful for the products safety assessment by performing comparative assessment in each product category.

**PS 969 Collaborative Project in JCIA for Testing Strategy of Skin Sensitization Using h-CLAT, DPRA and DEREK.**

O. Takenouchi<sup>1,11</sup>, K. Okamoto<sup>2,11</sup>, N. Imai<sup>3,11</sup>, D. Kyotani<sup>4,11</sup>, Y. Kato<sup>5,11</sup>, T. Kasahara<sup>6,11</sup>, A. Toyoda<sup>7,11</sup>, S. Watanabe<sup>8,11</sup>, Y. Seto<sup>9,11</sup>, T. Ashikaga<sup>10,11</sup> and M. Miyazawa<sup>1,11</sup>. <sup>1</sup>Kao Co., Tochigi, Japan; <sup>2</sup>Kanebo Cosmetics Inc., Kanagawa, Japan; <sup>3</sup>Kose Co., Tokyo, Japan; <sup>4</sup>Cosmos Technical Co., Ltd., Tokyo, Japan; <sup>5</sup>Nippon Menard Cosmetic Co., LTD., Aichi, Japan; <sup>6</sup>Fujifilm Co., Kanagawa, Japan; <sup>7</sup>Pola Chemical Industries, Inc., Kanagawa, Japan; <sup>8</sup>Lion Co., Kanagawa, Japan; <sup>9</sup>P&G Japan K.K., Hyogo, Japan; <sup>10</sup>Shiseido Co., LTD., Kanagawa, Japan; <sup>11</sup>Working Group for *In Vitro* Skin Sensitization Evaluation in Japan Cosmetic Industry Association (JCIA), Tokyo, Japan. Sponsor: J. Avalos.

For the replacement of the LLNA, the combination of several alternative methods is necessary. JCIA organized a working group to investigate testing strategies. In this study, considering the applicable domain, we demonstrated the utility of a testing strategy using the human Cell Line Activation Test (h-CLAT), Direct Peptide Reactivity Assay (DPRA) and the in silico system, DEREK. A total of 133 chemicals, some of which exhibit poor water-solubilities, were evaluated. For h-CLAT, THP-1 cells were exposed to each test chemical for 24 hours. The CD86 and CD54 expressions were analyzed by flow cytometry. For DPRA, model peptides were mixed with test chemical for 24 hours. The depletion of peptides was analyzed by HPLC. For DEREK, the alert of chemical structure was examined. For 133 chemicals, the accuracy of h-CLAT, DPRA and DEREK to predict LLNA results was 78, 74 and 74%, respectively. Next, we investigated 3 testing strategies: the Integrated Testing Strategy (A), a tiered approach (B), and a multiple regression analysis model (C). Each strategy had a high potential prediction (A:84%, B:81%, C:84%). Regarding false negative chemicals, some chemicals induced no cytotoxicity and other chemicals crystallized or separated in the medium and the buffer. The logP values of these chemicals were mostly above 3.5. If hydrophobic chemicals (logP>3.5) were removed from analysis, the accuracy was improved to A:88%, B:86%, C:87%. The sensitivity was improved to A:96%, B:97%, C:100%. All strategies provided an accuracy of 73% for the potency prediction. These results suggested that every strategy has high predictivity for the potential and potency.

**PS 970 Refinement of the Prediction Model of the Myeloid U937 Skin Sensitization Test (MUSST).**

C. Piroird, F. Ibanez, J. Faugere, C. Gomes, N. Alépée and S. Martinozzi-Teissier. *L'Oréal Research & Innovation, Aulnay sous Bois, France*. Sponsor: E. Dufour.

**Background:** In line with the 3Rs concept, in vitro alternatives methods are being developed based on the early events of the skin sensitization process. One of these is the capacity of skin dendritic cells to recognize a chemical as a danger. Since the late nineties, L'Oréal has actively worked on the Myeloid U937 Skin Sensitization Test (MUSST) which models this early event by measuring the up-regulation of CD86 expression, a co-stimulatory receptor. Year's in house use of this assay allowed us to demonstrate its value in combination with other assays (DPRA, Nrf-2 activation) for the prediction of sensitization hazard (Sensitizer S /NonSensitizer NS) of cosmetic ingredients. A third class was defined as "Inconclusive (INC)" where the MUSST is not able to conclude S or NS. The aim of this study was to refine the predictive model in order to reduce the number of INC, by maintaining the predictive capacities of the MUSST.

**Methods:** 208 substances with LLNA data were analyzed. MUSST results on this set gave 92 S, 56 NS predictions and 60 INC. Statistical methods based on a stacking scoring method were applied on raw data of these 60 INC in order to find additional rules to classify these substances into S or NS.

**Results:** a combination of 6 rules was identified, that allows to classify 44/60 INC into 23 S and 21 NS with a sensitivity of 95% and a specificity of 91%. The predictive performances of the MUSST on the 208 substances with the optimized prediction model composed of the original prediction model and the additional 6 rules-based model show 84% concordance, 87% sensitivity and 79% specificity against LLNA data. No false negative are observed among the extreme and strong sensitizers.

**Conclusion:** The optimized MUSST is an efficient assay for the skin sensitization hazard characterization, promising as a tool to be integrated within a battery of assays to perform a skin sensitization risk assessment.

**PS 971 *In Vitro* Phototoxicity Screening Assay for Systemically-Administered Pharmaceuticals Using a Reconstructed Skin Model EpiDerm.**

P. Hayden, Y. Kaluzhny, M. W. Kinuthia, L. d'Argembeau-Thornton, H. Kandarova and M. Klausner. *MatTek Corporation, Ashland, MA*.

According to current regulatory guidelines, photosafety testing is required for new compounds if they absorb light in the range of 290–700 nm or partition into the skin or eyes. The only approved non-animal in vitro phototoxicity assay, the 3T3 Neutral Red Uptake (3T3 NRU-PT), is overly-sensitive in predicting the in vivo photosafety hazard to humans and thereby eliminates valuable, new active pharmaceutical ingredients (API) from further development, even though they are safe to humans.

EpiDerm™, a normal human 3-dimensional (NHu-3D) skin model, is highly reproducible, contains an in vivo-like barrier, possesses in vivo-like biotransformation capabilities, and has been pre-validated for determining phototoxicity of topically applied materials. Here, we utilized EpiDerm to develop an in vitro assay for screening the phototoxicity of pharmaceuticals following systemic administration (sPHO). Test articles (n=42) were added into the culture medium and allowed to partition into the epidermal tissue. Tissues were exposed to solar radiation and phototoxic effects were determined by the comparing the tissue viability of UV irradiated vs. non-irradiated tissue models, using the MTT assay. A prediction model (PM) was established: a material is phototoxic after systemic administration if one or more test concentrations in the presence of irradiation (+UVR) decreases tissue viability by ≥30% when compared to identical concentrations in the absence of irradiation (-UVR); a material is non-phototoxic if the decrease in tissue viability is < 30%. The PM resulted in high sensitivity (91.7%) and specificity (100.0%) for 42 test materials (24 phototoxic/18 non-phototoxic). Results of sPHO assay were compared to in-house 3T3-NRU-PT assay.

The current protocol extends phototoxicity testing using EpiDerm for risk assessment to systemically administered chemicals and medications and will provide the pharmaceutical industry with an in vitro screening method to assess the phototoxic risk of new API.

**PS 972 Validation of *In Vitro* and Clinical Safety Assessment of Behentrimonium Chloride-Containing Leave-on Body Lotions Using Postmarketing Adverse Event Data.**

D. Cameron<sup>1</sup>, G. Costin<sup>2</sup>, L. Kaufman<sup>3</sup>, J. Avalos<sup>1</sup>, M. Downey<sup>1</sup>, W. Billhimer<sup>1</sup>, S. Gilpin<sup>1</sup>, N. Wilt<sup>2</sup> and A. F. Simion<sup>1</sup>. <sup>1</sup>Kao USA, Inc., Cincinnati, OH; <sup>2</sup>Institute for In Vitro Sciences, Inc. (IIVS), Gaithersburg, MD; <sup>3</sup>Scripterra Scientific, Cincinnati, OH.

Behentrimonium chloride (BTC) is a straight-chain alkyltrimonium chloride compound commonly used as an antistatic, hair conditioning, emulsifying-surfactant or preservative agent in personal care products. Although the European Union restricted the use of alkyltrimonium chlorides and bromides as preservative to ≤0.1%, these compounds have been safely used at ≤10% in hundreds of cosmetic products for other uses than as a preservative. *In vitro*, clinical, and controlled consumer usage tests in barrier-impaired individuals were conducted to determine if whole body, leave-on skin care products containing 1-3% BTC cause dermal irritation or any other skin reaction with use. BTC-containing formulations were predicted to be non-irritants by the EpiDerm™ skin irritation test and the bovine corneal opacity and permeability (BCOP)/chorioallantoic membrane vascular assay (CAMVA) ocular irritation test battery. No evidence of allergic contact dermatitis or cumulative dermal irritation was noted under the exaggerated conditions of confirmatory human occlusive patch tests. No clinically assessed or self-reported adverse reactions were noted in adults or children with atopic, eczematous, and/or xerotic skin during two-week and four-week monitored home usage studies. These results were validated by post-marketing data for five body lotions, which showed only 0.69 undesirable effects (skin irritation) reported per million shipped consumer units during 2006-2011. No serious undesirable effects were reported during in-market use of the products. Therefore, if formulated in appropriate conditions at 1-3%, BTC will not likely cause dermal irritation or delayed contact sensitization when used in a whole-body, leave-on product.

**PS 973 Collaboration Study on Eye Irritation Alternative Method with Human Corneal Model; LabCyte Cornea-Model24.**

H. Kojima<sup>1,2</sup>, N. Annaka<sup>2</sup>, S. Tsuchiya<sup>2</sup>, Y. Yoshitake<sup>2</sup>, R. Xu<sup>2</sup>, M. Suzuki<sup>2</sup>, W. Shimatani<sup>2</sup>, A. Kajita<sup>2</sup>, M. Nakamura<sup>2</sup>, M. Watanabe<sup>2</sup>, M. Nakajima<sup>2</sup>, K. Sakamoto<sup>2</sup>, R. Takeda<sup>2</sup>, M. Hisama<sup>2</sup>, H. Ikeda<sup>2</sup>, A. Inagaki<sup>2</sup>, Y. Munekihika<sup>2</sup>, Y. Yamamoto<sup>2</sup>, T. Kasahara<sup>2</sup>, T. Fukuda<sup>2</sup>, S. Nakahara<sup>2</sup>, S. Watanabe<sup>2</sup>, H. Kurata<sup>2</sup>, S. Shinoda<sup>2</sup> and M. Katoh<sup>3,2</sup>. <sup>1</sup>Division of Pharmacology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Japanese Society for Alternative to Animal Experiments, Tokyo, Japan; <sup>3</sup>Japan Tissue Engineering Co., Ltd., Aichi, Japan.

LabCyte CORNEA-MODEL24 is a human corneal model that was developed by Japan Tissue Engineering Co., Ltd. (J-TEC) as an alternative to animal tests for ocular irritation. It has been reported to provide highly-accurate predictions. A first step toward the future inclusion of this method in test guidelines is to verify transferability of the protocol. In collaboration with the Planning Committee of the Japan Society for Alternative to Animal Testing, a call for collaborating partners was issued, with respondents participating in a technical training session and a collaboration study to identify potential problems with the protocol. A total of twenty-four laboratories responded to the call for collaborating partners. These laboratories were divided into four groups, and four chemicals as well as a positive control were distributed to each group without coding. These sixteen chemicals and their control groups were tested using a WST-8 assay to determine cytotoxicity and thereby verify transferability of the protocol. As a result, we had a good inter- and intra-laboratory reproducibility in this study. On the other hand, a number of problematic points have already been noted, including several difficult-to-understand parts of the protocol and an inability to clear standard values for negative controls. The future inclusion of this method in established guidelines requires smooth implementation of a validation process, and a first step in that process is to verify the transferability of a suitable protocol.

**PS 974 Assessing Eye Irritation Potential of Cosmetic Products Using the STE Test.**

T. Abo<sup>1</sup>, Y. Nukada<sup>1</sup>, K. Ooshima<sup>2</sup>, T. Hayashi<sup>2</sup>, D. Araki<sup>2</sup>, D. Cameron<sup>3</sup>, J. Avalos<sup>3</sup>, A. F. Simion<sup>3</sup>, A. Kirst<sup>4</sup>, A. Fuchs<sup>4</sup>, R. Fautz<sup>4</sup>, H. Sakaguchi<sup>1</sup> and N. Nishiyama<sup>1</sup>. <sup>1</sup>Kao Corporation, Tochigi, Japan; <sup>2</sup>Kanebo Cosmetics Inc., Kanagawa, Japan; <sup>3</sup>Kao USA, Cincinnati, OH; <sup>4</sup>Kao Germany, Darmstadt, Germany.

Various in vitro assays that have been developed as an alternative for the Draize test are currently used to evaluate the eye irritation potential of cosmetic products and ingredients. A Short Time Exposure (STE) test, which we developed as a potential alternative test for eye irritation using rabbit cornea cells (SIRC), is planned for peer review and expected to be accepted as an OECD test guideline for classifying materials as Non-irritant/Irritant (NI/I). The test is expected to be able to evaluate cosmetic products as well as chemicals and cosmetic ingredients. Firstly, we evaluated the accuracy of the STE test against GHS classification for 20 cosmetic products (14 rinse-off and 6 leave-on products). Secondly, the results of STE test (including various rinse-off and leave-on products) were compared with the results of 43 cosmetic products tested in BCOP (bovine cornea opacity and permeability) test, 20 cosmetic products tested in HET-CAM, and 40 cosmetic products tested in CAMVA (two hen egg chorioallantoic membrane tests) in order to confirm the homology of in vitro assays used for evaluating eye irritation of the cosmetic products. In the first step, the accuracy for STE classifying a product as NI/I, compared to GHS, was 90% (18/20). Furthermore, STE test is able to provide a rank order (minimal irritant, moderate irritant and severe irritant) for materials based on the cell viability. The accuracy which compared GHS classification to a rank order of STE test was 75% (15/20). In the second step, comparison between STE test and three in vitro assays demonstrated that the accuracy of STE classifying a product as NI/I compared to BCOP, HET-CAM, and CAMVA was 79% (34/43), 80% (16/20), and 90% (36/40), respectively. Our findings show that STE test can be an alternative for the Draize test as well as for the three in vitro assays used to evaluate a cosmetic product.

**PS 975 The Interlaboratory Reproducibility of the STE Test for Assessing Eye Irritation of Cosmetic Products.**

Y. Nukada<sup>1</sup>, T. Abo<sup>1</sup>, A. Hilberer<sup>2</sup>, A. Heppenheimer<sup>3</sup>, M. Watanabe<sup>4</sup>, K. Ooshima<sup>5</sup>, D. Cameron<sup>6</sup>, A. Kirst<sup>7</sup>, H. Sakaguchi<sup>1</sup> and N. Nishiyama<sup>1</sup>. <sup>1</sup>Kao Corporation, Tochigi, Japan; <sup>2</sup>Institute for In Vitro Sciences, Inc., Gaithersburg, MD; <sup>3</sup>Harlan Cytotest Cell Research GmbH, Rosdorf, Germany; <sup>4</sup>Food and Drug Safety Center, Kanagawa, Japan; <sup>5</sup>Kanebo Cosmetics, Inc., Kanagawa, Japan; <sup>6</sup>Kao USA, Cincinnati, OH; <sup>7</sup>Kao Germany, Darmstadt, Germany.

The Short Time Exposure (STE) test, a potential alternative test for eye irritation using rabbit cornea cells (SIRC), is planned for peer review and expected to be accepted as an OECD test guideline for classifying materials as Non-irritant/Irritant (NI/I). Currently, we evaluated the technical transfer and inter-laboratory reproducibility of the STE test at 3 contract research laboratories and lead laboratory (Kao Corp). We first assessed the technical transfer at the 3 contract labs by using 5 chemicals (sodium lauryl sulfate, calcium thioglycolate, Tween 80, 1-octanol, and dodecane). Cell viability, following exposure to a 5% concentration, was used as an indicator of eye irritation potential, where a material is considered a NI if the viability was more than 70% and an I if the viability was less than 70%. Furthermore, a rank order (minimal irritant, moderate irritant and severe irritant) was given to materials based on scores obtained from exposures to 5% and 0.05% concentration. All 3 contract labs had reproducible and similar results for the 5 chemicals confirming the technical transfer among the contract labs. The inter-laboratory reproducibility was confirmed by using 21 cosmetic products (13 rinse-off and 8 leave-on products) and assessed by comparing the accuracy (i.e., ability to classify same materials as either NI or I, and same rank order) of the results among the 3 contract labs and Kao Corp. The respective accuracy for classifying as either NI/I for Lab A, B and C were 100, 81 and 95%. The respective accuracy for obtaining the same rank order for Lab A, B and C were 95, 67 and 76%. Overall, our findings show that a good inter-laboratory reproducibility was obtained for STE test using the finished cosmetic products.

**PS 976 Choosing the Appropriate Solvent for Solid Materials Tested in the Bovine Corneal Opacity and Permeability (BCOP) In Vitro Assay.**

G. Costin<sup>1</sup>, Y. Jeong<sup>2</sup>, D. Anderson<sup>2</sup>, J. E. Bader<sup>1</sup>, L. Krawiec<sup>1</sup>, J. R. Nash<sup>1</sup> and H. Raabe<sup>1</sup>. <sup>1</sup>Institute for In Vitro Sciences, Inc. (IIVS), Gaithersburg, MD; <sup>2</sup>The Dow Chemical Company, Midland, MI.

In compliance with OECD Test Guideline 437 for eye irritation (BCOP assay), non-surfactant solid materials are typically tested as 20% dilutions prepared in 0.9% sodium chloride solution, distilled water, or other solvent that has been demonstrated to have no adverse effects on the test system. However, the limited solubility of some chemicals adds technical challenges in finding a vehicle that would ensure the material's availability to the excised corneas and that itself would not affect the test system. In this study, we evaluated five solvents frequently used in the BCOP assay: distilled water, mineral oil, corn oil, polyethylene glycol (PEG)-400, and methocel solution (0.5%). Based on the available classification systems, our preliminary data showed that water, methocel, mineral oil and corn oil were predicted as non-irritants, while PEG-400 was predicted as a mild irritant. To demonstrate the influence of the type of solvent on the outcome/prediction of the BCOP assay for solid materials, we tested a 20% suspension of benzoic acid (BA) prepared in these solvents. BA has a non-polar benzoic ring that would preferably dissolve in non-polar solvents and a polar acidic group with affinity for polar solvents, thus making it a good model for testing its effect on corneas when dissolved in various solvents. Previous animal tests reported moderate to severe eye irritation induced by BA. Our results demonstrated that when mixed in water, mineral oil, corn oil, or methocel, BA was predicted to be a corrosive/severe irritant, while it was predicted to be a moderate irritant when mixed in PEG-400. These results support the need for further investigation of the solvent's influence in the BCOP assay to allow the correct prediction of the irritation potential of solid materials.

**PS 977 Predicting Eye Irritation of Agrochemical Formulations According to Different Classification Schemes by *In Vitro* Methods.**

S. N. Kolle<sup>1</sup>, A. Büchse<sup>2</sup>, T. Knieriemens<sup>3</sup>, M. Rey-Moreno<sup>1</sup>, W. Meyer<sup>3</sup>, A. van Cott<sup>4</sup>, S. Gröters<sup>1</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>*Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany*; <sup>2</sup>*Scientific Computing, BASF SE, Ludwigshafen am Rhein, Germany*; <sup>3</sup>*Agricultural Products Formulation Development, BASF SE, Ludwigshafen am Rhein, Germany*; <sup>4</sup>*Agricultural Products - Global Product Safety & Registration, BASF Corporation, Research Triangle Park, NC.*

The bovine corneal opacity and permeability (BCOP) test has been adopted by OECD for the identification of ocular corrosive and severe irritants (GHS category 1) for single component substances and multi-component formulations. Further, human reconstructed tissue models have been suggested for incorporation into a tiered test strategy to ultimately replace the Draize rabbit eye irritation test (OECD TG 405) and the value of the EpiOcular Eye Irritation Test (EIT) for the prediction of ocular non irritants (GHS no category) has been shown previously. The purpose of this study was to evaluate whether the BCOP including corneal histology and the EIT could be used to predict eye irritancy of agrochemical formulations according to different classification schemes including UN GHS, EPA and ANVISA systems. We have assessed opacity, permeability and histology in the BCOP assay and relative tissue viability in the EIT for 50 agrochemical formulations with available *in vivo* eye irritation data. Using the OECD TG guideline evaluation scheme for opacity and permeability in the BCOP did not prove predictive with respect to severe eye irritation potential for the 50 agrochemical formulations assessed here, while corneal histology grades and the EpiOcular tissue viabilities were useful predictors of eye irritancy potencies. Further we describe here statistical evaluation based on the experimental *in vitro* data to predict eye irritancy for the different classification schemes.

**PS 978 A Preliminary Investigation in the Use of Porcine Corneas As a Substitute for Bovine Corneas in the BCOP Assay.**

D. Wolfinger and D. R. Cerven. *MB Research Laboratories, Spinnerstown, PA.*  
Sponsor: G. DeGeorge.

The Bovine Cornea Opacity and Permeability Assay (BCOP) has been used since 1992 to provide estimates of ocular irritation. It has been accepted as an alternative to the use of rabbit in acute ocular safety testing. However in some areas of the world, access to bovine eyes is limited, and the Draize eye-scoring test, performed in rabbits, is still being utilized. In response to this, we have been investigating the replacement of excised bovine corneas with porcine corneas for evaluation of acute ocular irritation (PCOP). This preliminary investigation involved the evaluation of 100% ethanol, 0.1% Benzalkonium Chloride (BAK), and four cosmetic products, all of which had previously been tested in the BCOP as well as the Chorioallantoic Membrane Vascular Assay (CAMVA). Initially the results from the ethanol and BAK testing in the porcine corneas showed no correlation to the results from bovine corneas. These suggested the need for certain modifications to the trimming and mounting procedures for the porcine corneas, which are smaller than the bovine corneas. Thus, the trimming process to excise the cornea was modified, and the same chambers supplied with the opacitometer for use with bovine eyes was also used for the porcine eyes. After modifying the pre-testing procedures, we proceeded to test four cosmetic compounds successfully in the BCOP and PCOP. These investigations indicate that the *In Vitro* Scores obtained with porcine eyes are similar to those in bovine eyes. Additional evaluation with a wider range of chemical entities is underway.

**PS 979 *In Vitro* Ocular Irritation Testing Strategy for Prototype Cleaning Products.**

M. Bauman<sup>1</sup>, K. Norman<sup>2</sup>, G. Mun<sup>2</sup> and H. Raabe<sup>2</sup>. <sup>1</sup>*S.C. Johnson & Son, Inc., Racine, WI*; <sup>2</sup>*Institute for In Vitro Sciences, Gaithersburg, MD.*

The Bovine Corneal Opacity and Permeability (BCOP) assay can be used for predicting mild, moderate, and severe ocular irritation through quantitative assessment of the changes in opacity and permeability of bovine corneas. In addition, histological evaluation of the corneas may be performed to assess the depth of damage. The BCOP assay with histology was used to determine the ocular irritation potential of prototype cleaning products with antimicrobial claims according to the guideline provided by the EPA-Office of Pesticide Programs (OPP). Several prototype cleaners of similar formulation were evaluated along with a reference material. The results of the BCOP assay showed noticeable differences among the products. The *in vitro* score, determined by changes in opacity and permeability of the

corneas, ranged from ~15 to 80. These scores indicate mild, moderate, and severe irritation according to the guideline provided by the EPA-OPP. In addition, the histological evaluation of the corneas showed differences in the depth of damage to the stroma between moderate and severe category products, confirming the classification of the products by the *in vitro* score. These results demonstrate the utility of the BCOP assay with histology as a stand-alone assay for eye irritancy evaluation in the EPA-OPP program. Furthermore, this testing strategy distinguished the ocular irritation potential among similar prototypes demonstrating its effectiveness in the product development process.

**PS 980 Development of a Human Corneal Full Thickness Tissue for Eye Irritation Testing.**

L. d'Argembeau-Thornton, Y. Kaluzhny, H. Kandarova, P. Hayden and M. Klausner. *MatTek Corporation, Ashland, MA.*

The FDA and other regulatory agencies require ocular irritation testing of ophthalmologic pharmaceuticals and consumer products. Human reconstructed tissue models have been suggested for incorporation into a tiered testing strategy to replace the Draize eye irritation test (OECD TG 405) and for use as highly reproducible and cost effective *in vitro* alternatives.

A newly developed Ocular-Corneal Full Thickness (OCFT) tissue model includes epithelial, stromal, and endothelial layers. This model has been characterized in terms of tissue morphology, expression of specific markers for human corneal epithelium (Cytokeratins 12, 14, and 19, stratifin, tight junction proteins ZO-1, occluding, and claudin), and NaFl leakage and transepithelial electrical resistance (TEER) in response to chemical insults. Histological evaluation of the tissues was used to provide information on the type and depth of the chemical insult. Also, the OCFT model was used to assess tissue recovery following exposure to increasing concentrations of surfactants and TA spanning the range of irritancy. Significant recovery at 24 and 48 hours was observed for non-irritants (NI) chemicals. The OCFT tissue was also evaluated in a response to a battery of test articles (TA, n=65) spanning the range from ocular corrosives and severe irritants (I) to non-irritants (NI). *In vivo* irritancy levels were obtained from a published database and *in vitro* effects were determined using the MTT tissue viability assay and TEER. Using a tissue viability cutoff of 50%, the OCFT model was able to detect "I" with 100.0/75.0 and 87.7% specificity/sensitivity/accuracy.

The OCFT model will address the needs of ophthalmic and other formulators who need to screen their products for irritancy and efficacy. Similar to other *in vitro* assays, high levels of reproducibility at a low cost are anticipated. The OCFT model will facilitate the development and testing of ophthalmologic pharmaceuticals and allow for basic studies related to corneal physiology, wound repair, and pathologies.

**PS 981 Validation of *In Vitro* Eye and Skin Irritation Assays for Structurally Complex Pharmaceutical Chemicals.**

N. Foglio<sup>2</sup>, C. Villano<sup>1</sup>, C. Risatti<sup>1</sup>, H. Raabe<sup>3</sup> and J. Gould<sup>1</sup>. <sup>1</sup>*Bristol-Myers Squibb, New Brunswick, NJ*; <sup>2</sup>*Rutgers University School of Pharmacy, Piscataway, NJ*; <sup>3</sup>*Institute for In Vitro Sciences, Gaithersburg, MD.*

Identification of local ocular and dermal irritation effects is important for occupational health and hazard communication. OECD has published Test Guidelines (TG) 439 for *In Vitro* Skin Irritation (EpiDerm™ System, MatTek) and TG 437 for the Bovine Corneal Opacity and Permeability Test Method (BCOP) to replace or supplement *in vivo* tests, but their applicability to complex molecules found in the pharmaceutical industry has not been fully investigated. A validation study was conducted to compare *in vivo* eye (OECD TG 405) and skin irritation (OECD TG 404) to *in vitro* study data for Bristol-Myers Squibb (BMS) proprietary compounds. The validation set consisted of 15 compounds, which were selected to represent the BMS chemical space within six chemical classes:  $\alpha\beta$  unsaturated carbonyls,  $\alpha$ -halo ketones, aminoalcohols, boronic acids/esters, halogenated heterocycles, and nitroaromatics. The assay results were interpreted using OECD and GHS classification schemes and *in vitro* and *in vivo* results were compared using basic statistics. The BCOP assay accurately predicted 12 of 15 compounds when non- and mildly irritating classifications were grouped together. Both boronic compounds were under-predicted by BCOP, suggesting the assay may not be appropriate for this chemical class. The *in vitro* skin assay demonstrated high specificity by correctly identifying 12 of 13 negative *in vivo* skin irritants, but, the sensitivity could not be interpreted from the limited number of positive skin irritants in this study. Additional data are needed to assess the predictivity of positive skin irritants with greater confidence. Overall, the replacement of *in vivo* studies with these alternative *in vitro* irritation methods reduces and refines the tiered testing strategy for ocular and dermal hazard identification of pharmaceutical chemicals.

**PS 982 Surfactant Responses in the Bovine Corneal Opacity and Permeability Assay: Points to Consider for *In Vitro* Eye Irritation Testing.**

J. E. Bader, G. Costin, A. Hilberer, G. Mun, J. R. Nash, K. Norman, N. Wilt and H. Raabe. *Institute for In Vitro Sciences, Gaithersburg, MD.*

The Bovine Corneal Opacity and Permeability (BCOP) assay is an *ex vivo* test used to evaluate the ocular irritation of a broad range of chemicals. In the regulatory classification and labeling arena, BCOP can be used to identify severe and corrosive eye irritants according to the OECD Test Guideline (TG) 437. However, BCOP has historically under-predicted certain anionic surfactants, when tested according to the standard liquid protocol. TG 437 specifies that liquid surfactants may be tested as 10% aqueous dilutions for 10 minutes (although alternate dilutions and exposure times may be conducted with scientific rationale), and the relevant guidance document (GD) No. 160 suggests that solid and concentrated liquid surfactants may be diluted to 10% for testing. However, GD No. 160 further directs that surfactant-based formulations are usually tested neat, but could be diluted with justification, imparting some confusion in identifying the most appropriate test methods. Since neither the basis for selecting the appropriate surfactant test methods, nor the justification for modifications are clearly presented in TG 437 or GD No. 160, we present on the testing of sodium lauryl sulfate (SLS) in the BCOP assay, using standard and modified dilutions and exposures, to elucidate the impact of these variables on eye irritation prediction. For example, *in vitro* scores of 20.7, 28.4, and 28.3 were obtained when testing SLS at concentrations of 50, 20, and 10% for 10 minutes, showing that irritation responses were not fully concentration-dependent, but demonstrated optimally at intermediate doses. When tested using modified exposure times, SLS showed time-related responses, with improvements in irritation predictions at the 20 and 30 minute exposures. Histopathology was performed to assess the surfactant-induced corneal changes. Based upon these results, a framework for testing surfactants, and surfactant-based formulations is proposed.

**PS 983 New Detecting Method for Estimating the Eye Irritation Potential of Chemicals: An Alternative to the Draize Test.**

S. Cho, G. Nam, J. Kim, J. Cho and K. Shin. *AMOREPACIFIC Corporation R&D Center, Yongin-si, Republic of Korea.*

Determination of eye irritation potential is an essential part of the safety assessment of chemicals, pharmaceuticals, and cosmetics. For many years, the ocular irritation potential of chemicals has been mainly evaluated by the Draize rabbit eye irritation test (OECD Test Guideline 405). Because Draize rabbit eye irritation test is based on subjective visual scoring evaluation, significant variability has been observed. In addition, the test causes considerable discomfort and pain to the animal, and it has also been identified that the eye irritation response of rabbits does not always correspond to those of humans. For scientific reasons, animal welfare issues and the ban of cosmetics in animal eye irritation tests in the European Union (EU), there are many efforts to develop alternative methods replacing animal study. Using a human corneal cell line (HCE-T cells), we developed a new alternative method to assess the eye irritation potential of chemicals. We exposed HCE-T cells to 3 fixed concentrations of the 38 chemicals (5%, 0.5%, and 0.05%) for 1 h and measured the relative cell viability (RCV) at each concentration. Using the RCV values at 5%, 0.5%, and 0.05%, we developed a new criterion for eye irritation potential (total eye irritation score, TEIS) and estimated the ocular irritancy. We then assessed the correlation of the results of TEIS with those of the Draize rabbit eye irritation. TEIS results exhibited good correlations (sensitivity: 80.77%, specificity: 83.33%, and accuracy: 81.58% for TEIS). We conclude that the new *in vitro* model using HCE-T cells is a good alternative evaluation model for the prediction of the eye irritation potential of chemicals.

**PS 984 Neonatal Hyperoxia Promotes Lung Fibrosis Independent of Excessive Leukocyte Recruitment to the Lung following Influenza A Virus Infection.**

B. W. Buczynski<sup>1</sup>, M. Yee<sup>2</sup>, P. Lawrence<sup>1</sup> and M. A. O'Reilly<sup>2</sup>. <sup>1</sup>*Environmental Medicine, The University of Rochester, Rochester, NY;* <sup>2</sup>*Pediatrics, The University of Rochester, Rochester, NY.*

There is a growing appreciation that environmental exposures during critically important periods of development can influence the onset of many childhood and adult diseases. For example, preterm infants prematurely exposed to excess levels of oxygen (hyperoxia) at birth are at increased risk for impaired lung development and are often more sensitive to respiratory viral infections later in life. Similarly, adult

mice exposed to 100% oxygen during PND 0-4 exhibit persistent lung simplification, as well as an increase in inflammation and fibrosis following infection with influenza virus. Levels of the inflammatory chemokine MCP-1 are selectively increased following infection in these mice. Since increased levels of MCP-1 are often associated with pulmonary inflammation and fibrosis, we hypothesized that *Mcp-1*<sup>-/-</sup> mice exposed to hyperoxia at birth would have an attenuated inflammatory response and reduced fibrotic repair following infection with influenza virus. Prior to infection, lung simplification was evident and indistinguishable amongst *Mcp-1*<sup>+/-</sup> and *Mcp-1*<sup>-/-</sup> mice exposed to hyperoxia at birth. When infected, *Mcp-1*<sup>-/-</sup> mice exposed to hyperoxia had reduced mean body weight loss and leukocyte recruitment to the lung in comparison to *Mcp-1*<sup>+/-</sup> mice exposed to hyperoxia. Although leukocyte recruitment was not excessive following infection in *Mcp-1*<sup>-/-</sup> mice exposed to hyperoxia, they still developed pulmonary fibrosis, which was not observed in infected *Mcp-1*<sup>-/-</sup> mice exposed to room air. Thus, the aberrant fibrotic repair observed following infection in mice exposed to hyperoxia at birth occurs independently of excessive leukocyte recruitment to the lung. Our findings identify novel neonatal hyperoxia-mediated pathways disrupted in response to influenza virus infection, which may provide insight into how early-life exposure to high levels of oxygen leads to childhood and adult diseases later in life.

**PS 985 Integrating Genome and Transcriptome Data to Understand Susceptibility to Postnatal Lung Injury.**

J. Nichols<sup>1</sup>, A. Burkholder<sup>1</sup>, J. Lu<sup>1</sup>, Z. McCaw<sup>1</sup>, O. Suzuki<sup>2</sup>, D. Fargo<sup>1</sup>, P. Bushel<sup>1</sup>, T. Wiltshire<sup>2</sup> and S. R. Kleeberger<sup>1</sup>. <sup>1</sup>*NIEHS, Durham, NC;* <sup>2</sup>*Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Late lung development is a critical window of susceptibility as perturbations impair alveolarization and vascular development. Currently, genetic control of differential gene expression during lung development and injury is incompletely understood. We hypothesized that integration of genetics and genomics in expression quantitative trait loci (eQTL) analysis will identify genetic factors contributing to variability in the neonatal lung and characterize genetic susceptibility. Full term neonates from 30 inbred strains of mice were maintained in room air or exposed to 95% oxygen for 72hrs beginning on postnatal day 1 (P1). Lungs were collected from 3 neonates/group for each strain on P4. RNA was isolated for transcriptomic analysis using Illumina WG6v2.0 BeadChips. Transcript intensities were analyzed for differential expression, and associations between genetic polymorphisms and transcript intensity (eQTLs) were identified by haplotype association mapping with FastMap. 4513 differentially expressed transcripts were identified on P4, and cis-eQTL analysis, or associations between a transcript and polymorphism in the same gene, yielded 29 genes. Biologically interesting candidate genes included Adam17, Prdx1, Tnfip2, and Eif2ak2. After hyperoxia exposure, 5386 transcripts were differentially expressed. 1230 were specifically hyperoxia-induced and related to developmental and inflammatory pathways. 23 cis-eQTLs were identified and biologically interesting candidates included Vcp, Casp9, and Trim30. These analyses identified significant interstrain variation in transcript levels in the developing lung that is, in part, due to genetic background. Furthermore, network and pathway analysis of these candidate genes pointed to a novel role for the integrated stress response and proteostasis in neonatal lung development and injury.

**PS 986 Analysis of the Developmental Origins of Health and Disease (DOHaD) Grant Portfolio at the NIEHS.**

A. Haugen, T. T. Schug and J. J. Heindel. *Division of Extramural Research and Training, NIEHS, Research Triangle Park, NC.* Sponsor: M. Humble.

Environmental exposures combined with genetics can have a persistent influence on common chronic health conditions of children and adults. A growing body of research at the National Institute of Environmental Health Sciences (NIEHS) is focusing on environmental effects during early-life development and disease occurrence over the lifespan—a branch of scientific study referred to as Developmental Origins of Health and Disease or the “DOHaD paradigm.” This paper describes the evolution of DOHaD research at NIEHS and how extramural events, including Requests for Applications (RFA) in the areas of Fetal Basis of Adult Disease (FeBAD), children's health, and epigenetics, have stimulated the field of environmental health science as it relates to DOHaD. In order to build and analyze a portfolio of active NIEHS-funded grants in the area of DOHaD, the electronic Scientific Portfolio Assistant (eSPA) software application was used. DOHaD portfolios for the years 1991, 2001, and 2011 were analyzed for exposures, disease/organ endpoints, windows of exposure, study design, and impact on the field based on publication data. Priority exposures in the 1991 and 2001 portfolios comprise of metals (e.g. lead and mercury), PCBs, and air pollutants; but by 2011, the portfolio has evolved to include or expand the variety of endocrine disruptors (e.g. BPA, phthalates), pesticides/Persistent Organic Pollutants (POPs) (e.g.

organophosphates, organochlorines, PBDE, PAH), and metals (e.g. arsenic, manganese). Several disease endpoints related to brain/CNS are apparent across all three portfolios, whereas reproduction and cancer increase steadily over the same time period, and new endpoints like obesity are introduced by 2011. The analysis of NIEHS-funded DOHaD research provides insight into the institute's impact on the field, and will help determine how to improve the quality and health impact of future, funded DOHaD projects.

**PS 987 Effects of Gutkha Use during Pregnancy on Hepatic Parameters Later in Life.**

S. P. Doherty-Lyons<sup>1</sup>, C. Hoffman<sup>1</sup>, J. Odin<sup>3</sup>, I. Fiel<sup>3</sup>, F. Ganey<sup>2</sup>, D. J. Conklin<sup>4</sup> and J. T. Zelikoff<sup>1</sup>. <sup>1</sup>Environmental Medicine, New York University School of Medicine, Tuxedo, NY; <sup>2</sup>Memorial Sloan-Kettering Cancer Center, New York, NY; <sup>3</sup>Mount Sinai School of Medicine, New York, NY; <sup>4</sup>University of Louisville, Louisville, KY.

Gutkha, a popular smokeless tobacco (ST) herbal concoction made in India and sold throughout India and the U.S., is a combination of tobacco, lime, betel and areca nut, spices, and catechu. Recent evidence demonstrates that consuming gutkha during pregnancy may be linked to adverse obstetric consequences. However, whether gutkha exposure during pregnancy increases offspring risk of chronic disease later on in adulthood, as with combustible tobacco products, remains unknown. For this study, pregnant B6C3F1 mice were exposed daily to 21 mg of a water-soluble gutkha solution beginning on gestational day (GD) 2-4 until parturition. The main objectives of this study were to evaluate whether prenatal exposure to gutkha altered offspring susceptibility for hepatic disease later in life. After male pairing, female mice were exposed to a gutkha solution via the oral mucosa. Serum cotinine levels in pregnant mice were measured weekly and ranged from 24-44 ng/ml. Cotinine levels, also measured in the amniotic fluid and fetal liver on -GD 15, averaged 21-22 ng/ml. Beginning at 12-wk-of-age, a sub-group of male and female offspring were fed a high fat (HF) diet for 14 days. Male offspring prenatally exposed to gutkha and fed subsequently a HF diet had increased hepatic fat mass, fibrosis, and inflammation compared to the other groups. Additionally, female offspring exposed to gutkha alone had significantly higher serum levels of the hepatic injury markers, alanine transaminase and aminotransferase. In conclusion, findings from these studies demonstrate that gutkha usage during pregnancy may have persistent later life effects that increase the risk of adult liver disease. As gutkha use by pregnant women in the South Asian communities are increasing exponentially, such a menacing public health behavior requires immediate attention. Supported by Memorial Sloan Kettering Cancer Institute.

**PS 988 Transcriptomic Profiling of Embryos and Adult Female Brain Tissue Links a Developmental Origin of Atrazine-Induced Reproductive Alterations in Zebrafish.**

G. J. Weber<sup>1</sup>, S. M. Peterson<sup>1</sup>, S. S. Lewis<sup>2</sup>, M. S. Sepulveda<sup>2</sup> and J. L. Freeman<sup>1</sup>. <sup>1</sup>Health Sciences, Purdue University, West Lafayette, IN; <sup>2</sup>Forestry and Natural Resources, Purdue University, West Lafayette, IN.

Atrazine, an herbicide commonly applied to agricultural areas throughout the Midwest and a common contaminant of potable water supplies, is implicated as an endocrine disruptor and potential carcinogen. The specific adverse health effects associated with atrazine exposure and the underlying molecular mechanisms of these effects are not well defined. In an effort to delineate the mechanisms of atrazine toxicity, we exposed zebrafish embryos to environmentally relevant concentrations of atrazine shortly after fertilization through 72 hours post fertilization (hpf). Transcriptomic profiles immediately following the embryonic atrazine exposure were obtained and subsequent analyses identified an enrichment of genes with altered expression patterns that are involved in neuroendocrine development and function, cell cycle regulation and carcinogenesis. From these exposures a subset of individuals was permitted to mature under normal conditions to evaluate later life effects of the developmental exposure and in unexposed subsequent generations. A significant difference in the number of pairs that successfully bred in one of the atrazine treatment groups coupled with distinct altered reproductive histological and morphological alterations in female adult zebrafish was observed indicating a later life effect of the developmental atrazine exposure. Furthermore, gene ontology analysis from microarrays performed on adult female zebrafish brains showed enrichment for genes involved in neuroendocrine system function and disease. The reproductive alterations observed in the adult females along with decreased mating success and altered transcriptomic profiles provide support to the endocrine disrupting effects of this herbicide and warrant further mechanistic investigation. Current efforts are aimed at assessing transgenerational effects of this developmental atrazine exposure in subsequent unexposed generations.

**PS 989 Bisphenol A and Diethylstilbestrol Treated Mice Respond Differently to a Very High Fat Diet.**

L. Chalifour<sup>1,2</sup>, B. Patel<sup>1,2</sup> and I. A. Sebag<sup>1,2</sup>. <sup>1</sup>Lady Davis Institute, Montréal, QC, Canada; <sup>2</sup>McGill University, Montréal, QC, Canada.

**Rationale:** Bisphenol A (BPA) is an estrogenizing endocrine disruptor, and diethylstilbestrol (DES) is a non-steroidal estrogen. Some data suggest that BPA is an obesogen. We hypothesized that BPA and/or DES would increase the metabolic impact of a very high fat diet and that this obesity would reduce heart structure/function. **Methods:** C57bl/6n mice were exposed to Vehicle, oral BPA (5.0µg/kg/da) from gestation day 11 to weaning and then (0.5µg/kg/da) to 4 months, or diethylstilbestrol (DES, 1µg/kg/da) from GD 11-14. Mice were fed control (CD, 10% calories from fat) or very high fat (HFD, 60% calories from fat) diets from weaning. Body weight (BW) and body length (BL) were measured monthly. Body mass index (BMI) and body surface area (BSA) were calculated. Glucose tolerance was tested at 15 weeks. Echocardiography, organ weights and serum for cholesterol, triglycerides and leptin were collected at 16 weeks.

**Results:** All HFD mice had increased BW, BL, BMI and BSA. HFD VEH and BPA males had similar increases in total fat and total fat indexed to BW or BSA, but HFD BPA males were smaller in BW, BMI and BSA. HFD VEH and BPA females had similar total fat and total fat indexed to BW or BSA, BW, BMI and BSA. In contrast, HFD DES treated males and females had the least fat gain, BW, BMI and BSA. Cholesterol and triglycerides were increased with HFD in all males and leptin was increased in BPA and DES males. Cholesterol, triglycerides and leptin were increased with HFD identically in VEH, BPA and DES females. Glucose tolerance was reduced with HFD equally in all mice. Fractional shortening was unaffected, but HFD induced eccentric cardiac hypertrophy in VEH and BPA with DES mice showing the greatest increase.

**Conclusions:** Neither BPA nor DES worsened the response to a very HFD. VEH and BPA mice responded similarly to a very HFD. DES mice had a blunted metabolic response to a very HFD. Cardiac function was unaffected, but cardiac structure was affected by HFD.

**PS 990 Analysis of Transcriptional Profiles and Functional Clustering of Global Cardiovascular Gene Expression in Response to In Utero B(a)P Exposure.**

G. E. Jules<sup>1</sup>, S. Pratap<sup>2</sup>, A. Ramesh<sup>3</sup> and D. B. Hood<sup>1</sup>. <sup>1</sup>Neuroscience and Pharmacology, Meharry Medical College, Nashville, TN; <sup>2</sup>Microbiology & Immunology, Microarray/Bioinformatics Core, Meharry Medical College, Nashville, TN; <sup>3</sup>Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN.

Interest in the correlation between environmental toxicants and cardiovascular diseases has increased considerably over the past few decades. However, little is known of B(a)P's effect on the developing heart or the specific biological pathways altered by B(a)P. Functional comparative genomic analysis of the cellular and developmental effects of different polycyclic aromatic hydrocarbon (PAH) compounds is considered a helpful approach to distinguish the complex and specific effects of B(a)P exposure in utero. Using timed-pregnant Long Evans Hooded rat offspring, we characterize the genetic modulation in cardiovascular related genes for three concentrations of B(a)P (0, 600, and 1,200 µg/kg/BW) at postnatal days 0 and 53 (P-0 and P-53). In utero exposure to B(a)P at both 600 and 1,200 µg/kg/BW significantly modulated the expression of 89 out of 45,000 genes in offspring. The focused microarray approach identified important subgenomic differences in the pattern of cardiovascular disease cell-related gene expression in response to in utero B(a)P exposure. These molecular targets and deduced networks may be employed as a guide for classifying, monitoring and manipulating the molecular and pathological specificities of different PAHs in key cardiovascular related cell systems and for potential pharmacological application.

**PS 991 Maternal DDT Exposure Increases Risk of Metabolic Syndrome in Adult Offspring.**

M. La Merrill<sup>1,2</sup> and C. Buettner<sup>3,2</sup>. <sup>1</sup>Environmental Toxicology, University of California Davis, Davis, CA; <sup>2</sup>Metabolism Institute, Mount Sinai School of Medicine, New York, NY; <sup>3</sup>Endocrinology, Diabetes, Bone Disease, Mount Sinai School of Medicine, New York, NY; <sup>4</sup>Preventive Medicine, Mount Sinai School of Medicine, New York, NY.

DDT is associated with altered carbohydrate and lipid homeostasis in animals that have been exposed to relatively high doses, and with increased risk of type 2 diabetes and hypertension in human studies. We hypothesized that maternal exposure

to DDT would increase the risk of metabolic syndrome in the adult offspring of mice. We administered DDT to C57BL/6J mice from gestational day 11.5 to postnatal day 5, when litters were culled to six pups. We performed comprehensive metabolic phenotyping in offspring. Maternal DDT exposure increased diastolic and systolic blood pressure in adult offspring. Maternal DDT exposure also caused a mild obese phenotype in female offspring that was due to impaired thermoregulation (increased cold intolerance) and decreased energy expenditure while food intake was not different. When these female offspring were fed a diet high in fat, they developed elevated fasting insulin and lipids. Thus, the results from the current study suggest that maternal DDT exposure leads to metabolic syndrome in adult offspring.

**PS 992 Mechanisms Underlying Neurodevelopmental Defects in Weanling and Adult Rats Associated with Prenatal Exposure to Methylmercury.**

D. De Groot<sup>1</sup>, C. De Esch<sup>1</sup>, M. de Groot<sup>1</sup>, C. Kuper<sup>1</sup>, R. Stierum<sup>1</sup>, A. Wolterbeek<sup>1</sup>, E. De Vries<sup>2</sup>, N. Cappaert<sup>3</sup>, M. Radonjic<sup>1</sup> and R. Woutersen<sup>1</sup>.  
<sup>1</sup>TNO the Netherlands, Zeist, Netherlands; <sup>2</sup>Groningen University Medical Center, Groningen, Netherlands; <sup>3</sup>University of Amsterdam, Amsterdam, Netherlands.

A Developmental Neurotoxicity (DNT) study with MeHg was carried out in Wistar rats [Guidelines US-EPA OPPTS 870.6300/8600]. To map neurodevelopmental defects of MeHg and uncover underlying mechanisms, cerebellum and cerebrum of female F1-rats, prenatally exposed to MeHg via maternal diet (GD6 - PD10), were sampled at weaning (PD18-21) and adulthood (PD61-70). Brain tissues were analysed by [18F]FDG PET functional imaging, synaptic excitation analysis and microarray gene expression profiling. Brain activity and functionality of neurotransmission assessed by [18F]FDG PET imaging and synaptic excitation analysis revealed a delay in brain activity and impaired neural function. The findings were substantiated by genome-wide transcriptome analysis. The discovered transcriptional patterns revealed that exposure to MeHg causes (1) a delay in onset of neural development and/or function and (2) alterations in pathways related to structural and functional aspects of nervous system development. The latter includes changes in gene expression of developmental regulators, developmental-phase associated genes, small GTPase signaling molecules and representatives of all processes required for synaptic transmission. Marked repression of genes regulating brain development and neural function were observed particularly at PD70, showing that prenatal exposure to MeHg has long-lasting effects in adult brain. No effects of MeHg were found in tests proposed in DNT guidelines.

Summarizing, structural and functional defects associated with MeHg were demonstrated with [18F]FDG PET functional imaging, synaptic excitation analysis and microarray gene expression profiling, and molecular mechanisms underlying these developmental defects identified. The findings are relevant from a health perspective, but also show that the approaches used are sensitive and superior to conventional tests proposed in current DNT guidelines.

**PS 993 Vulnerability Windows of the Developing Rat Brain to TBTO Demonstrated by Animal-Friendly MRI.**

M. Berk<sup>1,2</sup>, S. Folkertsma<sup>1</sup>, M. de Groot<sup>1,3</sup>, A. Knaapen<sup>1</sup>, I. Waalkens<sup>1</sup>, A. Wolterbeek<sup>1</sup>, R. Woutersen<sup>1</sup>, A. Veltien<sup>2</sup>, A. Heerschap<sup>2</sup> and D. De Groot<sup>1</sup>.  
<sup>1</sup>TNO, the Netherlands, Zeist, Netherlands; <sup>2</sup>Radboud University Medical Center Nijmegen, Nijmegen, Netherlands; <sup>3</sup>IRAS, Utrecht University, Utrecht, Netherlands.

To design a proper strategy for safety evaluation of drugs for children and adolescents information on the vulnerability of the brain during critical phases of development is essential. In this study developmental and juvenile exposure windows proposed in current guidelines for toxicity testing were studied in a rat model with tributyltin oxide (TBTO).

Rats were exposed to 8mg TBTO/kg BW/day during development (TBTOdev: gestation day (GD)8 to postnatal day (PD)10) or adolescence (TBTOjuv: PD22-PD62). Brain weight (cerebrum and cerebellum separately) was determined at weaning (PD22) and young adult age (PD62). Brain (region) volume was estimated from magnetic resonance (MR) images. Brain specific gravity (SG) was calculated from the ratio [weight / volume]. Relative growth for these brain measures was calculated over time (from PD22 to PD 62) for control and TBTO-exposed brains.

Effect of TBTOdev included reduced cerebral weight but increased volume at PD22, whereas at PD62 both weight and volume appeared reduced. Effects of TBTOjuv implied reduced weight and increased volume at PD62. Effect of TBTOdev on brain SG was most pronounced on cerebrum at PD22, which was no

more observed at PD62. Effect of TBTOjuv (PD62) was most pronounced on SG of cerebellum/brainstem. MRI scans demonstrated that effects within cerebrum were located in particular in anterior regions.

Together, the results demonstrate the relevance of exposure windows relative to the vulnerability of the developing brain; under the circumstances of this study the brain appeared more vulnerable when exposed during development with largest effects on cerebrum at adolescent age (PD22). Effects of juvenile exposure appeared mild, and seemed to affect both cerebrum and cerebellum/brainstem (PD62). The results are discussed in light of TBTO-induced delayed development, persistent effects at adult age and a speculative role of TBTO as obesogen.

**PS 994 The Effects of Endocrine Disruption on the Maturation of the Developing Human Fetal Prostate.**

C. Saffarini<sup>1</sup>, E. V. McDonnell<sup>1</sup>, A. Amin<sup>2</sup>, S. J. Hall<sup>1</sup> and K. Boekelheide<sup>1</sup>.  
<sup>1</sup>Pathology and Laboratory Medicine, Brown University, Providence, RI; <sup>2</sup>Pathology and Laboratory Medicine, Rhode Island Hospital, Providence, RI.

The etiology of prostate cancer is unknown, although it has been suggested that early life exposures to various toxicants, such as estrogenic chemicals, may play an important role. Previous studies in rat models have demonstrated that early life exposures to estrogens is responsible for causing epithelial and stromal hyperplasia, inflammation, and prostatic intraepithelial neoplasia (PIN) lesions. We have developed a xenograft rodent model to characterize the growth and differentiation of human fetal prostate implants (gestational age 12-24 weeks). This model encompasses the effects of both early and later-life exposures to either corn-oil (control) or 250 ug/kg/body weight of 17 $\beta$ -estradiol 3-benzoate post-transplant. To ensure proper growth of implants, the renal subcapsular space was chosen as the site of implantation to allow for appropriate growth and vascularization of prostate tissue. This model was characterized based on the expression of key immunohistochemical markers responsible for epithelial and stromal maturation including p63, cytokeratins 18, alpha smooth muscle actin, vimentin, caldesmon, ki-67, prostate specific antigen, estrogen receptor- $\alpha$ , and androgen receptor. As expected, the human fetal implants grew and matured as demonstrated by the histopathology seen in 7, 14, 30, 90, 200 and 400 day xenografts. Interestingly, the human prostate xenografts exhibited marked differences in response to estrogen exposure compared to their endogenous rodent prostate counterparts. The endogenous rodent prostates exhibited atypical hyperplasia along with the presence of massive cellular debris after estrogen exposure, while the human prostates demonstrated basal cell hyperplasia as indicated by p63 staining. This study of human fetal prostate tissue will allow for future mechanistic studies investigating the origins of prostate disease.

**PS 995 Characterizing Later-Life Spatial Discrimination Deficit Phenotypes following *In Utero* Exposure to Benzopyrene.**

M. M. McCallister<sup>1</sup>, M. Maguire<sup>1</sup>, R. Rhoades<sup>1</sup>, B. Hudson<sup>2</sup>, A. Ramesh<sup>3</sup>, M. Newland<sup>2</sup> and D. B. Hood<sup>1</sup>. <sup>1</sup>Neuroscience and Pharmacology, Center for Molecular and Behavioral Neuroscience, Meharry Medical College, Nashville, TN; <sup>2</sup>Department of Psychology, Auburn University, Auburn, AL; <sup>3</sup>Department of Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN.

To characterize observed behavioral learning deficit phenotypes in offspring adult rodents arising from *in utero* exposure to benzo(a)pyrene [B(a)P], timed-pregnant Long Evans Hooded rats or Cytochrome p450- reductase (Cprlox/lox) mice were exposed to either B(a)P (0, 150, 300, 600 and 1200 $\mu$ g/kg BW or aerosol 100ug/m<sup>3</sup> on embryonic days 14 to 17. In the pre-weaning period, B(a)P metabolites were examined in cerebral cortex. No detectable levels of metabolites were found in the control offspring during the pre-weaning period but dose-related increases in B(a)P metabolites were seen in cerebral cortex and revealed a time-dependence for elimination during this period. Reversal learning was evaluated using a spatial discrimination-reversal procedure in adult offspring. Offspring that were exposed *in utero* to 600 and 1200  $\mu$ g/kg BW or 100ug/m<sup>3</sup> required a significantly higher number of sessions to complete the first reversal than control offspring. However, with original discrimination and subsequent reversals, exposed offspring behavioral profiles resembled their respective controls. This effect was seen in errors of commission, indicative of perseveration or resistance to extinction. Offspring that were exposed *in utero* also had shorter choice latencies than controls during the first session of a reversal. Activity related-cytoskeletal associated protein (Arc), an experience-dependent cortical protein marker known to be up-regulated in response to acquisition of novel behaviors, was also upregulated in B(a)P exposed animals that were trained in the behavioral paradigm. Collectively, the findings support the hypothesis that *in utero* exposure to B(a)P during the critical window for peak neurogenesis produces later-life learning deficit phenotypes in offspring.

**PS 996 Does the Barker Hypothesis Apply to Maternal Nanomaterial Exposure and Fetal Microvascular Function?**

P. G. Stapleton<sup>1</sup>, V. C. Minarchick<sup>1</sup>, J. Yi<sup>1</sup>, C. R. McBride<sup>1</sup>, K. Engles and T. R. Nurkiewicz<sup>2</sup>. *Physiology and Pharmacology, West Virginia University, Morgantown, WV.*

The continued development of engineered nanomaterials (ENM) has given rise to concerns over the potential for human health effects. While the lung is the primary site of exposure, the cardiovascular system is a principal site of impact. One of the most complex and acutely demanding circulations is the enhanced maternal system to support fetal development. The "Barker Hypothesis" proposes that metabolic impairments during gestation predispose future sensitivity. Herein we initiated testing at the microvascular level.

Pregnant (gestation day 10) Sprague-Dawley rats were exposed to nano-titanium dioxide aerosols (count mode aerodynamic diameter of 137 nm, 10 mg/m<sup>3</sup>, 4 hrs/day) for 10 days to evaluate the maternal and fetal consequences of maternal exposure. The calculated daily maternal deposition was 20 µg.

These exposures lead to fetal irregularities and maternal microvascular dysfunction. Isolated maternal uterine arteriolar (< 150 µm) reactivity was significantly impaired overall, consistent with a metabolically impaired profile. This dysfunction presented as blunted endothelium-dependent reactivity (acetylcholine, Ach, 10-9-10-4 M), reduced adrenergic responsiveness (phenylephrine, 10-9-10-4 M), and impaired myogenic responsiveness (transmural pressure, 15-120 mm Hg).

With respect to the fetal group, maternal exposures lead to a significant decrease in total fetal weight. Fetal tail arteries (< 150 µm) were isolated to assess microvascular alterations after maternal exposure. Interestingly, the vessels from the exposed group also demonstrate significant impairment to increasing concentrations of ACh (10-9-10-4 M), spermine-NONOate (10-9-10-4 M), and increases in transmural pressure.

Collectively, impaired uterine microvascular reactivity after ENM exposure during pregnancy can reduce nutrient exchange, drastically impacting fetal weight and number. This prenatal exposure may also lead to cardiovascular consequences for the developing fetus.

**PS 997 The AhR Contributions to Cardiovascular Development, Developmental Toxicity, and Adult Disease.**

V. S. Carreira<sup>1</sup>, Y. Fan<sup>1</sup>, J. Rubinstein<sup>2</sup>, M. Jiang<sup>2</sup> and A. Puga<sup>1</sup>. *<sup>1</sup>Environmental Health, University of Cincinnati, Cincinnati, OH; <sup>2</sup>Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Developmental disruption has been increasingly recognized as a key contributor to adult disease. Exposures to ubiquitous environmental persistent organic pollutants (POPs), which includes the pervasive organic pollutant 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD), can result in abnormalities of the cardiovascular system at the structural and functional levels. TCDD is a prototypical aryl-hydrocarbon receptor (AHR) ligand but the precise pathogenesis and phenotype of TCDD developmental toxicity remains poorly characterized. Our work aims at understanding how developmental perturbations (TCDD-exposure) or absence (knockout) of the AHR pathway affects the cardiovascular system in the embryo and adult. To characterize the toxicity phenotype, C57BL/6J pregnant dams were oral-gavaged with different doses of TCDD (0.1, 0.5, 1, 2.5, 5, and 50 µg/Kg) or vehicle control at key murine cardiogenesis time points (E7.5, 9.5, and 11.5). Embryos were harvested at E13.5, 15.5, and 18.5 or carried to term and adulthood. Additionally, C57BL/6J Ahr<sup>-/-</sup> mice were included in postnatal functional studies. At all studied doses, embryos could be carried to term; however, pups died within 24 hours post-partum at the three highest doses. Embryo cardiac toxicity was characterized by dynamic changes in morphometric parameters (right and left ventricular free wall thickness, cellular density, nuclear size, and extracellular matrix) as well as the changes in the expression of the Ahr and cellular proliferation proteins. The postnatal functional studies highlighted LV cavity dilatation in the Ahr<sup>-/-</sup> mice at PND60 and 90. These results corroborate the heart as a target of developmental disruption by in-utero exposure to a POP. Moreover, since all biological effects of TCDD exposure are believed to be mediated through AHR signaling, these results underscore the critical role for the AHR pathway in normal cardiovascular development. Supported by NIH Grant R01ES06273.

**PS 998 Exposure to 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) Changes Morphology of Dendritic Spines in the Developing Anteroventral Periventricular Nucleus (AVPV).**

J. Del Pino Sans<sup>1,2</sup> and S. Petersen<sup>2</sup>. *<sup>1</sup>Toxicologia y Farmacologia, University Complutense of Madrid, Madrid, Spain; <sup>2</sup>Veterinary and Animal Sciences, University of Massachusetts, Amherst, MA.*

Developmental exposure to TCDD interferes with masculinization of luteinizing hormone release patterns and sexual behaviors. Consequently, female-typical luteinizing hormone LH surge release and mating postures can be elicited by ovarian hormones in exposed males. Thus, it is likely that TCDD interferes with processes important for masculinization of the brain. Dendritic spine plasticity plays a role in sexual differentiation of preoptic areas important for sexual behavior, but no work has examined whether similar processes regulate differentiation of the anteroventral periventricular nucleus (AVPV), the brain region that controls LH surge release. Likewise, no work has previously investigated the effects of TCDD on modulation of dendritic spines morphology. In these studies, we used Golgi staining to examine sex differences and lasting effects of TCDD exposure on spine density and shape in the AVPV of rats. We found that compared with female counterparts, Postnatal Day 30 (PD30) control males had significantly more dendritic spines overall. In addition, the shapes of the spines differed between the sexes with males having more mushroom and stubby spines, but fewer thin dendritic spines than females. Lactational exposure to TCDD (600 ng p.o. to dams on PND1) did not change the overall density of dendritic spines in the AVPV. However, exposed males had more thin dendritic spines and stubby spines, but fewer mushroom spines than controls. These findings suggest that TCDD interferes with AVPV development by both replacing the high surface area mushroom dendritic spines with thin and stubby spines. Dendritic spines play a major role in neuronal plasticity and integration of signals, so by altering the number and shape, TCDD exposure during development may permanently alter gonadotropin release mechanisms.

**PS 999 Breast Cancer 1 (BRCA1)-Deficient Mice Develop Normally but Are More Susceptible to Ethanol- and Methamphetamine-Initiated Embryopathies.**

A. M. Shapiro<sup>1</sup>, L. Miller<sup>2</sup> and P. G. Wells<sup>1,2</sup>. *<sup>1</sup>Pharmaceutical Science, University of Toronto, Toronto, ON, Canada; <sup>2</sup>Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada.*

Brcal1 is a DNA repair gene associated with certain familial breast and ovarian cancers, and heterozygous (+/-) Brcal1-deficient mice develop normally but are more susceptible to cancer later in life. Little information is available on the developmental consequences of Brcal1 deficiencies, but homozygous (-/-) Brcal1 knockout mice are embryolethal and no confirmed cases of human -/- knockouts exist, even in families where both parents are carriers. To further investigate the role of Brcal1 deficiencies during embryonic development, a conditional Brcal1 knockout, driven by a Sox2 promoter, was implemented in an embryo culture system. Sox2-promoted Cre-expressing hemizygous males were mated overnight with floxed Brcal1 females (plug designated gestational day (GD) 1). On GD 9, embryos were explanted and grown in culture for 24 hours. Western blot analysis indicated a 35% reduction of Brcal1 expression in +/- conditional knockout progeny. As previously reported, untreated +/- Brcal1-deficient embryos developed normally relative to their wild-type littermates. However, following exposure to the reactive oxygen species (ROS)-initiating teratogens methamphetamine and ethanol, +/- Brcal1-deficient progeny exhibited increased embryopathies at concentrations that were not toxic in their wild-type Brcal1-normal littermates. Preliminary studies suggested an increase in oxidatively damaged DNA, measured as 8-oxoguanine (8-oxoG), in drug-exposed embryos, which was further enhanced with Brcal1 deficiencies. Ongoing studies are underway to localize the 8-oxoG lesions and investigate other forms of DNA damage. The protection by Brcal1 against embryonic ROS suggests a novel role for Brcal1, and has implications for drug exposure during pregnancy. [Support: Canadian Institutes of Health Research]

**PS 1000 Validation of a ToxCast Predictive Signature for Vascular Disruption in a Complex Angiogenesis Assay.**

N. Kleinstreuer<sup>1</sup>, R. Sarkanen<sup>2</sup>, T. Heinonen<sup>2</sup> and T. B. Knudsen<sup>1</sup>. *<sup>1</sup>NCCT, US EPA, Research Triangle Park, NC; <sup>2</sup>FICAM, Tampere, Finland.*

Analysis of the ToxCastDB Phase-I dataset revealed a strong in vitro signature for vascular disruption and developmental toxicity (>90% correlation) based on multiple angiogenic growth factors, chemokines, and receptors. Computer simulation with a multicellular agent-based model (ABM) predicted phenotypic effects on the structural integrity and complexity of a developing endothelial network.

Embryonic vascular development can be disrupted by diverse compounds (thalidomide, estrogens, endothelins, dioxin, retinoids, cigarette smoke, metals). Collaborative studies are underway to test these predictions across an array of assays (whole embryo culture, aortic explants, endothelial tubulogenesis, transgenic zebrafish, etc.). Here, we describe initial results with a complex human-cell based in vitro angiogenesis assay, on the first 7 of 20 ToxCast Phase I chemicals selected by a range of predicted activity as vascular disruptors (pVDCs). Degree of endothelial tubule formation in vitro was scored by AC50 values relative to cytotoxicity. Both chemicals predicted as non-pVDCs, imazamox and pymetrozine, showed no inhibitory activity. The predicted inhibitory potential of 5 pVDCs was confirmed for 4 out of 5 chemicals. Pyridaben, predicted as a strong pVDC, inhibited tubule formation in a concentration-dependent manner in the FICAM assay, first evident at 0.001  $\mu$ M and complete at 0.01  $\mu$ M. Other predicted pVDCs with different ToxCast activity profiles (BPA, oxytetracycline, fluazinam) inhibited endothelial tubulogenesis at concentrations ranging from 5- to 500  $\mu$ M. PFOS was the one inactive pVDC tested; however, the ToxCast prediction was based on inhibition of Ang1/Tie2 signaling that controls later stages of vessel stabilization – a subtle outcome in the ABM simulation. Overall, concordance between the tubulogenesis assay and computer ABM simulation demonstrates the utility of these in vitro and in silico models for predictive modeling and mechanistic understanding of vascular disruption in higher-order biological tissues. [This work does not reflect EPA policy].

### PS 1001 A Metabolite-Based Biomarker Approach to Predict Developmental Toxicity Using Human Embryonic Stem Cells.

A. M. Smith, J. A. Palmer, P. R. West, K. R. Conard, L. A. Egnash, M. E. Ross, B. R. Fontaine, P. Bais, E. L. Donley and R. E. Burrier. *Stemina Biomarker Discovery, Inc., Madison, WI*. Sponsor: L. Recio.

Birth defects are the largest cause of infant morbidity and mortality in the United States. Teratogens, defined as substances that cause fetal abnormalities during development, are responsible for 5-10% of all birth defects. The application of more predictive developmental toxicity screens would reduce the prevalence of birth defects and increase pharmaceutical and chemical safety. Human embryonic stem cell (hESC) technology provides an innovative and robust alternative in vitro model system to predict developmental toxicity of chemicals. We have developed a targeted, rapid and highly predictive assay based on specific biomarker metabolites identified after analysis of metabolomics data obtained from hESCs exposed to 23 known human teratogens and non-teratogens. The new model predicts the concentration at which hESCs respond to treatment indicating the potential teratogenicity based on treatment dose. We have tested this approach in over 60 compounds with varying degrees of toxicity in animal tests. hESCs were exposed to a 9-point dose curve of each compound. Spent media was collected and analyzed by high resolution LC/MS using a targeted metabolomics approach to determine the relative abundance of the biomarkers present in the model. We have built a database of the expected teratogenicity of the tested compounds in in vivo and in vitro tests. The results show excellent concordance with both human and animal teratogenicity data and compare well to other commonly used in vitro assays for developmental toxicity. This new targeted biomarker approach continues to utilize LC/MS analysis while allowing for an 8-fold increase in instrument throughput and simplified analysis. This biomarker based assay is an attractive new quantitative model providing faster turn around and lower cost, while retaining high predictivity for early assessment of the developmental toxicity potential across a broad range of chemicals at multiple treatment levels in an all human derived system.

### PS 1002 Metformin-Induced Folate Deficiency-Like Malformations in Cultured Rat Embryos: Potential for Novel Species Sensitivity.

C. Zhang<sup>1</sup>, J. Panzica-Kelly<sup>1</sup>, G. L. Gong<sup>2</sup> and K. Augustine<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb, Pennington, NJ; <sup>2</sup>Bristol-Myers Squibb Co., Princeton, NJ. Sponsor: L. Lehman-McKeeman.

Metformin has been used alone or in combination with other drugs, including those recently approved, for patients with Type II diabetes. Even though there has not been metformin associated teratogenic outcomes, about 7% of patients treated with metformin present subnormal vitamin B12 levels, suggesting the drug may attenuate folate metabolism. Some reports in rats indicated that metformin may have weak teratogenic properties resulting in a low incidence (~0.5-1%) of rare neural tube abnormalities, similar to those caused by folate deficiency. Mouse embryos cultured with metformin also presented delayed neural tube closure. Our objectives were to evaluate whether metformin causes adverse effects on neural tube development in rats (a standard test species for GLP teratology studies) using whole em-

bryo culture, and metabolomics to determine whether the compound disrupts folate processing. Neurulating rat embryos were exposed to metformin at concentrations observed in rats and humans. Embryos were evaluated for viability, growth, morphology, and metabolite profiles. Methotrexate was used as a positive control for adverse morphology and metabolomic profiles induced by disrupted folate signaling. Metformin caused concentration-related neural tube malformations and embryo lethality occurring at human clinical concentrations. Co-administered folic acid with metformin completely rescued the malformations as well as altered metabolites at rat concentrations and partially rescued the adverse effect at the sub-lethal human exposure concentration. Together, the studies suggested that rat neurulation may be sensitive to metformin, and the effects were related in part to folate signaling. Given the severity of neural tube findings at clinical concentrations that only caused recoverable anomalies in cultured mouse embryos and no reported effects in human pregnancy, the study suggests that the rat embryo may present novel species-sensitivity to metformin.

### PS 1003 Placental Transfer of <sup>125</sup>Iodinated Humanized Immunoglobulin G2Aa in the Sprague-Dawley Rat.

P. S. Coder<sup>1</sup>, J. A. Thomas<sup>1</sup>, D. B. Stedman<sup>2</sup> and C. J. Bowman<sup>2</sup>. <sup>1</sup>WIL Research, Ashland, OH; <sup>2</sup>Pfizer Inc, Groton, CT.

Biopharmaceuticals are a growing segment of the health care therapeutic arsenal and indications for these agents are rapidly expanding into patient populations that include women of child bearing potential. The fetus is typically not a target of these drug therapies, and thus effects on the developing conceptus are generally undesirable. While small molecules generally cross the placenta via passive diffusion throughout gestation, transfer of large molecules is limited and may be species dependent. Antibody-like biopharmaceuticals (Abs), that contain an Fc region, are unique and cross the placenta using active transport pathways normally reserved for maternal immunoglobulin G (IgG). Embryo/fetal, placental and maternal tissue concentrations of an Ab in Sprague Dawley rats were evaluated by 2 different biodistribution techniques following maternal injection of <sup>125</sup>Iodinated hIgG2Aa on different gestation days. Blood and tissue samples were collected for gamma counting or whole maternal carcasses were processed for quantitative whole body autoradiography. The results indicate the presence of maternally injected IgG in the conceptus as early as Gestation Day (GD) 11 and a >1000 fold increase in that amount by GD 21, with the overall tissue concentration generally remaining unchanged during gestation (within the same order of magnitude). In addition, fetal-maternal tissue concentration ratios remain stable during organogenesis with only a slight increase at the end of gestation. These data indicate that Abs with a target present in the developing conceptus have the potential to elicit an unintended biological response depending on the Ab affinity and potency. These data also demonstrate that maternally-administered Abs may be present during organogenesis and have the potential for adverse developmental outcomes in the rat based on direct embryo/fetal exposure.

### PS 1004 Evidence That Perfluorooctanoic Acid (PFOA) Does Not Activate Estrogen Receptor (ER) Activities In Vivo or In Vitro.

P. Yao<sup>1</sup>, D. J. Ehresman<sup>2</sup>, J. M. Caverly-Rae<sup>3</sup>, S. Chang<sup>2</sup>, S. R. Frame<sup>3</sup>, J. L. Butenhoff<sup>2</sup>, G. L. Kennedy<sup>3</sup> and J. M. Peters<sup>1</sup>. <sup>1</sup>The Pennsylvania State University, University Park, PA; <sup>2</sup>3M Company, St. Paul, MN; <sup>3</sup>Haskell Global Centers for Health and Environmental Sciences, Newark, DE.

We evaluated the potential of perfluorooctanoate to produce estrogenic activity in both an in vivo uterotrophic assay and an in vitro estrogen receptor (ER) activation assay. In the in vivo study, pre-pubertal female CD-1 mice born to dams fed an estrogen-free diet from PND 14 through weaning on postnatal day (PND 18) were given daily oral doses of 0, 0.005, 0.01, 0.02, 0.05, 0.1 or 1 mg/kg PFOA on PND 18-20. In addition, a positive control received daily 17 $\beta$ -estradiol (E2, 0.5 mg/kg). On PND 21, the uterus and vagina were weighed and prepared for histology. Transcripts concentrations for the ER responsive genes pS2, progesterone receptor (PR), and trefoil factor (TFF) were quantitated in the uterus (quantitative RT-PCR). Serum PFOA concentrations were determined by LC-MS/MS. PFOA caused no changes in body weights, uterine weights, transcripts for ER target genes, or in squamous hyperplasia and cornification of the vaginal epithelium. E2 administration produced increased relative uterine weight, increases in transcript concentrations for ER-responsive genes, and squamous hyperplasia and cornification of the vaginal epithelium. Mean serum PFOA ranged from 5 to 1200 ng/mL. In the in vitro study, PFOA at 0, 0.0005, 0.001, 0.005, 0.01, 0.05, 0.1, 0.5, 1, 5 or 10  $\mu$ g/ml in media failed to affect estrogen response element activity in a human ovarian carcinoma cell line (BG1-Luc4E2) that carried an estrogen response element (ERE)-luciferase reporter construct; whereas, E2 exhibited a marked increase. Collectively, these data do not support an estrogenic effect of PFOA either in vivo or in vitro.

**PS 1005 Effects of Di(2-Ethylhexyl)-Phthalate Exposure during the Peripubertal Period: An Analysis of the Evidence.**

A. D. Kraft, D. Segal and S. Makris. *National Center for Environmental Assessment, US EPA, Washington DC.*

Di(2-ethylhexyl)phthalate (DEHP) is a widely-used plasticizer and ubiquitous environmental contaminant. DEHP exposure during late gestation in rodents has been shown to cause a spectrum of adverse effects related to altered androgen function, collectively termed the "phthalate syndrome". Thus, many studies on DEHP have focused on exposures during this critical period of organ development and outcome measures in male offspring. A more limited database exists for other endpoints or following exposures that do not encompass fetal development. One such exposure paradigm involves DEHP treatment in young adult animals during the period of sexual maturation. Several of these peripubertal exposure studies suggest that the observed responses differ from those manifested following gestational DEHP exposure. In an effort to evaluate the consistency of these observations, data were collected from studies analyzing the effects of DEHP on adolescent humans or animals exposed during the peripubertal period. This evidence was cumulated by endpoint, the specific timing of DEHP exposure, and the age that the outcome was assessed. The observations were then compared to evidence from exposures during fetal development. The human evidence was difficult to interpret, as exposure timing could not be ascertained. Based on the animal data, several outcomes, including male reproductive system toxicity, showed evidence of differential effects following peripubertal exposure. Mechanisms that may explain these differences, such as proposed effects on postnatal androgen biosynthesis, were considered in light of biological plausibility to inform the interpretation of these data. Overall, our analysis suggests that the peripubertal period may be a stage of development sensitive to DEHP exposure; however, more comprehensive studies are needed to determine the impact of DEHP exposure on sexually immature adolescents. Disclaimer: The views expressed are those of the author and they do not represent U.S. EPA policy or guidance.

**PS 1006 Diet Acclimation of NZW Rabbits for Use in Embryo-Fetal Development Studies.**

K. Robinson<sup>1</sup>, A. I. Martin<sup>1</sup>, M. Freke<sup>1</sup>, I. Primakova<sup>1</sup>, R. Perras<sup>2</sup>, E. Lewis<sup>3</sup> and A. M. Hoberman<sup>3</sup>. <sup>1</sup>*Reproductive & Juvenile Toxicology, Charles River, Montréal, QC, Canada;* <sup>2</sup>*Charles River, St. Constant, QC, Canada;* <sup>3</sup>*Charles River, Horsham, PA.*

Poor food intake in pregnant rabbits can lead to adverse outcomes including abortion. Initial validation studies with a line of New Zealand White (NZW) rabbits, showed a high incidence of inappetence and adverse pregnancy outcomes. Several studies were conducted to optimize diet acclimation procedures at the breeding facility to match the certified diet used at the Testing Facility. Once the diet acclimation procedure was optimized, a study was conducted that met the ICH guideline for evaluation of embryo-fetal development (EFD). Naturally bred adult female NZW (CrI:KBL[NZW]) rabbits were received from Charles River, Canada on Day 0 or 1 postcoitum (pc). For the premating diet acclimation the does were fed increasing percentages of an irradiated version of PMI 5322 for 10 days before being given this diet alone at 150 or 180g/day for a further 10 days. The animals were fed 180g/day of PMI 5322 during the study. The does (22/group) were dosed with standard vehicles from Days 7 to 19 pc by oral gavage, intravenous injection, or inhalation; in addition there was a room control. Food consumption was measured daily and body weights were collected twice weekly. Clinical observations and any signs of abortion or premature delivery were recorded twice daily. Terminal examinations on Day 29 pc included a necropsy, corpora lutea counts and evaluation of the uterine contents. Live fetuses were weighed and examined for external, visceral and skeletal abnormalities. The does showed a high pregnancy rate and a low abortion rate. The occurrence of periods of inappetence during gestation was negligible. Ovarian, uterine and fetal parameters were comparable to other lines of NZW rabbits, but with slightly higher litter sizes and consequently slightly lower fetal weights noted. In conclusion, the diet acclimation procedure decreased the inappetence that was seen in previous rabbit reproductive toxicology studies and this line of NZW rabbit is considered suitable for use on EFD studies.

**PS 1007 Epigenetic and Physiologic Effects of Perinatal Lead Exposure.**

A. K. Barks, C. Faulk, J. Goodrich, O. S. Anderson, K. E. Peterson and D. Dolinoy. *Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI.*

Epidemiological and animal data suggest that development of chronic conditions such as obesity in adulthood is influenced by early life exposures. A proposed mechanism for this link is epigenetic modification. This study investigates effects of perinatal

lead (Pb) exposure on DNA methylation and alterations in physiologic parameters, including body composition and spontaneous activity. Using the viable yellow agouti (Avy) mouse, perinatal Pb exposure was modeled by a/a maternal exposure via drinking water supplemented with 0 ppm (control), 3.7 ppm (low), 27 ppm (medium), and 55 ppm (high) Pb two weeks prior to mating with an Avy/a male. Pb exposure continued through gestation and lactation. Epigenetic effects were evaluated by scoring coat color of Avy/a offspring (N=172), and physiologic parameters were evaluated in 3 month old wildtype a/a offspring (N=72) at the University of Michigan Nutrition and Obesity Research Center (MNORC). A statistically significant shift towards yellow coat color, indicative of DNA hypomethylation at the Avy allele, was observed in high dose Avy/a offspring, compared to controls (p=0.01). In a/a offspring, body weight was increased in high dose females, compared to controls (p=0.04). Females had increased % body fat and decreased % lean body mass across all exposure groups, compared to controls (p<0.05). Males showed significant differences in medium (decreased % lean mass) and high (increased % fat mass) Pb doses, compared to controls (p<0.05). Spontaneous activity was significantly decreased in females, but not males, in medium and high doses, compared to controls (p<0.05). There were no significant differences in food intake. Thus, perinatal Pb exposure resulted in both epigenetic and physiologic responses. Activity and body weight effects were more pronounced in females. Future work includes quantitation of methylation at specific target genes and life-course analysis of physiologic parameters of a/a offspring at 6 and 9 months of age. Funding: P20 ES018171/RD83480001 and P30 DK08950.

**PS 1008 Embryotoxic Potential of Epoxiconazole In Vitro and In Vivo.**

B. Flick<sup>1</sup>, F. DiRenzo<sup>2</sup>, S. Schneider<sup>1</sup>, S. Stinchcombe<sup>1</sup>, E. Menegola<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>*Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany;* <sup>2</sup>*Department of Biology, University of Milan, Milan, Italy.*

Some triazoles cause CYP26 inhibition of all-trans retinoic acid (RA) metabolism during organogenesis known to cause cleft palate (CP), via a mode of action (MoA) where altered tissue RA concentrations disrupt neural crest cell (NCC) migration, impairing development of the branchial arches (BA). Since very high-dose epoxiconazole (EPX) treatment induces clear maternal toxicity, causing CPs, we examined whether these are also caused by this MoA.

Both whole embryo culture tests (WEC) and in vivo studies were performed where the development of the embryos was examined morphologically, NCCs were visualized using whole immunostaining (WIS) for cellular retinoic acid binding protein, and embryonic tissue levels of EPX were analyzed with UPLC.

In WEC, embryos were exposed to 0, 1, 3, 10, 20, 30 mg/l for 48 hours starting at gestation day (GD) 9.5. EPX caused alterations in BA in 30% of the embryos at the LOAEC (3 mg/l) and dysmorphogenesis in 92% of embryos at 30 mg/l (embryonic tissue conc. = 8 mg/l). Embryos exposed to at least 10 mg/l exhibited an abnormal NCC distribution in the craniofacial region.

In the in vivo study, embryos were harvested on GD 11 from dams gavaged since GD6 with 0, 50, 100, and 180 mg/kg bw/d (the maximal tolerated dose which also causes CP). EPX caused maternal toxicity at 100 and 180 mg/kg; however, these embryos (embryonic tissue conc. = 6.4 mg/l) developed similarly to controls. No treatment-related increase in dysmorphogenesis, no alterations of BA, and no disturbance of NCC distribution were found.

The observed dysmorphogenesis of BAs and the impaired migration of the NCCs in the in vitro study supports the thesis that EPX alters CYP26-mediated RA metabolism, causing CP. But, despite comparable embryonic tissue levels in the in vivo study, neither the morphology nor the NCCs distribution was affected by EPX. These data do not support the theory that EPX-induced cleft palate in vivo is caused by alterations in RA metabolism.

**PS 1009 Perfluorooctanoic Acid-Induced Cytotoxicity in Primary Cardiomyocyte Culture.**

Q. Jiang and J. DeWitt. *Department of Pharmacology and Toxicology, East Carolina University, Greenville, NC.*

Perfluorooctanoic acid (PFOA) is a perfluorinated compound (PFC) that is widely used as a polymerization aid in the production of fluoropolymers. PFOA is environmentally persistent and is now detected ubiquitously in biota. Numerous studies have shown that PFOA can induce developmental toxicity in laboratory animal models. Epidemiological studies have demonstrated that PFOA exposure is associated with increased cholesterol levels and cardiovascular disease risk. We have previously reported that PFOA induces developmental cardiotoxicity in chicken embryos and hatchlings. To investigate the mechanism, we developed primary

cardiomyocyte cultures from D10 chicken embryo hearts and evaluated cell viability and reactive oxygen species (ROS) generation after in vitro PFOA exposure. Primary cardiomyocytes were treated with vehicle (0.1% DMSO in medium) or 0.1, 1, 10, 50, 75 or 100 µg/ml of PFOA for 1h or 36h. No statistical differences were detected between untreated and vehicle-treated groups. Viability was decreased by 74.5% in cells treated with 100 µg/ml of PFOA relative to the vehicle group ( $n=4-6$ ,  $P<0.05$ ) at the 1h time point. At the 36h time point, viability was statistically decreased at 10, 50, 75 and 100µg/ml concentrations, relative to the vehicle group (18.1%, 18.7%, 34.6% and 70.0%, respectively;  $n=4-6$ ,  $P<0.05$ ). At the 1h time point, an increase in ROS generation was observed at all doses; however, only 50 µg/ml of PFOA statistically increased ROS generation relative to the vehicle group (316.8%;  $n=3$ ,  $P<0.05$ ). Our results indicate that direct PFOA exposure to primary cardiomyocytes can induce cytotoxicity and ROS generation. Although additional studies are necessary to verify this effect in vivo, induction of cell death and generation of ROS may partially contribute to developmental cardiotoxicity associated with in ovo PFOA exposure in an avian model.

## PS 1010 Estradiol Modulates Paraoxonase-2 Expression in Mouse Brain.

G. Giordano<sup>1</sup>, C. E. Furlong<sup>2</sup>, T. B. Cole<sup>2</sup> and L. G. Costa<sup>1,3</sup>. <sup>1</sup>Department Environmental Occupational Health Sciences, University of Washington, Seattle, WA; <sup>2</sup>Division of Medical Genetics and Department of Genome Sciences, University of Washington, Seattle, WA; <sup>3</sup>Department of Neuroscience, University of Parma, Parma, Italy.

Paraoxonase 2 (PON2), a member of the PON gene family, is expressed in mouse brain; levels are highest in dopaminergic areas (e.g. striatum), and are higher in astrocytes than in neurons or microglia. As in other tissues, PON2 exerts a potent antioxidant effect in the CNS, and protects mouse neurons and astrocytes against oxidative stress. In all mouse tissues, including the brain, PON2 levels are higher in female than in male mice. In primary striatal astrocytes and neurons PON2 protein level in females is 2-3-fold higher than in males. Levels of PON2 mRNA and lactonase activity show similar gender differences. Male astrocytes and neurons are more sensitive (by 3-4-fold) than female cells to oxidative stress-induced toxicity, though GSH levels do not differ between cells isolated from the two genders. In contrast, no significant gender difference in susceptibility is seen in cells from PON2<sup>-/-</sup> mice, suggesting that PON2 is a major determinant of gender differences in susceptibility to oxidative stress-mediated neurotoxicity. Estradiol induces a time- and concentration-dependent increase in the levels of PON2 protein and mRNA in male (4.5-fold), and also in female (1.8-fold), astrocytes. Such effect is due to activation of estrogen receptors alpha. In ovariectomized mice serum estradiol levels are decreased to male levels; PON2 protein and mRNA are also decreased to male levels in brain areas and in liver. Neuroprotection by estradiol against oxidative stress-induced neurotoxicity is seen only in astrocytes from wild type mice, but not in cells from PON2<sup>-/-</sup> mice, suggesting again that PON2 represent a major, gender-dependent, factor in protective CNS cells against neurotoxins. The lower expression of PON2 in males may have broad ramifications with regard to susceptibility to diseases involving oxidative stress, including neurodegenerative diseases (Supp. in part by ES04696).

## PS 1011 Suppression of H19 Methylation in Mouse Exposed to Chlorpyrifos Methyl during Organogenesis Period.

H. Shin<sup>1</sup>, J. Seo<sup>1</sup>, S. Jeong<sup>2</sup>, S. Park<sup>1</sup>, Y. Park<sup>1</sup>, S. Son<sup>1</sup> and H. Kang<sup>1</sup>. <sup>1</sup>Toxicology & Residue Chemistry Division, QIA, Anyang, Republic of Korea; <sup>2</sup>GLP Research Center, Hoseo University, Asan, Republic of Korea.

Chlorpyrifos-methyl (CPM) is widely used organophosphorus insecticide. In Korea, more than sixty-five tons per year are used in agriculture. In our previous study, CPM showed anti-androgenic endocrine disruption activity. Lots of EDC shows the alteration of methylation in imprinting gene, which inherit to next generation. This study was performed to examine the effect of CPM on the H19 methylation in mouse.

After mating CAST/Ei (♂) and B6 (♀), CPM was administered at dose of 4 (CPM4), 20 (CPM20) and 100 (CPM100) mg/kg bw/day from embryonic day (ED) 7 to ED 17. Anogenital distance (AGD) was measured at post natal day (PND) 21. Clinical signs, body weights, feed and water consumption, organs weights, serum hormone values and H19 methylation level of organ and sperm were measured at PND63.

Body weights were significantly ( $p$  value  $<0.0.1$ ) lower than control until PND 6. AGD was significantly ( $p$  value  $<0.0.1$ ) decreased at CPM100 group in male and increased at CPM20 group in female. The weight of thymus and epididymis were

significantly ( $p$  value  $<0.0.1$ ) increased at all of CPM treatment in male. In CPM20 group, liver, kidney, heart, lung, spleen, prostate gland and testes were significantly increased. Testosterone level in serum was significantly ( $p$  value  $<0.0.1$ ) increased by CPM treatment in both male and female. H19 methylation level of liver and thymus showed decreased pattern by dose-dependent manner in male. The levels of H19 methylation in sperm were  $73.76\pm7.16\%$ (CTL),  $57.84\pm12.94\%$ (CPM4),  $64.24\pm3.79\%$ (CPM20) and  $64.24\pm3.79\%$ (CPM100).

CPM can disturb the early development of offspring development and disrupt H19 methylation in organ and sperm. Those altered methylation pattern may pass down to next generation through sperm.

## PS 1012 In Utero Growth Restriction and Dibutyl Phthalate Exposure May Cooperatively Disrupt Steroidogenesis.

J. Pike<sup>1</sup>, E. McDowell<sup>2</sup>, A. Kisilewski<sup>2</sup> and K. Johnson<sup>2</sup>. <sup>1</sup>Biological Sciences, University of Delaware, Wilmington, DE; <sup>2</sup>AI Dupont Hospital for Children, Wilmington, DE.

Masculinization of the male reproductive tract occurs in human gestational weeks 10-22, and rat gestational days 16-21. Fetal testes produce a surge of testosterone causing reproductive masculinization. Disruption leads to reproductive abnormalities including cryptorchidism and hypospadias. In humans, in utero growth restriction (IUGR) is a risk factor for cryptorchidism and hypospadias. Rat work shows that fetal steroidogenesis is disrupted by exposure to the anti-androgen dibutyl phthalate (DBP). While these fetal circumstances increase the prevalence of the same birth defects individually, we examined a possible cooperative effect of these treatments on steroidogenesis. A maternal under-nutrition model was examined in the rat. Pregnant Wistar rats were restricted to 50% ( $n=9$ ) of the food eaten by ad libitum controls ( $n=8$ ) beginning on gestational day (GD) 3. Restriction through GD17 caused a significant decrease in pup weight with no decrease in litter size. Fetal testes showed decreased testosterone production (40%) by radioimmunoassay. mRNA levels of steroidogenic genes including Scarb1 and Star were significantly decreased in the fetal testis after growth restriction. Food restriction ( $n=11$ ) from GD3-18 caused no malformations at postnatal days 1, 14, or 28 as compared to controls ( $n=10$ ). A coexposure study of IUGR and maternal dosing with the anti-androgen DBP was performed examining a cooperative effect on steroidogenesis. Analysis of fetal testes (GD17) following 50% food restriction from GD3-17 ( $n=11$ ) or exposure to DBP (250mg/kg/day) from GD15-17 ( $n=7$ ) showed a significant decrease in the expression of the steroidogenic genes Cyp11a1, Cyp17a1, Scarb1, and Star as compared to controls ( $n=7$ ). When 50% restriction was coupled with DBP exposure ( $n=10$ ), further decreased steroidogenic gene expression. While IUGR and DBP lead to a decrease in steroidogenesis separately, they also appear to work cooperatively to cause further disruption.

## PS 1013 A Comparison of Social Housing Opportunities during Developmental Toxicity Evaluation in Cynomolgus Monkeys.

S. M. Henwood<sup>1</sup>, C. Luetjens<sup>2</sup>, A. Fuchs<sup>2</sup> and G. F. Weinbauer<sup>2</sup>. <sup>1</sup>Nonclinical Safety Assessment, Covance Laboratories Inc., Madison, WI; <sup>2</sup>Nonclinical Safety Assessment, Covance Laboratories GmbH, Munster, Germany.

The demand for developmental toxicity studies in nonhuman primates (NHPs) has increased, mainly driven by biopharmaceutical drug development. Social housing of NHPs has become mandatory in many countries and this poses a specific challenge since NHPs with timed pregnancies cannot be obtained commercially. The cynomolgus fertility rate in a mating programme is typically 35-45% per mating cycle and 60% per female animal upon repeated mating trials. Hence, social housing of pregnant cynomolgus monkeys requires special approaches until a cage is populated by animals with confirmed pregnancy. Formation of new groups of sexually mature female cynomolgus monkeys has pronounced effects on ovarian cyclicity to the extent that some animals exhibit transient amenorrhea. Concern has been raised that social housing of pregnant animals might interfere with maintenance of gestation due to rank order fights, incompatibility, and other group-related adverse effects. On the other hand, in a social setting, animals experience birth events and handling of neonates by watching cage mates, and infants have cage mates of comparable ages to interact with. In the present work, qualitative assessment in more than 200 hundred pregnant control animals under social housing indicated good compatibility with little aggression toward each other. Interestingly, a reduction of pre- and postnatal loss by 25-30% was encountered under social housing when compared to single housing. Conceivably, the delivery process and managing the newborn was facilitated by social maternal housing. Moreover, maternal and infant body weight gains were significantly increased under social housing

compared to single housing. In conclusion, social housing is feasible for developmental toxicity studies in NHPs and provides distinct advantages over single housing and is, therefore, recommended for the conduct of NHP developmental toxicity studies and is now the default at Covance Laboratories.

#### **PS 1014 Feasibility of Mouse Continuous Intravenous Infusion for Fertility and Embryo-Fetal Development Studies.**

R. S. Bartlett and H. van Wijk. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: S. Kirk.

The rat and rabbit are routinely used in pre-clinical reproductive and developmental toxicity (DART) studies. However, where the rat and/or rabbit are not suitable, the mouse is an alternative model.

A model of continuous intravenous infusion using a surgically-implanted femoral vein catheter with tail cuff exteriorisation has been previously developed in the mouse. The reliability of this method decreased over time, with a success rate of only 74% after 28 days because of tail cuff constraints due to animal growth.

This study aimed to (1) determine whether a larger diameter tail cuff (6 mm) could extend the continuous infusion duration, and (2) determine the feasibility of evaluating DART parameters in mice using this surgical model in a combined fertility and embryo-foetal development study.

33 CD-1 female mice (approximately 7-9 weeks old) were surgically implanted with a femoral vein catheter exteriorised with a 6 mm tail cuff. After 6 days of recovery, they were intravenously administered 0.9% sodium chloride, by continuous infusion (4 mL/kg/hr) for 2 weeks prior to pairing, during pairing (with uncatheterised males) and through Gestation Day (GD) 18 (42 days). On GD18, females were killed and uterine contents examined.

Technical failure occurred in 9 females; this was attributed to the larger diameter of the tail cuff, which slipped down and allowed the catheter to be chewed. Of the 24 female mice remaining on study at the end of pairing, 23 (96%) were successfully mated and 22 (96%) were confirmed pregnant. Catheter failures or poor tail conditions resulted in early removal of 5 additional mice. However, those surviving to necropsy, uterine and foetal data were within background ranges, indicating no effects on reproductive or developmental parameters.

It is concluded that continuous intravenous infusion via this surgical model is a viable method of dosing mice in DART studies. The larger tail cuff did not increase reliability of the infusion technique for a period greater than 28 days, therefore separate fertility and embryo foetal development studies are recommended for mice.

#### **PS 1015 Addressing the Mode of Action for Developmental PFOA-Induced Mammary Gland Delays.**

M. B. Macon<sup>1,2</sup> and S. E. Fenton<sup>2</sup>. <sup>1</sup>*Curriculum in Toxicology, University of North Carolina, Durham, NC;* <sup>2</sup>*NTP Labs, NIEHS, NIH, Research Triangle Park, NC.*

Perfluorooctanoic acid (PFOA) exposure alters mammary gland (MG) development and function in mice. The mode of action (MOA) for these effects has not been elucidated, although activation of peroxisome proliferator activated receptor alpha (PPAR $\alpha$ ) has been implicated. To begin elucidation of a MOA, time pregnant CD-1 mice were gavaged with 0.0, 0.01, 0.1, or 1.0 mg PFOA/kg body weight on gestation days (GD) 10-17. Female offspring MGs were removed and prepared for RNA on multiple postnatal days (PND). A comparison of MG RNA from control and 1.0 mg/kg groups with Affymetrix 420.2 microarrays found differential regulation of 710 and 41 genes at PND 7 and 14, respectively. Adiponectin, estrogen receptor alpha, and WNT expression were reduced in PFOA-treated glands. PPAR $\alpha$  expression was not changed. These data were validated by PCR of MG RNA, using TBP as a reference gene. At PND 7, PFOA induced differential regulation of several genes compared to controls, even at 0.01 mg/kg. When considering developmental scores, glands with higher scores or more normal growth had increased RNA expression of WIF1, ESR1 and PGR at PND 21 and FABP3 and UCP1 at PND 56. PND 56 MG sections stained for PPAR $\alpha$  protein displayed robust expression in all glands regardless of treatment, yet there was higher expression in stromal tissues surrounding ducts in PFOA exposed mice compared to controls. Collectively, these findings suggest that PPAR pathway genes are altered in conjunction with PFOA-induced MG changes along with other pathways. Observed altered genes are involved in signaling of all PPAR isoforms including  $\alpha$ ,  $\beta/\delta$ , and  $\gamma$ . Both up and down regulation of these genes were found which suggests that multiple PPAR isoforms may work together to regulate PFOA-induced MG aberrations. In addition, prenatal PFOA exposure at 0.01 mg/kg leads to mammary gene changes at human-relevant levels. Future investigations will examine related gene pathways and protein levels compared to observed morphological and hormone outcomes. This abstract does not necessarily reflect NIEHS policy.

#### **PS 1016 Evaluation of Reproductive and Developmental Toxicity of Multiwall Carbon Nanotubes in Pregnant Mice After Intratracheal Instillation.**

N. Kobayashi<sup>1</sup>, M. Kawabe<sup>2</sup>, H. Nakashima<sup>2</sup>, T. Numano<sup>2,3</sup>, R. Kubota<sup>1</sup>, N. Sugimoto<sup>1</sup> and A. Hirose<sup>1</sup>. <sup>1</sup>*National Institute of Health Sciences, Setagaya, Japan;* <sup>2</sup>*DIMS Institute of Medical Science Inc., Ichinomiya, Japan;* <sup>3</sup>*Department of Molecular Toxicology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Some studies have reported that maternal exposure to nanoparticles may induce teratogenicity or transfer to their fetuses and affect the development and function of the central nervous systems. In order to evaluate the reproductive and developmental toxicity of multi-wall carbon nanotubes (MWCNTs) via inhalation exposure, we conducted intratracheal instillation study of MWCNTs dispersed in two different media (blood serum obtained from female mice and 2% of sodium carboxymethyl cellulose (CMC-Na) solution) in pregnant mice. MWCNTs (MWNT-7) dispersions were prepared by ultrasonication using an ultrasonic bath for 30 min. The above MWCNT dispersions were administered to pregnant Crlj:CD1(ICR) mice with gestation day 9 at dosage of 0, 3.0, and 5.0 mg/kg bw. Five mice per group were evaluated. The mice were dissected at 18 days of gestation period. MWCNT depositions in the tissues and the effect to embryos and fetuses were evaluated. The MWCNTs were deposited in the lungs as the black spots. No statistically significant difference between the control group and MWCNT-exposed groups in the number of corpora lutea, implantations, dead fetuses (early or late resorption site), live fetuses, and sex ratio. However, body weight of fetuses and placental weights were dose-dependently decreased in the both MWCNT-exposed groups. Furthermore, external malformations (i.e., oligodactyly, extensive contracture, cleft lip) were observed in the 3 mg/kg of CMC-Na treated MWCNT-exposed group and 5 mg/kg of blood serum treated MWCNT-exposed groups. Further information is needed to clarify the potential for the reproductive and developmental toxicity of MWCNTs.

#### **PS 1017 Histology of Selected Organs from the Göttingen Minipig Fetus from Days 60 (Midterm) and 110 (Term) of Gestation.**

M. Perron Lepage, J. Briffaux, C. Thuilliez, E. Marsden and M. Leroy. *Ricerca Biosciences SAS, St. Germain sur l'Arbresle, France.*

In a previous study, we demonstrated that chemically induced fetal abnormalities could be detected in the Göttingen Minipig shortly after mid term. At this time, it is possible to sex the minipig fetus by observation of the external genital area, although at gross soft tissue examination, the location, size and shape of the male and female gonads are similar at this stage. The aims of the present study were to compare the histological features of selected organs in the Göttingen Minipig fetus at GD 60 and GD 110 and to validate histologically the method of sexing the fetuses by macroscopic observation of the external genital area.

Four 7- to 13-month-old virgin Göttingen Minipig females were mated. Caesarean sections were performed on two females at mid term (GD 60) and on two others at term (GD110). The fetuses were weighed, sexed and submitted to standard gross external and visceral examinations. Selected organs (adrenal glands, heart, kidneys, liver, lungs, ovaries, thymus, thyroid gland, urinary bladder, uterus, vagina, epididymides and testes) were sampled and fixed in 10% formalin or modified Davidson's fluid. Five male and 5 female fetuses obtained at GD 60, and 2 male and 6 female fetuses obtained at GD110 were available for histological examination. The microscopic appearances and the differences between the two timepoints were described for each organ.

The histological appearance of the organs at GD110 was similar to that of juvenile minipigs. At GD 60, however, although all organs were identifiable, maturation and growth were obviously still incomplete.

This study reported the histology of selected organs in minipig fetuses at GD 60 and GD 110. At GD 60, there was complete concordance in establishing the sex of each fetus by microscopic examination and evaluation of the external genitalia.

#### **PS 1018 Mono-Ethylhexyl Phthalate (MEHP) Exposure Reduces Embryonic Nutrition and Induces Structural Defects in Mouse Whole Embryo Culture.**

K. E. Sant and C. Harris. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Di-2-ethylhexyl phthalate (DEHP) is a highly lipophilic endocrine disruptor and is the most abundant phthalate plasticizer in the environment. Exposure to DEHP and its primary active metabolite, mono-ethylhexyl phthalate (MEHP), have been associated with several adverse health effects, ranging from obesity to reproductive

dysfunction. The objective of this study was to determine whether MEHP can induce structural defects during embryonic development in vitro in whole embryo culture (WEC) and to assess whether decreased embryonic nutrition contributes to these defects. Gestational day (GD) 8 CD-1 mouse conceptuses were explanted into WEC. MEHP or DEHP at concentrations ranging from 100-1000 µg/ml were added directly to the culture media and conceptuses were exposed for 26 hours before complete morphological scoring and collection of visceral yolk sac (VYS) and embryo (EMB) tissues on GD 9. MEHP treatment significantly reduced total morphological scores at all doses, reaching a maximal decrease of 67% ( $p < 0.03$ ), while DEHP failed to produce any significant decreases in total morphology score. Morphological comparison of neural tube-specific endpoints revealed that MEHP produced a significant increase in incomplete neural tube closure ( $p < 0.001$ ). Clearance of FITC-albumin by the VYS was assessed after 3 h exposure to 100 or 250 µg/ml MEHP on GD 9 as a measure of histiotrophic nutritional activity. Treatment significantly reduced total clearance in a dose-dependent manner ( $p < 0.008$ ) by 29% and 43% for 100 and 250 µg/ml treatment, respectively. This work demonstrates that MEHP treatment reduces embryonic nutrition, limiting the substrates essential for normal metabolic activities, and induces structural defects, especially preventing closure of the neural tube.

**PS 1019 Development and Validation of an Analytical Method for Monobutylphthalate, a Metabolite of Di-n-Butylphthalate, in Harlan Sprague-Dawley Rat Plasma and Amniotic Fluid by UPLC-MS/MS.**

V. G. Robinson<sup>2</sup>, M. A. Silinski<sup>1</sup>, T. A. Freed<sup>1</sup>, R. A. Fernando<sup>1</sup>, C. S. Smith<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>RTI International, Research Triangle Park, NC; <sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC. Sponsor: K. Levine.

Di-n-butyl phthalate (DBP) is a common plasticizer used in a variety of consumer products. Its major metabolite is its monoester. Exposure to DBP is widespread, and its potential toxicity has been, and continues to be, investigated. The objective of this work was to develop, validate, and apply a method to quantitate mono-n-butyl phthalate (MBP), the major metabolite of DBP, in rat plasma and amniotic fluid. Samples were extracted by spiking 25 µL of plasma or amniotic fluid with 25 µL of water, 25 µL of internal standard solution (MBP-d4 in water), and 425 µL of 0.1% formic acid in acetonitrile. After centrifugation, 5 µL of supernatant was injected onto an Acquity UPLC HSS T3 column, and separation was performed using gradient elution. MS/MS analysis was conducted using electrospray ionization in negative ion mode and multiple reaction monitoring. The method was successfully validated over the range 25-5000 ng/mL in plasma, with cross-validation for amniotic fluid. Validation parameters included linearity ( $r > 0.99$ ), recovery, selectivity, sensitivity (LOD = 6.9 ng/mL), precision (%RSD < 15%), accuracy (%RE < 15%), and stability (% of Day = 100 +/- < 20%). It was also demonstrated that samples as high as 516,000 ng/mL could be accurately and precisely diluted into the calibration range.

The method is being applied for the analysis of MBP in plasma and amniotic fluid samples from rats administered 0, 300, 1000, 3000, or 10,000 ppm DBP in feed.

**PS 1020 Developmental and Reproductive Studies in Sprague-Dawley Rats with Gevokizumab, a Novel Monoclonal Antibody Targeting IL-1 Beta.**

C. A. Gasper<sup>1</sup>, B. Thorsrud<sup>2</sup>, L. Cao<sup>1</sup>, J. Chen<sup>1</sup>, L. Wong<sup>1</sup>, K. Der<sup>1</sup>, J. Ma<sup>1</sup>, A. Ahene<sup>1</sup> and K. Meyer<sup>1</sup>. <sup>1</sup>Nonclinical Safety Evaluation, XOMA (US) LLC, Berkeley, CA; <sup>2</sup>Developmental & Reproductive Toxicology, MPI Research, Mattawan, MI.

Gevokizumab, also coded XOMA 052 or S78989, is a humanized IgG2 monoclonal antibody that binds with high affinity to human interleukin-1 (IL-1) beta. Gevokizumab inhibits the activation of the IL-1 receptor, thereby modulating the cellular signaling events producing inflammation. Currently, gevokizumab is in Phase 3 clinical trials for non-infectious uveitis and Behçet's uveitis and in Phase 2 proof-of-concept studies for moderate to severe acne and erosive osteoarthritis of the hand. Developmental and reproductive studies (embryo fetal, fertility, and pre/postnatal development) in Sprague Dawley rats evaluated the effects of gevokizumab when administered subcutaneously once weekly at 3, 30, and 90 mg/kg/dose. The rat (usual rodent model for evaluating developmental and reproductive toxicity) was selected due to similar binding affinity and in vitro functional activity between human and rat IL-1 beta. Standard ICH S5(R2) study designs were followed. Observations included clinical signs, body weight, food consumption, drug levels in serum and milk, anti-drug antibodies (ADA), maternal uterine and ovarian examinations, fetal evaluations, macroscopic pathology, reproductive

performance, parturition, lactation to weaning, and F1 physical growth and development. Gevokizumab did not produce any mortality or significant adverse effects. Measurement of gevokizumab in serum (maternal, fetal, neonate) and maternal milk confirmed adequate exposure during the dosing periods. ADAs were detected in a few dams, without neutralizing activities. The NOAEL for maternal and developmental toxicity including teratogenicity, general reproductive toxicity in male and female rats, and general toxicity in the dam, including developmental and reproductive toxicity in the F1 offspring was considered to be at least 90 mg/kg/dose, the highest dose level tested. No gevokizumab-related findings were observed in any of the reproductive and developmental studies.

**PS 1021 Weight of Evidence Considerations for Developmental Toxicity Classification of Boric Acid.**

W. Ball and M. Harrass. Rio Tinto Minerals, Greenwood Village, CO.

Although reproductive and developmental effects have been demonstrated in laboratory animals exposed to high doses of boric acid (BA), similar effects have not been observed in highly exposed human populations or workers. Workers in boron (B) mining/processing industries represent the maximum possible human exposure. A weight of evidence approach was used in evaluating numerous independent studies on the determination of the hazard of BA to humans. Information that was considered together included results of in vitro tests, animal data, worker exposure data, epidemiological studies and mechanistic data. Extensive evaluations of sperm parameters in highly exposed workers in Turkey and China demonstrated no effects on male fertility. No evidence of developmental effects in humans attributable to B has been observed in studies of populations with high exposures to B. Collectively the epidemiological studies consistently show an absence of effects in highly exposed populations. A comparison of blood, semen and target organ B levels in studies of lab animals and B workers shows B industry worker exposures are lower than untreated control rats. Recent studies provide evidence that BA may act by similar mechanisms in causing developmental effects in mice as sodium salicylate (natural deacetylated form of aspirin) including effects on Hox gene expression and inhibition of embryonic histone deacetylases. Although aspirin is known to cause developmental effects in laboratory animals, similar effects have not been seen in controlled human studies. Similar mechanisms of action of BA and aspirin and the absence of effects in humans ingesting aspirin suggest that BA related developmental effects in humans are unlikely. Also, there is evidence that Zinc (Zn) interacts with B in the body reducing the toxicity of B. Zn levels in soft tissue in humans are over 2 x greater than in lab animals explaining in part the absence of fertility and developmental effects in humans. Based on the total weight of evidence, the data show that it is improbable that BA will cause reproductive or developmental effects in humans.

**PS 1022 Embryonic DNA Repair and Ethanol-Initiated Behavioural Deficits in Oxoguanine Glycosylase 1 (OGG1) Knockout Mice: A Role for Oxidatively-Damaged DNA and Protection by a Free Radical Spin Trapping Agent.**

L. Miller<sup>1</sup>, D. J. Pinto<sup>1</sup> and P. G. Wells<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada; <sup>2</sup>Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.

A mother's consumption of alcohol (ethanol, EtOH) during pregnancy can cause a spectrum of structural, cognitive and behavioural problems in the developing child termed Fetal Alcohol Spectrum Disorders (FASD). Reactive oxygen species (ROS) have been implicated in the mechanism of behavioural teratogenicity, although the role of embryonic DNA damage and repair are unclear. To determine the latter, DNA repair-deficient heterozygous (+/-) oxoguanine glycosylase 1 (OGG1) knockout mice were mated, and pregnant dams were treated once on gestational day 17 with EtOH (2 g/kg i.p.) or its saline vehicle, with or without pretreatment with the free radical spin trapping agent alpha-phenyl-N-tert-butyl nitro (PBN) (40 mg/kg i.p.). Saline-exposed progeny exhibited an ogg1 gene dose-dependent learning deficit in the passive avoidance test compared to wild-type (WT) littermates, demonstrating for the first time a phenotype in OGG1-deficient mice. EtOH-exposed progeny exhibited an enhanced learning deficit compared to saline controls at 6 and 9 weeks of age, also in an ogg1 gene dose-dependent fashion. PBN pretreatment significantly protected both WT and KO progeny, although this protection for EtOH was slightly less effective in +/- and -/- KO progeny. These results provide the first evidence to date that ROS-initiated embryonic DNA oxidation is involved in EtOH-initiated behavioural deficits, and embryonic DNA repair status may be a determinant of teratological risk. (Support: Canadian Institutes of Health Research)

**PS 1023 Hyperactivity of Rat and Mouse Induced by Lactational Exposure to Hydroxylated PCB (OH-PCB106).**

N. Koibuchi, A. Haijima, R. Lesmana, I. Amano, Y. Takatsuru, T. Iwasaki and N. Shimokawa. *Department of Integrative Physiology, Gunma University Graduate School of Medicine, Maebashi, Japan.*

Polychlorinated biphenyls (PCBs) are persistent environmental pollutants that may cause adverse health effects. Previous in vitro studies including ours have shown that various PCB congeners affect neurodevelopment through different mechanisms. However, behavioral alterations induced by lactational exposure to PCB and its neurochemical mechanisms have not yet been fully studied. In the present study, hydroxylated-PCB 106 (OH-PCB 106; 4-hydroxy-2',3,3',4',5'-pentachlorobiphenyl) was administered to lactating rat and mouse dams via gavage every second day from day 3 to 13 after delivery. The exposure did not affect the body weight of the dams or the physical development of the newborn pups in both sexes. Male rats and mice exposed to OH-PCB 106 showed hyperactivity that was characterized by increased locomotor activity in open field and circadian period. OH-PCB 106-exposed rats displayed abnormally high levels of dopamine and D2 dopamine receptor (D2DR), but not D1DR and D5DR, in the striatum, an important center for the coordination of behavior. These findings indicate that OH-PCB 106 has a significant neurotoxic effect on rodent behavior, which may be associated with increased D2DR mediated signals.

**PS 1024 Di-isobutyl Phthalate (DIBP) Hazard Identification.**

S. Y. Euling<sup>1</sup>, K. Hogan<sup>1</sup>, G. Cooper<sup>1</sup>, C. Cai<sup>1</sup>, K. Y. Christensen<sup>1</sup>, M. Lorber<sup>1</sup>, X. Arzuaga<sup>1</sup>, C. Sheth<sup>1</sup>, A. F. Sasso<sup>1</sup>, M. Pratt<sup>1</sup>, A. K. Hotchkiss<sup>2</sup> and J. C. Lambert<sup>3</sup>. <sup>1</sup>NCEA, US EPA, Washington DC; <sup>2</sup>NCEA, US EPA, Research Triangle Park, NC; <sup>3</sup>NCEA, US EPA, Cincinnati, OH.

The hazard potential for DIBP is being evaluated as part of EPA's Integrated Risk Information System (IRIS) Toxicological Review. DIBP is a plasticizer that confers flexibility and durability in industrial and consumer products. The epidemiology and animal toxicology databases are both relatively small. The small DIBP epidemiological database includes studies that assessed the relationship between urinary concentrations of the DIBP metabolite mono-isobutyl phthalate (MIBP) and developmental, neurodevelopmental, immunological or breast cancer outcomes. There is limited support for associations between MIBP and inflammatory biomarker levels, and decreased masculine play behavior. The animal toxicological database includes studies that assessed male reproductive developmental endpoints that constitute the phthalate syndrome after in utero DIBP exposure. The largest developmental study, Saillenfait et al. (2008), reported changes in anogenital distance, male reproductive organ weights, and litter incidence of phthalate syndrome endpoints in the lower dose range after early gestational exposure. Other studies observed increased fetal mortality, male postnatal and adult growth decrements, decreased fetal testicular testosterone and changes in expression of genes involved in androgen production pathways. The developmental reproductive effects observed in animal studies are consistent with the reduced testicular testosterone mode of action that is well-characterized for developmentally toxic phthalates. Effects on liver and kidney weight and function in both male and female adults were also reported. Research needs include epidemiologic studies that examine DIBP exposure, testosterone and related outcomes throughout development as well as multigenerational reproductive toxicity studies and cancer bioassays. The views expressed are those of the authors and do not necessarily reflect the views or policies of the US EPA.

**PS 1025 Establishment of a Molecular Embryonic Stem Cell Developmental Toxicity Assay.**

J. Panzica-Kelly<sup>1</sup>, K. Brannen<sup>2</sup>, Y. Ma<sup>1</sup>, C. Zhang<sup>1</sup>, O. Flint<sup>1</sup>, L. D. Lehman-McKeeman<sup>1</sup> and K. Augustine<sup>1</sup>. <sup>1</sup>Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ; <sup>2</sup>Charles River, Horsham, PA.

Efforts to reduce animal use for embryotoxicity testing of chemicals lead to the development of the embryonic stem cell test (EST), a 10-day low-throughput assay. The objective of this study was to shorten the assay's duration and increase throughput by incorporating molecular endpoints to detect aberrant changes in embryonic stem cell differentiation. Monolayers of mouse D3 embryonic stem (ES) cells were used to identify IC50 values in a 3-day cytotoxicity assessment. ES D3 cells were grown for 4 days as embryoid bodies for transcriptional profiling of 12 developmentally regulated genes (nanog, fgf5, gsc, cd34, axin2, apln, chst7, lhx1, fgf8, sox17, foxa2, and cxcr4). Embryoid bodies were exposed to a single compound concentration selected from the cytotoxicity assessment (0.1x IC20). A decision-tree model to classify compounds for teratogenicity potential was built with IC50 and relative expression values of the target genes after exposure to 65 compounds

(33 teratogens, 32 non-teratogens) of known in vivo teratogenicity. Compounds with IC50 values <22 µM were classified as teratogens without the use of transcriptional profiling. Compounds with IC50 values between 22 and 200 µM were categorized as teratogenic if ≥8 genes were deregulated by 10%. Compounds with IC50 values greater than 200 µM were categorized as positive for teratogenic potential if all 12 genes were deregulated by 10%. For teratogenic predictions of unknowns, the concordance for teratogens is 76% (22 out of 29), and for non-teratogens is 69% (25 out of 36) with a total concordance of 72% (47 out of 65) with a false positive error rate of 24%. The model was further tested with 12 additional compounds (5 positive, 7 negative) in which 10 were identified correctly (83% concordance) with a 0% false positive error rate. Increased throughput in combination with its low false positive error rate makes this assay ideal for first tier hazard identification screening of pharmaceutical compounds.

**PS 1026 A Tiered Screening Platform for Optimizing Predictivity, Throughput and Cost Effectiveness of In Vitro Developmental Toxicity Assays.**

K. Augustine, C. X. Zhang and P. Julie. *Discovery Toxicology, Bristol-Myers Squibb, Pennington, NJ.* Sponsor: L. Lehman-McKeeman.

In recent years, various laboratories have focused on generation and/or refinement of in vitro developmental toxicology assays for classification of teratogenic liability of small molecules. The impetus for this effort is multifaceted including increasing animal rights pressure, REACH legislation of chemicals and need for proactive safety optimization of pharmaceutical compounds. In response to these needs, our laboratory has developed three in vitro developmental toxicology assays: a molecular embryonic stem cell assay (MESCA), a dechorinated zebrafish embryo culture (ZEC) assay and a streamlined rat whole embryo culture (rWEC) assay. Individually, all three assays have demonstrated good utility for screening compounds for teratogenic liability, achieving ~80% overall concordance and relatively balanced error rates. This study describes the results of evaluating a test set of ~60 compounds across the 3 assays and generation of a tiered testing strategy. The cross-assay assessment identified the assays' attributes and deficiencies. For instance, the MESCA and ZEC assays were found to have 2 limitations: compound solubility and high misclassification rates of compounds with H1 receptor or GABAergic activity. In contrast, solubility limitations were rarely encountered in the streamlined rWEC assay and it also presented <20% misclassification error rates of compounds with H1 and GABAergic activity. As such, rWEC assay was found to be a cost effective stand alone assay for supporting poorly soluble compounds and/or ones with H1 or GABAergic activity. For all other compounds, using MESCA as a first tier and the dechorinated ZEC assay as a 2nd tier assay minimizes animal use and optimizes error rates, throughput and cost. To this end, compounds receive a final classification if found positive in the MESCA assay, and those that are negative are followed up in the ZEC assay resulting in overall error rates below 15%.

**PS 1027 The Devtox Project: A Comprehensive Source of Information on Developmental Abnormalities.**

J. Buschmann<sup>1</sup>, I. Chahoud<sup>2</sup>, R. Kellner<sup>1</sup> and R. Solecki<sup>2</sup>. <sup>1</sup>Fraunhofer ITEM, Hannover, Germany; <sup>2</sup>Federal Institute for Risk Assessment, Berlin, Germany; <sup>3</sup>Institute of Clinical Pharmacology and Toxicology, Berlin, Germany. Sponsor: C. Dasenbrock.

The potential of a compound to cause adverse effects in the developing embryo or fetus is an important consideration in human health risk assessment. The terms and diagnostic criteria used to describe fetal anomalies in animal experiments need to be consistent from one laboratory to another and must be harmonized between regulatory agencies.

Consequently, the DevTox Project ([www.devtox.org](http://www.devtox.org)) has the main objectives to harmonize the nomenclature used to describe developmental anomalies in laboratory animals and to assist in the visual recognition of developmental anomalies with the aid of photographs.

The use of a harmonized and internationally accepted nomenclature is a basic requirement for the operation of DevTox. A first approach of establishing such a harmonized terminology was made in 1997 by a publication of the International Federation of Teratology Societies IFTS (Teratology 55, 249-292, 1997). This terminology has recently been updated (Reproductive Toxicology 28, 371-434, 2009). In addition, in a series of Berlin Workshops working definitions for the two classification categories "malformation" and "variation" were agreed.

The results of all these activities were used to establish the DevTox data base. The easy-to-use Web interface allows different views of the nomenclature, images and data and a quick navigation throughout the complete site. DevTox currently contains more than 2,500 images, showing examples of external, skeletal, soft tissue and maternal-fetal anomalies in rats, mice, rabbits, hamsters, primates, Guinea

pigs, minipigs, dogs and birds. It provides short descriptions of each finding and in some cases synonyms and further diagnostic notes as well as a hierarchical structure for the localizations. The system is publicly accessible and allows the electronic download of the current version of the harmonized terminology.

**PS 1028 Reference Images for the Skeletal Examination of Cynomolgus Monkey Fetuses and Thalidomide-Induced Malformations.**

O. Foulon, F. Spezia, C. Dauzat, M. Da Silva, P. Barrow, B. Palate and R. Forster. *CiToxLAB, Evreux, France.*

In this poster selected images are presented to illustrate the normal and (drug-induced) abnormal skeletal morphology of the cynomolgus monkey at 100 days post-coitum. Very little is available in the literature in terms of reference images for the skeletal examination of cynomolgus monkey (*Macaca fascicularis*) fetuses in teratology studies. This poster will present photographs of the fetal skeleton on day 100 post-coitum. Normal (control) fetuses will be presented and compared with fetuses showing thalidomide-induced malformations. A total of 20 control and 3 thalidomide-treated fetal specimens were photographed. Dams were 3 to 8 years old at mating and weighed 2.0 to 4.5 kg. Mating was confirmed by the presence of sperm in a vaginal smear during cohabitation with a male. Pregnancy was confirmed 18 or 19 days later by ultrasound examination. The treated dams were given 20 mg/kg/day of thalidomide by oral gavage from days 25 to 30 of gestation. The control dams received a similar volume of water (10 mL/kg). The fetuses were removed by caesarean section on day 100 of gestation. Fetal and placental weights were recorded. Morphometric measurements (head circumference and crown rump-length) were taken. Each fetus was then given a detailed necropsy examination prior to processing for skeletal examination by the Dawson method: the ossified skeletal structures were visualised following clearing of the soft tissues in potassium hydroxide and staining with Alizarin Red S. The normal variation in the degree of skeletal maturity and the corresponding patterns of ossification can be assessed using the control images.

**PS 1029 Regulatory Embryofetal Development Studies in Minipigs: Optimisation of Techniques.**

A. Makin, T. K. Andreassen and J. Løgstød. *CiToxLAB, Lille Skensved, Denmark.*

Rats and rabbits are traditionally the species of choice for developmental toxicity (embryofetal development) studies. If for any reason these species are found unsuitable (e.g. due to issues of metabolism) a non-rodent alternative choice of species is the minipig. In our facility we have several years of experience with EFD studies in the Gottingen minipig. When working with non-standard species for studies of this nature, a reliable study design producing robust data is imperative. Control data are presented from 9 preliminary studies and 4 main studies performed over the last 5 years and intended for regulatory submission. On the basis of this experience, study designs have been reviewed and refined to ensure reliable and consistent results. Consideration was given to factors such as efficient synchronisation of estrus with the use of Regumate® (altrenogest) to maximise mating success. Using this approach a success rate of close to 100% is attained. In this way the required number of pregnant sows for the study can be accurately provided, allowing precise scheduling of the number of sows mated per day according to the facility capacity to perform the caesarean sections on the required day of gestation. The data presented show that our methods give a mating success and an average litter size that are superior to the published literature, thus ensuring that there are sufficient fetuses for interpretation of findings. Estrus synchronisation is also useful for the provision of neonatal piglets for juvenile toxicology studies. The present poster presents background data for all of the fundamental litter-based parameters and demonstrates the robustness of the methods. Data for Pregnancy rate, Uterus Weight, Litter Size, Resorptions, Implantations, Corpora Lutea and Pre and Post-implantation Loss are also presented.

**PS 1030 Exploring the Role of the Mediator Gene 'Med31' in Proliferation and Limb Development during Mouse Embryogenesis.**

K. Wolton<sup>2</sup>, J. Wright<sup>1</sup>, R. Doran<sup>1</sup> and K. Henges<sup>2</sup>. <sup>1</sup>*Faculty of Life Sciences, Manchester University, Manchester, United Kingdom;* <sup>2</sup>*Product Safety, Syngenta, Bracknell, United Kingdom.* Sponsor: *P. Botham.*

Birth defects are recognised as a common global human health concern and they may arise as a result of a multitude of factors. In terms of ameliorating such anomalies, it is important to gain a better understanding of the fundamental mechanisms

controlling embryonic development. A role for the Mediator complex gene Med31 in the developing embryo has been recognised using a random mutagenesis screen in mice. Developing embryos which lack the Med31 protein are substantially smaller than their wild type littermates, and show a delay in development. This is particularly noticeable in the developing limbs, which fail to grow to the same length as wild type, and demonstrate delays in normal ossification patterns. Analysis of embryonic fibroblast cultures has revealed a significant defect in cell proliferation in Med31 mutants, which is recapitulated in the Med31 mutant limb bud, at embryonic day (E)10.5.

Med31 forms part of the mediator complex, which acts as a bridge between transcription factors and the RNA Polymerase II to initiate transcription. Mutant embryos lacking Med31 have a reduction in the expression of the cell cycle genes mTOR and Cyclin B. In situ hybridisation has demonstrated that the mutants do not express Sox9, a master regulator of chondrogenesis, and this is particularly evident in the limb bud at E10.5, while genes such as Fgf8, a marker of limb patterning, retain a normal expression pattern.

These findings are being further investigated by exploring the genes which are under the transcriptional regulation of Med31 in limb development. These experiments will provide new insights into the mechanisms by which Mediator complex proteins regulate developmental processes.

1) Risley, M.D. Clowes, C. Yu, M. Mitchell, K. Hentges, K.E. (2010) *Developmental Biology*. 342. 146-156.

**PS 1031 Investigation of Methods for Anesthetization and Euthanization of Rat and Rabbit Fetuses in Developmental Toxicity Studies.**

H. Kato, R. Katagiri, A. Arima, Y. Ooshima and R. Nagata. *Shin Nippon Biomedical Laboratories, Ltd., Drug Safety Research Laboratories, Kagoshima, Japan.*

Japan Association for Laboratory Animal Medicine recommends humane handling of laboratory animal fetuses. However, it is a challenge to accept proposed euthanizing methods such as cervical dislocation, decapitation and/or intracardiac injection of potassium chloride, because these methods would damage fetal specimens for skeletal and visceral examinations in developmental toxicity studies. The present study aimed at finding better methodologies for rat and rabbit fetal euthanasia and anesthesia. We focused on, and evaluated, two parameters: fetal heart rate and response to touch stimulus. We were unable to accomplish fetal euthanasia directly in either species; however, we were able to euthanize fetuses under pain-controlled anesthesia.

Rat fetuses immersed in physiological saline at 10°C showed complete loss of reaction to touch stimulus within 10 minutes, and a mean heart rate of less than 20 bpm, suggesting that deep anesthesia had been achieved very rapidly. Therefore, it is recommended that hypothermia by immersion in cold physiological saline is an appropriate method for anesthetization of rat fetuses.

Rabbit fetuses intraperitoneally injected with pentobarbital sodium at 3.24 mg/body and retained in filter paper impregnated with physiological saline at 18°C showed complete loss of reaction to touch stimulus within 30 minutes. Therefore, it is recommended that intraperitoneal injection of pentobarbital sodium and hypothermia induced by cold physiological saline form an appropriate method for anesthetization of rabbit fetuses.

We further recommend that the fetuses should be euthanized promptly upon reaching anesthesia by exsanguination, removal of vital organs, or immersion in appropriate fixatives.

**PS 1032 Acute Intravenous Exposure to Silver Nanoparticles during Pregnancy Induces Particle Size and Vehicle-Dependent Changes in Vascular Reactivity.**

A. K. Vidanapathirana<sup>1</sup>, L. C. Thompson<sup>1</sup>, M. Herco<sup>1</sup>, J. O. Dawkins<sup>1</sup>, S. C. Sumner<sup>3</sup>, T. Fennell<sup>3</sup>, J. M. Brown<sup>2</sup> and C. J. Wingard<sup>1</sup>. <sup>1</sup>*Physiology, East Carolina University, Greenville, NC;* <sup>2</sup>*Pharmacology & Toxicology, East Carolina University, Greenville, NC;* <sup>3</sup>*RTI International, Research Triangle Park, NC.*

With increasing use of engineered silver nanoparticles (NP) in different settings there are concerns regarding their safety particularly in vulnerable life stages such as pregnancy. Effects of silver NP on maternal vascular reactivity have not been extensively investigated despite potential occupational, therapeutic and environmental exposure. Our hypothesis was: the acute intravenous (IV) exposure to silver NP during late stages of pregnancy increases the vasoconstrictor response in the uterine artery. Pregnant (17-19 days) Sprague Dawley rats were exposed to a single dose of 20 or 110 nm silver NP (200 µg) suspended in polyvinylpyrrolidone (PVP) or citrate solutions. 24 h post-exposure vasomotor responses of segments of the main uterine artery and thoracic aorta were assessed using wire myography. Cumulative dose-response curves were constructed for acetylcholine, angiotensin II, endothelin

1 and Rho kinase inhibitor (HA1077). The response to phenylephrine was studied in the presence and absence of COX inhibitor, indomethacin. Dose-response curves, maximum stress and EC50 values were different for silver NP exposed animals when compared with vehicle controls. Reciprocal changes were seen between the aortic and uterine vessels: greater vasoconstriction in uterine artery and greater vasodilation in aorta following 110 nm silver exposure. Exposure to 20 nm silver NP increased the HA1077 mediated vasodilation in aortic segments suggesting a possible mechanism underlying the changes of agonist mediated vasoconstrictor response following NP exposure. NP suspensions in citrate lead to higher stress generation in both vessels. IV exposure to silver NP during pregnancy induces particle size and vehicle dependent changes in vascular reactivity which can potentially influence blood supply to the fetus. This work is supported by NIEHS U19 ES019525.

### PS 1033 Gamma Secretase Inhibition: Effects on Fertility and Embryo-Fetal Development in Rats.

L. Sivaraman<sup>1</sup>, K. Thompson<sup>1</sup>, G. Pilcher<sup>2</sup>, T. Sanderson<sup>2</sup> and M. E. McNeerney<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb Co., New Brunswick, NJ; <sup>2</sup>Bristol-Myers Squibb Co., Mt. Vernon, IN.

BMS-708163 (avagacestat) inhibits  $\gamma$ -secretase (GS), a protease that cleaves amyloid precursor protein to produce amyloid  $\beta$  (A $\beta$ ) and amyloid plaques that are prominent lesions in Alzheimer's disease (AD). As part of the nonclinical reproductive safety evaluation, studies of embryo-fetal development as well as fertility and early embryonic development were conducted in female Sprague-Dawley rats. In the embryo-fetal development study, BMS-708163 was administered (oral gavage) to pregnant rats at 3, 10 and 30 mg/kg/day from Gestation Day (GD) 6 through GD 15. Cesarean sections were conducted on GD 21. Assessments of maternal well-being included clinical observations, body weight, and food consumption; evaluation of fetal viability, morphology and body weights comprised the assessment of developmental toxicity. BMS-708163 was a selective developmental toxicant at all doses tested, with dose-related increases in the incidence and severity of fetal malformations and variations in the absence of maternal toxicity. Malformations and variations included axial and appendicular skeletal anomalies. In the study of fertility and early embryonic development in female rats, BMS-708163 was administered for 14 days prior to cohabitation; then throughout cohabitation and early gestation, until presumed GD 7 at 1, 5, and 15 mg/kg/day. Mid-gestation cesarean sections were conducted (GD 13-15). Reproductive end points included estrus cycle length, mating and fertility rates, implantation and conceptus viability. Dose-dependent reductions in female fecundity at doses  $\geq$  5 mg/kg/day were attributed to impaired ovarian follicular development; this was reflected in dose-dependent reductions in implantation sites, litter size, and gravid uterine weights. These results occurred at exposures above those which lower brain A $\beta$  in rats; are consistent with inhibition of GS-mediated Notch processing, a key signaling pathway in cell-fate determination and embryonic development; and are considered no risk to the intended AD (> 65 yr) patient population.

### PS 1034 Flubendazole Embryotoxicity in Rat Embryos and Fetuses.

P. A. Colombo<sup>1</sup>, M. Longo<sup>1</sup>, S. Zanoncelli<sup>1</sup>, M. Messina<sup>1</sup>, R. Schnurbus<sup>1</sup>, I. Scandale<sup>2</sup> and G. Mazué<sup>3</sup>. <sup>1</sup>Accelera, Nerviano MI, Italy; <sup>2</sup>DNDi, Geneva, Switzerland; <sup>3</sup>Consultant, Mantry, France.

Filarial diseases affect millions in poverty-stricken areas. DNDi investigated Flubendazole Amorphous Solid Dispersion (ASD) as a possible drug candidate. Within its preclinical characteristics in particular potential embryotoxicity was evaluated. With this aim flubendazole ASD was administered orally to Sprague Dawley rats at 0, 2, 3.46, 6.32 and 13 mg/kg/day as flubendazole, during the recognized susceptible organogenetic period on GD (gestation day) 9.5 and 10.5 as identified in a previous whole embryo culture study. Fetuses were evaluated on GD 20. Flubendazole was embryolethal from 6.32 mg/kg/day (Cmax after single administration 0.801 ug/mL). In addition Flubendazole was teratogenic at 3.46 mg/kg/day (Cmax after single administration 0.539 ug/mL). No increase in resorptions was seen however 80% of fetuses showed malformations namely exencephaly, micro-/anophthalmia, small/absent kidneys, markedly enlarged renal pelvis/ureters, absent tail, anal atresia and disruption of skeletal ossification of head, spine and thoracic cage. Flubendazole did not interfere with rat embryonic development, apart from a minimal reduction in fetal and placental weights, at 2 mg/kg/day (Cmax after single administration 0.389 ug/mL) with treatment restricted to two days during pregnancy and with a limited number of animals. In order to evaluate the embryotoxic nature of Flubendazole, embryos of dams treated as above, were evaluated on GD 11.5 and 12.5, as a window for observing the origin of alterations detected at term.

Flubendazole confirmed to be embryolethal and teratogenic through its cytostatic properties.

At 6.32 mg/kg/day it initially induced a block of embryonic development through its cytostatic action, followed by cytotoxicity which led to 100% embryolethality within 48h while at 3.46 mg/kg/day, it markedly reduced embryonic development through its cytostatic action but did not show cytotoxic effects. Therefore, embryos still alive markedly retarded with consequent morphological alterations in specific areas namely brain vesicles, eye, maxillary structures and body axis.

### PS 1035 Double-Staining Technique for Minipig Fetal Skeletons at Gestation Day 60.

S. Baudet, J. Briffaux, C. Pique, P. Quesada and A. Jocteur-Monrozier. *Ricerca Biosciences SAS, St. Germain sur l'Arbresle, France.*

In a previous study, we have demonstrated that fetal abnormalities associated with a known human and swine teratogen (Pyrimethamine) could be detected in the minipig with fetal examinations performed close to mid-term instead of at term. The principal objective of the present study was to validate a double staining method for bone and cartilage of minipig fetuses obtained by caesarean section close to gestation day (GD) 60 in order to support skeletal examinations.

Two virgin Göttingen Minipig females were mated at the testing facility and subsequently submitted to caesarean section close to GD 60. Ten fetuses (5 in each litter) were available for the trials and the sexes were evenly split.

The fetuses were used in a number of staining trials based on our own established methods for other species, including the rat and rabbit. In the first step, the fetuses were stained, without prior fixing, following evisceration and skinning. Varying concentrations of ethanol, mixed together with Alizarin red S, Alcian blue and acetic acid, were tested to obtain the desired results. In order to establish the best conditions to fix the staining, the fetuses were then transferred to baths containing different concentrations of ethanol for varying durations. Following fixation, the specimens were transferred into potassium hydroxide solutions for maceration of the soft tissue. Finally, the soft tissues were cleared, firstly using Malls solution followed by glycerol at increasing concentrations. The fetuses from the successful trial were then ready for skeletal examination.

The technique is slightly more labour intensive than the single staining technique using Alizarin red S only. However, the time required to process the specimens for examination is approximately the same for both methods. Moreover, this new technique enhances the examination process for mid-term minipig fetal skeletons, at a time when ossification of the skeleton is obviously less advanced than at term. Our next step is to generate an atlas of the mid-term minipig fetal skeleton.

### PS 1036 Retrospective Review of Skin Irritation and Corrosion Hazards on the Basis of Existing Human Data.

D. Basketter<sup>1</sup>, D. Jirova<sup>2</sup> and H. Kandarova<sup>3</sup>. <sup>1</sup>DABMEB Consultancy Ltd., Sharnbrook, United Kingdom; <sup>2</sup>National Institute of Public Health, Prague, Czech Republic; <sup>3</sup>MarTek IVLSL, Bratislava, Slovakia.

Regulatory classification of skin irritation has historically been based on rabbit data, however current toxicology processes are transitioning to in vitro alternatives. The in vitro assays have to provide sufficient level of sensitivity as well as specificity to be accepted as replacement methods for the existing in vivo assays. This is usually achieved by comparing the in vitro results to classifications obtained in animals. Significant drawback of this approach is that neither in vivo nor in vitro methods are calibrated against human hazard data and results obtained in these assays may not correspond to situation in human.

The main objective of this review was to establish an extended database of substances classified according to their human hazard to serve for further development of alternative methods relevant to human health as well as resource for improved regulatory classification.

The literature has been reviewed to assemble all the available information on the testing of substances in the human 4 h human patch test, which is the only standardized protocol in humans matching the exposure conditions of the regulatory accepted in vivo rabbit skin irritation test.

A total of 81 substances tested according to the defined 4 h human patch test protocol were found and collated into a dataset together with their existing in vivo classifications published in the literature. While about 50% of the substances in the database are classified as irritating based on the rabbit skin test, on using the 4 h HPT test, less than 20% were identified as acutely irritant to human skin.

Based on the presented data, it can be concluded that the rabbit skin irritation test largely over-predicts human responses for the evaluated chemicals. Correct classification of the acute skin irritation hazard will only be possible if newly developed in vitro toxicology methods will be calibrated to produce results relevant to man.

**PS 1037 Influence of Acidic Extraction Conditions on Formazan Assay: Assessment of Test Substances Using *In Vitro* EpiSkin Skin Irritation Test Method by HPLC and Colorimetry.**

M. H. Grandidier, N. Alépée, B. Micheau, S. Grégoire and J. Cotovio. *L'Oréal Research & Innovation, Aulnay sous Bois, France.* Sponsor: E. Dufour.

The skin irritation potential of a test substance is typically determined by measuring cell viability in treated tissues by means of the colorimetric MTT reduction assay after topical application of a test substance. In the EpiSkin validated skin irritation test method, tetrazolium salt-based formazan assay is performed by using acidified isopropanol extraction conditions (ESAC 2007, OECD TG439 2010). The current work evaluated the data obtained with the EpiSkin model for the 20 reference chemicals (listed in the OECD TG439) following formazan extraction with acidified (IPA) or non acidified (IP) isopropanol solutions to evaluate the influence of acidic extraction conditions. Therefore the objectives of this work was to establish the use of HPLC measurements as a complementary assay to standard photometry assay for detection of reduced MTT, a known limitation for test substances that are highly coloured.

The cell viability in EpiSkin quantitatively measured after acidified (IPA) or non acidified (IP) isopropanol extractions from tissues were equivalent ranging from 6.4 to 104% by colorimetry (reference method). Following HPLC measurement, formazan quantitative analyses were comprised between 7.9 to 99.2%. The standard deviation between those 2 conditions was +/- 18%. Therefore, within-laboratory variability assessed in 3 runs showed similar concordance of classification for each condition. The sensitivity (based on 10 GHS Cat.2 substances) was 90% and the specificity (based on 10 No-category substances) was 70%. The HPLC provides data comparable to those using standard photometry assays for 20 test substances indicative of the use of HPLC as a complementary assay to photometry in EpiSkin skin irritation test method. Therefore, those results suggest that acidified isopropanol extraction conditions did not affect the EpiSkin skin irritation outcomes.

**PS 1038 Cytotoxic Effects of Dicyclohexylamine and Three Metalworking Fluids on Human Epidermal Keratinocytes.**

A. D. Linthicum<sup>1</sup>, A. O. Inman<sup>2</sup>, N. A. Monteiro-Riviere<sup>2</sup> and R. E. Baynes<sup>1</sup>.

<sup>1</sup>Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC; <sup>2</sup>Nanotechnology Innovation Center of Kansas State, Kansas State University, Manhattan, KS.

Many of the 1.2 million workers in the metal machining industry within the United States will be exposed to metalworking fluids via the dermal route, making it a major occupational health and safety concern. Dicyclohexylamine (DCHA), an anticorrosive agent used in the metalworking industry to prevent corrosion of fabricated materials, is known to permeate the skin and could potentially elicit a toxic response on human epidermal keratinocytes (HEK). HEK were exposed only to DCHA or one of the following three generic metalworking fluids: soluble oil, synthetic oil and semi-synthetic oil for 24h. Cells were dosed with solutions ranging from concentrations of 200-5000µg/ml. The highest concentration of 5000µg/ml is the relevant occupational exposure dose in the metal machining industry. Cells exposed to 200-5000µg/ml of DCHA resulted in a 24-91% decrease in cell viability in comparison to the media control. The soluble oil and semi-synthetic oil dosed from 200-5000µg/ml resulted in an 80-83% and 81-85% decrease in cell viability, respectively, in comparison to the media control. For synthetic oil, there was a 52-85% decrease in cell viability in comparison to the media control. DCHA and all metalworking fluid treatments caused a significant (p<0.05) decrease in HEK viability. In conclusion, metalworking fluids and DCHA had a cytotoxic effect to HEK. This data suggests that the concentration of DCHA in metalworking fluid formulations should be reduced while safer metalworking fluid formulations are developed. (Supported by NIOSH R01-01-03669)

**PS 1039 Aryl Hydrocarbon Receptor Repressor (AhRR) Function Revisited: Repression of Cyp1 Activity in Human Skin Fibroblasts Is Not Related to AhR Expression.**

J. Tigges<sup>1</sup>, H. Weithardt<sup>1</sup>, G. Christine<sup>1</sup>, I. Foerster<sup>1</sup>, H. F. Merk<sup>2</sup>, T. Haarmann-Stemmann<sup>1</sup>, J. Krutmann<sup>1</sup> and E. Fritsche<sup>1</sup>. <sup>1</sup>Leibniz Institute for Environmental Medicine, Duesseldorf, Germany; <sup>2</sup>Dermatology and Allergology, University Clinic RWTH, Aachen, Germany.

The skin reacts to environmental noxae by inducing cytochrome P450 (CYP)-catalyzed reactions via activation of the aryl hydrocarbon receptor (AhR). A drawback of this response is the generation of oxidative stress, which is especially dangerous for postreplicative cells such as dermal fibroblasts, in which damage may accumulate over time. Accordingly, in dermal fibroblasts, CYP1 expression is repressed and

it has been proposed that this is due to the AhRR, which is supposedly overexpressed in fibroblasts as compared with other skin cells. Here, we revisited this "AhRR hypothesis", which has been mainly based on ectopic overexpression studies and correlation analyses of high AhRR gene expression with CYP1A1 repression in certain cell types. In primary human skin fibroblasts (NHDFs) of 25 individuals, we found that (i) the AhRR was expressed only at moderate RNA copy numbers and that, against the common view, (ii) in some fibroblast strains, CYP1A1 mRNA expression could be induced by AhR activators. However, even the highest induction did not translate into measurable CYP1 enzyme activity, and neither basal expression nor mRNA inducibility correlated with AhRR expression. In addition, enhancement of CYP1A1 mRNA expression by trichostatin A, which inhibits AhRR recruited histone deacetylases at the CYP1A1 promoter, failed to induce measurable CYP1 activity. Finally, AhRR deficient mouse embryonic fibroblasts were not induced to biologically relevant CYP1 enzyme activity despite impressive mRNA induction. These data clearly indicate that repressed CYP1 activity in NHDFs is not causally related to AhRR expression, which may serve a different, yet unknown, biological function.

**PS 1040 Citotoxic Effect of the Temporary Hair Dye Basic Red 51 on Human Keratinocytes(HaCaT): Development and Application on a Reconstructed (3D) Artificial Skin.**

T. B. Zannoni<sup>1</sup>, M. T. dos Santos<sup>2</sup>, S. Barro<sup>2</sup>, S. Maria-Engler<sup>2</sup> and D. de Oliveira<sup>1</sup>. <sup>1</sup>Environmental Toxicology, University of São Paulo, Ribeirão Preto, Brazil; <sup>2</sup>Laboratory of Pathology and Clinical Cytology, University of São Paulo, São Paulo, Brazil.

Nowadays, hair dyes are being commonly used for cosmetics purposes. However in 2001, the Scientific Committee on Cosmetic products and Non-Food Products intended for consumers (SCCNFP) of the European Union recommended that hair dye ingredients should be re-analyzed. Since 2006, 22 hair dyes have been banned for not being considered safe. On the present work, we evaluated the cytotoxicity of a temporary hair dye "Basic Red 51" (CAS: 77061-58-6), an azo dye (-N=N-) that is currently being revised by the EU. We tested the toxicity of the "Basic Red 51" in immortalized keratinocytes (HaCaT) that are the primary route of exposure. Moreover, we reconstructed a human (3D) epidermis using HaCaT cells and dermal fibroblasts in order to create a new approach that would better represent the real exposure. For HaCaT cells in monolayer, the Basic Red 51 IC50 was 12.9 µg/mL, determined by Tripan Blue assay. Besides, this concentration of the dye induced cell cycle arrest at G2 phase. Using the clonogenic assay, we observed that 2.5 µg/mL of the dye was sufficient to inhibit completely cell growth after 48 hours of exposure. In the artificial skin model, we demonstrated that the exposure to Basic Red 51 at IC50 reduces the skin thickness, decreasing the number of cell layers. We also observed that the cells appear to be injured and undergoing apoptosis. It is important to point out that the IC50 used for these experiments (12.9 µg/mL) is much lower than the commercial concentration (2000µg/mL). We suggest that similar effects could be induced in humans after the exposure to Basic Red 51, mainly considering the effects in artificial skin. So, we concluded that the use of Basic Red 51 for cosmetic proposes should be carefully evaluated.

**PS 1041 Skin and Eye Lesions in the Long Evans Rat Produced by Oral 8-Methoxy-Psoralen (8-MOP) Application and Subsequent UV-A Irradiation.**

M. Sieber<sup>1</sup>, C. Simon<sup>1</sup>, K. Broich<sup>1</sup>, C. Maraschiello<sup>1</sup> and K. Weber<sup>2</sup>. <sup>1</sup>Harlan Laboratories Ltd., Itingen, Switzerland; <sup>2</sup>AnaPath GmbH, Oberbuchsiten, Switzerland. Sponsor: T. Ansai.

For assessment of the dermal and ocular response to the model phototoxicant 8-MOP, 6 female HsdBLu:LE (SPF) Long Evans rats received a single dose of 5.0 mg/kg body weight 8-MOP by oral gavage. 6 control rats were treated with the vehicle only. One pigmented and one unpigmented skin site were clipped free of hair and irradiated with 15 J/cm<sup>2</sup> UV-A (Bio-Spectra irradiation chamber, Vilber Lourmat Deutschland GmbH). Irradiation was performed 30 min after 8-MOP application under pentobarbitone anaesthesia. Visual assessment of the skin 4 h after irradiation showed erythema on the irradiated pigmented and non-pigmented skin of 8-MOP-treated rats and in control rats which increased in severity in 8-MOP-treated rats after 20 h and receded in control rats. Injection of Evans Blue showed moderate vascular leakage 24 h and 48 h after irradiation in all 8-MOP-treated rats, while only few of the control rats were affected at a lower severity. Histopathologically, corneal single cell necrosis was recorded in the irradiated eye of 2 of the 8-MOP-treated rats, but not in control rats. Dermal lesions in pigmented and unpigmented skin of 8-MOP-treated rats consisted of focal/multifocal epidermal hyperplasia, focal erosions/scab formation, ulceration, subcutaneous and/or dermal infiltration, follicular inflammation, focal/multifocal epidermal necrosis

and subcutaneous and/or dermal inflammation, showing a slightly higher incidence and severity in non-pigmented than in pigmented skin. An identical experiment with a higher irradiation dose of 35 J/cm<sup>2</sup> UV-A led to erythema and correlating histopathological findings in the skin of both 8-MOP-treated and control rats; however, corneal affections consisting of focal or single cell corneal necrosis, corneal epithelial vacuolation and/or focal corneal keratosis were recorded in 8-MOP-treated rats only. The results of the experiment confirmed that the test system is appropriate for the assessment of systemic phototoxicity.

### PS 1042 13-Week Dermal Toxicity of Triclosan in B6C3F1 Mice.

M. M. Vanlandingham<sup>1</sup>, J. Fang<sup>1</sup>, F. A. Beland<sup>1</sup>, B. E. Juliar<sup>1</sup>, G. R. Olson<sup>1</sup>, W. A. Harrouk<sup>2</sup> and R. E. Patton<sup>1</sup>. <sup>1</sup>National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>Center for Drug Evaluation and Research, US FDA, Silver Spring, MD.

Triclosan [5-chloro-2-(2, 4-dichlorophenoxy)phenol] is widely used as an antimicrobial agent, and humans in all age groups have the potential to receive lifelong exposures. We recently demonstrated that the dermal application of triclosan to mice results in systemic distribution of the compound. The goal of the present study was to evaluate the toxicities of triclosan administered dermally to B6C3F1 mice for 13 weeks and provide a scientific basis for dose selection for a subsequent chronic dermal carcinogenicity study. Groups of 10 male and 10 female mice received dermal application of 0, 5.8, 12.5, 27, 58, or 125 mg triclosan in ethanol per kg bw daily seven days per week for a period of 13 weeks. All mice survived the 13-week treatment. Body weights of female mice were not affected, while male mice administered 58 and 125 mg/kg weighed 91% and 83% of the control male mice. The mean weight of livers from females receiving 58 and 125 mg/kg was 11% and 40% greater than the controls; in males, the highest dose led to a higher mean liver weight (38% greater than the controls). Skin lesions (epidermal hyperplasia, inflammation, necrosis, ulceration, and parakeratosis; dermal fibrosis and inflammation) were observed in both sexes. The severity of the lesions was minimal at the 12.5 mg/kg dose, and both the severity and incidence of the lesions increased as the dose was increased. The highest dose of triclosan increased the percentage of reticulocytes in both sexes and the percentage of micronucleated normochromatic erythrocytes in females; in addition, the 58 mg/kg dose increased the percentage of reticulocytes in females. A significant dose-dependent decrease in the levels of T4 and cholesterol was observed in both sexes. There were no differences between treated and control mice in sperm or vaginal cytology measurements. The NOAEL, under the conditions of this subchronic assay, was 5.8 mg/kg. (Supported by Interagency Agreement between NCTR/FDA IAG #224-12-0003 and NIH AES12013.)

### PS 1043 Dermal Toxicokinetic Studies of Triclosan in B6C3F1 Mice.

J. Fang<sup>1</sup>, M. M. Vanlandingham<sup>1</sup>, F. A. Beland<sup>1</sup> and W. A. Harrouk<sup>2</sup>. <sup>1</sup>Division of Biochemical Toxicology, National Center for Toxicological Research, FDA, Jefferson, AR; <sup>2</sup>Center for Drug Evaluation and Research, FDA, Silver Spring, MD.

Triclosan [5-chloro-2-(2, 4-dichlorophenoxy)phenol] is widely used as an antimicrobial agent in personal care products, household items, and clinical settings. Due to its extensive use, there is potential for humans in all age groups to receive lifelong exposures to triclosan; however, data on the chronic dermal toxicity/carcinogenicity of triclosan are still lacking. The goal of the present study was to determine the absorption, distribution, metabolism, and excretion of triclosan following dermal administration to B6C3F1 mice. A single dose of [<sup>14</sup>C(U)]triclosan (10 or 100 mg per kg bw, 10 µCi per mouse) was administered to mice in two separate experiments: a vehicle selection experiment to compare the bioavailability of triclosan in male mice using propylene glycol, ethanol, and a generic lotion as vehicles; and a toxicokinetic experiment to evaluate sex differences in the absorption and deposition of triclosan and its metabolites. Three mice per sex in each group were killed at 0.5, 1, 2, 4, 6, 8, 12, 24, 48, and 72 h after administration, and excreta and tissues were collected and analyzed for radioactivity. Ethanol has the best properties of the vehicles evaluated. Maximum absorption of triclosan (80 ~ 86%) was obtained at 12 h after dermal application. There was some saturation of absorption at the 100 mg/kg. Radioactivity appeared in the excreta and in all tissues examined, with the highest level in gall bladder and the lowest level in brain. Triclosan was readily metabolized to triclosan sulfate and glucuronide conjugates, 2,4-dichlorophenol, and hydroxytriclosan. The metabolite profile was tissue-dependent and the predominant route of excretion was the feces (65 ~ 78%). There were no differences in bioavailability between males and females. Slightly lower absorption was observed with Elizabethan collar, suggesting some oral ingestion due to the normal behavior grooming. (Supported by Interagency Agreement between NCTR/FDA IAG #224-12-0003 and NIH AES12013.)

### PS 1044 Confocal Raman Microscopy—The Future for Dermal Absorption Studies.

T. Patel<sup>1</sup>, A. Ghaemmaghami<sup>1</sup>, P. Williams<sup>1</sup>, J. Wright<sup>2</sup>, C. Roberts<sup>1</sup> and F. Rose<sup>1</sup>. <sup>1</sup>School of Pharmacy, University of Nottingham, Nottingham, United Kingdom; <sup>2</sup>Syngenta Ltd., Bracknell, United Kingdom. Sponsor: P. Botham.

The activity and absorption of pesticides into the skin of the user is increasingly becoming a major problem within the Agrochemical industry. Fewer formulations are passing the regulatory process of pesticide approval as a result of unknown compound dermal accumulation and toxicity. Currently, 2 gold-standard methods are used to monitor dermal absorption and determine compound flux (µg/cm<sup>2</sup>/h) across the skin but limitations in measuring dermal accumulation most often results in compound failure. Confocal Raman Microscopy (CRM) is novel label free, rapid, optical method which allows compounds to be identified within dermal tissue at depths of ~300 µm. The aims of the investigations were to develop and establish CRM methods for in vitro dermal absorption investigations across ex vivo pig skin. A Lab Ra HR CRM was employed for the analysis of a range of concentrations (0.0 - 50.0 mg/mL) of benzoic acid, caffeine (both in 50% (v/v) ethanol (EtOH)) set at the following: IR laser at 785 nm a filter intensity of 100%, a hole 300 µm with a x50 objective. Depth profiling was also preformed on fresh pig skin samples from the surface to a maximum depth of ~300 µm (~50 µm increments). CRM spectra for the pig skin investigations demonstrated good reproducibility with some spectral differences noticed. Intensity of the spectra decreased with increased depth as expected. It was observed that a concentration of 50% (v/v) EtOH appeared to mask the signal of prominent identifiable peaks for benzoic acid and caffeine solutions at and below a concentration of 6.25 mg/mL. Compound concentrations equal to or higher than 20.0 mg/mL within a 50% (v/v) EtOH solution could be detected. This data suggests that this masking effect by EtOH requires further exploration to better understand the limitations of the technique. The CRM method has the potential to qualitatively determine dermal compound accumulation within mixed media and solutions ultimately, providing a powerful tool in identifying toxic compounds early on.

### PS 1045 Development of an Alternative Model for Assessing Barrier Function and Permeability for Infant Skin.

T. J. McCarthy<sup>1</sup>, N. K. Tierney<sup>1</sup>, S. G. Raney<sup>2</sup> and P. A. Lehman<sup>2</sup>. <sup>1</sup>Johnson & Johnson, Skillman, NJ; <sup>2</sup>PRACS Institute, Fargo, ND.

Recent published literature of non-invasive measures of skin barrier function of full-term human infants indicates a dynamic maturation process over the first year of life indicative of adaptation from in utero to the external environment. During this period, infant skin may be more vulnerable to penetration of topically applied ingredients, however, the magnitude of differences in non-invasive measures may not correlate to the magnitude of the difference in penetration of topical agents. While thriving demonstrates that a functional skin barrier exists at birth, differences in dermal permeability compared to adult skin could have an impact on the exposure assessment and safety of topically applied ingredients. The purpose of this study was to compare various indicators of skin barrier function (electrical impedance, TEWL), and permeability (tritiated water, <sup>14</sup>C-octanol, and 24-hr aqueous caffeine) across skin from donors of different ages. Fresh neonatal and pubescent porcine skins (animals culled for other purposes) were collected from a breeding colony. Cryopreserved ex vivo adult human skins were purchased from a skin bank. All measures of skin barrier function and permeability were equally applied to all skin samples. The barrier functions in the porcine skin varied, depending upon the measure. Average impedance indicated parity across age. TEWL and tritiated water flux was lower through neonatal skin versus either mature species. Neonatal skin octanol flux showed parity versus pubescent porcine skin while immaturity versus human cadaver skin. Caffeine absorption ranged from 1.5x to 4.5x higher through neonate skin than seen in either mature species. These data demonstrate that non-invasive measures of barrier function may be indicative, but not definitive, for determining the absorption of topical compounds. The current 10x intra-species safety factor used in risk assessment adequately captures the difference in neonatal barrier function.

### PS 1046 Modelling Diffusion of Therapeutic Drugs through the Skin In Vitro Does the Model Need to Be Complicated?

J. Jenner<sup>1</sup>, O. Payne<sup>1</sup>, C. Dalton<sup>1</sup>, S. Graham<sup>1</sup>, J. Azeke<sup>2</sup>, E. Braue<sup>2</sup> and J. S. Graham<sup>2</sup>. <sup>1</sup>Biomedical Sciences, DSTL, Salisbury, United Kingdom; <sup>2</sup>USAMRICD, Edgewood, MD.

A mathematical model accurately simulating diffusion of chemicals through the skin would be useful for predicting percutaneous absorption and aid understanding penetration mechanisms. Models of varying complexity have been validated using

in vivo and in vitro data. In the present study data from the penetration of four drugs was used to test the output of a simple one compartment model based on Fick's 1st law of diffusion.

Methods: Drugs, as off the shelf formulations, were applied to pig skin (500  $\mu$ m dermatomed slice) in Franz type diffusion static cells using stirred ethanol:water (1:1) as a receptor; surface temperature 32°C. Penetration of hydrocortisone, capsaicin, clobetasol and diclofenac were measured in the receptor fluid using Ultra Performance Liquid Chromatography. The experimental permeability constant (Kp) was estimated from the maximum flux rate (assumed to be steady state; Jss) and the applied concentration of drug (C0) using the equation:

$$Kp = Jss / C0$$

A penetration profile was predicted using a model with the skin as a single compartment of a thickness approximating the stratum corneum and using the experimental Kp to calculate flux of drug from vehicle into the barrier layer and from barrier layer into receptor fluid. A best fit (determined by least squares) was then obtained by adjusting the experimental Kp by a factor which gave an estimate of the accuracy of the model in predicting the experimental data.

Results: Model predictions needed to be adjusted by factor of between 1.1 and 1.35 to fit the experimental data as judged by a least squares method and assuming a membrane thickness of between 0.025 and 0.04 mm.

Discussion: this work has demonstrated that a very simple model is able to predict quite closely the penetration of some non-volatile compounds applied to the skin in a vehicle.

This work is supported by the US Army Medical Research and Materiel Command under contract W81XWH-08-C-0070.

#### **PS 1047 Prediction of Skin Disposition After Topical Application of Drugs—Simcyp Platform As a Tool for Capturing System Information and Safety Assessment.**

S. Polak<sup>1,2</sup>, N. Patel<sup>1</sup>, M. Jamei<sup>1</sup> and A. Rostami Hodjegan<sup>1,3</sup>. <sup>1</sup>Simcyp (a Certara Company), Sheffield, United Kingdom; <sup>2</sup>Faculty of Pharmacy, Jagiellonian University Medical College, Krakow, Poland; <sup>3</sup>School of Pharmacy and Pharmaceutical Sciences, University of Manchester, Manchester, United Kingdom. Sponsor: B. Wetmore.

There are reports where topical application of drugs, which is generally considered safe, results in health threatening side effects or drug-drug interactions. Simcyp platform separates the system information from those of drug and uses in vitro in vivo extrapolation approach to predict disposition of the topically administered drugs (Polak 2012). Administration of a single 0.4 mg of erythromycin (topical - 2cm<sup>2</sup> area of the forearm) with 40 mg simvastatin (oral) is used as a model scenario to assess anticipated interactions mimicking corresponding clinical study (van Hoogdalem 1996). Lotion formulation was simulated by modification of permeability/partition parameters (factor of 50 for stratum corneum and viable epidermis). Simulated residual amounts of erythromycin collected from the skin surface at various time and fraction of the dose recovered from stratum corneum after 6 hours were compared with the observed values. The results were consistent with observations and indicate significant systemic absorption. Subsequently oral simvastatin (40 mg SID) and topical ketoconazole (0.4 mg BID for two weeks, applied on upper arm) were simulated in 100 healthy individuals and by modification permeability/partition parameters (factor of 5 for stratum corneum) to account for occlusion. The average AUC<sub>inf</sub>/AUC and Cmax<sub>inf</sub>/Cmax ratios were 1.17 and 1.11 respectively, suggesting safe concomitant use. The maximum simulated ratios were 1.51 (AUC) and 1.32 (Cmax) indicating potential risk of significant interaction in some individuals. This is in agreement with the clinical observations suggesting general safety with rare occurrence of major side effects (e.g. Lareb Q 2009 report; myalgia).

#### **PS 1048 In Vitro Human Epidermal Penetration of IMX-101 Munitions Chemicals.**

W. C. McCain, L. R. Williams and G. Reddy. Toxicology Portfolio, US Army Public Health Command, Army Institute of Public Health, Aberdeen Proving Ground, MD.

Dermal exposure to ammunition chemicals is a major concern of the Army in assessing risk during manufacturing and field operations. The US Army Environmental Quality Technology (EQT) program is creating new, insensitive ordnance formulations to replace highly energetic compounds such as RDX and TNT. There are limited data on dermal absorption of munitions chemicals to support health risk assessment. We studied in vitro dermal penetration of a newly-developed munition, IMX-101 (Insensitive Munitions explosive) (as a mixture) and

its individual chemicals, 2,4-dinitroanisole (DNAN), 3-nitro-1,2,4-triazol-5-one (NTO), and nitroguanidine (NQ). Human epidermal membranes were prepared from frozen cadaver skin according to OECD guidelines and were mounted in Franz static diffusion receptor cells so that the visceral side was in contact with the receptor fluid. Neat test chemicals at infinite dose (100 mg powder) were carefully placed on the mounted skin in the donor chamber and at different times (1, 2, 4, 6 and 8 hrs) 0.1 mL of receptor fluid (buffer) was collected and quantified by HPLC. The rate of diffusion per cm<sup>2</sup> was calculated for each chemical. The analysis of absorbed chemical in the receptor fluid showed that steady state fluxes of neat NTO, DNAN and NQ were 332, 1.10 and 31.25  $\mu$ g/cm<sup>2</sup>/hr respectively. When complete IMX-101 was tested as 100 mg of mixture, the fluxes for NTO, DNAN and NQ independently were 135.9, 1.80, and 236  $\mu$ g/cm<sup>2</sup>/hr, respectively. NTO and NQ showed about 0.4 and 7 times greater rate of penetration in the combination mix than as individual compounds. These estimated values will be used to determine occupational exposure levels with dermal exposure.

#### **PS 1049 In Vitro Human Skin Penetration of Acetyl Hexapeptide-8 from a Cosmetic Formulation.**

O. A. Ogunsola<sup>1</sup>, W. Zhou<sup>2</sup>, P. G. Wang<sup>2</sup> and M. E. Kraeling<sup>1</sup>. <sup>1</sup>Office of Applied Research and Safety Assessment, US FDA, Laurel, MD; <sup>2</sup>Office of Regulatory Science, US FDA, College Park, MD.

Peptides are being incorporated into cosmetic creams marketed as anti-aging/anti-wrinkle products. Acetyl hexapeptide-8 may penetrate into the deep layers of the skin and potentially stimulate biological activity by interfering with neuromuscular signaling as its anti-wrinkle effect. The skin penetration of commercially available acetyl hexapeptide-8 (Ac-EEMQRR-amide) from a cosmetic formulation was determined in human cadaver skin assembled into in vitro diffusion cells. An oil-in-water emulsion containing 10% Ac-EEMQRR-amide was applied to skin at a dose of 2 mg/cm<sup>2</sup>. After a 24 hour exposure, the skin surface was washed to remove unabsorbed peptide. Skin discs were taped stripped to determine the amount of peptide in the stratum corneum. Removal of the stratum corneum layers was verified by confocal microscopy. The epidermis was heat separated from the dermis and each skin fraction was homogenized. Skin penetration of Ac-EEMQRR- was measured in skin layers by hydrophilic interaction liquid chromatography with tandem mass spectrometry (HILIC-MS/MS) using electrospray ionization (ESI) in the positive mode. Stable isotopically labeled hexapeptides were used as internal standards for the quantitation of native hexapeptides to correct for matrix effects associated with ESI. Results (% of applied dose) found the majority of the Ac-EEMQRR-amide was not absorbed and removed by washing (87%). Stratum corneum peptide levels decreased as each layer was removed by tape stripping. Total Ac-EEMQRR-amide found in the stratum corneum was 0.22 % and 0.01% in the epidermis. No peptide was detected in the dermis or receptor fluid. Hairless guinea pig skin penetration of Ac-EEMQRR-amide showed similar results where 0.51% remained in the stratum corneum and 0.01% penetrated into the viable epidermis. This skin penetration data will be useful for evaluating the safety of cosmetic products containing short-chain peptides.

#### **PS 1050 Nevirapine-Induced Skin Rash Is Caused by a Reactive Sulfate Metabolite Formed in the Skin.**

A. M. Sharma and J. Uetrecht. Pharmacy, University of Toronto, Toronto, ON, Canada.

Rationale: Nevirapine (NVP) treatment is associated with significant idiosyncratic immune-mediated skin rash and hepatotoxicity in humans. NVP causes a very similar rash in female Brown Norway rats, and we had previously shown that 12-hydroxylation of NVP is required to induce the rash. In this study we studied the further metabolism and covalent binding of NVP in the rat model and in human skin. Immune activation via IL-1 $\beta$  in the skin was also examined. Methods: An anti-NVP antibody was produced and used in immunoblotting studies to detect covalent binding of NVP, 12-OH-NVP, or NVP-sulfate to skin and liver proteins from rodents and humans. In vitro incubations of NVP or metabolites with hepatic microsomes or skin cytosolic fractions from humans, mice, or rats were also performed. The ability of SULT 1A1\*1 to metabolize NVP was studied and cutaneous IL-1 $\beta$  levels were examined by ELISA. Results: Covalent binding was observed in the epidermis of NVP or 12-OH-NVP-treated rats. Major modified bands appeared between 40K-60K. Depletion of PAPs decreased blood levels of NVP-sulfate but did not prevent rash or covalent binding in skin. Topical administration of 1-phenyl-1-hexanol (sulfotransferase inhibitor) prevented rash and covalent binding where applied, and also prevented covalent binding of 12-OH to cytosolic skin fractions and SULT 1A1\*1 in vitro. IL-1 $\beta$  levels were significantly upregulated in skin of rats with a rash as well as skin isolates. No skin rash or covalent binding was observed in the skin of NVP treated mice. Conclusions: In contrast to covalent

binding in the liver, which involves direct oxidation to a quinone methide, the reactive metabolite that covalently binds in the skin is a sulfate. The sulfate responsible for the rash is formed in the skin of rats and in human skin incubations but not in mice which develop no rash. Further work is being done to confirm the role of IL-1 $\beta$  in NVP-induced skin rash. Funding: Canadian Institutes of Health Research.

**PS 1051 In Vitro Discrimination of Skin Sensitizing Haptens and Prohaptens in a Modified Keratinsens Assay with an Added Metabolic Activation Step.**

A. Natsch<sup>1</sup>, T. Haupt<sup>1</sup> and G. Adamson<sup>2</sup>. <sup>1</sup>Givaudan Schweiz AG, Duebendorf, Switzerland; <sup>2</sup>Givaudan US, East Hanover, NJ.

Prohaptens are chemicals which may cause skin sensitization after being converted into electrophilic molecules by skin enzymes. In vitro sensitization assays ideally should detect the potential of molecules to act as prohaptens. The metabolic activation system most commonly used in in vitro toxicology is Aroclor-induced rat liver S9 fraction. Even if this system contains higher enzyme activities as compared to those reported in skin, it may serve as a surrogate system to study the potential of chemicals to form reactive, skin sensitizing metabolites. To test this concept, the luciferase induction in KeratinoSens reporter cells treated with chemicals in presence and absence of S9 fractions was measured. Suspected prohaptens such as methylisoeugenol, eugenol, trans-anethol or benzo(a)pyrene gave no, or weak, gene induction in absence of S9 fractions, and a strongly enhanced luciferase induction in presence of S9 proving their prohapten status. Haptens like DNCB or cinnamic aldehyde gave a reduced response in presence of S9. We then evaluated whether this metabolic activation assay might be implemented in a tiered screening strategy to screen negatives in the classical KeratinoSens<sup>TM</sup> assay to enhance sensitivity. To this aim all chemicals classified negative in the classical KeratinoSens<sup>TM</sup> assay were retested with this activation step. Among the 77 chemicals found as correct-negatives, 74 were also negative in presence of metabolic activation, thus this counter-screen does only slightly reduce specificity. However, based on this comprehensive screening, we found that only a small fraction of the known skin sensitizers need activation by the S9/P450 system, and thus the KeratinoSens<sup>TM</sup> -S9 assay may be useful for the in vitro evaluation of specific classes of potential prohaptens, rather than as a general screening approach. These results will be presented along with results on the predictivity and reproducibility of the KeratinoSens<sup>TM</sup> assay as accumulated during the prevalidation studies conducted for ECVAM.

**PS 1052 Toxicogenomic Characterization of Sensitizer and False-Positive Responses in the Local Lymph Node Assay (LLNA).**

D. Adenuga<sup>1</sup>, I. Kimber<sup>2</sup>, R. Dearman<sup>2</sup>, M. Woolhiser<sup>1</sup>, M. Black<sup>3</sup>, R. S. Thomas<sup>3</sup> and D. R. Boverhof<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>University of Manchester, Manchester, United Kingdom; <sup>3</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC.

Recent publications have highlighted chemistries which yield false positive responses in the LLNA when compared with guinea pig and human data. A toxicogenomic approach was applied to provide insight into the molecular and cellular mechanisms that may explain these differential responses. Auricular lymph node gene expression responses were evaluated in female CBA mice exposed to equipotent doses of 9 chemical sensitizers and 7 false positives per the standard LLNA dosing regimen. Lymph nodes were analyzed for 3HTdR incorporation on day 6 and gene expression responses on study days 4 and 6. Statistical analyses identified 779 and 473 differentially expressed genes (DEGs) between sensitizers and false positives on days 4 and 6. Class-based comparison of DEGs showed that the most enriched functional categories in the sensitizer-specific subsets were consistent with mechanisms involved in the acquisition of antigen-mediated skin sensitization. Key immune responses at the 4 day time point were restricted to genes involved in early T-cell development including pathways involved in IL2 regulation (IL2 and Egr4), Tbeta and the pre T-cell receptor alpha (Ptcra). Day 6 responses were more consistent with a mature T-cell response and included genes involved in the DC/T-cell maturation process such as IL21, Lag3 and Fxyd4. In contrast, false positives exhibited a strong pro-inflammatory expression profile including markers for activated macrophages and neutrophils such as Cd51, IL12b, Mpo, Defa4 and class I steffins. Expression of these genes in the absence of dermal irritation suggested these responses were not solely driven by skin irritation. These gene expression profiles suggest a differential cellular recruitment to the lymph nodes following skin exposure to true sensitizers and false positives and provide a potential new endpoint that could be applied to address false positives and enhance the predictive value of the LLNA.

**PS 1053 Inductive Effects on Reactivity of the Contact Allergen Benzoquinone and Its Derivatives to Proteins.**

W. Mbiya<sup>1</sup>, I. Chipinda<sup>2</sup>, P. Seigel<sup>2</sup> and R. Simoyi<sup>1</sup>. <sup>1</sup>Chemistry, Portland State University, Portland, OR; <sup>2</sup>Health Effects Laboratory Division, NIOSH, Morgantown, WV.

Benzoquinone (BQ) and substituted benzoquinones (SB) are used for dye and cosmetics production. BQ is an electrophile known to covalently modify proteins via Michael Addition (MA) but the reactivity, reaction mechanistic domains and allergenicity of SB are unknown. Electron withdrawing and electron donating substituents on BQ were assessed for effects on BQ reactivity and allergenicity. Alternative potential protein binding mechanisms were explored. BQ binding to Cys34 on human serum albumin (HSA) was studied and for BQ and SB reactivity studies, nitrobenzenethiol (NBT) was used as a model nucleophile. Hammett and Taft (HT) constants were used to evaluate the influence of these substituents on chemical reactivity. Both NBT binding studies and HT values demonstrated chlorine SB to be more reactive than methyl and t-butyl SB. Production of semiquinone radicals from SB and characterization of SB-NBT adducts demonstrated that haptenation may also occur via free radical mechanism which is pH dependent, and vinylic substitution mechanisms, in addition to the predominant MA. BQ and SB dermal allergenicity as evaluated in the murine local lymph node assay (LLNA) was consistent with that predicted by reactivity and HT data. These results demonstrate the effect of substituents on BQ reactivity and allergenicity while suggesting potential utility of chemical reactivity data and HT values for electrophilic allergen identification and potency ranking.

**PS 1054 Interaction of Para-Phenylenediamine with Human N-Acetyltransferases.**

S. Scheitza, D. Dierolf, J. Bonifas and B. Blömeke. Department of Environmental Toxicology, University Trier, Trier, Germany.

The contact allergen para-phenylenediamine (PPD) is known as a good substrate for N-acetyltransferase 1 (NAT1) but we also found that concentrations above 50  $\mu$ M are accompanied by inhibition of NAT1 activity in human keratinocytes. Here, we investigated the substrate and inhibition characteristics of PPD on NAT enzymes. First we measured whether next to PPD and mono-acetylated PPD (MAPPD) the PPD oxidation product Bandrowskis Base (BB) can also be acetylated. We therefore incubated PPD, MAPPD and BB with human recombinant NAT1 and NAT2 and found them to be good substrates for both enzymes. NAT1 inhibition characteristic of PPD was further studied using the THP-1 cell line which served as model for antigen-presenting cells. Both PPD and MAPPD are N-acetylated by THP-1 and the acetylation is accompanied by NAT1 inhibition. Concentrations above 1  $\mu$ M PPD clearly reduced enzyme activity already after 8h while 47% reduction was measured after 24h (200  $\mu$ M). Independent of the substrate-based enzyme inhibitions, certain compounds are known to oxidize the catalytic cysteine or form adducts with NAT protein. Therefore we studied whether PPD, MAPPD and/or oxidized PPD including BB also interact with recombinant NAT protein itself in the absence of acetyl coenzyme A. All but MAPPD interact with the protein after 2h and the greatest inhibition was found for oxidized PPD (up to 50%). From these results we can conclude that the observed NAT inhibition may be caused by both substrate dependent and independent effects. NAT1 activity in PPD-treated THP-1 cells was completely restored after incubation in fresh culture medium for 24h, whereas inhibition caused by 24h treatment with MAPPD could be restored for only 10%. In sum our data indicate that PPD and its oxidation products can inhibit NAT in two different ways. In addition we demonstrated that PPD and BB are acetylated by NAT1 and 2, suggesting that certain amounts of PPD and eventually formed BB inside the body may be detoxified by NAT1 in skin and additionally by NAT2 expressing organs.

**PS 1055 Pharmacodynamic Profiling of EGFR Inhibitors in HaCaT Cells.**

K. Balavenkatraman, P. Couttet, A. Vicart, B. Bertschi, M. Marcellin, N. Rathfelder, U. Hopfer, O. Grenet, R. Funhoff, S. Chibout, A. Lambert, J. Moggs, E. Pognan and A. Wolf. Discovery and Investigative Safety, Novartis Institutes for Biomedical Research Basel, Basel, Switzerland.

Skin Rash is a serious adverse effect of EGFR inhibitors observed during anticancer therapy in the clinic and appears to be linked to inhibition of the target pathway. The EGFR inhibitors erlotinib and afatinib were investigated at increasing concentrations (0, 0.001, 0.01, 0.1, 1 and 10  $\mu$ M) in the human keratinocyte cell line

HaCaT at different time points (0, 4, 8, 24 hours). Apoptosis, cytokine gene expression and protein release, and the EGFR-downstream signaling events Akt and Erk phosphorylation, were investigated as EGFR pathway pharmacodynamic read-outs.

The tested EGFR inhibitors induced dose-dependent pharmacodynamic responses in HaCaT cells that reflected their differential potencies in recombinant EGFR protein IC50 assays. Analysis of cytokine modulation (CCL-2, CCL-5 CXCL-10, IL-8, TGF- $\alpha$ ) also revealed a very good correlation between the mRNA and protein levels upon treatment with EGFR inhibitors.

These results suggest that HaCaT cells might be a useful model for the profiling of new compounds for potential EGFR pathway inhibitory activities.

## PS 1056 Cytokine-Induced Liver Hepatotoxicity of Trovafloxacin in Co-Culture of Hepatocytes and Kupffer Cells.

E. L. LeCluyse<sup>1</sup>, K. Rose<sup>1</sup>, K. Freeman<sup>2</sup>, S. S. Ferguson<sup>2</sup> and R. P. Witek<sup>2</sup>. <sup>1</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>Life Technologies, Durham, NC.

Immune-mediated chemical-induced hepatotoxicity, i.e. indirect hepatocellular toxicity resulting from immune cells activating liver inflammatory responses, is often overlooked as a potential mode of action due to unavailability of appropriate in vitro models. Kupffer cells are the largest population of resident macrophages in the liver and thus play a critical role in immune-mediated hepatotoxicity and liver injury. For this reason, we have established a co-culture system of rat primary hepatocytes and Kupffer cells that can be used to model chemical-induced immune reactions resulting in acute hepatotoxicity. Hepatocytes and Kupffer cells were cultured for 24-72 hours with various amounts of lipopolysaccharide (LPS) and trovafloxacin (TVX), a compound associated with immune-response-mediated hepatotoxicity in vivo. IL-6 and TNF $\alpha$  levels were assessed by ELISA or Luminex<sup>®</sup> bead assays and CYP3A was measured using Luciferin-IPA as a probe substrate to monitor endotoxin-induced functional changes in metabolic capacity. LPS-treated co-cultures showed marked down-regulation of CYP3A activity, which correlated with up-regulation of IL-6 production. This response was blunted in co-cultures treated with LPS and TVX, showing no changes to CYP3A activity and significantly lower production of IL-6. However, TNF $\alpha$  production was unaffected in TVX/LPS-treated co-cultures and markedly up-regulated in Kupffer cell monocultures. LPS/TVX-treated co-cultures also exhibited increased hepatocellular injury, represented by decreased ATP content and increased LDH leakage. This data suggests that shifts in cytokine profiles, especially IL6/TNF $\alpha$  ratios may play a role in immune-mediated chemical-induced hepatotoxicity. Co-culture of hepatocytes and Kupffer cells may represent a powerful in vitro tool to predict adverse liver effects resulting from indirect adaptive immune reactions during chemical exposure.

This project was supported by funding from the Long-Range Research Initiative (LRI) of the American Chemistry Council (ACC).

## PS 1057 Drugs Associated with Idiosyncratic Drug-Induced Liver Injury Synergize with Inflammatory Mediators to Produce Cytotoxicity in a Human Hepatoma Cell Line.

A. Maiuri<sup>1,2</sup>, R. Parkins<sup>3</sup>, P. E. Ganey<sup>1,2</sup> and R. Roth<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Idiosyncratic drug-induced liver injury (IDILI) typically occurs in a small fraction of patients and often results in removal of otherwise efficacious drugs from the pharmaceutical market. The mechanisms of IDILI are unknown, and animal models of IDILI are few. Several animal models have been developed that suggest that inflammation plays an important role in IDILI. Moreover, the inflammatory mediators tumor necrosis factor alpha (TNF $\alpha$ ), interferon gamma (IFN $\gamma$ ), and neutrophil-derived elastase (EL) are essential to the pathogenesis of liver injury in these models. The goal of the present study was to determine if two non-steroidal anti-inflammatory drugs associated with IDILI in humans synergize with TNF $\alpha$ , IFN $\gamma$  +/- TNF $\alpha$ , or EL +/- TNF $\alpha$  in producing hepatocellular toxicity in vitro. HEPG2 cells were treated with either diclofenac or sulindac sulfide (the active metabolite of sulindac) and with TNF $\alpha$ , IFN $\gamma$  +/- TNF $\alpha$ , or EL +/- TNF $\alpha$ . Cytotoxicity was significantly increased when cells were treated with diclofenac or sulindac in the presence of TNF $\alpha$  compared to cells treated with drug or TNF $\alpha$  alone. IFN $\gamma$  potentiated the cytotoxicity caused by either drug in the presence of TNF $\alpha$ . EL increased the cytotoxicity caused by diclofenac in the presence of TNF $\alpha$ . These results indicate that some of the events that occur in drug-inflammatory stress models in vivo can be reproduced in cultured cells and suggest the possibility of developing in vitro systems that can predict IDILI liability of drug candidates. (Supported by NIH grant RO1DK061315 and T32 GM092715-01A1).

## PS 1058 Serial Survival Liver Biopsies in Dogs and Monkeys.

V. Dinkel, M. Taschwer, J. Nelson, R. Haas, A. Wathen, A. Kamholz, J. Stuhler, J. Lindsay and F. Thalacker. Covance Laboratories Inc., Madison, WI.

The liver plays a key role in metabolism and excretion of endogenous compounds and xenobiotics and is an area of strong experimental focus. The liver may also be a target for efficacy (e.g. antiviral therapeutics) or toxicity. Animal models are critical for studying xenobiotic metabolism, biomarkers, and pharmacological/toxicological effects on the liver; however the ability to obtain adequate liver tissue samples for analyses in a survival model has been lacking. A surrogate matrix (e.g. blood, plasma, bile) is often used as an indirect measure for liver as its location within the body cavity makes it generally inaccessible for non-terminal sampling. In general, terminal sampling procedures have been needed when larger samples are required and survival procedures have typically been limited to a single collection per animal; the prospect of additional collections being dependent on whether minor (laparoscopic) or major techniques were used. The limitation of a single collection per animal increases the number of animals required to obtain the same data. We have developed laparoscopic surgical techniques for serial survival liver biopsies of ~100 mg, 18 hours apart in dogs and monkeys. We have also developed techniques, at least one laparoscopic, for serial survival biopsies of 1+ g in monkeys with samples taken over a period of weeks. All techniques allow for multiple phases and animal use has been decreased from 50-88%. In all cases, animals recovered completely following each procedure. They have been BAR (bright, alert, responsive), eating and mobile on the same day of surgery and display no signs of pain or distress, indicating exceptional pain management. Also, there have been no significant changes in body weight or clinical pathology and no surgical complications. Overall this work has resulted in the ability to obtain serial liver biopsies in multiple species, providing a significant advantage over current techniques and supporting the 3R philosophy through substantial reductions in animal use without compromising animal welfare.

## PS 1059 Quantitative Relationship Between Intracellular Lithocholic Acid (LCA) and Toxicity in Rat Sandwich-Cultured Hepatocytes (SCH): Incorporation into a Mechanistic Model of Drug-Induced Liver Injury (DILI).

K. Yang<sup>1</sup>, J. L. Woodhead<sup>2</sup>, R. St. Claire<sup>3</sup>, P. B. Watkins<sup>2</sup>, S. Q. Siler<sup>2</sup>, B. A. Howell<sup>2</sup> and K. L. Brouwer<sup>1</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>The Hammer-UNC Institute for Drug Safety Sciences, Research Triangle Park, NC; <sup>3</sup>Qualyst Transporter Solutions, Research Triangle Park, NC.

One proposed mechanism of DILI is inhibition of the bile salt export pump resulting in cellular accumulation of toxic bile acids (BAs). The purpose of this study was to establish the quantitative relationship between intracellular LCA concentrations and toxicity. This information is essential to link BA kinetics to toxicity in a BA transport inhibition model constructed within DILIsym<sup>™</sup>, a mechanistic model of DILI. Day3 rat SCH in 24-well plate were incubated with LCA (25–200 $\mu$ M) for 6, 12, and 24hr. Cytotoxicity was assessed by LDH release from damaged cells and intracellular ATP levels. Intracellular LCA/metabolites were measured by LC-MS/MS analysis of lysate after hepatocytes were incubated for 5min with Ca<sup>2+</sup>-free HBSS buffer to open tight junctions using B-CLEAR<sup>®</sup> technology. LCA, and its taurine (TLCA) and glycine (GLCA) conjugates, accumulated extensively in rat SCH. Cellular LCA concentrations increased with increasing LCA medium concentrations; cellular TLCA and GLCA decreased at LCA doses above 100 $\mu$ M, potentially due to saturation of amidation. LC<sub>50</sub> values estimated based on medium and intracellular LCA concentrations at 12hr were 143 and 1098 $\mu$ M, respectively. An E<sub>max</sub>-type relationship was observed between cellular LCA exposure (AUC<sub>LCA</sub>) and toxicity; half maximal toxicity was observed at AUC<sub>LCA</sub> of 10.4 and 16.3mM\*hr for the 12 and 24hr incubations, respectively. Decreased intracellular ATP concentrations preceded the toxicity measured by LDH. AUC<sub>ATP,0-24hr</sub> was correlated with toxicity at 24 hr (r<sup>2</sup>=0.97) and AUC<sub>LCA,0-24hr</sub> (r<sup>2</sup>=0.95). These results provide mechanistic insight that increased cellular exposure of unconjugated LCA leads to ATP depletion and subsequent toxicity.

Supported by NIH R01 GM41935 and DILI-sim initiative.

## PS 1060 Transformation of CO<sub>2</sub> Evolution Assays into Multiwell Plate Format Assays to Assess Effects of Compounds on Substrate Oxidation in Rat Hepatoma H4IIE Cells.

P. A. Cosgrove and J. W. Lawrence. Comparative Biology and Safety Sciences, Amgen Inc., Thousand Oaks, CA. Sponsor: S. Sawant.

Perturbations of metabolic processes are involved in several pathologies including cardiac hypertrophy, hepatic vacuolation, and steatosis. Different substrates can be used to distinguish between electron transport chain, the citric acid cycle,  $\beta$ -oxida-

tion, glycolysis, and amino acid metabolism pathway inhibition. The conventional assay for assessing substrate oxidation is through the use of  $^{14}\text{C}$ -labeled substrates and measuring the formation of  $^{14}\text{CO}_2$ . Historically, these assays are run with septum sealed flasks that are awkward to use, prone to sample loss, and have low throughput. We have adapted the  $\text{CO}_2$  capture method to a 96-well format by using a standard 96-well plate for cell incubation with substrate. A neoprene gasket is used to seal the environment to ensure  $\text{CO}_2$  is collected on a 96-well capture filter plate aligned on top.  $^{14}\text{C}$ -labeled glucose, pyruvate, glutamine, butyrate, octanoate, or palmitate were used as substrates and their oxidation was assessed in H4IIE cells. Etomoxir, an inhibitor of carnitine palmitoyl transferase-1, demonstrated a concentration dependent decrease in palmitate oxidation, however, glucose oxidation increased after treatment suggesting a fuel switching to compensate for the defect in fatty acid oxidation. Methylene cyclopropyl acetic acid (MCPA), a reported inhibitor of medium-chain acyl-CoA dehydrogenase, inhibited both butyrate and octanoate oxidation and had minimal effects on palmitate oxidation. An increase in glucose oxidation was observed after MCPA treatment, similar to that observed with etomoxir suggesting a similar fuel switching. Antimycin A, an electron transport chain inhibitor, decreased the oxidation of multiple substrates with similar potencies, suggesting inhibition at a point in the metabolic pathway common to all substrates. In conclusion, by transforming the classical  $\text{CO}_2$  evolution assay into a 96-well format, the effect of various compounds on various substrates can be assessed in an easier, higher throughput manner.

**PS 1061 Effect of Trichloroethylene Exposure on Autoimmune-Mediated Cholangitis in NOD.c3c4 Mice.**

A. K. Kopec, B. P. Sullivan and J. Luyendyk. *Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.*

Epidemiological studies support the hypothesis that exposure to environmental chemicals increases the risk of developing autoimmune liver diseases. Despite this association, the identity of specific chemical perpetrators and the mechanism whereby environmental chemicals modify liver disease is unclear. Previous studies have shown that trichloroethylene (TCE) can trigger autoimmunity in susceptible mice. We investigated whether modulation of hepatic gene expression by TCE exposure modified the pathogenesis of autoimmune cholangitis in mice. NOD.c3c4 mice spontaneously develop autoimmune-mediated liver disease with features including biliary cyst formation, portal lymphocytic inflammation, and fibrosis. Nine-week-old NOD.c3c4 mice were exposed to TCE (0.5 mg/ml) or its vehicle (1% Cremaphor-EL) via the drinking water for 4 weeks. TCE exposure had little effect on changes in clinical chemistry, biliary cyst formation, or CD3 T cell accumulation. Rather, global microarray profiling and Ingenuity Pathways (IPA) analysis revealed marked differential expression of PPAR $\alpha$  target genes, in agreement with a computational IPA prediction of PPAR $\alpha$  activation. TCE exposure significantly down-regulated cholesterol metabolism genes, and resulted in a ~3-fold suppression of early growth response 1 (Egr1). Consistent with a link between Egr1 suppression and liver fibrosis, we found that TCE exposure increased Type 1 collagen mRNA and protein levels in livers of NOD.c3c4 mice. In contrast, TCE exposure did not increase type 1 collagen expression in Nod.ShilT mice, which do not develop liver disease. These results suggest that in the context of concurrent autoimmune liver disease with a genetic basis, modification of hepatic gene expression by TCE may increase profibrogenic signaling in liver. Moreover, these studies further highlight the potential use of NOD.c3c4 mice as a model to study gene-environment interactions critical for development of autoimmune-mediated liver disease.

**PS 1062 Identification and Categorization of Transcriptional Profiles and Potential Biomarkers of Liver Injuries Related to a Drug Pair.**

Y. Wang, W. Ge, Z. Liu, M. Lee and W. Tong. *Bioinformatics and Biostatistics, National Center for Toxicological Research, US FDA, Jefferson, AR.*

Amiodarone and benziodarone share similar chemical structure and pharmacological effects, but induce different types of liver injuries in humans. This aspect of the difference can not be seen with the current conventional preclinical toxicity assessments. We hypothesize that the difference in liver gene expression profiles between two drugs correlate with the difference in their injury types. Thus, the aims of this study are to differentiate the drug-induced liver injury mechanisms between amiodarone and benziodarone by analyzing liver gene expression profiles in rats exposed to both drugs. Gene expression profiles of rat liver treated with amiodarone or benziodarone for consecutively 28-days were analyzed and compared to their concurrently control rats to identify the transcriptional changes. Three doses were used, where maximum tolerated dose (MTD) determined from dose range finding studies were considered as the high dose for each molecule while low and middle

doses were calculated from the ratios of the MTD. Several common upstream regulators such as PPAR- $\alpha$ , pirinixic acid, clofibrate were identified spontaneously in rat livers treated with two drugs. Sets of genes were detected to show a dose-response pattern from liver tissues treated with amiodarone and benziodarone, respectively. We suspected that this alteration of genes may be important in the biological progress relating to the different liver injuries caused by the drug pair. Using these differentially expressed genes, biological pathways and networks were developed to categorize the correlation and interaction of each factor in relating to liver injuries and in differentiating hepatotoxicity induced by amiodarone and benziodarone. The results of this study suggested that genomic profiles can be a good starting point in developing mechanism-based biomarkers for prediction and differentiation of liver injuries related to amiodarone benziodarone in early stage of drug discovery and development.

**PS 1063 In Vitro Assessment of Drug Induced Liver Injury (DILI) Using a High Content Cellular Imaging System.**

M. L. Wolfe<sup>1</sup>, S. Einhorn<sup>2</sup>, V. Ott<sup>2</sup> and H. Ma<sup>1</sup>. <sup>1</sup>*Cellular and Molecular Biology, MPI Research, Maitland, MI;* <sup>2</sup>*Cellular Dynamics International, Madison, WI.*  
Sponsor: T. Rogers.

Drug-induced liver injury (DILI) is a leading cause of drugs failing during clinical trials and being withdrawn from the market. In vivo safety testing in pre-clinical species ensures that drugs which enter clinical trials do not cause reproducible and dose-dependent liver injury in man, but is of limited value for exploration of underlying mechanisms and does not assess potential to cause rare idiosyncratic DILI. Implementation of an in vitro cell-based predictive assay early in the drug discovery process would help improve early compound attrition and develop safer drug candidates. We tested compound-treated human hepatocellular carcinoma Hep G2 cells, human induced pluripotent stem cell (iPSC)-derived hepatocytes (iCell® Hepatocytes) and primary human hepatocytes using the Thermo Scientific ToxInsight® IVT platform and DILI Assay Cartridge to determine the hepatotoxicity risk of a compound through the measurement of multiple toxicity biomarkers in individual cells. The compounds we investigated include a number of known hepatotoxic compounds (Ticlopidine, Troglitazone, Naladixic acid, Mefenamic acid, Phenylbutazone and Aflatoxin B1) and non-hepatotoxic compounds (Aspirin, Fluoxetine and Melatonin). Each compound was tested at eight concentrations in triplicate. The DILI Assay Cartridge allows for the high sensitivity and specificity for predicting hepatotoxicity by simultaneously detecting five multiplexed cellular targets and properties associated with cell loss, cellular redox stress, and mitochondrial stress. The hepatotoxicity prediction using the multiparametric data generated for the test compounds demonstrates high specificity across the three hepatocyte models but varying sensitivity for each hepatocyte model system.

**PS 1064 Altered-Hepatic Catabolism of Branched Chain Amino Acids in Progressive Human Nonalcoholic Fatty Liver Disease.**

A. D. Lake<sup>1</sup>, P. Novak<sup>3</sup>, P. Shipkova<sup>2</sup>, N. Aranibar<sup>2</sup>, D. Robertson<sup>2</sup>, M. D. Reily<sup>2</sup>, L. D. Lehman-McKeeman<sup>2</sup>, R. R. Vaillancourt<sup>1</sup> and N. J. Cherrington<sup>1</sup>. <sup>1</sup>*Pharmacology & Toxicology, University of Arizona, Tucson, AZ;* <sup>2</sup>*Bristol-Myers Squibb Co., Princeton, NJ;* <sup>3</sup>*Institute of Plant Molecular Biology, Ceske Budejovice, Czech Republic.*

Branched chain amino acids (BCAAs) and their catabolism have essential roles in metabolic homeostasis. BCAAs are capable of activating the mammalian target of rapamycin (mTOR) during states of over-nutrition resulting in an increased risk of insulin resistance and altered lipid homeostasis. Nonalcoholic fatty liver disease (NAFLD) is closely associated with features of the metabolic syndrome and over-nutrition. Approximately 30-40% of the United States population is afflicted with NAFLD while 5.7-17% is estimated to have severe nonalcoholic steatohepatitis (NASH). A 'two-hit' model has been used to describe the pathological progression of NAFLD to steatosis and then NASH, although the exact mechanisms for disease progression are not known. The hypothesis of this study is that these two 'hits' drive alterations in hepatic branched chain amino acid (BCAA) composition and catabolism while enhancing disease progression. Hepatic transcriptomic and metabolomic data sets representing the entire spectrum of human NAFLD (healthy, steatosis, NASH Fatty, and NASH Not Fatty livers) were utilized to investigate the role of BCAAs in the mechanisms of NAFLD pathophysiology. An increase of the BCAAs leucine (127% of normal), isoleucine (139%) and valine (147%) were observed in NASH samples. Increased BCAA catabolism through upregulated branched chain aminotransferase enzyme appears to drive increases of acylcarnitine products that include butyryl carnitine (353% of normal) and lauryl carnitine (403% of normal). The hepatic overload of BCAAs also potentiates mTOR signaling thereby increasing metabolic dysregulation. Overall, these findings demonstrate altered catabolism of BCAAs in NASH with important downstream signaling implications for lipotoxicity and insulin resistance in the progression of NAFLD.

**PS 1065 Altered Hepatic and Renal Drug Transporter Expression in Multiple Rodent Models of Nonalcoholic Steatohepatitis.**

M. Canet, R. N. Hardwick, A. D. Lake and N. J. Cherrington. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Nonalcoholic fatty liver disease (NAFLD) is the most common form of chronic liver disease in Western society representing a spectrum of liver damage ranging from simple steatosis to the more advanced nonalcoholic steatohepatitis (NASH). Experimental models of NASH include diet-induced models such as the methionine and choline deficient (MCD) diet and genetically obese models such as the leptin-deficient, ob/ob mice. Previous studies have demonstrated alterations in the expression and activity of multiple drug transporters in human NASH, but little information is known regarding the most appropriate animal models for predictive toxicology to extrapolate in vivo hepatic and renal drug disposition data to human NASH populations. The purpose of the current study was to determine which experimental NASH model best recapitulates human disease pathology as well as alterations in drug transporter expression. Both rat and mouse NASH models were utilized in this investigation and include; MCD diet, atherogenic diet, ob/ob and db/db mice, and fa/fa rats. Histologic and pathological evaluations confirmed that the MCD and atherogenic rats and MCD, ob/ob and db/db mice all developed NASH. In contrast, the fa/fa rats did not develop pathological NASH. Hepatic mRNA levels of drug transporters showed that the rat and mouse MCD diet model and the ob/ob and db/db mice best recapitulate the expression profile seen in human NASH. In general, the majority of efflux transporters are induced whereas uptake transporters are decreased. Similar to the liver, efflux transporter expression in the kidney is also induced at both the mRNA and protein level. However, renal uptake transporter expression across these models is differentially altered and is transporter and model-specific. These results suggest that the MCD rat, and the ob/ob and db/db mouse models may be more useful preclinical models to determine the effect of NASH on drug disposition as well as determining extra-hepatic alterations in drug transporter expression.

**PS 1066 Regulation of ABCC2 Internalization in Nonalcoholic Steatohepatitis.**

A. L. Dzierlenga, R. N. Hardwick, J. Clarke and N. J. Cherrington. *Pharmacology & Toxicology, University of Arizona, Tucson, AZ.*

Non-alcoholic fatty liver disease affects 30-40% of the United States population and can progress to non-alcoholic steatohepatitis (NASH) which is characterized by an accumulation of fat, oxidative stress, fibrosis and inflammation. It has been previously shown that NASH can have a significant effect on the disposition of many drugs and potentially contribute to the occurrence of adverse drug reactions. NASH-associated altered drug disposition has, in part, been linked to stress-induced alterations of the expression and function of hepatic transporters such as ABCC2. ABCC2 is located on the canalicular membrane and transports xenobiotic substrates into the bile for elimination from the body. By mechanisms that are not entirely understood, ABCC2 has been shown to be internalized in rodent and human NASH livers, as well as the in vitro conditions of acute oxidative stress and lipopolysaccharide exposure. Previous reports have suggested that the activation and cellular localization of radixin, protein phosphatase 1, phosphoinositide 3-kinase, protein kinase A, and protein kinase C (PKC) may be involved in the internalization of ABCC2. The purpose of this study is to identify potential mechanisms responsible for ABCC2 internalization in NASH. Sprague-Dawley rats were fed a control methionine and choline supplemented diet or a methionine choline deficient diet (MCD) to model NASH. It was found that in NASH livers there was an increase in the membrane association of the PKC $\epsilon$  isoform compared to control livers, but not PKC $\delta$  or PKC $\alpha$ , implicating PKC $\epsilon$  as a potential regulator of ABCC2 internalization. Additionally, the cellular localization of radixin was not found to change in NASH livers. Further insight into the mechanisms behind functional perturbations of hepatic drug transporters such as ABCC2 has implications for improved understanding and identification of targets for alleviating adverse drug reactions in clinical NASH.

**PS 1067 A RNA-Interference Screen Identifies Novel Regulators of the Ubiquitinase A20/TNFAIP3 As Critical Determinants of Drug-Induced Liver Injury Responses.**

B. van de Water, B. Herpers, L. Fredriksson, G. Benedetti and M. de Graauw. *Division of Toxicology, Leiden University, Leiden, Netherlands.*

The cytokine tumor necrosis factor alpha (TNFalpha) acts in synergy with different drugs, including diclofenac, to initiate drug-induced liver injury (DILI). This is directly related to the inhibition by these drugs of TNFalpha-induced NFkB activation as demonstrated by an inhibition of the NFkB nuclear oscillatory translocation

response. Here we investigated the underlying mechanism of the drug/TNF synergy. We used a live-cell imaging-based siRNA screen to identify individual kinases, (de)ubiquitinases and sumoylases that control the NF-kB oscillatory response. We applied high content confocal laser scan microscopy in combination with multiparametric image analysis to follow the NF-kB oscillation in ~300 individual cells per condition simultaneously. Out of the ~1500 genes screened, we identified 115 that significantly affected the NF-kB oscillatory response. Using 4 individual siRNAs, we confirmed the action for 46 genes, which affected: i. the amplitude or duration of nuclear oscillations; ii. the time between oscillations, leading to an increase or decrease of the number of nuclear translocations; or iii. an inhibition of the response altogether. In this last category we identified six genes, four novel, whose reduced expression protected against the diclofenac/TNFalpha-induced apoptosis. Interestingly, the knockdown of these six genes led to a basic up-regulation of A20 expression. In accordance, A20 knockdown promoted the NF-kB oscillation and enhanced apoptosis. Double knockdown experiments indicated a direct relationship between these four genes and A20 in the control of the NF-kB activation. These findings indicate that the (de)ubiquitinase A20 is a master regulator in the life-death decision upon TNFalpha stimulation in drug-induced hepatotoxic responses, which, in turn, is kept under control by a network of genes that control its expression level.

**PS 1068 Hepatic Transporters in HepaRG Cells and Sandwich-Cultured Human Hepatocytes.**

C. Guugen-Guillouzo<sup>1,2</sup>, P. Bachour-El Azzi<sup>1,3</sup>, R. Li<sup>2</sup>, A. Charanek<sup>1</sup>, Z. Abdel-Razzak<sup>3</sup>, A. Guillouzo<sup>1</sup> and C. Chesne<sup>2</sup>. <sup>1</sup>INSERM 991, Rennes University, Rennes, France; <sup>2</sup>BIOPREDIC, Rennes, France; <sup>3</sup>Lebanese University, Hadath, Lebanon. Sponsor: M. Robin.

Reestablishment of polarized excretory function and maintenance of expression and activity of transporters in liver cell models are critical for in vitro analysis of drug and bile acid excretion as well as toxicity testing. Previous studies have shown that conventional primary hepatocytes and HepG2 cells do not correctly mimic the in vivo situation whereas sandwich-cultured hepatocyte conditions do restore cell polarity for a few days. In the present work we have analyzed expression, activity and distribution of several canalicular and basolateral transporters in hepatocytes from human HepaRG cells compared to sandwich-cultured primary human hepatocytes. Differentiated HepaRG hepatocytes exhibited high polarity with typical bile canalicular structures characterized by F-actin accumulation and restricted by connexin 32-positive tight junctions. In previous reports, most influx and efflux transporters were found to be expressed in HepaRG cells and adult hepatocytes, at the transcriptional level. Using the immunofluorescence technique and imaging analysis their specific distribution was investigated. MRP2 was localized in both models, at the canalicular membrane domain while both MRP3 and MRP4 and the influx transporter NTCP, were demonstrated at the basolateral plasma membrane domains. Trafficking polarization toward canalicular structures through MRP2 and MDR1 was evidenced by using specific substrates coupled with fluorescein and/or mitotracker and Ca<sup>2+</sup> regulation of canalicular excretion was clearly documented. In addition, uptake and release of bile acid taurocholate was investigated in HepaRG cells using H3-taurocholate; both active influx via NTCP activity and canalicular efflux were evidenced. Moreover, addition of chlorpromazine, a compound known to induce cholestasis in vivo, resulted in bile salt efflux inhibition mainly at the canalicular pole. Together, these data support the view that HepaRG hepatocytes represent a suitable in vitro model to investigate human drug and bile acid excretion.

**PS 1069 Deep Sequencing of miRNA in Livers of Rats Exposed to Hepatotoxics.**

M. Flores Torres<sup>1</sup>, J. Wright<sup>1</sup>, R. Currie<sup>2</sup>, C. Koufaris<sup>1</sup> and N. J. Gooderham<sup>1</sup>. <sup>1</sup>Biomolecular Medicine, Imperial College London, London, United Kingdom; <sup>2</sup>Safety Assessment, Syngenta, Jealotts Hill, United Kingdom.

MicroRNAs (miRNAs) are small non-protein coding RNAs. They act as regulators of gene expression, by inhibiting mRNA translation or promoting mRNA degradation, and are involved in diverse physiological and pathological events. Recently we have shown (Koufaris et al. Toxicol Sci: 128, 532, 2012) that the CAR activator phenobarbital (PB) induces deregulation of the hepatic miRNAome in the livers of rats. Next Generation Sequencing (NGS) analysis of small RNAs is a powerful tool that can be used for miRNA expression profiling, and offers a deeper understanding of molecular toxicology. Here we explore the liver miRNAome associated with CAR activation, and to compare this with the effects of the hepatotoxicant dimethylarsinic acid (DMA), which is known to induce mitochondrial perturbation. Male rats were dosed with PB (50 or 1000 ppm) or DMA (4 or 40 ppm) in the diet for 28 days, and sacrificed after 2, 4, 15, and 28. Histopathological evaluation revealed centrilobular hypertrophy at 15 and 28 days after PB treatment and multifocal inflammatory foci with necrosis at 28 days after DMA treatment. Total RNA

was isolated from frozen samples, and library constructs for NGS were generated (TrueSeq Small RNA kit, Illumina). Bioinformatics was used to prioritise potential gene targets of deregulated miRNAs, and qPCR to validate expression of miRNA families and potential gene targets. Consistent with our previous report, miR200 family was induced by 28 days of treatment with PB at 1000ppm, but not by 50ppm. There was a dose-dependent reduction in the zeb1 and zeb2 transcription factors, which are known and validated targets of the miR200 family. The zeb1 and zeb2 transcription factors regulate the epithelial to mesenchymal transition, thus PB-mediated miR200 family induction appears to be a homeostatic response to protect the epithelial nature of hepatocytes. NGS permits a more detailed exploration of the response of the miRNAome to hepatotoxicants such as PB, thereby aiding an understanding of the underlying pathways.

#### PS 1070 High-Content Imaging of Rat Hepatocytes Long-Term Cultures to Predict Specific Drug-Induced Liver Toxicity.

D. Germano, M. Uteng, P. Couttet, O. Grenet, S. Chibout, F. Pognan and A. Wolf. *Discovery and Investigative Safety, Novartis Institutes for Biomedical Research Basel, Basel, Switzerland.*

Primary rat hepatocytes were investigated for liver-specific functional changes after repetitive treatments with model liver toxicants at low concentrations for two weeks. Cells were cultured in the Collagen I/Matrigel™ sandwich configuration. High content imaging (HCI) was performed by using the Cellomics™ Arrayscan®. The liver-specific pathologies cholestasis/hyper-bilirubinemia, steatosis and phospholipidosis were investigated by means of fluorescence dyes. Mrp2-mediated canalicular transport, intra-cellular accumulation of neutral lipids and phospholipids were assessed by carboxy-DCFDA, BODIPY or LipidTOX™ Red, respectively. Unspecific cytotoxicity was measured by ATP contents and LDH releases. Cyclosporin A (CsA), Amiodarone (AMD), Rosiglitazone (RGZ), Chlorpromazine (CPZ), Troglitazone (TGZ), Metformin (MET), Fenofibrate (FFB), Ibuprofen (IBU), Acetaminophen (ACT), Valproic Acid (VPA) and EMD335823 (EMD) were evaluated at four different concentrations and at five time points (day 1, 3, 7, 10, 14). The results showed that inhibition of canalicular transport, induction of phospholipidosis and steatosis occurred after multiple treatments at clinical relevant doses in absence of cytotoxicity in the hepatocytes. CsA, CPZ and TGZ treatment caused time- and concentration-dependent inhibition of Mrp2-mediated transport, while AMD and CPZ induced dose-dependent accumulation of phospholipids. CsA was also associated with intracellular accumulation of lipids, whereas VPA did not induce steatosis. Taken together, the current data suggest that the current testing strategy has a high predictive value for compounds inducing hyperbilirubinemia/cholestasis and phospholipidosis, but not for drug-induced steatosis. In addition, the present work illustrates that HCI is a sensitive and reproducible tool for the evaluations of specific cellular functions and that HCI can be applied in safety profiling of drug candidates. Study is part of the European FP7 PREDICT-IV consortium (grand no 202222).

#### PS 1071 Gene Expression Profiling Identifies Molecular Mechanisms of Tamoxifen-Induced Hepatotoxicity in Mice.

V. Tryndyak, T. Han, M. Churchwell, B. Montgomery, J. C. Fuscoe, J. R. Latendresse, F. A. Beland and I. P. Pogribny. *US FDA-NCTR, Jefferson, AR.*

Tamoxifen is an anti-estrogenic drug widely used for the treatment and prevention of estrogen-receptor-positive breast cancer. However, despite the indisputable benefits of tamoxifen, its use has been associated with the induction of hepatic steatosis. The goal of this study was to investigate the underlying molecular mechanisms associated with tamoxifen-induced hepatotoxicity. Female and male WSB/Eij mice were fed a diet containing 420 ppm tamoxifen for 12 weeks. The livers of tamoxifen-fed mice exhibited moderate pathomorphological changes, as evidenced by glycogen depletion, despite having profound genotoxic and non-genotoxic alterations. Specifically, the livers of tamoxifen-fed mice were characterized by extensive sex-independent accumulation of tamoxifen-DNA adducts and marked changes in the gene expression. To identify tamoxifen-responsive genes that were differentially expressed between the control and tamoxifen-exposed mice, a t-test,  $p < 0.01$ , coupled with a fold-change cut-off  $> 1.5$  was applied. A total of 1245 and 2100 genes were found to be differentially expressed in the livers of tamoxifen-exposed female and male mice, respectively. Interestingly, 361 of the genes were differentially expressed in both female and male mice treated with tamoxifen. Most of these genes were associated with altered lipid metabolism, inflammation, cell death and proliferation, and development of liver fibrosis. These results demonstrate the importance of gene-expression profiling in identify early hepatic molecular events associated with the chronic administration of tamoxifen.

#### PS 1072 A 3D Co-Culture Model-Based Assay to Assess Liver Kupffer-Cell Activation and Functionality.

S. Shetty<sup>2</sup>, K. Adkins<sup>2</sup>, M. Roy<sup>2</sup>, I. Agarkova<sup>1</sup>, J. M. Kelm<sup>1</sup> and S. Messner<sup>1</sup>. <sup>1</sup>InSphero AG, Zurich, Switzerland; <sup>2</sup>Drug-Safety R&D, Investigative Toxicology, Pfizer, Groton, MA. Sponsor: A. Wolf.

Adverse drug reactions in the liver are one of the major causes of attrition in drug development with both small and large molecules. Novel therapeutic modalities such as antibodies and other biologicals can be taken up by non-parenchymal cells, such as phagocytic cells in the liver (mainly Kupffer cells) and can limit drug exposure and cause liver toxicity. Therefore, evaluating Kupffer-cell uptake can serve as an indirect screen for liver toxicity. However, due to lack of suitable organotypic in vitro models, Kupffer cell uptake has been difficult to study. Here, the use of primary heterotypic 3D rat liver microtissues for assessment of drug-induced Kupffer-cell activation is demonstrated. Morphological characterization of rat liver microtissues demonstrated the presence of ED1 and ED2-positive Kupffer cells within the hepatospheres. Electron-microscopy confirmed layering of Kupffer cells between hepatocytes in the rat liver microtissues. Lipopolysaccharide (LPS) treatment of the rat liver microtissues resulted in increased uptake of acetylated LDL (ac-LDL), whereas incorporation of ac-LDL was reduced when the phagocytosis inhibitor gadolinium chloride was applied, indicating ac-LDL uptake by Kupffer cells is dependent on phagocytosis. An increase in IL-6 secretion was also observed at 48 and 120 hrs post-treatment with LPS, indicating Kupffer cell activation. Together these data demonstrate the suitability of heterotypic rat liver microtissues for assessing Kupffer cell activation and functionality by external stimuli, and highlight the potential of 3D rat liver models for evaluating liver toxicity.

#### PS 1073 Organic Solute Transporter Ostα-Ostβ As a Potential Therapeutic Target for the Metabolic Syndrome.

S. Gorman, C. Hammond, P. Hinkle and N. Ballatori. *Environmental Medicine, University of Rochester, Rochester, NY.*

The metabolic syndrome has increased in occurrence in recent decades, and as a result has become a major health concern. Environmental contaminants have been linked to this, as common toxicants have been found to increase susceptibility to weight gain and/or insulin resistance, key features of the metabolic syndrome. This has resulted in a need for pharmaceuticals that lower fat accumulation and improve insulin sensitivity, and this study identifies a novel potential therapeutic target, the bile acid transporter Ostα-Ostβ. Our laboratory has generated an Ostα<sup>-/-</sup> mouse in the C57Bl6 background, a strain susceptible to age-related weight gain. Interestingly, Ostα<sup>-/-</sup> mice have a significant reduction in bile acid pool size. The major purpose of bile acids is to emulsify dietary lipids in the small intestine and facilitate their absorption, but they have also recently been shown to function as signaling molecules that affect lipid and glucose homeostasis. This study aimed to explore differences in lipid and glucose homeostasis in Ostα<sup>-/-</sup> mice. A comparison of whole body and fat pad weights of Ostα<sup>-/-</sup> and wild type mice at 5 and 12 months of age revealed no differences in these parameters at 5 months, but at 12 months, Ostα<sup>-/-</sup> mice had accumulated less fat and had lower total body weights. Similarly, extraction of liver lipids indicated less accumulation of total lipid and cholesterol in hepatic tissue with age. At both ages, increased fecal lipid excretion and altered expression of genes involved in bile acid and lipid homeostasis were noted, and glucose and insulin tolerance tests also revealed significant improvement in glucose tolerance and insulin sensitivity at both ages. These studies indicate that Ostα<sup>-/-</sup> mice excrete more lipids in feces, are resistant to age related weight gain and have improved insulin sensitivity and glucose tolerance, suggesting an inhibitor of Ostα-Ostβ may be useful in treating the metabolic syndrome. (NIH Grant DK067214, NIEHS Training Grant ES07026 and Center Grant ES01247)

#### PS 1074 Predictivity of Drug-Induced Liver Toxicity Using High-Content Screening in 384-Well Cultures of HepG2 Cells and Primary Human Hepatocytes.

K. F. Marcoe<sup>1</sup>, H. J. Garside<sup>2</sup>, J. Chesnut-Speelman<sup>1</sup>, A. J. Foster<sup>2</sup>, U. Warrior<sup>1</sup>, J. Baumgartner<sup>1</sup>, D. Muthas<sup>3</sup>, J. G. Kenna<sup>2</sup> and J. Bowes<sup>2</sup>. <sup>1</sup>Eurofins Panlabs, Bothell, WA; <sup>2</sup>Global Safety Pharmacology, AstraZeneca, Macclesfield, United Kingdom; <sup>3</sup>Global Safety Assessment, AstraZeneca, Molndal, Sweden. Sponsor: J. Valentin.

Drug-induced liver injury (DILI) is a major cause of failed drug development and drug withdrawal. Predictive toxicology screening assays are therefore required for early de-selection of compounds that may cause DILI. Although previous investigators have reported several potentially promising in vitro approaches, it is unclear which cell systems and endpoints can provide the greatest predictive power. In this

study we used multiplexed high content screening, with automated fluorescence microscopy and image analysis, to assess the *in vitro* toxicity of 122 drugs associated with DILI in man and 22 drugs not reported to cause DILI. Studies were undertaken in HepG2 cells with and without rat S9 fraction and in cryopreserved primary human hepatocytes. Toxicity was determined at 4, 24 or 48 h. The parameters assessed were: cell proliferation (nuclear dyes); apoptosis (anti-activated caspase 3); cell cycle (anti-pHistone H3); stress (anti-HSP70/72); reactive oxygen species generation (H2DFFDA dye); mitochondrial damage (TMRE dye); phospholipid and neutral lipid accumulation. All cell systems provided highly specific discrimination (>90%) between those that caused DILI and non-hepatotoxic drugs. The highest sensitivity was observed in HepG2 cells without S9, using the apoptosis (29%) and phospholipidosis (22%) endpoints. Addition of S9 did not increase the sensitivity of any of the parameters studied. In human hepatocytes, the 24 h H2DFFDA assay had a sensitivity of 20%, whereas the other endpoints had sensitivities of <11%. We conclude that toxicity studies in HepG2 cells enabled detection of compounds which may cause DILI in humans with high specificity but low sensitivity and that neither the addition of S9 nor the use of human primary hepatocytes provided improved predictivity.

## PS 1075 Studying Drug-Induced Cholestasis with a Novel Cellular Model Coexpressing Major Bile Salt Transporters in the Liver.

M. S. Warren, J. X. Zhang, J. Huang, P. Druzgala and Y. Huang. *Optivia Biotechnology Inc., Menlo Park, CA.*

Drug induced cholestasis and hepatocellular injury are two major manifestations of drug induced liver disease (DILI). Research has shown such injuries are often attributed to inhibition of bile salt transporters in the liver. NTCP, OATP1B1, BSEP and MRP2 have been identified as the major transporters modulating hepatic clearance of bile salts and their conjugates.

We recently demonstrated that canalicular excretion and intracellular retention of bile salts can be studied with a polarized MDCK cell model concomitantly expressing three major bile salt transporters in the liver, i.e., OATP1B1, NTCP and BSEP. To evaluate the utility of this model in studying drug-induced cholestasis, we tested 20 drugs and their major metabolites that have been reported to cause cholestasis in the human. More than half of the drugs or their metabolites, including traglitzone, benzbromarone and bosentan, significantly inhibited B>A transcellular transport (canalicular excretion) of [3H]Taurocholate at clinically relevant concentrations, suggesting that blocking transporter mediated canalicular excretion of bile salts is a major mechanism of drug induced-cholestasis *in vivo*. Furthermore, a few drugs, such as Rifampicin, remarkably elevated intracellular concentration of Taurocholate (which has been suggested to lead to hepatocellular damage), suggesting that at high concentrations, these drugs are more likely to cause cholestatic hepatitis than the others. Other agents, such as estradiol-17-beta-glucuronide, tamoxifen and pyrazinamide, did not exhibit significant inhibitory effect on Taurocholate transport under the test conditions, which suggests there may be other mechanism(s) involved.

In summary, our study demonstrates that the novel OATP1B1/NTCP/BSEP triple transporter expression model can be a useful economical tool for early-stage screening and for mechanistic study of compounds with cholestasis liability.

## PS 1076 Use of a Multiplexed Endpoint Assay Strategy to Assess Model Bioactivated Compounds in Sandwich-Cultured Hepatocytes.

K. Wille<sup>1</sup>, A. L. Niles<sup>2</sup>, J. J. Cali<sup>2</sup> and E. L. LeCluyse<sup>1</sup>. <sup>1</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>Promega Corporation, Madison, WI.

Sandwich-cultured rat hepatocytes (SCRH) represent a metabolically competent *in vitro* model for screening and identifying potentially hepatotoxic compounds that correlates well with *in vivo* results. In this study, we employ a novel strategy for multiplexing a broad complement of metabolic plater reader assays using SCRH to measure hepatotoxicity of model bioactivated compounds, such as acetaminophen (APAP). This approach yields a profile of early toxicity indicators that provides greater mechanistic insight from fewer experimental replicates. SCRH in 24- or 48-well plates were exposed to 8 concentrations of APAP in the presence or absence of the CYP inducer, dexamethasone (DEX); CYP inhibitor, 1-aminobenzotriazole (ABT); and the glutathione synthesis inhibitor, L-buthionine sulfoximine (BSO). Toxicity was assessed at 24 and 48 hours for Cyp3A activity (Promega P450-Glo<sup>TM</sup>), ATP content (Promega CellTiter-Glo<sup>®</sup> Assay), lactate dehydrogenase leakage (Promega CytoTox ONE<sup>TM</sup> Homogenous Membrane Assay), and glutathione content (Promega Glutathione-Glo<sup>TM</sup> Assay). Resulting ATP, glutathione, and LDH data showed dose- and time-dependent APAP toxicity which was moderated, especially at the 24 hour time point, by ABT and exacerbated by DEX. CYP3A ac-

tivity was induced up to 4-fold by DEX and significantly inhibited by ABT (5% of DMSO controls). BSO nearly eliminated intracellular glutathione levels by 48 hours and increased hepatocyte APAP sensitivity. Collectively, these data demonstrate the utility of SCRH as a model to assess bioactivated compounds for hepatotoxicity. The multiparameter assay approach offers greater mechanistic insight into the nature and timing of the toxicity.

This project was supported by the Long-Range Research Initiative (LRI) of the American Chemistry Council (ACC) and Promega Corporation, Madison, WI.

## PS 1077 Cytotoxic Interaction of Inflammagens with Trovafloxacin in Spheroid Cultures of Rat Liver Cells.

R. A. Roth<sup>1</sup>, P. C. Wilga<sup>2,1</sup>, K. L. Poulsen<sup>1</sup>, K. M. Beggs<sup>1</sup>, J. Prezenger<sup>2</sup>, A. Maiuri<sup>1</sup>, P. E. Ganey<sup>1</sup> and J. McKim<sup>2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>CeeTox, Inc., Kalamazoo, MI.

Idiosyncratic, drug-induced liver injury (IDILI) typically escapes detection in pre-clinical safety evaluation of drug candidates due to paucity of predictive models. Recently, models have arisen in which liver injury occurs in rodents treated with trovafloxacin (TVX) or other IDILI-associated drugs and coexposed to an inflammagen such as bacterial lipopolysaccharide (LPS). The hepatocellular injury depends on tumor necrosis factor- $\alpha$  (TNF) and possibly other cytokines released by nonparenchymal cells (NPCs) and therefore cannot be reproduced in monocultures of hepatic parenchymal cells (HPCs). Accordingly, the cytotoxicity of TVX in the presence and absence of LPS was evaluated in 3-dimensional (3D) spheroid cultures (InSphero) containing equal numbers of HPCs and NPCs and compared to data obtained from HPCs in standard sandwich culture. Spheroids or standard HPC cultures were exposed to various concentrations of TVX (10 -100  $\mu$ M) alone or with LPS (10  $\mu$ g/ml) or TNF (10 ng/ml) for 24 hr. TNF was detected in the culture medium of spheroids cotreated with LPS and TVX, but not with either agent alone, and no TNF was detected in HPC cultures treated similarly. Cytotoxicity, as assessed by decreases in intracellular ATP content, was evident only in spheroids cotreated with LPS and TVX. In contrast, treatment of either spheroids or HPC cultures with TNF in the absence or presence of TVX did not result in consistent cytotoxicity. Levofloxacin (LVX) is in the same pharmacological class as TVX, but has far less IDILI liability; interestingly, there was no cytotoxic interaction with LVX and LPS or TNF. These results show that LPS-stimulated inflammatory mediator production and cytotoxicity occurred in 3D spheroid cultures containing NPCs cotreated with TVX. 2D-sandwich HPC cultures were less sensitive to cytotoxicity from the TVX-inflammation interaction, suggesting that spheroids may afford advantages in evaluating interactions between drugs and inflammatory mediators.

## PS 1078 Trovafloxacin Induces Cell Cycle Arrest and Sensitizes HepG2 Cells to TNF-Induced Cytotoxicity by an ATR-Dependent Mechanism.

K. M. Beggs<sup>1,3</sup>, K. Miyakawa<sup>2,3</sup>, M. A. Scott<sup>2</sup>, P. E. Ganey<sup>1,3</sup> and R. A. Roth<sup>1,3</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI; <sup>3</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Trovafloxacin (TVX) is an antibiotic associated with idiosyncratic hepatotoxicity in humans, though the mechanism for this toxicity is unknown. In mice, TVX is not hepatotoxic by itself but synergizes with tumor necrosis factor- $\alpha$  (TNF) to produce liver injury. Moreover, treatment with combinations of TVX and TNF were cytotoxic to HepG2 human hepatoma cells, whereas neither TVX nor TNF alone caused cytotoxicity. It was demonstrated previously that TVX is a weak inhibitor of eukaryotic topoisomerase-II  $\alpha$  activity and inhibits HepG2 cell proliferation. These results led to the hypothesis that signaling mechanisms important in cell cycle regulation contribute to cytotoxicity from TVX/TNF interaction. In HepG2 cells treated with both TVX and TNF, activities of caspases 9 and 3 were increased starting 8 hr after treatment, which is a time before the onset of cell death. Cytologic evaluation revealed that cells treated with TVX or with TVX/TNF were arrested in the prophase of mitosis compared to vehicle or TNF-treated cells, which appeared in all stages of the cell cycle. The PI3K-like kinases, ataxia telangiectasia mutated (ATM), ataxia telangiectasia and Rad3-related (ATR), and DNA protein kinase (DNAPK), as well as the tumor suppressor protein p53, all play a role in regulating cell cycle. Pharmacologic inhibitors of ATM, DNAPK, and p53 had no significant effect on the cytotoxicity caused by TVX/TNF treatment, whereas an inhibitor of ATR attenuated cytotoxicity. Taken together, these data suggest that increased activity of caspases 9 and 3 is associated with TVX/TNF-induced cytotoxicity of HepG2 cells and that ATR plays a role in this cell death response. (Supported by NIH grant R01DK061315.)

**PS 1079 MicroRNA Regulation of Alcoholic and Nonalcoholic Fatty Liver Disease.**

S. Kondraganti<sup>1</sup>, T. K. Varma<sup>2</sup>, B. S. Kaphalia<sup>1</sup> and G. Ansari<sup>1</sup>. <sup>1</sup>Pathology, The University of Texas Medical Branch, Galveston, TX; <sup>2</sup>Anesthesiology, The University of Texas Medical Branch, Galveston, TX.

Alcoholic liver disease (ALD) and non-alcoholic fatty liver disease (NAFLD) are histologically similar diseases as both induce fatty liver (hepatic steatosis) through mechanisms not yet fully understood. MicroRNAs (miRNAs), small non-coding RNAs are involved in regulation of various biological process and dysregulated microRNA expression is observed in various diseases including fatty liver. To understand the role of miRNAs in inducing hepatic steatosis, miRNAs were analysed in the livers of both ALD and NAFLD models. Male Fischer-344 rats were fed with or without 5% alcohol via Lieber-DeCarli diet for one, two or three months or L- aminoacid rodent diet with or without methionine-choline for one week. We observed differential expression of eleven miRNAs in both treatment models. Increased expression of miR-122 and miR-34a was observed in ethanol treated rat livers as time progressed while miR-122 expression decreased and no change in miR-34a expression was observed in rat livers fed with methionine-choline deficient (MCD) diet. Contrary, expression of miR-451 was increased in both ethanol fed rats with time as well as MCD diet fed rats. However, the increase in miR-451 expression was more pronounced in MCD diet fed rat livers. miR-122 is known to be involved in hepatic lipid metabolism and sterol synthesis, miR-34a is involved in lipid metabolism, cell cycle and apoptosis while miR-451 is involved in regulation of insulin dependent (gluconeogenesis) pathway. Our miRNA expression data also supported the differential regulation of genes involved in lipid metabolism such as sterol regulatory element-binding protein (SREBP), AMP-activated protein kinase (AMPK), peroxisome proliferator-activated receptor alpha (PPAR- $\alpha$ ), sirtuin-1 and acyl-CoA synthetase long-chain family member 1 (ACSL-1). In conclusion, our studies show that differential expression of miRNAs results in steatosis in both models but could be via different mechanisms.

**PS 1080 Characterization of HepaRG-EP Cells As a Surrogate for Primary Human Hepatocytes.**

J. J. Cali<sup>1</sup>, M. Sobol<sup>1</sup>, D. Ma<sup>1</sup> and D. Steen<sup>2</sup>. <sup>1</sup>Research, Promega Corporation, Madison, WI; <sup>2</sup>Biopredic International, Overland Park, KS. Sponsor: T. Riss.

HepaRG-EP (EP) cells are a next generation version of HepaRG (HRG), a human hepatoma cell line with substantial similarity to primary human hepatocytes (HH). We characterized cryopreserved EP from Biopredic International to evaluate their suitability as a HH surrogate for in vitro toxicity and ADME studies, and for comparison to HRG (Biopredic). The DMSO content of the EP cryopreservation medium was low enough for compatibility with a no spin thaw/recovery protocol that yielded about 90% viable cells (HRG required DMSO removal). One cryopreserved vial of EP provided for two full confluent 96 well plates of cells, which exceed the yield from typical commercially sourced vials of HH. EP cell viability was relatively constant over a period of 7 days in culture. Like HRG, EP established an adherent co-culture of hepatocytes and cholangiocytes but EP had a higher hepatocyte/cholangiocyte ratio. Consistent with this hepatocyte enrichment, EP also had higher activity for CYP1A2, -2D6, -2B6 but similar CYP3A4 activity, and these activities were within the range typically observed in HH. The initial EP CYP3A4 activity remained elevated for the first 24 hours, but then declined to a lower yet still robust level that averaged about 25% of the initial activity over the next 6 days. As a marker of metabolic capacity, the sustained CYP3A4 activity suggests EP will provide a good model for acute or extended drug metabolism studies. Omeprazole, phenobarbital and rifampicin respectively caused substantial inductions of CYP1A2, -2B6 and -3A4 activities with a more pronounced CYP1A2 response in EP compared to HRG. In common with HH, dose-dependent aflatoxin-B1 toxicity was observed with HRG and EP, indicating their competence for detecting metabolism-based toxicities. In summary, EP provides a convenient model for hepatotoxicity, metabolism and CYP induction studies with the reproducibility inherent to a cell line. For the properties tested EP is a reasonable HH surrogate with enhanced metabolic capacity and convenience over HRG.

**PS 1081 Use of a Multiparametric Assay on Isolated Mouse Liver Mitochondria to Predict Drug-Induced Liver Injury in Human.**

A. Borgne-Sanchez<sup>1</sup>, M. Porceddu<sup>1</sup>, N. Buron<sup>1</sup>, C. Roussel<sup>1</sup> and B. Fromenty<sup>2</sup>. <sup>1</sup>Mitologies Research Laboratory, Mitologies SAS, Paris, France; <sup>2</sup>INSERM U991, Faculté de Pharmacie, Rennes, France. Sponsor: N. Claude.

Drug-induced liver injury (DILI) is difficult to predict using classical in vitro assays and regulatory animal studies leading to interruption of clinical trials or even to market withdrawal after commercialisation. Consequently, drug-induced mito-

chondrial dysfunction should be detected early, ideally during pre-clinical screening of potential drug candidates. This could be done by investigation of drug-induced mitochondrial dysfunction which appears as a major mechanism of DILI. To achieve this detection, we have developed a dedicated high-throughput screening platform using isolated mouse liver mitochondria to measure several parameters related to mitochondrial function and integrity. Indeed, this multiparametric assay measures in isolated mouse liver mitochondria: 1) global mitochondrial membrane permeabilization (swelling), 2) transmembrane potential, 3) outer membrane permeabilization (cytochrome c release) and 4) oxygen consumption through respiratory chain complex I and complex II. A pool of 124 drugs was tested revealing a highly significant relationship between drug-induced mitochondrial toxicity and DILI occurrence in patients ( $P < 0.001$ ) with an excellent sensitivity (94 or 92% depending on cut-off) and a high positive predictive value (89 or 82%) [1]. Moreover, our study disclosed for the first time the identification of several drugs triggering mitochondrial toxicity. Investigation of drug-induced loss of mitochondrial integrity and function with this assay should be considered for integration into basic screening processes at early stage to select drug candidates with lower risk of DILI in human. This multiparametric assay is also a valuable tool for assessing the mitochondrial toxicity profile and investigating the mechanism of action of new compounds and marketed drugs.

**PS 1082 CAR Activation Increases Bile Flow, Excretion of Major Bile Acids, and Bile Acid Synthesis, As Well As Transport Genes in Mice.**

A. J. Lickteig, I. L. Csanaky, M. Pratt-Hyatt and C. D. Klaassen. *Internal Medicine (Division Gastroenterology), University of Kansas Medical Center, Kansas City, KS.*

Activation of Constitutive Androstane Receptor (CAR) has been shown to protect against bile acid (BA)-induced liver injury. However, the effect of CAR activation on bile flow, BA profile, and BA synthesis and transport genes in liver is not well understood. Therefore, the purpose of the present study was to determine the effect of CAR activation on BA homeostasis. The CAR ligand 1,4-Bis-[2-(3,5-dichloropyridyloxy)]benzene (TCPOBOP) was administered intraperitoneally (3 mg/kg) daily to male C57BL6/N wild-type mice for 4 days, followed by collection of serum, liver, and bile. BAs of serum and bile were quantified by UPLC-MS/MS. TCPOBOP induced a CAR-dependent increase in bile flow by 67%. TCPOBOP increased biliary excretion of two of the three quantitatively major bile acids in mice, T $\alpha$ MCA (3.5-fold) and T $\beta$ MCA (80%), as well as the quantitatively minor bile acids TUDCA (38%) and TCDCA (224%). Additionally, TCPOBOP increased biliary excretion of unconjugated bile acids by 74%. These increases in biliary excretion correlated with increased liver mRNA of the two major canalicular efflux transporters Mrp2 (3.2-fold) and Bsep (2.4-fold). Interestingly, TCPOBOP induced BA synthesis genes Cyp7a1 (4.3-fold) and Cyp27a1 (110%). Also in livers of TCPOBOP-treated mice, the sinusoidal efflux transporters Mrp3 (17-fold) and Mrp4 (14-fold) were markedly increased. Surprisingly, there were no changes in serum concentrations of total BAs, taurine-conjugated BAs, unconjugated BAs, or primary BAs, but the serum secondary BAs were decreased 61%. In summary, while CAR activation has relatively minor effects on serum BA profile, CAR activation increases bile flow and biliary excretion of T $\alpha$ MCA, T $\beta$ MCA and total unconjugated BAs. (R01ES009649, R01DK081461, F32DK092069)

**PS 1083 Role of Aryl Hydrocarbon Receptor (AhR) in Maintaining Plasma Concentrations and Biliary Excretion of Bile Acids.**

I. L. Csanaky, A. J. Lickteig, M. Pratt-Hyatt and C. D. Klaassen. *Department of Internal Medicine, University of Kansas Medical Center, Kansas City, KS.*

Failure in regulation of bile acid (BA) homeostasis contributes to several liver diseases. It is generally accepted that hepatic FXR-SHP and intestinal Fgf15/19 regulate BA homeostasis. However, the contribution of other hepatic transcription factors to BA homeostasis is not clear. The adaptive role of the aryl hydrocarbon receptor (AhR) in protecting against BA related liver damage is unknown. The AhR may be critical for mediating an adaptive response that involves induction of genes responsible for the metabolism or transport of BAs. To study the role of the AhR in BA homeostasis, sera, livers, and bile of 12-week-old male wild-type and AhR-null mice were collected, and BA concentrations in serum and bile, as well as the mRNA expression of hepatic BA synthesis and transport genes were quantified. Surprisingly the lack of AhR increased serum total BAs (62-fold), taurine conjugated-BAs (52-fold), and unconjugated-BAs (113-fold). Similarly the biliary excretion of total BAs (2.3-fold), taurine conjugated-BAs (2.3-fold), and unconjugated-BAs (3.8-fold) increased in AhR-null mice compared with controls. In livers of

AhR-null mice the mRNA expression of Fgfr4 (111%), SHP (83%), Cyp7a1 (170%), Cyp8b1 (70%), BAL (60%), Bsep (50%), and Mrp3 (80%) were increased, whereas Cyp7b1 (-64%) was decreased in comparison to wild-type mice. In conclusion, lack of the AhR receptor results in an increase in (1) mRNA of the majority of BA synthesis and transport genes, (2) conjugated and unconjugated BAs in serum, as well as (3) the biliary excretion of conjugated and unconjugated BAs. These findings suggest that AhR has a fundamental role in suppressing synthesis, transport, plasma concentrations, and biliary excretion of BAs. (Supported by NIH grants ES009649, ES013714, DK092069)

#### PS 1084 Screening of AMPK Activator from Herbal Extract.

S. Lee and M. Dong. *School Lifesciences and Biotechnology, Korea University, Seoul, Republic of Korea.* Sponsor: B. Lee.

AMP-activated protein kinase (AMPK) is a key sensor and regulator of glucose, lipid, and energy metabolism throughout the body. Activation of AMPK improves metabolic abnormalities associated with metabolic diseases including obesity and type-2 diabetes. AMPK phosphorylation inhibits sterol regulatory element-binding protein-1 (SREBP-1) activity which plays an important role in lipid metabolism. In this study, we established in vitro screening methods for potential activators of AMPK from herbal extracts to develop the inhibitor of hepatic steatosis. First, the phosphorylation of AMPK and its substrate ACC-1 were screened by In-cell-western assay which is an immunocytochemical assay performed in 48 well-microplate format and then confirmed them using Western blot in HepG2 cells. Oil Red O staining is performed to observe the accumulation of lipid droplets in cell and then tested the expression of genes related lipid synthesis and metabolism. When we screened over 50 herbal extracts, we found three extracts which were significantly increased the phosphorylation of AMPK and its substrate ACC-1 in a dose-dependent manner. They also reduced the palmitic acid induced lipid droplets accumulation determined by Oil Red O staining. Among them, one extract was selected and observed SREBP-1 transcriptional activity using a SRE-luc reporter gene assay and SREBP-1 target genes expression using RT-PCR. In this study, we could identify the natural extracts for the development of AMPK activator for diabetes and the metabolic syndrome.

#### PS 1085 Gender Differences in mRNA and Protein Expression of Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) and Nrf2-Dependent Genes.

P. Rohrer and J. E. Manautou. *Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor that positively regulates the expression and activity of cytoprotective genes during periods of oxidative stress. It has previously been shown that some of these cytoprotective genes are more highly expressed in livers of female than male mice. This could explain previously reported gender-related differences in susceptibility to acetaminophen (APAP) hepatotoxicity in mice. In this study, we examined the presence of differences in basal mRNA and protein expression for Nrf2 and Nrf2-dependent genes between naïve fed male and female mice. Hepatic mRNA and protein levels were measured by quantitative PCR and western blotting, respectively. Basal Nrf2 mRNA expression was significantly lower in livers of female than male mice. Furthermore, mRNA expression of the Nrf2-regulated genes NAD(P)H quinone oxidoreductase 1 (Nqo1), heme oxygenase 1 (Ho-1) and multidrug resistance-associated protein transporter 4 (Mrp4) was less pronounced in livers of male than female mice, although these differences were not statistically significant. Conversely, mRNA levels of glutamate cysteine ligase catalytic subunit (Gclc), glutamate cysteine ligase modifier subunit (Gclm), and multidrug resistance-associated protein transporter 3 (Mrp3) appeared more pronounced in male mice than female mice, but these difference were not significant either. Protein levels of Nqo1 and Mrp4 were similar between genders, while protein levels of Mrp3 and Gclm were significantly lower in livers of female than male mice. In agreement with mRNA levels of Nrf2, lower protein expression of Nrf2 was seen in female mice, although this difference was not significant. Collectively, these results indicate that female mice do not have higher global expression of Nrf2-related genes and that other factors might be responsible for the lower susceptibility of female mice to APAP hepatotoxicity. Supported by NIH DK069557.

#### PS 1086 Metabolomics Evaluating Protective Effects of Green Tea Extract on Acetaminophen-Induced Hepatotoxicity in Mice.

J. Sun<sup>1</sup>, Y. Lu<sup>1,2</sup>, X. Yang<sup>1</sup>, J. Greenhaw<sup>1</sup>, W. F. Salminen<sup>1,3</sup>, D. L. Mendrick<sup>1</sup> and R. D. Beger<sup>1</sup>. <sup>1</sup>NCTR/US FDA, Jefferson, AR; <sup>2</sup>Jiangsu Institute for Food and Drug Control, Jiangsu, China; <sup>3</sup>PAREXEL International, Boston, MA.

Green tea has a considerable amount of polyphenolic catechins (potent antioxidants) and it has shown to have protective effects on oxidative stress-related diseases. Acetaminophen (APAP) is a widely used analgesic drug that can cause liver injury if overdose. The aim of this study was to explore the effects of green tea extract (GTE) on APAP-induced hepatotoxicity using an LC/MS-based metabolomic approach. Male B6C3F1 mice were orally administered GTE (500 or 1000 mg/kg) either 3 h prior to 200 mg APAP/kg oral treatment, or for three consecutive days (once daily) followed by 300 mg APAP/kg on the fourth day. Blood and liver tissue samples were collected 24 h after APAP administration for clinical chemistry, histopathological and metabolomic analysis. LC/MS-based metabolomics profiling was utilized to examine metabolic changes in liver extracts. The partial least squares discriminant analysis of the LC/MS data showed that groups dosed with APAP alone were the most distinct from controls, while animals dosed with 500 mg GTE/kg followed by APAP treatment were located between these two and those pre-treated with 1000 mg GTE/kg groups were nearest to control group. These results were consistent with histopathological data showing that 3h single or 3d consecutive dosing with 1000 mg GTE/kg prior to APAP exposure significantly alleviated some of the hepatocyte necrosis. Similar results were observed for ALT and AST. Dose dependent changes were observed in the energy pathway-related metabolites, including acylcarnitines (mitochondrial injury biomarker) and lysophosphatidylcholines, which returned to controls levels after 3h or 3d consecutive dosing GTE prior to APAP treatment compared to APAP treatment alone. These results indicate that GTE treatments prior to APAP dosing could relieve liver injury.

#### PS 1087 Oleoic Acid Produces Cholestatic Liver Injury in Mice.

J. Liu, Y. Lu, Y. Zhang, K. C. Wu and C. D. Klaassen. *Internal Medicine, University of Kansas Medical Center, Kansas City, KS.*

Oleoic acid (OA) is a triterpenoid that exists widely in fruits and medicinal herbs. OA is effective in protecting against hepatotoxins. However, we recently found that whereas a low dose of OA is hepatoprotective, higher doses and long-term use of OA produce cholestasis. This study characterized OA-induced cholestatic liver injury. Adult C57BL/6 mice were given OA at doses of 0, 50, 100, 200, and 300 µmol/kg, sc (suspended in 2% Tween-80 saline) for 5 days, and cholestatic liver injury was observed at doses of 200 µmol/kg and above, as evidenced by increases in serum total bilirubin, serum activities of alanine aminotransferase and alkaline phosphatase, as well as by histopathology with feathering-like degeneration indicative of cholestasis. Serum bile acid (BA) concentrations were dramatically increased not only for unconjugated bile acids (CA, CDCA, DCA, αMCA and βMCA), but also for taurine conjugated bile acids (TCA, TCDCA, TDCA, TUDCA, and TaβMCA), as determined by UPLC-MS/MS. The mRNAs of hepatic bile acid uptake transporter for unconjugated BAs Oatp1b2 and conjugated BAs Ntcp, as well as canalicular efflux transporter Bsep were decreased in a dose-dependent manner. OA decreased OSTα but increased OSTβ. Hepatic uptake transporter Oatp1a1, 1a4, and 2b1 were suppressed, while the efflux transporters Abca1, Abst, and Bcrp were increased. OA decreased the mRNA of the nuclear receptors CAR, FXR, PPARα, but had no effects on AhR and PXR. The mRNA of the BA biosynthesis limiting enzyme Cyp7a1 was decreased. Taken together, higher doses of OA produces cholestatic liver injury in mice and this effect appears to be associated with the alteration of liver transporters resulting in disruption of BA homeostasis.

#### PS 1088 Apoptogenic, Necrogenic, and Unique Patho-Morphological Changes Induced by Bio-Activation-Dependent Hepatotoxins.

P. Patel, M. E. Kiersma and S. D. Ray. *Pharmaceutical Sciences, Manchester University College of Pharmacology, Fort Wayne, IN.*

The diagnosis of drug-induced liver disease is an intriguing question often accompanied by insufficient clinical data and the difficulty of interpreting histopathology after exposure to toxins. This study investigated the histopathological changes induced by several different bioactivation-dependent hepatotoxins, such as, acetaminophen (an analgesic; 500mg/Kg, ip), carbon tetrachloride (CCl4; a hepatotoxin), dimethylnitrosamine (DMN; a potent carcinogen), doxorubicin (DOX; an antineoplastic agent), furosemide (FUR; a loop diuretic) and streptozotocin (STZ;

an inducer of hyperglycemia) to characterize most common and most uncommon pathological traits in order to hypothesize whether a subset of lesions can be used to diagnose toxicity profile of a particular toxin. Mice were administered CCl<sub>4</sub> (1ml/Kg, po), DMN (50 mg/Kg, ip), DOX (60 mg/Kg, ip), Fur (500 mg/Kg, ip) and STZ (100 mg/Kg, ip 2 consecutive doses) and sacrificed 24-72 hours later. Blood was collected for serum chemistry and liver sections for histopathology. PAS or H&E stained liver sections were examined under a brightfield microscope to determine similarities concerning: sinusoidal dilatation, centrilobular necrosis, excessive vacuolization, cells with apoptotic morphology, microvesicular steatosis, ballooning degeneration, pericentral or periportal or indiscriminate necrosis, glycogen depletion trend, inflammation, and formation of ground glass hepatocytes. Results indicated that all the toxins caused massive liver injury with limited overlapping profiles. The most common features were indiscriminate glycogen depletion and ballooning of hepatocytes. Results also indicated various other characteristic morphological changes such as macrovesicular steatosis, bridging necrosis, portal tract fibrosis and some unique but yet to be reported feature induced by DOX, i.e., prominent sinusoidal dilation. Thus, our study made a serious effort in differentiating and profiling the varied patho-morphological changes induced by diverse hepatotoxins. [Suppo. by Dept. of PSCs, AMS Coll of Pharm & HSCs]

### PS 1089 Cholestyramine Liver Effects in Healthy Human Subjects.

R. Singhal<sup>1</sup>, A. H. Harrill<sup>3</sup>, F. Menguy-Vacheron<sup>2</sup>, Z. Jayyosi<sup>1</sup>, H. Benzerdjeb<sup>2</sup> and P. Watkins<sup>3</sup>. <sup>1</sup>Sanofi, Inc., Framingham, MA; <sup>2</sup>Sanofi, Chilly-Mazarin, France; <sup>3</sup>The Hammer Institute, Research Triangle Park, NC.

Cholestyramine is an orally administered, an ion exchange non-absorbable resin with a high affinity for biliary acids used as a cholesterol lowering agent as well as to accelerate clearance from the body of xenobiotics and to treat itching in patients with advanced cholestatic liver disease. This treatment has been associated with elevations in serum alanine aminotransferase (ALT), a sensitive biomarker of liver injury, but has never been associated with clinically important liver injury. A recent clinical trial in healthy adults receiving cholestyramine provided an opportunity to use current serum biomarkers to investigate mechanisms underlying this phenomenon. After a double blind, placebo controlled study cholestyramine (8 gm/tid X 11 days) was administered to healthy adult subjects to accelerate clearance of the new drug candidate given in the active arm. During cholestyramine therapy, eleven subjects previously treated with placebo experienced elevations in serum ALT levels exceeding three-fold the upper limit of normal (>3x ULN; mean 6.9 fold; range 3-28 fold). Serum samples from those subjects were assayed for additional mechanistic biomarkers. Compared to predose baseline values, there was a significant (<0.05) 13-fold mean increase in miR-122 confirming a liver source for the serum ALT. Mean serum levels of GLDH (8-fold), cytokeratin 18, and HMGB1 (1.7 fold) were elevated supporting ongoing necrosis. Caspase-cleaved cytokeratin 18 was also increased (1.7 fold) supporting apoptosis. Serum ALT elevations observed during cholestyramine treatment reflect both hepatocellular necrosis and apoptosis. The wealth of clinical data available with cholestyramine indicate that this effect on the liver is self-limited and not a significant safety concern.

### PS 1090 Sterile Inflammation and Neutrophil Activation during Injury Resolution following Acetaminophen Overdose in Mice and Humans.

C. D. Williams, M. R. Sharpe, M. R. McGill, M. Bajt and H. Jaeschke. <sup>1</sup>UAMS, Little Rock, AR; <sup>2</sup>Arkansas Children's Nutrition Center, Little Rock, AR.

Following acetaminophen (APAP)-overdose, there is a robust inflammatory response triggered by the release of cellular contents from necrotic hepatocytes into systemic circulation which recruits neutrophils (PMNs) into the liver. PMNs do not contribute to APAP-induced injury in mice, but their role, and the role of NADPH oxidase, in injury resolution is unclear. C57BL/6 mice were treated with APAP and were euthanized (6h - 72h) for assessment of liver injury and regeneration. Informed and consented human APAP-overdose patients (ALT >800U/L) had serial blood draws during injury and recovery phases for determination of liver function tests (LFTs) and flow cytometric analysis. Blood PMNs (mouse, human) and liver PMNs (mouse) were evaluated by flow cytometry (CD11b, reactive oxygen priming, phagocytosis). To test the importance of phagocyte ROS production, gp91phox-/- (NADPH oxidase defective) mice were compared to C57BL/6 mice for hepatocyte proliferation and injury resolution. PMNs in the peripheral blood of mice showed increasing activation status during and after the peak of injury but returned to baseline levels prior to injury resolution. Hepatic sequestered PMNs showed an increased and sustained CD11b expression, but no ROS priming was

observed. Confirming that NADPH oxidase is not essential for recovery, gp91phox-/- mice following APAP-overdose displayed no difference in injury resolution. APAP-overdose patients also showed increased PMN activation status after the peak of injury, and PMNs remained in an activated state even as LFTs began to normalize. The time course of PMN activation status in the peripheral blood was similar in mice and humans, and markers of activation were increased and sustained well after active liver injury had subsided. The similar findings between surviving patients and mice indicate PMN activation may be a critical event for injury resolution following APAP-overdose in man, but not a contributing factor to APAP-induced injury.

### PS 1091 Ethyl Tertiary-Butyl Ether Induces Oxidative Stress and 8-OHdG Formation in the Liver of F344 Rats via Activation of CAR, PXR and PPAR Nuclear Receptors.

A. Kakehashi<sup>1</sup>, A. Hagiwara<sup>2</sup>, N. Imai<sup>2</sup>, Y. Doi<sup>2</sup>, K. Nagano<sup>3</sup>, M. Banton<sup>4</sup>, F. Nishimaki<sup>5</sup>, H. Wanibuchi<sup>1</sup> and S. Fukushima<sup>6</sup>. <sup>1</sup>Department Pathology, Osaka City University Graduate School of Medicine, Osaka, Japan; <sup>2</sup>DIMS Institute of Medical Science, Ichinomiya, Japan; <sup>3</sup>Nagano Toxicologic-Pathology Consulting, Kanagawa, Japan; <sup>4</sup>Toxicology and Risk Assessment, LyondellBasell Corporate HSE, Houston, TX; <sup>5</sup>Japan Petroleum Energy Center, Tokyo, Japan; <sup>6</sup>Japan Bioassay Research Center, JISHA, Kanagawa, Japan.

To elucidate the mode of action (MOA) of hepatotumorigenicity in rats for non-genotoxic chemical ethyl tertiary-butyl ether (ETBE), male F344 rats were treated with ETBE at doses of 300 and 2000 mg/kg/day by gavage and 500 ppm phenobarbital (PB) in diet for the comparison analysis for 1 and 2 weeks. Significant increases of hydroxyl radicals and P450 total content levels at weeks 1 and 2 in 300, 2000 mg/kg/day ETBE and PB groups accompanied the accumulation of P450 isoenzymes CYP2B1/2, CYP3A1/2 and CYP2C6 in the cytoplasm of hepatocytes. Specific up-regulation of CYP2E1 and CYP1A1 was obvious in the high dose ETBE group. Conspicuous elevation of 8-hydroxydeoxyguanosine (8-OHdG) and apoptosis in the liver tissue observed in 2000 mg/kg/day ETBE and PB groups was associated with suppression of Ki-67 positive-cell index, cyclin D1 mRNA expression and down-regulation of 8-OHdG repair enzyme, DNA glycosylase 1 (Ogg1) after 2 weeks of application. Results of QSTAR LC/MS/MS and IPA analyses indicated that upstream regulators of gene expression altered by ETBE included CAR, PXR and PPAR. High dose ETBE induced peroxisome proliferation in hepatocytes at week 2 detected by TEM. These results indicated that MOA of ETBE hepatotumorigenicity in rats is due to induction of oxidative stress and 8-OHdG formation, subsequent cell cycle arrest and apoptosis, suggesting regenerative cell proliferation, predominantly induced by activation of CAR and PXR nuclear receptors by a mechanism similar to that of PB, and furthermore peroxisome proliferation by specific activation of PPAR. The MOA of ETBE hepatotumorigenicity in rats is indicated to be not relevant to human.

### PS 1092 Expression Profiles of Hematopoietic Stem Cell, Endothelial Cell, and Myeloid Cell Antigens in Spontaneous and Chemically Induced Hemangiomas and Hemangiosarcomas in Mice.

S. Kakiuchi-Kiyota<sup>1,2</sup>, C. A. Torrie<sup>3</sup>, L. L. Arnold<sup>1</sup>, K. L. Pennington<sup>1</sup>, J. C. Cook<sup>2</sup>, D. Malarkey<sup>4</sup> and S. M. Cohen<sup>1</sup>. <sup>1</sup>Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE; <sup>2</sup>Drug Safety Research & Development, Pfizer Inc., Groton, CT; <sup>3</sup>Experimental Pathology Laboratories, Research Triangle Park, NC; <sup>4</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

It is unclear whether the process of spontaneous and chemically induced hemangioma (HA) and hemangiosarcoma (HS) formation in mice involves the transformation of differentiated endothelial cells (ECs) or recruitment of multipotential bone marrow-derived hematopoietic stem cells or endothelial progenitor cells (EPCs) which show some degree of endothelial differentiation. In the present study, immunohistochemical staining for hematopoietic stem cell markers (CD45 and CD34), EC markers (VEGFR2, CD31, and Factor VIII-related antigen (FVIII RAg)), and a myeloid lineage marker (CD14) was used to assess the origin of HA and HS in mice and compare with results of canine and human EC tumors reported in previous literature. We showed that the staining for CD45, FVIII RAg, and CD14 was negative in spontaneous and chemically induced HA and HS, whereas cells stained positive for CD34, VEGFR2, and CD31 in these tumors. These results indicate that mouse HA and HS are composed of cells derived from EPCs expressing CD34, VEGFR2, and CD31, but not FVIII RAg. The lack of

CD45 expression suggests that mouse vascular tumors may arise from EPCs that are at a stage later than hematopoietic stem cells. Since FVIII RAg expression is known to occur later than CD31 expression in EPCs, our observations may indicate that these tumor cells are arrested at a stage prior to complete differentiation, in contrast to vascular tumor cells in humans and canines, which express both CD31 and FVIII RAg. In addition, unlike human infantile HA or canine HS, myeloid lineage cells do not appear to contribute to HA and HS formation in mice. Our results may indicate that mouse HA and HS may arise by a different mechanism than canine or human EC tumors.

### PS 1093 Role of the Circadian Clock in the Differential Susceptibility of Rat Strains to Mammary Carcinogenesis.

M. Fang and H. Zarbl. *Environmental Occupational Medicine, University of Medicine and Dentistry of New Jersey, Piscataway, NJ.*

Disruption of circadian rhythm is associated with increased risk of breast cancer incidence and malignancy. DNA damage responsive and repair pathways are controlled by and also modulate the molecular circadian oscillators. In order to investigate the role of the circadian clock on the susceptibility to mammary tumor, we compared circadian expression patterns of genes involved in circadian rhythm and DNA damage responsive and repair pathways in mammary glands of susceptible Fisher 344 (F344) and resistant Copenhagen (COP) rats. The mammary tissue of susceptible F344 rats showed a 4-hr delay in the rhythmic expression of clock genes (e.g., *Per2* and *Bmal1*) and much higher amplitude on *Rev-ErbA $\alpha$*  expression compared to resistant COP rats. In mammary glands of COP rats, 45.1% of DNA responsive and repair genes (total 82 genes) were up-regulated in a circadian pattern with peak expression levels over 2 folds at Zeitgeber Time (ZT)12 (lights off) compared to ZT0 (lights on). By contrast, in the susceptible F344 rats, 30.5% of these genes showed a circadian pattern of down-regulation, with only one gene being up-regulated in the active phase. Exposure to a single carcinogenic dose of N-nitroso-N-methylurea (NMU) disrupted the rhythmic expression of *Per2* in mammary gland of F344 rats after two days and further abolished after 30 days. In contrast, NMU induced a significant increase in the rhythmic expression of *Per2* gene in the COP rats in 2 days, and the increase was sustained for at least 30 days post exposure. Moreover, the ratio of NAD<sup>+</sup>/NADH and NAD<sup>+</sup>-dependent Sirt1 activity, were also significantly increased in NMU-treated COP, but were dramatically decreased in treated F344 rats. Taken together, we speculate that the genetic block to tumor progression in COP is, at least in part, due to the ability to maintain or enhance circadian rhythm, and hence DNA repair upon exposure to carcinogens. (Supported by NIEHS grants, U19ES011387, P30ES007033, and P30ES005022).

### PS 1094 Transcriptomic Profiling of Hepatoblastomas and Associated Hepatocellular Carcinomas in B6C3F1 Mice.

S. Bhusari<sup>1</sup>, A. Pandiri<sup>1,4</sup>, Y. Wang<sup>1</sup>, J. Foley<sup>1</sup>, H. Hong<sup>1</sup>, T. Ton<sup>1</sup>, K. R. Shockley<sup>2</sup>, S. Peddada<sup>2</sup>, K. E. Gerrish<sup>3</sup>, D. Malarkey<sup>1</sup>, R. Sills<sup>1</sup> and M. Hoenerhoff<sup>1</sup>. <sup>1</sup>Cellular and Molecular Pathology, National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>Biostatistics Branch, NIEHS, Research Triangle Park, NC; <sup>3</sup>Microarray Core, NIEHS, Research Triangle Park, NC; <sup>4</sup>Experimental Pathology Laboratories, Research Triangle Park, NC.

The cell of origin of hepatoblastoma (HB) is unknown; it is thought to be a transformed hepatocyte, an oval cell, or a multipotent hepatic progenitor cell. Many investigators believe that HBs arise solely within hepatocellular carcinoma (HCC), and therefore are a more malignant form of HCC. Comparison of differential gene expression changes in HB to HCC in which they arise may identify alterations specific to each tumor type, as well as alterations shared by both tumor types. Such studies may provide information on the possible cell of origin and pathogenesis of these tumors. In the current study, frozen samples from chemically-induced HB, associated HCC, tumor-associated normal (AN) liver, and vehicle control normal (VN) liver from a 2-year National Toxicology Program (NTP) bioassay were laser capture microdissected from B6C3F1 mouse liver tumor samples. RNA was isolated, amplified, and global gene expression profiling was performed to identify differential transcriptomic changes between sample groups. Principal component analysis of the normalized transcriptomic data showed that the HB samples clustered distinctly from HCC. When compared to AN, there were increased numbers of differentially expressed genes in HB (10,386 genes) compared to HCC (1,073 genes). Genes involved in Wnt/ $\beta$ -catenin signaling, hepatic embryonic stem cell-like phenotype and genomic imprinting were significantly altered in HB compared to HCC, pathways prominent in human HB pathogenesis. Meta-analysis of HB tumors revealed high concordance with murine embryonic liver E10.5 to 12.5d gene expression. Understanding the molecular differences between HB and HCC

will provide a more accurate assessment of the pathogenesis of chemically-induced HB and HCC, and may have an impact on hazard identification of compounds important in human health risk.

### PS 1095 Methionine Sulfoxide Stimulates Hepatocarcinogenesis in Mouse; Possible Role of Free Radical-Mediated DNA Methylation.

K. Kawai<sup>1</sup>, H. Kasai<sup>1,4</sup>, Y. Li<sup>1</sup>, M. Song<sup>1</sup>, A. Kakehashi<sup>2</sup>, H. Wanibuchi<sup>2</sup> and A. Ootsuyama<sup>3</sup>. <sup>1</sup>Department of Environmental Oncology, University of Occupational and Environmental Health, Kitakyushu, Japan; <sup>2</sup>Department of Pathology, Osaka City University Medical School, Osaka, Japan; <sup>3</sup>Department of Radiation Biology, University of Occupational and Environmental Health, Kitakyushu, Japan; <sup>4</sup>OHG Institute, Kitakyushu, Japan.

Methylation of the cytosine C-5 position in the promoter region of tumor suppressor genes is an important mechanism of carcinogenesis in addition to gene mutation. However, the actual mechanisms of de novo methylation are not clear. We have reported the formation of 5-methylcytosine from cytosine in vitro, with methyl radicals generated from methionine sulfoxide (MetO). To confirm this reaction in vivo, MetO was added to the drinking water and administered to non-alcoholic steatohepatitis (NASH) mice, which develop hepatitis caused by endogenous oxidative stress. All of the animal experimental procedures were performed in accordance with the guidelines for the care and use of laboratory animals at Univ. Occup. Environ. Health. Histopathological examinations revealed incidences of hepatocellular carcinoma of 16.7% and 90% in the 0% and 3% MetO groups, respectively. Higher DNA methylation was detected in the promoter region of the *p16* gene isolated from the livers of MetO-treated mice. The higher incidence of liver tumors may be due to the methyl radical-mediated formation of 5-methylcytosine in DNA, which triggers epigenetic changes.

### PS 1096 Differential Activation of Mitogenic Signaling through the Insulin Receptor or the Insulin-Like Growth Factor 1 Receptor of Various Clinical Relevant Insulin Analogues.

B. ter Braak<sup>1</sup>, K. Siezen<sup>3</sup>, B. van de Water<sup>1</sup> and J. van der Laan<sup>2,3</sup>. <sup>1</sup>Toxicology, LACDR, Leiden University, Leiden, Netherlands; <sup>2</sup>National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands; <sup>3</sup>Medicines Evaluation Board (MEB), Utrecht, Netherlands.

Several epidemiological studies suggest an association between the use of some insulin analogues and cancer incidence in diabetic patients. Different insulin analogues might affect the affinity and activation of these analogues towards the insulin receptor (INSR) and the insulin-like growth factor 1 receptor (IGF1R). A switch towards higher IGF1R affinity is likely to emphasize cellular signalling pathways that promote mitogenesis rather than glucose metabolism.

To investigate this hypothesis we have performed in vitro exposure experiments with several insulin analogues including glargine, AspB10, aspart, glulisine, lispro and detemir. To separate INSR versus IGF1R activation motifs of these analogues, we used human breast cancer cell lines (MCF7) that either ectopically express the INSR (A or B isoform) in conjunction with a stable knockdown of the IGF1R, or the IGF1R in conjunction with a stable knockdown of the INSR. Using Western blots we measured the activation of INSR and IGF1R as well as downstream mitogenic signalling cascades including ERK and Akt. We revealed differences in activation patterns between the different insulin analogues tested. While insulin primarily acted through the INSR, the mitogenic signalling activation pattern of the long-acting insulin glargine was highly similar to that of known mitogenic compounds like insulin AspB10 or insulin like growth factor 1 (IGF1) and acted mainly via the IGF1R. These findings correlated with the proliferative effect of insulin glargine: at low insulin glargine concentrations a clear increase in cell proliferation was observed. This occurred despite the fact that the EC50 for the proliferative effect was not much different from regular insulin. Therefore, these data suggest that insulin glargine is similar in mitogenic potency to AspB10 and IGF1, at least at low and presumably physiological concentrations.

**PS 1097 Deletion of Hepatocyte Nuclear Factor 4 Alpha Promotes Diethylnitrosamine-Induced Hepatocellular Carcinoma.**

C. Walesky<sup>1</sup>, S. Gunewardena<sup>2</sup>, G. Edwards<sup>1</sup>, P. Borude<sup>1</sup> and U. Apte<sup>1</sup>.  
<sup>1</sup>Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS; <sup>2</sup>Kansas Intellectual and Developmental Disabilities Research Center, University of Kansas Medical Center, Kansas City, KS.

HNF4 $\alpha$  is known as the master regulator of hepatocyte differentiation. However, role of HNF4 $\alpha$  in regulation of hepatocyte proliferation is not known. We investigated role of HNF4 $\alpha$  in regulation of hepatocyte proliferation using a novel tamoxifen-inducible hepatocyte specific HNF4 $\alpha$  knockdown mouse model. Hepatocyte specific deletion of HNF4 $\alpha$  in adult mice resulted in increased hepatocyte proliferation with a significant increase in liver/body weight ratio. RNA sequencing-mediated global gene expression analysis revealed that a significant number of the 500+ up-regulated genes are associated with cell proliferation and cancer. Further, a combined bioinformatics analysis of ChIP-sequencing and RNA-sequencing data indicated that a substantial number of up regulated genes are putative HNF4 $\alpha$  targets. IPA-mediated functional analysis revealed the most significantly activated gene network after HNF4 $\alpha$  deletion is regulated by c-Myc. To determine role of HNF4 $\alpha$  in pathogenesis of HCC, we performed the classic initiation-promotion experiment using diethylnitrosamine (DEN). Deletion of HNF4 $\alpha$  resulted extensive promotion of DEN-induced hepatic tumors. HNF4 $\alpha$  deletion resulted in 4-fold higher hepatic tumors, which were highly proliferative and less differentiated. Further, the HCC observed in HNF4 $\alpha$  deleted mice exhibited significant up regulation of c-Myc and its target genes. These data indicate that HNF4 $\alpha$  inhibits hepatocyte proliferation, is a potential tumor suppressor in the liver and plays a critical role in chemical carcinogenesis.

**PS 1098 EGCG Elicits Stage-Specific Sensitivity in a Novel Prostate Cancer Progression Model.**

M. A. Moses<sup>1</sup>, W. A. Ricke<sup>2</sup> and T. A. Gasiewicz<sup>3</sup>. <sup>1</sup>Department of Pathology, University of Rochester, Rochester, NY; <sup>2</sup>Department of Urology, University of Wisconsin-Madison, Madison, WI; <sup>3</sup>Department of Environmental Medicine, University of Rochester, Rochester, NY.

Epigallocatechin gallate (EGCG), a major tea catechin, has been shown to have protective effects in a mouse model of PRCA, however, the relevance to human PRCA and the mechanism of action are less understood. We made the novel discovery that EGCG is a heat shock protein 90 (hsp90) inhibitor. Therefore, we utilized non-tumorigenic, tumorigenic, and metastatic PRCA cells from a human PRCA progression model to test the hypothesis that malignant cells are more sensitive to EGCG in a stage-specific manner and that sensitivity is related to the ability of EGCG to act as a hsp90 inhibitor. Treatment of cells with EGCG (25-50 $\mu$ M) *in vitro* decreased the viability and proliferation, and induced apoptosis selectively in PRCA cells compared to non-tumorigenic cells. EGCG also led to a decrease in the motility of tumorigenic PRCA cells, as analyzed by scratch assay, at the same concentrations tested. Moreover, when tumorigenic or metastatic cells were grown *in vivo*, mice supplemented with 0.06% EGCG in drinking water had significantly smaller tumors than those of the untreated group. To elucidate the mechanism of EGCG sensitivity, we performed affinity chromatography with EGCG-sepharose. Binding assays revealed that hsp90 from metastatic cells had a higher affinity for EGCG than non-tumorigenic cells. Furthermore, EGCG disrupted hsp90 complex formation, as analyzed by Native PAGE, leading to an accumulation of dimeric hsp90, and promoted the degradation of hsp90-client proteins such as HER2, p-Akt, and Raf1 in metastatic cells at concentrations that affected viability. These data suggest that EGCG may be an efficacious small molecule for the treatment of PRCA because it selectively targets PRCA cells and inhibits a molecular chaperone involved in many pro-cancer signaling cascades. Future studies will test if analogs of EGCG are more stable/bioavailable, and therefore more potent hsp90 inhibitors, for the treatment of PRCA. Funded by NIH Grant AT006366.

**PS 1099 Fluopyram: Mechanistic Investigations to Elucidate the Moa for Thyroid Tumor Formation in the Mouse.**

D. Rouquié<sup>1</sup>, O. Blanck<sup>1</sup>, H. Tinwell<sup>1</sup>, P. Maliver<sup>1</sup>, F. Schorsch<sup>1</sup>, S. Wason<sup>1</sup>, D. Geter<sup>2</sup> and R. Bars<sup>1</sup>. <sup>1</sup>Bayer CropScience, Sophia Antipolis, France; <sup>2</sup>Bayer CropScience, Research Triangle Park, NC.

Fluopyram, a broad spectrum fungicide, caused an increased incidence of thyroid follicular cell (TFC) adenomas in males at the highest dose evaluated (750 ppm equating to 105 mg/kg/d) in the mouse oncogenicity study. Mechanistic studies were conducted in the male mouse to characterize the mode of action (MoA) for the thyroid tumor formation and to determine if thresholds exist for each key event. The proposed MoA consists of an initial effect on the liver by activating the

constitutive androstane (CAR) and pregnane X (PXR) nuclear receptors causing increased elimination of thyroid hormones followed by an increased secretion of in thyroid stimulating hormone (TSH). This change in TSH secretion results in an increase of TFC proliferation which leads to hyperplasia and eventually adenomas after chronic exposure. CAR/PXR nuclear receptors were shown to be activated from as early as 3 days of treatment as indicated by increased activity of specific Phase I enzymes (PROD and BROD respectively). Furthermore, evidence of increased T4 metabolism was provided by the induction of phase II enzymes known to preferentially use T4 as a substrate. Additional support for the proposed MoA was given by an increase of Tsh transcripts in the pituitary gland. Finally, increased TFC proliferation (BrdU incorporation) was observed after 28 days of treatment. In these dose response studies, clear thresholds were established for liver enzyme activities, T4 and TSH changes and TFC proliferation. Furthermore, each early change was shown to be reversible following fluopyram withdrawal. In conclusion, these studies indicate that fluopyram is a threshold carcinogen and the resultant increased incidence of TFC adenoma in the male mouse is mediated by CAR/PXR activation, with subsequent TFC proliferation. Since liver mediated thyroid toxicity has been reported to be rodent specific, it is unlikely that fluopyram would induce thyroid changes and tumours in humans.

**PS 1100 Oncogene PKC Epsilon Inhibits Transcription Factor Nrf2 through Phosphorylation of Its Regulatory Molecule INrf2 (Keap1).**

S. K. Niture and A. K. Jaiswal. *Pharmacology, University of Maryland, Baltimore, MD.*

Nrf2:INrf2 (Keap1) serve as sensors of chemical and radiation stress and are critical in protection against oxidative stress and cellular transformation. INrf2 functions as an adaptor protein for Cul3-Rbx1-mediated ubiquitination and degradation of Nrf2. Exposure to stressors leads to dissociation of Nrf2 from INrf2, stabilization and nuclear translocation of Nrf2 and activation of Nrf2 downstream cytoprotective proteins leading to cellular protection and survival. The molecular signal(s) that control INrf2 control of Nrf2 remains elusive. In this report, we demonstrate that oncoprotein protein kinase C epsilon (PKC $\epsilon$ ) phosphorylates INrf2 at amino acid positions Ser599 and Ser602 that is essential for INrf2:Nrf2 interaction and ubiquitination/degradation of Nrf2. Therefore, PKC $\epsilon$  by regulating INrf2 controls Nrf2 and expression of downstream cytoprotective proteins and cell survival. PKC $\epsilon$  phosphorylation of INrf2 appears specific for recognizing Nrf2 since it does not affect INrf2 interaction with other proteins including ubiquitin factors Cul3/Rbx1. Inhibition of PKC $\epsilon$  or MEFs lacking PKC $\epsilon$  or INrf2S602A mutant all failed to phosphorylate INrf2 and led to reduced degradation of Nrf2 and enhanced Nrf2 downstream signaling resulting in increased cell survival, proliferation and drug resistance. An analysis of protein microarray data from human lung and liver tumors showed lower PKC $\epsilon$  and higher Nrf2. This inverse relationship between PKC $\epsilon$  and Nrf2 in tumors presumably contributed to cancer cell survival and drug resistance. In conclusion, this is the first report that demonstrates a role of PKC $\epsilon$  in phosphorylation of INrf2 and control of Nrf2 with significant implications in survival of cancer cells that often express lower levels of PKC $\epsilon$ .

**PS 1101 A Weight-of-Evidence Approach to Determine the Leydig Cell Tumor Mode-of-Action (MoA) for Pronamide.**

R. J. Rasoulpour<sup>1</sup>, A. K. Andrus<sup>1</sup>, M. J. LeBaron<sup>1</sup>, S. Marty<sup>1</sup>, L. H. Pottenger<sup>1</sup>, S. Papineni<sup>2</sup> and D. L. Eisenbrandt<sup>2</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences, Indianapolis, IN.

Pronamide, a herbicide, caused an increased incidence of Leydig cell tumors (LCT) in CD rats at 1000 ppm (27% vs. 9% in controls) and liver hypertrophy after two years of dietary exposure. There was no Leydig cell hyperplasia or tumors at the 12-month interim necropsy. Dose levels of 40 or 200 ppm had LCT incidences similar to controls, identifying a clear effect threshold. A series of studies was performed to elucidate the MoA for rat LCT and its relevance to humans. Pronamide was negative for mutagenicity/clastogenicity, which is the only known LCT MoA with clear human relevance. Other LCT MoAs have little to no relevance to humans and all commonly affect the endocrine system. Pronamide was negative for androgen and estrogen receptor binding, aromatase inhibition, steroidogenesis alterations, and estrogen receptor transactivation. Despite no evidence of direct action upon the endocrine system, *in vivo* MoA studies revealed a slight, but consistent, increase in circulating levels of luteinizing hormone (LH), estradiol, and estrone in rats at  $\geq$  1000 ppm. It is proposed that the high-dose hormonal alterations are secondary to induction of liver-based testosterone metabolism/inactivation, coincident with liver hypertrophy and increased cytochrome P450s. Secondary increases in LH are proposed to result in mitogenic stimulation of rat Leydig cells, which are quantitatively more sensitive than human Leydig cells to LH-driven proliferative response, based

primarily upon >10-fold more LH receptors per cell in rats vs. humans. This difference in sensitivity is supported by the >1,000-fold difference between background incidence of human LCT vs. the rat. Overall, the weight-of-evidence for pronamide-induced rat LCT supports a threshold-response (i.e., nonlinear) approach for risk assessment due to the lack of genotoxicity, absence of direct endocrine effects, clear NOAEL for the LCT response (200 ppm), and an adequate margin of exposure for an effect in a uniquely sensitive animal model.

## PS 1102 Hepatic Nongenotoxic Carcinogen-Induced Temporal Changes in the Hepatic miRNAome.

K. Chen<sup>1</sup>, W. Jayne<sup>2</sup>, R. Currie<sup>2</sup>, C. Koufaris<sup>1</sup> and N. J. Gooderham<sup>1</sup>.

<sup>1</sup>Biomolecular Medicine, Imperial College London, London, United Kingdom; <sup>2</sup>Safety Assessment, Syngenta, Jealotts Hill, United Kingdom.

Non-genotoxic carcinogens are capable of inducing carcinogenesis via means other than direct modification of DNA structure. While there are many tests readily available for detecting genotoxic substances, methods for detecting and screening non-genotoxic chemical carcinogens are limited. Here we explore the potential of miRNA dysregulation as an indicator of non-genotoxic carcinogens by assessing the temporal-dependent changes in the miRNAome of Fisher rats. Ten chemical compounds, including: Phenobarbital (PB, 1000ppm), Chlorendic Acid (Chl Ac, 1250ppm), Diethylhexylphthalate (DEHP, 1200ppm), Monuron (Mon, 1500ppm), Methapyrilene Hydrochloride (MP HCl, 250ppm), 2-Aminoacetylfluorene (genotoxic, 2-AAF, 40ppm), cinnamon anthranilate (CA, 30,000ppm), Diethylhexyldipate (DEHA, 25,000ppm), Benzophenone (BP, 1250ppm) and Diethylthiourea (DETU, 250ppm), were fed in the diet to Fisher rats for a period of up to three months and liver samples were harvested at 7, 28 and 90 days. The total RNA was purified and analysed with Agilent Rat miRNA Microarrays Kit (Release 16.0). The expression of multiple hepatic miRNAs was found to be altered in response to chemical treatment in a temporally-dependent manner. Chemicals with a similar mode of action (eg: DEHP and DEHA) induced similar responses on the hepatic miRNAome, confirmed by hierarchical clustering analysis qPCR. In the case of DEHA and DEHP, miR-101 family and miR-212 were transiently elevated (at least 3 fold) at 7 days of treatment. In contrast MiR-200 family expression was unaffected at 7 days but was significantly induced at 90 days of treatment. MiR-101 family and miR-212 family are predicted to regulate MAPK3 pathway and target myc gene in the p53 feedback pathway, whereas the miR-200 family are involved in regulating the epithelial-mesenchymal transition and metastasis. These data suggest that miRNAs are potential biomarkers of nongenotoxic hepatocarcinogens and understanding the consequences of miRNA dysregulation aids the understanding of the mechanisms of carcinogens.

## PS 1103 Dietary Carcinogen PhIP Induces Early DNA Damage and p53 Pathway Activation in CYP1A-Humanized Transgenic Mice.

J. Chen<sup>1,2</sup>, G. Li<sup>2</sup>, H. Wang<sup>2</sup>, A. Liu<sup>2</sup> and C. S. Yang<sup>2</sup>. <sup>1</sup>Joint Graduate Program in Toxicology, UMDNJ-Rutgers University, Piscataway, NJ; <sup>2</sup>Department of Chemical Biology, Rutgers, The State University of New Jersey, Piscataway, NJ.

2-Amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP) is a dietary carcinogen and the most abundant heterocyclic amine generated from high temperature cooking of meat and fish. PhIP is activated via N2-hydroxylation to a proximate carcinogen primarily by cytochrome 1A2. CYP1A-humanized (hCYP1A) mice, which replaced the murine Cyp1a1 and Cyp1a2 with human CYP1A1 and CYP1A2, mimic human metabolism of PhIP. Previous study in our lab demonstrated that in hCYP1A mice, a single oral administration of PhIP induces high-grade prostatic intraepithelial neoplasia, mainly in the dorso-lateral glands (DLGs). Because murine DLGs correspond to the human prostate peripheral zone, the most common site of prostate cancer, PhIP-induced carcinogenesis in hCYP1A mice is a relevant mouse model for studying early stage prostate carcinogenesis. Herein, we investigated the early cellular and molecular events induced by PhIP in the dorso-lateral prostate of hCYP1A mice. Using immunohistochemistry, we detected strong positive staining of 8-Oxo-2'-deoxyguanosine as well as  $\gamma$ -H2AX in the DLGs on Days 1 and 3 after PhIP treatment, suggesting DNA damage and DNA strand breaks. Through gene expression profiling analysis and RT-qPCR, we found changes in expression of numerous p53-associated genes, including p21 and cyclin D1, indicating p53 activation and likely cell cycle arrest in PhIP-treated hCYP1A mice. Similar gene alterations were not observed in the PhIP-treated wild-type C57BL/6J mice. Altogether, these results suggest PhIP-induced DNA damage causing activation of the p53 pathways that may be involved in the early stage of carcinogenesis in the prostate. (Supported by NIEHS training grant 5T32ES007148-25 and NIH grant RO1CA133021 as well as shared facilities funded by CA72720 and ES05022).

## PS 1104 Reexamination of Initiator Dose in Ultra-Short-Term Carcinogenicity Study in RASH2 Mice.

H. Tsutsumi<sup>1</sup>, K. Urano<sup>1</sup>, M. Suguro<sup>2</sup>, M. Kawabe<sup>2</sup>, T. Numano<sup>2,3</sup> and F. Furukawa<sup>2</sup>. <sup>1</sup>Testing department, Central Institute for Experimental Animals, Kawasaki, Japan; <sup>2</sup>DIMS Institute of Medical Science, Inc., Ichinomiya, Japan; <sup>3</sup>Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.

We have established an ultra-short-term carcinogenicity study in which the target organ was the skin, one of the common targets in rasH2 mice. Although we previously reported that the suitable dose of 7,12-dimethylbenz[a]anthracene (DMBA) as an initiator was 50 mg at SOT 2010, several tumors were induced in DMBA treated groups without promotion, suggesting the dose of DMBA as an initiator was too high. In this study, we reexamined the suitable dose of DMBA as an initiator. Several compounds were applied to shaved dorsal skin of female rasH2 mice one week after 12.5 or 25  $\mu$ g DMBA application: oleic acid diethanolamine condensate (OADC, 30 mg/kg, 7 times/week) or benzethonium chloride (BC, 1.5 mg/kg, 5 times/week), known to have no promoting effect, 99.5 % ethanol (7 times/week) or anhydrous ethanol (5 times/week) as vehicles, or benzoyl peroxide (BPO, 20 mg/head, 5 times/week) as a positive tumor promoter. Applied skin was studied histopathologically at eight weeks after DMBA application. Although no tumors were induced in OADC, BC or vehicle treated groups, skin tumors were induced at five weeks after DMBA application in BPO treated groups, and the incidence of skin tumors reached 100 % by seven weeks after DMBA application. The number of skin tumors, which were diagnosed as hyperplasia and/or papilloma, at necropsy were 29.2 and 35.6 in 12.5  $\mu$ g and 25  $\mu$ g DMBA treated groups, respectively. Therefore, we concluded that 12.5  $\mu$ g DMBA was suitable to initiate the skin of rasH2 mice in an ultra-short-term skin carcinogenicity study.

## PS 1105 Modulation of Cocarcinogenic Effect of Aflatoxin B1 and Fumonisin B1 in a Short-Term Bioassay by Uniform Particle Size NovaSil Clay.

L. Tang<sup>1</sup>, G. Qian<sup>1</sup>, S. Lin<sup>1</sup>, Z. Yang<sup>1</sup>, M. Kang<sup>1</sup>, N. J. Mitchell<sup>2</sup>, J. Su<sup>1</sup>, W. Gelderblom<sup>3</sup>, R. Riley<sup>4</sup>, T. Phillips<sup>2</sup> and J. Wang<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Texas A&M University, College Station, TX; <sup>3</sup>Medical Research Council, Tygerberg, South Africa; <sup>4</sup>USDA ARS, Athens, GA.

Co-contamination of AFB1 and FB1 in corn-based food and feed is a health concern for their combinative toxic effects as well as potential co-carcinogenic effect. Uniform particle size NovaSil (UPSN) clay has been used as an enterosorbent to reduce AFB1 and FB1 exposure in animals and humans. In this study male F344 rats (150g) were randomly divided into five groups: negative control group, AFB1+FB1 group, AFB1+ FB1+low UPSN (0.25%) group, AFB1+FB1+high UPSN (0.5%) group, and positive control group treated with diethylnitrosamine and 2-acetylaminofluorene. All treated animals were sacrificed after their last exposure. Liver were dissected and processed with regular H&E staining for examination of histological alterations. Liver tissue slides were also immunohistochemically stained for examination of formation of placental form glutathione S transferase positive (GST-P+) foci. No detectable lesions were found in the negative control group, while the positive control group showed significant high rates of dysplasia (262  $\pm$  29), prolific foci (53  $\pm$  16), and nodules (15  $\pm$  10), as well as high rate of GST-P positive liver foci (58  $\pm$  11), which demonstrates the success of the experiments. Co-exposure to AFB1 and FB1 induced comparable rate of dysplasia (258  $\pm$  40) to the positive control group and a higher rate of apoptosis (26  $\pm$  8) than the positive control group (4  $\pm$  4). UPSN in both low and high groups significantly inhibited formation of preneoplasia in liver: For dysplasia, reduction of 46% (140  $\pm$  29) and 56.6% (113  $\pm$  20); for apoptosis, reduction of 42% (15  $\pm$  4) and 57% (11  $\pm$  4); for prolific foci, reduction of 74% and 94%; for GST-P positive foci numbers, areas, and mean areas, the reduction of 77% and 88%; 83% and 94%; and 31% and 53% were found, respectively. These results demonstrate significant modulation of UPSN on reducing potential co-carcinogenic effect in this short-term bioassay.

## PS 1106 Validation of Cocarcinogenic Effects of Aflatoxin B1 and Fumonisin B1 in a Short-Term Bioassay.

J. Wang<sup>1</sup>, G. Qian<sup>1</sup>, S. Lin<sup>1</sup>, L. Tang<sup>1</sup>, Z. Yang<sup>1</sup>, M. Kang<sup>1</sup>, N. J. Mitchell<sup>2</sup>, J. Su<sup>1</sup>, W. Gelderblom<sup>3</sup>, R. Riley<sup>4</sup> and T. Phillips<sup>2</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Texas A&M University, College Station, TX; <sup>3</sup>Medical Research Council, Tygerberg, South Africa; <sup>4</sup>USDA ARS, Athens, GA.

A short-term animal assay using Aflatoxin B1 (AFB1) as the initiator and fumonisin B1 (FB1) as the promoter demonstrated dramatic increase in formation of placental form glutathione S transferase positive (GST-P+) foci in rat liver. In this

study, we validated this short-term bioassay and studied potential interactions between AFB1 and FB1 on the biochemical and histological changes and the formation of liver GST-P+ foci through a modified treatment protocol. AFB1 (150 ppb) containing diet caused dramatic dysplastic hepatocytes, mild bile duct proliferation and necrosis, and proliferation foci formation. In contrast, FB1 (250 ppm) containing diet induced less dysplastic hepatocytes and more apoptotic bodies while no proliferation foci were found. Additive effects on increasing serum ALP, ALT and AST activities were found in co-exposed animals as compared to single AFB1 or FB1 treated. Sequential co-exposure to AFB1 and FB1 lead to significantly increased numbers of dysplastic hepatocytes, apoptosis and proliferation foci. Co-exposure of AFB1 and FB1 also significantly increased the numbers of liver GTP-P+ foci by approximately 7.2 and 12.2 folds ( $p < 0.01$ ), and increased the mean sizes of GST-P+ foci by 6.0 and 7.5 folds ( $p < 0.01$ ), as compared to single AFB1 or FB1 treated, suggesting strong synergistic effects in enhancing the preneoplastic lesion in liver. This study validates co-carcinogenic effects of AFB1 and FB1 in the short-term bioassay in rat liver and provides evidence for the use of this model in future intervention studies and mechanistic investigations.

## PS 1107 Tumor Promoter Action of Chromium-Containing Stainless Steel Welding Particulate Matter in the Lungs of A/J Mice.

P. C. Zeidler-Erdely, T. G. Meighan, A. Erdely, L. A. Battelli, M. L. Kashon, M. Keane and J. M. Antonini. *HELD, NIOSH, Morgantown, WV.*

Epidemiology studies show that occupational exposure to metal-rich welding particulate matter (PM) increases lung cancer risk. However, animal studies are lacking to conclusively link welding with an increased cancer risk. PM derived from stainless steel (SS) welding practices, in particular, contains carcinogenic metals such as hexavalent chromium and nickel. Previously, we found that PM derived from gas metal arc (GMA) welding of SS caused a borderline increase in lung tumor incidence and a significant, chronic immune response in the lungs of mice. Thus, we hypothesized that welding PM may act as a tumor promoter and increase lung tumor multiplicity. In this study, the capacity of GMA-SS welding PM to promote lung tumors was evaluated using a 2-stage (initiation-promotion) model in lung tumor susceptible A/J mice. Age and weight-matched male mice ( $n=26-29/\text{group}$ ) were treated either with the initiator 3-methylcholanthrene (MCA; 10  $\mu\text{g/g.i.p.}$ ) or vehicle (corn oil; CO) followed by 5 weekly pharyngeal aspirations of GMA-SS (340 or 680  $\mu\text{g}$ ) or PBS. Lung tumors were enumerated at 30 weeks following initiation with MCA. Body weights were recorded at 2 week intervals and no effect of treatment was found. MCA initiation followed by GMA-SS exposure promoted lung tumor multiplicity in both the lower dose ( $12.0 \pm 1.5$  tumors/mouse;  $p=0.0001$ ) and high dose ( $14.0 \pm 1.8$  tumors/mouse;  $p=0.0001$ ) groups significantly above that of MCA/PBS ( $4.77 \pm 0.7$  tumors/mouse). Not only was this highly significant for the average total number per mouse, multiplicity was also increased ( $p < 0.004$ ) across all five individual lung regions of GMA-SS-exposed mice. No treatment effects were found in the corn oil groups at 30 weeks and also, as expected, tumor incidence was greater than 93% in the MCA treated groups which verified its carcinogenic potency. In conclusion, GMA-SS welding PM acts as a lung tumor promoter in vivo. These novel findings implicate that susceptible individuals may be at greater risk for lung cancer development after exposure to welding PM.

## PS 1108 Induction of 1, 3-Dichloropropene Rat Liver Tumors through a Nongenotoxic Mode of Action.

S. C. Gehen<sup>1</sup>, R. Billington<sup>2</sup>, Z. Wang<sup>3</sup>, P. J. Klein<sup>3</sup> and J. E. Klaunig<sup>3</sup>. <sup>1</sup>Dow AgroSciences LLC, Indianapolis, IN; <sup>2</sup>Dow AgroSciences LLC, Abingdon, United Kingdom; <sup>3</sup>Indiana University, Bloomington, IN.

1,3-Dichloropropene (1,3-D) is a soil fumigant used for control of parasitic nematodes. It was previously shown that dietary exposure to 1,3-D was associated with an increased incidence of benign hepatocellular adenomas in male rats in one of two rat cancer studies. In in vivo genotoxicity studies, 1,3-D was shown consistently to be non-mutagenic in studies where physiologic levels of glutathione and glutathione S-transferases were present and genotoxic stabilizers were not present, thus supporting liver tumorigenesis through a non-genotoxic mode-of-action (MoA). The present study was undertaken to investigate the hypothesis that 1,3-D induces rat liver tumors by acting as a tumor promoter in the liver carcinogenesis process. To assess potential 1,3-D tumor promotion, diethylnitrosamine-initiated Fischer 344 rats were treated by gavage with 25 mg/kg/day 1,3-D or 80 mg/kg/day phenobarbital (PB) for either 30 or 60 days, or for 30 days followed by 30 days recovery. Staining for the placental form of glutathione S-transferase (GSTP) was conducted post-exposure as a phenotypic marker of preneoplastic foci. While having no effect on GSTP positive foci, 1,3-D significantly enhanced the number and size of GSTP negative lesions at 30 and 60 days. Importantly, after 30 days recovery, the number and size of GSTP negative lesions in 1,3-D treated animals returned to control levels thus demonstrating 1,3-D promotion of foci and not

tumor initiation. Also supportive of tumor promotion, the hepatocyte labeling index in GSTP-negative preneoplastic foci was significantly increased in 1,3-D treated rats at 30 and 60 days and returned to control levels after 30 days recovery. PB, a well recognized non-genotoxic rodent liver carcinogen, produced an expected reversible increase in number and size of the GSTP positive lesions. The results presented are consistent with 1,3-D inducing liver carcinogenesis through a non-genotoxic MoA by induction of reversible proliferation of non-GSTP staining focal populations of hepatocytes.

## PS 1109 Effects of Long-Term Administration of the Tissue-Selective Estrogen Receptor Modulator Bazedoxifene on Survival and Tumor Formation in Rats.

D. J. Wright<sup>1</sup>, R. Perry<sup>1</sup>, C. A. Thompson<sup>2</sup>, N. J. Earnhardt<sup>3</sup>, S. Bailey<sup>1</sup>, B. Komm<sup>4</sup>, D. R. Minck<sup>5</sup> and M. A. Cukierski<sup>1</sup>. <sup>1</sup>Drug Safety, Pfizer, Groton, CT; <sup>2</sup>Abbott Laboratories, Abbott Park, IL; <sup>3</sup>Pharmacokinetics, Dynamics, and Metabolism, Pfizer, La Jolla, CA; <sup>4</sup>Medical Affairs, Pfizer, Collegeville, PA; <sup>5</sup>Division of Metabolism and Endocrinology, US FDA, Silver Spring, MD.

Bazedoxifene acetate (BZA) is a selective estrogen receptor modulator that is approved in a number of countries for the prevention and/or treatment of osteoporosis in postmenopausal women. To assess for carcinogenic potential, BZA was administered ad libitum in the diet to male and female rats for 2 years. BZA resulted in a reduction and a delayed onset in total tumor burden in both male and female rats. Survival rates were enhanced due to decreased pituitary (males and females) and mammary tumors (females) and decreased body weight gain in BZA-treated animals compared to controls. BZA caused an increased incidence of benign ovarian tumors and renal tubular tumors (males). Results from separate studies suggested that BZA caused an increase in LH, which stimulated formation and persistence of ovarian cysts, which eventually progressed into benign ovarian granulosa cell tumors. The reductions in pituitary and mammary gland tumors were attributed to BZA-related antagonism of endogenous estrogens at the estrogen receptors. The greater increase in renal tumor incidence in male rats given BZA was associated with the increased survival and increased time for development of late onset tumors. These findings are consistent with a non-genotoxic mechanism, unique to male rats, that involves test article-induced corticomedullary mineralization, renal tubular injury, and exacerbation of naturally occurring chronic progressive nephropathy in aged male rats that leads to proliferative changes and tumor formation. In conclusion, BZA elicited agonistic or antagonistic effects in a tissue-selective manner which was generally consistent with expression and/or activity of estrogen receptors in those tissues.

## PS 1110 Resveratrol Exposure Reduces Benzo(a)pyrene-DNA Adduct Concentrations in Apc<sup>Min</sup> Mouse Model of Colon Cancer.

A. C. Huderson, P. V. Rekhadevi, M. S. Niaz, S. E. Adunyah and A. Ramesh. *Biochemistry & Cancer Biology, Meharry Medical College, Nashville, TN.*

Colon cancer is the third leading cause of cancer cases and related deaths as per the statistics provided by the American Cancer society. Exposure to toxicants such as benzo(a)pyrene (BaP) is one of the contributing factors to the development of sporadic colon cancer. Our studies have shown a decrease in the size, and number of adenomas in the colon of mice exposed to BaP and resveratrol (RVT), compared to BaP exposure alone. We have also shown that RVT exposure caused a decrease in the expression and activity of CYP1A1/1B1 enzymes and BaP metabolite concentrations both in liver and colon. Since DNA damage is one of the key events in carcinogenesis, the objective of this study was to investigate whether RVT exposure simultaneously or prior to BaP treatment alters BaP-DNA adduct concentrations in Apc<sup>Min</sup> mouse. The treatment consisted of BaP only administration (in peanut oil) at a dose of 100  $\mu\text{g/kg}$  bw via oral gavage over a 60 day period (group I); BaP (100  $\mu\text{g/kg}$  bw) co-administered with RVT (in 10% ethanol + 90% deionized water) at a dose of 45  $\mu\text{g/kg}$  bw (group II); RVT administered for 1 week prior to BaP dosing (group III). Post exposure, DNA was isolated from colon and liver samples, and analyzed for BaP-DNA adducts by the <sup>32</sup>P-postlabeling method using a four-directional TLC system. The adduct concentrations showed a trend that mirrored the concentrations of BaP metabolites in the organs studied with low concentrations in RVT-treated mice compared to BaP-treated mice. Between the two RVT-treatment strategies, concurrent administration of RVT appeared to affect the BaP bioactivation compared to RVT treatment prior to BaP exposure as reflected by the low adduct concentrations in the former group III compared to groups I & II. Overall, our results suggest that RVT provides a preventive effect against BaP-induced colon cancer progression in Apc<sup>Min</sup> mouse (funded by NIH grants 1F31ES019432-01A1, 5R01CA142845-02, 5T32HL007735-12, and 5R25GM059994-11).

**PS 1111 Triclosan Promotes the Development of Hepatocellular Carcinoma in Mice.**

M. Yueh, V. Jiang and R. H. Tukey. *Laboratory of Environmental Toxicology, Departments of Chemistry & Biochemistry and Pharmacology, University of California San Diego, La Jolla, CA.*

Triclosan (TCS), a chlorophenol, is used in a large number of personal care products as an antibacterial agent. TCS has endocrine disruption properties, has been detected in microgram per liter levels in various water ways in the US, and is considered to be a major environmental contaminant in aquatic ecosystems. Daily exposure to TCS has resulted in its detection in humans with studies showing its presence in plasma, breast milk, and urine. Studies have increasingly linked TCS to a range of health and environmental effects; however, there are no mechanism-based studies that directly address TCS exposure to negative health effects in humans. Using wild type and Car-/- mice, TCS has been shown to effectively induce hepatic Cyp2b10 in a CAR-dependent manner. However, transient transfection experiments revealed that TCS is not a direct CAR agonist but behaves as a phenobarbital-like inducer that indirectly activates CAR and facilitates its translocation to the nucleus. Using the chemical procarcinogen diethylnitrosamine (DEN) to initiate tumorigenic episodes in mice, TCS exposure through drinking water promotes the development of hepatocellular carcinoma (HCC). The development and promotion of HCC by TCC compared to DEN-only treated mice proceeds in a CAR-independent fashion. This finding stands in contrast to CAR-dependent tumor induction with the liver tumor promoter phenobarbital. HCC tumors produced by DEN-TCS exposure lead to a number of changes in the liver including histological alteration in hepatocytes, increases in liver-to-body weights, elevated levels of  $\alpha$ -fetoprotein, and enhanced levels of tumor-promoting cytokines IL-6 and TNF $\alpha$ . In addition, tumor-bearing livers significantly alter the expression profile for genes associated with drug metabolism. The identification of TCS as a liver tumor promoter may be significant because of its abundance and long term use in consumer products and its propensity for rapid absorption into the systemic circulation. (Supported by USPHS grant ES010337)

**PS 1112 Kupffer Cells Modulate Wyeth-14, 643 and Phenobarbital-Induced Hepatocyte Proliferation in Naïve and Diethylnitrosamine (DEN)-Initiated Mice.**

T. Peat, Z. Wang, S. Zhou and J. E. Klaunig. *Indiana University, Bloomington, IN.*

Kupffer cells (KC) play an important role in liver homeostasis. Upon activation, KC release inflammatory and growth regulatory mediators that have been linked to acute and chronic liver responses including hepatic cancer. Wyeth 14,643 (WY) and Phenobarbital (PB) are non DNA reactive hepatic carcinogens in rodents. The present study was conducted to investigate the role of KC in liver cell proliferation in naïve and focal lesion containing mice. In our initial study, KCs in male C3H mice were depleted using liposome encapsulated clodronate (Lip-clod, 0.1 ml/10 g, iv). LPS, a known KC activator, was used as a positive control (1 mg/kg, ip, 2X/wk). Lip-clod treatment resulted in depletion of 99% of KC as confirmed by F4/80 positive staining cells. WY treatment increased the relative liver weight and DNA synthesis in naïve mice after 7 and 21 d treatment. LPS and PB increased hepatic DNA synthesis (7 and 21 d). Following KC depletion, the induction of DNA synthesis by LPS and PB were significantly decreased, while WY-induced DNA synthesis was not altered. In the second study, mice were injected with DEN (50 mg/kg, ip, 1X/wk for 4 wk). Following development of focal lesions, mice were treated with WY or PB for 28 d. Treatment with PB or WY increased the relative focal volume and depletion of the KC decreased the relative focal volume. WY and PB increased DNA synthesis in both basophilic and eosinophilic lesions, similar to LPS. Upon KC depletion, a decrease in DNA synthesis was seen in PB treated mice. In the surrounding non-lesion tissue, PB produced a marginal increase in DNA synthesis (2-fold) and that was decreased following KC depletion compared to control. In comparison, DNA synthesis increased greatly (10-fold) when treated with WY. These results show that the KC modulated hepatocyte proliferation both in naïve mice and in the preneoplastic focal lesions in PB and WY treated mice.

**PS 1113 Bioassay-Directed Fractionation of Diesel and Biodiesel Emissions.**

E. Mudu<sup>1,2</sup>, S. H. Warren<sup>1</sup>, C. King<sup>1</sup>, W. P. Linak<sup>1</sup>, D. G. Nash<sup>1,3</sup>, I. Gilmour<sup>1</sup> and D. M. DeMarini<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, Durham, NC; <sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>ORISE, Oak Ridge, TN.

Biofuels are being developed as alternatives to petroleum-derived products, but published research is contradictory regarding the mutagenic activity of such emissions relative to those from petroleum diesel. We performed bioassay-directed frac-

tionation and analyzed the polycyclic aromatic hydrocarbon (PAH) levels of particles generated using petroleum diesel (B0) and those from soy-based biodiesel where the soy accounted for 20, 50 or 100% of the fuel (B20, B50, B100) from a Yanmar L70 diesel engine. We also evaluated a composite sample of diesel-exhaust particles (C-DEP) generated from petroleum diesel with a 30-kW 4-cylinder Deutz BF4M1008 diesel engine connected to an air compressor. The biodiesel and C-DEP particles were extracted with dichloromethane (DCM), and the percentage of extractable organic material of these complex environmental mixtures were determined. The extracts were then solvent exchanged into dimethyl sulfoxide and evaluated for mutagenicity in various *Salmonella* strains +/-S9. We calculated the mutagenic emission factors (revertants/megajoule, rev/MJ) from data from strain TA100 +S9, which responds to PAH-type mutagenicity. These mutagenic emission factors for the biodiesels were 3X less (B20), 6X less (B50), and 8X less (B100) than that of petroleum diesel (B0). The whole extract of C-DEP (petroleum diesel) was sequentially fractionated with solvents of increasing polarity, and >50% of the mass eluted in fraction 1; this fraction was not mutagenic. The 2nd fraction had 60% of the TA100+S9 activity, indicative of PAHs; the 3rd fraction contained 60% of the TA98-S9 activity, indicative of nitroarenes. We conclude that under these experimental conditions, emissions from biodiesel were less mutagenic than those from petroleum diesel, and based on the fractionation of the C-DEP, most of the activity is associated with PAHs. [Abstract does not necessarily reflect the views or policies of the U.S. EPA.]

**PS 1114 Phenotypic Characterization of CarG-box Binding Factor-A (CBF-A) Knock-out Mice.**

J. T. Barrett<sup>1</sup>, X. Zhang<sup>3</sup>, J. Richardson<sup>1,2</sup>, M. Fang<sup>1,2</sup> and H. Zarbl<sup>1,2,3</sup>. <sup>1</sup>Environmental and Occupational Medicine, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ; <sup>2</sup>Environmental and Occupational Health Sciences Institute, Robert Wood Johnson Medical School, Piscataway, NJ; <sup>3</sup>Environmental and Occupational Health Sciences, Robert Wood Johnson Medical School, Seattle, WA.

CarG-box binding factor-A is a member of the heterogeneous nuclear ribonucleoprotein (hnRNPs) family of RNA-binding proteins involved in a variety of cellular functions, including transcriptional regulation. We showed that CBF-A (hnRNP A/B) regulates the expression of the Ha-ras oncogene by binding to enhancer elements (ets-like) in the promoter region. Deregulated expression of CBF-A isoforms is associated with mammary carcinogenesis in NMU-treated rats. CBF-A is a regulator of epithelial-mesenchymal transition (EMT), an important process in the cancer progression. To evaluate the role of CBF-A, we generated knock-out mice. Behavioral evaluation in the elevated plus maze showed that CBF-A null mice spent ~300% more time in the open arms of the maze compared to the wild-type, suggesting that loss of CBF-A results in a low-anxiety behavioral phenotype. This behavioral abnormality may be related to the role of CBF-A in regulating the expression of vasopressin in the brain. To further study the role of CBF-A in tumorigenesis, we exposed wild-type mice, as well as CBF-A null and heterozygous mice to a single dose of the mutagenic, DNA-alkylating agent ENU (10 mg/mL at 9-10 weeks of age). While administration of ENU decreased the survival rate in all genotypes compared to vehicle control mice, CBF-A null mice had a decreased survival rate and tumor-free survival rate compared to the wild-type. Taken in concert, these data suggest that CBF-A plays an important role in maintaining both normal growth control and behavior.

Supported by Grants from the DOD(BC971045), the NIEHS funded Toxicogenomics Research Consortium (ES011387), NIEHS Center Grants (ES005022 and ES007033) and CINJ (CA072720).

**PS 1115 Inhibition of Hepatocyte Nuclear Factor 1 and 4 Alpha (HNF1 $\alpha$  and HNF4 $\alpha$ ) As a Mechanism of Arsenic Carcinogenesis.**

A. Hernandez<sup>1,2</sup>, A. Pastor<sup>1</sup> and R. Marcos<sup>1,2</sup>. <sup>1</sup>Genetics and Microbiology, Autonomous University of Barcelona, Bellaterra, Spain; <sup>2</sup>CIBER-ESP, ISCIII, Madrid, Spain. Sponsor: A. Sampayo-Reyes.

Inorganic arsenic (i-As) is a naturally occurring toxic metalloid affecting millions of people worldwide. It is known to be carcinogen, liver being a potential target, and related to the prevalence of diabetes in arseniasis-endemic areas. Hepatocyte nuclear factor 1 and 4 alpha (HNF1 $\alpha$  and HNF4 $\alpha$ ) are key members of a transcriptional network essential for normal liver architecture. Changes in HNF1 $\alpha$  and HNF4 $\alpha$  expression are clearly associated with the development of liver malignancies and diabetes in humans. In this work, hepatic HepG2 cells and Golden Syrian hamsters were exposed to sub-toxic, environmentally relevant doses of sodium arsenite (SA; up to 10  $\mu$ M in vitro, 15 mg/L in vivo) in order to evaluate whether arsenic is able to compromise the expression of hepatocyte nuclear factors (HNFs). Also, liver hisopathological examination was carried out and several markers of hepatocyte dif-

ferentiation and glucose metabolism status were determined as a measure of i-As-induced effects. Results show a consistent down-regulation of HNF1 $\alpha$  and HNF4 $\alpha$  under an scenario of exposure where HepG2 cells (i) gained resistance to arsenic-induced toxicity/apoptosis, (ii) attained loss of tissue specific features (as shown by the observed downregulation of ALDOB, PEPCK and CYP1A2, the triggering of the epithelial-to-mesenchymal transition program (EMT) and the hypersecretion of matrix metalloproteinase-2 and 9), (iii) failed to maintain balanced the expression of the "stemness" genes C-MYC, OCT3/4, LIN28 and NOTCH2 and (iv) showed glucose metabolism impairment. We conclude that the i-As-induced down-regulation of HNF1 $\alpha$  and HNF4 $\alpha$  under chronic settings may play a central role in the features of disease and cancer observed both in vivo and in vitro.

## PS 1116 Carcinogenicity of Diesel (DEE) and Gasoline Engine Exhausts (GEE).

L. Benbrahim-Tallaa, R. Baan, Y. Grosse, B. Secretan-Lauby, F. El Ghissassi, V. Bouvard, N. Guha, D. Loomis and K. Straif. *IARC Monographs, IARC, Lyon, France.*

Recently, an IARC Monographs Working Group (WG) reevaluated the carcinogenic hazards to humans of DEE and GEE. DEE was classified as "carcinogenic to humans" (Group 1) and GEE as "possibly carcinogenic to humans" (Group 2B). A US study in non-metal miners included a cohort analysis and a nested case-control analysis adjusted for tobacco smoking. Both showed positive trends in lung cancer risk with increasing exposure, with a 2-3-fold increased risk in the highest categories of cumulative or average exposure. A 40% increased risk for lung cancer was observed in U.S. railroad workers exposed to DEE. Indirect adjustment for smoking and a more accurate exposure assessment strengthened the validity of the results. A large cohort study reported a 15-40% increased lung cancer risk in US truck drivers and dockworkers with exposure to DEE, with a significant trend of increasing risks with longer duration of employment, adjusted for tobacco smoking. Findings in other occupational groups and case-control studies including various occupations with similar exposures supported the WG's conclusion of "sufficient evidence" in humans for the carcinogenicity of DEE. The WG concluded that there was "sufficient evidence" in experimental animals for the carcinogenicity of whole DEE, DEE particles, and extracts of the particles, which also induced, in vitro and in vivo, various forms of DNA damage. Positive genotoxicity biomarkers of exposure and effect were also observed in humans exposed to DEE. The WG concluded that there is "strong evidence" for the ability of whole DEE to induce cancer in humans through genotoxicity. GEE and cancer risk was investigated in only a few epidemiological studies and, because of the difficulty to separate the effect of DEE and GEE, evidence for carcinogenicity was evaluated as "inadequate". Organic extracts of GEE condensate induced a cancer in mice, and in rats, GEE condensate also induced cancer in rats. The WG concluded that there was "sufficient evidence" in experimental animals for the carcinogenicity of condensates of GEE.

## PS 1117 Suicide Inhibition Is Responsible for the Paradoxical Absence of CYP2B10 Enzyme Activity in Mouse Liver following Nitrapyrin- or Pronamide-Induced CAR Activation.

M. J. LeBaron<sup>1</sup>, H. L. Kan<sup>1</sup>, M. R. Schisler<sup>1</sup>, S. Papineni<sup>2</sup>, D. L. Eisenbrandt<sup>2</sup> and B. Gollapudi<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences, Indianapolis, IN.

Establishing a mode of action (MoA) for a toxicological finding requires the identification of key events (both causal and associative) that progress to the apical end point of interest. In the case of constitutive androstane receptor (CAR)-mediated rodent hepatocarcinogenesis, the first key event is activation of the CAR signaling pathway, which is often measured via the empirically observable biomarker of Cyp2b10 induction (transcript, protein, and/or enzyme activity). The agrochemicals pronamide (herbicide) and nitrapyrin (nitrification inhibitor) induced hepatocellular tumors in mice as a result of high-dose, long-term dietary administration. Subsequent MoA studies for each chemical were consistent with a role for CAR-activation in the mouse liver tumorigenesis. With both chemicals significant increases in Cyp2b10 transcript as well as protein were observed; however, there was no associated change in the activity of the enzyme as measured by PROD. To investigate the role for suicide inhibition in this paradoxical finding, *in vitro* experiments were conducted with phenobarbital (PB)-induced microsomes. These microsomes were treated with PB (negative control), curcumin (positive control), nitrapyrin, or pronamide. In this system, nitrapyrin and pronamide inhibited PROD activity in a dose-related manner and up to 97% and 56% at 500  $\mu$ M, respectively. While PB had no effect on PROD activity, curcumin had a dose-related inhibition of Cyp2b-mediated PROD activity of up to 63% at 40  $\mu$ M. These results indicate that the two agrochemicals and/or their metabolites irreversibly inhibit Cyp2b10-mediated PROD activity and elucidate the apparent inconsistency between protein levels and enzyme activity of treated livers while supporting the CAR-mediated MoA for liver

tumorigenesis. Further, these data indicate that measurement of transcript levels as biomarkers for CAR activation is more appropriate than traditional enzyme activity (e.g., PROD) measurements.

## PS 1118 Structure-Dependent Effect of Diindolylmethane Derivatives on Inactivation of the Oncogenic NR4A1/NR4A2 Receptor in Colon Cancer Cells.

X. Li<sup>1</sup>, S. Lee<sup>2</sup> and S. H. Safe<sup>1, 2, 3</sup>. <sup>1</sup>College of Medicine, Texas A&M Health Science Center, College Station, TX; <sup>2</sup>Institute of Biosciences & Technology, Texas A&M Health Science Center, College Station, TX; <sup>3</sup>Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX.

The nuclear receptor 4A (NR4A) subfamily members TR3 (NR4A1) and Nurrl (NR4A2) have been investigated in this laboratory as novel drug targets for clinical treatment of pancreatic cancer. Inactivating of these oncogenic transcription factors by analogs derived from the chemopreventive phytochemical diindolylmethane (DIM) exhibit promising in vitro and in vivo chemotherapeutic effects. Knockdown of NR4A1 and NR4A2 by RNA interference in colon cancer cells decreased cell proliferation, induced apoptosis and inhibited colon cancer cell invasion. Using NR4A-responsive promoter elements (monomer-binding NBRE and dimer-binding NurRE) linked to a luciferase reporter gene, we investigated the structure-dependent activity of over forty 1,1-bis(3'-indolyl)-1-(substituted phenyl)methane (DIM-C-Ph) and 1,1-bis(3'-indolyl)-1-(heteroaromatic)methane (DIM-C-heteroaromatic) analogs as inactivators of NR4A1, NR4A2 or both receptors. In colon cancer cells we identified DIM-C-Ph analogs containing para-hydroxy, chloro, methyl, or trifluoromethoxy groups that inactivated NR4A1 and the 3-pyridine analog (DIM-C-Pyr-3) inactivated NR4A2-mediated transactivation. In contrast, several other p-substituted phenyl analogs containing fluoro, iodo or cyano groups were potent inactivators of both receptors. The mechanisms of NR4A inactivation by C-DIMs were investigated and the possible role of site-specific phosphorylation was determined using several protein kinase inhibitors including LY294002, PD98059 and SP600125. The results show that in RKO colon cancer cells transfected with NBRE-luciferase construct and treated with DIM-C-pPhCN, NR4A inactivation was inhibited by PD98059. These results indicate that the chemotherapeutic properties of C-DIMs are outcomes of NR4A inactivation and the NR4A1/NR4A2-dependent pathways and role of kinases are currently being investigated.

## PS 1119 Evaluation of microRNAs in Blood for Detection of Chemical-Induced Carcinogenesis.

T. Chen<sup>1</sup>, F. Meng<sup>1</sup>, J. Yan<sup>1</sup> and K. L. Thompson<sup>2</sup>. <sup>1</sup>National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>Center for Drug Evaluation and Research, US FDA, Silver Spring, MD.

MicroRNAs (miRNA) are emerging as a valuable tool in toxicological applications due to their role in regulation of gene expression in different biological pathways. Multiple studies have revealed that miRNAs are present and relatively stable in clinically accessible biofluids such as blood. miRNAs in biofluids may provide a non-invasive way of detecting chemical carcinogenicity. In this study, we evaluated whether microRNA profiling and individual miRNAs in mouse blood can predict carcinogenesis induced by N-ethyl-N-nitrosourea (ENU). Male B6C3F1 mice were treated with either a single dose of 140 mg/kg ENU or vehicle alone. Blood was collected on post-treatment days (PTDs) 1, 2, 3, 7, 14, 28, and 42. Profiling of total miRNAs in the blood showed that a number of miRNAs associated with carcinogenesis were altered by the ENU treatment. The temporal alteration of one of these miRNAs, miR-34a, a tumor suppressor, by ENU was characterized further. The level of miR-34a expression was significantly increased by ENU as early as PTD 1, reached a maximum level of about 10-fold over controls at PTD 7, and then decreased to control levels at PTD 42. Serum levels of miR-34a were also examined to assess the contribution of blood cells to miR-34a levels in whole blood. The results suggest that miRNAs have potential use as early sensitive circulating biomarkers of carcinogen exposure.

## PS 1120 Hemodynamic Changes, Arrhythmias, and Sudden Death in Dogs following Repeated Dosing of AKT/pp70S6K Inhibitor.

E. Blasi<sup>1</sup>, P. Harris<sup>1</sup>, M. Engwall<sup>2</sup>, S. Ralston<sup>3</sup> and L. Burns Naas<sup>4</sup>. <sup>1</sup>Drug Safety, Pfizer, San Diego, CA; <sup>2</sup>Drug Safety, Amgen, Thousand Oaks, CA; <sup>3</sup>Drug Safety, Abbott, Abbott Park, IL; <sup>4</sup>Drug Safety, Gilead, San Francisco, CA.

PF-04176340 (PF) is an inhibitor of AKT & pp70S6K. Target organs in GLP repeat dose studies in dogs included eye, GI, liver, testes. In addition, unexplained deaths were observed. In a 10d dose range-finding study (3, 10, 30 mpk/d), mor-

tality occurred in 1/4 male dogs at 30 mpk/d on d4 with no preceding signs. Similar observations were noted on d2 & d4 in a 1mo IND-enabling study in 2/5 male dogs at 20 mpk/d. In a SP study in telemetered male dogs (n=4), 10 & 15 mpk caused a significant increase in BP & dP/dT. Peak effect & duration were not related to expected exposure profile. An early study was conducted to investigate if the unexplained deaths were related to CV events as there was no evidence of direct cardiac toxicity in those animals. Conscious, unrestrained telemetered male dogs (n=4) were treated with VH or 20 mpk/d PF-04176340 continuously for 5d. Serum drug concentrations, glucose, insulin, troponin, clin chem, & electrolytes were measured predose & 5h postdose daily. Clinical signs were assessed by visual monitoring. PF produced transient cardiac arrhythmias (isolated PVC, polymorphic tachyarrhythmias) on d2 (Dog 3) & d3 (Dog 2) approx 6h postdose, and were associated with significant changes in LVP & dramatic drops in BP, and spontaneously resolved. Arrhythmias repeated multiple times on the day they were observed but were not on any other day. Arrhythmias were prolonged in Dog 3. Arrhythmic events did not appear to be correlated with plasma drug levels. During arrhythmic events, dogs were observed to be sleeping. Remaining telemetry data were consistent with the prior SP study. Treatment with PF also produced marked increases in glucose & insulin. No changes were noted in troponin, clinical chemistry, or electrolytes. It was concluded that the cardiovascular events observed in Dog 3 may explain the mortality in the repeat dose studies since without spontaneous resolution, prolonged arrhythmias may instigate a fatal decrease in cardiac output.

### PS 1121 The Role of Endothelial Cell-Specific Nitric Oxide Synthase in Causing Drug-Induced Vascular Injury.

G. A. Tobin<sup>1</sup>, D. G. Goodwin<sup>1</sup>, C. González<sup>1</sup>, J. Zhang<sup>1</sup>, L. Xu<sup>1</sup>, S. Stewart<sup>1</sup>, A. Knapton<sup>1</sup>, M. P. Lawton<sup>2</sup>, B. E. Enerson<sup>2</sup> and J. L. Weaver<sup>1</sup>. <sup>1</sup>Division of Drug Safety Research, US FDA, Silver Spring, MD; <sup>2</sup>Drug Safety Research and Development, Pfizer, Inc., Groton, CT.

The finding of drug-induced vascular injury (DIVI) in preclinical toxicology studies is a major cause of attrition in the development of many classes of drugs. In previous studies with the phosphodiesterase-4 inhibitor, CI-1044, we found that elevation of serum Nitric Oxide (NO) levels through endothelial cell-specific Nitric Oxide Synthase (eNOS) was critical for producing mesenteric vascular lesions in a rat model of DIVI. Furthermore, phosphorylation of key regulatory amino acids in eNOS such as S615, S1177, and S633 was significantly altered in response to CI-1044. The aim of the current study was to examine if other classes of drugs would produce similar lesions and whether these effects are mediated through eNOS activity. We examined the effect of a phosphodiesterase-3 inhibitor (SK&F 95654), a vasopressor (midodrine), and a vasodilator (nicorandil), in causing mesenteric vascular lesions in the rat. We also used SIN-1 or L-NAME to determine if levels of NO production, as measured by serum nitrate levels, correlated with vascular lesions. The combination of SK&F 95654 and SIN-1 led to a ~2-fold increase in serum nitrate and vascular injury over controls, while SK&F 95654 in combination with L-NAME caused a complete inhibition of vascular injury, with a three-fold inhibition of serum nitrate production, suggesting that this drug acts in a similar way to CI-1044. Interestingly, phosphorylation at S1177 was increased in response to SK&F 95654, in contrast to CI-1044. Although SIN-1 caused a ~2-fold increase in serum nitrate by midodrine, this led to a 4-fold inhibition of DIVI. Nicorandil, an NO donor, caused a ~300-fold increase in serum nitrate, either alone or in combination with SIN-1 or L-NAME. Our results illustrate that among the wide variety of drugs that can cause DIVI, modulation of eNOS activity may be a common feature of the mechanism leading to vascular injury.

### PS 1122 Soluble Components of Ultrafine Particles Induce Cellular Procoagulant Activity through Oxidant Signaling.

S. J. Snow<sup>1</sup>, A. Wolberg<sup>2</sup> and M. Carraway<sup>3</sup>. <sup>1</sup>Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>NHEERL, US EPA, Chapel Hill, NC.

Mechanisms that underlie the strong association between air pollution exposure and adverse cardiovascular health remain unknown. We hypothesize that soluble components of ultrafine particles (soluble UF) initiate procoagulant activities in endothelial cells through tissue factor (TF) induction via reactive oxygen species (ROS) production. Human coronary artery endothelial cells (HCAEC) were exposed to soluble UF and assessed for their ability to trigger procoagulant activity in platelet free plasma. HCAEC triggered faster thrombin generation and fibrin clot formation following exposure, which was abolished by an anti-TF antibody, indicating that the effects are TF-dependent. We found that TF mRNA expression was increased following soluble UF exposure without significant compensatory changes in mRNA levels of key anti-coagulant proteins, confirming that TF upregulation

plays an important role in this imbalance in the coagulation system. To study early events that might regulate TF expression, we measured H<sub>2</sub>O<sub>2</sub> production in HCAEC following exposure to soluble UF. There was an immediate induction of extra- and intracellular H<sub>2</sub>O<sub>2</sub> production following soluble UF exposure, and pretreatment with antioxidants attenuated the UF-induced upregulation of TF, linking the procoagulant response to ROS formation. Multiple chemical inhibitors indicated NOX as the source of increased TF mRNA, which was confirmed by the finding that NOX-4 siRNA prevented UF-induced upregulation of TF mRNA. These data show that exposure to soluble UF induces endothelial procoagulant activity, which requires new TF synthesis through ROS production and by NOX-4. These novel findings provide mechanistic insight into the enhanced thrombosis and endothelial dysfunction associated with air pollution exposure and increased risk for CV morbidity and mortality.

### PS 1123 Evaluation of Age and Sex Effects on Mitochondria-Related Gene Expression in Rat Heart.

V. Vijay, T. Han, C. Moland, J. C. Kwekel, J. C. Fuscoe and V. Desai. *Systems Biology, National Center for Toxicological Research, US FDA, Jefferson, AR.*

Age-related susceptibilities and sex-based differences in cardiovascular diseases are known and the underlying mechanisms need further investigation. Mitochondria are critical for normal cardiac function so alterations in such at different ages and sexes may affect the way the heart responds to drugs. To understand the role of mitochondria in age- and sex-related differences in the heart, we investigated the expression levels of mitochondria-related genes. Gene expression in the heart of male and female Fischer 344 rats at 8 (young), 21 (adult) and 78 (old) weeks of age was measured using Agilent whole genome rat arrays. Out of 18,435 unique genes on the Agilent rat microarray, 869 unique genes were determined to be mitochondria-related. Age effect was evaluated by using ANOVA coupled with pair-wise t-test (p<0.05) between each age group, and sex difference was evaluated at each age using t-test (p<0.05). The expression levels of genes involved in oxidative phosphorylation (Ox Phos), membrane transporters, and fatty acid (FA) metabolism were the highest at 21 wks compared to 8 or 78 wks in both males and females. A significant age related effect was observed in 21% and 7% of Ox Phos genes and 15% and 7% of membrane transporter genes in males and females, respectively, at all age groups. Only male rats showed significant age-related effects on the expression levels of genes (21%) involved in FA metabolism. Significant sex-based differences were observed in the expression levels of genes involved in Ox Phos at 78 wks (19%); higher expression levels were noted in female rats compared to males. Membrane transporters showed significant sex differences at 8 wks (21%), 21 wks (40%) and 78 wks (13%). Genes involved in FA metabolism also showed sex based differences at 8 (34%), 21 wks (29%) and 78wks (10%); most of the genes had higher expression in females than males. These findings may provide important insights into understanding the role of mitochondria in cardiovascular diseases in terms of sex based differences or altered susceptibility with age.

### PS 1124 Assessment of Postmarket Cardiac Adverse Events in Patients Treated with Antipsychotic Drugs.

D. Bi, R. Benz, J. Kerner, J. Willard and T. Colatsky. *Center for Drug Evaluation and Research, US FDA, Silver Spring, MD.*

This study assessed the cardiac adverse events (cAEs) induced by antipsychotic drugs, and evaluated their relationship to hERG affinities, clinical drug exposure and the magnitude of clinical QTc prolongation. Data were collected from public regulatory documents (e.g. Summary Basis for Approvals) and supplemented with published literature data. The incidence of each cardiac toxicity endpoint was calculated using the total number of all adverse events reported for each drug as a denominator. The incidence of QT prolongation was 5.1, 3.4, 0.5, 1.0, 0.9 and 1.9% for thioridazine, ziprasidone, quetiapine, risperidone, olanzapine, and haloperidol, respectively, which were correlated to the magnitude of QTc change from baseline (dQTc) of 40.7, 26.4, 19.5, 15.8, 12.7 and 11.3 msec, respectively. The incidences of Torsade de pointes (TdP) were 0.9, 0.7, 0.1, 0.2 and 0.1% for thioridazine, ziprasidone, quetiapine, risperidone and olanzapine, respectively, which were highly correlated to the dQTc. Furthermore, the incidence of QT prolongation was correlated to the ratio of total plasma C<sub>max</sub>/hERG IC<sub>50</sub> for the same group of drugs. Pimozide, one of the most potent hERG blockers (hERG IC<sub>50</sub> = 18 nM), had the highest incidences in causing QT prolongation (7.2%), TdP (3.4%), long QT syndrome (0.7%), syncope (3.4%) and sudden cardiac death (0.3%). The incidences of ventricular arrhythmia and cardiac arrest were greater than or equal to 5% in patients receiving diazepam, imipramine, thioridazine, haloperidol, amitriptyline, pimozide, or trazodone. The incidences of sudden death were more than 1% in pa-

tients treated with desipramine, thioridazine, ziprasidone or pimozide. In conclusion, relatively high incidences of potentially serious cardiac side effects, including QT prolongation, TdP, and lethal outcomes occurred in patients treated with the antipsychotics. The hERG affinities combined with the levels of clinical drug exposure may serve as one of the predictors for drug-induced cardiac toxicity by antipsychotics.

## PS 1125 Ozone Coexposure Modifies Cardiac Function Responses to Fine and Ultrafine Particulate Matter in Mice.

R. McIntosh-Kastrinsky<sup>1</sup>, H. Tong<sup>2</sup>, N. Kurhanewicz<sup>1</sup>, L. Walsh<sup>2</sup>, A. K. Farraj<sup>2</sup> and M. S. Hazari<sup>2</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Public Health Division, US EPA, Research Triangle Park, NC.

There is growing evidence from epidemiological studies that show acute exposure to particulate matter (PM) increases the risk of cardiovascular morbidity and mortality. Although the data supporting these findings are increasingly more convincing, the immediate impact of PM inhalation on cardiac function needs to be further clarified; this is particularly true of multipollutant exposures. Thus, this study was designed to evaluate the cardiac effects of concentrated ambient fine (PM<sub>2.5</sub>) and ultrafine (UFP) particles with and without ozone (O<sub>3</sub>) co-exposure. Based on previous findings, we hypothesized that UFP would cause the greatest decrement in cardiac function and that O<sub>3</sub> co-exposure would worsen the response. Mice were exposed by whole-body inhalation to either 200 µg/m<sup>3</sup> PM<sub>2.5</sub> or 100 µg/m<sup>3</sup> UFP with or without 0.3 ppm O<sub>3</sub>; separate groups were exposed to either filtered air or O<sub>3</sub> only. Twenty-four hours after exposure, cardiac function was assessed using a Langendorff cardiac perfusion preparation. Coronary flow, left ventricular developed pressure (LVDP) and contractility were measured before and after cardiac ischemia/reperfusion (I/R) injury. PM<sub>2.5</sub> or O<sub>3</sub> alone, or co-exposure to UFP+O<sub>3</sub> caused a significant decrease in baseline LVDP and contractility. Interestingly, UFP alone or PM<sub>2.5</sub>+O<sub>3</sub> did not cause significant decrements in cardiac function when compared to controls, nor were there significant differences in recovery LVDP or contractility between any group after I/R injury. These data suggest that the cardiac effects of PM inhalation are dependent on particle size and that O<sub>3</sub> interacts with PM<sub>2.5</sub> and UFP differently, resulting in varied cardiac impacts. Thus, these findings indicate that the cardiovascular effects of particle and gas co-exposures are not simply additive or generalizable, which increases the complexity of risk assessment. (This abstract does not reflect EPA policy)

## PS 1126 An Integrative Approach to Identify Functional, Structural and Pathological Biomarkers of Doxorubicin-Induced Cardiotoxicity.

H. R. Mellor<sup>1</sup>, L. Cove-Smith<sup>2</sup>, J. Kirk<sup>1</sup>, A. Hargreaves<sup>1</sup>, S. Price<sup>1</sup>, C. Betts<sup>1</sup>, C. Dive<sup>2</sup>, P. Hockings<sup>1</sup> and N. Woodhouse<sup>1</sup>. <sup>1</sup>Global Safety Assessment/PHB Imaging Group, AstraZeneca R&D, Macclesfield, United Kingdom; <sup>2</sup>The Paterson Institute For Cancer Research, University of Manchester, Manchester, United Kingdom. Sponsor: R. Roberts.

Doxorubicin is an anthracycline antibiotic commonly used in treatment regimens for a wide range of malignancies, including hematological cancers, many types of carcinoma and soft tissue sarcomas. Cardiotoxicity is a major safety complication associated with the clinical use of doxorubicin, several other marketed anti-cancer drugs and with many pre-clinical drug candidates. There is a need for novel, translational biomarkers to aid cardiac structural and functional monitoring in both patients at risk of cardiotoxicity and in pre-clinical species administered early drug candidates. In the present study, a detailed characterization of the effects of chronic doxorubicin treatment on rat heart structure and function has been performed using a range of approaches. A rat model of doxorubicin-induced cardiomyopathy was developed, involving 8 weekly intravenous boluses of doxorubicin hydrochloride followed by a 4 week 'washout' period. A timecourse assessment of cardiac function using multiple MRI biomarkers was performed under recovery anaesthesia, prior to dosing, on days 1 (baseline), 15, 29, 43, 57 and under terminal anaesthesia prior to necropsy on day 78. Reductions in cardiac output and ejection fraction were observed in treated animals from day 15. Peak myocardial enhancement was observed at day 57 onwards and correlated with serum cardiac troponin I elevations. A detailed immunohistochemical cardiac assessment is currently being performed to provide an understanding of the relationship between the development of pathological and functional MRI changes, serological biomarker elevations and cardiac pathological lesions. The ultimate aim is to apply the learning to pre-clinical drug discovery in order to support safety validation of drug targets, to optimize chemical design and to ultimately progress the safest molecules into later pre-clinical and clinical testing.

## PS 1127 Both Vitamin D Excess and Deficiency Increase Blood Pressure, but Only Excess Increases Arterial Stiffness.

N. Z. Mirhosseini<sup>1</sup>, K. Bohaychuk<sup>1</sup>, H. Vatanparast<sup>2</sup>, G. George<sup>3</sup> and L. P. Weber<sup>1</sup>. <sup>1</sup>Veterinary Biomedical Sciences, University of Saskatchewan, Saskatoon, SK, Canada; <sup>2</sup>Nutrition and Pharmacy, University of Saskatchewan, Saskatoon, SK, Canada; <sup>3</sup>Geology Department, University of Saskatchewan, Saskatoon, SK, Canada.

Vitamin D deficiency has been linked to an increased risk of hypertension, myocardial infarction and stroke. Recently, the Tolerable Upper Intake Level of 1, 25-dihydroxyvitamin D (D<sub>3</sub>) has been increased to 4000 IU/d, but levels of 10,000 IU/d for treatment of inflammatory conditions and 50,000 IU/week for short-term supplementation in deficient individuals have been suggested. High doses of D<sub>3</sub> may cause arterial calcification and cardioneurosis, but the velocity of the adverse events related to regular D<sub>3</sub> intake in doses higher than 10,000 IU/d, threshold for these changes and links to arterial calcification or hypertension are unclear. The objective of this study was to examine the effect of dietary doses of D<sub>3</sub> equivalent to recommended human doses after 1 month in male rats (n = 4/group): 0 IU/d (deficiency), 600 (recommended daily intake; control), 10,000 (upper therapeutic dose), 30,000 & 150,000 IU/d on cardiovascular function. Blood pressure telemetry and carotid artery Doppler ultrasonography were done at the baseline and weekly during diet testing. After 4 weeks, both systolic and diastolic blood pressure increased significantly (~15 mmHg; p<0.05, 1-way ANOVA, Duncan's Post-hoc test) in both D<sub>3</sub> deficiency and groups receiving ≥30,000 IU/d compared to the 10,000 IU/d group. Carotid artery luminal diameter was significantly smaller in 0 and ≥30,000 IU/d D<sub>3</sub> compared to control, which could indicate either increased arterial wall thickness or contractility. Pulse wave velocity and peak acceleration decreased over time in control and D<sub>3</sub> deficiency, but increased in groups receiving ≥30,000 IU/d D<sub>3</sub> indicating increased arterial stiffness. In conclusion, based on increased blood pressure, caution needs to be taken with D<sub>3</sub> supplementation ≥30,000 IU/d. Future studies will be directed at confirming the dose threshold and examining mechanisms for D<sub>3</sub>-induced arterial stiffness and hypertension.

## PS 1128 Fatty Acids Down Regulate and Inhibit Secretion of Adiponectin in Adipocytes through Oxidative Stress.

S. R. Kotha, T. O. Gurney, A. B. Shelton, S. I. Sherwani, U. J. Magalang and N. L. Parinandi. Division of Pulmonary, Allergy, Critical Care, and Sleep Medicine, The Ohio State University College of Medicine, Columbus, OH.

Adipose tissue is not merely a storage depot for the fat, but has emerged as a vital organ capable of synthesizing and releasing adipokines which act as regulators of diverse physiological functions. Adiponectin (30 kDa) protein, an important member of the adipokine family is known to regulate insulin action, NADPH oxidase activity, and lipid mobilization. Adiposity, release of free fatty acids from the adipose fat, and adiponectin secretion by the adipocyte are interconnected. These phenomena appear as crucial factors in cardiovascular and sleep disorders. Reports have been made on decreased circulating adiponectin levels in obese individuals, suggesting a link between fat load in adipose tissue and decrease in adiponectin release by adipose tissue. However, polyunsaturated fatty acids (PUFA) have been established as essential dietary fats and recently n-3 fatty acids (Omega-3) have gained importance in health, nutrition and disease. Having this as the premise, here, we hypothesized that PUFA load would modulate adiponectin secretion by adipocytes. To test our hypothesis, we loaded the 3T3 differentiated adipocytes with different PUFAs including linoleic (C18:2), linolenic (C18:3), arachidonic (C20:4), eicosapentaenoic (20:5; EPA), and docosahexaenoic (22:6; DHA) acids for 24 h and then analyzed the secreted adiponectin, intracellular adiponectin, fatty acid composition, triglyceride accumulation, cytotoxicity, and extent of lipid peroxidation (formation of 4-hydroxy-2-nonenal, 4-HNE) in the cells. Our results revealed that PUFA loading suppressed both adiponectin release by the cells and intracellular adiponectin, increased cellular PUFA content and triglyceride accumulation, and induced lipid peroxidation (intracellular formation of 4-HNE). Overall, our results suggested that the essential PUFAs suppressed secretion and synthesis of adiponectin in adipocytes through elevated lipid peroxidation and oxidative stress.

**PS 1129 Diesel Exhaust-Induced Cardiac Dysfunction Is Mediated by Sympathetic Dominance in Heart Failure-Prone Rats.**

A. P. Carll<sup>1,2</sup>, M. S. Hazari<sup>2</sup>, C. M. Perez<sup>3,2</sup>, Q. Krantz<sup>2</sup>, C. King<sup>2</sup>, D. W. Winsett<sup>2</sup>, D. L. Costa<sup>4</sup> and A. K. Farraj<sup>2</sup>. <sup>1</sup>Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Public Health Division, US EPA, Research Triangle Park, NC; <sup>3</sup>Curriculum in Toxicology, University of North Carolina Chapel Hill, Chapel Hill, NC; <sup>4</sup>ORD, US EPA, Research Triangle Park, NC.

Short-term exposure to vehicular emissions is associated with adverse cardiac events. Diesel exhaust (DE) may provoke cardiac events through defective co-ordination of the two main autonomic nervous system (ANS) branches. We exposed heart failure-prone rats once to DE (500 µg/m<sup>3</sup> PM<sub>2.5</sub>, 4 h, whole-body inhalation) and tested for ANS-mediation of cardiotoxicity by several interventions, including post-DE sympathetic agonism (dobutamine) before and after parasympathetic ablation (vagotomy) and, separately, sympathetic or parasympathetic inhibition (atenolol or atropine) during- and treadmill exercise after-DE exposure. Left ventricular pressure (LVP), heart rate (HR), HR variability (HRV), and blood pressure (BP) were measured to determine cardiac function and autonomic balance. During exposure hour 2, DE markedly increased HR, BP and contractility in saline-pretreated rats, and atenolol entirely inhibited these effects, indicating DE caused mid-exposure sympathetic excitation. DE increased body temperature regardless of pretreatment. Upon exercise recovery at 4 h post-exposure, HRV and HR indicated that DE increased parasympathetic influence. Conversely, during exercise recovery at 21 h post-exposure, DE increased sympathetic influence in saline-pretreated rats, while it impaired contractility and decreased systolic BP in saline- and atropine-pretreated rats. Atenolol inhibited all of these effects. LVP at 1 d post-DE indicated systolic and diastolic dysfunction and changes in diastolic and chronotropic responses to dobutamine mediated partly through sympathetic dominance. Thus, DE-induced autonomic dysregulation of the heart involves time-dependent oscillations between sympathetic and parasympathetic dominance, with the former mediating DE's cardiotoxic effects. (Does not reflect EPA policy. Funded by EPA/UNC CR-83515201-0)

**PS 1130 Remote Subcutaneous and Intravenous Administration in Large Animals: Impact on Cardiovascular Safety Pharmacology Data and Sensitivity.**

R. Mikaelian<sup>1</sup>, S. Authier<sup>1,2</sup>, A. Ascah<sup>1</sup>, M. Pouliot<sup>1</sup>, E. Troncy<sup>2</sup> and R. Forster<sup>1</sup>. <sup>1</sup>CIToxLAB North America, Laval, QC, Canada; <sup>2</sup>Faculty of Veterinary Medicine, University of Montréal, St-Hyacinthe, QC, Canada.

The regulatory guideline S7A supports the use of unrestrained models for safety pharmacology assays. Parenteral bolus administrations including the intravenous (IV) and subcutaneous (SC) routes are associated with CMax achieved immediately or within minutes of dosing for some compounds. In this context, animal handling can constitute a major interference to data quality and can obscure pharmacodynamic responses. The current investigation compared cardiovascular changes after remote SC and IV delivery in telemetered cynomolgus monkeys and Beagle dogs with restrained administration in the same species. Remote parenteral administrations were associated with a substantial decrease in data variance and consequently improved minimum detectable differences. Mean heart rate variations from baseline in the first 30 min after restrained IV saline dosing reached a maximum of 27% compared to 9.7% for remote administration. Baseline systolic arterial pressure following remote SC saline dosing in cynomolgus monkeys ranged from 93.7 and 116.4 mmHg while post-dose values in the initial 60 min post-dose ranged from 94.0 and 116.3 mmHg. Recovery of cardiovascular parameters to baseline levels after animal handling was 25 to 120 minutes in both species which can constitute a major confounder to evaluation of short half-life drug candidates. Remote dosing presented optimal results when the animals remained completely undisturbed (i.e. no staff present in the animal room). Remote IV dosing is generally recognized to improve telemetry data quality but the current investigation also demonstrate beneficial effects of remote SC injections on sensitivity of cardiovascular investigations in safety pharmacology studies using telemetry in cynomolgus monkeys and Beagle dogs.

**PS 1131 Acute Silver Nanoparticle Exposure Increases Cardiac Ischemic/Reperfusion Injury in Sprague-Dawley Rats.**

C. J. Wingard<sup>1</sup>, R. Urankar<sup>1</sup>, J. Shananhann<sup>2</sup>, A. K. Vidanapathirana<sup>1</sup>, L. C. Thompson<sup>1</sup>, S. Sumner<sup>3</sup>, T. Fennell<sup>3</sup>, J. M. Brown<sup>2</sup> and R. M. Lust<sup>1</sup>. <sup>1</sup>Physiology, East Carolina University, Greenville, NC; <sup>2</sup>Pharmacology & Toxicology, East Carolina University, Greenville, NC; <sup>3</sup>RTI International, Research Triangle Park, NC.

The expanding use and production of silver nanoparticles (AgNP) as anti-bacterial/fungal agents is raising concerns regarding their safety to human health. The diversity of nanosized silvers (AgNP) and coatings for dispersion may produce combinations that minimize potential toxic effects on the cardiovascular system. We hypothesized that acute intratracheal (IT) exposure to 20 nm (S; small) or 110 nm (L; Large) AgNP coated with either polyvinylpyrrolidone (P) or citrate (C) would increase the susceptibility of cardiac tissue to a regional ischemic reperfusion (I/R) injury. Young male Sprague Dawley rats were exposed to 200 µg of AgNP. 24 hrs post-exposure, cardiac ischemia was induced for 20 mins followed by 2 hrs of reperfusion in situ. Hearts were sectioned stained with Evans blue to demarcate Area at Risk (AAR) and counter stained with TTC to determine % of AAR infarcted. Bronchoalveolar lavage fluid (BALF) and serum was collected post I/R injury to evaluate pulmonary injury and circulating markers of injury. Neither P (22 ± 2% Infarct/AAR) nor C (24 ± 1% Infarct/AAR) altered the extent of infarcted cardiac tissue as compared to naive (22 ± 2% Infarct/AAR). However, the installation of all forms of AgNP significantly increased the extent of cardiac I/R injury. As a group the P-coated AgNP developed larger infarcts than C-coated. The 20 nm were more effective at enhancing I/R Injury (SP 43 ± 2.0 % Infarct/AAR, SC 37 ± 3 % Infarct/AAR) than the 110 nm size (LP 37 ± 3 % Infarct/AAR, LC 31 ± 2 % Infarct/AAR). The opposite pattern was observed in the BALF endpoints with P and L AgNP having greater effects. Our results suggest IT exposure to AgNP have differential effects on pulmonary and cardiac tissues following the application of I/R injury. This work is supported by NIEHS U19 ES019525.

**PS 1132 Effect of Pulmonary Exposure to Welding Fumes on Cardiomyocyte Contractility.**

H. Kan<sup>1</sup>, J. M. Antonini<sup>1</sup>, M. Ye<sup>1</sup>, W. Zheng<sup>1</sup>, R. Salmen<sup>1</sup>, R. Popstojanov<sup>2</sup> and V. Castranova<sup>1</sup>. <sup>1</sup>PPRB, NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV.

Studies have found that pulmonary exposure to welding fumes is positively associated with a higher incidence of cardiovascular events. We reported previously that pulmonary exposure to welding fumes, manual metal arc-hard surfacing (MMA-HS), has a negative impact on cardiac function as evidenced by reduced heart contractility. However, the mechanisms underlying MMA-HS-induced depression of cardiac contractility remain unclear. To study the mechanisms, rats were given an intratracheal instillation of MMA-HS welding fumes (2 mg/rat) or saline once a week for seven weeks. Cardiomyocytes were isolated at 1 and 7 days post-exposure. Cardiomyocyte contractility and intracellular calcium level in response to increasing concentrations of adrenoceptor agonist isoprenaline and extracellular calcium were assessed using a Myocyte Calcium Imaging/Cell Length System. Pulmonary exposure to MMA-HS blunted contractile function in response to both isoprenaline and calcium at 1 day post-exposure (P < 0.01; P < 0.05, respectively). A blunted contractile response was also observed with welding fume treated rats at 7 days post-exposure in response to isoprenaline and calcium (P < 0.01). Intracellular calcium level in response to extracellular calcium stimulation was reduced at 7 days post-exposure (P < 0.05). These findings suggest that pulmonary exposure to welding fumes impairs cardiac function by decreasing cardiomyocyte contractility through a defect in the adrenergic signaling pathway and intracellular calcium handling.

**PS 1133 Silver Nanoparticle Exposure Increases Vasoconstrictor Response in Nonpregnant Female Sprague-Dawley Rats.**

J. O. Dawkins<sup>1</sup>, A. K. Vidanapathirana<sup>1</sup>, L. C. Thompson<sup>1</sup>, S. J. Sumner<sup>3</sup>, T. Fennell<sup>3</sup>, J. M. Brown<sup>2</sup> and C. J. Wingard<sup>1</sup>. <sup>1</sup>Physiology, East Carolina University, Greenville, NC; <sup>2</sup>Pharmacology & Toxicology, East Carolina University, Greenville, NC; <sup>3</sup>RTI International, Research Triangle Park, NC.

The use and production of silver nanoparticles (AgNP) is growing rapidly raising concerns regarding their safety to human health, particularly following translocation to the circulatory system. Previous findings from our lab have shown intravenous (IV) exposure to AgNP changes the vasoconstrictor response in both pregnant and male Sprague Dawley (SD) rats. We hypothesized, acute IV exposure to AgNP in non-pregnant females will increase vascular reactivity of arterial vessels

from mesenteric and uterine vascular beds and aortas and these changes will be influenced by NP size and coating. Female, non-pregnant, SD rats were intravenously exposed to 200  $\mu\text{g}$  of 20 or 110 nm AgNP coated with polyvinylpyrrolidone (PVP) or citrate and suspended in water. 24 hrs. post-exposure, wire myography tested the vasomotor responses in aortic, first order mesenteric and main uterine artery vessel segments. Cumulative dose response curves were created for phenylephrine (PE), angiotensin II (ANGII), and endothelin 1 (ET1). Segments of uterine artery and aorta from AgNP exposed animals generated larger stress when compared to vehicle controls. No significant differences were observed in the mesenteric artery responses. Maximum stress values in the uterine artery were greater ( $p < 0.05$ ) in response to ET1 and ANGII stimulation following exposure to 110 nm PVP AgNP ( $16.4 \pm 2.7$  and  $14.5 \pm 2.2$  mN/mm<sup>2</sup>, respectively) as compared to 110 nm citrate AgNP ( $8.0 \pm 1.0$  and  $6.9 \pm 0.8$  mN/mm<sup>2</sup>, respectively). Conversely, maximum stress in response to PE in aortic segments was greater ( $p < 0.01$ ) following exposure to 20 nm PVP AgNP ( $1.3 \pm 0.2$  mN/mm<sup>2</sup>) as compared to 20 citrate nm AgNP ( $2.8 \pm 0.3$  mN/mm<sup>2</sup>). Our results suggest IV exposure to AgNP has differential effects on increasing the vasoconstrictor responses that are dependent on the vascular bed, size of the NP and type of coating. This work is supported by NIEHS U19 ES019525.

### PS 1134 Intravenous vs Intratracheal Administration of C60 Differentially Promotes Constriction or Impairs Relaxation of the Isolated Coronary Artery.

N. A. Holland<sup>1</sup>, L. C. Thompson<sup>1</sup>, A. K. Vidanapathirana<sup>1</sup>, J. O. Dawkins<sup>1</sup>, S. J. Sumner<sup>3</sup>, A. Lewin<sup>3</sup>, T. Fennell<sup>3</sup>, J. M. Brown<sup>2</sup> and C. J. Wingard<sup>1</sup>.  
<sup>1</sup>Physiology, East Carolina University, Greenville, NC; <sup>2</sup>Pharmacology & Toxicology, East Carolina University, Greenville, NC; <sup>3</sup>RTI International, Research Triangle Park, NC.

The potential uses of C60 fullerenes have grown to include roles in both commercial industry and medicine, but the impacts on human health are not completely understood. Data from our lab suggests that C60 may exacerbate cardiac ischemia/reperfusion injury. We hypothesized that exposure to C60 would promote enhanced vasoconstriction and impaired endothelial-dependent relaxation responses of the coronary artery. Male Sprague-Dawley rats were exposed to a single 93.3  $\mu\text{g/kg}$  dose of intravenous (IV) or intratracheal (IT) C60 or polyvinylpyrrolidone vehicle. Twenty-four hours following exposures, coronary artery segments were isolated and evaluated using wire myography. Cumulative dose responses to serotonin (5-HT), acetylcholine (ACh), or sodium nitroprusside (SNP) were constructed. We found that IT exposure to C60 resulted in a leftward shift ( $P = 0.05$ ) of the 5-HT EC50 ( $558.4 \pm 104.5$  nM) compared to vehicle ( $870.7 \pm 129.7$  nM), but that IV exposure to C60 did not significantly shift the 5-HT EC50 values (C60:  $762 \pm 112.3$  nM vs. vehicle:  $669.3 \pm 59.4$  nM). Conversely, IV exposure to C60 led to a rightward shift ( $P = 0.09$ ) in the EC50 for ACh ( $232.5 \pm 68.9$  nM) compared to vehicle ( $100.9 \pm 48.8$  nM), but IT C60 exposure did not produce any differences in ACh EC50 (C60:  $245.7 \pm 37.4$  nM compared to vehicle:  $222.4 \pm 31.6$  nM). The relaxation responses to SNP were not different between any groups. The route of exposure to C60 appears to influence an enhancement of smooth muscle contraction by IT and impaired endothelial relaxation by IV administration. Based on these data we conclude that C60 exposure could enhance coronary vascular tone, possibly compromising dilatory flow during reperfusion, and thus exacerbating myocardial infarction. This work is supported by NIEHS U19 ES019525.

### PS 1135 Intratracheal Exposure to Silver Nanoparticles Promotes Enhanced Coronary Vascular Tone.

L. C. Thompson<sup>1</sup>, A. K. Vidanapathirana<sup>1</sup>, J. O. Dawkins<sup>1</sup>, S. J. Sumner<sup>3</sup>, T. Fennell<sup>3</sup>, J. M. Brown<sup>2</sup> and C. J. Wingard<sup>1</sup>. <sup>1</sup>Physiology, East Carolina University, Greenville, NC; <sup>2</sup>Pharmacology & Toxicology, East Carolina University, Greenville, NC; <sup>3</sup>RTI International, Research Triangle Park, NC.

Silver nanoparticles (AgNP) have physicochemical and antimicrobial properties that make them useful in both industrial and biomedical applications. In regard to human exposures, little is known about the way AgNP may impact physiological systems. We tested the hypothesis that coronary responsiveness to serotonin (5-HT) and acetylcholine (ACh) would be augmented 24 hrs following exposure to AgNP, and be dependent on particle sizes and the dispersants used to coat the particles. We used male Sprague-Dawley rats (10-12 weeks old) and delivered AgNP (1 mg/kg), of either 20 nm (SS) or 110 nm (LS) diameters, and suspended in either polyvinylpyrrolidone (PVP) or citrate (Cit), by intratracheal (IT) instillation or intravenous (IV) injection. After 24 hrs we isolated segments of the left anterior descending coronary artery for wire myography analysis of 5-HT and ACh dose-responses. Our data indicate no differences in coronary responses from AgNP groups

compared to their vehicle groups. We did observe some unique dispersant- and AgNP size-dependent comparisons in the coronary responses. Maximal 5-HT stresses were higher ( $P < 0.05$ ) in the SSCit-IT group ( $4.3 \pm 0.5$  mN/mm<sup>2</sup>) compared to the SSPVP-IT group ( $2.9 \pm 0.3$  mN/mm<sup>2</sup>) or the LSCit-IT group ( $3.2 \pm 0.4$  mN/mm<sup>2</sup>). ACh responses were impacted in a dispersant-dependent manner, shifting the EC50 from  $106.6 \pm 16.6$  nM in the LSPVP-IT group to  $50.4 \pm 19.9$  nM in the LSCit-IT group. We found no significant differences between coronary responses from rats exposed intravenously to AgNP or their vehicles. We conclude that pulmonary exposure to AgNP activates biological response pathways that are sensitive both the dispersant and AgNP size. This work is supported by NIH U19 ES019525.

### PS 1136 Environmental Predictors of Oxidized Ldl Cholesterol (oxLDL) in Navajo Populations Exposed to Uranium-Contaminated Mining Sites.

M. E. Harmon<sup>1</sup>, C. Miller<sup>2</sup>, M. J. Campen<sup>1</sup>, C. Shuey<sup>3</sup>, M. Cajero<sup>2</sup>, B. Pacheco<sup>2</sup>, E. Erdei<sup>1</sup>, J. DeGroat<sup>2</sup>, G. Stark<sup>2</sup>, S. Henio-Adeky<sup>3</sup>, S. Ramone<sup>3</sup>, T. Nez<sup>3</sup> and J. Lewis<sup>2</sup>. <sup>1</sup>College of Pharmacy, University of New Mexico, Albuquerque, NM; <sup>2</sup>Community Environmental Health Program, University of New Mexico, Albuquerque, NM; <sup>3</sup>Southwest Research and Information Center, Albuquerque, NM.

Numerous abandoned mines within the Navajo Nation contribute uranium, arsenic and other heavy metals to the soil and groundwater. Environmental exposure to heavy metal contaminants may promote or exacerbate cardiovascular disease. The prevalence of type 2 diabetes, a risk factor for cardiovascular disease, has increased among the Navajo community. Evidence is emerging that pre-existing metabolic disease may increase an individual's susceptibility to vascular toxicity of heavy metal contaminants. To assess the potential impact of these contaminants on cardiovascular health of exposed individuals, we examined traditional (IL-6, CRP) and novel (oxLDL, LOX-1 receptor) plasma biomarkers in a large community of the Navajo Nation. Samples and data were obtained through a culturally appropriate community-based participatory approach, incorporating data collection and outreach by Navajo community staff. Biomarker data were linked to geospatial data on contamination sites using traditional linear regression and Bayesian models. When we used a binary model for uranium and arsenic drinking water levels, we observed that the estimated annual intake of arsenic was a significant predictor of oxLDL; age, the occupational exposure score, and the distance-environmental exposure score were also significant predictors. Diabetes, based on glycated hemoglobin, was a significant predictor of oxLDL. No environmental factors were correlated with LOX-1, CRP, or IL6. In summary, oxLDL does not seem to trend with environmental exposure to abandoned uranium mines or their heavy metal contaminants, but oxLDL does seem to trend with arsenic in drinking water. While still preliminary, these results indicate that arsenic intake may increase markers of cardiovascular risk.

### PS 1137 Pulmonary Nanoparticle Exposure Enhances Cardiac Parasympathetic Signaling.

T. L. Knuckles, J. Yi and T. R. Nurkiewicz. Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV.

Pulmonary nanoparticle exposure has been associated with alterations in autonomic signaling in the peripheral microcirculation. One possible mechanism linking pulmonary nanoparticle exposure to remote effects is modulation of autonomic influences. Several studies have indicated an increase in parasympathetic signaling in the heart following particle exposure. We have recently reported that nanoparticle exposure alters microvascular responses to sympathetic nerve stimuli. Thus, we developed a model of baroreceptor function reflexes to determine the relative autonomic contributions. Rats were exposed to titanium dioxide (nano-TiO<sub>2</sub>) for 4 hr for 1 day at 9 mg/m<sup>3</sup>. 24-hours post-exposure, baroreflex sensitivity was determined by i.v. infusion of sodium nitroprusside (SNP; 5-20  $\mu\text{g/kg}$ ) or phenylephrine (PE; 1-16  $\mu\text{g/kg}$ ), with or without atropine (1 mg/kg) to diminish parasympathetic signaling. Nano-TiO<sub>2</sub> exposure did not alter PE-induced (4  $\mu\text{g/kg}$ ) changes in mean arterial pressure ( $\Delta\text{MAP}$ ;  $25 \pm 5$  mm Hg Sham,  $26 \pm 3$  mm Hg Exposed). However, nano-TiO<sub>2</sub> exposure increased the magnitude of  $\Delta\text{heart rate}$  in beats per minute ( $\Delta\text{BPM}$   $-20 \pm 2$  control vs.  $-26 \pm 3$  exposed), suggesting an enhanced parasympathetic response. When these experiments were repeated in the presence of atropine, PE-induced  $\Delta\text{BPM}$  was diminished in both groups; however, atropine significantly altered  $\Delta\text{BPM}$  in nano-TiO<sub>2</sub> compared to sham ( $-18 \pm 1$  Sham,  $-12 \pm 2$  Exposed), suggesting an enhanced sensitivity to muscarinic receptor blockade. Atropine treatment did not significantly alter  $\Delta\text{MAP}$  in either group. Nano-TiO<sub>2</sub> exposure did not significantly alter SNP-induced changes in  $\Delta\text{MAP}$  ( $-36 \pm 5$  mm Hg control vs.  $-41 \pm 2$  mm Hg exposed), or heart rate ( $\Delta\text{BPM}$   $18 \pm 7$  control vs.  $26 \pm 7$  exposed). Because parasympathetic projections in cardiovascular system are largely confined to the heart, these data suggest that nano-TiO<sub>2</sub> exposure

alters cardiac vagal tone, perhaps as a compensatory mechanism to enhanced sympathetic influence. Future work will focus on mechanisms that precipitate alterations in autonomic function. NIH RO1-ES015022 (TRN)

**PS 1138 Cigarette Smoke Induces Ventricular Remodeling through Activation of the Aryl Hydrocarbon Receptor.**

J. Bradley, M. C. El Hajj and J. D. Gardner. *Louisiana State University, Health Science Center, New Orleans, LA.*

Cigarette smoking is the major cause of preventable morbidity and mortality, with 5 million deaths annually worldwide. Cigarette smoke (CS) increases the risk of cardiovascular disease, including myocardial infarction and coronary artery disease. Of the 4700 identified components in CS, 60 are known carcinogens with polycyclic aromatic hydrocarbons (PAH) the most abundant carcinogenic agent. Chronic exposure to PAH can lead to ventricular dilation and dysfunction. Previously, we found the 5 wks of exposure to diesel exhaust particulates (DEP), which contain a high level of PAH similar to that in CS, induced ventricular dilation and dysfunction. DEP exposure impaired ventricular remodeling through activation of the aryl hydrocarbon receptor (AHR). Because of the similarities in chemical composition, we hypothesized that chronic exposure to CS would activate the AHR pathway inducing ventricular extracellular (ECM) remodeling. Male Sprague Dawley rats were exposed to six cigarettes per day (Kentucky 2R4F) for 12 wks using a modified version of the Griffith snout exposure method. CS exposure resulted in increased expression of AHR in the left ventricle. Furthermore, these animals had increased cardiac expression of cytochrome P450 1A1, an enzyme upregulated by AHR activation. CS exposure reduced cardiac collagen as assessed through decreased levels of hydroxyproline. In addition, CS increased the expression of MMP-9, a key regulator in collagen turnover. These in vivo findings were confirmed in isolated cardiac fibroblasts, where 10% CS extract reduced the secretion of collagen by cardiac fibroblasts. In all, our findings indicate that CS alters ventricular ECM remodeling through the reduction of myocardial collagen by an AHR dependent mechanism.

**PS 1139 The Association of Vascular Disease with Exposure to Diesel Exhaust.**

M. Peterson<sup>1</sup>, P. Valberg<sup>2</sup> and C. Long<sup>2</sup>. <sup>1</sup>Gradient, Seattle, WA; <sup>2</sup>Gradient, Cambridge, MA.

Cardiovascular disease (CVD) includes numerous heart- and circulatory-system related conditions, many of which are related to the buildup of plaque in the walls of coronary (heart) arteries, in which case the disease is called coronary artery disease (CAD). CVD is the leading cause of mortality in the US, with about 25% of all deaths related to some form of this disease. While the majority of research on the health effects of exposure to disease exhaust (DE) has focused on pulmonary endpoints, there is a growing body of research on the cardiovascular effects of DE particulate inhalation. Because DE exposure in the US is widespread, both occupationally and regionally, possible cardiovascular effects from DE could have significant public health implications. We performed a weight-of-evidence evaluation of the potential for DE to cause CAD, considering the mechanistic, toxicological, and epidemiological aspects of DE. Based on our research and analysis, we find little evidence to support an association of CAD with DE exposure at low (ambient) exposure levels. In particular, the occupational epidemiology studies fail to provide consistent evidence of increased risk. We identified twelve studies of diesel-exposed worker populations in which cardiovascular health endpoints were studied. Several of these studies found significantly increased risks of one or two endpoints (or in one or two subpopulations), while other studies reported significantly decreased risks for some endpoints/subpopulations. Overall, there was not a consistent effect observed across the literature. Moreover, because of a lack of dose-response between DE particulate levels and CVD mortality, the results of our evaluation also have implications for assigning cardiovascular mortality risk to ambient air PM<sub>2.5</sub>, as is often done in assessing monetary value of PM<sub>2.5</sub> reductions.

**PS 1140 FGF21 Expresses in Diabetic Hearts and Protects from Palmitate- and Diabetes-Induced Cardiac Cell Death In Vitro and In Vivo via Erk1/2-Dependent p38 MAPK/AMPK Signaling Pathway.**

C. Zhang<sup>1,2</sup>, X. Li<sup>1,2</sup> and L. Cai<sup>1,2</sup>. <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>Wenzhou Medical College, Wenzhou, China.

The present study examined whether fibroblast growth factor (FGF) 21 expresses in the heart of diabetic mice and also protects from fatty acid (palmitate)- and diabetes-induced cardiac apoptosis. Streptozotocin (STZ) induced type 1 diabetes increased FGF21 expression about 40 fold at 2 months and 1.5 fold at 6 months. To

define if the up-regulated cardiac FGF21 expression offers a protective effect on fatty acid- or diabetes-induced cardiac damage, H9C2 cells were exposed to palmitate at 62.5  $\mu$ M for 15 h, which significantly increased apoptosis. Pre-incubation of palmitate-treated cells with FGF21 significantly reduced the apoptosis, examined by DNA fragmentation and cleaved caspase-3. Mechanistically FGF21 inhibited palmitate down-regulated phosphorylation levels of Erk1/2, p38 MAPK and AMPK. Via application of inhibitor of each kinase and Erk1/2 siRNA, FGF21 was found to prevent palmitate-induced cardiac apoptosis via up-regulating Erk1/2-dependent p38 MAPK/AMPK signaling pathway. To confirm these in vivo, STZ-induced diabetic mice were treated with FGF21 for 10 days, which significantly prevented diabetes-induced cardiac apoptosis along with up-regulation of Erk1/2, p38 MAPK and AMPK phosphorylation. The cardiac protection of FGF21 was completely blocked by Erk1/2 inhibitor. FGF21 also protected cardiac apoptosis in acute fatty acid-treated mice via the same signaling pathway. More importantly, compared to wild-type mice, FGF21 gene knock-out mice are highly susceptible to diabetes-induced cardiac cell death and inhibition of Erk1/2, p38 MAPK and AMPK phosphorylation, which could be prevented by FGF21 treatment. These results strongly suggest that the early stage increase in FGF21 mRNA expression may represent an early protective mechanism; Application of FGF21 to diabetic mice or acute fatty acid-treated mice can prevent cardiac cell death via ERK1/2-dependent p38 MAPK and AMPK signaling pathway.

**PS 1141 Effects of Nicotine on Cardiovascular Remodeling in a Mouse Model of Systemic Hypertension.**

E. S. Colombo<sup>1,2</sup>, J. Davis<sup>1</sup>, M. Makvandi<sup>1</sup>, M. Aragon<sup>1</sup>, M. Paffett<sup>1</sup> and M. J. Campen<sup>1</sup>. <sup>1</sup>College of Pharmacy & Internal Medicine, University of New Mexico Health Science Center, Albuquerque, NM; <sup>2</sup>Internal Medicine, University of New Mexico, Albuquerque, NM.

The association of cigarette smoking and hypertension with the development of heart disease and aortic aneurysms is clear. The use of nicotine-alone formulations, such as the nicotine patch, gum or 'smokeless' electric cigarettes is increasing, as they are perceived as healthier alternatives to traditional cigarettes. Unfortunately, there is little data available on the effect of isolated nicotine on myocardial and aortic remodeling in healthy subjects or in the setting of hypertension. We hypothesized that nicotine would exacerbate the effects angiotensin-induced hypertension, as evidenced by reduced left ventricular wall thickness and aortic wall remodeling. For this study we utilized subcutaneous osmotic minipumps to administer angiotensin II, nicotine, nicotine plus angiotensin II (Ang-II) or saline to C57Bl/6 (n=6) mice for a total of 4 weeks. Ventricular wall thickness, activity of matrix metalloproteinase 2 and 9 (MMP2/9) and presence of type 1 collagen was assessed as evidence of cardiac remodeling. Heart weights were increased by treatments, with control<nicotine<ang-II<nicotine+ang-II, but a statistical interaction of nicotine x ang-II was not noted. Activity levels of MMP-2 mirrored these changes and demonstrated clear additivity between nicotine and ang-II. Additionally, histopathological analysis of aortas revealed that combined nicotine and ang-II treatment induced significant hypertrophy compared to all other groups. This pilot project reveals possible cardiotoxic interactions between nicotine and angiotensin-II induced hypertension. These data indicate that in the presence of hypertension, nicotine alone can drive development of cardiovascular, which has important implications on labeling and marketing of nicotine replacement therapy. These data also raise the possibility that angiotensin inhibitors may be specifically efficacious in prevention of cardiovascular disease among hypertensive individuals using nicotine.

**PS 1142 Metallothionein Preservation of Akt2 Function by Down-Regulating TRB3 Restores Diabetic Inhibition of Cardiac Insulin Signaling.**

Y. Tan<sup>1,2</sup>, Y. Wang<sup>3,1</sup>, X. Li<sup>2</sup> and L. Cai<sup>1,2,3</sup>. <sup>1</sup>Pediatrics, University Louisville, Louisville, KY; <sup>2</sup>CARIDC, Wenzhou Medical College, Wenzhou, China; <sup>3</sup>Jilin University, Changchun, China.

Cardiac insulin resistance is a key pathogenic factor for diabetic cardiomyopathy, but its mechanism remains largely unclear. Here we demonstrated that streptozotocin-induced diabetes significantly inhibited protein kinase B (Akt) Ser473 and Thr308 phosphorylation from 2 weeks to 2 months. In cardiac-specific metallothionein-transgenic (MT-TG) diabetic mice, both Akt phosphorylation sites were preserved normally at all time-points. Analysis of Akt isoforms revealed that Akt2, but not Akt1, expression and phosphorylation were decreased at all time-points in wide-type (WT) mice, but not MT-TG mice. Diabetes also increased Akt negative regulator tribbles (TRB)3 expression only in WT mice, suggesting possible contribution of MT prevention of diabetic up-regulation of Akt negative regulator to

Akt2 function preservation. For mechanistic study, cardiac H9c2 cells with and without forced MT overexpression (MT-H9c2) were treated with tert-butyl hydroperoxide (tBHP, an organic oxidant). tBHP did not affect basal Akt phosphorylation, but significantly inhibited insulin-stimulated total Akt phosphorylation and increased TRB3 expression only in H9c2 cells. Furthermore, tBHP reduced Akt2 phosphorylation in the basal and insulin-stimulating conditions, which were significantly, but not completely, attenuated in MT-H9c2 cells. Silencing TRB3 expression with its siRNA completely blocked tBHP-induced inhibition of insulin-stimulated Akt2 phosphorylation, while overexpression of TRB3 in MT-H9c2 cells transfected with recombinant TRB3 plasmid completely abolished MT preservation of insulin-stimulated Akt2 phosphorylation in response to tBHP. These results suggest that oxidative stress-attenuated cardiac Akt, especially Akt2, function via up-regulating Akt negative regulator plays a critical role in diabetic inhibition of insulin signaling in the heart. MT preservation of Akt2 function by inhibition of Akt negative regulator prevents diabetic inhibition of cardiac insulin signaling.

#### **PS 1143 Development of an Ultrasound Imaging Biomarker of Drug-Induced Vascular Injury.**

T. A. Swanson<sup>1</sup>, M. P. Lawton<sup>2</sup>, S. Portugal<sup>2</sup>, L. Obert<sup>2</sup>, J. Kreeger<sup>2</sup> and B. E. Enerson<sup>2</sup>. <sup>1</sup>*Comparative Medicine, Pfizer Worldwide Research, Groton, CT;* <sup>2</sup>*Drug Safety Research, Pfizer Worldwide Research, Groton, CT.*

Acute drug-induced vascular injury (DIVI) is caused by several classes of drugs, including Phosphodiesterase (PDE) inhibitors and dopamine agonists. The finding of DIVI in preclinical toxicity studies presents a significant challenge for pharmaceutical companies, with many compounds terminated from development because of the inability to monitor DIVI in the clinic. Ultrasound imaging is a non-invasive technique that can be used to measure blood flow and vessel diameter in multiple tissues and across species, and therefore has the potential to be a translatable biomarker of DIVI. Our objective was to demonstrate the utility of high-frequency ultrasound imaging for measuring hemodynamic changes in mesenteric arteries of male Sprague Dawley rats treated with fenoldopam and CI-1044 (PDE4 inhibitor). Blood flow and vessel diameter were measured in the superior mesenteric arteries and right renal arteries at 4, 8 and 24 hours after dosing and the rats were subsequently necropsied at each time point. Microscopic observations consistent with DIVI were found in animals treated with fenoldopam at 24 hours and included mild to moderate perivascular accumulations of mononuclear cells, neutrophils in tunica adventitia and superficial tunica media as well as multifocal hemorrhage and necrosis in the tunica media. Animals dosed with both drugs show marked increases in flow and shear stress as early as 4 hours after dosing, with the fenoldopam-treated rats exhibited the large changes in these parameters. Vessel diameter and blood flow were used to calculate shear stress and regression analysis was used to model the relationship between the presence of lesions and various hemodynamic parameters and indicated that peak blood flow velocity was the best predictor of lesion formation. This data suggests that ultrasound imaging may provide a translatable and non-invasive functional biomarker for localized hemodynamic changes that may correlate with acute vascular lesion formation in specific target tissues.

#### **PS 1144 Environmentally-Persistent Free Radicals (EPFRs) Exacerbate Cardiac Dysfunction during Ischemia-Reperfusion (I-R) Injury.**

B. Burn, S. Mahne, V. Subramaniam and K. Varner. *Pharmacology, Louisiana State University Health Sciences Center, New Orleans, LA.*

EPFRs have been identified in the particulate matter (PM) milieu at Superfund sites. These EPFRs, capable of redox cycling and the continual generation of radical species, form during combustion processes as halogenated hydrocarbons chemisorb to transition metal-oxide-containing particles. We showed that short-term nose-only inhalation of EPFRs decreased stroke volume (SV) and cardiac output (CO) in rats secondary to increased pulmonary resistance and decreased ventricular filling. EPFRs also increased markers of oxidative stress and inflammation both systemically and in the left ventricle. Epidemiological studies link PM exposure to increased cardiac morbidity and mortality from ischemic events. Therefore, the current study sought to determine if prior exposure to EPFRs would increase cardiac vulnerability to I-R injury. The EPFRs (0.2 µm diam) tested were surrogates consisting of 1,2-dichlorobenzene chemisorbed to a silica/CuO particle at 230°C (DCB230). Rats were exposed via nose-only inhalation to DCB230 (171 µg), silica particles or vehicle for 20 min/day for 7 days. Ventricular function was measured in vivo using pressure-volume catheters. I-R injury was induced by ligating the left anterior descending coronary artery for 20 min followed by 60 min of reperfusion.

Compared to controls, baseline CO, stroke work and SV were significantly reduced by exposure to DCB230. These parameters were further reduced during ischemia and remained below control throughout reperfusion. Although not significantly different from controls, end diastolic volume and heart rate trended lower in DCB230 treated rats throughout, possibly contributing to the reduced ventricular function. Indices of contractility and diastolic function were not different between the groups. These data show that EPFRs reduce baseline ventricular function and exacerbate the decrease in ventricular function elicited during I-R injury. Supported by NIH P42-ES013648 (subaward 61365).

#### **PS 1145 The Role of Nickel in Systemic Inflammation and Blood Coagulative Effects Induced by PM2.5.**

F. Deng, P. Xia and X. Guo. *Occupational & Environmental Health Sciences, Peking University School of Public Health, Beijing, China.*

Exposure to fine particles (PM2.5) is associated with adverse cardiopulmonary health effects; however, the causative components in PM2.5 are limited. Nickel is one of the major elements of ambient particulate matters. This study was designed to investigate the acute cardiovascular systemic toxicity induced by PM2.5 on Wistar rats and the role of nickel sulfate in it. Male Wistar rats were exposed by intratracheal instillation to blank membrane (control), fine particles with the doses of 7.5, 15 and 30mg/kg body weight and balanced saline (control), Nickel sulfate at dosages of 7.5, 75 and 750µg/kg Ni; The rats were sacrificed after 24h, blood samples were collected and parameters of inflammation, cytokines, coagulative effects and the nickel levels in serum were measured to estimate the cardiovascular injury. The results showed that both of PM2.5 and Nickel sulfate induced a significant increase of serum C-reactive protein, IL-6 and TNF-α, PT levels in the plasma decreased significantly in PM2.5-treated rats compared with the control group. Plasma fibrinogen increased significantly at 15 mg/kg and 30 mg/kg PM2.5 groups. The PT and APTT showed no changes in NiSO4-treated rats, Plasma fibrinogen levels increased significantly at 750 µgNi /kg NiSO4-treated rats. The TF concentrations in plasma increased significantly at 75 µgNi/kg and 750 µgNi/kg dosage groups (P<0.05), there was a slight increase at low dosage (7.5 µgNi/kg) group. To be compared with the corresponding concentration of NiSO4, the acute effects of PM2.5 were more stronger. Our results suggest that water-soluble nickel in PM2.5 may play an important role in PM2.5 toxic effects on animal cardiovascular system.

Key words: PM2.5; Nickel sulfate ; Cardiovascular Toxicity

Note: This experiment was carried out in accordance with the Peking University Society's criteria for the care and use of animals in research.

#### **PS 1146 Involvement of Shear Stress in Fenoldopam and Dopamine-Induced Mesenteric Medial Arterial Necrosis.**

D. Dalmas, K. Frazier, H. Thomas and M. Scicchitano. *Safety Assessment, GlaxoSmithKline, King of Prussia, PA.*

Extrapolation and relevance of drug-induced rat vascular injury to humans has hampered drug development due to lack of understanding of the pathologic mechanisms involved. Although vasodilatation and increased shear stress (SS) have been hypothesized to be involved in the pathogenesis of these lesions, the exact role of SS on primary target cells, vascular smooth muscle (VSMC) and endothelial cells (EC) in vivo remain unclear. Dopaminergic DA1 agonists such as Fenoldopam and Dopamine reproducibly induce mesenteric medial arterial necrosis (MAN) in rats following single vasotoxic doses. To investigate the involvement of SS in the development of MAN, rats were given vehicle, Dopamine or Fenoldopam for 4 days. Yohimbine, a alpha-2 adrenoreceptor antagonist, also vasoactive but lacking MAN was given to rats for 4 days for comparison. To evaluate the timecourse of lesion development, rats were also given vehicle or a single vasotoxic dose of Fenoldopam and necropsied 1-, 4-, 6-, 12- or 24 hours postdose. Mesentery from each rat was collected and frozen in OCT, then EC and VSMC were microdissected from rat mesenteric arteries, and RNA was amplified and analyzed. Regulations of 37 shear stress responsive genes were evaluated using TaqMan® gene expression profiling. Many of the genes evaluated were confirmed to be differentially expressed by Dopamine and Fenoldopam in EC- and/or SMC-enriched samples as compared to controls and Yohimbine following 4 daily doses. A number of SS responsive genes were also shown to be differentially regulated beginning 1- and/or 4-hours post-Fenoldopam treatment and prior to histological evidence of MAN (which was initially observed beginning at 12-hours). Evaluation of this panel of genes has provided evidence of the involvement and regulation of SS responsive genes in both EC and VSMC during the development of Dopamine and Fenoldopam-induced vascular injury.

**PS 1147 Direct Interaction between Multiwalled Carbon Nanotubes and the Coronary Microcirculation.**

T. R. Nurkiewicz<sup>1</sup>, B. T. Chen<sup>2</sup>, D. Frazer<sup>2</sup>, R. R. Mercer<sup>2</sup>, J. F. Scabilloni<sup>2</sup>, V. Castranova<sup>2</sup> and P. G. Stapleton<sup>1</sup>. <sup>1</sup>Physiology and Pharmacology, West Virginia University, Morgantown, WV; <sup>2</sup>National Institute for Occupational Safety and Health, Morgantown, WV.

Recently our collaborative group identified multi-walled carbon nanotube (MWCNT) translocation from the lung to the heart, liver, and kidneys within 24 hours after pulmonary exposure. From this finding, we continued to examine the microvascular ramifications associated with this direct interaction. To model drug delivery platforms, as well as lung migration, MWCNT were injected into the tail vein of rats (25-900 µg, suspended in 900 µL normosol). 24-hours later, coronary arterioles (<170 µm in diameter) from the left anterior descending artery distribution were isolated for reactivity assessments based on responses to transmural pressure (myogenic responsiveness), intraluminal flow (shear stress), phenylephrine (10-9-10-4 M), acetylcholine (10-9-10-4 M), A23187 (10-9-10-5 M), and spermineNONOate (10-9-10-4 M). Myogenic responsiveness was not altered after MWCNT injection. However, MWCNT injection at all concentrations robustly attenuated reactivity. The coronary microvascular dysfunction associated with MWCNT injection is significant, impacting endothelium-dependent, -independent, adrenergic, and flow-mediated dilation pathways. These alterations, in combination with previous findings, indicate that the microvascular impairments that follow MWCNT injection are more severe than those observed after ingestion or inhalation exposure. Studies are currently underway to further evaluate mechanistic differences between these routes of exposure. NIH-RO1-ES015022 and RC1-ES018274 (TRN)

**PS 1148 Phosgene-Induced Lethal Lung Edema Correlate with Persistent Stimulation of Cardiopulmonary Reflexes.**

W. Li<sup>1</sup> and J. Pauluhn<sup>2</sup>. <sup>1</sup>Department of Toxicology, Fourth Military Medical University, Xi'an, China; <sup>2</sup>Toxicology, Bayer Pharma AG, Wuppertal, Germany.

Phosgene gas is a lower respiratory tract irritant. As such, it stimulates nociceptive vagal C-fiber related reflexes in a dose-rate and concentration x exposure duration (Cxt)-dependent manner. In rats this reflex is characterized by extended apnea time periods, bradycardia, and hypothermia. While inhalation exposures at non-lethal Cxt products show rapid reversibility of reflexively induced changes in respiratory patterns, lethal Cxt products seem to cause their prolonged stimulation after discontinued exposure to phosgene. This observation has been taken as indirect evidence that phosgene-induced lethal lung edema is likely to be caused by dysfunctional neurogenic control of cardiopulmonary and microvascular physiology. In order to verify this hypothesis, data from respiratory function measurements during and after the inhalation exposure to phosgene gas were compared with time-course measurements of respiratory and cardiac function over 20 hours post-phosgene exposure. These data were complemented by time-course analyses of nitric oxide (NOe) and carbon dioxide in exhaled breath, including time-dependent changes of extravasated protein in bronchoalveolar lavage fluid (BALF) and hemoglobin in blood. The nitric oxide synthetase inhibitors L-NAME and L-NIL were used to further elucidate the role of NOe in this type of acute lung injury and whether its analysis can serve as an early biomarker of pulmonary injury. Collectively, the sequence and time-course of pathological events in phosgene-induced lung edema appear to suggest that over-stimulated, continued sensorimotor vagal reflexes trigger changes in cardio-pulmonary hemodynamics. In the absence of any successful intervention, this imbalance progresses eventually to a refractory, self-perpetuating and self-amplifying acute lung edema within 24 hours post-phosgene exposure. The continued excessive parasympathetic tone appears to be the major etiopathology in this type of high permeability lung edema following acute high-level exposures to phosgene gas.

**PS 1149 Role of Nrf2 Antioxidant Defense in Mitigating Cadmium-Induced Oxidative Stress in the Olfactory System of Zebrafish.**

L. Wang and E. P. Gallagher. Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Exposure to trace metals can disrupt olfactory function in fish leading to a loss of behaviors critical to survival. Cadmium (Cd) is an olfactory toxicant that elicits cellular oxidative stress as a mechanism of toxicity while also inducing protective cellular antioxidant genes via activation of the nuclear factor (erythroid-derived 2)-like 2 (Nrf2) pathway. However, the molecular mechanisms of Cd-induced olfactory injury have not been characterized. In the present study, we investigated the role of

the Nrf2-mediated antioxidant defense pathway in protecting against Cd-induced olfactory injury in zebrafish. A dose-dependent induction of Nrf2-regulated antioxidant genes associated with cellular responses to oxidative stress was observed in the olfactory system of adult zebrafish following 24 h Cd exposure. Zebrafish larvae exposed to Cd for 3 h showed increased glutathione S-transferase pi (*gst pi*), glutamate-cysteine ligase catalytic subunit (*gclc*), heme oxygenase 1 (*hmox1*) and peroxiredoxin 1 (*prdx1*) mRNA levels indicative of Nrf2 activation, and which were blocked by morpholino-mediated Nrf2 knockdown. The inhibition of antioxidant gene induction in Cd-exposed Nrf2 morphants was associated with disruption of olfactory driven behaviors, increased cell death and loss of olfactory sensory neurons (OSNs). Nrf2 morphants also exhibited a downregulation of OSN-specific genes after Cd exposure. Pre-incubation of embryos with sulforaphane (SFN) partially protected against Cd-induced olfactory tissue damage. Collectively, our results indicate that oxidative stress is an important mechanism of Cd-mediated injury in the zebrafish olfactory system. Moreover, the Nrf2 pathway plays a protective role against cellular oxidative damage and is important in maintaining zebrafish olfactory function. This work was supported by the University of Washington Superfund Research Program (NIEHS P42ES004696).

**PS 1150 Cadmium Enhances Instability of Lysyl Oxidase Messenger RNA.**

Y. Zhao, S. Gao, P. Toselli and W. Li. Biochemistry, Boston University School of Medicine, Boston, MA.

Lysyl oxidase (LO), a copper-dependent enzyme, catalyzes crosslinking of collagen and elastin essential for tissue and organ morphogenesis and repair. Our previous studies have shown the critical role of downregulation of LO in cadmium (Cd)-induced emphysema pathogenesis *in vitro* and *in vivo*. The present studies further investigate Cd effects on posttranscriptional modification of the LO gene in rat fetal lung fibroblasts (RFL6). Treatment of cells with Cd (1-5 µM) inhibited levels of LO steady-state mRNAs in a dose-dependent manner. RFL6 cells displayed a relatively stable LO mRNA stability as assessed by the actinomycin D (an inhibitor of mRNA synthesis, 5 µg/ml) chase assay with the  $t_{1/2} = 24$  h. In contrast, in cells treated with 5 µM Cd plus actinomycin D, the  $t_{1/2}$  for LO mRNA decay was reduced to 0.75-h (45 min). Thus, Cd facilitates the LO mRNA decay. Rat LO mRNA contains two AU-rich elements (ARE, AUUUA), the stability determinant, at 174/178 and 200/204 downstream of the translation stop codon in the 3'-UTR. We cloned the entire LO 3'-UTR (1/229) and the ARE fragment (152/229) into the pGL3-Promoter vector after the coding region of the SV40 promoter-driven luciferase gene. The LO 3'-UTR or the ARE fragment strongly stabilized the reporter mRNAs manifested by increased luciferase activities in transfected cells. Mutation of two AREs abolished the enhancement of reporter mRNA stabilities by the LO 3'-UTR or the ARE fragment. Notably, luciferase activities driven by the LO 3'-UTR or ARE in recombinant constructs were significantly inhibited in cells treated with 5 µM Cd, indicating Cd enhancement of the decay of LO 3'-UTR or ARE-driven reporter mRNAs. HuR, a major ARE binding protein, enhances the mRNA stability. RNA immunoprecipitation (RIP) assay indicated that Cd effectively blocked the binding of HuR into the LO mRNA AREs. Thus, Cd targeting the HuR may be a critical mechanism for LO mRNA instability by this metal ion (supported by the grant of NIEHS 011340).

**PS 1151 Involvement of Inhibition of UBE2D Family Gene Expressions on Cadmium-Induced p53 Dependent Apoptosis in Human Proximal Tubular Cells.**

M. Tokumoto<sup>1,2</sup>, J. Lee<sup>2</sup>, Y. Fujiwara<sup>2</sup> and M. Satoh<sup>2</sup>. <sup>1</sup>Showa Pharmaceutical University, Machida, Japan; <sup>2</sup>School of Pharmacy, Aichi Gakuin University, Nagoya, Japan.

Cadmium (Cd), known to be a causative agent of *Itai-itai* disease, produces severe toxic effects in the kidney, liver, lung and bone. Particularly, chronic exposure to Cd causes renal dysfunction. Recently, we have found that overaccumulation of p53 may relate to Cd-induced apoptosis and may be due to the suppression of p53 degradation through the inhibition of gene expressions of Ube2d family in rat proximal tubular cells (NRK-52E cells). In this study, we examined the effects of Cd on the expressions of UBE2D family, accumulation of p53 and apoptosis in human proximal tubular cells (HK-2 cells). TUNEL positive cells, indicators of apoptosis, were increased by treatment with 20 µM Cd for 18 h. Moreover, using real-time RT-PCR, we demonstrated that Cd caused significant decrease of UBE2D2 mRNA levels from 6-h treatment, and UBE2D4 mRNA levels from 12-h treatment. Western blot analysis showed that Cd drastically increased p53 protein levels in HK-2 cells, even though the mRNA levels of p53 were decreased by Cd. Additionally, knockdown of UBE2D family genes by siRNA increased cellular protein levels of p53. These results indicate that Cd induces apoptosis through p53 accumulated by suppressions of UBE2D family gene expressions, in human proximal tubular cells as well as in rat proximal tubular cells.

**PS 1152 Serum and Hepatic Alkaline Phosphatase Activity in Rats Exposed Chronically to Cadmium.**

E. Brambila, S. Treviño-Mora, A. Andrade-García, B. León-Chávez and P. Aguilar-Alonso. *Clinical Chemistry Research Laboratory, Facultad de Ciencias Químicas, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico.*

Changes of serum and hepatic alkaline phosphatase activity in rats administered with 65 ppm of Cd<sup>2+</sup> in drinking water were studied during a 3 months period. After metal administration, Cd<sup>2+</sup> in rat livers showed an accumulation of 21 µg/g tissue. Serum alkaline phosphatase activity decrease in 3 months Cd-exposed rats. Liver alkaline phosphatase activity increased after 1 month Cd-exposed rats, however, later enzymatic activity decreased in the rats exposed to the metal by 3 months. In order to determine if Cd accumulated in liver had an inhibitory effect on enzyme activity, hepatic alkaline phosphatase from non-exposed and 3-month exposed rats to Cd was isolated and apo-alkaline phosphatase was prepared using chelex-100. Apo-alkaline phosphatase was reactivated with Zn<sup>2+</sup> and Mg<sup>2+</sup>. Reactivation assays shown that liver alkaline phosphatase isolated from Cd-exposed rats had 2-fold more activity as compared with the enzyme isolated from Cd-non-exposed rats. Protein alkaline phosphatase did not show changes between non-exposed and metal-exposed rats as determined by western-blot and ELISA assays. Results of this work suggest that chronic Cd-exposure has an inhibitory effect on serum and hepatic alkaline phosphatase activity, and the mechanism of inhibition can involve the substitution of native zinc in the enzyme by the Cd progressively accumulated in the tissue.

**PS 1153 The Cadmium-Responsive Genes *Numr-1* and *Numr-2* Are Regulated by Multiple Pathways.**

Q. Ding and J. H. Freedman. *NIEHS, Research Triangle Park, NC.*

Exposure to the carcinogenic metal cadmium can activate multiple signaling pathways to affect the expression of hundreds of genes. However, the molecular mechanism by which cadmium affects transcription is not completely understood. Whole genome microarray studies in the nematode *C. elegans* showed nuclear metal-responsive gene-1 (*numr-1*) mRNA levels increased 7-fold following a 24h cadmium exposure. Subsequent genomic analysis identified a second gene, *numr-2*, that is 99% identical to *numr-1*, in both coding and regulatory regions. Both *numr*'s are developmentally regulated and expressed in identical cells: constitutively in a subset of neurons in the head, vulva and tail; and in intestinal and pharyngeal cells following metal exposure. Metals and calcium, but not other environmental stressors, induce *numr-1/2* transcription. Bioinformatic analysis identified 25 putative, upstream regulatory elements in the *numr* promoters. The roles of the cognate DNA binding proteins on *numr-1* expression in the absence and presence of cadmium was examined in loss of function mutants or by RNAi. Among the tested genes, two alleles of *osm-9* (TRPV channel protein), *ok1677* and *ky10*, showed significant gene-cadmium interactions, suggesting *osm-9* regulates cadmium-induced *numr-1/2* transcription. Three other genes may also be involved in *numr-1/2* transcriptional regulation: *ceb-20* (homeodomain protein), *unc-86* (POU-type homeodomain protein) and *gem-4* (calcium-dependent phosphatidylserine binding protein). In addition to *osm-9*, *unc-86* and *ceb-20* are expressed in neurons, suggesting a link between neuronal activity and metal-inducible *numr-1/2* transcription. The four candidate genes are present in independent signaling pathways, which suggest that cadmium-induced *numr-1/2* transcription is regulated by multiple signaling pathways. Further analyses disrupting these signal transduction pathways will be used to define the role of these genes in cadmium-induced *numr-1/2* transcription.

**PS 1154 SRC Kinase Participation in MT-II Production and Acetylation STAT3 in Mouse Hepatocytes Exposed to Cadmium.**

K. Martínez<sup>1</sup>, V. Souza<sup>1</sup>, A. López<sup>1</sup>, A. López-Reyes<sup>2</sup>, D. Clavijo<sup>1</sup>, L. Bucio<sup>1</sup>, L. Gómez-Quiroz<sup>1</sup> and M. Gutiérrez-Ruiz<sup>1</sup>. <sup>1</sup>Ciencias de la Salud, Universidad Autónoma Metropolitana, Mexico City, Mexico; <sup>2</sup>Dirección de Investigación, Instituto Nacional de Rehabilitación, Mexico City, Mexico.

Cadmium(Cd), a toxic metal initially accumulated in the liver, forms high affinity complexes with metallothionein-II (MT-II). This protein requires the activation of transcription factors such as STAT3. Phosphorylation is crucial to regulate the activity of several proteins, as well as acetylation, has been linked in gene expression processes giving greater affinity for the transcription factors to DNA. This process has been reported in STAT3 to form more stable dimers. There is evidence that this modification is carried out by the p300 coactivator protein, which is characteristic

because of its histone acetyltransferase activity and its Stat3 C-terminal affinity. MT-II production also has been associated with Src; however, molecular mechanisms induced by Cd have not been yet fully understood. The aim was to evaluate the participation of Src in Stat3 activation and its relation with MT-II production and acetylation in hepatocytes treated with 5µM CdCl<sub>2</sub>. Primary mouse hepatocytes were treated with different Cd concentrations determining phosphorylation of STAT3, Src, ERK1/2 and the induction of p300 and MT-II by Western-blot. A pretreatment for 30 min with Src inhibitor SU6656 was performed to evaluate the relationship between STAT3 activation and MT-II content; the same approach was done with the ERK1/2 inhibitor PD98059, used to correlate STAT3 activation and ERK signaling. We proved that Cd induced STAT3 acetylation. Cd increased activation of STAT3, Src, ERK1/2, p300, and MT-II. STAT3 phosphorylation and ERK1/2 were significantly reduced by Src, ERK1/2 inhibitors. MT-II expression diminished with Src inhibitor. Our results suggest that Cd induces STAT3 phosphorylation by a mechanism dependent of Src and ERK1/2, while STAT3 induces acetylation by p300 likely to increase production of MT-II as a biological response to Cd. **PS 1155 Overaccumulation of p53 and Induction of Apoptosis in Renal Tubules of C57BL/6 Mice Chronically-Exposed to Cadmium.**

J. Lee<sup>1</sup>, M. Tokumoto<sup>1,2</sup>, Y. Fujiwara<sup>1</sup> and M. Satoh<sup>1</sup>. <sup>1</sup>School of Pharmacy, Aichi Gakuin University, Nagoya, Japan; <sup>2</sup>Showa Pharmaceutical University, Tokyo, Japan.

Long-term exposure to cadmium (Cd) affects adversely to renal tubules. We have recently demonstrated that Cd induces p53-dependent apoptosis through the inhibition of gene expression of Ube2d family in rat proximal tubule cells (NRK-52E cells). In this study, we examined the effect of chronic exposure to Cd on the localization of p53-dependent apoptosis in kidney of mice. Five weeks old female C57BL/6 mice were fed diet containing 300 ppm Cd without restraint for 12 months. After 6- and 12-month feeding, we evaluated renal toxicities, and measured mRNA levels of Ube2d family and protein levels of p53 in kidney. In order to examine the localization of p53, we used immunostaining with anti-p53 antibody. Localization of apoptosis was examined by TUNEL staining. Although exposure of mice to Cd induced mild renal toxicity, significant decreases of mRNA levels of Ube2d family and accumulation of p53 were detected in kidney. Interestingly, not only overaccumulation of p53 proteins but also induction of apoptosis was triggered specifically in renal tubules of mice by Cd exposure. These results indicate that Cd may induce apoptosis through p53 accumulated by suppressions of Ube2d family expressions, specifically in renal tubules.

**PS 1156 Effects of Cadmium on the Urinary Excretion and Localization of Cystatin C in Kidney.**

W. C. Prozialeck<sup>1</sup>, A. Van Drael<sup>1</sup>, S. Zawdzka<sup>1</sup>, J. Edwards<sup>1</sup>, C. D. Ackerman<sup>1</sup> and V. S. Vaidya<sup>2</sup>. <sup>1</sup>Department of Pharmacology, Midwestern University, Downers Grove, IL; <sup>2</sup>Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Cadmium (Cd) is a nephrotoxic environmental pollutant for which there is an urgent need for improved biomarkers of toxicity. Cystatin C is a low molecular weight protein that has been shown to be a sensitive biomarker for ischemic, and some types of toxic, kidney injury. The objective of the present study was to determine if cystatin C might be a useful early biomarker of Cd nephrotoxicity. Adult male rats were given subcutaneous injections of Cd (0.6 mg/kg, 5 days per week). At 6, 9 and 12 weeks, urine samples were collected and analyzed for cystatin C, protein, creatinine and kidney injury molecule-1 (Kim-1). Serum was analyzed for creatinine and cystatin C, and kidneys were processed for histopathologic analyses. Cd caused a 1-2 fold increase in urinary excretion of cystatin C and larger increases in Kim-1 excretion that were evident at 6, 9 and 12 weeks. No change in urinary protein was evident until 12 weeks. Cd had no effect on urinary creatinine or serum levels of creatinine and cystatin C. Histochemical analyses revealed evidence of proximal tubule injury in the Cd-treated samples, along with alterations in the pattern of cystatin C distribution. Control samples showed a speckled pattern of cystatin C labeling beneath the apical surface of the proximal tubule cells, whereas, Cd treated samples exhibited diffuse labeling in the cytoplasm and on the cell surface. The pattern of cystatin labeling paralleled that of the brush border transport protein megalin, which has been implicated as a mediator of cystatin C uptake in the proximal tubule. These results indicated that Cd increases the urinary excretion of cystatin C, and they suggest that this effect may involve disruption of megalin-mediated uptake of cystatin C by epithelial cells of the proximal tubule. Supported by Midwestern University and NIH Grant RO1 ES006478 to WCP.

**PS 1157 Cadmium Exposure Affects Insulin Signaling in *Caenorhabditis elegans*.**

Y. Sun and J. H. Freedman. *BSB, DNTP, NIEHS, Research Triangle Park, NC.*

Diabetes mellitus (DM) and diabetes-related kidney disease are serious, world-wide health problems. Although there is no direct evidence linking cadmium (Cd) to DM, Cd exposure alters blood glucose levels and potentiates diabetic nephropathy. The insulin/insulin-like growth factor signaling (IIS) pathway regulates multiple biological functions including glucose metabolism and longevity. The model organism *C. elegans*, which has an IIS pathway homologous to that of mammalian species, was used to investigate mechanistic links among Cd, transcription, and insulin signaling. The focus of this investigation was the *C. elegans* Cd-responsive gene *cdr-1*, whose transcription is up-regulated almost 800-fold exclusively by Cd. To identify regulatory factors and pathways that control *cdr-1* transcription, an integrated transgenic strain of *C. elegans* containing GFP under the control of the 5'-regulatory region of *cdr-1* was constructed. Following cadmium exposure (10  $\mu$ M, 24 h) in the transgenic strain, GFP expression increases in intestinal cells. In a candidate screen, genes involved in various stress response pathways were tested for their potential role in controlling *cdr-1* expression. Genes were knocked out either by genetic crosses to known loss-of-function *C. elegans* mutants or by RNAi. Changes of *cdr-1* transcription were then determined by measuring GFP expression or qRT-PCR. The expression of *cdr-1*, in both the absence and presence of Cd (100  $\mu$ M, 5 h) was suppressed when genes in the IIS pathway; *daf-2*, *age-1*, *daf-18*, *pdsk-1*, *akt-2*, *sgk-1* and *daf-16*; were knocked down. Statistically significant interactions between Cd and IIS pathway genes were observed. Furthermore, knocked down of IIS pathway-related genes; *skn-1*, *hsf-1*, *pha-4*, *pop-1*, *lin-14*, *tor-2*, *ras-1*, *wnk-1*; also inhibited *cdr-1* expression in response to Cd. These results suggest that the IIS pathway mediates Cd-inducible transcription. In addition, they support a model where Cd exposure could induce elevated blood glucose levels by directly affecting the IIS pathway. The mechanism by-which Cd activates the IIS pathway is currently being investigated.

**PS 1158 Investigating a Protective Role of the Antioxidant N-Acetylcysteine against Cadmium-Induced Damage to Bone Extracellular Matrix.**

D. D. Wright, W. S. Wright and S. J. Heggland. *Biology, The College of Idaho, Caldwell, ID.*

Environmental pollution of cadmium, a heavy metal commonly utilized in electronics, is a global human health concern. Bone is a known target site for cadmium. One mechanism to protect against cadmium-induced osteotoxicity and bone loss is by reducing oxidative stress. Our lab previously demonstrated that n-acetylcysteine (NAC) rescues osteoblasts from cadmium-induced apoptosis. Others have shown that reactive oxygen species generated through oxidative stress decreases bone mineral density, in part, through targeting the collagen component of the extracellular matrix (ECM). We hypothesize that the antioxidant NAC will protect against cadmium-induced damage to ECM produced by osteoblasts. Saos-2 cells were induced to mineralize and treated with 1mM NAC or 5 $\mu$ M CdCl<sub>2</sub> only or in combination for 6 or more days. Upon termination cell viability, phosphate ECM deposition, and collagen secretion and distribution in the ECM were evaluated using MTT, von Kossa, SircolTM collagen assay, and immunofluorescence, respectively. Treatment with CdCl<sub>2</sub> for 6 days resulted in increased phosphate deposition, which was restored to that of control in the presence of NAC. We also examined collagen, the main organic component of the ECM. When osteoblasts were induced to form an ECM, treatment with CdCl<sub>2</sub> led to significantly less collagen secretion which was reflected in less collagen deposition into the ECM; these effects were reversed in the presence of NAC. Further, NAC and NAC combined with CdCl<sub>2</sub> significantly increased cell viability compared to control, leading us to also investigate cell cycle progression. These studies provide further evidence that antioxidants promote bone health by reducing the toxic effects of cadmium. Research funded by NIH-INBRE P20 RR016454 and P20 GM103408 and NIH R15ES015866 grants.

**PS 1159 Cadmium Causes Injury to Pancreatic Islets That Is Associated with Caspase-3 Labeling.**

J. Edwards and Y. Bahrami. *Pharmacology, Midwestern University, Downers Grove, IL.*

Diabetes is a growing worldwide epidemic. There is increasing interest in how environmental contaminants can contribute to the onset of type II diabetes. Impaired insulin release is a hallmark of type I diabetes and is key in the progression of type II diabetes. Multiple epidemiological and experimental studies show that exposure

to the metal cadmium (Cd), is associated with diabetes and reduced serum insulin. To examine the cytotoxic effects of Cd within pancreatic islets, male Sprague Dawley rats were injected subcutaneously with either saline (control) or Cd (0.6 mg Cd/kg/day, 5 days per week). After 6, 9 and 12 weeks of Cd treatment, pancreatic tissue samples were removed then fixed in formalin. Pancreata were sectioned and H&E stained to identify islets then examined for changes in islet histology. A trained veterinary pathologist scored each sample for cytoplasmic vacuolization and signs of necrosis and apoptosis. All pancreata from Cd treated animals had elevated scores for signs of vacuolization, apoptosis and necrosis. However, these changes in cell viability did not appear to change with longer Cd exposure times. In another study using the same pancreas samples, tissue was labeled for the apoptosis indicator, active caspase 3. In this study, pancreatic samples were counter stained with hematoxylin so that immuno-labeled islets could be identified. This study resulted in similar findings. Islets from Cd-treated animals had greater caspase-3 labeling and as before, the intensity of labeling appeared to be time independent. These preliminary results show that Cd acts to injury pancreatic islets which may result in diminished insulin release.

**PS 1160 Regulation of Glutathione Synthesis in Cadmium-Treated Cultured Choroid Plexus.**

S. Francis Stuart, R. Young and A. Villalobos. *Interdisciplinary Faculty of Toxicology and Nutrition & Food Science, Texas A&M University, College Station, TX.*

In primary cultures of rat choroid plexus we have shown that exposure to cadmium (Cd) induces oxidative stress, stimulates apical choline uptake, and alters glutathione (GSH) synthesis. Our aim is to characterize the regulation of GSH availability and synthesis in response to low dose exposure to Cd and assess the significance of GSH in cellular adaptation to Cd. We treated choroid plexus primary cultures with 0 or 500 nM CdCl<sub>2</sub> in serum free medium (SFM) for 12 h and collected samples at 3, 6, 9, and 12 h. Induction of heme oxygenase-1 (HO-1), heat-shock protein 70 (HSP70), and metallothionein-1 (MT-1) in Cd-treated cells was compared to time-matched controls by immunoblot and qRT-PCR analyses. HO-1 protein was induced at 3 h and gradually increased through 12 h. HO-1 gene expression was maximally induced by 70-fold at 6 h and was sustained through 12 h. HSP70 protein was maximally induced by 5-fold at 12 h. MT-1 gene expression was induced by 50-fold at 12 h. Cd induced the catalytic and modifier subunits of glutamate-cysteine ligase (GCL), the rate-limiting enzyme in GSH synthesis. GCLC protein levels peaked at 6 h while GCLM peaked at 9 h. Gene expression of GCLC and GCLM increased by 5-fold and 4-fold at 12 h. To elucidate the effects of Cd on GSH concentration, cells were pretreated (12 h) without or with buthionine sulfoximine (BSO, 100  $\mu$ M) then treated with 0 or 250 nM CdCl<sub>2</sub>  $\pm$  BSO in SFM for 12 h. Intracellular GSH and oxidized glutathione (GSSG) concentrations were assayed and compared to control. Cd increased GSH by 2-fold and increased GSSG by 30-fold. In Cd-treated cells, BSO reduced GSH concentrations by 92% but increased GSSG concentrations by 15-fold above controls. Inhibiting GSH synthesis with BSO augmented induction of HO-1, HSP70, and MT-1 and enhanced stimulation of apical choline uptake in Cd-treated cells. These data indicate that Cd stimulates GSH synthesis at points of transcription and translation, and the inhibition of GSH synthesis accentuates cellular stress.

**PS 1161 Stable Expression of FRET-Based Cd(2<sup>+</sup>) Biosensor for Advanced Research of Cytotoxic Cd(2<sup>+</sup>).**

D. Yang<sup>1,2</sup> and T. Chiu<sup>2,1</sup>. <sup>1</sup>Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taiwan; <sup>2</sup>Institute of Biophotonics & Biophotonics and Molecular Imaging Research Center (BMIRC), National Yang-Ming University, Taipei, Taiwan.

Cadmium ion (Cd<sup>2+</sup>) causes lots of human tissue damages. Several ion channels and transporter proteins as the molecular gateway of different ions have been previously proposed to be the cytotoxic entry mechanism(s) of Cd<sup>2+</sup>. However, the solid conclusions have not been made. Here we tried to explore this issue through establishing human cell line stably expressing the fluorescent resonance energy transfer (FRET)-based Cd<sup>2+</sup> biosensor for monitoring content of intracellular Cd<sup>2+</sup>. This newly constructed Cd<sup>2+</sup> sensor Met-cad 1.57 contains part of Cd<sup>2+</sup>-binding protein CadR originated from bacteria *Pseudomonas putida* as the Cd<sup>2+</sup> sensing key. Through G418 selection, the HEK293 line stably expressing Met-cad 1.57 HEK-MCD157 cells have been archived. The spectral patterns and sensing ranges of Met-cad 1.57 for intracellular Cd<sup>2+</sup> sensing were characterized in vivo under 96-well plate. Under both a fluorescence spectroscopy and a FRET microscopic ratio imaging, the contents of Cd<sup>2+</sup> were than monitored within living HEK-MCD157 cells. The dynamic range of Met-cad 1.57 from 0 to 100  $\mu$ M of Cd<sup>2+</sup> is 2–4.4 (2.2

fold) with a dissociation constant  $K_d$  around 271 nM. The role of voltage-gated  $Ca^{2+}$  channels as the candidate of  $Cd^{2+}$  entry gateway was further explored with the HEK-MCD157 cells. In summary, a human embryonic kidney cell line HEK-MCD157 stably expressed FRET-based  $Cd^{2+}$  biosensor Met-cad 1.57 was constructed for both reliable and convenient investigations on content measurement of  $Cd^{2+}$  within live-cell including the identification of  $Cd^{2+}$  entry pathway and subcellular sequestration.

## PS 1162 Blood Cadmium Level of Residents Living near the Abandoned Metal Mines in Korea.

D. Kim<sup>1</sup>, S. Ahn<sup>1</sup>, J. Ryu<sup>1</sup>, S. Yu<sup>1</sup> and D. Park<sup>2</sup>. <sup>1</sup>*Environmental Health, National Institute of Environmental Research, Incheon, Republic of Korea;* <sup>2</sup>*Environmental Health, Korea National Open University, Seoul, Republic of Korea.*  
Sponsor: J. Park.

**Introduction:** Preliminary biological exposure monitoring study selected 38 among 906 metal mines abandoned in Korea as the relative high risk areas for national surveillance subjects. They were surveyed from 2008 to 2011 under the environmental health policy by Ministry of Environment. The purpose of this study is to assess the blood cadmium levels from people living around a total of 38 abandoned metal mine areas and to determine if those areas have influenced exposure to cadmium of residents.

**Methods:** Blood cadmium levels were quantified using graphite furnace atomic absorption spectrometry (AAS) through appropriate blood collection, storage and pretreatment procedure. People living less than 3 km from the abandoned mine area were classified as the exposure group ( $n=4,687$ ). Control group ( $n=2,643$ ) was selected from people living in non-mining areas.

**Results:** Blood cadmium level from exposure group was found to be 1.59 ug/L as geometric mean (GM) (95 % CI: 1.56 - 1.62 ug/L) and 1.91 ug/L as arithmetic mean (AM) (95 % CI = 1.88-1.94 ug/L). Those levels were significantly higher than those from control group (GM=1.28 ug/L, 95 % CI=1.25-1.31 ug/L, AM= 1.52 ug/L, 95 % CI = 1.49-1.56 ug/L) ( $p<0.0001$ ). In addition, 79.5% ( $n=3,728$ ) of exposure group and 69.6% ( $n=1,840$ ) of control group exceeded the reference value (1.0 ug/L) derived by German human biomonitoring commission. Multiple regression model found that exposure group was significantly higher than that of control group after age, gender and smoking status were all adjusted (adjusted  $R^2=16.5\%$ ,  $p<0.0001$ ).

**Conclusions:** We found that blood cadmium level of people residing near abandoned metal mine area was significantly high, compared with those of control group. Our findings suggested that the abandoned mine areas may have elevated blood cadmium level of people in the vicinity of those areas.

## PS 1163 One-Week and Four-Week Inhalation Toxicity Studies of Nickel Sulfate and Nickel Subsulfide in Rats.

D. E. Dodd<sup>1</sup>, H. J. Clewell<sup>1</sup>, M. A. Sochaski<sup>1</sup>, H. G. Wall<sup>2</sup>, G. A. Willson<sup>2</sup> and A. R. Oller<sup>3</sup>. <sup>1</sup>*The Hamner Institutes for Health Sciences, Research Triangle Park, NC;* <sup>2</sup>*Experimental Pathology Laboratories, Inc., Research Triangle Park, NC;* <sup>3</sup>*NiPERA, Inc., Durham, NC.*

Inhalation toxicity studies of nickel sulfate ( $NiSO_4$ ) and Ni subsulfide ( $Ni_3S_2$ ) were conducted in F344 rats to evaluate cellular pathway responses in lung distal airways using gene expression analysis. Supportive data included lung histopathology, bronchoalveolar lavage (BAL) fluid analysis, and total Ni lung burden analysis. Groups of 5 to 8 male F344 rats were exposed to 0 (control), 0.125, 0.25, 0.5, or 1.0 mg/m<sup>3</sup>  $NiSO_4$  hexahydrate aerosol (0.8-1.2  $\mu$ m MMAD) or 0, 0.04, 0.08, 0.15, or 0.6 mg/m<sup>3</sup>  $Ni_3S_2$  aerosol (2.2-3.2  $\mu$ m MMAD) for one or four weeks duration (6 hr/day, 5 days/week).  $NiSO_4$ -exposed rats showed the following BAL results at 4 weeks: decrease in macrophage percentage, increases in neutrophil and lymphocyte percentages ( $\geq 0.5$  mg/m<sup>3</sup>); increases in LDH, total protein, and NAG, with a decrease in ALP levels (1.0 mg/m<sup>3</sup>). Minimal to slight/mild bronchial epithelial degeneration/hyperplasia and slight/mild alveolus inflammation were observed in the 1.0 mg/m<sup>3</sup> rats. Total Ni in lungs of exposed rats could not be directly measured due to interference with RNAlater solution. Ni concentrations were estimated at 0.7 to 1.0 ug Ni per g lung following 0.5 or 1.0 mg/m<sup>3</sup>  $NiSO_4$ . In the  $Ni_3S_2$  study, BAL results were similar to those for  $NiSO_4$ . Macrophage percentage was decreased, neutrophil and lymphocyte percentages were increased ( $\geq 0.15$  mg/m<sup>3</sup>), and increases in LDH, total protein, and NAG, with a decrease in ALP were observed. Minimal peribronchiolar/perivascular inflammation and alveolus inflammation were observed in the 0.6 mg/m<sup>3</sup> rats following one week exposure. Minimal to slight/mild alveolus inflammation was observed at 4 weeks ( $\geq 0.15$  mg/m<sup>3</sup>). Quantitative results of total Ni in lung indicated a range of 1.6 to 14.4 ug Ni per g

lung following 4 weeks  $Ni_3S_2$  exposure (0.04 to 0.6 mg/m<sup>3</sup>). These data will be integrated with results of gene expression analysis to evaluate mode of action pathways of Ni toxicity.

## PS 1164 Gene Expression Profiles in Peripheral Blood Mononuclear Cells of Chinese Nickel Refinery Workers with High Exposures to Nickel and Control Subjects.

A. B. Munoz<sup>1</sup>, A. Arita<sup>1</sup>, J. Niu<sup>1</sup>, Q. Qu<sup>1</sup>, N. Zhao<sup>2</sup>, Y. Ruan<sup>2</sup>, K. Kiok<sup>1</sup>, T. Kluz<sup>1</sup>, H. Sun<sup>1</sup>, Y. Chervona<sup>1</sup>, H. A. Clancy<sup>1</sup>, M. Shamy<sup>3</sup> and M. Costa<sup>1</sup>. <sup>1</sup>*Environmental Medicine, New York University Graduate School of Arts and Sciences, New York, NY;* <sup>2</sup>*Lanzhou University School of Public Health, Lanzhou, China;* <sup>3</sup>*Environmental Sciences, King Abdulaziz University, Jeddah, Saudi Arabia.*

**Background:** Occupational exposure to nickel (Ni) is associated with an increased risk of lung and nasal cancers. Ni compounds exhibit weak mutagenic activity, alter the cell's epigenetic homeostasis, and activate signaling pathways. However, changes in gene expression associated with Ni exposure have been only investigated in vitro. This study was conducted in a Chinese population to determine whether occupational exposure to Ni was associated with differential gene expression profiles in the peripheral blood mononuclear cells (PBMCs) of Ni-refinery workers when compared to referents.

**Methods:** Eight Ni-refinery workers and ten referents were selected. PBMC RNA was extracted and gene expression profiling was performed using Affymetrix exon arrays. Differentially expressed genes between both groups were identified in a global analysis and findings were validated using real-time PCR.

**Results:** A total of 2167 differentially expressed genes displayed a greater than 1.25 fold-change in Ni-refinery workers. DNA repair and epigenetic genes were significantly overrepresented ( $p<0.0002$ ). Of 31 DNA repair genes, 29 were repressed in the high exposure group and two were overexpressed while these genes were not repressed in the control group. Of the 16 epigenetic genes 12 were repressed in the high exposure group and 4 were overexpressed.

**Conclusions:** The results of this study indicate that occupational exposure to Ni is associated with alterations in gene expression profiles in PBMCs of subjects.

**Impact:** Gene expression may be useful in identifying patterns of deregulation that precede clinical identification of Ni-induced cancers.

## PS 1165 Differential Severity of Chromium-Induced Hepatotoxicity in a Day.

N. Miura<sup>1</sup>, M. Togawa<sup>2</sup> and T. Hasegawa<sup>2</sup>. <sup>1</sup>*National Institute of Occupational Safety and Health (NIOSH), Kawasaki, Japan;* <sup>2</sup>*Yamanashi Institute Environmental Science, Yamanashi, Japan.*

The diurnal variation of cadmium-induced mortality is our topic (*J Toxicol Sci*, 37, 191, 2012). We presented further evidences for the Cd-induced diurnal variation and considered the mechanism of these in SOT 2012 meeting. In this study, we report the diurnal susceptibility of chromium-induced toxicity in mice. Male C57BL/6J mice adapted for 14 days with assigned to 6 groups of 5 animals were administered intraperitoneally (i.p.) with hexavalent chromium ( $K_2Cr_2O_7$ , 35 mg/kg) at different hours in the day (10:00, 14:00, 18:00, 22:00, 2:00 and 6:00 h), describing as zeitgeber time (ZT); ZT2, ZT6, ZT10, ZT14, ZT18 and ZT22. In case of dark period (ZT14, ZT18 and ZT22), administrations were performed under red light. The mortality was determined during 14 consecutive days. Mice were most sensitive to Cr administered at ZT10, while least sensitive at ZT22. In contrast, the susceptibility to Cd-induced mortality was higher at ZT6 but lower at ZT18. Therefore, the daily fluctuation of metal sensitivity differed depending on metal compounds, probably depending on the valence of metal ion. The GPT value, an index of hepatotoxicity, also showed higher at ZT10 injection of Cr. The hepatic levels of Cr determined by ICP-MS were not significantly different between both time (ZT10 and ZT22), thus Cr accumulation in the liver was not a determination factor for this diurnal variation. Our results clearly indicate the susceptibility of metal-induced toxicity is markedly different in a day. We believe this viewpoint should be introduced into toxicology as "chronotoxicology" becoming indispensable in the future toxicology.

## PS 1166 Speciation of Chromium Released from Metal-On-Metal Hip Implants.

K. Thuet<sup>1</sup>, B. L. Finley<sup>1</sup>, P. K. Scott<sup>2</sup> and D. J. Paustenbach<sup>1</sup>. <sup>1</sup>*ChemRisk, LLC., San Francisco, CA;* <sup>2</sup>*ChemRisk, LLC., Pittsburgh, PA.*

Increased blood chromium (Cr) concentrations have been measured in many patients with hip prosthetic devices containing cobalt-chromium-molybdenum alloy. To date, no studies have attempted to analytically distinguish between non-toxic

trivalent Cr, Cr(III), and potentially harmful hexavalent Cr, Cr(VI), in these patients. However, it is known that Cr(VI) preferentially accumulates in red blood cells (RBCs), while Cr(III) remains largely confined to the serum compartment of the blood. Hence, the relative distribution of Cr into RBCs and serum is often used as an indirect measure of Cr valence. We reviewed 231 blood samples from six different studies involving patients with Cr-containing hip implants. Samples were generally collected pre-implant and then at three or six month intervals post-implant for up to two years. The ratio of serum to RBC Cr concentrations was highly consistent. Post-implant serum Cr concentrations (median values of 0.17-2.39 µg/L) typically increased by several fold over pre-implant concentrations (median value of approximately 0.2 µg/L), but the RBC concentrations did not increase over time. Specifically, the RBC Cr concentrations did not change pre- vs. post-implant (median values of 0.26 to 2.5 µg/L). These data indicate that the Cr released from the implants is in the form of Cr(III).

**PS 1167 E162 Protects against Chromium (VI)-Induced Cytotoxicity and Genotoxicity in Human Lung Fibroblast Cells.**

M. Braun<sup>1,2</sup>, J. Lechner<sup>2</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME.

Hexavalent chromium [Cr(VI)] is a ubiquitous environmental toxicant. Studies show that Cr(VI) induces many forms of DNA damage that may lead to cancer if they are not repaired. Nutraceuticals, because of their antioxidant properties, have the potential to decrease toxicity. The purpose of this study was to assess the protective effects of E162, a soluble powder made from crushed beets, on Cr(VI)-induced toxicity. We compared the levels of damage generated after co-treatment with Cr(VI) and E162 in human lung fibroblasts to those after Cr(VI) treatment alone for both acute and chronic exposures. Sodium chromate was used as a representative soluble Cr(VI) compound. After a short-term exposure, there was no protective effect of E162. After chronic exposure, however, E162 had a noticeable protective effect on sodium chromate-induced cytotoxicity and genotoxicity. For example, at 1 µM sodium chromate, only 19 percent of cell colonies survived compared to control, while E162 co-exposure increased that number to 35. 1 µM sodium chromate generated 23 total chromosomal aberrations, while E162 co-exposure decreased the number of lesions to 6. There were 49 percent of aneuploid metaphases at 1 µM sodium chromate but only 35 percent after the addition of E162. Uptake studies were performed, indicating that the protective effect of E162 was not a result of decreasing Cr(VI) uptake. Therefore, E162 may have a direct protective effect on cells against sodium chromate-induced toxicity. This work was funded by the NIEHS grant ES016893 (J.P.W.), the Maine Center for Toxicology and Environmental Health (JPW), and the Maine Space Grant Consortium (MB).

**PS 1168 Method: Measuring Protein-Bound and Free Cobalt(II) in Human Serum—Size Exclusion Liquid Chromatography with ICP-MS.**

B. D. Kerger<sup>1</sup>, B. L. Finley<sup>2</sup> and D. J. Paustenbach<sup>2</sup>. <sup>1</sup>ChemRisk, LLC., Aliso Viejo, CA; <sup>2</sup>ChemRisk, LLC., San Francisco, CA.

Cobalt (Co) ions are known to have a strong affinity for sulfhydryl proteins and amino acids in the blood and tissues, and sufficiently high concentrations of free ionic Co(II) can lead to adverse health effects in humans and animals. We describe a method using size exclusion liquid chromatography (SEC) to resolve protein-bound Co fractions from cyanocobalamin and free Co(II) after direct injection of serum samples stabilized with 0.1M acetic acid. Highly sensitive detection using ICP-MS was coupled with SEC to provide a method detection limit of 0.12µg/L in human serum for one higher molecular weight protein-bound Co peak (likely Co(II) bound to human serum albumin (66 kDa) and other large serum proteins), as well as for cyanocobalamin (1.3 kDa) and for free Co(II). Validation studies show that this novel method demonstrates good accuracy with >98% mean recovery and 10.4% relative percent deviation. Good precision was demonstrated for matrix spikes at 0.5 µg Co/L with 92.7% mean recovery and 4% relative percent deviation. Other metal cations known to compete with Co(II) for protein binding sites (Fe(II), Zn(II), Mn(II), Cd(II), Cu(II), Ni(II), Pb(II)) did not significantly alter Co(II) quantitation in the stabilized acetate solution. The sum of protein-bound and free ionic Co species provided >90% mass balance when compared to total Co measurements analyzed by acid digestion and ICP-MS in the same human serum samples. We conclude that this method complies with the method performance criteria outlined by the U.S. Depart. of Health and Human Services guidance for industry bioanalytical method validation. These measurements focusing on

identifying protein-bound and free Co(II) concentrations are likely to be more informative with respect to understanding blood and tissue Co concentrations associated with adverse health effects in people with workplace Co exposures, dietary Co supplement users, and patients with elevated Co blood levels due to cobalt-chromium alloy prosthetic devices.

**PS 1169 Chronic Exposure to Particulate Chromate Induces Persistent DNA Double-Strand Breaks in Human Lung Cells.**

Q. Qin<sup>1,2,3</sup>, H. Xie<sup>1,2,3</sup>, A. Holmes<sup>1,2,3</sup>, S. Wise<sup>1,2,3</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME.

DNA double strand breaks (DSB) are one of the most deleterious lesions that are induced by particulate chromate. If left unrepaired or misrepaired, DSB can cause mutations or chromosomal aberrations leading to genomic instability. The aim of this study is to determine the genotoxicity of particulate chromate and investigate cellular responses of repair proteins after chronic exposure. We found chromate exposure induced concentration-dependent increases in DSB and with longer exposure time, the amount of breaks remained constant. To address whether this reflected a cycle of breakage and repair or deficient repair, we developed a human lung cell line that stably express GFP-53BP1 and generated time-lapse videos of chromate treated cells. 53BP1 forms discrete nuclear foci at sites of DSB. By monitoring foci kinetics of these cells treated with chromate, we observed residual foci after 24 h, indicating some breaks persist presumably due to deficient repair. Therefore, we investigated the repair proteins involved in homologous recombination (HR) and non-homologous end joining (NHEJ) repair. We found that the nuclear fraction of phosphorylated ATM and Rad51 increased in 24 hours indicating HR is active. However, it largely decreased over time. We also observed concentration- and time-dependent decrease in Rad51 foci formation, which confirms that HR was inhibited. In contrast, protein expression of Ku80 and DNA-PKcs increased during chronic exposure to chromate. These results suggest that there is a signaling switch between HR and NHEJ during chronic exposure to chromate. Future work will focus on identifying key proteins that regulate the transitions between two repair pathways. This work was supported by NIEHS grant ES016893 (J.P.W.) and the Maine Center for Toxicology and Environmental.

**PS 1170 Repeated Particulate Chromate Exposure Induces Chromosome Instability, a DNA Double-Strand Break Repair-Deficient Phenotype, and Neoplastic Transformation in Human Lung Cells.**

S. Wise<sup>1,2,3</sup>, A. Holmes<sup>1,2,3</sup>, H. Xie<sup>1,2,3</sup>, W. Thompson<sup>2,3</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME.

One leading hypothesis for the carcinogenicity of hexavalent chromium (Cr(VI)) posits that Cr(VI) causes a DNA double strand break (DSB) repair deficiency which leads to chromosome instability and neoplastic transformation. However, no studies have been done to determine if Cr(VI) can cause DSB deficiency in human lung cells. To begin to test this possibility, we exposed human lung cells to lead chromate for three sequential 24 h periods, each separated by about a month. After each treatment, cells were seeded at colony forming density, cloned, expanded and retreated. Each generation of clones was tested for chromium sensitivity, chromosome complement, DNA repair capacity and ability to grow in soft agar. We found that after the first treatment, lead chromate-treated cells exhibited a normal chromosome complement though a few clones showed a repair deficient phenotype. After the second exposure, more than half of the clones acquired an abnormal karyotype including numerical and structural alterations and many showed deficient DNA DSB repair. The third treatment resulted in more abnormal clones, previously abnormal clones acquiring additional abnormalities, and most clones were repair deficient. Further investigation revealed that some clones were unable to form Rad51 foci in response to radiation, suggesting a defect in the homologous recombination repair pathway. Finally, clones from the third generation were able to form colonies in soft agar suggesting that the cells have neoplastically transformed. This work was supported by NIEHS grant ES016893 (J.P.W.) and the Maine Center for Toxicology and Environmental Health.

**PS 1171 Fin Whale Cells Are More Resistant to Particulate Chromate Cytotoxicity Than Human Cells.**

C. Wise<sup>1,2</sup>, S. Wise<sup>1,2,3</sup>, A. Holmes<sup>1,2,3</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME.

Hexavalent chromium (Cr(VI)) is present in the marine environment and is a known human carcinogen and skin irritant. Cr(VI) is the form of chromium that is well absorbed through the cell membrane. It is also the most prevalent form in seawater. We compared the cytotoxicity of Cr(VI) in fin whale and human skin cells. Our data show that particulate chromium is cytotoxic to human and fin whale cells in a concentration-dependent manner. Specifically, data show that Cr(VI) is less cytotoxic to fin whale skin cells than human skin cells. For fin whale cells, we found that concentrations of 0.1, 1.0, 5, 10 and 20 µg/cm<sup>2</sup> lead chromate induced 91, 72, 55, 40 and 38 percent relative survival, respectively. In human cells we found that concentrations of 0.1, 0.5, 1.0, 5 and 10 µg/cm<sup>2</sup> lead chromate induced 64, 28, 10, 0 and 0 percent relative survival, respectively. These data indicate that fin whale skin cells were 7.2 times more resistant to Cr(VI) than human skin cells. When corrected for intracellular ion uptake fin whale skin cells remained more resistant. We considered whether this effect was due solely to the chromate ion. Our data show that soluble chromium was also cytotoxic to human and fin whale cells in a concentration-dependent manner. They also indicate that fin whale skin cells were more resistant to soluble Cr(VI) than human skin cells. However, these soluble Cr(VI) differences were accounted for by intracellular ion uptake, which indicates that the difference cytotoxic effects are due to something other than the chromium ion by itself. Further investigations will look into the genotoxic effects of hexavalent chromium on these two species. This research is supported by The Environmental Protection Agency's Undergraduate Research Opportunities Fellowship (CFW), NIEHS grant ES016893 (JPW) and the Maine Center for Toxicology and Environmental Health (JPW).

**PS 1172 Cellular Defense against Telomere Dysfunction Induced by Hexavalent Chromium.**

H. C. Pope-Varsalona, F. Liu and P. L. Opreko. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Dysfunctional telomeres, the protective caps at chromosome ends, contribute to a variety of pulmonary diseases. Our previous work established that DNA replication stress induced by the environmental pollutant hexavalent chromium Cr(VI) causes telomere loss and aberrations. Chronic inhalation of Cr(VI) leads to a variety of lung diseases, including fibrosis, and cancers. Cr(VI) forms DNA lesions that impede DNA replication and can cause collapse of the replication fork and chromosomal breakage. Telomeres are fragile DNA sites prone to breakage during replication stress. Cells have mechanisms for bypassing lesions that block replication forks called translesion synthesis (TLS). We hypothesize that Cr(VI)-induced DNA replication stress activates TLS DNA polymerase  $\eta$  (pol $\eta$ ) that suppress Cr(VI)-induced mutagenesis and telomere dysfunction. Our research is investigating several endpoints of telomere dysfunction in human cells proficient and deficient in pol $\eta$ . We observe that cells deficient in pol $\eta$  are 53 fold more sensitive to low levels of Cr(VI) compared to isogenic controls. Using a combination of immunofluorescence and telomere fluorescence in situ hybridization (IF-teloFISH), quantification of replication stress at genomic and telomeric DNA show a severely reduced recovery from Cr(VI)-induced replication stress in cells lacking functional pol $\eta$ . Moreover, we observe that Cr(VI) induces pol $\eta$  mobilization to stalled DNA replication sites at genomic and telomeric regions in human cells. Post Cr(VI) exposures, we identify telomeric aberrations in senescent cells, a critical endpoint of telomere dysfunction, by staining metaphase chromosomes with a fluorescent telomeric probe using teloFISH. Currently, we are assessing cellular senescence through various biomarkers. Our study attests to one mechanism by which Cr(VI) directly interacts with the genome, alters telomere integrity, and the cellular pathways that protect telomeres in the face of genotoxic replication stress.

**PS 1173 Reactive Oxygen Species Regulate PI3K/AKT-Dependent Activation of GSK-3 $\beta$ /Catenin and mTOR signaling in Cr(VI)-Induced Carcinogenesis.**

Y. Son, J. Lee, P. Poyil, L. Wang and X. Shi. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Cr(VI) compounds are known human carcinogens that especially target lungs. Reactive oxygen species (ROS) are well produced by Cr(VI), however, the relevance of ROS and the underlying signaling pathways in Cr(VI)-induced carcinogenesis

remain to be elusive. The present study reports that chronic exposure of human bronchial epithelial cells to Cr(VI) at the low nanomolar range (10 - 100 nM) for 2 months induced cell transformation, as evidenced by anchorage-independent growth in soft agar and clonogenic assays. Chronic Cr(VI) treatment also increased the potential of these cells to invade and migrate. Injection of Cr(VI)-stimulated cells into nude mice resulted in the formation of tumors. In contrast, the Cr(VI)-mediated increases in colony formation, cell invasion, migration, and xenograft tumors were prevented by transfection with catalase, superoxide dismutase-1 (SOD1), or SOD2. In particular, chronic Cr(VI) exposure led to activation of signaling cascades involving PI3K/ AKT/GSK-3 $\beta$ /catenin, and PI3K/ AKT/mTOR and transfection with each of the above antioxidant enzymes markedly inhibited Cr(VI)-mediated activation of these signaling proteins. Inhibitors specific for AKT or  $\beta$ -catenin almost completely suppressed the Cr(VI)-mediated increase in total and active  $\beta$ -catenin proteins and colony formation. In addition, Cr(VI) inhibited autophagy under nutrition deprivation condition. Moreover, there was a marked induction of AKT, GSK-3 $\beta$ ,  $\beta$ -catenin, mTOR, and carcinogenic markers in tumor tissues formed in mice after injection with Cr(VI)-stimulated cells. Collectively, our findings suggest that ROS is a key mediator of Cr(VI)-induced carcinogenesis, and it activates PI3K/AKT dependent GSK-3 $\beta$ /catenin and inhibits autophagy through upregulation of mTOR signaling in this process.

**PS 1174 Instability of Metallothionein Inhibits Mitochondrial Activities following Exposure to Silver Nitrate in Human Bronchial Epithelial Cells.**

T. Miyayama<sup>1</sup>, Y. Arai<sup>2</sup>, N. Suzuki<sup>2</sup> and S. Hirano<sup>1,2</sup>. <sup>1</sup>Risk Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Japan; <sup>2</sup>Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan.

Silver (Ag) has been reported to generate reactive oxygen species (ROS) and to bind sulfhydryl groups in metabolic enzymes and non-enzymatic proteins such as metallothionein (MT). In the present study, we assessed toxicity of AgNO<sub>3</sub> in human bronchial epithelial cells (BEAS-2B) focusing on the intracellular Ag distribution and ROS production. The cells were exposed to 0 - 100 µmol/l AgNO<sub>3</sub> for 0 - 24 h and cytotoxicity was assayed with a modified MTT method. The cell viability was decreased by AgNO<sub>3</sub> in a dose-dependent manner (IC<sub>50</sub> = 2.5 µmol/l). Concentration of Ag in culture media decreased with time and stabilized at 12 h after exposure. Concentrations of Ag and Ag-bound MT in the soluble fraction of cells were sharply increased up to 3 h and then decreased, indicating that cytosolic Ag relocated to the insoluble fraction of cells shortly after Ag exposure. mRNA levels of major human MT isoforms, MT-IA and MT-IIA, paralleled concentrations of Ag, Cu and Zn-MT. The ROS-derived fluorescence intensity appeared to be elevated at mitochondria after treatment of the cells with Ag. To evaluate effects of Ag on mitochondrial respiration and activities of electron transport chain complex, mitochondria were obtained from rat liver tissues. The electron transport activities of all mitochondrial complexes (I to IV) were inhibited by Ag. We observed that a concentration of cytosolic H<sub>2</sub>O<sub>2</sub> was increased up to 11.6 pmol per 1.0 x 10<sup>6</sup> cells. Ag as well as Cu and Zn were released from isolated MT by H<sub>2</sub>O<sub>2</sub> at concentrations as low as 0.001%. In conclusion, exposure to Ag increased MT synthesis and Ag was sequestered immediately by MT. 3 h after exposure, MT was decomposed by cytosolic H<sub>2</sub>O<sub>2</sub>. Ag released from MT relocated to insoluble cellular fractions and inhibited electron chain transfer of mitochondrial complexes, which eventually led to cell damage.

**PS 1175 Development and Optimization of a Procedure for the Determination of Indium-Tin Oxide Particle Size and Concentration in Cellular Media.**

K. Levine<sup>1</sup>, L. Han<sup>1</sup>, W. M. Gwinn<sup>2</sup>, D. L. Morgan<sup>2</sup>, A. S. Essader<sup>1</sup>, R. A. Fernando<sup>1</sup>, C. S. Smith<sup>2</sup> and V. G. Robinson<sup>2</sup>. <sup>1</sup>RTI International, Research Triangle Park, NC; <sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC.

Indium-tin oxide (ITO) is a solid mixture often comprised of approximately 90% indium oxide (In<sub>2</sub>O<sub>3</sub>) and 10% tin oxide (SnO<sub>2</sub>) by weight. ITO is employed as a transparent conductive coating for flat panel, liquid crystal, and plasma displays and is typically deposited after sintering as a thin film on the desired substrate through a variety of technologies. Fatal cases of interstitial pneumonia and alveolar proteinosis have been reported for workers exposed to ITO particles. *In vitro* studies of ITO are planned in order to better understand the toxicity of this compound. Comprehensive characterization of ITO test materials is required prior to toxicity testing. Characterization of ITO particle size under the conditions of laboratory testing is important because this physicochemical parameter can significantly impact bioavailability and cellular toxicity.

In these studies we developed, optimized, and applied a dynamic light scattering (DLS) sample preparation and measurement protocol for determining hydrodynamic particle size in a suite of sintered/non-sintered ITO samples. ITO samples were prepared in cellular growth media at doses ranging from 0.3 – 0.4 mg/mL. Sonication times of particle suspensions were evaluated from 15 – 90 minutes. Times ranging from 30 – 60 minutes yielded the most stable suspensions with respect to hydrodynamic particle size over a 24-hour period. Resulting suspensions from samples with 30 – 60 minute sonication times were stable for 10 – 24 hours after sonication, with respect to hydrodynamic particle size. Throughout the 24-hour DLS measurement period, suspensions were analyzed for indium content by inductively coupled plasma mass spectrometry (ICP-MS) to confirm ITO concentrations. The developed protocol enabled investigators to use ITO suspensions of known particle size and concentration in their *in vitro* cellular studies.

## PS 1176 Tungsten Exposure Increases Lung Metastases in an Orthotopic Murine Breast Cancer Model.

A. M. Bolt<sup>2,1</sup>, V. Sabourin<sup>2,1</sup>, J. Janiak<sup>2,1</sup>, A. Kelly<sup>2,1</sup>, G. Ursini-Siegel<sup>2,1</sup> and K. K. Mann<sup>2,1</sup>. <sup>1</sup>McGill University, Montréal, QC, Canada; <sup>2</sup>The Lady Davis Institute for Medical Research, Montréal, QC, Canada.

Tungsten is a strong, flexible metal that until recently had been thought to be an “inert” metal. These properties led to its incorporation into the manufacturing of medical devices. In a recent clinical trial, a tungsten-based shield was used in the treatment of breast cancer patients undergoing intraoperative radiotherapy. Following the procedure, the women were left with residual tungsten in their breasts. Elevated tungsten levels in the blood and urine indicate that tungsten is not remaining in the breast tissue. Tungsten was detected in the urine of patient even 8 months after mastectomy, indicating another reservoir has been created. Based on previous data, we hypothesize this reservoir to be the bone. Animal studies suggest that tungsten may contribute to carcinogenesis and can alter development and increase DNA damage in the immune system. In order to evaluate the effect of tungsten on breast cancer, female Balb/C mice were exposed to 15 ppm of sodium tungstate for 1 month followed by injection of 66cl4 cancer cells into the mammary fat pad. The size of primary tumor, the extent of lung metastases and immune parameters were evaluated. Tungsten did not alter the growth of the primary tumor. However, the number and average size of lung metastases was significantly greater in the tungsten-exposed animals. This model is not known to metastasize to the bone, but we found that tumor-bearing mice had 3-fold more tungsten in the bone than non-tumor bearing mice. Tungsten increased the peripheral blood leukocyte count in non-tumor bearing mice, but decreased the massive granulocytosis associated with tumor growth. These data suggest that tungsten increases the extent of breast cancer metastasis to the lung, which could have a significant impact on individuals who have cancer and are also exposed to tungsten. The levels of tungsten deposition within the bone and immune cell parameters were also altered, which could also impact metastasis in this model.

## PS 1177 Genetic Variation of Iron Metabolism in Mice.

K. E. Page<sup>1</sup>, D. W. Killilea<sup>2</sup>, E. Eskin<sup>3</sup>, A. J. Lusis<sup>3</sup> and C. Vulpe<sup>1</sup>. <sup>1</sup>Nutritional Sciences and Toxicology, University of Berkeley, Berkeley, CA; <sup>2</sup>Children's Hospital Oakland Research Institute, Oakland, CA; <sup>3</sup>David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA.

Iron deficiency is the most common disease in the world with an estimated 4-5 billion affected persons. Debilitating fatigue, altered immune function, decreased work capacity and anemia are among the deleterious consequences of this pervasive disorder. Similarly, liver iron overload is a significant health concern. Multiple genetic disorders of iron metabolism in man, rodents and other vertebrates suggest multiple loci can contribute to the susceptibility of iron deficiency and severity of iron overload. Previous studies have shown genetic variation in iron metabolism between inbred strains of mice. We hypothesize that this genetic variation underlies the differences seen in iron metabolism between inbred mice. Our aim is to map the quantitative trait loci responsible for the strain specific differences in iron metabolism. To do this we will use high resolution SNP analysis to “in silico” map the genetic loci responsible for the divergent iron related phenotypes using the hybrid mouse diversity panel (HMDP) [1]. Here we show the phenotypic analysis of the variation in iron metabolism for these mice, and how the overall elemental profiles change for each strain.

## PS 1178 ICP-MS Determination of Tissue Iron Levels in the Rat.

J. Bouchard<sup>1</sup>, C. Sabadie<sup>1</sup>, J. Decorde<sup>1</sup>, L. Jaillet<sup>1</sup>, P. Elford<sup>2</sup> and R. Forster<sup>1</sup>. <sup>1</sup>CiToxLAB, Evreux, France; <sup>2</sup>Azad Pharmaceuticals, Bern, Switzerland.

Iron is an essential trace element associated with toxicities when present in excess, as for example in conditions such as heterochromatosis. We have developed and validated a reliable and rapid quantitative method for the exploration of endogenous levels of total iron in rat plasma, heart, liver, spleen, kidney, stomach, lung and bone marrow. The analysis by ICP-MS (Inductively Coupled Plasma Mass Spectrometry) was selected among all other techniques, because of its easy handling of simple or complex matrices requiring very little sample preparation. The method was evaluated for accuracy, precision, linearity, matrix effect and instability derived from adsorption on container walls. Precision and accuracy for all matrices ranged from >4.3% to <7.9% and >1.5% to <12.2% respectively. Matrix effect was negligible and the assays for the evaluation of instability showed no adsorption of iron on container walls, either in glass, polypropylene or polyethylene. Iron levels were determined over a 28-day period, on 145 rats aged 7 to 8 weeks at the beginning of the study. In general a low to moderate inter-animal variability of endogenous iron levels was observed. The levels of total iron in plasma, heart, liver, stomach and bone marrow were stable over time with concentrations <5000 ng/mL in plasma and <18.0 µg/g (heart), <70.0 µg/g (liver), <8.00 µg/g (stomach), <140 µg/g (bone marrow) respectively. In spleen and kidney, the concentrations increased over time, from <80.0 µg/g to <400 µg/g in spleen and <15.0 µg/g to <30.0 µg/g in kidney and this was attributed to the ageing of the animals. A moderate to marked inter-animal variability was observed in lung, ranging from 5.00 µg/g to 40.0 µg/g. In conclusion, a reliable and rapid quantitative ICP-MS method was used to determine endogenous levels of total iron in rat plasma and tissues. This method can readily be adapted for the study of endogenous iron levels in other laboratory animal species.

## PS 1179 Development of a Transportable Neutron Activation Analysis System to Quantify Manganese in Bone *In Vivo*—Feasibility and Methodology.

Y. Liu<sup>1</sup>, D. S. Koltick<sup>2</sup>, P. Byrne<sup>1,3</sup>, W. Zheng<sup>1</sup> and L. Nie<sup>1</sup>. <sup>1</sup>Health Sciences, Purdue University, West Lafayette, IN; <sup>2</sup>Physics, Purdue University, West Lafayette, IN; <sup>3</sup>Medical Physics Consultants, Indianapolis, IN.

Manganese (Mn) is a vital element in human body for growth and other functions. However, overdose to Mn compounds can lead to many adverse health effects. An important issue in assessing Mn exposure is to select a proper biomarker. Over 40% of Mn in human body is stored in bone and bone Mn represents long term chronic Mn exposures. Hence it is attractive to develop a technology to quantify the concentration of Mn in human bones. *In vivo* neutron activation analysis (IVNAA) is a promising non-invasive technique which can determine the concentrations of various elements in the human body. In our study, we investigated the possibility and feasibility of developing a transportable IVNAA system for Mn quantification in hand bone by Monte Carlo (MC) simulations using a portable deuterium-deuterium (DD) neutron generator as neutron source. Experiments were conducted with a deuterium-tritium (DT) generator available in our lab to validate the MC simulation results. The count rates calculated from MC simulations were in agreement with those obtained from the experiments for the DT generator system setup. Different types of moderator and reflector for DD setups were simulated and paraffin was selected as the best material for both of the moderator and reflector. Then the optimal thicknesses for the reflector and moderator were determined. Assuming normal concentration of Mn in bone is about 1 µg/g and neutron yield is 4×10<sup>8</sup>/sec, the count rate is 0.324 counts/sec if we use a 4π NaI detector with 100% efficiency. The corresponding dose to the hand for 10 minutes irradiation time is about 43.704 mSv from MC simulation, which corresponds to about 48.64 µSv total body equivalent dose. In conclusion, it is feasible to develop a transportable NAA system to quantify Mn in bone *in vivo* with a minimum radiation dose exposure to the subject.

## PS 1180 Relative and Absolute Quantification of Metallothionein Isoforms in Human Kidney Cells Using Stable Isotope Labeling of Cysteines and MALDI-TOF/TOF Mass Spectrometry.

A. Mehush<sup>1,2</sup>, J. B. Shabb<sup>2</sup>, W. W. Muhonen<sup>2</sup>, S. H. Garrett<sup>1</sup>, S. Somji<sup>1</sup>, M. Sens<sup>1</sup> and D. A. Sens<sup>1</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND; <sup>2</sup>Biochemistry, University of North Dakota, Grand Forks, ND.

Human metallothioneins (MTs) are known to chelate the naturally accumulated heavy metal pollutant cadmium in the renal cortex and their expression has been shown to be altered in different types of cancers. The current study was initiated to

develop analytical means to measure each isoform of this diverse protein family. The twelve human MT isoforms share 70 to 90% amino acid sequence identity which hampers antibody-based methods of isoform-specific quantification at the protein level. Trypsin digestion yields an N-terminal MT peptide that has a unique mass for each MT isoform. Each of these peptides contains five Cys residues, is N-terminally acetylated, and once alkylated is relatively hydrophilic. The human kidney HK-2 epithelial cell line expressing stably transfected MT-3 was used as a model system. Cytosol was prepared from control cells and cells exposed to 9  $\mu$ M cadmium for 3 days. The cytosol was then denatured with urea, reduced with DTT, and alkylated with either 14N- or 15N- iodoacetamide. For absolute quantification, ~145 pmols of MT isoform-specific 15N-labeled N-terminal acetylated peptides was added to the samples. The light and heavy-labeled samples were combined and digested with trypsin. Strong cation exchange (SCX) and C18 reverse-phase liquid chromatography (rp-HPLC) successively enriched the N-terminal MT peptides followed by MALDI-TOF/TOF MS and MS/MS. The ratio of light (control) vs. heavy (induced) MT peak intensities were calculated for each MT isoform detectable in both the control and Cd-induced samples. Seven MT isoforms were detected and quantified in the HK-2 MT-3 cells. MT-1F showed the largest induction (10-fold) from 9  $\mu$ M Cd treatment. Metallothionein 3 was induced 2-fold. This study describes an iodoacetamide stable isotope-labeling mass spectrometry-based method for simultaneous relative and absolute quantification of human metallothionein isoforms.

### PS 1181 Identification of Metallothionein-3 Interacting Proteins in the Human Proximal Tubule Cells.

A. Slusser<sup>1,2</sup>, C. Bathula<sup>1</sup>, J. R. Dunlevy<sup>1</sup>, J. B. Shabb<sup>2</sup>, D. A. Sens<sup>1</sup>, S. Somji<sup>1</sup> and S. H. Garrett<sup>1</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND; <sup>2</sup>Biochemistry, University of North Dakota, Grand Forks, ND.

Metallothionein 3 (MT-3) is a small, cysteine-rich protein that binds to essential metal ions required for normal cellular processes, as well as heavy metals that have the potential to exert toxic effects on cells. MT-3 is expressed by epithelial cells of the human kidney, including the cells of the proximal tubule. This laboratory has previously shown that the mortal cultures of human proximal tubule (HPT) cells express MT-3 and could form domes in the cell monolayer, a morphological feature indicative of vectorial active transport. However the immortalized proximal tubular cell line HK-2 lacked the expression of MT-3 and failed to form domes. Transfection of the HK-2 cells with the MT-3 gene restored dome formation in the cells suggesting that MT-3 may have a role in vectorial active transport. Recent in vivo and in vitro studies have reported that MT-3 is interacting with other proteins and these interactions are thought to be playing an important role in execution of some of its functions. Thus the goal of this study was to identify the binding partners of MT-3, which would allow us to understand the mechanism through which MT-3 is regulating vectorial active transport and cell differentiation in HPT cells. For this purpose cell extracts were prepared using the immortalized human proximal tubule cell line HK-2. MT-3 pull-down experiments were performed followed by SDS-PAGE and mass spectrometry analysis. Data analysis revealed an interaction between MT-3 and myosin 9, gelsolin, beta-actin, and tropomyosin 3. Immunofluorescence studies further confirmed that MT-3 co-localizes with these proteins. These studies demonstrate that MT-3 is interacting with proteins that are involved in cytoskeleton reorganization of the cell and thereby regulating vectorial active transport and cell differentiation.

### PS 1182 The Unique N and C-Terminal Domains of Metallothionein-3 Influence the Growth and Differentiation of MCF-7 Breast Cancer Cells.

B. Voels, D. A. Sens, S. H. Garrett and S. Somji. Pathology, University of North Dakota, Grand Forks, ND.

Toxic insult from the heavy metal cadmium ( $\text{Cd}^{2+}$ ) is known to induce the expression metallothioneins (MT) which are heavy metal binding proteins. Previous work from our laboratory has shown that over-expression of MT-3 in breast cancers is associated with poor patient outcome. Furthermore, MT-3 has shown to inhibit the growth of breast cancer and prostate cancer cell lines. Studies have shown that the MT-3 protein contains 7 additional amino acids that are not present in any other member of the MT gene family, a 6 amino acid C-terminal sequence and a Thr in the N-terminal region. The unique N-terminal sequence is responsible for the growth inhibitory activity of MT-3 in the neuronal system. The goal of this study was to characterize the function of the N and C-terminal domains of MT-3 in the breast cancer cell line, MCF-7. For this purpose six different constructs of MTs were prepared which were as follows: wild type (WT) MT-3, MT-3 N-terminal deletion (MT-3 NT), MT-3 C-terminal deletion (MT-3 CT), WT MT-1E, and MT-1E mutated to contain the N-terminal of MT-3 or the C-terminal or both the

N- and the C-terminal of MT-3. Each of these constructs was transfected into MCF-7 cells and the growth rates and the transepithelial resistance (TER) was measured. The data obtained suggests that the N-terminal region of MT-3 is involved in growth inhibitory activity whereas the C-terminal region is involved in vectorial active transport which is indicated by the formation of domes in cell culture and an increase in TER. In conclusion, this study further characterizes the unique properties of the N- and the C-terminal domain of MT-3 and the potential role that it may play in the differentiation of certain breast cancers.

### PS 1183 Fluoride, Aluminum, and Mixtures: Histological Changes in the Liver of Mouse, *Mus norvegicus albinus*.

A. Vijaya Bhaskara Rao. Ecology and Environmental Sciences, Pondicherry University, Puducherry, India. Sponsor: I. Rusyn.

Fluoride is one of the chemical contaminants of water causing several health problems in man and animals. Aluminum is one of the most abundant metals in the environment. Although aluminum has been historically considered as a non toxic metal, which is toxic in its trivalent ( $\text{Al}^{3+}$ ) form. Earlier studies exhibited fluorosis and aluminosis when fluoride and aluminum exposed individually. However, it is important to study two different toxicants in combination to know whether they can act as synergistic or antagonistic. In this study the toxic effects exerted by the accumulation of fluoride, aluminum and their mixtures were studied in the liver of mice. Six different doses were tested for a period of 30 days and 60 days for their toxic effect in the liver. Microscopic study of liver tissue revealed interesting pathological changes in all the fluoride treated mice. The damage to the tissue was dose- and time dependent. The aluminum treated mice showed conspicuous histopathological changes in higher dose, which was more significant with the increase in period of exposure. Whereas, the histopathological changes, were not much conspicuous in lower dose groups, and also decreased with period of exposure. In the mixture of fluoride and aluminum treated mice, mild to severe changes were observed in the higher dose of fluoride with aluminum, whereas very mild and insignificant changes were observed in the mice exposed to lower dose of fluoride with aluminum.

### PS 1184 Both the Metal Moiety and the Organic Backbone of Ethylene Bisdithiocarbamate Fungicides Maneb and Mancozeb Contribute to Toxicity in Human Colon Cells.

L. Hoffman and D. Hardej. Pharmaceutical Sciences, St. John's University, Queens, NY.

Ethylene bisdithiocarbamate (EBDC) pesticides are used primarily as broad range contact fungicides on a wide variety of crops. A subset of the metal containing EBDC pesticides include Maneb (MB), Mancozeb (MZ), and Zineb (ZB), which are complexed with the transition metals manganese, zinc, or in the case of MZ, both manganese and zinc. While these agents are reported to possess low human toxicity, previous testing in our laboratory has established the toxicity of these compounds to transformed colon cells, HT-29 and Caco2, and to normal colon cells, CCD-18Co. Significant decreases in viability were observed with MB and MZ in HT-29 and CCD-18Co (80-260 $\mu$ M), and Caco2 cells (40-180 $\mu$ M). ZB exposure however, produced no significant decrease in cell viability in all cell types up to 800 $\mu$ M. Therefore, the purpose of this study was to determine if the metal moieties of MB and MZ contributes to the generation of toxicity. To determine if the manganese and zinc can accumulate within HT-29 and Caco2 cells and initiate toxicity, inductively coupled plasma-optical emission spectroscopy was performed. MB exposure resulted in a dose dependent increase in intracellular manganese levels within HT-29 and Caco2 cells (20-200 $\mu$ M). MZ exposure also resulted in a significant accumulation of zinc within HT-29 and Caco2 cells (40-200 $\mu$ M). To investigate whether manganese and/or zinc was a critical factor in the cytotoxic process, HT-29, Caco2, and CCD-18Co cells were treated with manganese chloride ( $\text{MnCl}_2$ ) and zinc chloride ( $\text{ZnCl}_2$ ).  $\text{MnCl}_2$  and  $\text{ZnCl}_2$  exposure produced no significant loss of viability in all cell types up to 400 $\mu$ M. The lack of toxicity observed following treatment with ZB within the same concentration range as MB and MZ suggests that the manganese portion of these agents may play a key role in generating the effects seen upon exposure. However, the lack of differences in the cytotoxicity of  $\text{MnCl}_2$  and  $\text{ZnCl}_2$  treated cells indicates that the EBDC backbone may act in conjunction with the metal moiety to cause toxicity.

**PS 1185 Signalling Pathways and Oxidative Stress Involved in Metal-Induced Cytokine Responses in Human Epithelial Lung Cells.**

M. Låg, J. Øvrevik, E. M. Lilleaas, A. Thormodsrø, A. I. Totlandsdal, J. A. Holme, P. E. Schwarze and M. A. Røfnes. *Department of Air Pollution and Noise, Norwegian Institute of Public Health, Oslo, Norway.* Sponsor: M. Løvik.

Inhalation of metals is associated with development and aggravation of lung and cardiovascular diseases, and inflammation is considered to be a central pathological mechanism. In this study we have investigated expression of inflammation-related genes in human bronchial epithelial cells (BEAS-2B) exposed to cadmium (Cd), zinc (Zn), arsenic (As), vanadium (V), manganese (Mn) and nickel (Ni), metals often found in polluted air. As measured by real-time PCR array, Cd, Zn and As induced cytokine expression patterns differing from V, Mn and Ni, with higher levels of CXCL8, CXCL5, IL-6 and CCL26. Furthermore, Cd, Zn and As, but not V, Mn and Ni, induced increased levels of 1-heme oxygenase indicative of oxidative stress. Thus, the mechanisms of Cd-, Zn- and As-induced cytokine responses were investigated further. In line with the gene-expression data, Cd, Zn and As also induced high levels of CXCL8 and IL-6 protein-release, and addition of antioxidants reduced the metal-induced cytokine responses. Moreover, the metals activated the mitogen activated protein kinases (MAPK) p38, JNK and ERK and the p65 subunit of NF-κB, measured as protein-phosphorylation by Western blotting after 2 and 4 hr. Use of MAPK-inhibitors and siRNAs against p65 revealed that these signalling pathways were involved in the cytokine responses. The p38 pathway seemed most important for both IL-6 and CXCL8 release induced by all three metals, whereas JNK seemed to be mainly involved in As-induced CXCL8 and ERK in As-induced IL-6 and CXCL8 releases. In conclusion, among the tested metals Cd, Zn, As were potent inducers of inflammatory responses and oxidative stress in epithelial lung cells. NF-κB and p38 signalling seemed central to metal-induced IL-6 and CXCL8 responses, whereas the relative involvement of JNK and ERK differed depending on the metal and cytokine.

**PS 1186 Development of an Immortalized Urothelial Cell Line to Study Metal-Induced Bladder Carcinogenesis.**

A. Holmes<sup>1,2,3</sup>, M. Hebert<sup>1,2</sup>, C. Case<sup>4</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, University of Southern Maine, Portland, ME; <sup>4</sup>Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom.

Numerous metals are well-known human bladder carcinogens. Despite the significant occupational and public health concern of metals and bladder cancer, the carcinogenic mechanisms remain largely unknown. In order to fully understand how metals transform a normal urothelial cell into a cancerous cell, it is important to study the process in a normal human urothelial cell line. Primary urothelial cells are insufficient for this purpose because of their very short lifespan, but currently, the effects of metals in a near-normal urothelial cell line with an extended lifespan are unknown. The objective of this study was to characterize chromate toxicity in primary human urothelial cells and to determine if an hTERT-immortalized human urothelial cell line exhibited a similar response to metals as primary cells. Hexavalent chromium (Cr(VI)) induced a concentration- and time-dependent increase in chromosome damage with the hTERT-immortalized cells exhibiting more chromosome damage than the primary cells. Chronic exposure to Cr(VI) also induced a concentration-dependent increase in aneuploid metaphases in both cell lines which was not observed after a 24 h exposure. Aneuploidy induction was higher in the hTERT-immortalized cells. When we correct for uptake, Cr(VI) induces a similar amount of chromosome damage and aneuploidy suggesting that the differences in Cr(VI) sensitivity between the two cell lines was due to differences in uptake. Therefore, the hTERT-immortalized cell line had a similar response to metals and will be a good tool for studying metal-induced bladder carcinogenesis. This work was supported by NIEHS grant ES016893 (J.P.W.) and the Maine Center for Toxicology and Environmental Health.

**PS 1187 Metallothionein Transcriptional Regulation, Aging, and the Insulin Signaling Pathway.**

J. Hall<sup>1</sup>, M. McElwee<sup>2</sup> and J. H. Freedman<sup>1,2</sup>. <sup>1</sup>BSB, DNTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>LTP, NIEHS, Research Triangle Park, NC.

Metallothioneins (MTs) are highly conserved, cysteine-rich metal-binding proteins that function in metal homeostasis and detoxification, as well as free-radical scavenging. To better understand the role of MT in cadmium-associated cellular re-

sponses, regulatory factors and pathways that control the expression of the *C. elegans* MT gene, *mtl-1*, were identified through genetic screens. A mutagenesis screen identified a mutant, JF99 that harbored a mutation affecting *atf-7*, a negative transcription factor involved in the JNK/p38 pathway. In both JF99 and an *atf-7* deletion mutant, steady-state *mtl-1* mRNA levels were identical but significantly greater than levels in wild type nematodes in the absence of cadmium. In addition to *atf-7*, mutations in *pmk-1* caused a decrease in *mtl-1* expression, suggesting that PMK-1 regulated ATF-7 activity. A candidate gene screen identified three insulin signaling pathway genes (PDK-1 and the AKT-1/AKT-2 complex) that functioned independently of this pathway. Further genetic analysis confirmed that these genes act upstream of PMK-1 and ATF-7 to regulate *mtl-1* transcription. Based on our genetic pathway data and previous work, we propose that ATF-7 resides on the promoter region of *mtl-1* to inhibit the constitutively active transcription factor ELT-2, which is important for intestinal cell specific transcription. In the presence of cadmium, upstream factors signal PDK-1 and the AKT-1/2 complex to phosphorylate PMK-1 causing it to translocate to the nucleus and phosphorylate ATF-7, allowing ELT-2 to initiate transcription. The activation of this pathway results in an increase in MT, which scavenges cadmium and free radicals. In mammalian cells, knock-down of PDK1 and ATF7 resulted in changes in MT-1 expression, suggesting that this pathway was not unique to *C. elegans*. The insulin signaling pathway affects the aging process, thus an association between cadmium exposure and the activation of portions of the insulin signaling pathway provides a mechanistic link between metal homeostasis, ROS and aging.

**PS 1188 Metal-Regulatory Transcription Factor-1 Regulates Metal-Responsive Transcription of *Fosl1*.**

E. Braithwaite and J. H. Freedman. *NIEHS, Research Triangle Park, NC.*

The transcription factor fos related antigen-1 (*fosl1*) is an AP-1 protein whose expression is often elevated in tumors and transformed cells. Previous studies show that *fosl1* is transcriptionally regulated through the activity of the fos transcription factor and the MAPK pathway. In addition, *fosl1* is induced after exposure to cadmium; however, the mechanism by which this induction occurs has not been elucidated. Metals, such as cadmium, are able to induce the expression of a wide variety of genes through the activation of metal-regulatory transcription factor 1 (MTF-1). Upon activation, MTF-1 translocates to the nucleus and binds to metal responsive elements (MREs) in the promoters of metal-inducible genes. To determine if MTF-1 participates in cadmium-inducible *fosl1* regulation, a five kilobase region upstream of the transcription start site and the coding region of *fosl1* were analyzed for MRE sequences. Seven MREs were identified and chromatin immunoprecipitation (ChIP) analysis performed to determine if MTF-1 had the ability to bind the *fosl1* promoter after metal exposure. ChIP assays showed that MTF-1 localized to the *fosl1* promoter and bound each MRE sequence to varying degrees. To assess the biological impact of this binding, MTF-1 null (dko7) cells and dko7 cells transduced with MTF-1 (dko7 + MTF-1) were exposed to cadmium and RNA was isolated at various time periods to evaluate steady state mRNA levels of *fosl1* by real-time PCR (RT-PCR). These studies showed a biphasic increase in *fosl1* mRNA in dko7 + MTF-1 cells up to 12 hours after exposure to 5 μM cadmium after which the mRNA levels declined to background levels at 24 h. In contrast, dko7 cells showed a steady increase in *fosl1* mRNA accumulation for the duration of the study. These data suggest that MTF-1 is recruited to the *fosl1* promoter and may be a negative regulator of *fosl1* mRNA expression.

**PS 1189 Visualization of Reactive Oxygen Species (ROS) Using High-Content Image Analysis (HCA) in Undifferentiated Human Embryonic Stem Cells Exposed to Methyl Parathion (MP).**

J. S. Madren-Whalley and J. W. Sekowski. *ECBC, US Army RDECOM, Gunpowder, MD.*

Organophosphate (OP) pesticides represent a threat to soldiers, first responders and other civilians since they are highly toxic and widely accessible chemicals used in crop, industrial, and home applications. However, for many OP pesticides such as MP, there is incomplete toxicological data in humans. Most of the reports are epidemiological studies, adult and juvenile animal studies, or in vitro studies using transformed cell lines. Since undifferentiated human embryonic stem cells (hESC) maintain the ability to differentiate into any somatic cell in the body, they offer a unique vantage point to measure the effect of toxicants on the very early human development and cell repair system.

From our earlier metabolomics work examining the secretome of hESCs following exposure to MP, we hypothesized that ROS is generated during the toxic response to MP. In this follow-on work, we chose to visualize and quantitate: 1) the presence

and location of ROS, and 2) cell and nuclear morphology in MP-exposed WA09 hESC using the Cellomics Oxidative Stress I Assay on a Thermo Scientific Cellomics® ArrayScan® HCA System.

While low levels of oxidative stress are necessary for normal cell metabolism, high levels are associated with cellular dysregulation and pathologies such as cancer. As expected, our imaging data indicated that the cells did not change structurally, nor did they undergo senescence or apoptosis in response to the MP exposures we examined. While we were able to measure cellular oxidative stress (fluorescent conversion of dihydroethidium, DHE), the amount measured in the nuclei was much less than we had predicted. All other DHE was scattered and punctuate throughout the cell. These data, combined with other studies suggesting that hESC lose their robust ROS nuclear protection mechanism as they become more differentiated, opens up a new avenue of investigation to define the point in embryonic differentiation when cells become more vulnerable to the ROS-induced toxic effects of MP.

## PS 1190 Pluripotency Factors Silence Expression of the Aryl Hydrocarbon Receptor in Embryonic Stem Cells.

C. Ko, Q. Wang and A. Puga. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

OCT4, SOX2, and NANOG are transcription factors that maintain pluripotency and self-renewal of embryonic stem cells (ESC) in culture: on the one hand, they activate expression of self-renewal genes, and on the other hand they prevent differentiation by silencing the expression of developmental genes. Unlike DNA methylation, polycomb group (PcG) proteins are chromatin modulators that repress the expression of developmentally important genes, such as those in the Hox family. PcG-mediated repression represents a plastic and dynamic way to keep genes poised to be reactivated during development. Promoters of developmental genes in ESC are often bivalently marked by trimethylation on lysine-4 (H3K4me3) and lysine-27 (H3K27me3) of histone H3, with PcG-mediated repression allowing these genes to be ready for reactivation upon differentiation. The aryl hydrocarbon receptor (AHR) has long been believed to mediate xenobiotic toxicity; increasing evidence suggests that it also plays a role during embryogenesis. To study AHR functions during early development, we have analyzed the regulation of AHR expression in C57Bl/6 mouse ESC and their in vitro differentiated progeny. In ESC, Ahr expression is silenced through bivalent marks in its promoter. Specifically, H3K27 is trimethylated in both distal and proximal promoter regions (dpr and ppr) and H3K4 is trimethylated in the ppr. We also detect the specific binding of pluripotency factors and PcG proteins in the dpr. RNA polymerase II appears to be paused in the ppr, producing short aborted Ahr transcripts. Upon differentiation, the Ahr promoter resolves into a H3K4me3 monovalent state and recruits Sp factors, leading to transcription activation. These results define an ESC-specific silencer domain located 2kb upstream of the Ahr gene transcription start site, responsible for the low, if any, Ahr expression in ES cells. Directed silencing, resulting from cooperation between pluripotency and PcG-repressive factors suggests that the Ahr may play a significant role in maintenance of pluripotency. Supported by NIH Grant 5R01ES06273

## PS 1191 Hypersensitivity of Stem Cells and Cancer Stem Cells to Cadmium Toxicity.

E. J. Tokar, M. Rogers and M. P. Waalkes. *NTP, NIEHS, NIH, Research Triangle Park, NC.*

Stem cells (SCs) generally are resistant to toxicants compared to mature cellular counterparts. Normal SCs (NSCs) can be malignantly transformed to cancer SCs (CSCs) which then likely drive the carcinogenic process. Cadmium (Cd), a known human carcinogen, can also be an effective anti-tumor agent in rodents, selectively destroying advanced tumors but leaving normal tissue intact, implying cancer cell sensitivity. CSCs likely are key to cancer maintenance, propagation, metastasis and repopulation. Thus, to help explain this paradox with Cd, we examined the effects of Cd on the human prostate NSC line, WPE-stem, and its isogenic mature parental cell line (PCL), RWPE-1, and a malignant CSC transformant from NSCs, As-CSC. The untransformed lines had similar LC50 values (NSC = 12.2  $\mu$ M; PCL = 13.9  $\mu$ M). However, the NSCs were much more sensitive to sub-chronic Cd exposure (90% cell loss at 1 week) compared to the mature PCL (15% loss). This is unusual as SCs are typically toxicant resistant. Various factors involved in Cd toxicity were then assessed. Anti-apoptotic *BCL2* decreased in NSCs (50%) but increased in the PCL (225%), and pro-apoptotic *BAX* increased in the NSCs (216%) but was unchanged in the PCL suggesting enhanced apoptosis was involved in this Cd hypersensitivity. The transport protein *ZnT1* effluxes zinc, which protects against Cd toxicity, while *ZIP8* aides in zinc and Cd uptake. Cd exposure increased *ZnT1* transcript 650% in NSCs but only 200% in the PCL. *ZIP8* levels increased 248% in NSCs but showed no change in the PCL. These data support a biokinetic

basis to higher Cd toxicity in NSCs. To define sensitivity in CSCs, we exposed the As-CSC and found them even more sensitive to Cd (LC50 = 6.0  $\mu$ M) than NSCs (12.2  $\mu$ M). Similar apoptotic and/or Cd uptake/efflux factors seen in the untransformed cells were involved in CSC hypersensitivity. Thus, Cd sensitivity may be related to differentiation stage and increased Cd sensitivity in SCs helps explain the initial loss of SCs during Cd transformation. Further, CSC hypersensitivity to Cd may be a major factor in Cd's ability to destroy certain cancers.

## PS 1192 Recruitment of Normal Stem Cells into an Oncogenic Phenotype by Noncontiguous Carcinogen-Transformed Malignant Epithelia Is Dependent on the Transforming Carcinogen.

Y. Xu, E. J. Tokar, R. J. Person, R. Orihuela and M. P. Waalkes. *NTP, NIEHS, NIH, Research Triangle Park, NC.*

Cancer stem cells (CSCs) are likely key to carcinogenesis. In prior work we found that arsenic-transformed malignant epithelial cells (MECs) recruit nearby, but non-contiguous normal stem cells (NSCs) into a CSC-like phenotype. Here, we tested if this recruiting effect on NSCs occurs with MECs transformed by other carcinogens. Normal human prostate epithelial SCs (WPE-stem) were co-cultured via transwell dishes that separate cells but not secreted factors with isogenic MECs derived from normal human prostate epithelial RWPE-1 cells by cadmium or N-methyl-N-nitrosourea (MNU) exposure (called Cd-MECs or MNU-MECs, respectively). SCs co-cultured with normal RWPE-1 cells served as control. After 2 weeks of Cd-MEC co-culture, SCs showed high secretion of metalloproteinase-9 (MMP-9, 3.6-fold of control) and MMP-2 (2.2-fold), increased colony formation (1.8-fold) and invasion (2.5-fold), formation of aggressive ductal structures in Matrigel and loss of tumor suppressor gene, *PTEN*, expression (62% of control), all indicative of cancer phenotype. MNU-MEC co-culture had no such effects on SCs. Epithelial-to-mesenchymal transition occurred in Cd-MEC co-cultured SCs, as shown by cell morphology and *VIMENTIN* over-expression, but not in MNU-MEC co-cultured SCs. During Cd-MEC co-culture, loss and regain of SC-related gene expression (*ABCG-2*, *OCT-4* and *WNT3*) occurred, likely as a key to MEC recruitment of NSCs into CSCs. Overall, the data indicate SCs gain a cancer phenotype with Cd-MEC co-culture but not with MNU-MECs. Analysis showed Cd-MECs secreted high levels of the tumor microenvironmental related factor, TGF $\beta$ -1. Direct TGF $\beta$ -1 treatment of NSCs duplicated most responses from Cd-MEC co-culture. Since recruitment of NSCs into CSCs can also occur with arsenic-transformed MECs, we conclude that the effects of nearby MECs on NSCs are not carcinogen specific but apply to some, but not all, carcinogens. This phenomenon may be important in chemically-induced tumor extension and dissemination.

## PS 1193 Aberrant microRNA Expression Correlates with RAS Activation in Malignant Transformation of Human Prostate Epithelial and Stem Cells by Arsenic.

N. N. Ngalame, E. J. Tokar and M. P. Waalkes. *NTP, NIEHS, NIH, Research Triangle Park, NC.*

Inorganic arsenic (iAs) is a human carcinogen probably targeting the prostate and can malignantly transform the human prostate epithelial cell line, RWPE-1 (to CAsE-PE cells) and a derivative stem cell (SC) line, WPE-stem (to As-CSC cells) by unclear mechanisms. MicroRNAs (miRNA) are non-coding but exert negative control on expression by degradation or translational repression of target mRNAs. Aberrant miRNA expression is likely a key factor in carcinogenesis. By miRNA array of 84 miRNAs in CAsE-PE and As-CSC cells, for 29 and 13 miRNAs respectively, expression changed by >1.5 fold of control, and 7 were common in both cells. Target gene expression correlated with miRNA changes (suggested by TargetScan and microRNA.org) in transformants with shared pathways like oncogenesis, miRNA biogenesis, SC differentiation, and metastasis and invasion. KRAS oncogene was induced in CAsE-PE but not by mutation or promoter hypomethylation. Overexpression of KRAS protein was very intense in As-CSC cells. In both cell types, iAs transformation decreased miRNAs targeting KRAS and RAS superfamily members. Reduced miR-134 (15 fold), miR-373 (11 fold), miR-155 (4 fold), miR-138 (4 fold), miR-205 (4 fold), miR-181d (3 fold), and miR-181c (2 fold) in CAsE-PE cells correlated with increased target RAS oncogenes, *RAN*, *RAB27A*, *RAB22A* mRNAs and KRAS protein. Reduced miR-143 (5 fold), miR-34c-5p (3 fold), and miR-205 (2 fold) in As-CSC cells correlated with increased target *RAN* mRNA, and KRAS, NRAS, and RRAS proteins. The RAS/ERK signaling pathway helps control cell survival, differentiation, and proliferation, and if

dysregulated promotes a cancer phenotype. Within the RAS/ERK pathway iAs transformation increased expression of RAF kinase protein, and ERK kinase mRNA in CAsE-PE cells, and MEK1/2, ERK and MAP4K4 kinase mRNAs in AsCSC cells. Thus, dysregulated miRNA expression appears to impact RAS activation in both iAs transformants, and appears key to iAs-induced acquired cancer phenotype in these human prostate cells.

**PS 1194 Aryl Hydrocarbon Receptor Contributes to Mouse Embryonic Stem Cell-Derived Cardiomyocyte Differentiation.**

Q. Wang, C. Ko, Y. Fan, Y. Wang and A. Puga. *University of Cincinnati, Cincinnati, OH.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous toxicant persistent in the environment. It is a prototypic ligand for the aryl hydrocarbon receptor (AHR), a ligand-activated transcription factor whose activation upon ligand binding regulates the expression of many xenobiotic detoxification genes. Besides being a critical mediator of gene-environment interactions, AHR has functions beyond those of a xenobiotic interacting protein. Studies in Ahr-/- mice have shown that AHR has physiological roles in hematopoiesis and heart development. To characterize these roles and the consequences of TCDD exposure in cardiomyocyte specification, we studied the effects of TCDD exposure during mouse embryonic stem cells (mESCs) differentiation into cardiomyocytes. mESCs were allowed to spontaneously differentiate via embryo-like aggregates (embryoid bodies, EB) into contracting cardiomyocytes. Immunocytochemistry on contracting EBs indicates that AHR colocalizes with the cardiac markers cardiac troponins T and I and NKX2.5. ShRNA knockdown of AHR during differentiation or TCDD treatment significantly decreased the percentage of contracting EBs. A time series of TCDD treatment revealed that the time between day 0 and day 3 of mESC differentiation was the most critical window for TCDD toxicity. An ESC clone containing a stably integrated plasmid bearing a Cyp1a1 promoter-driven puromycin-IRES2-eGFP was allowed to differentiate in the presence of TCDD followed by puromycin selection. Real-time PCR analyses of the puromycin resistant selected cells showed that many mesoderm marker genes were up-regulated while both endoderm and ectoderm markers were down-regulated, indicating that early AHR activation might be committed to mesodermal lineages. Our data suggest that AHR is involved in the regulation of cardiomyocyte differentiation during embryonic development and that TCDD exposure during early differentiation is toxic to cardiomyocyte development. Supported by NIH Grant 5R01ES06273.

**PS 1195 Exposure to Concentrated Air Particles Depletes Bone Marrow Hematopoietic Stem Cells.**

T. O'Toole, W. Abplanalp, J. Lee, D. J. Conklin and A. Bhatnagar. *Diabetes and Obesity Center, University of Louisville, Louisville, KY.*

Results from several epidemiological and laboratory studies suggest that exposure to airborne particulate matter (PM) is associated with an increase in cardiovascular disease (CVD) risk. While acute PM exposures have been linked to arrhythmias, thrombosis, inflammation, endothelial dysfunction, myocardial infarction and stroke, long term exposures increase the risk of mortality due to heart failure, cardiac arrest, and ischemic heart disease arrhythmias. Despite these associations however, relatively little is known about the molecular mechanisms linking exposures to CVD risk. In previous studies we have shown that circulating endothelial progenitor cells (EPCs) were depleted in humans exposed to natural variations in fine particulate matter (PM<sub>2.5</sub>) and in mice exposed to concentrated air particles (CAPS). However the effects of exposure on other progenitor cell types remains unknown. Hence, to examine how PM affects other stem cell populations we exposed mice to CAPS generated from downtown Louisville, Kentucky air using a versatile aerosol concentration enrichment system (VACES) for 9 days and examined levels of bone marrow-derived hematopoietic stem cells (HSCs) and mesenchymal stem cells (MSCs) using colony forming assays. In CAPS-exposed mice we observed an approximate 35% decrease in CFU-GM (colony forming unit-granulocyte, macrophage) colonies compared to filtered air-exposed, control mice. However the absolute number of colonies and the relative decrease versus air controls varied directly with CAPS levels. Flow cytometry-based phenotypic analysis of these colonies suggested a uniform decrease of multiple hematopoietic lineages rather than a decrease in a specific subset. In contrast no change was observed in BFU-E (burst forming unit-erythroid) colonies between the filtered air and CAPS treatments, or in the number of bone marrow-derived MSCs. These results suggest that HSC depletion may contribute to the cardiovascular complications resulting from chronic PM exposure by affecting immune responses to injury and dysfunction.

**PS 1196 Cadmium Concurrently Affects Cell Cycle, Total Histone Protein Production (THP) and H3 Histone Modification Pathways in Mouse Embryonic Stem Cells.**

S. R. Gadha and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy and Health Sciences, Queens, NY.*

The fetal basis of adult disease (FEBAD) theorizes that embryonic challenges initiate pathologies in adult life through epigenetic modification of gene expression. We previously reported (2012) that cadmium (Cd) exerts differential toxicity in mouse embryonic stem cells (mESC) by targeting THP production and H3 (a core histone protein) early in stem cell development, while H3K27 mono-methylation (H3K27me1, associated with transcriptional activation) is affected in later stages of differentiation. Thus, low dose acute Cd exposure selectively disrupts chromatin structure, an effect not seen in differentially mature cells. In this study we tested the effects of Cd on cell cycle progression (flow cytometry), chromatin structure and epigenetic pathways (THP and H3K27me1 analysis, respectively) in undifferentiated mESC after 1-h and 24-h exposures plus recovery. The data suggest that mESC do not recover from Cd insult at 0.032 mM (IC<sub>50</sub> for MTT assay), whereas cells recovered from 1-h exposure at 0.01 mM (IC<sub>25</sub> for MTT assay). This confirms our previous results that maximum cytotoxicity is seen during the first few hours of exposure at low concentrations. Additionally, THP production is suppressed to a greater extent than cell proliferation at 0.01 mM (24-h). Interestingly, 1-h exposure plus recovery resulted in a significant increase in THP production. Furthermore, 24-h exposure (with recovery) suppressed both cell proliferation and THP production, indicating that Cd targets THP production at longer exposure times and disrupts repair mechanisms. Flow cytometry data demonstrates that 0.01 mM Cd, for 24- and 48-h, increases DNA synthesis and percent of cells in G1 phase as well as percent of cells in mitosis; differentiation is affected at 72-h only. Thus presently we report that low dose acute Cd toxicity is cumulative and disrupts DNA repair, while concurrently affecting cell cycle progression, repair mechanisms, chromatin structure and transcriptional state in mES cells.

**PS 1197 Cadmium Induces Up-Regulation of Genes Associated with Early Embryonic Development in Mouse Embryonic Stem Cells.**

A. Aliberti and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy and Health Sciences, Queens, NY.*

Cadmium (Cd) alters gene expression and increases cell proliferation, but the exact mechanism of its nongenotoxic effect has yet to be elucidated. Previously we reported that exposure to low concentrations of Cd (80 nM to 5 µM) causes a toxicologically relevant increase in cell proliferation, as determined by [<sup>3</sup>H]-thymidine incorporation, in undifferentiated pluripotent mouse embryonic stem cells (mESC). Since epigenetic mechanisms are important during early embryonic development, we evaluated the potential of Cd to disrupt normal epigenetic processes in these cells. Using trypan blue exclusion, exposure of cells to Cd (up to 75 µM for 24 hours) resulted in inhibitory concentrations 50% (IC<sub>50</sub>) and 25% (IC<sub>25</sub>) of 40 and 20 µM, respectively. Real-time PCR analysis of genes associated with epigenetic chromatin modification during early embryonic development indicates that treatment of cells with IC<sub>50</sub> and IC<sub>25</sub> concentrations results in a greater than 2-fold up-regulation of *Aurke*, *Setd1b*, and *Smyd1*. *Aurke*, a member of the Aurora kinase family, has a significant influence on cell proliferation of the pre-implantation blastocyst. *Setd1b* is a component of the histone methyltransferase complex that trimethylates H3K4 (histone 3, a core histone protein, at position lysine 4), resulting in downstream expression of *Oct-4*. *Smyd1* is involved early in embryonic development of cardiac progenitor cells. The results suggest that Cd up-regulates genes that are important in early mitosis and blastocyst formation, methyltransferase activity, and cellular differentiation, the consequences of which implicate the potential role of the metal to alter the normal processes that are coupled with embryonic development *in vivo*.

**PS 1198 Colony-Forming Cell (CFC) Assays Predict for Increased Clinical Neutropenia Resulting from Combination Therapies.**

E. Clarke, A. Mergaert and G. Dos Santos. *ReachBio LLC, Seattle, WA.*

Combination therapy can be more efficacious than monotherapy in preventing progression of certain diseases. Unfortunately, this increased therapeutic efficacy often comes with increased hemotoxicity. In a randomized study of 646 patients with Multiple Myeloma, Orłowski et al. (2007) saw clinical neutropenia in 20% of patients receiving Bortezomib alone as compared to 35% of patients receiving Bortezomib and Doxorubicin. Shah et al. (2007) reported clinical neutropenia in

25% of patients receiving Imatinib and Hydroxyurea in patients with recurrent malignant glioma. Some myelotoxic combinations may be unintentional: Hachem et al. (2003) reported myelosuppression in bone marrow transplant patients treated with Linezolid that also happened to be on selective serotonin reuptake inhibitors (SSRIs). To see if in vitro CFC assays could predict the clinical neutropenia observed with these combinations, we tested the compounds alone and in combination on CFU-GM inhibition. Normal bone marrow cells and single compounds (range of concentrations) were mixed in methylcellulose-based media (ColonyGel 1102) and plated in 35mm dishes (3 replicates/concentration). CFU-GM were enumerated on day 14. Compound IC50 values were: Bortezomib (B) 12µM; Doxorubicin (D) 28 µM; Imatinib (I) 2.6 µM; Hydroxyurea (H) 31 µM; Linezolid (L) 109 µM; and the SSRI Fluoxetine (F) 27 µM.

Drug pairs (B+D; I+H; and L+F) were then tested using a matrix design. When compounds were combined at their IC50 equivalent values, there was an additional inhibition of CFU-GM: 69% with B+D, 84% with I+H and 75% with F+L. These data suggest that the CFU-GM assay may be a useful tool to evaluate drug combinations and predict for clinical neutropenia in a variety of circumstances: when concern of increased hemotoxicity with a strategic therapeutic combination exists; when there is limited information on the drug combinations to be employed; when a drug is to be used on pre-treated patient populations. CFC assays may also be useful in evaluating compounds with potential myeloprotective effects in combination with myelotoxic compounds.

### PS 1199 The Effect of TCDD on the Development of Human Hematopoietic Stem Cells to Lineage-Committed B Cells.

J. Li<sup>1,2</sup>, A. Phadnis<sup>1,2</sup>, R. B. Crawford<sup>2,3</sup> and N. E. Kaminski<sup>1,2,3</sup>. <sup>1</sup>Genetics Program, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is an ubiquitous environmental contaminant that exhibits a broad spectrum of toxicity. Epidemiological studies have identified an association between exposure to TCDD and B cell disorders, such as suppression of humoral immunity and increased incidence of B cell leukemia. Although extensive studies have been dedicated to explicate the mechanism underlying suppression of mature B cell function by TCDD, little is known whether TCDD will alter the sequential progression of human hematopoietic stem cells (HSC) to lineage-committed B cells. To address this question, we established a co-culture system using irradiated human marrow stromal cells as a supportive microenvironment to drive the differentiation of human cord blood CD34+ HSC in the presence of cytokines (IL-3, IL-7, SCF and Flt3L). In three weeks of culture, we observed increased expression of IL-7R, which is a hallmark of lymphopoiesis. Furthermore, generation of lineage-committed B cells was detected by the co-expression of B220 and CD19 in 20% of the cell population. To test the effect of TCDD on B cell development, we treated CD34+ HSC with 1nM, 10nM and 30nM TCDD. Compared to the vehicle control, the cell proliferation was remarkably arrested by TCDD in a concentration-dependent manner. We also observed a significant decrease of IL-7R expression in TCDD-treated cells. These data illustrate establishment of an in vitro model system to drive the development of cord blood HSCs to lineage-committed B cells. Preliminary studies showing downregulation of IL-7R suggest a role by TCDD in altering early B cell development.

### PS 1200 New Methodology for the Production of Thin-Layered Cardiomyocyte Tissue from Human-Induced Pluripotent Stem Cells (hiPSCs) Derived Cardiomyocytes for Use in High-Throughput Electrophysiological Platforms and High-Content Imaging Systems.

S. Yoshida<sup>1</sup>, K. Tsuzaki<sup>2</sup>, S. Tomizawa<sup>2</sup> and Y. Asai<sup>1</sup>. <sup>1</sup>ReproCELL Inc., Kanagawa, Japan; <sup>2</sup>Drug Safety Testing Center Co., Ltd., Saitama, Japan.

We have been developing functional cardiomyocytes derived from human iPS cells for many years. We have previously reported on cryopreserved cardiomyocytes, ReproCardio 2, derived from human iPS cells that demonstrate stable cardiac characteristics such as αMHC, cTnT, MLC-2a, MLC-2v, and Cx43. Using ReproCardio 2 clumps on electrophysiological assay systems, we have further developed our QTempo® assay (on the MEA platform) to better predict the drug induced QT interval prolongation (DIQTIP).

The use in cardio-toxicity assays requires the reliable assay platform like tissue. We have been developing this technology to make functional thin layered cardiac tissue, which has improved beating synchronization and stability, and better reliability for use in cardio toxicity assays. The thin-layer tissue derived from ReproCardio 2 stained positive for cTnT especially around the synchronized beating cell area. We

have developed a calcium flux assay (inotropic assay) using the thin layered cardiomyocytes that demonstrate a robust and synchronized calcium flux (Fluo8) and high content imaging technologies. Furthermore, the thin-layer showed advantages over monolayers, especially its robust signal with changes in serum concentration, which is preferable for high throughput screening (HTS) platforms. When using electrophysiology platforms, ReproCardio 2 thin-layer also demonstrated a more robust electrophysiological output similar to that seen with beating cardiomyocyte clumps especially the dose response to DIQTIP causing compounds such as E-4031 and Cisapride. In fact, the results were similar to that obtained in the clinical. The thin-layer cardiomyocytes have shown to be the preferred format giving rise to a robust and sustainable platform for measuring prolonged QT-interval and other cardiotoxic parameters such as calcium flux, and in turn will produce a more predictive format for toxicity assays in drug discovery.

### PS 1201 Proteomic Analyses of Human Primary Hepatocytes and Stem Cell-Derived Hepatocytes Identifies Hepatocyte Maturity Markers and Shows Improved Phenotype Maintenance in an Air-Liquid Interface Culture Model.

C. Rowe<sup>1</sup>, C. Goldring<sup>1</sup>, D. Gerrard<sup>2</sup>, N. Hanley<sup>2</sup>, M. Storm<sup>3</sup>, D. Tosh<sup>3</sup>, K. Piper Hanley<sup>2</sup> and B. Park<sup>1</sup>. <sup>1</sup>MRC Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom; <sup>2</sup>Centre for Endocrinology & Diabetes, University of Manchester, Manchester, United Kingdom; <sup>3</sup>Centre for Regenerative Medicine, University of Bath, Bath, United Kingdom. Sponsor: D. Mendrick.

Failure to predict hepatotoxic drugs in pre-clinical testing makes it imperative to develop better liver models with a stable cultured phenotype. Stem cell-derived models offer promise with hepatocyte-like cells currently considered to be 'fetal-like' in their maturity. This is based on limited biomarkers and lacks the required proteomic datasets that directly compares fetal and adult hepatocytes. Here, we quantitatively compare the proteomes of human fetal liver, adult hepatocytes, HepG2 cells and ES-derived hepatocyte-like cells. In addition, we investigate the changes in human fetal and adult hepatocytes when cultured in an air-liquid interface format and in extracellular matrix sandwich culture. The proteomes were qualitatively similar across all samples but hierarchical clustering showed that each sample type had a distinct quantitative profile. Hepatocytes cultured at the air-liquid interface retained a proteome more closely clustered to fresh cells than conventional culture, which acquired myofibroblast features. Principal component analysis extended these findings and identified sets of proteins as specialized indicators of hepatocyte differentiation. Our quantitative datasets are the first that directly compare multiple human liver cells, define a model for enhanced maintenance of hepatocytes in culture and provide new protein markers for determining human hepatocyte phenotype and maturity.

### PS 1202 Scalable, HTS/HCI-Amenable and NURR1-Expressing Dopaminergic Progenitor Cells Derived from Human Embryonic Stem Cells.

J. Chilton<sup>1</sup>, B. R. Culp<sup>1</sup>, K. L. Galland<sup>1</sup>, J. N. Le<sup>1</sup>, J. A. McCabe<sup>2</sup>, Z. Lin<sup>2</sup>, N. M. Filipov<sup>2</sup> and S. L. Stice<sup>1,2</sup>. <sup>1</sup>Aruna Biomedical, Inc., Athens, GA; <sup>2</sup>University of Georgia, Athens, GA.

One of the most common neurodegenerative diseases, Parkinson's disease (PD) affects approximately 1-2% of the population over age 65. The lack of an appropriate and scalable cell type hinders progress in PD drug discovery and elucidating disease mechanisms. Our goal was to generate human dopaminergic progenitor cells, derived from human embryonic stem cells (hESCs), which are homogeneous, expandable for high throughput screening (HTS) and high content imaging (HCI) assays and demonstrate a propensity for dopaminergic differentiation. We isolated cells exhibiting > 95% immunoreactivity for nuclear receptor related 1 protein (NURR1 or NR4A2), a transcription factor essential for generating midbrain dopaminergic neurons. We refer to these cells as DopaPro™ cells, which display normal karyotype, form adherent monolayers and proliferate over multiple passages. DopaPro™ cells were differentiated with leukemia inhibitory factor (LIF), brain derived neurotrophic factor (BDNF), glial derived neurotrophic factor (GDNF), transforming growth factor beta 3 (TGF-β3), forskolin and ascorbic acid (AA). By 3 weeks, differentiated DopaPro™ cells showed tyrosine hydroxylase (TH) expression. We asked whether DopaPro™ cells, as putative midbrain progenitor cells, required regionalization signals such as Sonic Hedgehog (SHH) or fibroblast growth factor 8 (FGF8), which are normally used in directed differentiation of hESCs to dopaminergic neurons. DopaPro™ cells did not require, nor was their differentiation to TH positive populations significantly enhanced, when cultures were exposed to SHH and FGF8 for 2 weeks prior to LIF, BDNF, GDNF,

TGF- $\beta$ 3, forskolin and AA. SHH and FGF8 were also not required for dopamine production. Here, hESC-derived progenitor cells poised for potential dopaminergic cell derivation were generated, thus reducing time and need for midbrain induction factors. Results show DopaPro™ cells are a unique, renewable and scalable cell source for PD research.

## PS 1203 Conditions for Isolation and Maintenance of Rat Hepatic Stem/Progenitor Cell Colonies.

J. A. Harrill<sup>1</sup>, J. Rowlands<sup>2</sup>, R. S. Thomas<sup>1</sup> and L. M. Reid<sup>3</sup>. <sup>1</sup>ICSS, The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>TERC, The Dow Chemical Company, Midland, MI; <sup>3</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC.

Hepatic stem cells, hepatoblasts, and committed hepatocytic and biliary progenitors constitute a stepwise maturational lineage which produces all mature cells of the liver. Hepatic stem/progenitors are localized to the Canals of Hering: periportal ductular structures derived from ductal plates in fetal and neonatal livers. These periportal stem cell niches are enriched in a variety of extracellular matrix molecules including certain types of collagens (III, IV and V) and hyaluronans, non-sulfated polymers of D-gluronic acid + D-N-acetylglucosamine. We have compared the ability of hyaluronans, as well as type III and type IV collagens, to support the proliferation of hepatic stem/progenitors isolated from neonatal and adult rat livers. Cells were isolated either by suspension digestion (neonates) or perfusion digestion with collagenase (adult) and cultured in a serum-free medium (Kubota's Medium) designed to culture-select endodermal stem/progenitors. Cells from either age seeded onto collagen III or IV (5 ug/cm<sup>2</sup>) yielded hepatic stem/progenitor cell colonies which expanded for 5-7 days of culture, at which time the mesenchymal cell components overgrew the plating surface. By contrast, a substratum of hyaluronans (5 – 100 ug/cm<sup>2</sup>), in combination with Kubota's Medium, promoted coordinated attachment and growth of discrete hepatic stem/progenitors and their mesenchymal cell progenitor partners. Colonies consisted of hepatic stem /progenitors growing on top of mesenchymal cell progenitors. Neonatal liver-derived colonies had large expansion potential, increasing in area by more than 100-fold by 10 days in culture. It is hypothesized that the expansion potential of adult-derived cells was more limited due to the need for an alternate method of isolation or addition of exogenous growth factors. This novel culture system provides an opportunity to study the effects of hepatotoxicants on early lineage stages consisting of rat hepatic stem/progenitor cells.

## PS 1204 The *In Vitro* Human CFU Assay Combined with Automated Image Analysis of Colony Morphology Markedly Improves Assessment of Hematopoietic Toxicity of AZT and Other Nucleoside Inhibitors.

M. Huber<sup>1</sup>, D. Raj<sup>1</sup>, C. Grande<sup>1</sup>, J. Parrott<sup>1</sup>, O. Egeler<sup>1</sup>, K. Tse<sup>1</sup>, C. Farzim<sup>1</sup>, A. Eaves<sup>1,2</sup> and J. Damen<sup>1</sup>. <sup>1</sup>STEMCELL Technologies Inc, Vancouver, BC, Canada; <sup>2</sup>Terry Fox Laboratory, BC Cancer Agency, Vancouver, BC, Canada.

Antiviral nucleoside analogs target viral polymerases but can also inhibit cellular polymerases, leading to a decrease in cell proliferation and ultimately suppression of hematopoiesis, resulting in anemia and neutropenia. For assessment of hematotoxicity in this compound class, the FDA's *Guidance for Industry: Antiviral Product Development – Conducting and Submitting Virology Studies to the Agency* recommends the use of the colony-forming unit (CFU) assay, which utilizes primary hematopoietic stem and progenitor cells. In 2003, the European Centre for the Validation of Alternative Methods (ECVAM) published a standardized CFU assay methodology that is validated for the prediction of the maximum tolerated dose (MTD) of myelosuppressive compounds (Pessina *et al.*, Tox Sci. 2003. 75:355-367). This *in vitro* assay is a key tool for assessing toxicity prior to initiation of costly *in vivo* studies and human clinical trials. Unfortunately, in these standardized CFU assays, nucleoside inhibitors such as azidothymidine (AZT) do not exhibit high toxicity (IC<sub>50</sub> = 100-200  $\mu$ M), despite the fact that they are well known to perturb hematopoiesis in patients. Although AZT does not strongly reduce the number of hematopoietic colonies in the CFU assay, it does have a dramatic effect on their morphology. To quantitate changes in colony morphology, we utilized the STEMvision™ platform for automated advanced image analysis in conjunction with the CFU assay. Our results indicate that IC<sub>50</sub> values for AZT based on the quantitation of morphological changes such as colony size were ~20-fold lower (5-10  $\mu$ M) than the IC<sub>50</sub> based on colony numbers (100-200  $\mu$ M). These data suggest that quantitation of colony morphology is a key parameter to predict drug potency and *in vivo* toxicity in this drug class.

## PS 1205 Investigation of a Redox-Sensitive Predictive Model of Mouse Embryonic Stem Cell Differentiation via Quantitative Nuclease Protection Assays and Glutathione Redox Status.

K. J. Chandler<sup>1</sup>, J. M. Hansen<sup>2</sup>, E. S. Hunter<sup>1</sup> and T. B. Knudsen<sup>1</sup>.

<sup>1</sup>NHEERL/NCC, US EPA, Research Triangle Park, NC; <sup>2</sup>Department of Pediatrics, Emory University School of Medicine, Atlanta, GA.

Mouse embryonic stem cells (mESCs) recapitulate developmental signals that occur *in vivo* and are amenable to high-throughput profiling of chemical-induced effects. *In silico* models of impaired mESC differentiation identified 19 ToxCast™ assays that distinguished chemical effects on cardiomyocyte differentiation versus cytotoxicity (Wilcoxon rank sum, p=0.03). Taken together, these assays connect a redox-sensitive pathway(s) as a likely target of a chemical set that impaired mESC differentiation. To evaluate this predictive model, a custom quantitative nuclease protection assay (qNPA) array (HTG Molecular Diagnostics) of 41 redox-sensitive targets and differentiation markers was designed. The concentration-dependent effects of twelve ToxCast chemicals were evaluated using the qNPA array. The highest concentration produced AC 20 cytotoxicity in mESCs and the remaining were half logarithmic decrements. Cells were harvested on days 4 and 9 of culture. The prediction model correctly identified that pyridaben would disrupt redox signaling in mESCs. Expression of the redox-responsive transcription factors Nrf2, Hif1 $\alpha$  and Mtf2 increased upon exposure. Pyridaben showed significant concentration-dependent effects on markers for endoderm, ectoderm and mesoderm differentiation on day 4 of culture (decreased Fgf5, Otx2, and Fgf8 expression and increased Tbx3 expression) without producing a 50% decrease in cardiomyogenesis in the standard assay on day 9. Preliminary data evaluated the redox status (glutathione/glutathione disulfide) of mESCs at 3, 6, 9 and 24 hours following chemical exposure and indicated a unique pattern of redox status for predicted redox disrupting chemicals. These experiments document the importance of using multiple differentiation endpoints and support the linkage of our predictive model to altered differentiation in chemical profiling. This abstract does not reflect EPA policy.

## PS 1206 Arsenic Trioxide Alters Regulation of Differentiation in Mouse Embryonic Stem Cells.

T. Lee and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy and Health Sciences, Queens, NY.*

Arsenic trioxide (As<sub>2</sub>O<sub>3</sub>) is a known human carcinogen yet it is currently approved by the Food and Drug Administration as a chemotherapeutic agent for the treatment of acute promyelocytic leukemia. As<sub>2</sub>O<sub>3</sub> alters cellular differentiation by mechanisms of which are yet not clearly understood. Thus, in the current study, we investigated the influence of As<sub>2</sub>O<sub>3</sub> on differentiation of mouse embryonic stem cells (mESC). These pluripotent stem cells are derived from the inner cell mass of the blastocyst, and are capable of continuous proliferation, self-renewal and differentiation into the three germ layers. Undifferentiated cells express early specific stem cell markers, including *Oct-3/4*, *Nanog*, and *Sox-2*, which have an important role in developmental regulation and differentiation. In our initial studies, 1.0  $\mu$ M to 6  $\mu$ M As<sub>2</sub>O<sub>3</sub> reduced cell viability over 24-h with increasing concentrations, whereas significant reductions were observed at or below 1  $\mu$ M only with 48-h exposures, a concentration which is equivalent to therapeutic administration. End point PCR analysis revealed that increasing concentrations of As<sub>2</sub>O<sub>3</sub> reduced gene expression of stem cell markers. This supports the western blot results, protein levels decreased with decreased in gene expression. Western blot analysis for *Oct-3/4* and *Sox-2* protein expression at the same concentrations indicated that protein levels were decreased by As<sub>2</sub>O<sub>3</sub> in a dose- and time-dependant manner. While *Oct-3/4* and *Sox-2* protein expression levels are crucial for maintaining mESC in their undifferentiated state, the reductions in the presence of arsenic imply the loss of "stemness". Consequently, it appears that As<sub>2</sub>O<sub>3</sub> exposure reduces the ability of the stem cells to maintain proper state of differentiation.

## PS 1207 Vascular Endothelial Cells Exposed to PCB 153 Show Increased Expression of Stem Cell Markers.

J. K. Das and Q. H. Felty. *Environmental & Occupational Health, Florida International University, Miami, FL.*

The contribution of PCB exposure to the development of vascular disease is an area of research that has received little attention. The stability of these chemicals has allowed them to persist in the environment and consequently continues to expose the general population to PCBs. Since PCBs have been reported in human blood; vascular toxicity from PCB exposure is a public health concern. Vascular lesions from the lung of patients with severe PAH have been characterized with excessive EC proliferation and markers of angiogenesis. The exact cell type from where vascular

lesions originate from is not clear. However, our studies have focused on ECs as the origin of vascular lesions because EC stem-like cells have been reported to be involved in vascular injury. The theory that malignancies depend on stem-like cells for proliferation has received much attention, but there have been few studies which support a pathogenic role for stem cells in vascular disease. Thus, the objective of this study was to determine whether exposure to the PCB congener 153 can increase the level of stem cell markers in vascular ECs. ECs overexpressing ID3 were used to study the effects of PCB153 in 3D spheroid cultures. Co-culture model of EC with SMCs and fibroblasts was used to study the expression of stem cell markers in a monolayer by confocal microscopy. The effect that PCB153 had on cell cycle progression was also determined by flow cytometry. We observed PCB153 significantly increased expression of stem cell markers CD34+, CD133+, VEGFR-3 in spheroids overexpressing ID3. ECs exposed to PCB153 showed stable sphere formation in B27 medium at 10 days. ECs exposed to PCB153 in co-cultures showed increased expression of stem markers CD34+ and Nanog as well as increased angiogenic phenotype. Cell cycle analysis confirmed that more stem like cells exposed to PCB153 were in G1 phase. Our results show that PCB153 exposure increased expression of stem cell markers and may be related to mechanisms by which vascular disease depends on stem-like cells for proliferation.

**PS 1208 Evaluation of Iontropic and Chronotropic Compounds In Vitro Using Human iPS-Derived Cardiomyocytes and Impedance-Based Contractility Assay.**

X. Zhang, B. Xi, X. Wang, X. Xu and Y. A. Abassi. *Acea Biosciences, San Diego, CA.*

The  $\beta$ -adrenergic receptor ( $\beta$ AR) signaling system is one of the most powerful regulators of cardiac ionotropic and chronotropic function.  $\beta$ AR antagonists, commonly known as beta-blockers ( $\beta$ -blockers) have been used for decades to treat hypertension, ischemic heart disease, some arrhythmias, and more recently to treat congestive heart failure. Up to date, 3 types of  $\beta$ -blocker drugs have been developed for therapeutic purpose. In order to better understand the cardiac effects of different types of  $\beta$ -blockers, we have developed an in vitro assay using human iPS-derived cardiomyocytes in conjunction with impedance measurement. We evaluated the activities of six  $\beta$ -blocker drugs and compounds including (1) non-selective  $\beta$ -blockers; (2) cardioselective  $\beta$ -blockers; and (3) nonselective  $\alpha$  and  $\beta$ -blockers. The data as measured by impedance readout revealed that the  $\beta$ -blockers from different classes displayed subtle but unique profile of acute impedance changes post compound addition. With the exception of atenolol and metoprolol, pindolol, alprenolol, propranolol and carvedilol significantly decreased the cell beating rate (BR) and even temporally led to beating arrest at the highest tested concentration (3  $\mu$ M). In addition, the 1 hour pretreatment with all these four compounds at higher doses abolished the isoproterenol-induced positive chronotropic effects on BR. Carvedilol was the only drug that appeared to profoundly reduce cell beating amplitude (CA) in a dose-dependent manner. The in vitro assay used here indicates that human iPS-derived cardiomyocytes respond similarly to the  $\beta$ -blockers from the same group. However, each type of  $\beta$ -blockers generates distinct profiles and do have different chronotropic and ionotropic effects which we will summarize in the current poster.

**PS 1209 Selection of CYP3A4<sup>+</sup> hESC-Derived Hepatocytes for Drug Metabolism and Toxicity Assays.**

K. Bonham<sup>1</sup>, R. Rodriguez<sup>1</sup>, S. Ogawa<sup>2</sup>, C. Blanco<sup>1</sup>, H. Xian<sup>1</sup>, R. Stull<sup>3</sup>, G. Keller<sup>2</sup> and R. Snodgrass<sup>1</sup>. <sup>1</sup>VistaGen Therapeutics, Inc., South San Francisco, CA; <sup>2</sup>McEwen Centre for Regenerative Medicine, Toronto, ON, Canada; <sup>3</sup>Stem CentRx, South San Francisco, CA.

The ability to produce human hepatocytes that express adult levels of drug metabolizing enzymes including CYP3A4 in a stable and reproducible system will greatly benefit the drug development process by decreasing costs, reducing animal studies, and increasing drug safety. Many groups are trying to develop hepatocytes from human stem cells to address the lack of availability, quality, and reproducibility of primary hepatocytes, however, most protocols produce immature hepatocytes with minimal expression of the adult enzymes related to drug metabolism. Since CYP3A4 is the most abundant P450 expressed in adult liver and metabolizes 50% of drugs on the market, it is imperative that assay systems express relevant levels of this enzyme. To this end, we previously reported the generation of a hESC reporter line (3A4BLA) containing humanized beta-lactamase (hBLA) inserted in frame with the CYP3A4 gene. Here we show that 3A4BLA-hepatocytes can be used to: 1) monitor the differentiation of mature hepatocytes; 2) sort for mature hepatocytes; 3) monitor drug induction of CYP3A4; and 4) develop in vitro assays for drug metabolism and toxicity. Using an optimized protocol for hES-hepatocyte differentiation, we demonstrate CYP3A4 in 25-40% of the cells and show that these cells produce levels of CYP3A4 mRNA approaching primary hepatocytes, express high

levels of ALB, and store glycogen. More importantly, they metabolize testosterone and midazolam and respond properly to inducers of CYP3A4 like Rifampicin and Phenobarbital. With this system we can obtain a relative measure of CYP3A4 expression on a per cell basis in response to compounds and correlate those data with cell metabolism, CYP3A4 activity, and secretion of albumin and urea. Taken together, these data demonstrate development of a robust system with the potential of purifying human hepatocytes with more mature functions, as well as assaying drug effects on CYP3A4 expression, activity, and metabolism.

**PS 1210 Adapting the MTT Assay for Use with Human Embryonic Stem Cells (hESC).**

R. Z. Behar, V. Bahl, Y. Wang, J. Weng, S. Lin and P. Talbot. *University of California Riverside, Riverside, CA.*

hESC are difficult to adapt to 96-well plate assays because they survive best when plated as colonies, which are difficult to count and plate accurately. To address this problem, two protocols were developed to perform the MTT assay using hESC. In the first protocol, plating was done with Rho-associated kinase inhibitor (ROCKi), which allows accurate counting and plating of single hESC. The second protocol involved plating hESC as small colonies without ROCKi but with adaptations to allow accurate counting and plating of small colonies. In the ROCKi protocol, 5,000 cells/well are counted using a hemocytometer then plated and incubated for 96-hours, while the small colony method calls for 20,000-30,000 cells/well followed by 72-hours of incubation. To enable rapid and uniform plating of small hESC colonies, we developed a spectrophotometric method to accurately determine hESC concentration. The percent transmittance for multiple readings of the same sample produced a coefficient of variation (COV) of 1.5%. Next, we determined the cell concentration needed to carry out an experiment in a 96-well plate by plating various cell concentrations and determining the optimal concentration needed for a 72-hour experiment. Finally, to confirm that the correct cell number was pipetted accurately into each well, control wells were subjected to the MTT assay and used to calculate the COV, which ranged from 0.7 to 8.5%, showing that pipetting of small colonies was uniform. The small colony protocol was validated using the NIH Plate Uniformity and Signal Variability Assessment, which tested for signal separation, drift and edge effects. When comparing the ROCKi protocol to the small colony protocol, it was found ROCKi caused a shift in the IC50 from 1.34e-3 to 1.45e-4 M. In addition, hESC morphology was altered with ROCKi treatment, which appeared to stress the cells, while cells in the small colony protocol appeared healthier, tightly packed, and cobblestone-like. Both protocols allow the MTT assay to be carried out rapidly and accurately with high reproducibility between replicate experiments using hESC.

**PS 1211 Differential Regulation of Pluripotency Maintenance and Differentiation Genes in Undifferentiated Human Embryonic Stem Cells (hESC) Exposed to Methyl Parathion (MP) and Its Active Metabolite Methyl Paraaxon (MPO).**

J. W. Sekowski and J. S. Madren-Whalley. *ECBC, US Army RDECOM, Gunpowder, MD.*

Given their wide spread use, ease of procurement, and potential for serious health consequences if deployed by terrorists, toxic industrial chemicals (TICs) represent a real threat to warfighters and civilians at home and abroad. Unfortunately, for a vast number of TICs, including the widely-used organophosphate insecticide, MP, there is incomplete knowledge regarding the basic molecular consequences of exposure in humans. Although the literature suggests diverse toxicological consequences for MP exposure during early fetal development, it is primarily based on human epidemiological studies, in vivo animal studies, or in vitro studies using immortal, transformed cell lines. Furthermore, the relative contribution and the molecular mechanism(s) of action of the parent compound, MP, versus the active metabolite, MPO, has not yet been elucidated in an early developmental system. In an in vivo model, the MP is converted by hepatic and extra hepatic phase I and II metabolism to MPO, and the relative ratios can vary depending on the in vivo system. Given that undifferentiated hESCs do not produce the enzymes necessary to carry out the conversion of MP to MPO, they provide a unique opportunity to examine the individual influence of the parent and active metabolite on molecular pathways influencing very early human development.

In this study we compared the expression of 84 genes known to be important in the maintenance of pluripotency and differentiation in hESCs cells following a 24 hour exposure of cells to either MP or MPO. These RT-PCR data indicate several key differences in the expression of genes following exposure to MP and MPO. The results of this study have opened a new avenue toward understanding how MP and its active metabolite MPO specifically interfere with some of the earliest steps in human embryonic development.

**PS 1212 IQ-PSLG Nonclinical to Clinical Translational Safety Database Initiative.**

T. Monticello<sup>1</sup>, V. Kadambi<sup>2</sup>, M. Graziano<sup>3</sup>, M. Sommer<sup>4</sup>, K. Blanchard<sup>5</sup>, Q. Zhu<sup>5</sup> and M. Liu<sup>6</sup>. <sup>1</sup>Angen, Thousand Oaks, CA; <sup>2</sup>Millennium: The Takeda Oncology Company, Cambridge, MA; <sup>3</sup>Bristol-Myers Squibb, Princeton, NJ; <sup>4</sup>Pfizer, Groton, CT; <sup>5</sup>Boehringer Ingelheim, Ridgefield, CT; <sup>6</sup>IQ, Washington DC.

The International Consortium for Innovation and Quality in Pharmaceutical Development (IQ) is a science-focused organization of pharmaceutical and biotechnology companies. The mission of the Preclinical Safety Leadership Group (PSLG) of the IQ is to advance science-based standards for nonclinical development of pharmaceutical products and to promote high quality and effective non-clinical safety testing and human risk assessment. The IQ-PSLG is creating an industry-wide database to determine accuracy with which the interpretation of nonclinical safety assessments in animal models correctly predicts human risk in the early clinical development of biopharmaceuticals. This initiative aligns with the 2011 FDA strategic plan to advance regulatory science and modernize toxicology to enhance product safety. Eighteen member companies will contribute datasets from over 150 molecules. Though similar in concept to the initial industry-wide concordance dataset conducted by HESI/ILSI (Olson, et al. 2000 Reg Tox Pharmacol 32:56), the IQ-PSLG database will include both large and small molecules, be contemporary (circa 2005-2011) and will proactively track concordance from recently completed Phase I clinical studies. Database details, preliminary dataset results and the individual queries to be mined from the dataset will be presented. In summary, the output from this work will help identify actual human and animal adverse event data to define both the reliability and potential limitations of nonclinical data and testing paradigms in predicting human safety in Phase I clinical trials.

**PS 1213 Target Organ Toxicities in Studies Conducted to Support First Time in Human Dosing: An Analysis across Species and Therapy Areas.**

R. Roberts, D. Ryan, R. Callander, K. Stamp, S. Horner and S. Robinson. *Global Safety Assessment, AstraZeneca, Macclesfield, United Kingdom.*

Before a new chemical entity can enter human clinical trials, safety and tolerability must be assessed in non-clinical rodent and non-rodent toxicology studies. We conducted an analysis of target organ toxicities identified for 77 AstraZeneca candidate drugs (CDs) in these studies across a range of therapy areas and targets. Our analysis showed that in the rodent, the most frequently affected organ was the liver followed by the adrenal glands, kidney, spleen, bone marrow and thymus. In the non-rodent, the liver and thymus were the most frequently affected organs, followed closely by the testis and GI tract. This pattern was largely similar across intended therapy areas with the exception of oncology and infection where a larger range of organs was affected with higher incidences for adrenal glands, femur, spleen and thymus. Of those CDs for which no target organ toxicity was seen in one or both pre-clinical species, the majority were from the CNS/pain therapy area. Another important consideration is the need for a second species in toxicology testing. For the 75 CDs where both rodent and non-rodent studies were conducted, 1 or more new target organs were identified in rodents for 52 CDs (69%) and 1 or more new target organs were identified in non-rodents for 40 CDs (53%). Notably, the changes seen only in non-rodents included tissues of high relevance for human risk assessment such as the male reproductive tissues. There was only a single CD in our data set for which the target organ profile was identical in both preclinical species. In summary, our data show that liver, thymus, adrenal gland, spleen, kidney, bone marrow and lymph nodes are the most frequent target organs in preclinical studies. This profile is largely similar across therapy areas except for oncology and infection CDs, where a higher incidence of target organ toxicities across a wider range of organs was seen. The data additionally demonstrate the value of a second species in toxicity testing to support human safety.

**PS 1214 Quantitative Protein Expression Profiling of HepG2 Cells Treated with Compounds Implicated in Drug-Induced Liver Injury (DILI).**

A. Tavendale, C. Vazquez-Martin, D. Lamont and P. Ajuh. *Dundee Cell Products Ltd., Dundee, United Kingdom.* Sponsor: C. Elcombe.

Drug induced liver injury (DILI) is the single most common reason for removing approved drugs from the market, or issuing warnings and modifications of use. However, there is little knowledge of the key cellular mechanisms at the molecular level that underlie DILI. Insight into these mechanisms and the cellular pathways involved will enable the design of predictive assays to remove compounds that pose a toxicity risk early on in the drug discovery and development process.

In this study, we used a "toxicoproteomics" approach and SILAC (Stable Isotope Labeling with Amino acids in Cell culture) to study the changes in the proteome of the human hepatocellular carcinoma cell line HepG2 following treatment with a set of seven compounds (Labetalol, Nicotinic Acid, Diclofenac, Amoxicillin, Cefaclor, Rifampin and Tacrine) previously reported to be involved in DILI. We identified over 4,000 proteins by high-resolution mass spectrometry with a false discovery rate of 1%. We used MaxQuant software for protein identification and the quantitative analysis of data from mass spectrometry and DAVID Bio-informatics - GO (gene ontology) analysis tools to determine protein changes and biological processes/pathways affected by the treatment of cells with the drugs. Our results indicate that the levels of some enzymes with potential effects in drug toxicity were reduced when treated with the compounds. These include carnitine O-acyltransferase activity (involved in the metabolism of fatty acids), nucleotide-excision repair (DNA repair function) and Glutathione S-transferase A1 (detoxification of electrophilic compounds). Biological processes generally affected as determined by the GO analysis include the response to metal ion and nitrogen compound biosynthetic processes. These results provide further insight into possible cellular mechanism(s) linked to the toxic activities of the drugs analysed. Undoubtedly, quantitative proteomics could play a pivotal role in deciphering toxicity mechanisms at the molecular level.

**PS 1215 Demonstration of a Unique *In Vitro* to *In Vivo* to Clinical Correlation of Drug-Induced Phototoxicity.**

T. Su, P. Stetsko, J. Gong, W. Washburn, S. C. Griffen and T. Reilly. *Research & Development, Bristol-Myers Squibb, New Brunswick, Hopewell, and Lawrenceville, NJ.*

Drug-induced phototoxicity, which occurs when undesirable effects are elicited after exposure of the skin or eyes to ultraviolet (UV) light, has been an impediment to therapeutic use of a variety of drugs and can negatively impact pharmaceutical research and development. Moreover, proposed screening strategies often over predict in vivo hazards. Herein we report an example where in vitro data not only predicts in vivo animal effects but these effects are further translated to humans. As part of the toxicologic evaluation of a drug candidate for obesity, BMS-819881 ('881) absorbed UV light in the 290-310 nm range and was thus screened in an in vitro mouse fibroblast 3T3 cell assay. The compound had a phototoxicity factor  $\geq 18$  ( $>5$  indicates phototoxic potential). In a subsequent rat tissue distribution assay, '881 and its metabolites were found to distribute to the skin. In a definitive single-dose study in pigmented Long-Evans rats, '881 (given as a prodrug) induced various degrees of erythema, edema and/or flaking of the skin in a dose-dependent fashion after exposing to UV light at  $\geq 150$  mg/kg [AUC<sub>0-24h</sub>  $\geq 327$   $\mu\text{g}\cdot\text{h}/\text{mL}$ , C<sub>max</sub>  $\geq 21.7$   $\mu\text{g}/\text{mL}$ ; 5x margin to clinical exposures at 600 mg in a multiple ascending dose (MAD) study]. To investigate its potential mechanism of phototoxicity, '881 was tested for photostability and reactive oxygen species (ROS) production, a common causation for photosensitivity. BMS-819881 and its ketone metabolite were photolabile ( $\leq 85\%$  degraded) resulting in substantial production of singlet oxygen after exposure to UV light. Furthermore, in a 4-week MAD trial with '881 (given as a prodrug at  $\leq 600$  mg) in obese subjects, symptoms consistent with photosensitivity reactions (eg, sustained redness and itching) were reported in a dose-dependent manner. These data support a unique nonclinical prediction of clinical photosensitivity and suggest the potential added utility of photostability and ROS production assays in phototoxicity testing, at least in some circumstances.

**PS 1216 Preclinical Profiling and Computational Differentiation of Human Vascular Response to 95 Drugs Using Next-Gen RNAseq Transcriptomics.**

R. Figler, M. J. Lawson, A. J. Mackey, E. L. Berzin, J. C. Anstey, P. D. Schoppe-Bortz, R. W. Tilghman, B. R. Blackman and B. R. Wamhoff. *HemoShear, LLC, Charlottesville, VA.* Sponsor: A. Dash.

**BACKGROUND:** The ability to de-risk and validate preclinical compounds for on- or off-target vascular response is critical for drug development. Animal models and static cell culture systems are poor predictors of the human response. METH-ODS: We have established a human primary vascular endothelial and smooth muscle cell co-culture system which recapitulates hemodynamic forces and restores cell biology and responsiveness to drugs at physiologically relevant levels. We assayed 95 clinically relevant drugs at concentrations consistent with plasma levels following therapeutic dosing. Therapeutic areas included: dyslipidemia, inflammation, depression, diabetes, hypertension, thrombosis, and obesity, among others. Using RNAseq, we profiled the transcriptional responses observed in both cell types, across 5 biological replicates, to each drug versus its vehicle control. **RESULTS:**

Our analysis detected and corrected for small but persistent batch effects related to sample processing and employed multi-dimensional methods for differential statistics in >1000 samples. Each transcriptomic drug response profile differentiates drug-specific on- and off-target activities between cell types, within drug classes, and between drug classes, as well as estimating relative molecular pathway activity between drugs within a class. For example, preliminary analysis of TZD-class responses ranked the on-target "insulin receptor signaling pathway" for pioglitazone at 6th, but rosiglitazone at 159th, and troglitazone at 259th, while off-target "cancer" and "cell remodeling" pathways dominated the top 10 signaling pathways for troglitazone and rosiglitazone, consistent with clinical history of these drugs. **CONCLUSIONS:** Methods combining human-relevant systems with mining drug-specific profiles in conjunction with external drug annotation databases (FDA's AERS, Altman's OFFSIDES, EPA's ToxCast, Broad's Connectivity Map) serves to enhance ability to make broader human vascular drug response predictions.

**PS 1217 Towards a Platform of BAC-GFP Transgenomics-Based Pathway of Toxicity Reporters for Automated High-Content Imaging-Based Chemical Safety Assessment.**

S. Wink, B. Herpers, S. Hiemstra and B. van de Water. *Toxicology, LACDR, Leiden, Netherlands.*

Adaptive cellular stress responses are paramount in the healthy control of cell and tissue homeostasis after cell injury during hypoxia, oxidative stress or unanticipated side-effect of medications and other chemical exposures. Genome-wide transcriptomics analysis has revealed the detailed cellular stress response landscape and thereby the diversities of organelles and cell functions that are being affected upon exposure to diverse chemicals. Individual toxicological relevant stress responses have also been termed pathways of toxicity (PoT). We find that activation of PoT occur well before the typical ultimate outcome of chemical cell injury: cell death by necrosis or apoptosis. Understanding the activation of PoT caused by chemicals is complex because many simultaneous biochemical cellular perturbations may occur thereby affecting different PoT in parallel or a defined order. To increase our understanding of chemically-induced PoT activation and its contribution to safety assessment we believe that a time-resolved, sensitive and multiplex readout of chemical-induced toxicological relevant PoT will be essential.

For that purpose, we are currently developing a automated live-cell high-content imaging-based platform containing a panel of distinct PoT reporter cell lines. To conserve the endogenous regulation we tag selected target genes with GFP using BAC-transgene-omics approaches. So far we have generated 23 different human hepatoma HepG2 reporter cell lines that define autophagy, mitochondrial organization, Golgi structure, nucleosomes, ER morphology and stress, oxidative stress response and DNA damage responses.

Here we report the current status of our BAC-GFP PoT reporter platform and demonstrate that individual reporter cell lines are sensitive to their corresponding model stress responses. We anticipate that ultimately a phenotypic PoT profiling platform will allow a high throughput and time-resolved classification of chemical-induced stress responses in the safety assessment of chemicals.

**PS 1218 High-Throughput Respirometric Assay Identifies Predictive Toxicophore of Mitochondrial Injury.**

L. P. Wills<sup>2</sup>, G. Beeson<sup>1,2</sup>, R. Trager<sup>1</sup>, C. Lindsey<sup>1</sup>, Y. Peterson<sup>1</sup>, C. Beeson<sup>1,2</sup> and R. G. Schnellmann<sup>1</sup>. <sup>1</sup>Medical University of South Carolina, Charleston, SC; <sup>2</sup>MitoHealth, Charleston, SC.

Many environmental chemicals and drugs negatively affect human health through deleterious effects on mitochondrial function. Currently there is no chemical library of mitochondrial toxicants, and no reliable methods for predicting mitochondrial toxicity. We hypothesized that discrete toxicophores defined by distinct chemical entities can identify previously unknown and future mitochondrial toxicants. We used a respirometric assay to screen 1760 compounds (5  $\mu$ M) from the LOPAC and ChemBridge DIVERSet libraries. Thirty-one of the assayed compounds decreased uncoupled respiration, a stress test for mitochondrial dysfunction, prior to a decrease in cell viability and were toxic to isolated mitochondria. The mitochondrial toxicants were grouped by chemical similarity and two clusters containing four compounds each were identified. Cheminformatic analysis of one of the clusters identified previously uncharacterized mitochondrial toxicants from the ChemBridge DIVERSet. This approach will enable the identification of mitochondrial toxicants and advance the prediction of mitochondrial toxicity for both drug discovery and risk assessment. This project was funded through grant numbers GM084147, F32 ES020103-01, and 2R44-ES019378-02.

**PS 1219 Nonclinical Toxicology Profiling of the First-In-Class Sodium-Glucose Co-Transporter 2 (SGLT2) Inhibitor Dapagliflozin.**

M. Tirmenstein<sup>1</sup>, A. Bergholm<sup>2</sup>, E. Janovitz<sup>1</sup>, D. Hagan<sup>1</sup>, J. Whaley<sup>1</sup> and T. Reilly<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb Research & Development, Princeton, NJ; <sup>2</sup>AstraZeneca Research & Development, Mölndal, Sweden.

Dapagliflozin (Dapa) is a novel SGLT2 inhibitor that directly increases urinary glucose excretion as a mechanism for treating diabetes. To support its safe use during clinical development, Dapa was evaluated in a rigorous battery of in vitro and in vivo nonclinical safety studies. In vitro screening of >300 diverse targets indicated no significant off-target activities for Dapa or its primary metabolite. The complete set of in vivo safety studies included dosing up to 12-months in dogs and a lifetime (~2 years) in mice and rats. As expected, most of the effects were related to Dapa-induced pharmacology (i.e. SGLT2 inhibition) such as glucosuria with osmotic diuresis and mild loss of electrolytes, and limited body-weight gains despite increased food consumption. At extremely high doses, Dapa also caused intestinal glucose malabsorption. This effect only occurred in rats at extremely high doses (> 2000x clinical exposures) and was related to increased intestinal calcium absorption, a consequence of exacerbated carbohydrate fermentation in the rodent gut related to SGLT1 inhibition, which ultimately contributed to thickened trabeculae in long bones and soft tissue mineralization. Of particular importance, chronic Dapa treatment at >600x clinical exposures did not result in hyperplasia or any adverse effect on the kidneys or urinary tract nor at > 100x clinical exposures any increases in the incidence of or shortening in the latency period for tumor development. There was also no indication that SGLT2-/- mice had adverse urinary tract morphology or function when compared to their wild type counterparts in a 15-month observational study. Thus, the pharmacologic activity of Dapa in nonclinical species and the rigorous attempts to test supra- and off-target pharmacology allowed us to thoroughly evaluate its potential toxicity profile, providing us with confidence in its safety in patients with diabetes.

**PS 1220 Bone Assessments in Enhanced Pre-Postnatal Toxicity Study in Pregnant Cynomolgus Monkeys with up to 6-Months Postnatal Evaluation.**

A. Varela<sup>1</sup>, S. Y. Smith<sup>1</sup> and G. Chellman<sup>2</sup>. <sup>1</sup>Bone Research, Charles River, Montréal, QC, Canada; <sup>2</sup>Charles River, Reno, NV. Sponsor: M. Vézina.

Assessment of potential test article-related bone liability is becoming increasingly important, not only in the mature skeleton but also in the developing skeleton. Skeletal assessments were developed to evaluate potential liability in pregnant monkeys and offspring in an enhanced pre postnatal development (ePPND) toxicity study. Assessment in mothers during gestation and lactation included bone markers C-telopeptide (CTx), tartrate-resistant acid phosphatase active isoform 5b (TRAP5b), osteocalcin (OC), and bone specific alkaline phosphatase (bALP). In infants, assessment included bone markers, radiology, ex vivo bone densitometry (pQCT) and biomechanical testing.

Control mothers had generally high values of bone markers during early pregnancy and lactation. At GD20, most had OC levels above the upper limit of quantification then decreased at other time points during gestation, and increased during lactation. bALP and CTx increased at the end of the gestation and during lactation. TRAP-5b increased during pregnancy but decreased during lactation. In control infants, OC, bALP and TRAP-5b were increased up to 2, 4 or 10 fold, respectively, compared to historical data for 3-4 year-old animals. Radiographs were evaluated for skeletal abnormalities and bone length: age-related changes in epiphyseal mineralization, growth plate morphology, and increases in bone length were noted over time. Femur and lumbar vertebra geometry (pQCT) changed with increasing age with lower increases in density. Femur 3-point bending and vertebral compression showed increases in strength parameters with age (2-fold between BD1 and BD 180).

Skeletal changes were consistent with gestation and lactation in mothers, and with development and growth in infants. These data support the use of bone markers, densitometry, radiology, and biomechanical testing in toxicology studies, including ePPND studies, to provide a comprehensive evaluation of the maternal and developing skeleton in nonclinical drug development.

**PS 1221 Characterization of Batracylin-Induced Renal and Bladder Toxicity in Rats.**

L. Rausch<sup>1</sup>, D. Bunin<sup>1</sup>, K. Altera<sup>1</sup>, S. Samuelsson<sup>1</sup>, R. Kinders<sup>2</sup>, M. Davis<sup>3</sup> and T. Parman<sup>1</sup>. <sup>1</sup>SRI International, Menlo Park, CA; <sup>2</sup>SAIC-Frederick, Frederick, MD; <sup>3</sup>National Cancer Institute, Bethesda, MD.

Batracylin (NSC-320846; BAT) is an investigational anticancer agent that reached Phase I clinical trials. BAT is a dual inhibitor of DNA topoisomerases I and II and induces histone gamma-H2AX, a biomarker of DNA damage in vitro. Hemorrhagic cystitis was one of the dose limiting toxicities observed during clinical trials, and bladder and kidney were postulated to be responsible for the hematuria observed in the clinic. We investigated the mechanism of bladder and renal toxicity in Fisher 344 rats, a physiologically relevant model. The studies were designed to 1) examine the effect of BAT administration on rat bladder histology, 2) further characterize the previously reported renal toxicity of BAT, and 3) measure DNA damage in the kidney and bone marrow after BAT administration in rats using gamma-H2AX immunofluorescence. Once daily oral administration of 16 or 32 mg/kg BAT to Fisher 344 rats for 4 days caused overt toxicity. Abnormal clinical observations, adverse effects in clinical pathology, urinalysis, kidney and bladder were seen. Gamma-H2AX immunofluorescence indicated DNA damage in kidney and bone marrow. Furthermore, after administration of BAT, defects in the superficial and intermediate urothelial layers were observed using scanning electron microscopy. The maximum tolerated dose is estimated to be <16 mg/kg/day. Mesnex<sup>TM</sup> is known to reduce the incidence of hemorrhagic cystitis induced by ifosfamide or cyclophosphamide, but BAT toxicity in rats was not alleviated by twice daily intraperitoneal administrations of 80 mg/kg mesna. Thus, the mechanism of BAT-induced bladder and renal toxicity was not mediated by urotoxic mechanisms similar to those of ifosfamide or cyclophosphamide. These studies show that BAT causes renal and urothelial damage in rats that may be related to DNA damage, a previously identified mechanism of action for BAT. Work supported by NCI Contract N01-CM-42203 and N0-CM-2011-00028.

**PS 1222 NKTR-181, a Novel Opioid Agonist, Demonstrates Mu-Opioid Agonist Effects and Minimal CNS Side Effects in Both Rat and Dog.**

E. Tonkin, A. Odinecs and T. D. Sweeney. *Nektar Therapeutics, San Francisco, CA.*

NKTR-181 is a novel orally available mu-opioid agonist designed using Nektar's advanced polymer conjugate technology to achieve slower kinetics of entry into the brain relative to other opioids, while still producing analgesic efficacy. Previous studies of NKTR-181 in rodent models have demonstrated a clear separation of analgesia from unwanted CNS side effects compared with oxycodone. To assess the safety of this novel opioid, NKTR-181 was evaluated after daily oral dosing for 2 and 13 weeks in rats and dogs at doses up to 600 and 75 mg/kg/day, respectively. Clinical observations, body weights, clinical chemistry, and histopathology were performed and NKTR-181 plasma concentrations were analyzed by LC-MS/MS. Findings in both species were consistent with the pharmacology of a mu-opioid agonist; no off-target toxicity was observed. In rats, the major clinical sign was foot sores due to increased paw chewing at 200 to 600 mg/kg/day, a known opioid effect in rodents. Mild to moderate gait and activity changes were noted at 600 mg/kg/day in a neurobehavioral assessment in the 2-week study. The incidence of clinical findings diminished with repeated dosing. Decreased mean body weights relative to controls was observed in males at ≥200 mg/kg/day and in females at 600 mg/kg/day. In dogs, major clinical signs were post-dose emesis at doses ≥15 mg/kg/day and mild, transient hypoactivity at 75 mg/kg/day. Accommodation to both emesis and hypoactivity was observed. Decreased mean body weights relative to controls were observed at 75 mg/kg/day in the 13-week study. No adverse clinical pathology or histopathological changes were noted in the rat or the dog. The NOAEL was determined to be 200 mg/kg in rats and 75 mg/kg in dogs (human equivalent doses of 32 and 42 mg/kg, respectively). Plasma levels (AUC) at the NOAEL after 13 weeks of dosing were 170,034 hr\*ng/mL in rats and 33,026 hr\*ng/mL in dogs. These studies demonstrate that NKTR-181 is well tolerated and produces minimal CNS side effects in both rat and dog.

**PS 1223 Safety Assessment of NU100 in a 6-Month Cynomolgus Monkey Study.**

H. Hu<sup>1</sup>, V. Tammara<sup>2</sup>, D. Hobson<sup>3</sup>, E. Shaw<sup>2</sup>, D. Zeng<sup>2</sup> and A. M. Brooks<sup>1</sup>. <sup>1</sup>Covance Laboratories Inc., Madison, WI; <sup>2</sup>Nuron Biotech Inc., Exton, PA; <sup>3</sup>LoneStar PharTox LLC, Boene, TX.

NU100 is recombinant human interferon beta-1b (IFN beta-1b) being developed for treating multiple sclerosis. NU100 has a better purity profile (aggregate-free and HAS free) compared to other marketed products. A GLP monkey study for NU100

safety assessment was conducted which was originally planned as a 6-month subcutaneous injection study with a 28-day recovery. Male and female cynomolgus monkeys were assigned to 5 groups (4 or 6 animals/sex/group), and were dosed once daily or every other day with NU100, Betaferon and placebo at dose levels of 0, 0.01, 0.06, or 0.28 mg/kg/dose. Animals were monitored clinically, and blood samples were collected for evaluation of serum levels of IFN beta-1b, neopterin (a biomarker for IFN beta-1b pharmacodynamics), and anti-drug antibodies (ADA). No NU-100-related adverse clinical findings were noted during the study. IFN-beta-1b serum concentration peaked in circulation within 2 to 4 hours after administration of NU100 on Days 1 and 15 with a higher level on Day 15; however, by Weeks 18 and 22, IFN beta-1b level returned to the baseline levels. Similarly, neopterin concentrations increased on Day 1 following administration of NU100 in a dose-dependent manner. Mean predose neopterin concentrations remained slightly elevated on Day 15 compared with Day 1 baseline levels. Nevertheless, no further induction of neopterin was noted on Day 15. By Weeks 18 and 22, neopterin concentrations returned to predose levels. At week 2, 12.5% animals treated with NU100 and 37.5% treated with Betaferon were confirmed positive for ADA. All NU100 treated primates were confirmed positive for ADA at weeks 2, 4, 8, 12, and 18 during the study. Due to the loss of IFN-beta-1b activity resulting from the generation of anti-IFN beta-1b antibodies, the dosing phase of the monkey study was terminated one month earlier than planned, following discussion with and approval from the FDA. In conclusion, NU100 was well tolerated by monkeys in this chronic toxicology study.

**PS 1224 BPM31510 Is a Novel Regulator of Mitochondrial Function That Mitigates/Rescues Drug-Induced Toxicity—Evidence in Drug-Induced Cardiotoxicity and Cancer Chemotherapy Using *In Vitro* and *In Vivo* Models.**

R. Sarangarajan<sup>1,2,3</sup>, T. Walshe<sup>2</sup>, A. Lee<sup>2</sup>, R. Ouro-djubo<sup>2</sup>, L. M. Mauro<sup>4</sup>, V. Vishnudas<sup>1,2</sup>, J. J. Jimenez<sup>4</sup> and N. R. Narain<sup>1,2,3</sup>. <sup>1</sup>Berg Pharma LLC, Natick, MA; <sup>2</sup>Berg Biosystems, Natick, MA; <sup>3</sup>Berg Diagnostics, Natick, MA; <sup>4</sup>University of Miami, Miller School of Medicine, Miami, FL.

In a large cohort of drugs routinely used in clinical practice, disruption of mitochondrial function represents a common thread associated with incidence of organ specific toxicities. An example is the incidence of cardiotoxicity associated with anti-diabetic drugs, cancer chemotherapeutics and anti-retroviral agents. Ubidecarenone is a mitochondrial resident molecule with multiple functionalities including electron transport and generation of ATP. The delivery of ubidecarenone to the mitochondria is a challenge due to its physiochemical properties. BPM31510 is a nanodispersion formulation containing ubidecarenone incorporated into a novel lipid mixture with improved ability to deliver ubidecarenone with ability to influence mitochondrial function. The effect of BPM31510 on the toxicity profiles of several cancer chemotherapeutic agents was tested in cell cultures and animal models of cancer and on the cardiotoxicity potential of an anti-diabetic drug in primary cultures of normal human cardiomyocytes. BPM31510 significantly enhanced the efficacy of multiple chemotherapeutic agents used for treatment of cancers of the pancreas, prostate, breast and colon in in-vitro and in-vivo models. In addition, BPM31510 mitigated chemotherapy induced toxicity in primary cultures of normal human liver, fibroblast and prostate cells. Furthermore, BPM31510 reversed mitochondrial dysfunction resulting from exposure to an anti-diabetic drug. BPM31510 represents a novel technology effectuating a multimodal physiological response in which it does not interfere with the normal therapeutic mechanism of action of chemotherapy drugs, yet confers protection to normal tissues. BPM31510 is currently in clinical trial as a mono-therapy for solid-tumors with no reported adverse effects.

**PS 1225 Etirinotecan Pegol Nonclinical Toxicology Studies Establish a Margin of Safety to Support an Every Three-Week Clinical Dosing Schedule.**

T. D. Sweeney, E. Tonkin, U. Hoch and C. Ji. *Nektar Therapeutics, San Francisco, CA.*

Background: Etirinotecan pegol, formerly NKTR-102, is a unique targeted topoisomerase I inhibitor designed for prolonged tumor cell exposure. Etirinotecan pegol has demonstrated a favorable tolerability profile in nonclinical and clinical studies with improved safety over irinotecan. Toxicology studies were conducted in dogs to further evaluate etirinotecan pegol safety and establish dose-related toxicities. Methods: Etirinotecan pegol was administered as an IV infusion to dogs for 3 months using a q14d schedule at doses up to 30 mg/kg (600 mg/m<sup>2</sup>) irinotecan equivalents. Direct comparison to irinotecan was evaluated in dogs using a q7dx4 schedule (Persson et al, 2008). Clinical observations, clinical chemistry, and histopathology were performed and toxicokinetic samples were collected and assayed by LC-MS/MS for etirinotecan pegol, irinotecan, SN38, SN38-Glucuronide,

and APC. Results: Etririnecan pegol-treated dogs (25 mg/kg, 500 mg/m<sup>2</sup>) had reduced neutropenia and diarrhea and no mortality compared to irinotecan-treated animals at the same dose when given q7dx4. When given q14d for 3 months, etirinecan pegol-treated dogs (30 mg/kg, 600 mg/m<sup>2</sup>) had no neutropenia and minimal diarrhea at SN38 exposure levels up to 5-fold above those in patients given 145 mg/m<sup>2</sup> etirinecan pegol on a q21d schedule. Body weight gain suppression and decreased food intake were the primary side effects observed at this etirinecan pegol dose and schedule. No test-article related alopecia was noted in animals treated with etirinecan pegol in any of the toxicology studies in contrast to literature reports of alopecia in both humans and in animals treated with irinotecan. Conclusions: Nonclinical toxicology studies show that etirinecan pegol produces markedly less neutropenia and diarrhea with no mortality when directly compared to irinotecan. Etririnecan pegol is well-tolerated for 3 months at doses that provide a good safety margin (based on SN38 exposure) to support a clinical regimen of 145 mg/m<sup>2</sup> given every 3 weeks.

**PS 1226 Transient Thrombocytopenia without Coagulopathy in Rats following Single IV Bolus of Oxycyte®, a Perfluorocarbon (Pfc) Based Oxygen Carrier.**

S. Anderson<sup>1</sup>, L. Bernard<sup>2</sup>, J. Szabo<sup>2</sup> and T. Bradshaw<sup>1</sup>. <sup>1</sup>*Oxygen Biotherapeutics, Morrisville, NC;* <sup>2</sup>*Ricerca Biosciences, Concord, OH.*

Oxycyte®, a 60% w/v perfluoro(t-butylcyclohexane)[FtBu] intravenous emulsion, is being developed for treatment of traumatic brain injury (TBI). Transient thrombocytopenia (TTP), a known class effect of PFCs, may pose a risk for TBI patients. A rat model of intracranial hemorrhage (ICH) is under development to ascertain whether TTP subsequent to Oxycyte administration exacerbates ICH and whether platelet transfusion will ameliorate TTP associated ICH. As part of model development, studies were conducted to determine hematology, coagulation, cytokine, and PK profiles following Oxycyte administration. Male rats received a single IV bolus of Oxycyte at 3, 6, or 12 mL/kg. Blood was collected via jugular cannula (n=3/group) at 10 post administration time points and analyzed for FtBu concentration. Additional rats (n=5/group/time point) were sacrificed on Study Days (SD) 2, 3, 4, 5, 7, 10, 14, and 30 for hematology and blood cytokine analyses. Blood T1/2 following 3, 6, or 12 mL/kg was 4.2, 3.9, and 6.3 hours respectively. AUC was 12- and 48-fold higher for rats receiving 6 and 12 mL/kg compared to 3 mL/kg. There was a 30-40% decrease in PLT counts on SD3-5 in rats receiving 3 or 6 but not 12 mL/kg suggesting Oxycyte-induced PLT sequestration (TTP) rather than PLT destruction. Mean platelet volumes were increased in all Oxycyte groups through SD7 with a decrease in reticulocyte (RTC) counts and elevated fibrinogen levels through SD5. Except for elevated fibrinogen concentrations, there were no significant changes in coagulation parameters. No elevations in IL-6, TNF- $\alpha$ , and IL-1 $\beta$  levels were detected. Liver and spleen weights were elevated at all time points. RTC changes were considered a pharmacologic response to Oxycyte with no concurrent changes in erythrocyte counts. Increased liver and spleen weights were expected effects due to removal of Oxycyte by the reticuloendothelial system, the known mechanism for clearing PFC particles.

**PS 1227 Immunomodulatory Activity of Orphan Drug Elmiron® in Female B6C3F1/N Mice.**

S. Thakur<sup>1</sup>, N. Abraham<sup>2</sup>, K. L. White<sup>3</sup>, M. J. Smith<sup>3</sup>, W. Auttachoat<sup>3</sup> and D. R. Germolec<sup>1</sup>. <sup>1</sup>*Division of National Toxicology Program, NIEHS, NIH, Research Triangle Park, NC;* <sup>2</sup>*Integrated Laboratory Systems, Research Triangle Park, NC;* <sup>3</sup>*Virginia Commonwealth University, Richmond, VA.*

Interstitial cystitis/painful bladder syndrome (IC/PBS) is a chronic disorder characterized by bladder discomfort and urinary urgency in absence of identifiable infection. Elmiron® (EMR; sodium pentosan polysulfate) is the only approved oral therapy for treatment of IC/PBS. Based on the lack of chronic toxicity data and potential for long term use in the treatment of IC/PBS, NTP conducted 90-day and 2-year toxicity studies for EMR. The results suggested that EMR could potentially modulate the immune system. Therefore, this study was conducted to evaluate the immunomodulatory effects of EMR when administered for 28-days via oral gavage to female B6C3F1/N mice, at doses of 63, 125, 250, 500 or 1000 mg/kg. Mice treated with EMR had a significant increase in absolute liver weights (500 and 1000 mg/kg). The absolute numbers of splenic macrophages (63, 500 and 1000 mg/kg) and natural killer (NK) cells (250 and 1000 mg/kg) were significantly increased. EMR treatment did not affect the humoral immune response (antigen specific antibody response to sheep red blood cells [SRBC]) or cell-mediated immunity (mixed leukocyte response). However, innate immune responses such as phagocytosis of radiolabelled SRBC by liver macrophages (1000 mg/kg) and NK

cell activity were enhanced (500 and 1000 mg/kg). Further analysis using a disease resistance model showed that EMR-treated mice demonstrated significantly increased anti-tumor activity against B16F10 melanoma cells at the 500 and 1000 mg/kg doses, where the numbers of tumor nodules were decreased by 55% and 68%, respectively. Collectively, we conclude that EMR administration stimulates the immune system, increasing numbers of specific cell populations and enhancing phagocytosis and NK cell activity in female B6C3F1/N mice.

**PS 1228 Assessment of Long-Term Preclinical Safety of Inhaled Technosphere® Particles and Afrezza® Inhalation Powder.**

S. Greene<sup>1</sup>, K. Nikula<sup>2</sup>, D. Poulin<sup>3</sup>, K. McNally<sup>4</sup> and J. Reynolds<sup>5</sup>. <sup>1</sup>*MannKind Corp, Valencia, CA;* <sup>2</sup>*Seventh Wave Laboratories, Chesterfield, MO;* <sup>3</sup>*Charles River Laboratories, Montréal, QC, Canada;* <sup>4</sup>*ITR Laboratories, Montréal, QC, Canada;* <sup>5</sup>*JA Reynolds & Associates, Madison, CT.*

The inhalable insulin, AFREZZA® inhalation powder and novel excipient, FDKP (fumaryl diketopiperazine which self assembles into Technosphere® Particles), were evaluated in nonclinical safety studies for the treatment of diabetes. Daily doses of either Technosphere particles or AFREZZA inhalation powder were administered by nose-only route in chronic repeat dose and carcinogenicity studies in rats or oronasal route in dogs. With the exception of transient exaggerated pharmacological effects of insulin, inhalation administration for up to 104 weeks in rats and 39 weeks in dogs was well-tolerated. There were no adverse effects on body weight, food consumption, ophthalmoscopy, clinical pathology parameters or electrocardiography (dogs). There were no indications of carcinogenic potential or proliferation related to AFREZZA inhalation powder in pulmonary tissues by immunostaining using proliferating cell nuclear antigen assay. Non-proliferative lesions were limited to minimal goblet cell hyperplasia and eosinophilic accumulation in the olfactory/respiratory epithelium in rats; and minimal neutrophil infiltration in lung in dogs. Maximum systemic concentrations of insulin and FDKP were rapidly attained. Terminal half life was approximately 20 and 60 min for insulin and FDKP, respectively. In dogs, systemic exposure of FDKP and insulin was generally dose proportional with no sex differences or accumulation. In rats, insulin exposures were generally higher in females compared to males. Exposure to insulin was inversely related to dose-dependent decreases in serum glucose levels. Based on the data from these chronic inhalation studies, the no adverse effect level was established as the highest studied doses for AFREZZA inhalation powder and Technosphere particles in both species.

**PS 1229 NF- $\kappa$ B Activation in the Hippocampus during Multiple Subthreshold Exposures to Seizurogenic Compounds.**

J. A. Miller<sup>1</sup>, K. S. Kirkley<sup>1</sup>, Y. H. Rao<sup>2</sup>, M. Patel<sup>3</sup>, R. A. Bialecki<sup>4</sup> and R. B. Tjalkens<sup>1</sup>. <sup>1</sup>*Center for Environmental Medicine, Colorado State University, Fort Collins, CO;* <sup>2</sup>*Department of Pediatric Neurology, University of Colorado, Denver, CO;* <sup>3</sup>*Department of Pharmaceutical Sciences, University of Colorado, Denver, CO;* <sup>4</sup>*Safety Assessment, AstraZeneca, Boston, MA.*

Drug-induced seizures have been documented for broad classes of pharmaceuticals including CNS and Non-CNS targeted drugs. A better understanding of the early molecular signaling events involved in promoting seizures is necessary to identify potential proconvulsive liability of new pharmacologic agents earlier in the development process. The NF- $\kappa$ B pathway is involved in regulating a number of stress genes and its activation may conceivably be an early indicator of potential seizure liability. Presently, we employed a NF- $\kappa$ B-dependent GFP reporter mouse to investigate the role of NF- $\kappa$ B signaling in rendering hippocampal neurons hyperexcitable. Utilizing EEG recordings and video documentation we established a sub-threshold dose level of the seizurogenic compound kainic acid (KA). Transgenic reporter mice were exposed to multiple sub-threshold doses of KA and regional and cell specific NF- $\kappa$ B activity was assessed after each dose. Under control levels reporter expression was absent in the hippocampus except for a slight basal expression in the CA3 pyramidal layer. Upon multiple exposures to KA, a pronounced expression of the GFP reporter was observed in the stratum moleculare, dentate gyrus molecular layer and in the dentate hilus. Additionally we exposed reporter mice to multiple low levels of a different seizurogenic compound, pentylenetetrazole (PTZ). After multiple doses of PTZ, a global increase in GFP expression was observed. Comparison of the two compounds suggests a regionally selective expression consistent with the distinct mechanisms of action for each compound. Utilizing cultured slices from the reporter mice we observed similar selective GFP expression in response to the two compounds demonstrating the potential utility of this method for the assessment of proconvulsive properties of new pharmacologic compounds.

**PS 1230 Starting Dose Selection for First-in-Human Trials Using Model-Based Approaches.**

V. Kadambi, S. Palani, A. Lynn, J. Senn, S. Ottinger, J. Mettetal, S. Chong, E. Fedyk, W. Shyu and A. Chakravarty. *Millennium: The Takeda Oncology Company, Cambridge, MA.*

Selection of the safe starting dose (SSD) in oncology represents a critical decision point in the drug development process, as under- or over-prediction of the SSD can have serious consequences in Phase I, exposing patients to doses that are either sub-therapeutic or unsafe.

The SSD is commonly estimated by determining if 1/10th the severely toxic dose in rodents (STD10) is tolerated by non-rodents, and if so, using 1/10th of the rodent STD10 dose as the SSD. In general, the STD10 is estimated from GLP toxicology studies where relatively large numbers of animals are divided into a few dose groups to increase statistical power within a group.

Here, we propose an alternative method to estimate the STD10 based on logistic regression curve-fitting, (a standard technique for modeling binary outcomes in the clinical setting) with mortality as a binary endpoint. To this end, we simulated mortality data based on 400 different sigmoidal dose-mortality curves with a probabilistic model, and predicted STD10 by logistic regression, comparing this approach to the traditional dose-picking methodology for the same datasets. Model-predicted STD10 values outperformed the traditional method, with better accuracy (absence of downward bias) and precision relative to the true STD10. Additionally, this approach was resistant to the effect of outliers (unexplained mortality). More importantly, the superior accuracy and precision of the STD10 values determined by logistic regression could be achieved with fewer animals used in the conventional approach. A retrospective analysis of an anticancer compound currently in Phase I clinical trials demonstrated potential to narrow the gap between the human Maximum Tolerated Dose and SSD from 110-fold to 10-fold.

By using the information from all animals in a study, logistic regression curve-fitting provides the potential for a more robust and less biased SSD, while at the same time decreasing the number of animals utilized.

**PS 1231 Application of Electrorretinography (ERG) in Early Drug Development for Assessing Ocular Toxicity in Rats.**

W. W. Collette, M. Twamley, Q. Peng, S. Aguirre, W. Huang, A. Saccaan and A. John-Baptiste. *Worldwide Safety Sciences, Pfizer Inc., La Jolla, CA.*

Retinal ocular toxicity is among the leading causes of drug development attrition in the pharmaceutical industry. Electrorretinography (ERG) is a non-invasive functional assay used to assess neuro-retinal physiological integrity by measuring the electrical responses of various retinal cell types. When applied in the pre-clinical setting, ERG may be utilized to evaluate potential ocular toxicity of drug candidates. Studies were designed to assess the sensitivity and specificity of ERG to detect ocular toxicity in Wistar Han rats using several drugs with varied activity in the retina ranging from no evidence to those with demonstrated microscopic retinal degeneration. To directly assess the utility of ERG, these studies were conducted following a single intravitreal injection (IVT). Doses were selected based on an in-vitro retinal pigment epithelium (RPE) cytotoxicity assay and compound solubility limit. Serial collections of ERG assessments were conducted over a two week period. In addition, EDTA blood samples were obtained for miRNA retinal toxicity biomarker analysis, in-direct ophthalmic examinations were performed, and eyes were collected at the end of the study for histopathology evaluation. Here we report IVT administration of AG-012986 resulted in decreases in b-wave amplitude correlating with increases in plasma levels of retinal toxicity biomarkers (miR-124a and miR-183) as well as marked retinal degeneration as revealed by microscopic evaluation. By contrast, administration of vehicle or acetaminophen did not result in any changes in b-wave amplitude. This work suggests that ERG assessment of retinal toxicity following a single IVT treatment may be a sensitive and reliable screening tool in rodents to identify compounds that have a potential risk for ocular toxicity.

**PS 1232 Absolute Quantitation of Low-Abundance Protein Adducts Using a Novel Accelerator Mass Spectrometry Liquid Sample Interface.**

B. Stewart<sup>1</sup>, A. T. Thomas<sup>2</sup>, T. Ognibene<sup>2</sup>, K. W. Turteltaub<sup>1</sup> and G. Bench<sup>2</sup>. <sup>1</sup>Biosciences and Biotechnology Division, Lawrence Livermore National Laboratory, Livermore, CA; <sup>2</sup>Center for Accelerator Mass Spectrometry, Lawrence Livermore National Laboratory, Livermore, CA.

Drug characterization studies including the detection and quantitation of protein adducts arising from reactive drug metabolites provide important information about a drug candidate's potential to cause adverse reactions. Current methods for

characterizing protein adducts are limited by low sensitivity and difficulty identifying modified proteins. We report the use of a novel accelerator mass spectrometry (AMS) liquid sample interface for absolute quantitation of protein modification by <sup>14</sup>C-iodoacetamide and identification of peptide modification patterns. Competitive binding experiments showed that covalent adducts of cysteine residues in bovine serum albumin can be quantified at the attomole level in microgram-size samples of intact protein. Tryptic digestion and HPLC separation of albumin peptides followed by peptide analysis using the liquid sample interface and electrospray ionization and tandem mass spectrometry (ESI-MS/MS) showed reproducible patterns of adduct formation, with modifications localized to specific regions of the protein corresponding to regions predicted by known chemical reactivity. Measurements of whole protein adducts using the liquid sample interface were comparable to values measured by standard graphitization with AMS analysis. This technology presents an important novel method for absolute quantitation of <sup>14</sup>C-labeled proteins and peptides. Potential applications include microdosing studies using <sup>14</sup>C-labeled protein therapeutics and investigation of post-translational and chemical modifications of proteins.

**PS 1233 Evaluation of Respiratory Function in the Conscious, Nonrestrained Cynomolgus Monkey Using Respiratory Inductive Plethysmography.**

J. Le Bigot, J. Maucotel, F. El Amrani, S. Loriot, A. El Amrani, J. Legrand and R. Forster. *CiToxLAB France, Evreux, France.*

Evaluation of the potential alteration of respiratory function is mostly performed in rodents using whole body plethysmography, while cardiovascular telemetry studies are usually conducted in large animals. The purpose of the present study was to evaluate the use of respiratory inductive plethysmography (RIP) as a method that might be suitable for routine evaluation of respiratory function in primates.

Four monkeys were equipped with jacketed external telemetry devices including abdominal and thoracic belt sets (JET, DSI). Thoracic and abdominal signals were recorded and analysed using Ponemah software. After an acclimation period, animals received theophylline (100 mg/kg, p.o), clonidine (100 µg/kg, i.m) and corresponding vehicle (0.5% methylcellulose, p.o or NaCl 0.9%, i.m). Respiratory rate (RR), tidal volume (TV) and minute volume (MV) were recorded continuously over 24 hours.

Theophylline induced increases in TV, MV and RR when compared to vehicle (Emax: +55%, +118% (p < 0.01) and + 41% (p < 0.01), respectively). Clonidine produced significant decreases in TV and MV and RR (Emax: -12%, -29 % (p < 0.01) and -27% (p<0.05)).

The results demonstrate the validity of the RIP method for the assessment of respiratory function in the monkey for a long period (24 hours). These findings support the use of the RIP method for combined assessment of potential effects of drug candidates on cardiovascular and respiratory functions. The methodology could allow the integration of respiratory investigations into regulatory toxicology studies in primates. Such an approach is particularly applicable for the safety evaluation of biotechnology-derived products, for which rodents are often not applicable models.

**PS 1234 Impact of Food and Fecal Contamination on Dog Urinalysis Data.**

M. Felix, V. Allegret, N. Oleas, S. Y. Smith and F. Poitout. *Charles River, Montréal, QC, Canada.* Sponsor: *M. Vézina.*

Suspected aberrant urinalysis results were observed in dogs urinating limited urine volumes, or presenting clinical diarrhea, prompting an investigation to determine potential causes of contamination. Diet consumed and feces were identified as potential sources. Dietary effects on blood urine contents were determined using two laboratory diets: Certified Canine Chow No. 5007 and Harlan Teklan Certified 25% Lab Dog Diet (2025). Urine was collected from animals deprived of food and water, previously fed either diet during a 5 hour period as well as following an overnight collection period. Each diet was mixed with saline to mimic contamination. Five hour small urine samples collected from animals fed diet 5007, and 5007 diet-saline suspensions, both tested positive for moderate (3+) to large (4+) amounts of blood measured semi-quantitatively with urine dipsticks (Multistix 10SG, Siemens). 2025 diet-saline suspensions tested positive for traces of blood. Larger volumes and more dilute urine collected following overnight collection tested negative for blood indicating levels were below the detection threshold. The effect of fecal contamination, in dogs presenting diarrhea, on several markers of kidney function was also evaluated. Varying amounts of feces, from 1 to 5 grams were added to approximately 8 mL urine to mimic contamination. Contaminated and uncontaminated samples were analyzed for N-Acetyl-B-D-glucosaminidase (NAG), Gamma-glutamyl-transferase (GGT) and protein, with values corrected for urinary creatinine concentration. Increases in kidney markers were proportional

to the amount of fecal contamination, with the highest amount of fecal contamination tested showed NAG/creatinine ratio was increased by 38 fold, GGT/creatinine ratio by 24 fold and protein/creatinine ratio by 8 fold. In conclusion, the type of diet and feces were demonstrated as sources that may impact data obtained from contaminated and/or small urine samples. Optimally, urine should be collected from dogs deprived of food but with access to water (plus a water catcher), or by cystocentesis or bladder catheterization to minimize contamination.

**PS 1235 High-Resolution Isotope Dilution (HRID) Quantitative Analysis: Metabolites in Safety Testing (MIST) Application to Diclofenac.**

J. Vrbanc<sup>1</sup>, A. Hilgers<sup>1</sup>, B. Shilliday<sup>1</sup>, T. Dubnicka<sup>1</sup>, D. Humphries<sup>2</sup> and R. Hayes<sup>2</sup>. <sup>1</sup>ADME, MPI Research, Mattawan, MI; <sup>2</sup>Analytical Sciences, MPI Research, Mattawan, MI.

During early clinical development it is important to understand the identity and amount of circulating metabolites in man. Are there human specific metabolites? Guidelines have been issued by regulatory agencies to address this question (CDER, 2008). We are interested in applying the metabolism of isotope labeled drugs [<sup>14</sup>C alone or both <sup>14</sup>C and <sup>13</sup>C] and HRID to accurately determine MIST liability in the clinic in a manner that is both rapid and not excessively expensive (e.g., involve AMS, de novo synthesis and bioanalytical method development for relevant drug metabolites). Simplicity and ruggedness are also important aspects of these efforts. This work investigated diclofenac (D). Diclofenac, [<sup>14</sup>C]D (62.7 mCi/mmol) and [<sup>13</sup>C<sub>6</sub>]D were purchased. Human hepatocytes were purchased from Life Technologies, Grand Island, NY. Incubations were conducted following Life Technologies procedures. Chromatographic separation was achieved using an Agilent 1200 HPLC system and detection of radioactivity was by an IN/US β-Ram Model 3. MS analysis was by Thermo LTQ Orbitrap Discovery MS (+ ESI). No special tuning was done for D metabolite analysis. Since the specific activity of the label was known and fixed, the amount of drug metabolite/parent drug in the incubates at 60 minutes were determined using LC-RAM. Assuming that the amounts of drug metabolites produced from [<sup>13</sup>C<sub>6</sub>]D was similar to the amount produced for the [<sup>14</sup>C<sub>6</sub>]D allowed for the construction of standard curves for all drug-related material within the limits of detection. This allowed for the quantitative analysis of drug-related material including, 4-hydroxy-D and D-glucuronide. The method resulted in acceptable linearity, sensitivity and reproducibility for all analytes. A second key concept is that using HRMS compared to MS-MS using tandem quadrupole affords considerable advantages in simplicity and ruggedness, a key objective.

**PS 1236 12-Week Intrathecal Administration Study in Port Catheterized Juvenile Cynomolgus Monkeys.**

S. H. Korte<sup>1</sup>, C. B. Rose<sup>1</sup>, M. Niehoff<sup>1</sup> and M. Butt<sup>2</sup>. <sup>1</sup>Covance Laboratories GmbH, Muenster, Germany; <sup>2</sup>Tox Path Specialists, Frederick, MD. Sponsor: G. Weinbauer.

The cynomolgus monkey is the predominant NHP species when it comes to pre-clinical safety evaluation of new medical products. Assessment of juv. toxicity within this species represents an emerging field, requiring established techniques for 12 month or younger monkeys. The objective of the study was to determine the feasibility of bi-weekly bolus delivery in an intrathecally implanted port catheter system to the juv. monkey for 12 wks and to assess the feasibility of CSF collection. Vehicle or PBS was administered to 6 implanted (between L2-L5) monkeys (8-13.5 months; ~800 g). Clinical signs, bw, neurological examinations, CSF, and clinical pathology data were obtained. Perfusion necropsy, spinal cord brain trimming and pathology were conducted. There were no indications for procedural-related clinical signs, bw development, clinical pathology or neurological findings. Increased AST was observed on day 2, most likely related to manual restraint of the animals on day 1. Necropsy confirmed the placement of the catheter tips at T11/T12 in 4/6 animals. There were no adverse effects noted at the site of the catheter in the intrathecal space and in particular, no evidence of pronounced reactions at the catheter tips. At the catheter tip, tissue reactions were consistent with those reported to occur with the placement of intrathecal catheters in multiple species (M Butt, 2011). Changes at the catheter tip included slight to minimal fibrosis, adhesion to the overlying dura, and slight compression of the spinal cord (no cord damage). Overall lumbar CSF sampling through the port was only possible in 1/6 animals. However, spinal lumbar CSF sampling under sedation using a Pencan Paed® needle proved to be successful on all occasions. Obtained CSF indicated a low level of white blood cells after surgery, and minimum of red blood cells contamination. In conclusion, lumbar intrathecal administration of juvenile cynomolgus monkeys for up to 12 wks using a surgically implanted port catheter system is considered feasible.

**PS 1237 BMS-964210, a Pegylated Bispecific Adnectintargeting EGFR and IGF-1R, Demonstrates Improved Class-Specific Toxicity Profile in Cynomolgus Monkeys.**

M. Guha<sup>1</sup>, R. W. Lange<sup>1</sup>, J. Gokemeijer<sup>2</sup>, R. White<sup>1</sup>, B. Silver<sup>2</sup>, N. Marsh<sup>2</sup>, K. Manson<sup>2</sup>, T. P. Sanderson<sup>1</sup> and R. T. Bunch<sup>1</sup>. <sup>1</sup>Drug Safety Evaluation, Bristol-Myers Squibb, Mount Vernon, IN; <sup>2</sup>Early Candidate Assessment, Adnexus, Waltham, MA.

Simultaneous modulation of epidermal growth factor receptor [EGFR] and insulin like growth factor receptor 1 [IGF-1R] signaling, as an oncology therapeutic strategy, is based on cross talk between the two signaling pathways to overcome resistance developed if only a single pathway is targeted. However, evidence of class-related adverse effects of individual anti-EGFR and anti-IGF-1R agents in humans including diarrhea, acne form skin rash and interstitial pneumonitis (EGFR-specific) and hyperglycemia, thrombocytopenia and cardiovascular toxicities (IGF-1R-specific) has emerged in clinical and non-clinical toxicity studies. In contrast to marketed anti EGFR monoclonal antibodies which bind to domain III of the extracellular portion of EGFR, BMS 964210 binds with high affinity to domain I and overlaps the EGF and TGFα binding pocket of both human and cynomolgus monkey EGFR and IGF 1R. In a 4 week intravenous (2QW) toxicology study with BMS-964210 in cynomolgus monkeys (6, 12 and 25 mg/kg), pharmacodynamic elevation of plasma biomarkers of EGFR and IGF 1R blockade (TGFα, amphiregulin, and IGF 1) were observed. Despite the generation of anti BMS 964210 antibodies, systemic exposures following first dose were dose proportional and elimination was linear. No evidence of rash, pulmonary findings, hyperglycemia or thrombocytopenia was noted, and there were no drug related deaths or effects on neurologic, respiratory, or ophthalmologic endpoints. At the highest dose, two female monkeys suffered body weight loss and dehydration that required fluid administration for 3 days. Based on the highest non-severely toxic dose (HNSTD) of 12 mg/kg, there is sufficient safety margin to the proposed clinical starting dose of 0.5 mg/kg (QW). These preliminary data suggests that BMS-964210 may have an improved tolerability profile compared to marketed anti-EGFR mAb and deserves further evaluation in clinical studies.

**PS 1238 Subcutaneous Injection Sites: Is the Quality of the Diagnosis Improved When More Than One Tissue Section Is Examined?**

J. Briffaux, C. Thuilliez, C. Clément and M. Perron Lepage. *Ricerca Biosciences SAS, St. Germain sur l'Arbresle, France.*

At our Laboratory, the microscopic examination of subcutaneous injection sites involves the evaluation of three longitudinal sections per tissue sample. We conducted a retrospective study to evaluate the relevance of the diagnoses in subcutaneous injection sites if only one section is examined.

Two rat studies and three primate studies were reviewed. All animals received saline or test item injected subcutaneously in the dorsum. At necropsy, 3 pieces, each 3 mm wide, were trimmed from each site. Piece 1 was in the middle, piece 2 lateral to it and piece 3 medial to it. The original study pathologists formulated overall diagnoses for each site, taken from evaluation of each of the 3 pieces.

One pathologist reviewed the three sections from each site with reference to the findings recorded by the original study pathologists and attributed each of the original diagnoses to the section(s) where it was observed. In each species, animals receiving saline or test item were evaluated separately. Statistical analysis was performed, comparing section 1 with the other two sections and with the original overall diagnosis.

In the rat, section 1 had a statistically significantly higher number of findings when compared to other sections, in control and treated animals. In the primate, section 1 did not differ from the other sections in control and treated animals. In both species, however, section 1 had a statistically significantly lower number of findings when compared with the original overall diagnosis.

Contrary to the results we obtained in a previous study concerning intramuscular sites, this retrospective study reveals that examination of three sections of subcutaneous injection sites improves the quality of diagnosis. For microscopic changes induced by subcutaneous injections, particularly in primates, one middle piece is not considered to be sufficiently representative of the whole site.

**PS 1239 Internal Exposure of Common Environmental Pollutants in a Chinese Population.**

S. Chen<sup>1</sup>, Y. Lei<sup>1</sup>, S. Zhang<sup>1</sup>, A. Wang<sup>2</sup> and W. Shi<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology and Biochemical Pharmaceutics, Zhejiang University, Hangzhou, China; <sup>2</sup>Hangzhou EPIE Bio-detection Technology Limited, Hangzhou, China. Sponsor: D. Thomas.

Studies indicated that exposure to environmental pollutants could increase the potential risk of human's health. Many efforts have been made to detect the environmental pollutions, but, such data cannot be of concern to ordinary people for no one knows how many environmental pollutants and at what amounts were exposed to themselves. In order to provoke the attention of public and point out the individual who is at risk mostly, it is necessary to measure the internal exposure of environmental pollutants instead of external exposure of environmental pollutants. These data can directly reflect the exposure of those pollutants to ordinary people. In present study, we measured the total urinary concentrations of eleven common pollutants in a Chinese population by GC, GC-MS, HPLC and ELISA. We found the percentage of people with detectable levels of an individual chemical ranged from 13% to 100%. Cotinine (COT) was detected in 88% of the persons (n=2100), dibutyl phthalate (DBP) was detected in 97% of the persons (n=800), the detection rate of aflatoxin (AFT) and toluene (TOL) were 85% and 13%, respectively (n=600), organophosphorus (Org-p) was detected in 49% (n=400), tartrazine (TAR) was detected in 78% (n=351), the detection rate of diethylstilbestrol (DES), methanoic acid (MA), Styrene (STY), tetrachlorodibenzo-p-dioxin (TCDD) and nonyl phenol (NP) were 100%, 100%, 96%, 32% and 21%, respectively (n=100). The 95th percentiles of COT, DBP, AFT, TOL, Org-p, TAR, DES, MA, STY, TCDD and NP were 44 ng mL<sup>-1</sup>, 9 ng mL<sup>-1</sup>, 0.73 ng mL<sup>-1</sup>, 39 ng mL<sup>-1</sup>, 0.28 ng mL<sup>-1</sup>, 33.92 ng mL<sup>-1</sup>, 22, 000 ng mL<sup>-1</sup>, 23, 000 ng mL<sup>-1</sup>, 930 ng mL<sup>-1</sup>, 1,600 ng mL<sup>-1</sup> and 0.33 ng mL<sup>-1</sup>, respectively. The present data show that people in China are widespread exposure to multiple pollutants. Therefore, in order to describe the real risk of individual, a well designed study is needed to evaluate the associations between internal exposure of those pollutants and potential adverse health consequences.

**PS 1240 Occurrence of Gaseous Pesticides and Other Hazardous Volatiles in Sea Containers Arriving in Sweden.**

G. Johanson<sup>1</sup> and U. Svedberg<sup>2</sup>. <sup>1</sup>Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden; <sup>2</sup>Occupational and Environmental Medicine, Sundsvall Hospital, Sweden.

Individuals who enter containers for inspection, unloading or cleaning may be exposed to gaseous pesticides (fumigants) and other volatiles. Previous reports from Hamburg and Rotterdam, as well as a few incidents in Sweden, have raised concerns about the exposure situation in Swedish container terminals. Since systematic studies in Sweden are missing, we performed a pilot study to investigate the occurrence of hazardous volatile chemicals in import containers. Air was sampled from 101 randomly selected containers in the port of Gothenburg. Air samples were drawn without opening the containers, as they passed and briefly halted at the import inspection station, and analysed by FTIR spectrometry. One container (1%) contained detectable residues of fumigant (1 ppm carbonyl sulphide), although none was labeled as fumigant treated. As in the two previous studies, a number of other volatile chemicals were detected. The most common ones were methanol (78%) and carbon monoxide (45%), with all readings below the occupational short term excursion limits (STEL). These substances are likely degradation products from the plywood flooring as they were also detected in empty containers. Other frequently detected chemicals include hydrocarbons (unspecified, 47%) and ammonia (15%), with some readings above or well above the STELs or ceiling limits (CL). In our judgement, based on the present and two previous studies, the probability of life-threatening exposure is low. However, violations of STELs and CLs do occur, thus prolonged or repeat visits in unchecked containers may constitute a significant health hazard. In conclusion, extensive and systematic investigations of import and export containers are greatly needed as basis for risk management measures. Methods for rapid and efficient ventilation should be developed. Prior to entering it should be ensured, by adequate measurements and/or ventilation, that the container is safe.

**PS 1241 Interactions between Urinary 4-Tert-Octylphenol Levels and Metabolism Enzyme Gene Variants on Idiopathic Male Infertility.**

Y. Qin<sup>1</sup>, M. Chen<sup>1</sup>, W. Wu<sup>1</sup>, B. Xu<sup>1</sup>, G. Du<sup>1</sup>, C. Lu<sup>1</sup>, J. D. Meeker<sup>2</sup>, Z. Zhou<sup>1</sup>, Y. Xia<sup>1</sup> and X. Wang<sup>1</sup>. <sup>1</sup>Nanjing Medical University, Nanjing, China; <sup>2</sup>University of Michigan School of Public Health, Ann Arbor, MI.

Background: Octylphenol (OP) and Trichlorophenol (TCP) are the representative members of alkylphenols and chlorophenols, which act as endocrine disruptors and have effects on male reproductive function.

Objectives: We studied the interactions between 4-tert-Octylphenol (4-t-OP), 4-n-Octylphenol (4-n-OP), 2,3,4-Trichlorophenol (2,3,4-TCP), 2,4,5-Trichlorophenol (2,4,5-TCP) urinary exposure levels and polymorphisms in selected xenobiotic metabolism enzyme genes among 589 idiopathic infertile male patients and 396 controls in a Han-Chinese population.

Methods: Ultra high performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) was used to measure alkylphenols and chlorophenols in urine. Polymorphisms were genotyped using the SNPstream platform and the Taqman method. We used likelihood ratio tests (LRT) to explore these gene-environment interactions in idiopathic male infertility, and used false discovery rate (FDR) to adjust for multiple testing.

Results: Among four phenols that were detected, we found that only exposure to 4-t-OP increased the risk of male infertility (Ptrend=1.70×10<sup>-7</sup>). The strongest interaction was between 4-t-OP and rs4918758 in CYP2C9 (Pinter=6.05×10<sup>-7</sup>). It presented a significant monotonic increase in risk estimates for male infertility with increasing 4-t-OP exposure levels among men with TC/CC genotype (low level compared with non-exposed, odds ratio (OR) =2.26, 95% confidence intervals (CI) =1.06, 4.83; high level compared with non-exposed, OR=9.22, 95% CI=2.78, 30.59; but no associations observed among men with TT genotype). We also found interactions between 4-t-OP and rs4986894 in CYP2C19, and between rs1038943 in CYP1A1, on male infertile risk (Pinter=8.09×10<sup>-7</sup>, 3.73×10<sup>-4</sup>, respectively). Conclusions: We observed notable interactions between 4-t-OP exposure and metabolism enzyme gene polymorphisms on idiopathic infertility in Han-Chinese men.

**PS 1242 Smartphone Technologies Coupled with Environmental Models Allow for Large Scale Community Outreach and Risk Assessment.**

A. J. Larkin<sup>1,2,3</sup>, S. K. Krueger<sup>3,4</sup>, D. E. Williams<sup>1,3,4</sup> and W. M. Baird<sup>1,3</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR; <sup>2</sup>Statistics, Oregon State University, Corvallis, OR; <sup>3</sup>Superfund Research Center, Oregon State University, Corvallis, OR; <sup>4</sup>Linus Pauling Institute, Oregon State University, Corvallis, OR.

Chronic exposure to several air pollutants has been identified by the EPA as a major source of concern for human health. Environmental models have been created to predict spatial distributions of air pollutants, but are unable to account for daily travel among the general US population. Several GPS-based methods of tracking a person's movement through areas of concern have been developed, but require expensive or bulky GPS units, have limited ability to provide timely results to participants, and are dependent on user compliance. Smartphones are widely popular across all demographic groups, with more than 100 million US smartphone users. We developed iPhone and Android applications with GPS functionality to predict personal and population-wide exposures to fine particulate matter (PM<sub>2.5</sub>), coarse particulate matter (PM<sub>10</sub>), and ozone. Environmental distribution models were created using Kriging algorithms with MODIS satellite imagery and Oregon Department of Environmental Quality hourly PM<sub>2.5</sub>, PM<sub>10</sub>, humidity, ozone, and temperature measurements. Geographic locations were sampled from four smartphone devices at 30 minute intervals (n>10000 sampling events). Locations and corresponding times were sent to a database running the environmental modeling software. Predicted exposure levels, times, and locations were returned to corresponding smartphones and were anonymously added to a data set of predicted exposures collected from all participants. Personal exposure levels were presented to participants as interactive smartphone maps and graphs. Hotspot exposure sites were predicted by partitioning Oregon into 10 km<sup>2</sup> regions and mapping daily group exposure levels within each region. This project was created with open-source software and can be scaled to larger groups with minimal cost. This research was supported by NIH P42 ES014465.

**PS 1243 A High-Throughput Analytical Method for Enhanced Toxicological Studies.**

C. Y. Usenko, E. M. Robinson, E. D. Bruce and S. Usenko. *Baylor University, Waco, TX.*

Toxicology studies are moving to high-throughput methodologies, however, often times the chemical concentrations are not analyzed or verified. Historically, analytical methods capable of measuring organics in aqueous solutions (including fish water and cell media) often relied on more complicated techniques. The technique presented here has reduced 99% of the historically used sample preparation. Thereby reducing the time per sample associated with preparation from ~90 minutes to <1 minute. This technique essentially eliminates the chance for target analyte loss during sample preparation and therefore eliminates the need for surrogate standards, such as <sup>13</sup>C-labeled, which is typically used to correct for analyte loss during sample preparation. This method utilizes an innovative liquid-liquid extraction, where ~10-25 µL of cell media or water is transferred to a gas chromatography (GC) vial with 1 mL of hexane and 50 mg of sodium sulfate. Target analytes partition from the water to hexane and the water is captured by the sodium sulfate. Overall extraction efficiency is ~100%. The utility of the novel method was demonstrated with a proof of concept experiment that evaluated BDE 47 water concentrations overtime from glass and plastic (48-well plate) wells. BDE 47 concentrations measured in the glass well remained consistent over 24 hrs; however there was a rapid decrease in BDE 47 water concentrations (~80%) within the first 8 hrs in the plastic well. These results demonstrate that this method is simple and useful for both water and cell media studies and offers the ability to monitor the same well over time. Many exposures in toxicology studies start at concentrations above solubility and are used in plastic plates. While this has been an acceptable method of rapidly obtaining LC and IC50 values, it may not be an accurate representation of the actual water concentration. By accurately analyzing the concentration and determining the uptake, more accurate results may be obtained and used for risk assessment and mechanistic determinations, while adding increased study to study comparability.

**PS 1244 Evaluating High-Throughput Exposure Models with NHANES Data.**

W. Setzer and J. F. Wambaugh. *National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.*

Prioritizing screening and testing for large sets of chemicals for potential risk requires rapid exposure assessment, ideally based on chemical properties that are easily measured or computed. There are currently few such approaches, but like any predictive methodology these need to be evaluated against real exposure data. We evaluated two models, "Risk Assessment, Identification and Ranking" (RAIDAR; [www.arnotresearch.com/index.html#!/page\\_RAIDAR\\_DL](http://www.arnotresearch.com/index.html#!/page_RAIDAR_DL)) and USEtox™ ([www.usetox.org](http://www.usetox.org)) against the National Health and Nutrition Examination Study (NHANES) 2005 and 2011 data on urine concentrations of xenobiotics. Using NHANES to evaluate exposure models requires addressing several issues: chemicals measured in urine need to be linked back to potential exposures, and there may be multiple relationships between parent chemicals to which people are exposed and the product chemicals measured in urine; many chemicals were below limits of quantitation for a large fraction of the sampled subjects; variation among chemicals is a function of variation of exposure, pharmacokinetic (PK) variability, and the distribution of relative times of exposure and sampling. Steady state PK assumptions and a Bayesian statistical framework were used to infer parent exposures from NHANES urine products. We further use Bayesian statistical methods to evaluate the regression of median population exposure to the parent chemicals on RAIDAR and USEtox predictions, estimated production volume, and simple indicators of household use. Household use was the single most important factor. Among those chemicals with a consumer use, median exposure was correlated with production volume, but there was little evidence of a relationship between estimated exposure and any of the predictors among chemicals with no household use. The resulting model can be used for predicting exposure potential for new chemicals, along with the uncertainty of that prediction. Refining what constitutes 'household exposure', as well as including more exposure datasets, should reduce the uncertainty of the current model. [This abstract does not necessarily reflect EPA policy.]

**PS 1245 Haematology and Erythrocyte Osmotic Fragility Indices in Domestic Chicken following Exposure to a Polyvalent Iodophorous Disinfectant in Water Treatment.**

O. I. Azeez<sup>1</sup>, A. A. Oyagbemi<sup>1</sup> and O. T. Iji<sup>2</sup>. <sup>1</sup>Department of Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Nigeria; <sup>2</sup>Federal College of Animal Health and Production Technology, Moor Plantation, Apata, Ibadan, Nigeria.

The effect of prolonged use of Iodosteryl, a polyvalent iodophorous compound, as water disinfectant, on the hematology and erythrocyte osmotic fragility of the domestic chicken was investigated. Twenty-eight adult male domestic chickens of the Nera black strain were divided into four groups of seven birds per group. Birds in groups B-D were given potable water containing 1 mL, 2 mL and 4 mL/l Iodosteryl respectively for six weeks. Group A served as the control. Blood samples were collected from each bird after six weeks and analyzed immediately. No significant changes were observed in the packed cell volume (PCV), haemoglobin (Hb), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC), platelet total and differential leucocytes values. However, red blood cells (RBC) were slightly lower while erythrocyte osmotic fragility and erythrocyte sedimentation rate (ESR) was higher in those birds exposed to Iodosteryl compared with control. This study confirms that prolonged use of Iodosteryl is stressful and may lead to intravascular haemolysis as indicated by the higher erythrocyte fragility and ESR values, respectively. The damage observed, may be due to peroxidation of erythrocyte membrane lipids, proteins by generation of free radicals induced by iodine.

**PS 1246 How Inaccurate Are Serum-Lipid Unadjusted Organochlorine Levels?**

S. Koifman, C. Freire, R. J. Koifman, A. S. Rosa and P. N. Sarcinelli. *National School Public Health/ FIOCRUZ, Rio de Janeiro, Brazil.* Sponsor: E. Silbergeld.

Introduction. Organochlorine pesticides (OCs) have been banned by many countries, but they are still detected in human and animal tissues worldwide. An empiric assessment comparing serum lipid adjusted and unadjusted OC levels has been, so far, not reported in the literature. Objective. To estimate how inaccurate are lipid-unadjusted OCs serum levels compared to adjusted ones. Methods. In a survey carried out in a rural population in Brazil exposed to OCs since early 1960's, blood samples were obtained from 995 residents of both sexes and all ages. Serum concentrations of 19 OCs were determined by gas chromatography with electron-capture detection and were further adjusted by triglyceride and cholesterol content. Pearson correlation coefficients and determination coefficients (R<sup>2</sup>) of serum lipid-adjusted and unadjusted concentrations of p,p'-DDE, beta-HCH and aldrin were calculated. Results. Among male and female adults (> 14 yr.), median (1st and 3rd quartiles) of serum-lipid adjusted concentrations were, respectively: 8.32 (2.86-21.9) and 9.64 (3.45-28.9) for p,p'-DDE; 6.0 (2.08-15.4) and 6.98 (2.81-17.6) for beta-HCH; 1.89 (0.73-11.0) and 2.44 (0.77-14.1) for aldrin. Determination coefficients of serum lipid-adjusted and unadjusted OCs were R<sup>2</sup>= 0.91 for p,p'-DDE, R<sup>2</sup>= 0.90 for beta-HCH, and R<sup>2</sup>= 0.93 for aldrin. Correlation between serum lipid-adjusted and unadjusted concentrations was indeed higher for those OCs with serum levels < 50 ng/mL. Conclusion. When serum lipid content is unavailable, unadjusted OC levels can be reasonably used to estimate internal dose of these chemicals, particularly when concentrations are < 50 ng/mL.

**PS 1247 Revised Methods for Estimating Potential Re-Entry Exposure Associated with Indoor Crack and Crevice Application.**

J. H. Driver<sup>1</sup>, J. H. Ross<sup>2</sup>, S. Selim<sup>3</sup>, J. Sharp<sup>4</sup> and M. Pandian<sup>5</sup>. <sup>1</sup>risksciences.net, LLC, Manassas, VA; <sup>2</sup>risksciences.net, LLC, Sacramento, CA; <sup>3</sup>Selim & Associates, Inc., Fresno, CA; <sup>4</sup>McLaughlin Gormley King Company, Minneapolis, MN; <sup>5</sup>infoscientific.com, Inc., Henderson, NV.

Surface deposition of insecticides applied as indoor residential foggers, baseboard or perimeter sprays, spot sprays and crack-and-crevice sprays represent pathways of unintentional, and unavoidable post-application exposure of children and adults. Estimation of the magnitude of this exposure following an application event is associated with uncertainty due to many factors including 1) surface residue deposition and distribution, 2) access to and the nature of contact with treated surfaces based on time-activity patterns of residents, and 3) the role of residue removal mechanisms such as cleaning treated surfaces, pesticide degradation or redistribution, hand washing and bathing following contact. A comparative spatial deposition study was conducted involving broadcast, perimeter and crack and crevice application methods. Residues measured using a spatial grid of deposition dosimeters on floor surfaces demonstrated significantly lower residue concentrations in readily

accessible areas following crack and crevice and perimeter applications, versus broadcast treatment. Analyses of other monitoring studies support this finding. The implications of these findings are discussed for both screening-level and higher tier probabilistic post-application, residential exposure assessment. In addition to surface deposition studies, published biomonitoring data from adults and children support  $\geq 9$ -fold lower estimates of exposure for perimeter and crack and crevice applications than EPA's default of 2-3 fold lower than broadcast. We propose an alternative "random walk" algorithm to provide an alternative to professional judgment when evaluating exposure in rooms where only a fraction of the room has been treated.

**PS 1248 Derivation of Biomonitoring Equivalents for Chlorpyrifos Using a Pharmacokinetic/Pharmacodynamic Model of Oral Exposures.**

S. M. Arnold<sup>1</sup>, A. Morriss<sup>2</sup>, J. Velovitch<sup>3</sup>, D. R. Juberg<sup>3</sup>, P. Price<sup>1</sup>, C. Burns<sup>1</sup>, M. Bartels<sup>1</sup>, A. T. McCoy<sup>1</sup>, M. Aggarwal<sup>2</sup> and T. Poet<sup>4</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences, Milton Park, United Kingdom; <sup>3</sup>Dow AgroSciences, Indianapolis, IN; <sup>4</sup>Battelle, Richland, WA.

Blood chlorpyrifos (CPF) and its main urinary metabolite (3,5,6-trichloro-2-pyridinol, TCPy) are often included in general population-based biomonitoring data. Methods that put human internal dose measurements in a health-risk context have been lacking. The concept of Biomonitoring Equivalents (BEs) seeks to address this shortfall. BEs incorporate pharmacokinetic models to calculate biomarker levels consistent with continuous exposure at exposure guidance values (e.g., USEPA reference doses). BEs rely upon the underlying toxicological endpoints used in setting the guidance values and reduced uncertainty factors (UFs). Here, we calculate BE values for blood CPF and urinary TCPy using a physiologically based pharmacokinetic/pharmacodynamic (PBPK/PD) model. The model allows the direct determination of CPF blood concentration associated with a 10% inhibition in red blood cell cholinesterase (RBC ChE), the USEPA regulated endpoint, for oral exposures. This model also predicts age-specific individual human variability of blood levels associated with a 10% inhibition in RBC ChE using Monte Carlo analysis, which allows determination of blood levels protective of sensitive humans. Thus, no additional UFs are required to derive the BE. The preliminary blood BE value for CPF in adults is 3.5 µg/L. This level is about 1000 fold higher than the current reported blood levels in US pregnant women. The preliminary urinary BE for TCPy is 2,000 µg/L. The 95th percentile urinary TCPy in the general US adult population was 12.4 µg/L (CDC exposure years 2001-2002). Assuming that 10% of the reported levels occur from CPF exposure (the remainder is assumed direct exposure to environmental TCPy in non-worker populations), then the BE for TCPy will also be about 1000 fold larger than current levels. These findings suggest that current US adult dietary exposures to CPF are well below levels that could cause 10% inhibition of RBC ChE.

**PS 1249 Gene Expression of sFLT1 Links Prenatal Arsenic Exposure to Increased Risk on Small for Gestational Age.**

S. Remy<sup>1,3</sup>, E. Govarts<sup>1</sup>, B. Wens<sup>1,3</sup>, L. Bruckers<sup>2</sup>, M. Paulussen<sup>1</sup>, E. Den Hond<sup>1</sup> and G. Schoeters<sup>1,3</sup>. <sup>1</sup>Flemish Institute for Technological Research (VITO), Mol, Belgium; <sup>2</sup>Hasselt University, Hasselt, Belgium; <sup>3</sup>Antwerp University, Antwerp, Belgium. Sponsor: P. Hoet.

In the Flemish Environment and Health Study (2007-2011) we aimed: 1) to explore the relationship between prenatal arsenic exposure and the resulting effect on prenatal growth, and 2) to obtain more insight in the molecular basis of these relationships. Levels of arsenic were measured in cord blood samples of 255 newborns and the transcriptome of cord blood mononuclear cells was determined by Agilent whole human genome microarrays.

Arsenic levels ranged from 0.01 to 8.20 µg/L. Logistic regression analyses showed that a higher exposure to arsenic was statistically significantly associated with an increased risk for having a Small for Gestational Age (SGA)-baby, adjusted for a priori fixed confounders and statistically significant covariates ( $p < 0.05$ ). The odds of having an SGA-baby was multiplied with 1.65 (95% CI: 1.15-2.37) for an interquartile range increase of 0.93 µg/L arsenic.

To identify gene transcripts that link prenatal arsenic exposure to increased risk on SGA, we focused on the subset of most extreme samples (i.e. a group of lowest arsenic exposure ( $n=30$ ) and a group of highest arsenic exposure ( $n=30$ )). The list of transcripts that discriminate both groups was screened for genes involved in embryonic growth regulation. As such sFLT1 (soluble fms-like tyrosine kinase-1) was detected, a protein known to inhibit placental angiogenesis. This gene was significantly higher ( $p = 0.004$ ) expressed among high exposed individuals. Moreover, 75% of SGA-babies were found to show expression levels above median.

Our data suggest that disturbed placental angiogenesis, via upregulation of sFLT1, may link prenatal arsenic exposure to increased risk on SGA.

The studies of the Flemish Center of Expertise on Environment and Health are commissioned, financed and steered by the Ministry of the Flemish Community (Department of Economics, Science and Innovation; Flemish Agency for Care and Health; and Department of Environment, Nature and Energy).

**PS 1250 Plasma Polybrominated Diphenyl Ethers (PBDEs) in Californian Women at High Risk for Birthing an Autistic Child.**

Y. Lin<sup>1</sup>, I. Hertz-Picciotto<sup>2</sup>, D. Tancredi<sup>2</sup>, I. N. Pessah<sup>1</sup> and B. Puschner<sup>1</sup>. <sup>1</sup>Department of Molecular Biosciences, School of Veterinary Medicine, University of California Davis, Davis, CA; <sup>2</sup>Department of Public Health Sciences, School of Medicine, University of California Davis, Davis, CA.

Exposure to the polybrominated diphenyl ethers flame retardants (PBDEs) is a major preventable health concern. Little is known about the extent and patterns of PBDE exposures during pregnancy, especially in populations susceptible to heritable neurodevelopmental disorders. We measured plasma PBDE levels in Californian women participating MARBLES (Markers of Autism Risk in Babies-Learning Early Signs) who are at high risk for birthing an autistic child. BDE-28, -47, -49, -52, -95, -99, -100, -136, -153, and -183 were measured using GC/MS/MS in plasma samples collected from 79 women at each trimester and at delivery (215 samples total). PBDEs were normalized to plasma volume (ng/ml) and total lipids (ng/g). The concentrations of maternal PBDEs in MARBLES were compared to data from the National Health and Nutritional Examination Survey (NHANES 2003-2004). All ten congeners were detectable in the maternal samples from MARBLES, with BDE-100 ( $0.792 \pm 0.540$  ng/ml,  $163.5 \pm 117.5$  ng/g) and BDE-47 ( $0.661 \pm 0.458$  ng/ml,  $141.1 \pm 117.6$  ng/g) contributing the highest abundance. Compared to NHANES, women enrolled in MARBLES had significantly higher mean concentrations of BDE-47 (23.9 versus 141.1 ng/g), -99 (5.51 versus 92.3 ng/g), -100 (6.06 versus 163.5 ng/g) and -153 (9.90 versus 28.7 ng/g). Plasma PBDE (ng/ml) in women 25 to 35 years of age increased during gestation, but decreased if they were older than 35 years. Because of the increase of total plasma lipids during gestation, PBDE expressed on an ng/g lipid basis decreased in all age groups with gestational stage. Fluctuations in maternal plasma PBDE levels during pregnancy illustrate the importance of gestational age and underscore the non-linear relationship between volume- and lipid-corrected PBDE concentrations.

**PS 1251 Estimation of Dietary Lead Exposure for US Children Using a New Method: Implications for the Integrated Exposure Uptake Biokinetic Model for Lead in Children.**

M. Follansbee<sup>1</sup>, M. Ballew<sup>2</sup>, J. Brown<sup>2</sup>, M. Burgess<sup>2</sup>, M. Stifelman<sup>2</sup> and B. Thayer<sup>1</sup>. <sup>1</sup>SRC, Inc., East Syracuse, NY; <sup>2</sup>US EPA, Washington DC. Sponsor: G. Diamond.

In addition to site-specific inputs, the Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK model) uses national defaults that are recommended when site-specific information is not available. As part of a periodic evaluation of inputs to the IEUBK model, the methodology underlying the basis for default calculations of dietary lead intake has been updated. Previously, the food consumption values in the IEUBK model were based on information reported by Pennington (1983) and the lead in food values were based on food residue data from the ongoing FDA Total Diet Study; the latter are updated periodically as new data become available from FDA.

Recent advances in methods for estimating dietary intake provide a current and scientifically sound basis to develop nationally-representative, age-group specific values for food consumption. The dietary component of NHANES, called the What We Eat in America (WWEIA) Dietary Survey, includes two 24-hour dietary recall interviews during which each respondent reports the amount of all foods they consumed during the prior day. The food consumption values (grams/day) were estimated using a non-linear mixed model developed by the National Cancer Institute (the NCI method). The NCI method uses information on meal sizes and frequency (probability) with which specific food items are consumed to estimate daily consumption rates.

The NCI method produced estimates of dietary lead intake that were 18 to 219% higher than the previously estimated values, depending on the food item. Further analysis revealed the increase in the dietary lead intake values was largely due to an increase in the estimated daily consumption values rather than higher lead concentrations in food.

**PS 1252 Using Doubly-Labeled Water Energy Data for Estimating Ventilation Rates for the Integrated Exposure Uptake Biokinetic Model for Lead in Children.**

B. Thayer<sup>1</sup>, M. Follansbee<sup>1</sup>, J. Brown<sup>2</sup>, M. Burgess<sup>2</sup> and M. Stifelman<sup>2</sup>. <sup>1</sup>SRC, Inc., East Syracuse, NY; <sup>2</sup>US EPA, Washington DC. Sponsor: G. Diamond.

The default values in the IEUBK model (Version 1.1, Build 11) are based on values reported in the Office of Air Quality Planning and Standards report (U.S. EPA, 1989) and the IEUBK Model Technical Support Document (U.S. EPA, 1994). More recent data provide a more scientifically sound basis to further develop nationally-representative, age-group specific values for ventilation rates in children. The default values in the IEUBK model were derived based on body size in combination with smoothed data from Phalen et al. (1985). EPA's (2008) Child-Specific Exposure Factors Handbook provides recommendations for long-term (> 30 days) ventilation rates that are based on the average of several studies (Arcus-Arth and Blaisdell, 2007; Brochu et al., 2006; Stifelman, 2007).

Because Arcus-Arth and Blaisdell (2007) used indirect measures of ventilation rates based on dietary and activity survey responses, it was not considered acceptable for derivation of default values for the IEUBK model. Brochu et al. (2006) and Stifelman (2007), however, were based on the doubly-labeled water (DLW) energy data from the Institute of Medicine. DLW energy data are recognized as the gold standard for energy expenditure and an improvement over ventilation estimates based on dietary recall or activity survey data.

Ventilation rate was calculated from total energy expenditure using Layton's approach as described by Stifelman (2007). The analysis was on pooled data for males and females. More detailed analysis of ventilation rates as a function of age and gender showed the estimated ventilation rates to be parallel and 7% greater in males than females. The resulting ventilation rate values are between 19-66% higher than the existing IEUBK model defaults. Because these values are derived from energy expenditure information, they provide a more scientifically defensible basis for the default values in the IEUBK model.

**PS 1253 Conducting Probabilistic Reverse Dosimetry Calculations to Estimate Exposure Concentrations from Biomarker Data—An Example of Perchlorate.**

M. B. Phillips<sup>1</sup>, C. M. Grulke<sup>1</sup>, Y. Yang<sup>2</sup>, K. Holm<sup>1</sup>, D. T. Chang<sup>1</sup>, R. Goldsmith<sup>1</sup>, R. Tornero-Velez<sup>1</sup>, C. C. Dary<sup>3</sup> and C. Tan<sup>1</sup>. <sup>1</sup>US EPA ORD NERL, Research Triangle Park, NC; <sup>2</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>US EPA ORD NERL, Las Vegas, NV.

Given the growing number of population-based biomonitoring surveys, there is an escalating interest in converting biomarker measurements (chemical/metabolite concentrations) to exposure concentrations (e.g., daily dose) to help support risk assessment. The conversion involves two steps: (1) formulating a model that describes the dose-biomarker relationship (forward dosimetry); and (2) solving for the plausible doses that are consistent with observed biomarker concentrations (reverse dosimetry). The objective of this study is to use probabilistic reverse dosimetry to estimate the distribution of average daily doses of perchlorate based on the National Health and Nutrition Examination Survey (NHANES) urinary biomarker data. Perchlorate was selected for its abundance in both exposure and biomarker data. First, Monte Carlo simulations of a physiologically based pharmacokinetic (PBPK) model for perchlorate were performed to account for variability/uncertainty in exposure factors and PK. Next, the simulated exposure-biomarker relationship was used to convert urinary perchlorate concentrations to a distribution of daily doses. The conversion was conducted using a web-based tool, Probabilistic Reverse dosimetry Estimating Exposure Distribution (PROCEED), with two methods: the Exposure Conversion Factor and Discretized Bayesian methods. The means of the estimated dose distributions were comparable to average daily doses estimated using other methods (point estimates), such as food concentrations multiplied by consumption rate. Probabilistic reverse dosimetry, however, also provides the distribution of dose estimates to represent the variability/uncertainty in exposure factors and PK.

[This abstract has been cleared by the EPA but solely expresses the view of the authors]

**PS 1254 The Effect of Clothing Care Activities on Textile Formaldehyde Content.**

R. Novick, M. G. Lew, M. A. McKinley, G. L. Anderson and J. J. Keenan. ChemRisk, San Francisco, CA.

Textiles are commonly treated with formaldehyde-based finishing agents that can potentially cause allergic contact dermatitis in sensitive individuals. There is limited data on the current formaldehyde content in textiles and the potential for reduction

through clothing care activities. This study sought to provide information on the formaldehyde content in clothing specifically focusing on 100% cotton permanent press shirts and pants, a clothing category that is generally treated with formaldehyde-based resins. Textiles were purchased and tested for formaldehyde content using the Japanese method 112. Several items (~20%) exhibited measurable levels of formaldehyde (> 20 ppm). Textile samples with the greatest formaldehyde content were hand or machine washed in hot or cold water, dried on a line or in a dryer, and ironed. Ironing did not appear to affect the textile formaldehyde content. The washing and drying procedures reduced formaldehyde content between 28 and 74% compared to the control. Differences in the temperature or type of washing and drying did not result in a clear trend in the formaldehyde content data. Understanding the formaldehyde content in commercially available permanent press clothing and the potential reduction through clothing care activities may be useful for manufacturers and sensitive individuals.

**PS 1255 Exposure Associated with Power Stripping of Asbestos Containing Insulation from Electrical Cable.**

C. L. Blake<sup>1</sup>, A. Jurkowski<sup>1</sup>, G. Johnson<sup>2</sup> and R. D. Harbison<sup>2</sup>. <sup>1</sup>Bureau Veritas North America, Inc., Kennesaw, GA; <sup>2</sup>Environmental and Occupational Health, University of South Florida, Tampa, FL.

Efforts to recycle copper from electrical conductors have led to the development of specialized machines which automatically remove insulating covers from wires and cable products. In the past, certain wire and cable products were insulated using chrysotile asbestos. This research was undertaken to determine the asbestos fiber exposure risks associated with power stripping machinery to remove asbestos-containing insulation materials from electrical wire or cable. A Rigby Machinery, Inc., Model 4H electric powered wire/cable insulation stripping machine was acquired along with approximately 42 m of asbestos insulated cable. During two separate, but nearly identical, test sessions, a laborer used the wire stripper to remove the asbestos-containing insulation from the subject cable. This work took place within a closed metal building with a total interior volume of 2,500 m<sup>3</sup>. Industrial hygiene personal and area air samples were collected for airborne fibers throughout all wire stripping periods. Collected air samples were analyzed using phase contrast microscopy (PCM) and transmission microscopy (TEM). The results of analysis using PCM for personal samples (n=3) taken during periods of continuous cable stripping activity showed test period airborne fiber exposures ranging from 0.034 to 0.068 (mean 0.056 f/ml). Follow-up analysis of these personal samples using TEM indicated asbestos adjusted PCM exposures ranging from 0.017 to 0.045 (mean 0.033 f/ml). Area air samples taken at distances ranging from 2 to 9 meters from the wire stripper (n=16) showed asbestos adjusted PCM concentrations ranging from less than 0.0001 to 0.041 f/cc (mean 0.007 f/ml). The process of power stripping asbestos-containing insulation from electrical wires and cables can cause exposure to airborne asbestos fibers. However, the levels of such exposure are not expected to exceed the current day occupational exposure limits for asbestos of 0.1 f/ml as an 8-hr TWA or 1.0 f/ml averaged over a 30-minute exposure period.

**PS 1256 N, N'-Di-Tert-Butylacetamide: Integrated Toxicity Testing Approach to Establish an Occupational Exposure Guideline.**

J. A. Hotchkiss, R. Sura, S. M. Krieger, J. Thomas and L. Andrews. The Dow Chemical Company, Midland, MI.

N,N' di-tert-butylacetamide (AMD; CAS # 54838-72-1) is a raw material and principal hydrolysis product of a new metalorganic molecule. An integrated testing strategy involving the assessment of multiple hazard endpoints was used to provide essential toxicologic data to set an occupational exposure guideline for AMD. The acute oral LD<sub>50</sub> was estimated to be 341.4 mg/kg (95% C.I. = 280-550 mg/kg). In a 28-day dietary study no target organ toxicity was identified. A no adverse effects level (NOAEL) of 150 mkd was based on decreased food consumption and body weight gains at 500 and 1000 mkd. A modified acute inhalation toxicity study with scheduled necropsies 1- and 14-d post-exposure and analysis of bronchoalveolar lavage, airway epithelial cell proliferation, and histopathology of the respiratory tract was conducted to determine the LC<sub>50</sub> and to assess airway epithelial injury and repair. The 4-h LC<sub>50</sub> was 388 ppm (506 mg/kg) and 404 ppm (527 mg/kg) AMD for male and female F344/DuCrI rats, respectively. Histopathologic changes were concentration-dependent and restricted to the olfactory, respiratory and transitional epithelium lining the anterior nasal airways. Increased cell proliferation was evident 1- and 14-d post-exposure. Epithelial regeneration was incomplete 14-d post-exposure. An RD<sub>50</sub> assay was conducted to assess the sensory irritation potential of inhaled AMD. Based on the concentration-dependent decrease in respiration rate the RD<sub>50</sub> was calculated to be 123.4 ppm (95% C.I. = 59-188). Based on these data an 8-h time-weighted average (TWA) occupational exposure level of 5 ppm with a 15 ppm short-term exposure limit (STEL) was established. These exposure limits are similar to ACGIH threshold limit values of 5-10 ppm for short-chain

aliphatic amines and suggest that the toxicity of AMD is similar to other alkyl amines such as dimethyl- and diethyl-amine. The integrated testing strategy used in this study represents an important approach for reducing animal use and rapidly adopting exposure guidelines for new materials to assure worker safety.

## PS 1257 Lipidomics of Subchronic Low Level Cadmium Exposure in the Rat.

O. O. Ogunrinola, O. Ademuyiwa, A. D. Wusu, O. K. Afolabi, E. O. Abam, D. O. Babayemi, E. A. Balogun and O. O. Odukoya. *Biochemistry, University of Agriculture, Abeokuta, Nigeria.*

Epidemiological studies suggest an association between cadmium in drinking water and vascular diseases. However, the precise cadmium mechanism of action remains enigmatic. This study was undertaken to investigate the effect of cadmium on lipid metabolism of Wistar male albino rats by exposing the animals to 100, 200 and 300 ppm cadmium doses for 12 weeks in their drinking water. Control animals received distilled water for the same period. At the end of 12 weeks, dyslipidemia induced by the cadmium doses exhibited different patterns. Dose-dependent hypocholesterolemia and hypotriacylglyceridemia characterised the effect of cadmium exposure at all doses whereas plasma free fatty acid (29%) was increased by cadmium exposure. Reverse cholesterol transport was inhibited by all the cadmium doses as evidenced by 65% decreased HDL cholesterol concentrations whereas hepatic cholesterol was decreased by 55%. Renal and brain cholesterol (46%, 65%) and triacylglyceride (62%, 50%) were dose-dependently decreased by cadmium exposure respectively; on the other hand, exposure to cadmium depleted cardiac cholesterol by 45%, but enhanced/balanced triacylglyceride content. Cadmium at all doses of exposure inhibited both hepatic and brain HMG CoA reductase by 49% and 61% respectively. We observed positive association between tissue cadmium levels and plasma FFA, and negative associations between tissue cadmium levels and HDL cholesterol. Our findings indicate that in contrast to strengthening a dose-dependent effect phenomenon as observed with many other compounds, cadmium up- or down-regulate different pathways in the lipid metabolism spectrum at "low" or "high" doses and this might be responsible for the insidious vascular effects.

## PS 1258 Serum Great Lakes Pollutant Levels in Lake Ontario Fish and Wildlife Consumers.

E.D. Stephen<sup>1</sup>, L. A. Georger<sup>1</sup>, M. R. Bonner<sup>3</sup>, P.J. Kostyniak<sup>2</sup>, J.R. Olson<sup>2,3</sup>, M. S. Bloom<sup>4</sup> and J. E. Vena<sup>3</sup>. <sup>1</sup>Math & Natural Sciences, D'Youville College, Buffalo, NY; <sup>2</sup>Pharmacology & Toxicology, SUNY Buffalo, Buffalo, NY; <sup>3</sup>Social & Preventive Medicine, SUNY Buffalo, Buffalo, NY; <sup>4</sup>Environmental Health Sciences, SUNY Albany, Albany, NY; <sup>5</sup>Epidemiology and Biostatistics, University of Georgia, Athens, GA.

Industrialization of the Great Lakes region resulted in the discharge of many halogenated aromatic hydrocarbons (HAHs) into the Lake Ontario basin. Due to their persistence and lipophilicity, HAHs can biomagnify in the food chain and are a potential source of human exposure to polychlorinated biphenyls (PCBs), polychlorinated dibenzo-p-dioxins (PCDDs), dibenzofurans (PCDFs) and pesticides. Consumption of Lake Ontario fish and wildlife is one factor that contributes to higher serum levels of persistent HAHs and potentially greater risk of adverse human health effects. The New York State Angler Cohort Study (NYSACS) is a large prospective cohort of licensed anglers from 16 New York counties in close proximity to Lake Ontario, 18 to 40 years of age established in 1991. Previously, 394 members of the NYSACS donated blood and were screened for serum PCB and pesticide levels. For this analysis, participants with the highest serum PCB153 levels (n=27) and with self reported consumption of Lake Ontario fish were chosen, and matched to subjects having never consumed Lake Ontario fish by age, sex and geographic area (n=16). We examined serum levels of PCBs, PCDDs, PCDFs and pesticides by GC/ECD and GC/MS. The consumer group had significant elevated levels of 20 PCBs, including PCB 126, 153, 138, 180 and 170. The consumer group also had a 1.6-fold increase in 2,3,7,8-TCDD, a 1.4-fold increase in 1,2,3,7,8-PentaCDD, a 1.54-fold increase in 2,3,4,7,8-PentaCDF, a nine-fold increase in mirex, a 2.5-fold increase in DDE and a two-fold increase in t-nonachlor relative to the non-consumer group (all values p<0.05). Together, the results indicate that consumption of fish and wildlife from Lake Ontario is a source of exposure to mirex and other HAHs. (Supported in part by ATSDR, Grant H75-ATH 298338)

## PS 1259 Exposure to Environmental Tobacco Smoke Causes Endotoxin Tolerance.

T. Muthumalage<sup>2</sup>, K. Hunter<sup>3,2</sup>, D. Redelman<sup>4</sup>, K. Pritsos<sup>1</sup> and C. A. Pritsos<sup>1,2</sup>. <sup>1</sup>Agriculture, Nutrition and Veterinary Sciences, University of Nevada, Reno, Reno, NV; <sup>2</sup>Environmental Sciences Program, University of Nevada, Reno, Reno, NV; <sup>3</sup>Microbiology and Immunology, University of Nevada, Reno, Reno, NV; <sup>4</sup>Physiology and Cell Biology, University of Nevada, Reno, Reno, NV.

Exposure to cigarette smoke is known to increase susceptibility to and severity of pulmonary diseases such as bronchitis and emphysema. During tobacco manufacturing processes, in which the temperature and humidity are brought to an optimum level for fermentation, tobacco is colonized by fungi and bacteria. Lipopolysaccharide (LPS), a gram negative bacterial component, has been found in tobacco smoke. In this study, we wanted to assess whether acute exposure to environmental tobacco smoke (ETS) could alter the immune response caused by exposure to the bacterial endotoxin, LPS. Using a C57BL/6 mouse model, we compared the inflammatory cytokine levels secreted by LPS stimulated alveolar macrophages in ETS exposed and unexposed (control) groups. Tumor necrosis factor-alpha (TNF-α) levels were significantly attenuated in the ETS exposed groups after ex-vivo exposure to LPS in comparison to the control group. We observed that whether the ex-vivo LPS exposure was performed immediately after the ETS exposure or a full day post-exposure, the TNF-α cytokine level was decreased by 30-40%. No significant difference was observed in alveolar macrophage recovery between the two groups. Also, no significant difference was found in cell viability between the two groups. This suggests that TNF-α attenuation in ETS exposed groups resulted from endotoxin tolerance caused by LPS or LPS-like constituents in ETS. This endotoxin tolerance resulting from acute ETS exposure can suppress the immune function and subsequently increase susceptibility to bacterial infections. These results provide insights into the weaker immune defense observed in smokers and secondhand smokers. This study was supported by the Flight Attendants Medical Research Institute grant 072083.

## PS 1260 Mitochondrial-K<sup>+</sup>-ATP Channel Activation Rescues of Phosgene-Induced Toxic Inhalational Lung Injury.

A. Senft<sup>1</sup>, J. D. McDonald<sup>1</sup>, W. Weber<sup>1</sup>, L. Fredenburgh<sup>2</sup>, G. Southan<sup>3</sup> and A. P. Salzman<sup>3</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>2</sup>Harvard Brigham and Womens College, Boston, MA; <sup>3</sup>Radikal Therapeutics, Boston, MA.

To determine whether R-801, a mitochondrial-K<sup>+</sup>-ATP channel activator, is effective in rescuing acute lung injury (ALI) induced by phosgene (COCl<sub>2</sub>), C57/BL6 mice were exposed to COCl<sub>2</sub> (5 ppm) or filtered air (FA) for 20 min. Animals were administered intraperitoneal (IP) R-801 (80 mg/kg/dose) or vehicle (hydroxypropyl cyclodextrin, HPCD) at 2 and 6 h after COCl<sub>2</sub>. Animals were tracheostomized, bronchoalveolar lavage (BAL) performed, and lungs harvested at 24 and 48 h. COCl<sub>2</sub>-exposed animals developed severe lung injury compared to controls, with interstitial and alveolar edema, hemorrhage, and recruitment of inflammatory cells. Treatment with R-801 led to significant reduction in histologic lung injury and near normalization of lung histology. Immunostaining for Ly-6G (Gr-1) at 48 h demonstrated significant neutrophil (PMN) accumulation around bronchovascular bundles in COCl<sub>2</sub>-exposed animals which was profoundly attenuated in R-801-treated COCl<sub>2</sub>-exposed animals. Furthermore, levels of the pro-inflammatory cytokines and BALF protein were dramatically reduced compared with controls. Treatment with R-801 restored epithelial barrier integrity after COCl<sub>2</sub> with striking attenuation in BALF protein levels 48 h after COCl<sub>2</sub>. Taken together, our findings demonstrate that selective mito-K<sup>+</sup>-ATP channel opening with R-801 is highly effective at rescuing COCl<sub>2</sub>-induced ALI via attenuation of inflammation, restoration of epithelial tight junction barrier integrity, and induction of endogenous surfactant protein expression.

## PS 1261 Systematic Review of BPA "Low Dose" Literature in the Context of Human Dosimetry Exposes a Need to Set Standards for Responsible Communication of Both Toxicity and Exposure Data.

S. Hanson-Drury and J. G. Teeguarden. *Systems Toxicology and Exposure Science, Pacific Northwest National Laboratory, Richland, WA.*

BPA is a weakly estrogenic monomer used for making polycarbonate plastics and food packaging liners. At sufficient exposures, BPA is toxic in rodent non-human test systems. Uncritical reference to many toxicity studies as "low dose" has led to the belief that exposure levels in these studies are similar to human exposure levels,

implying that BPA is toxic to humans at current exposures. However, a comprehensive comparison of exposures in humans and test systems has not been conducted. Applying the fundamental principles of biomonitoring, exposure assessment and dosimetry, we conducted a systematic review of BPA exposure levels in 130 peer-reviewed *in vivo* and *in vitro* BPA toxicity studies self-referring as "low-dose." Total daily human exposure to BPA is ~ 0.03 µg/kg/day. In contrast, >90% of "low dose" BPA toxicity studies were conducted at doses exceeding human exposure by 10-1000,000 fold. Human blood concentrations from a single oral bolus dose of BPA equal to total daily BPA exposure are in the low pM range. In comparison, concentrations used in >90% of *in vitro* "low dose" studies were 10 to 1000,000 higher. We conclude that the use of the "low dose" descriptor is largely inconsistent with the state of our knowledge of human exposure. Looking forward, as human exposure data continue to emerge from large biomonitoring studies, we believe that there is a need to adopt standards for the conduct and reporting of toxicity studies that include objective comparisons to human exposures.

**PS 1262 Secondary Particulate Health Effects Research (SPHERES)**  
**Program: Secondary Organic Aerosol Effects on the Cardiovascular System.**

A. Rohr<sup>2,1</sup>, E. Knipping<sup>2</sup>, A. K. Lund<sup>1</sup>, M. J. Campen<sup>3</sup>, M. Doyle-Eisele<sup>1</sup> and J. D. McDonald<sup>1</sup>. <sup>1</sup>LRRI, Albuquerque, NM; <sup>2</sup>EPRI, Palo Alto, CA; <sup>3</sup>University of New Mexico, Albuquerque, NM.

The SPHERES research program was created to examine the role of inhaled secondary organic aerosol (SOA) on cardiovascular outcomes in mice, benchmarking effects against those observed from motor vehicle emissions (MVE). SOA was generated in a reaction chamber with either alpha-pinene or toluene, combined with (1) NO<sub>x</sub>; (2) NO<sub>x</sub> + SO<sub>2</sub>; (3) NO<sub>x</sub> + NH<sub>3</sub>; or (4) NO<sub>x</sub> + NH<sub>3</sub> + SO<sub>2</sub>. To examine the effects of these mixtures on progression of atherosclerosis, 8 wk old male Apo E<sup>-/-</sup> mice, on a high fat diet were exposed for 7 days, and resulting vascular oxidative stress and expression of molecular markers were assayed. Exposure to MVE resulted in enhanced vascular oxidative stress, measured by vascular TBARS and HO-1 levels. SOA caused a milder response than MVE, and the biological responses that were observed differed depending on the composition of the mixture. The only SOA exposure in which a statistical increase in TBARS was measured, compared to controls, was the "neutral" α-pinene (e.g. α-pinene reacted with NO<sub>x</sub>). All other SOA exposure conditions yielded only slight, or no, increase in TBARS expression, which is consistent with other studies in the literature (Lemos et al., 2011; rev. in Godleski et al., 2011). Several of the SOA exposure conditions yielded significant increases in expression of vascular HO-1 transcript. The "acidic" α-pinene mixture, as well as α-pinene + NH<sub>3</sub> (both neutral and acidic) and the neutral toluene exposure all resulted in statistically significant increases in HO-1 mRNA. Conversely, both the acidic and neutral toluene + NH<sub>3</sub> exposures showed significant decreases in vascular HO-1 expression. In aggregate, the results suggest that SOA causes mild cardiovascular responses that are dependant on composition. Research Funded by the Electric Power Research Institute.

**PS 1263 Pulmonary Toxicity of Oxygen and Carbon Dioxide Degraded Amines Used for Carbon Capture and Storage.**

D. Kracko<sup>1</sup>, C. Wegerski<sup>1</sup>, J. D. McDonald<sup>1</sup>, M. Doyle-Eisele<sup>1</sup>, S. Shaw<sup>2</sup>, E. Knipping<sup>2</sup> and A. Rohr<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>2</sup>Electric Power Research Institute, Palo Alto, CA.

Carbon dioxide (CO<sub>2</sub>) adsorption with aqueous amine solvents is among the leading candidates for use in carbon capture and sequestration (CCS) techniques aimed at reducing greenhouse gas emissions from flue gases (coal-fired power plants, refineries, etc). The environmental consequences from utilizing this technology have been poorly characterized. A concern is that amines or by-products that may occur due to interaction with flue gases are emitted creating unintended human exposure. This study evaluated the inflammatory response associated with inhalation exposure to amines and amine degradation products. Three model amines (monoethylamine (MEA), methyldiethanolamine (MDEA), piperazine (PIP)) and their laboratory-generated degradation products formed via addition of CO<sub>2</sub> and O<sub>2</sub> were evaluated. C57BL/6N mice were exposed for three days by whole-body inhalation to 6-25 ppm amine or the equivalent concentration of degraded amines. Inflammatory response in lungs was assessed by counting inflammatory cells in bronchoalveolar lavage fluid and measurement of cytokine expression in lung tissue. Inhalation exposure to O<sub>2</sub>-degraded MEA showed significant increases in total cells, neutrophils, and lymphocytes compared to control mice. Significant increases in inflammatory cytokine expression were seen in mice exposed to the O<sub>2</sub> degraded MDEA atmosphere, and minimal inflammation was observed with piperazine or

degraded piperazine. CO<sub>2</sub> degraded amines overall showed only mild inflammatory response. Characterization of the degraded amines showed numerous degradation products including carbonyl compounds, such as formaldehyde, and nitrosamines, a class of compound of which some species are carcinogenic. These are the first known studies to evaluate the potential inhalation hazard of amine degradation products. Research supported by the Electric Power Research Institute.

**PS 1264 Volatile Organic Compounds Released from Expanded Polystyrene.**

N. Pajaro-Castro, J. Perez-Romero and J. Olivero-Verbel. *Environmental and Computational Chemistry Group Pharmaceutical Sciences, University of Cartagena, Cartagena, Colombia.*

The importance of plastic materials for different applications in everyday life has continuously increased over the years. Manufactured goods made of polymers are generally complex materials. These are composed of polymers or copolymers themselves, together with a variety of additives with different volatilities. Currently, polystyrene is among the most widely used plastic in the form of foam containers. However, under certain conditions polystyrene foam may liberate residual styrene monomers, and other compounds, with well-known toxic properties. The aim of this study was to analyze the release of chemicals from expanded polystyrene (EPS) commercially available in Colombia. Headspace solid-phase micro-extraction with a 100 µm carboxen-polydimethylsiloxan fiber was utilized to capture organic compounds volatilized by heating EPS at different temperatures (55-85 Celcius). Volatiles were characterized by GC/MS after thermal desorption. The results demonstrated that for different EPS products, such as lunch carriers, dishes and soup containers, there is a temperature-dependent emission of several compounds, including styrene, benzaldehyde, ethylbenzene, (2-phenylcyclobutyl)benzene and tetradecane, among others. Data mining suggested these molecules possess a broad spectrum of toxicities. Taken together, these findings should encourage citizens to be careful while using EPS containers as carriers for hot foods or beverages. Vice-Rectoria for Research. UniCartagena. 2011-2012. Colciencias-UniCartagena, Colombia. Grant 110749326186 (2009).

**PS 1265 Assessment of Biomarkers of Benzene Exposure and Effect in Petrochemical Workers.**

S. Inayat-Hussain<sup>1,2</sup>, M. Sabtu<sup>2</sup>, F. S. Chin<sup>2</sup> and M. K. Chan<sup>1</sup>. <sup>1</sup>Environmental Health and Industrial Safety Program, Faculty of Health Sciences, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia; <sup>2</sup>UKM Medical Molecular Biology Institute, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia.

This study was conducted to assess biomarkers of benzene exposure and effect, and the relationship between these parameters in petrochemical plant workers during a major turnaround. Pre and post shift blood and urine samples were obtained from 35 workers including smokers and non-smokers who were potentially exposed to low air level of benzene. Air monitoring results showed that the benzene level in air samples was less than the Permissible Exposure Level (PEL) which is 0.5 ppm. Interestingly, there was a 2.1 fold increase of the biomarker of exposure namely urinary S-phenylmercapturic acid (SPMA) in workers as assessed by ELISA. There were 18 out of 35 workers who had levels of post-shift SPMA higher as compared to the pre shift data. Specifically, 6 workers showed levels of SPMA above the Biological Exposure Index (25µg/g creatinine). In workers who were smokers, there was an increase of 2.1 fold in the level of DNA strand breaks as assessed by Alkaline Comet assay whereas the increase of oxidized base (8-OHdG) was 1.1 fold as measured using ELISA. However, the non-smokers demonstrated a significant increase in 8-OHdG level (1.3 fold) but not significant for the DNA strand breaks (1.2 fold) (p<0.05). Notably, a strong correlation between SPMA and 8-OHdG (r=0.709) was observed in the post shift data for non-smokers. Taken together, these results suggest that biomonitoring of workers during exposure to low level of benzene may be important to protect workers' health.

**PS 1266 Identification of Sulfated Metabolites of 4-Chlorobiphenyl (PCB3) in the Serum and Urine of Male Rats.**

K. Dhakal<sup>1,4</sup>, L. Hans-Joachim<sup>1,4</sup>, L. M. Teesch<sup>2</sup>, M. W. Duffel<sup>1,3</sup> and L. W. Robertson<sup>1,4</sup>. <sup>1</sup>Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa City, IA; <sup>2</sup>High Resolution Mass Spectrometry Facility, The University of Iowa, Iowa City, IA; <sup>3</sup>Department of Pharmaceutical Sciences and Experimental Therapeutics, The University of Iowa, Iowa City, IA; <sup>4</sup>Department of Occupational and Environmental Health, The University of Iowa, Iowa City, IA.

Polychlorinated biphenyls (PCBs) are legacy pollutants that exert toxicity of various mechanisms. Lower chlorinated or lighter PCBs (LC-PCBs) are semi-volatile, and air-borne. In the old public school building in New York City, the EPA in 2012 has

estimated that students are inhaling six times more PCBs than they are receiving from dietary sources. However, LC-PCBs or metabolites have been rarely reported in the serum of population at risk. LC-PCBs are bioactivated to phenols and further to quinone electrophiles with genotoxic/carcinogenic potential. We hypothesized that phenolic LC-PCBs are subject to phase II conjugation and excretion via urine. Our objective was to identify the final metabolites in the urine that could be potentially employed in the exposure analysis of LC-PCBs. Male Sprague Dawley rats (150-175 g) were housed in metabolism cages and received a single intraperitoneal injection of 600  $\mu\text{mol/kg}$  body weight of PCB3. Control animals received corn oil only. Urine was collected every four hours, euthanized at 36 h, and serum was collected. The LC-MS analysis showed that PCB3 sulfates were the major metabolite in both urine and serum. Approximately 3% of the dose excreted in the urine as sulfate; with peak excretion occurring at 10-20 h of post-exposure. The major metabolites were 4'PCB3sulfate, 3'PCB3 sulfate, 2'PCB3 sulfate and presumably a catechol sulfate. Serum level of 4'PCB3 sulfate was  $6.18 \pm 2.16 \mu\text{g/mL}$  while 4'OH-PCB3 was only  $0.095 \pm 0.055 \mu\text{g/mL}$ . This is the first report that sulfated metabolites of PCBs are formed in vivo.

## PS 1267 Significant Megacluster of Total Cancer Mortality among the US Non-White Population.

J. Beaubier<sup>1</sup> and L. Russell<sup>2</sup>. <sup>1</sup>US EPA, Washington DC; <sup>2</sup>US EPA, Washington DC. Sponsor: J. Murphy.

NCI and EPA collaborated to describe the U.S. population cancer mortality experience for the 1950's, 60's and 70's. All mortality data are official statistics including 8 million records. For the 30 years, for all anatomic cancer sites, there was a significant difference in the percentage rate of increase between White and Non-white U.S. males. The White male increase was 17 %. For the same period, Non-white males experienced a 46 % increase. For both White and Non-white males highest rates of increase were in the Southeastern United States. The project also examined lung cancer. For White male lung cancer mortality, all ~3050 U.S. counties were ranked by percentile of their absolute rates. The counties were marked as red (99-98 percentile of absolute rates), orange (97-95 %), yellow (94-90 %), tan (89-75 %) and blue background (74-1 %). In the 1970s a significant megacluster of White male lung cancer mortality emerged in the Southeastern U.S. The counties show up as strings along rivers. But the important unit of analysis is not the rivers, but U.S. Geological Survey (USGS) hydrologic units. Principal component analysis showed some USGS hydrologic units were more informative: USGS Region 08-02 St. Francis river valley experienced a 300% increase in White male lung cancer mortality in the 1970s, or a 10 % increase per year. The heavily forested, rich bottom lands of the river valley were cut down and planted in cotton sprayed with DDT. DDT induces male rat lung cancers. The strings of high rate White male lung cancer counties lie predominately in the USGS Coastal Plains physiographic domain. During late Cenozoic and Tertiary Eras the Coastal Plains filled in with unconsolidated gravels and sands, porous to pollutants leaching into shallow wells and aquifers. Relative risk of a red county being within the Coastal Plains was 5.3 times greater than being in another part of the U.S. Color coded counties showed a "dose-related" effect - the higher the county rate, the more likely it was located in the Coastal Plains. Authors solely responsible for conclusions herein and do not reflect authors' institutions.

## PS 1268 Airborne Diacetyl from Cooking and Consumption of Microwave Popcorn: Estimation of Consumer Exposure with a Two-Zone Near-Field/Far-Field Model.

H. M. Bolstad<sup>1</sup>, K. M. Unice<sup>2</sup>, J. R. Maskrey<sup>2</sup>, D. M. Hollins<sup>1</sup>, B. D. Kerger<sup>3</sup> and D. J. Paustenbach<sup>1</sup>. <sup>1</sup>ChemRisk, San Francisco, CA; <sup>2</sup>ChemRisk, Pittsburgh, PA; <sup>3</sup>ChemRisk, Orange County, CA.

Diacetyl is a volatile diketone used to impart a butter flavor to foods such as microwave popcorn. Occupational exposure to airborne diacetyl has been reported to be associated with obstructive lung disease, and recent concerns have emerged regarding exposures to diacetyl by consumers. Given the absence of data on the airborne concentrations in the home, we estimated consumer exposure using a two-zone near-field/far-field model in which the near-field is a hemisphere above the microwave popcorn bag, and conducted Monte Carlo uncertainty and sensitivity analyses. A recent study revealed that an average of  $778.9 \pm 135 \mu\text{g}$  diacetyl was emitted during the popping, opening, and 40 minutes following opening. As part of the input to the model, we estimated that diacetyl is released into the breathing zone over a 40 minute period (a typical consumption duration) comprised of popping (2.5 min), opening (15 sec), and consumption (37.25 min). Based on available information, we estimated that 98.9% of the total diacetyl emitted was re-

leased during opening. The popcorn and the bag were assumed to be an arm length away from the nose of the consumer and present for the duration of the scenario. The estimated mean airborne diacetyl concentration in the breathing zone from one bag of microwave popcorn was 0.0030 ppm, whereas the 5th and 95th percentile concentrations were 0.0018 and 0.0048 ppm, respectively. Assuming complete absorption following inhalation and a breathing rate associated with light activity (0.6 m<sup>3</sup>/hr), the estimated mean total intake by inhalation per bag was 5.3  $\mu\text{g}$ . By comparison, the daily intake associated with occupational exposure at the eight hour TWA and 15 minute STEL Threshold Limit Values set by ACGIH (0.01 and 0.02 ppm, respectively) are 66 and four-fold greater, respectively.

## PS 1269 Examination of Specificity of Retinoid-Like Compounds for RXRs, RARs and RORs.

P. P. Albrecht<sup>1</sup>, K. Toyokawa<sup>1</sup>, E. Maddox<sup>1</sup>, P. Cramer<sup>1</sup>, B. Sher<sup>1</sup> and J. Vanden Heuvel<sup>1,2</sup>. <sup>1</sup>Indigo Biosciences, State College, PA; <sup>2</sup>Department of Veterinary and Biomedical Sciences, Pennsylvania State University, University Park, PA.

Vitamin A (retinol) and its metabolites play many physiological roles including cell differentiation, cell proliferation, energy homeostasis, circadian rhythm and immune response. Vitamin A and its metabolites are known to act through retinoid acid receptors (RARs), retinoid-related orphan receptors (RORs) and retinoid x receptors (RXRs). These receptors are also important drug targets, although the specificity of many retinoid-like compounds for the retinoid receptors has not been carefully explored due to the lack of robust and selective assays. In the present work we examined the retinoid-like compounds 4-hydroxyphenylretinamide, 4-hydroxyretinoic acid, 9-cis retinoic acid (9CRA), 13-cis retinoic acid (13CRA), AC-55469, Acitretin, Adapalene, AM-580, All-trans retinoic acid (ATRA), BMS961, Docosahexanoic acid (DHA), EC23, Eicosapentaenoic acid (EPA), ER50891, HX531, HX630, Methoprene, Methoprene acid, MM11253, Puerarin, RO 41-5253, SR1001, TO901317, TTNPB, and Ursolic acid for their ability to regulate RAR $\alpha$ ,  $\beta$ ,  $\gamma$ , RXR $\alpha$ ,  $\beta$ ,  $\gamma$ , and ROR $\alpha$ ,  $\beta$ ,  $\gamma$ . The compounds were tested for agonistic as well as antagonistic activities towards these receptors. Additionally cytotoxicity assays were performed to assess true antagonistic activity. Many of these compounds show a broad range of receptor activity (for example, EC23 shows agonistic activity for all three RARs) while others were highly selective. The data further illustrate the need to test new retinoic acid like drugs across the panel of RXRs, RARs and RORs to limit untoward effects.

## PS 1270 Oxidative Formation of the High Affinity Endogenous Aryl Hydrocarbon Receptor Ligand 6-Formylidolo(3, 2-B)Carbazole (FICZ).

U. Rannug<sup>1</sup>, A. Smirnova<sup>1</sup>, L. Vikström Bergander<sup>2</sup>, E. Wincent<sup>2</sup>, T. Alsberg<sup>3</sup> and A. Rannug<sup>2</sup>. <sup>1</sup>Department of Genetics, Microbiology & Toxicology, Stockholm University, Stockholm, Sweden; <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Department of Applied Environmental Science, Stockholm University, Stockholm, Sweden.

The endogenous high affinity aryl hydrocarbon receptor agonist FICZ is formed upon irradiation of tryptophan with UV or visible light. To elucidate the mechanisms in more detail photooxidation products were analyzed by HPLC and LC/MS. The results revealed that the formation of FICZ was dependent on H<sub>2</sub>O<sub>2</sub> since additions of catalase inhibited the reaction. It was also evident that indole-3-acetaldehyde (I-3-A) was a precursor that spontaneously generated FICZ. Monoamine oxidases (MAOs) catalyze the oxidative deamination of monoamines resulting in the corresponding aldehydes. Human recombinant MAO A and MAO B were therefore incubated with tryptamine to yield I-3-A. After the reaction and a post treatment period the amounts of I-3-A and FICZ were measured. Both enzymes generated I-3-A, which was then spontaneously converted to FICZ. Subsequently, tryptophan was incubated with H<sub>2</sub>O<sub>2</sub> at 37 °C in the dark. The mixture was concentrated on Sep-Pak C18, and HPLC and MS analyses confirmed the formation of FICZ from tryptophan by H<sub>2</sub>O<sub>2</sub>. From these and other experiments it can be concluded that tryptophan can give rise to FICZ in an oxidative environment, i.e. containing or producing reactive oxygen species. In addition, whenever I-3-A is formed there is a possibility for spontaneous formation of FICZ. Altogether, this implies that there are several different conditions under which the endogenous Ah receptor ligand FICZ can be formed in the body. Of great interest in this respect is a recent demonstration of FICZ in the skin of vitiligo patients characterized by a massive epidermal oxidative stress and high levels of H<sub>2</sub>O<sub>2</sub> (Schallreuter et al., FASEB J, 2012). It therefore seems likely that FICZ is ubiquitous in the human body but expected to be present at low steady state levels under normal conditions.

**PS 1271 The Aryl Hydrocarbon Receptor Regulates the Expression of Multiple Growth Factors in Highly Metastatic Head and Neck Squamous Cell Carcinoma Cell Lines.**

K. John<sup>1,2</sup>, J. Hughes<sup>1</sup>, T. S. Lahoti<sup>1</sup>, K. Wagner<sup>1</sup> and G. H. Perdew<sup>1</sup>. <sup>1</sup>Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA; <sup>2</sup>DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.

The aryl hydrocarbon receptor (AHR) is a ligand activated transcription factor implicated in the regulation of diverse cellular processes. Previous studies in head and neck squamous cell carcinoma cell lines (HNSCC) have revealed considerable constitutive and ligand inducible AHR transcriptional activity. Antagonism of AHR activity through AHR antagonist treatment was found to greatly attenuate the highly metastatic and proliferative phenotype of these cells, suggesting that AHR plays a significant role in contributing to the 'aggressive' phenotype of these cells. Therefore, this study sought to use expression profiling to identify putative novel targets of the AHR repressed by AHR antagonist treatment that are associated with cancer cell survival and tumor invasiveness. Three growth factor targets were considered; amphiregulin (AREG), epiregulin (EREG) and platelet-derived growth factor A (PDGFA) identified by expression profiling and from previous studies. Quantitative PCR analysis revealed an attenuation of basal and/or induced gene expression levels of these growth factors in two HNSCC lines after AHR antagonist treatment. ELISA analysis revealed attenuation of both basal and induced protein levels of the growth factors examined in these cell lines. In addition, siRNA-mediated knock down of AHR exhibited attenuation of growth factor expression. In silico analysis revealed these growth factors possess dioxin-like response elements. Additionally, two other AHR ligands, 6-formylindolo[3,2-b]carbazole and benzo(a)pyrene also exhibited induction of the AHR target genes examined. In conclusion, AREG, EREG and PDGFA were identified as three key growth factor targets of the AHR associated with metastatic phenotype of head and neck cancers.

**PS 1272 Hepatocarcinogenesis Induced by a Potent, High Affinity Human PPAR $\alpha$  Agonist Is Diminished in PPAR $\alpha$ -Humanized Mice.**

J. E. Foreman<sup>1</sup>, T. Koga<sup>1</sup>, O. Kosyk<sup>2</sup>, L. R. Kramer<sup>1</sup>, F. J. Gonzalez<sup>3</sup>, I. Rusyn<sup>2</sup> and J. M. Peters<sup>1</sup>. <sup>1</sup>Pennsylvania State University, University Park, PA; <sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>National Cancer Institute, Bethesda, MD.

PPAR $\alpha$ -null mice and PPAR $\alpha$ -humanized mice are both resistant to hepatocarcinogenesis induced by a PPAR $\alpha$  agonist Wy-14,643, a compound that has higher affinity towards the mouse PPAR $\alpha$  as compared to the human PPAR $\alpha$ . While the studies demonstrating these differences suggest that the mouse PPAR $\alpha$  is a key mediator in the hepatocarcinogenic effects of PPAR $\alpha$  agonists and that species differences exist, it was noted the duration of the studies was limited to ~1 year, and the PPAR $\alpha$  agonist has higher affinity for the mouse PPAR $\alpha$  as compared to the human PPAR $\alpha$ . Thus, the present study examined the effect of a potent, high affinity human PPAR $\alpha$  agonist (GW7647) on hepatocarcinogenesis in wild-type, PPAR $\alpha$ -null, or PPAR $\alpha$ -humanized mice. Dietary administration of GW7647 for up to 18 months caused severe hepatomegaly in wild-type mice. This effect was not found in similarly treated PPAR $\alpha$ -null mice and was diminished in humanized-PPAR $\alpha$  mice. Mortality prior to 18 months of treatment was generally found in greater proportion in wild-type mice fed GW7647 as compared to similarly treated PPAR $\alpha$ -null or PPAR $\alpha$ -humanized mice. Administration of GW7647 for up to 18 months caused close to 100% incidence of hepatocarcinogenesis in wild-type mice, but this effect was largely diminished in PPAR $\alpha$ -null mice and PPAR $\alpha$ -humanized mice. Tumors were present in some PPAR $\alpha$ -null and PPAR $\alpha$ -humanized mice, but they occurred in both control and treated animals at frequencies well below those found in wild type mice. Gross examination and results from additional molecular analysis suggests a difference in mechanism between these tumors and those induced by GW7647 in wild-type mice, but further analysis will be important for determination of mode of action. Results from these studies provide further mechanistic evidence for the species difference in the hepatocarcinogenesis of a high affinity human PPAR $\alpha$  agonist. **PS 1273 Arsenic Inhibits 3T3-L1 Adipogenesis and Suppresses Induction of Nuclear Receptors during the Earliest Stages of Differentiation.**

F. Zandbergen<sup>1</sup>, A. Adebayo<sup>1,2</sup>, M. M. Vantagoli<sup>1,2</sup>, V. Chatikavanij<sup>1</sup> and J. W. Hamilton<sup>1,2</sup>. <sup>1</sup>Marine Biological Laboratory, Woods Hole, MA; <sup>2</sup>Brown University, Providence, RI.

Chronic environmental exposure to inorganic arsenic (As) is associated with an increased risk of serious illnesses, including type 2 diabetes and cardiovascular disease (CVD), which in turn are often associated with aberrant blood lipid levels and excess adipose tissue. Since we had previously shown that inorganic arsenite (As) can suppress activation of steroid and other nuclear hormone receptors we hypothesized that it might also affect adipose lipid metabolism by targeting these or other members of the nuclear receptor family. Treatment of mouse 3T3-L1 cells with As during their differentiation into adipocytes resulted in reduced lipid content and suppressed induction of the master adipogenic transcription factors PPAR $\gamma$  and C/EBP $\alpha$  and their target genes. Transient As exposures showed that final lipid content was reduced most in cultures that had been exposed during the initial induction phase of adipogenesis. As did not decrease protein and phosphorylation levels of C/EBP $\beta$  - the transcriptional regulator of PPAR $\gamma$  and C/EBP $\alpha$ . C/EBP $\beta$  acquires its transactivation activity when growth-arrested 3T3-L1 preadipocytes re-enter the cell cycle and undergo a couple of mitoses in response to a combination of hormones, an event required for their differentiation into adipocytes. Interestingly, As increased protein expression of the cell cycle inhibitor p27, suggesting it blocks mitotic clonal expansion, and this may be the proximal event resulting in a cascade of downstream effects. Interference of As with differentiation of adipocytes and/or adipocyte-regulated lipid metabolism in vivo might lead to pathophysiological changes in plasma lipid levels and regulation of lipid storage in adipose tissue and liver, which in turn may contribute to the known association between As exposure and increased risk of type 2 diabetes, CVD and other metabolic disorders. (Funded by NIH-NIEHS SRP (P42 ES007373), and NIH-NRSA (2 T32 ES 7272-21))

**PS 1274 Liver X Receptor and Pregnane Xenobiotic Receptor Crosstalk on Direct Repeat 4 (DR4) Response Elements Is Sequence Dependent.**

K. Falkner<sup>1</sup>, B. Wahlang<sup>1</sup>, H. Bellis-Jones<sup>1</sup>, H. Clair<sup>1</sup>, R. Prough<sup>3</sup> and M. Cave<sup>1,2</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY; <sup>3</sup>Biochemistry, University of Louisville, Louisville, KY.

As both the human Liver X-Receptor  $\alpha$  (LXR) and the human Pregnane Xenobiotic Receptor (PXR) bind to a Direct Repeat 4 (DR4) response elements (RE), we compared the effects of co-transfection of either LXR, PXR or a combination of both receptors on their ability to transactivate different DR4 response elements containing reporter genes. Animal studies suggested that over-expression/activation of either of these receptors results in steatosis. Both reporters contained the same hexa-nucleotide (AGTTCA) core repeat but vary in the sequences in the immediate 5' and 3' positions. HepG2 cells were transfected with plasmids expressing human PXR and human LXR; receptor-responsive reporter plasmid, pGL3-PXRE-luciferase and tk-LXR-RE-luciferase. Cells were treated with known positive ligands for the respective receptors. The first reporter, optimized for PXR binding, was activated by co-transfection of PXR treated with 10 $\mu$ M rifampicin and known LXR ligand T0901317 (100nM), demonstrating that T0901317 is a PXR agonist. This reporter was also activated by LXR in the presence of T0901317. In combination, co-transfection resulted in increased fold induction of this reporter with both rifampicin and T0901317. Our LXR selective DR4 reporter was activated by T0901317 when LXR was co-transfected. The reporter was not activated by PXR either in the presence of rifampicin or T0901317. In contrast to the PXR optimized DR4 construct, co-transfection of both receptors resulted in a loss of LXR dependent activation of the reporter by T0901317. These results suggest that both positive and negative interactions are possible between these receptors and therefore, the response of target genes may vary considerably, based in part on minor differences in the nucleotide sequence of the DR4 response elements. Major crosstalk should be anticipated between the predominantly endobiotic LXR $\alpha$  and the predominantly xenobiotic receptor, PXR.

**PS 1275 Selective Activation of Human Pregnane X Receptor, Vitamin D Receptor, and Glucocorticoid Receptor by Flavonols.**

A. Lau and T. K. Chang. Faculty of Pharmaceutical Sciences, The University of British Columbia, Vancouver, BC, Canada.

Pregnane X receptor (PXR), vitamin D receptor (VDR), and glucocorticoid receptor (GR) regulate the expression of many genes, including those involved in the bioactivation and detoxification of drugs, toxicants, and endogenous chemicals.

Naturally occurring flavonols have been reported to possess paradoxical biological activities in vitro and in rodents; e.g. chemoprevention and exacerbation of estrogen-induced tumorigenesis. Previously, quercetin, kaempferol, and tamarixetin were reported to activate human PXR (hPXR). However, it is not known whether there is a structure activity relationship in the activation of hPXR by flavonols and whether they activate human VDR (hVDR) and human GR (hGR). In the present study, we compared the effects of structurally related flavonols (i.e. flavonol, galangin, datiscetin, kaempferol, morin, quercetin, isorhamnetin, tamarixetin, myricetin, and syringetin) on the activity of hPXR, hVDR, and hGR. Only flavonol, galangin, isorhamnetin, tamarixetin, and quercetin activated hPXR, whereas none of them activated hGR or hVDR, as determined in dual-luciferase reporter gene assays in transfected HepG2 human hepatoma cells. Dose-response experiments indicated that the minimum effective concentration for hPXR activation by these flavonols was 10-30  $\mu$ M. Flavonol and galangin, but not isorhamnetin, tamarixetin, or quercetin, recruited steroid receptor coactivator-1 (SRC-1), SRC-2, and SRC-3 to the ligand-binding domain of hPXR, as assessed by mammalian two-hybrid assays. Flavonol and galangin bound to the ligand-binding domain of hPXR in a time-resolved fluorescence resonance energy transfer competitive ligand-binding assay. Overall, flavonols activate hPXR in a receptor-selective and chemical-dependent manner. The addition of OH or OCH<sub>3</sub> group at C2' and C5' positions in Ring B of flavonol appears to be unfavorable. Therefore, a minor change in chemical structure leads to abolishment of hPXR activation, implying that flavonols may have differential impact on hPXR-mediated effects. [Supported by CIHR and MSFHR]

### PS 1276 A Novel Aryl Hydrocarbon Receptor 1 Sequence from Rainbow Trout (*Oncorhynchus mykiss*) Brain.

A. M. Kalinoski, J. M. Preslar, M. M. DeRocher, D. M. Hollis and E. V. Hestermann. *Biology Department, Furman University, Greenville, SC.*

The aryl hydrocarbon receptor (AhR) is a cytosolic protein receptor that mediates the toxic effects of polynuclear aromatic hydrocarbons, polychlorinated biphenyls, and other halogenated aromatic hydrocarbons. Two isoforms of AhR (AhR2 $\alpha$  and AhR2 $\beta$ ) have been described in rainbow trout (*Oncorhynchus mykiss*). However, AhR1 (the presumed ortholog of mammalian AhR) has yet to be sequenced. A novel AhR sequence was obtained through Rapid Amplification of cDNA Ends (RACE) of *O. mykiss* whole brain cDNA. Comparison of amino acid sequence in the conserved bHLH and PAS regions and phylogenetic analysis revealed that the new sequence is an AhR1. Tissue-specific expression of all three AhR forms was studied by qRT-PCR. AhR2 $\alpha$  and 2 $\beta$  showed similar patterns of expression and were found in the highest concentration in the heart, gill, and bulbus arteriosus. AhR1 was found in the highest concentration in the white muscle, heart, and brain. These results suggest that the newly sequenced AhR1 is functionally distinct from the previously described AhR2 forms.

### PS 1277 Ginsenosides Are Novel AH Receptor Ligands.

Q. Hu<sup>1</sup>, G. He<sup>2</sup>, J. Zhao<sup>2</sup>, A. Soshilov<sup>2</sup>, M. S. Denison<sup>2</sup>, H. Yin<sup>3</sup>, Q. Xie<sup>1</sup> and B. Zhao<sup>1</sup>. <sup>1</sup>State Key Laboratory of Environmental Chemistry and Ecotoxicology, Research Center for Eco-Environmental Sciences, Beijing, China; <sup>2</sup>Department of Environmental Toxicology, University of California Davis, Davis, CA; <sup>3</sup>Xiyuan Hospital, China Academy of Chinese Medical Sciences, Beijing, China.

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that mediates many of the biological and toxicological actions of structurally diverse chemicals. In this study we have examined the ability of a series of ginsenosides extracted from ginseng, a traditional Chinese medicine, to bind to and activate/inhibit the AhR signal pathway. The ability of the ginsenosides to stimulate/inhibit AhR-dependent luciferase gene expression was examined using a recombinant guinea pig adenocarcinoma (G16L1.1c8) cell line containing a stably integrated DRE-driven firefly luciferase reporter plasmid pGudLuc1.1. Our data show that the ginsenosides Rc and Rh1 are not only relatively weak inducers of AhR dependent gene expression compared to that of TCDD, but we demonstrated their ability to compete with [3H]TCDD for binding to and stimulate transformation and DNA binding of the guinea pig cytosolic AhR in vitro by utilizing a combination of ligand and DNA binding assays. The overall ability of these ginsenosides to stimulate AhR signal transduction demonstrates that these ginsenosides are a new class of naturally occurring AhR agonists. The weaker activity of these compounds may be due to their relatively large size, which results in steric hindrance within the AhR ligand binding pocket, although it remains to be determined whether the entire compound fits into the binding pocket. Considering the currently large consumption of ginseng, further studies into the molecular mechanisms of ginsenosides action, including involvement of the AhR pathway, are needed in order to better understand the diverse effects of these chemicals.

### PS 1278 Comparison of Serum Chemistry and Tissue Phenotypes in Aryl Hydrocarbon Receptor Knockout Rats and Mice.

R. Budinsky<sup>2</sup>, J. A. Harrill<sup>1</sup>, R. Hukkanen<sup>2</sup>, J. Rowlands<sup>2</sup> and R. S. Thomas<sup>1</sup>. <sup>1</sup>ICSS, The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>TERC, The Dow Chemical Company, Midland, MI.

An aryl hydrocarbon receptor knockout (AHR-KO) rat was generated on a Sprague-Dawley outbred background in order to investigate the mode-of-action of 2,3,7,8-tetrachlorodibenzo-dioxin (TCDD) tumorigenesis. Aside from its role as a xenobiotic receptor, there is evidence that the aryl hydrocarbon receptor (AHR) plays a critical role in the development of some tissues. Previous reports describe a variety of tissue abnormalities in the liver, heart and kidney in AHR-KO mice. We conducted a comparative study of gross tissue pathology, histology and serum chemistry in AHR-KO rats and mice, and corresponding wild-types at 1, 6 and 12 weeks of age (n = 5 / sex / genotype / species) in order to evaluate the role of the AHR in tissue development across species. Adult AHR-KO mice, but not AHR-KO rats, had alterations in many serum chemistry markers associated with compromised liver function as compared to wild-type. Similarly, in adult AHR-KO mice, decreased liver-to-body weight and increased kidney- and heart-to-body weight ratios were observed. Similar changes were not observed in AHR-KO rats, save increased kidney-to-body weight ratios in females. Hepatic developmental abnormalities including portal hypercellularity, biliary reduplication, hepatocellular vesiculation and increased extramedullary hematopoiesis were observed in 1 week old AHR-KO mice and gradually dissipated across 6 and 12 week time points. Adult AHR-KO mice also had patent ductus venosus. None of these histological or gross morphological liver phenotypes were observed in AHR-KO rats. In contrast, AHR-KO rats had severe urinary tract pathology including hydronephrosis, hydronephrosis with secondary renal pelvic dilation, epithelial hyperplasia and mineralization leading to degenerative and inflammatory changes in cortical nephrons. Renal pathology was not observed in AHR-KO mice. Overall, these data indicate that the endogenous role of AHR in tissue development differs significantly between rats and mice.

### PS 1279 Selective AhR Modulator-Mediated Suppression of Acute Joint Edema Associated with Gouty Arthritis.

I. Murray, T. S. Lahoti, G. Krishnegowda, S. G. Amin and G. H. Perdew. *Pennsylvania State University, University Park, PA.*

Gouty arthritis is an inflammatory condition associated with the joints of subjects with high circulating levels of uric acid. Multiple factors promote the deposition of uric acid salt crystals within the synovium, which initiates an immune response resulting in a proinflammatory cytokine cascade and subsequent acute joint inflammation. Here, we examine the topical efficacy of the selective AHR modulator (SAHRM) SGA360 as an antiinflammatory therapy to suppress biomarkers associated with the *in vivo* monosodium urate (MSU) crystal model of gouty arthritis in C57BL/6J mice. Intraarticular (i.a.) injection of MSU into the ankle joints of subjects prompted a dose dependent increase in joint edema over sham controls, as determined through micrometry. Peak inflammation was manifest 24-36 h post injection and resolved over time. Edema was associated with significantly enhanced gene expression of the inflammatory mediators *Il1b*, *Cxcl1*, *Saa3*, *Ptgs2* and *Sphk1*, as assessed by quantitative PCR. Topical application of SGA360 at 6 h intervals after i.a. injection of MSU identified an attenuation of joint edema at 24 h when compared to controls. *Ahr* null mice revealed no significant difference in the level of MSU-induced edema when compared to wild-type. MSU-dependent edema in *Ahr* null mice proved to be refractory to the effects of SGA360 and thus established a requirement for AHR to mediate its antiinflammatory potential. Substitution of SGA360 with an AHR antagonist failed to inhibit MSU-induced edema in wild-type mice suggesting the action of SGA360 is independent of competition with endogenous AHR agonists. Analysis of MSU-induced gene expression in the context of SGA360 revealed a suppression of the mediators *Il1b*, *Cxcl1*, *Saa3*, *Ptgs2* and *Sphk1*. Furthermore, exposure to SGA360 following the establishment of edema revealed an increased rate of inflammatory resolution when compared to controls. These studies indicate that SAHRMs such as SGA360 may provide an effective topical therapy against acute inflammation associated with gouty arthritis.

**PS 1280 Aryl Hydrocarbon Receptor (AHR) Regulates Growth Factor Expression, Proliferation, Protease-Dependent Invasion and Migration in Primary Fibroblast-Like Synoviocytes from Rheumatoid Arthritis Patients.**

T. S. Lahoti<sup>1</sup>, K. John<sup>1,2</sup>, J. M. Hughes<sup>1</sup>, B. Zhu<sup>1</sup>, I. Murray<sup>1</sup>, J. M. Peters<sup>1</sup> and G. H. Perdew<sup>1</sup>. <sup>1</sup>Veterinary Sciences, Pennsylvania State University, University Park, PA; <sup>2</sup>DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.

Rheumatoid arthritis (RA) is a chronic autoimmune disease. It is characterized primarily by proliferation of cells in the synovial lining such as fibroblast-like synoviocytes (FLS). Under non-RA settings, FLS are a highly differentiated unicellular cell type. However, under inflammatory milieu, they become hyperplastic, invasive and highly migratory. Epidemiological studies have identified a positive correlation between cigarette smoking, a source of agonistic AHR ligands, and the progressive phenotype of RA. Thus, under inflammatory conditions, we hypothesize the AHR plays an important role in the expression of several growth factors in FLS. Our AHR gene knockdown data in IL-1B activated primary FLS suggest a positive link between ablation of AHR protein activity and suppression of inducibility of vascular endothelial growth factor-A (*VEGF-A*) and epiregulin (*EREG*) mRNA levels. GNF351, a potent AHR antagonist, was also shown to suppress cytokine-mediated upregulation of *VEGF-A*, *EREG* and basic fibroblast growth factor (*FGF-2*) expression, further validating the AHR dependency. ELISA was performed on supernatants collected from FLS-RA cells pre-exposed to GNF351, followed by stimulation with IL-1B, which revealed AHR antagonist-mediated suppression of VEGF-A activity. Cytokine dependent activation of growth factors has been shown to enhance FLS cell proliferation, which was attenuated by GNF351 pretreatment. Upon activation by cytokines, FLS have been shown to become invasive and highly migratory. Treatment of FLS with GNF351 mitigated cytokine-mediated expression of matrix metalloproteinases (MMP) -2 and -9 mRNA levels and also diminished FLS invasive phenotype. Overall, these results suggest that the AHR may be a viable therapeutic target in amelioration of disease progression in rheumatoid arthritis.

**PS 1281 Pregnane X Receptor and Cytochrome P450 CYP2 and CYP3 Gene Responses to Potential Agonists for PXR and AhR2 in Developing Zebrafish.**

A. Kubota, J. Goldstone, B. Lemaire, M. Takata, B. Woodin and J. Stegeman. Biology Department, Woods Hole Oceanographic Institution, Woods Hole, MA.

We addressed responses of developing zebrafish to potential agonists for the pregnane X receptor (PXR; also Steroid Xenobiotic Receptor SXR) and the aryl hydrocarbon receptor (AHR) to determine involvement and interaction of PXR and AHR signaling pathways in regulation of genes in cytochrome P450 subfamilies CYP2 and CYP3. Zebrafish embryos were exposed to 5-pregnen-3 $\beta$ -ol-20-one (pregnenolone; 1-10  $\mu$ M) or to carrier (DMSO) for 24 h, starting at 48 hours post-fertilization (hpf), and then harvested at day 3. We also exposed one-day-old embryos to 3,3',4,4',5-pentachlorobiphenyl (PCB126) or DMSO for 24 h and then held in clean water until day 4. Expression of PXR and selected CYP genes that are potential targets in the PXR signaling was assayed. Pregnenolone caused a concentration-dependent increase in mRNA expression of PXR, some CYP2AAs, CYP3A65 and CYP3C1, all of which peaked at 3  $\mu$ M and then declined. An AHR agonist PCB126 also upregulated the transcript levels of those genes in most cases in a concentration-dependent manner. We next sought to examine the role of the PXR and AHR in the modified expression of those potential target genes by using morpholino antisense oligonucleotides (MO or morpholino) to block initiation of translation of the PXR or AHR. Treatment of embryos with the PXR-MO, but not the control morpholino, partially inhibited pregnenolone-induced expression of PXR, CYP2 and CYP3 genes. Similarly, AHR2-MO treatment blocked PCB126-induced transcript expression of PXR and some CYP2 and CYP3 genes. The present study shows that PXR is not only self-upregulated, but also upregulated via activation of AHR2 in developing zebrafish. Selected zebrafish CYP2 and CYP3 genes appear to be in part under the regulation of PXR and AHR2. They include some CYP2AAs that were first identified in zebrafish. [Support: JSPS Postdoctoral Fellowships for Research Abroad no. 820 (A.K.), and NIH Superfund Research Program grant P42ES00738 (J.S.)]

**PS 1282 Aryl Hydrocarbon Receptor Reduces Cholesterol Absorption by Regulating NPC1L1 Expression.**

R. Tanos, A. Kusnadi and G. H. Perdew. Pennsylvania State University, University Park, PA.

Activation of Ah receptor (AHR) by an exogenous ligand such as dioxin is known to mediate the expression of target genes (e.g. CYP1A1), by binding to dioxin response element (DRE) sequences in their promoter region. We have previously demonstrated the ability of the receptor to attenuate the hepatic expression of cholesterol synthesis genes in a DRE-independent manner in mice and humans without affecting the levels of SREBP2. We opted to look at any changes in the levels of the NPC1L1 protein, a transcriptional target of SREBP2. NPC1L1 is known to mediate the intestinal absorption of dietary cholesterol and is clinically targeted by the drug Zetia, usually used in combination treatment with statins. NPC1L1 is also expressed in the liver although its exact function in this tissue has not been determined conclusively. To examine the effect of AHR activation on NPC1L1 expression, C57BL/6J mice and primary human hepatocytes were exposed to the AHR agonist B-naphthoflavone or selective ligand SGA 360 and results revealed a dramatic repression in the hepatic gene expression of NPC1L1. Attenuation of the expression levels of this gene was also confirmed in the intestine of C57BL/6J mice and a human intestinal cell line (Caco-2 cells). Additionally, activation of the receptor was capable of overcoming the statin-induced increase in NPC1L1 gene expression. Through mutagenesis experiments targeting the two DRE sequences present in the promoter region of the NPC1L1 gene, we established that the repression does not require functional DRE sequences; while knock-down experiments demonstrated that this regulation is AHR-specific and independent of the co-factor p300 and the transcription factor YY1. Finally, cholesterol absorption was shown to be reduced in human intestinal cells following AHR activation. These observations clearly establish a role for the AHR as a key regulator of cholesterol absorption and indicate the potential use of this receptor as a target for the treatment of metabolic diseases.

**PS 1283 Generation and Characterization of a Hairless Mouse Model to Study the Role of Aryl Hydrocarbon Receptor Activation in Response to Ultraviolet Light Exposure.**

K. J. Smith, T. S. Lahoti, J. A. Boyer, K. Wagner, I. Murray and G. H. Perdew. Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.

The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor known to be a mediator of biological responses to external stimuli. Reports suggest that endogenous ligands of the AHR include tryptophan photoproducts generated upon exposure to ultraviolet (UV) light, such as 6-formylindolo[3,2-*b*]carbazole (FICZ), linking the AHR to cellular processes occurring in response to UV light. Despite advances in treating UV-related pathologies, the prevalence of detrimental health effects due to UV light indicate that novel therapies are needed. To determine the *in vivo* role of the AHR in UV-mediated inflammation, mouse strains expressing the high affinity ligand binding allele (*Ah<sup>b</sup>*) and low affinity ligand binding allele (*Ah<sup>h</sup>*) of the AHR were generated on an SKH1 hairless mouse background. These strains were characterized using genotyping, AHR proteotyping, and saturation ligand binding assays. The *Ah<sup>b</sup>* allele hairless strain was functionally characterized by the application of FICZ to the ears and compared to SKH1 mice, which exhibit the *Ah<sup>h</sup>* allele, to determine levels of *Cyp1a1* induction, an indicator of AHR transcriptional activity. The *Ah<sup>b</sup>* hairless mice showed greater induction of *Cyp1a1* when compared to the SKH1 mice upon FICZ treatment. *Ah<sup>b</sup>* and *Ah<sup>h</sup>* hairless mouse strains were exposed to UV (360 mJ/cm<sup>2</sup>), followed by skin treatment with a selective AHR modulator (SAhRM), to determine the level of induction of inflammatory genes, and the role of selective activation of the AHR in decreasing inflammatory gene expression. Similar induction of inflammatory genes (e.g., *Ptgs2*, *Il6*, *Il1b*) in untreated skin exposed to UV was seen in both mouse strains, but preferential repression of *Il1b* upon SAhRM treatment was observed only in the *Ah<sup>b</sup>* hairless mice. These strains will be useful in determining how the activity of the AHR can be pharmacologically modified to reduce inflammation upon UV exposure.

**PS 1284 Inhibition of Heat Shock Protein-90 Prevents the Transactivation and Translocation of Human Constitutive Androstane Receptor.**

T. Chen, E. M. Laurenzana, D. M. Coslo, F. Chen and C. J. Omiecinski. *Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

17-(Dimethylaminoethylamino)-17-demethoxygeldanamycin (17-DMAG) is currently in clinical trials for cancer treatment. 17-DMAG is a hydrophilic derivative of geldanamycin (GA), and its analog, 17-(allylamino)-17-demethoxygeldanamycin (17-AAG), all inhibitors of the molecular chaperone, heat shock protein-90 (HSP90). 17-DMAG offers a potential advantage over 17-AAG and GA due to its increased bioavailability, limited metabolism and reduced in vivo toxicity. HSP90 inhibition results in defective protein folding, conformation and assembly of its client proteins, promoting their destabilization and degradation. Client proteins of HSP90 include transmembrane tyrosine kinases (e.g., HER2, EGFR), intermediary signaling kinases (e.g., AKT, p53) and nuclear receptor family members (e.g., AHR, PXR). Previous reports demonstrated that HSP90 is a cytosolic tethering partner of the constitutive androstane receptor (CAR). The present investigation evaluated the potential effects of 17-DMAG on human CAR transcriptional activation and nuclear translocation. 17-DMAG treatments repressed CAR-mediated CYP450 induction in cultured human primary hepatocytes. Cell-based gene reporter assays verified that 17-DMAG inhibited hCAR in a dose-dependent manner. Intracellular localization studies revealed that phenobarbital-stimulated nuclear translocation of hCAR in hepatocytes was completely blocked by 17-DMAG, as well as GA. Immunoprecipitation analyses indicated that the suppression of hCAR activity by 17-DMAG resulted from an enhanced interaction between hCAR and HSP90. Mammalian two-hybrid assays further demonstrated that 17-DMAG disrupted the interaction of hCAR with the nuclear co-activator, SRC1. Together, the data indicate that these targeted HSP90 inhibitors markedly disrupt normal hCAR function, suggesting that their clinical use may potentially impact CAR-mediated drug metabolism and clearance.

**PS 1285 Activation of Transient Receptor Potential Ankyrin-1 by Wood Smoke Particulate Material.**

D. Shapiro, C. E. Deering-Rice, E. G. Romero, G. S. Yost, J. M. Veranth and C. A. Reilly. *Pharm/Tox, University of Utah, Salt Lake City, UT.*

Exposure to wood smoke particulate matter (WSPM) has been linked to exacerbation of asthma, development of chronic obstructive pulmonary disease (COPD), and premature death. Combustion-derived PM (cdPM) such as cigarette smoke (CS), diesel exhaust (DEP), and WSPM, activate transient receptor potential ankyrin-1 (TRPA1) which promotes neurogenic inflammation/edema and airway irritation/cough. The mechanism of TRPA1 activation by DEP and CS involves the electrophilic/oxidant binding (3CK) and menthol-binding (ST) sites, and a novel mechanosensitive site. We hypothesized that WSPM would activate TRPA1 through one or more of these sites similar to other cdPM. Pine and mesquite PM were generated in the laboratory. Both types of WSPM particles activated TRPA1 in human TRPA1 over-expressing HEK-293 and primary mouse trigeminal (TG) neurons. WSPM also activated TRPA1 in A549 cells, a human alveolar adenocarcinoma cell line, which has recently been shown to express TRPA1. HC-030031, a TRPA1 specific antagonist, attenuated the calcium flux due to WSPM treatment in both human A549 cells and mouse primary TG neurons. Several known chemical components of WSPM, including 3,5-di-tert-butylphenol and agathic acid were TRPA1 agonists. Both WSPM and agathic acid activated TRPA1 primarily via binding the 3CK site, based on inhibition of calcium flux by glutathione and mutation of the 3CK site. Conversely, 3,5-di-tert-butylphenol activated TRPA1 through the ST site. This study established the mechanism by which WSPM and associated chemical components activated TRPA1 which may help tailor effective therapeutic treatments for WSPM pneumotoxicity. Support: NIEHS ES017431 and the University of Utah Undergraduate Research Opportunities Program.

**PS 1286 Exploratory Phenotype and Molecular Analysis Study in ROR-Gamma Knockout Mice.**

M. J. Horner<sup>1</sup>, R. Guzman<sup>1</sup>, C. Karbowski<sup>1</sup>, J. Schroeder<sup>1</sup>, C. DiPalma<sup>2</sup>, Y. He<sup>2</sup> and C. Afshari<sup>1</sup>. <sup>1</sup>Amgen Inc, Thousand Oaks, CA; <sup>2</sup>Amgen Inc., Seattle, WA.

Retinoid-related orphan receptor  $\gamma$  (ROR $\gamma$ ) is an orphan nuclear hormone receptor that is widely expressed in several tissues including liver and skeletal muscle. Previous gene expression profiling of liver from ROR $\gamma$  knockout (KO) mice suggested a possible role for ROR $\gamma$  in metabolism of steroids, bile acids, and xenobiotics (Jetten et al. 2007). ROR $\gamma$  has also been shown to regulate several metabolism

genes in skeletal muscle cells. The current study was designed to investigate the effects on pathology and genomics of knocking out the ROR $\gamma$  nuclear receptor in mice with a focus on liver and skeletal muscle tissues. Male and female wild type, heterozygote, or homozygote ROR $\gamma$  KO mice (10/group) were assessed at 10 weeks of age. Study endpoints included clinical observations, body weights, organ weights, gross and microscopic examination of tissues, and gene expression evaluation using RNA isolated from liver, skeletal muscle, and spleen. There was no impact with respect to clinical observations, body weight, and pathology on the phenotype of the heterozygous animals when compared with controls. Although no differences in clinical observations or body weights were observed in the homozygous animals, significant microscopic lesions were present in the thymus (thymic hyperplasia and lymphoma), spleen (increased cellularity), and lymph node (absent). These findings were not unexpected and are in line with established literature (Eberl and Littman 2003; Ueda et al. 2002). Pathway analysis of gene expression changes indicated that a majority of the altered pathways were related to immune response, an expected outcome. Skeletal muscle gene changes suggested a possible role for ROR $\gamma$  in energy homeostasis. However, no perturbations in pathways relevant to toxicological consequences were noted. Taken together, the data showed that knocking out of ROR $\gamma$  in mice led to expected changes in immune-associated pathology and gene expression, but did not reveal any additional phenotypic or genotypic toxicologically relevant effects.

**PS 1287 Estrogen Receptor  $\alpha$  and Aryl Hydrocarbon Receptor Are Not the Sole Determinants of Aminoflavone-Mediated Growth Inhibition.**

A. M. Brinkman<sup>1,2</sup> and W. Xu<sup>1,2</sup>. <sup>1</sup>Molecular and Environmental Toxicology Center, University of Wisconsin Madison, Madison, WI; <sup>2</sup>Department of Oncology, University of Wisconsin Madison, Madison, WI.

Numerous studies have suggested that the aryl hydrocarbon receptor (AhR) may be a potential therapeutic target for several human diseases, including estrogen receptor  $\alpha$  (ER $\alpha$ ) positive breast cancer. Aminoflavone (AF), an activator of AhR signaling that is structurally related to phytochemicals called flavonoids, is currently in clinical trials for the treatment of solid tumors. It has been hypothesized that ER $\alpha$  may be a predictor for response to AF-mediated growth inhibition, with ER $\alpha$ -positive cell lines being sensitive to the drug, and ER $\alpha$ -negative cell lines being resistant. However, the scope of cell lines tested in the literature is limited. Here, we show that ER $\alpha$ -negative human breast cancer cell lines express greater amounts of AhR protein compared to ER $\alpha$ -positive human breast cancer cell lines, giving reason to further characterize AF's efficacy in these models. Using cell counting assays to measure GI<sub>50</sub> values, we show that two ER $\alpha$ -negative breast cancer cell lines, MDA-MB-468 and Cal51, exhibit sensitivity to AF (GI<sub>50</sub> < 1 $\mu$ M), suggesting that ER $\alpha$  is not the sole predictor of responsiveness to AF. To examine the mechanism of AF-mediated growth inhibition, a doxycycline-inducible AhR knockdown system was created in these two cell lines. We show that there is no significant difference in growth inhibition caused by AF treatment in cells where AhR is knocked down and cells with endogenous levels of AhR. This suggests that a portion of the mechanism involved in AF-mediated growth inhibition in MDA-MB-468 and Cal51 cells is AhR-independent, or that compensatory mechanisms may exist. Overall, this work suggests that while ER $\alpha$  is not the sole determinant of sensitivity to AF, this compound may also be inhibiting cell growth in an AhR-independent fashion. **PS 1288 Understanding the Physiological Role of Aryl Hydrocarbon Receptor Repressor (AhRR) Using Gene Knock-Down and Targeted Mutagenesis in Zebrafish.**

N. Aluru<sup>1</sup>, S. I. Karchner<sup>1</sup>, M. J. Jenny<sup>1,2</sup> and M. E. Hahn<sup>1</sup>. <sup>1</sup>Biology, Woods Hole Oceanographic Institution, Woods Hole, MA; <sup>2</sup>Biological Sciences, University of Alabama, Tuscaloosa, AL.

The aryl hydrocarbon receptor repressor (AhRR) is a transcriptional repressor of the aryl hydrocarbon receptor (AHR) and is regulated by an AHR-dependent mechanism. In humans, AhRR has been linked to tumorigenesis and reproductive defects. Zebrafish have two AhRR genes; AhRRa regulates constitutive AHR signaling during development, while AhRRb regulates polycyclic aromatic hydrocarbon-induced gene expression. The goal of this study was to elucidate the endogenous role of AhRRs during zebrafish development using two loss-of-function approaches: morpholino oligonucleotide (MO) knock-down and zinc finger nuclease (ZFN)-based gene targeting (knock-out). Zebrafish embryos were microinjected with MOs against AhRRa or AhRRb to knock down the expression of these proteins, followed by microarray analysis of gene expression in embryos at 72 hours post-fertilization. In AhRRa-MO injected embryos, 97 genes were upregulated and 182 genes were downregulated. The latter included cone type photoreceptor-specific

genes, suggesting a role for AHRRa in photoreceptor development. In addition, AHRRa knock-down caused upregulation of embryonic hemoglobin (hbbe3), suggesting a role in hematopoiesis. Knock-down of AHRRb caused upregulation of 31 genes and downregulation of 85 genes, without enrichment of genes related to any specific biological process. These results suggest that AHRRa plays an important endogenous role in development. To understand the role of AHRRa beyond development, we targeted *ahrra* using ZFNs. Microinjection of ZFN mRNA into zebrafish embryos caused a 7 base pair frame shift mutation at the *ahrra* locus. We screened for germline mutants and identified a founder fish that was outcrossed to generate heterozygous mutant offspring. Heterozygous mutants were crossed to generate *ahrra* mutant homozygotes. Using these homozygotes we are investigating the role of AHRRa in normal physiology and toxicology. [Supported by NIH R01ES006272]

**PS 1289 Tissue-Specific Expression of Cytokines and Chemokines in TCDD-Treated B6 and Aryl Hydrocarbon Receptor Repressor Transgenic Mice.**

C. Vogel<sup>1,2</sup>, D. Wu<sup>2</sup>, J. Baek<sup>2</sup>, S. Kado<sup>2</sup>, T. Singh<sup>2</sup>, G. Yang<sup>3</sup>, P. Leung<sup>3</sup>, E. Gershwin<sup>3</sup>, T. Herrmann-Stemmann<sup>4</sup> and E. Matsumura<sup>1,2</sup>. <sup>1</sup>*Environmental Toxicology, University of California Davis, Davis, CA*; <sup>2</sup>*Center for Health and the Environment, University of California Davis, Davis, CA*; <sup>3</sup>*Division of Rheumatology, Allergy and Clinical Immunology, University of California Davis, Davis, CA*; <sup>4</sup>*Institute for Environmental Research, University of Duesseldorf, Duesseldorf, Germany*.

The aryl hydrocarbon receptor (AhR) has been identified as an important transcription factor regulating the responses of immune cells including T cells and dendritic cells but the role of the AhR Repressor (AhRR) is less clear. The AhRR has been first described to suppress AhR activity as an inducible negative feedback loop, then again, there are many unanswered questions, as we know now that the basal or induced cytochrome P450 1A1 (CYP1A1) mRNA level rarely correlates with AhRR expression. To gain insight into the function of AhRR in vivo we developed a transgenic AhRR B6 mouse (AhRR Tg). These transgenic mice express significantly higher levels of AhRR mRNA in all tissues examined such as liver, lymph-node, kidney, spleen, and thymus. Treatment of B6 and AhRR Tg mice with TCDD causes significant induction of AhRR and CYP1A1 in most tissues examined. However, TCDD-induced expression of CYP1A1 was not significantly suppressed in most of the tissues of AhRR Tg mice. The most consistently observed trend in AhRR Tg mice was a repressed induction of several inflammatory markers induced by TCDD as compared to B6 mice. The TCDD-mediated induction in B6 mice as well as the repression in AhRR Tg mice of markers such as IL-1 $\beta$ , IL-6, KC, and COX-2 was tissue-specific. Results show that the AhRR may suppress AhR-mediated induction of inflammatory marker genes and that the AhRR may control AhR activity in the immune system. The cross-talk of AhR with other transcription factors including NF- $\kappa$ B has been well described. Therefore, this study suggests that AhRR interacts especially with alternative AhR pathways rather than simply blocking the classical AhR/ARNT pathway.

**PS 1290 Caloric Restriction Induces Nrf2-Dependent Effects on Lipid Metabolism.**

L. Armstrong, S. R. Kulkarni, J. Xu and A. L. Slitt. *Biomedical and Pharmaceutical Sciences, URI, Kingston, RI.*

Toxcast screening has identified the Nrf2 transcriptional pathway as being highly correlative to chemical promiscuity. Nrf2 is classically defined to have a role in mediating cytoprotection against oxidative stress, but recent work points to a more fundamental metabolic role in lipid metabolism. Studies have indicated that the Nrf2-Keap1 pathway is inducible in adipose tissue, and Nrf2 may have a role in mediating the beneficial effects of caloric restriction (CR). CR promotes the utilization of fat depots and fatty acid mobilization by altering fatty acid synthesis and  $\beta$ -oxidation through modulating Ppar- $\alpha$  and Ppar- $\gamma$  signaling. The potential role of Nrf2 in regulation of lipid metabolism during CR is essential in understanding the metabolic response of white adipose tissue (WAT) to low nutrient conditions. The purpose of the study was to determine the role of Nrf2 in the regulation of lipid metabolism during CR. Adult female lean (C57/BL6) mice and Nrf2KO mice were fed ad-libitum (AL) or placed on a 25% (kCal) reduced diet for 5-7 weeks. Body weight and blood glucose concentrations were monitored. Serum, liver, and white adipose tissues were collected. Hepatic triglycerides, serum free fatty acids, and lipogenic mRNA gene expression in WAT were determined. Overall, CR C57/BL6 mice had a greater percent weight loss (21%) and greater decrease in WAT mass (84%) compared to AL than CR Nrf2KO (11%, 49% respectively). CR C57/BL6

had a 4-fold lower liver triglyceride concentration than AL and 2.5-fold lower concentration compared to CR Nrf2KO. Further analysis of lipogenic genes in adipose tissue supported a dysregulation of the lipogenic pathway in Nrf2KO mice that leads to the resistance of fat utilization during CR. CR increased both Ppar- $\gamma$  and - $\alpha$  along with downstream gene expression (Lpl, Cd36, Scd-1, and Acc-1) in WAT from C57BL/6 mice compared to Nrf2KO mice. Determining whether Nrf2 has a role for mediating beneficial effects for lipid oxidation in WAT could have impact in multiple research areas—including toxicological studies that focus on obesogenic mechanisms.

**PS 1291 Electrophilic Metabolites of Aromatic Hydrocarbons Cause AhR Activation and Up-Regulation of CYP1A1 in HepG2 Cells: Involvement of S-Arylation of Cellular Proteins.**

Y. Abiko<sup>1,2</sup>, A. Puga<sup>2</sup> and Y. Kumagai<sup>1</sup>. <sup>1</sup>*Environmental Medicine Section, University of Tsukuba, Tsukuba, Japan*; <sup>2</sup>*Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

It is well established that aromatic hydrocarbons with 1 or 2 benzene rings and without chlorine substituents are not ligands of the arylhydrocarbon receptor (AHR), a cytosolic ligand activated transcription factor, the main factor responsible for the induction of the *CYP1A1* gene following nuclear translocation. We have recently found that *tert*-butyl-1,4-quinone (TBQ) and 1,2-naphthoquinone (1,2-NQ), electrophilic metabolites of *tert*-butylated hydroxyanisole and naphthalene, respectively, activate NRF2 through S-arylation of its negative regulator, KEAP1. To our knowledge there have not been any reports to indicate that electrophiles that covalently bind to cellular proteins might activate the AHR. In this study, we addressed this question by exposing cells in culture to several of these agents and using immunocytochemistry 12 hours later to determine AHR nuclear translocation. Exposure of HepG2 cells to TBQ, 1,2-NQ, 1,4-NQ or 1,4-benzoquinone, resulted in AHR translocation and *CYP1A1* induction, whereas both measures of AHR activation were negative after treatment with BHA, or naphthalene. Similar results were seen in A459 cells and RAW264.7 cells. TBQ treatment also enhanced the interaction of AHR with ARNT. Interestingly, pretreatment with BSO and NAC to modulate cellular GSH levels enhanced and suppressed 1,2-NQ-mediated activation of AHR, respectively, suggesting that covalent modification of these cellular proteins, possibly through S-arylation of cysteine residues, contributes to the activation. These results suggest that electrophilic metabolites of aromatic hydrocarbons can serve as bifunctional inducers through activation of both AHR and NRF2.

**PS 1292 AhR-Independent Gene Regulation by TCDD in Mouse Liver and Kidney.**

T. M. Seibel<sup>1</sup>, C. Lohr<sup>1</sup>, K. Andresen<sup>2</sup> and D. Schrenk<sup>1</sup>. <sup>1</sup>*Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany*; <sup>2</sup>*Institute of Biotechnology and Drug Research, Kaiserslautern, Germany.*

Arylhydrocarbon receptor (AhR)-deficient mice have been shown to be resistant to a variety of adverse effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Furthermore, AhR-deficient mice of various origins exhibit various phenotypes although the physiological function(s) of the AhR still await(s) elucidation. Here, we investigated the effects of TCDD on liver and kidney gene expression in adult female wild-type (wt) and AhR-deficient mice (originating from Finnish Public Health Institute, Kuopio, Finland) from our own breeding five days after treatment with either TCDD, single dose, 25  $\mu$ g/kg body weight, or with corn-oil (vehicle) given by oral gavage. Subsequently, RNA was isolated and Microarray analysis was performed using Agilent Whole Mouse Genome Oligo Microarray 4x44k. In wt mice, 282 genes were more than 2-fold up-regulated by TCDD in the liver including some of well-known AhR target genes like cytochrome P450 (CYP) 1A1, 1A2 and 1B1; 152 genes were up-regulated in the kidney. In AhR-deficient mice, 242 hepatic and 90 renal genes showed an increased expression after TCDD treatment. Among those, 15 hepatic and 13 renal genes were up-regulated in both wt and AhR-deficient animals. None of the core genes of the 'AhR gene battery' except CYP1B1 was up-regulated in AhR-deficient mice. The AhR-independent, TCDD-regulated genes comprise genes involved in lipid, carbohydrate, and amino acid metabolism, and in immune regulation. In wt mice, 203 hepatic and 20 renal genes were more than 2-fold down-regulated. In AhR-deficient mice, 234 hepatic genes including CYP1A2 and CYP3A44 and 235 renal genes showed a decreased expression. In addition, 18 hepatic genes were down-regulated in both wt and AhR-deficient animals. Our results demonstrate that TCDD can cause a broad spectrum of alterations in gene expression in mouse liver and kidney in an AhR-independent manner.

**PS 1293 Coexposure to Aryl Hydrocarbon Receptor and Thyroid Receptor Agonists Enhances Induction of Responsive Genes in Cultured Frog Cells and Prometamorphic Frogs.**

J. D. Taft and W. H. Powell. *Biology, Kenyon College, Gambier, OH.*

Amphibian metamorphosis is a postembryonic developmental process driven by thyroid hormone (TH) and mediated by the thyroid receptor (TR). 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) can disrupt TH function in humans and other species. Toxicity of dioxin-like compounds is mediated by the aryl hydrocarbon receptor (AHR). Here we used the African Clawed Frog (*Xenopus laevis*) as a model to probe the interaction of TR and AHR signaling. We quantified relative mRNA expression of both TR and AHR target genes in prometamorphic tadpoles and in XLK-WG cells following exposure to both TR and AHR agonists. Tadpoles (NF 53-55) were exposed to 5 nM TCDD and/or 10 nM T3 for 18 hours. TR targets *BTEB*, *TRβa*, and *TRβb* were not strongly induced by TCDD alone, and AHR target *CYP1A6* was not responsive to T3. However, exposure to both compounds resulted in elevated transcriptional responses of both transcript classes. Compared with T3-exposed animals, *BTEB*, *TRβa*, and *TRβb* mRNAs were 40-70% more abundant following co-exposure with TCDD. Similarly, *CYP1A6* mRNA was ~50% more abundant in tadpoles following T3 co-treatment than with exposure to TCDD only. Comparable patterns were observed in XLK-WG cells. The effect of TCDD on circulating TH varies with species and can differ for T4 and T3. While the superinduction of TH-responsive frog genes could involve TCDD-related alteration of TH levels, the requirement for co-treatment and the effect in cultured cells suggest the possibility of a transcriptional mechanism. We examined the promoter regions of *BTEB*, *TRβb*, and *CYP1A6*, finding potential cognate binding elements for each receptor. Overall, our results suggest some degree of co-regulation of the expression of several genes by both AHR and TR. Frogs display great insensitivity to TCDD toxicity, and frog AHRs bind TCDD with low affinity. We hypothesize that the induction of TR-regulated genes by AHR may represent an additional mechanism for protection of metamorphosis from disruption by xenobiotic or endogenous AHR agonists. (NIH: R15 ES011130)

**PS 1294 A Global Genomic Screening Strategy Reveals Diverse Activators of Constitutive Activated Receptor (CAR).**

K. Oshida<sup>1</sup>, N. Vasani<sup>1</sup>, B. Chorley<sup>1</sup>, S. Hester<sup>1</sup>, W. Ward<sup>1</sup>, R. S. Thomas<sup>2</sup>, D. Applegate<sup>3</sup>, L. M. Aleksunes<sup>4</sup>, C. D. Klaassen<sup>5</sup> and C. Corton<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>Hammer Institute, Research Triangle Park, NC; <sup>3</sup>Regenomed, Inc, San Diego, CA; <sup>4</sup>Rutgers University, New Brunswick, NJ; <sup>5</sup>KUMC, Kansas City, KS.

A comprehensive survey of conditions that activate CAR in the mouse liver has not been carried out but would be useful in understanding their impact on CAR-dependent liver tumor induction. A gene signature dependent on CAR activation was identified by comparing the transcript profiles after exposure to three CAR activators (phenobarbital, TCPOBOB, CITCO) in wild-type and CAR-null mice. In independent experiments using transcript profiles from the livers of chemically-exposed male or female mice, the signature correctly predicted activation of 3 CAR activators but not 9 activators of other pathways. The signature was used with 5 classification methods (e.g., support vector machines, K-nearest neighbors) to identify conditions in which CAR was activated in an Affymetrix compendium of ~750 mouse liver transcript comparisons encompassing a broad range of chemical, dietary and genetic perturbations. We found that CAR is activated by a large number of chemicals, dietary regimens and genetic mutations. Specific and novel findings include activation by 1) two PXR activators in a PXR-dependent manner indicating crosstalk between CAR and PXR, 2) 12 out of 15 chemical and triglyceride activators of PPARα to greater levels in PPARα-null mice than in wild type mice indicating that most PPARα activators are also CAR activators and there exists antagonism between CAR and PPARα, and 3) null mutations in a number of transcription factors (AhR, Fxr, Hnf1a, Pxr) that control expression of genes involved in metabolism of exogenous and endogenous chemicals. The findings increase our understanding of the factors that impact CAR activation and that could contribute to increases in CAR-dependent liver tumors. This abstract does not represent EPA policy.

**PS 1295 Effects of Munitions Compounds on Xenobiotic-Activated Nuclear Receptors and Cell Signaling Pathways.**

D. R. Johnson<sup>1</sup>, C. Y. Ang<sup>2</sup>, T. Habib<sup>2</sup> and E. J. Perkins<sup>1</sup>. <sup>1</sup>Environmental Laboratory, US Army Engineer Research & Development Center, Vicksburg, MS; <sup>2</sup>Badger Technical Services, Vicksburg, MS.

Exposure to certain munitions compounds is known to alter physiological functions in test organisms, however little is known about their molecular and cellular effects. The objective of this study to characterize the effects of new and existing

munitions compounds on xenobiotic-activated nuclear receptors and cell signaling pathways. Munitions compounds (0.01-10 mg/l) (e.g., nitroaromatics, cyclic nitramines, and new insensitive munitions) were added to wells containing transfected cells containing high constitutive levels of nuclear receptors for 24 h, then examined for nuclear activation according to in-house and commercially available kits. In general, nitroaromatic compounds had greater effects on nuclear receptor activity decreased nuclear receptor activity than other munitions compounds. Nitroaromatic munitions decreased activation of constitutive androstane receptor (CAR), peroxisomal proliferator activated receptors (PPAR), liver x receptor (LXR) at higher concentrations examined, whereas some nitroaromatic compounds activated the Ah receptor. Effects on 45 cell signaling pathways were examined using the Signal Finder multi-pathway reporter array kit that reverse-transfected transcription factor-firefly luciferase reporter plasmids into HepaRG liver cells. Cells were then exposed to munitions compounds for 24 h, then examined for signal pathway activation. Trinitrotoluene (TNT) and its environmental byproducts differentially activated cell signaling pathways, with at least two pathways commonly shared (AhR and Nrf2/Nrf1). 2,4-Dinitroanisole, a new TNT replacement munitions, activated fewer cell signaling pathways than TNT. These results create a more comprehensive picture of munitions effects within cells and potential down-stream effects within organisms. Furthermore, rapid nuclear bioassays, such as the ones described above, may help material scientist predict biochemical pathways that may be impacted by newly developed munitions earlier in the development process.

**PS 1296 The Aryl Hydrocarbon Receptor Depletion in Human MDA-MB-231 Breast Cancer Cell Line Attenuates *In Vivo* Tumor Growth and Pulmonary Metastasis in a Nude Mouse Model.**

G. Goode and S. E. Eltom. *Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN.*

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor that is best characterized for its role in mediating the toxic responses elicited by environmental poly aromatic hydrocarbons (PAH). However there is compelling evidence for a PAH-independent role of AhR in breast cancer. AhR is overexpressed and constitutively activated in several human breast carcinoma cell lines and shows strong correlation with the degree of the tumor malignancy. In the present study we examine the effect of depleting AhR expression in the highly metastatic MDA-MB-231 human breast cancer cell line on tumor growth and experimental pulmonary metastasis in a nude mouse model. The AhR was stably knocked down using shRNA targeting AhR gene. Clonal cell line of MD231 HBC with approximately 80% depletion of AhR and its scramble control cells were transfected to stably and constitutively express luciferase gene for the purpose of *in vivo* bioluminescence imaging of tumors. Cells were injected either orthotopically in the mammary fat pad for monitoring the primary tumor growth, or intravenously in the lateral tail vein, for monitoring pulmonary experimental metastasis. Results showed that knock down (KD) of AhR expression significantly reduced incidence of mice with tumor growth, prolonged the latency and reduced tumor size in those mice which developed tumors compared to controls. Mice with AhR KD in the experimental metastasis group showed a significant reduction in the number of animals with lung metastasis compared to control, and decreased numbers and sizes of pulmonary metastasis in those, which manifested metastasis. Global gene expression profiling identified sets of genes associated with tumor growth and metastasis that have been altered subsequent to depletion of AhR, and are likely to account for these phenotypes. Our data provide the first *in vivo* evidence for the role of AhR in regulating breast cancer metastasis and identified it as a therapeutic target for metastatic breast cancer.

**PS 1297 Species Specificity of the Peroxisome Proliferator Response in Primary Hepatocytes.**

P. D. McMullen, S. Bhattacharya, C. G. Woods, R. A. Clewell, E. L. LeCluyse, K. M. Yarborough, L. Pluta, P. Lu, J. Dong, J. Pi and M. E. Andersen. <sup>1</sup>Clinical Research Program, NIEHS, Durham, NC; <sup>2</sup>Cell Adhesion Group, NIEHS, Durham, NC; <sup>3</sup>Pharmacology and Toxicology, East Carolina University, Greenville, NC; <sup>4</sup>National Toxicology Program (NTP), NIEHS, Durham, NC.

Perturbations induced by environmental chemicals often lead to different physiological outcomes in humans and rodents, calling into question the applicability of animal-based toxicity testing for human risk assessment. For example, peroxisome proliferators, which include several purported endogenous fatty acids as well as a number of synthetic ligands, induce lipid metabolism enzymes in humans and have been used successfully as therapeutic strategies for various dyslipidemias and diabetes. For rodents, in addition to their role in regulating fatty acid metabolism, peroxisome proliferators also influence peroxisome assembly, inflammatory responses,

and cellular proliferation. Understanding the basis for differences in clinical repercussions across species is essential to translating information from animal models to human health.

Here we present a genomic characterization of the response of human and rat primary hepatocytes to the PPAR $\alpha$ -specific agonist GW7647. We used gene expression microarray experiments to compile a highly resolved time- and dose-response characterization of the difference of the PPAR $\alpha$ -mediated response in these two species. Consistent with the qualitative differences in the response to peroxisome proliferators, we identified a substantially larger set of differentially expressed genes in rat cells compared to human. These additional genes include a suite of developmental processes that may account for the increased toxicity of peroxisome proliferators in rodents. Surprisingly, in both species, we found that the canonical nuclear receptor response mechanism accounts for only a small fraction of detected response, suggesting a larger role for non-genomic mechanisms than was previously thought.

## PS 1298 Development of a Rapid, Cell-Based Screen for Disruptors of the Retinol (Vitamin A) Signaling Pathway.

Y. Chen and D. H. Reese. *OARSA/CFSAN, US FDA, Laurel, MD*. Sponsor: T. Flynn.

A central goal in the 2007 National Research Council's vision for Toxicity Testing in the 21st Century is the development of a comprehensive suite of in vitro tests covering the major signaling pathways (toxicity pathways) in mammals that can be used for evaluating chemical toxicity while reducing or eliminating the use of animals. Our research focuses on the development of in vitro screens for detecting chemicals in food additives, supplements, and contaminants that can disrupt the major cellular signaling pathways in mammals. One of these pathways, the retinol (vitamin A) signaling pathway, is essential for life in all mammals. It is required for both normal embryonic development and maintenance of cellular phenotype in adult organisms; chemicals that cause even minor interference with its normal function and output are potential fetal and adult toxicants. We have developed a rapid (24 h) screen for detecting chemicals that disrupt this essential signaling pathway. It uses the mouse pluripotent P19 stem cell line and a medium-throughput 96-well format gene-expression assay to detect disrupting chemicals. It has detected all known retinol signaling pathway disruptors and some chemicals that are closely related, structurally, to known disruptors. Significantly, it also has detected members of a class of chemicals, the endocrine disruptors, which have not been associated previously with disruption of this pathway; chemicals that caused disruption included xenoestrogens (DES, BPA, 4-n-nonylphenol, and genistein and phthalate esters (dibutyl phthalate and diphenyl phthalate but not bis(2-ethylhexyl) phthalate). The effects of members of this class of chemicals on the pathway suggest the existence of an additional non-genomic mechanism of action by which some endocrine disrupting chemicals cause toxicity.

## PS 1299 Asian Ginseng (*Panax ginseng*) Potentiates Ethanol-Induced Cardiovascular Dysfunction in Medaka Embryogenesis (*Oryzias latipes*).

M. H. Haron<sup>2,1</sup>, L. A. Walker<sup>1,2</sup>, I. A. Khan<sup>1</sup> and A. K. Dasmahapatra<sup>1,2</sup>.  
<sup>1</sup>National Center for Natural Product Research, University of Mississippi, University, MS; <sup>2</sup>Department of Pharmacology, University of Mississippi, University, MS.

Alcohol is a teratogen, induces fetal alcohol spectrum disorder (FASD) which has serious central nervous system (CNS), cardiovascular, and craniofacial defects affecting the entire lifetime of an individual. Prevention of FASD, other than women abstaining from drinking alcohol during pregnancy, is not known. The synthetic drugs recommended for the treatment of alcoholism cannot be used by women during pregnancy which led us to investigate on natural products. Due to ethical constraints FASD studies in humans are very limited and several animal models are used to understand the molecular mechanisms. We have observed that developmental ethanol exposure of medaka (*Oryzias latipes*) embryos generates features which are analogous to human FASD phenotypes. We hypothesize that ethanol metabolism generates oxidative stress which can disrupt embryonic development of medaka. In the present experiment, we have used root extracts of Asian ginseng (*Panax ginseng*) as a preventive agent of FASD. Fertilized medaka eggs within 4 h post fertilization (hpf) were exposed to methanolic extracts (50-100  $\mu$ g/ml) of ginseng root (PG) or ethanol (300 mM) either alone or in combination. After 48 h of treatment the viable embryos were transferred to clean hatching solution and on 6 dpf the embryos were examined for vessel circulation followed by mRNA analyses of enzymes related to ethanol metabolism and oxidative stress. It was observed that ethanol (300 mM) alone was able to disrupt vessel circulation and cotreatment of PG (50-100  $\mu$ g/ml) with ethanol was able to enhance the effect; PG (100  $\mu$ g/ml) alone has no effect. mRNA analysis of alcohol metabolizing enzymes or oxidative

stress-related enzymes did not show any significant alterations in any of these treatment conditions. It is therefore concluded that potentiation of ethanol-induced cardiovascular deformities in medaka by PG may be mediated through a different mechanism rather than oxidative stress.

## PS 1300 Toxicology Profile of Virginia Cedarwood Oil Delivered via Dermal Application.

I. Surh<sup>1</sup>, R. A. Herbert<sup>2</sup>, G. S. Travlos<sup>2</sup>, M. Vallant<sup>3</sup>, L. M. Fomby<sup>4</sup>, M. R. Hejtmancik<sup>4</sup> and P. Chan<sup>1</sup>. <sup>1</sup>Toxicology Branch, Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>Cellular and Molecular Pathology Branch, DNTP, NIEHS, Research Triangle Park, NC; <sup>3</sup>Program Operations Branch, DNTP, NIEHS, Research Triangle Park, NC; <sup>4</sup>Battelle, Columbus, OH.

Virginia cedarwood oil (CWO), which is extracted from *Juniperus virginiana* trees, is widely used as an insect repellent and a fragrance in cosmetic formulations resulting in human exposure. To investigate the toxicological effects of CWO, 90-day studies in F344 N rats and B6C3F1/N mice were conducted. CWO was administered by dermal application to male and female rats and mice at concentrations of 0, 6.25, 12.5, 25, 50% (v/v) in 95% ethanol or 100% daily (excluding weekends) for up to 14 weeks with an untreated control included. In rats, there were no effects on survival or body weights except in the 100% males in which 2 rats were terminated on day 79 due to severe skin lesions and a 13% lower group final mean body weight than that of the untreated control. All male and female mice in the 100% group were terminated during week 10 due to the severity of skin lesions. Final group mean body weights for females given 12.5, 25 or 50% and males given 50% were less than 90% of the controls. At the site of application, treatment related irritation, thickened skin, and ulcer formation were observed in all treated groups of rats and mice, except the 6.25% groups in rats. Clinical pathology showed an inflammatory leukogram secondary to dermal ulcers/inflammation in both rats and mice; mice also had a decreased erythron. In rats and mice there were dose-dependent increases in incidences and severity of skin lesions at the site of application, and bone marrow hyperplasia. In rats, there were dose-dependent increases in incidences and severity of kidney lesions in males. Male mice demonstrated increased incidences of kidney nephropathy and thymus atrophy.

## PS 1301 Novel Antiplatelet Activity of Protocatechuic Acid through Inhibition of High Shear Stress-Induced Platelet Aggregation.

K. Kim<sup>1</sup>, K. Lim<sup>1</sup>, J. Noh<sup>1</sup>, S. Kang<sup>1</sup>, K. Chung<sup>2</sup>, O. Bae<sup>3</sup> and J. Chung<sup>1</sup>.  
<sup>1</sup>College of Pharmacy, Seoul National University, Seoul, Republic of Korea; <sup>2</sup>School of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea; <sup>3</sup>College of Pharmacy, Hanyang University, Ansan, Republic of Korea.

Bleeding is the common and serious adverse effect of currently available antiplatelet drugs. Many efforts are being made to develop novel anti-thrombotic agents without bleeding risks. Shear stress-induced platelet aggregation (SIPA) which occurs under abnormally high shear stress plays a crucial role in the development of arterial thrombotic diseases. Here we demonstrated that protocatechuic acid (PCA), a bioactive phytochemical from *Lonicera* (honeysuckle) flowers, selectively and potently inhibits high shear (>10,000 s<sup>-1</sup>)-induced platelet aggregation. In isolated human platelets, PCA decreased SIPA and attenuated accompanying platelet activation including intracellular calcium mobilization, granule secretion and adhesion receptor expression. Anti-SIPA effect of PCA was mediated through blockade of von Willebrand factor (vWF) binding to activated GPIb, a primary and initial event for the accomplishment of SIPA. Conspicuously, PCA did not inhibit platelet aggregation induced by other endogenous agonists like collagen, thrombin or ADP that are important both in pathological thrombosis and normal haemostasis. Anti-thrombotic effects of PCA were confirmed in vivo in rat arterial thrombosis model, where PCA significantly delayed the arterial occlusion induced by FeCl<sub>3</sub>. Of a particular note, PCA did not increase bleeding time in rat tail trans-section model, while conventional anti-platelet drugs, aspirin and clopidogrel substantially prolonged it. Collectively, these results suggest that PCA may be a novel antiplatelet agent which can prevent thrombosis without increasing bleeding risks.

## PS 1302 The Soy-Associated Phytoestrogen, Genistein, Does Not Protect Against Alcohol-Induced Osteoporosis in Male Mice.

C. Yang<sup>1</sup>, K. Mercer<sup>1</sup>, L. Suva<sup>1</sup>, T. M. Badger<sup>2,1</sup> and M. Ronis<sup>2,1</sup>. *The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

Alcohol abuse acts as a risk factor for osteoporosis by increasing osteoclast activity and decreasing osteoblast activity in bone. These effects can be reversed by estradiol. Soy diets are also suggested to have protective effects on bone loss in men and

women, as a result of the presence of soy protein-associated phytoestrogens such as genistein and daidzein. In this study, male mice were pair fed (PF) a control diet, an EtOH diet or EtOH diet supplemented with genistein (250 mg/kg) for 8 weeks. Ex vivo microCT analyses of formalin fixed tibias from each group revealed a significant decrease in trabecular bone in the EtOH group in comparison with the pair-fed control in regards to bone volume (BV/TV), trabecular number (Tb.N), and trabecular separation (Tb.Sp), ( $p < 0.05$ ). No protective effect by genistein was observed in the EtOH+genistein group compared to the EtOH group in BV/TV, Tb.N, and Tb.Sp. Interestingly, there was an increase in trabecular thickness (Tb.Th) in the PF+genistein group compared to the PF ( $P < 0.05$ ), suggesting genistein can affect bone remodeling. In ex vivo bone marrow cultures, EtOH exposure decreased the number pre-osteoblasts compared to PF controls. In contrast, exposure to EtOH+genistein increased pre-osteoblast numbers compared to the EtOH-treated group, ( $p < 0.05$ ). These findings suggest that genistein has a partial protective effect on bone formation. In conclusion, genistein does not protect against ethanol induced bone loss despite increasing osteoblastogenesis. Supported in part by R01 AA18282 (M.J.R.) and UAMS INBRE award 8 P20 GM103429-11.

### PS 1303 Toxicological Safety Assessment of a Hydroethanolic Extract of *Caralluma fimbriata*.

J. R. Endres<sup>1</sup>, N. Deshmukh<sup>2</sup> and A. G. Schauss<sup>1</sup>. <sup>1</sup>AIBMR Life Sciences, Inc., Puyallup, WA; <sup>2</sup>INTOX Pvt. Ltd., Pune, India.

A toxicological safety assessment was conducted on a hydroethanolic extract of *Caralluma fimbriata*, an ingredient marketed as an appetite suppressant, to predict safety with oral consumption by humans. *Caralluma fimbriata* extract (CFE) is standardized to contain no less than 25% pregnane glycosides and no less than 10% saponin glycosides. The extract is >98% soluble in water. CFE is currently sold as the trademarked ingredient Slimaluma™. Two genotoxicity studies were conducted and no evidence of mutagenicity or genotoxicity was observed in the presence or absence of a rat liver S9 metabolic activation system at concentrations up to 5,000 µg of extract/plate (Ames Bacterial Reverse Mutation Assay) or 5,000 µg of extract/mL in a chromosomal aberration assay. Studies conducted in Wistar rats included a 14-day acute oral toxicity study, and a 90-day repeated oral toxicity study. A 6-month repeated oral toxicity study was conducted in Sprague-Dawley rats. In the 14-day study, the NOAEL was determined to be 5 g/kg bw. While a few statistically significant ( $p < 0.05$ ) findings were observed in the 90-day Wistar rat study, it was considered to be a sound basis for conducting a 6-month study. In the 6-month Sprague-Dawley rat study, the no observed effect level (NOEL) was concluded as 1,000 mg/kg bw/d, the highest dose group tested. Finally, in a developmental toxicity study in Sprague-Dawley rats no fetal abnormalities related to administration of the test article were observed.

### PS 1304 The Antidiabetic Activities of the Soft Drink Leaf Extract of *Phyllanthus amarus* (Order Euphorbiales; Family Euphorbiaceae) in Laboratory Animals.

A. A. Adedapo and S. O. Ofuegbi. *Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Nigeria.*

*Phyllanthus amarus* Schum (Family Euphorbiaceae) is an annual herbal shrub which has been used in traditional medicine in Nigeria to treat some disease conditions. This study evaluated the soft drink extract (SDE) of the plant for anti-diabetic activities in rats.

SDE was prepared by dissolving fresh aerial parts of the plant in 7up soft drink for 48 h, filtered, lyophilized and then used for the pharmacological investigations. Standard phytochemical methods were used to test for the presence of phytoactive compounds in the plant. Acute toxicity was carried out in mice to determine safe doses for this plant extract. The anti-diabetic activities of the SDE of the plant were assessed using some standard tests as well as histological changes in liver, kidney and pancreas. Diabetes mellitus was induced in rats using alloxan while glibenclamide at 0.2mg/kg was the reference drug used in this study.

The SDE at 200 and 400mg/kg body weight caused a significant reduction of fasting blood glucose, significant change in the oral glucose tolerance test, marked effect in the hypoglycaemic activity test, and pronounced reduction on the glucose, cholesterol and triglyceride levels of diabetic rats. The haemograms of all treated diabetic rats experienced recovery. Histopathologically, the liver of the diabetic non-treated and glibenclamide-treated groups showed widespread vacuolar change in the hepatocytes but there was no visible lesion seen in the kidney and pancreas of extract-treated and glibenclamide-treated groups. No lesion was also seen in the liver of SDE-treated group.

In conclusion, the results from this study may have validated the traditional basis for the use of *Phyllanthus amarus* as antidiabetic agent. The pharmacological activities noted in this study may be attributed to the presence of flavonoids and other phenolics contained in this plant. At the doses used, SDE also appeared safer than glibenclamide even though the latter is more potent.

### PS 1305 Protective Effects of Methanolic Root Extract of *Balanites aegyptiaca* (L.) Delile on Carbon Tetrachloride (CCl<sub>4</sub>)-Induced Hepatotoxicity in Rats.

O. A. Salawu<sup>1</sup>, F. Tukur<sup>2</sup>, A. Y. Tijani<sup>1</sup>, J. Ejiofor<sup>2</sup> and S. Ahmed<sup>3</sup>.

<sup>1</sup>Pharmacology and Toxicology, National Institute for Pharmaceutical Research and Development (NIPRD), Abuja, Nigeria; <sup>2</sup>Pharmacology and Therapeutics, Ahmadu Bello University, Zaria, Nigeria; <sup>3</sup>Pathology, Ahmadu Bello University Teaching Hospital, Zaria, Nigeria.

Objective: *Balanites aegyptiaca* (BA), a widely grown desert tree found in Africa and Asia is used as a remedy for several ailments including liver and spleen diseases. This study evaluated the protective activity of the methanol extract of BA root by direct (curative and prophylactic models) and indirect (barbiturate-induced sleep model) methods in CCl<sub>4</sub>-induced hepatotoxic rats.

Methods: In the curative study, 0.5 ml/kg CCl<sub>4</sub> was given intraperitoneally (ip) on alternate days, for 5 days, followed by 100, 200 and 400mg extract/kg orally daily, for 7 days. Other groups received the vehicle only, CCl<sub>4</sub> and the vehicle, and CCl<sub>4</sub> and the standard drug, silymarin (100 mg/kg/day) respectively. In the prophylactic study, all the rats received the treatment respectively for the first 7 days followed by CCl<sub>4</sub> as above. Degree of liver protection was measured in the rats by biochemical parameters (serum alanine transaminase, aspartate transaminase, alkaline phosphatase, albumin, bilirubin, triglycerides and cholesterol levels) monitoring, physical (weight) and histopathological changes in the liver. The indirect method was same as in prophylactic study but on the 13th day, the rats were given 25mg pentobarbitone sodium/kg ip and observed for onset and duration of sleep.

Results: Pre-treatment with the extract significantly ( $P < 0.05$ ) decreased CCl<sub>4</sub>-induced elevation of serum levels of the biochemical parameters, better than silymarin. In the curative study, its effect was comparable with that of silymarin. It also significantly decreased pentobarbitone sleeping time. There was improved tissue histopathology in both studies.

Conclusion: These results showed that BA root has significant hepatoprotective activities and could be useful as 'lead' in the development of new hepatoprotective agent.

### PS 1306 The Effects of Citrus Auraptene in Combination with All-Trans Retinoic Acid on Human Squamous Cell Carcinoma in a Xenograft Model.

H. E. Kleiner<sup>1</sup>, E. R. Lane<sup>1</sup>, J. Mathis<sup>2</sup>, J. McLarty<sup>3</sup>, M. S. Prince<sup>1</sup>, S. R. Crooks<sup>1</sup>, J. L. Clifford<sup>4</sup> and E. A. Orchard<sup>1</sup>. <sup>1</sup>Department of Pharmacology Toxicology & Neuroscience, Louisiana State University Health Sciences Center, Shreveport, LA; <sup>2</sup>Anatomy and Cellular Biology, Louisiana State University School of Health, Shreveport, LA; <sup>3</sup>Medicine, Louisiana State University Health Sciences Center, Shreveport, LA; <sup>4</sup>Biochemistry & Molecular Biology, Louisiana State University Health Sciences Center, Shreveport, LA.

Over 2,000,000 new cases of non-melanoma skin cancer (NMSC) are expected in the United States in 2012. Our group has previously demonstrated that citrus auraptene (AUR), combined with all-trans retinoic acid (ATRA), can inhibit the growth of human skin squamous cell carcinoma (SCC) tumors from the cell line SRB12-p9 (P9WT) in SCID/bg mice. ATRA is known to inhibit the STAT3 pathway, whereas AUR suppresses the activation of NF-κB and induces antioxidant enzymes such as glutathione S-transferase (GST). NF-κB and STAT3 are both hyperactivated in cancer. We hypothesize that suppressing both pathways by these compounds will produce a greater chemopreventive effect than by using either agent alone. Groups of 10 each female SCID/bg mice were injected with  $1 \times 10^6$  P9WT cells, s.c. Mice were dosed with AUR (0, 100, 200, 400 mg/kg bw) ± ATRA (2 mg/kg bw), p.o., beginning 4 days prior to tumor cell injection and 4 days/wk for the duration of the study (48 days). Tumor volumes were estimated by caliper. At the end of the tumor study, necropsies were performed, and tissues taken for further analyses. Statistical analyses revealed no effect of AUR by itself on tumor volumes. ATRA alone suppressed tumor volume by 16-fold. However, ATRA was so effective at blocking tumor volume that any additional effects of AUR may have been masked. ATRA also caused a loss of body weight, but the liver/body weight ratios were not different across groups, and the activity index of the mice was within range. In conclusion, this study will be repeated using lower doses of ATRA, in combination with AUR to determine the minimum effective dose of ATRA, (known to be toxic) while assessing the effect of the AUR. (SR21CA149761-02)

**PS 1307 Toxicological Evaluation of the Aqueous Extract of *Morinda morindoides* Root Bark.**

M. O. Abatan<sup>1,2</sup>, J. O. Olukunle<sup>2</sup>, O. L. Ajayi<sup>3</sup>, M. O. Olaniyi<sup>3</sup> and O. T. Adenubi<sup>2</sup>. <sup>1</sup>Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Nigeria; <sup>2</sup>Veterinary Physiology and Pharmacology, University of Agriculture, Abeokuta, Abeokuta, Nigeria; <sup>3</sup>Veterinary Pathology, University of Agriculture, Abeokuta, Abeokuta, Nigeria.

Toxicological evaluation of *Morinda morindoides* root bark was carried out using hematological and serum biochemical changes accompanying prolonged administration of the aqueous leaf extract of the plant in Wistar rats. Twenty rats were randomly but equally divided into four groups. Rats in groups I were administered with 0.9% physiological saline (10ml/kg b.w) as the control animals, while rats in groups II, III and IV were administered with aqueous extract at 400, 800 and 1600 mg/kg body weight respectively once daily for 28 days according to the acute toxicity study carried out. Parameters evaluated were complete blood count, serum protein, metabolites and enzymes. Samples from liver, spleen, heart, and kidney were processed for histopathology. Data were expressed as mean  $\pm$  Standard Error of Mean and analyzed using one way ANOVA. Difference of means are considered statistically significant at  $p < 0.05$ .

There were no significant changes in the hematological parameters between the treated groups and the control group. Rats in group IV exhibited significant increase in the serum levels of alkaline phosphatase, aspartate amino transaminase, alanine amino transferase and creatinine. Histopathology revealed mild diffuse degeneration of the liver, mild tubular nephrosis and mononuclear cellular infiltration in the heart. It was concluded that ethnomedicinal application of *Morinda morindoides* is quite safe at lower doses but it is hepatotoxic, nephrotoxic and cardiotoxic at higher doses.

**PS 1308 Antidiarrheal Evaluation of Aqueous and Ethanolic Leaf Extracts of *Acacia sieberiana* DC (*Fabaceae*) in Albino Rats.**

C. J. Dawurung, I. L. Elisha, N. V. Offiah, J. G. Gotepe, O. O. Oladipo, M. S. Makoshi, S. Makama and D. Shamaki. *Drug Development Unit, Biochemistry Division, National Veterinary Research Institute (NVRI) Vom, Jos, Nigeria.*

Sequel to reports on the use of *Acacia sieberiana* leaves in the management of animal diarrhea in some parts of Plateau State Nigeria, the anti diarrheal activity of aqueous and ethanolic extracts of the leaves of *A. sieberiana* were evaluated in albino rats. Studies were carried out on castor oil induced diarrhea and gastrointestinal transit at doses of 300, 600, and 1200 mg/Kg body weight. Both extracts did not show any significant ( $P > 0.05$ ) inhibitory effect in both assays when compared to the negative controls. The standard drugs, loperamide (10 mg/Kg) and atropine sulphate (3 mg/Kg) significantly ( $P < 0.05$ ) inhibited diarrhea and reduced the distance travelled by the activated charcoal in the intestine respectively. Phytochemical screenings of the extracts revealed the presence of saponins, cardiac glycosides, and flavonoids in both extracts, while tannins were present only in the ethanolic extract. In the toxicity test (limit test), no deaths or any apparent signs of toxicity or side effects were observed in the animals following the oral administration of both extracts at 2000 mg/Kg. The traditional use of *A. sieberiana* leaves in the management of diarrhea could not be justified by this study. Further work to assess the antibacterial, antiviral, anthelmintic and antiprotozoal activity of the leaves and antidiarrheal evaluation of other parts of the plant is necessary to verify the folkloric claims for its use in diarrheal management.

**PS 1309 Protection by Fish Oil against D-Galactosamine-Induced Hepatic Injury and Biochemical Alterations in the Plasma and Liver of Rats.**

Y. Shen, M. C. Parikh and C. A. Lau-Cam. *Pharmaceutical Sciences, St. John's University, Flushing, NY.* Sponsor: B. Billack.

The present study has investigated the actions of fish oil (FO) on D-galactosamine (GalN)-induced changes in plasma glucose (GLC), bilirubin, total proteins (TP) and enzymatic indices of hepatic damage; and in the levels of plasma and hepatic triglycerides (TG) and cholesterol (CHOL). Groups of 6 male Sprague-Dawley rats, 220-50 g in weight, were treated for 3 consecutive days with a 600 mg/kg oral dose of FO, as an emulsion in 0.9% NaCl-tween 20. On day 4, the rats received a single intraperitoneal, 400 mg/kg, dose of GalN in 0.9% NaCl. Additional rats received only the vehicles of the treatment solutions (control group), only GalN or only FO. All the rats were sacrificed by decapitation under isoflurane anesthesia 24 hr after receiving GalN, and their blood and livers were collected. The plasma fraction was analyzed for GLC, TG, CHOL, total (TB) and direct (DB) bilirubin, TP,

alanine transaminase (ALT), aspartate transaminase (AST) and alkaline phosphatase (ALP). A portion of liver was made into a 1:20 (w/v) homogenate in phosphate buffered saline pH 7.5 which was analyzed for its contents in TG and CHOL. Relative to control values, GalN increased the plasma GLC (41%), ALT (>200%), AST (>110%), ALP (+ 54%), TB (6.3-fold), DB (46-fold), TG (5.3-fold) and CHOL (1.6-fold) while decreasing those of TP (by 59%) (all at  $p \leq 0.01$ ). In addition, GalN increased the liver weight to body weight ratio (35%) and the levels of TG (61%) and CHOL (400%) significantly ( $p \leq 0.01$  vs. control). A pre-treatment with FO was able to attenuate the changes in plasma and liver components as well as in the liver weight to body weight ratio to a significant extent ( $p \leq 0.05$ ). By itself, FO was found to raise the plasma (98%) and liver TG (23%) and the liver CHOL (33%) significantly ( $p \leq 0.05$ ), but not as much as GalN. In conclusion, FO is found to protect the liver against GalN-induced hepatic injury, dysfunction and fat buildup and to attenuate accompanying changes in circulating GLC, TP, TG and CHOL.

**PS 1310 The Phototoxicity of Tagetes Oil and Absolute Evaluated Utilizing a Human Epidermal Model and Patch Testing.**

J. F. Lalko and A. Api. *Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ.*

Tagetes essential oil and absolute (*Tagetes minuta* L.) are utilized as fragrance ingredients in a variety of consumer and personal care products. Spectral analysis shows that the materials absorb UV wavelengths in the critical region of 290 – 700nm, and therefore have the potential to be photoactivated. In order to determine the potential for phototoxic effects, both materials were assessed in a phototoxicity test on a three dimensional human epidermal model (EST1000). This assay is based upon a comparison of the cytotoxic effects of the test material following exposure to a non-toxic dose of UV light. Cytotoxicity is expressed as a reduction in the mitochondrial conversion of MTT [(3-4,5-dimethyl thiazole 2-yl) 2,5-diphenyl-tetrazoliumbromide] to formazan. A material is considered to have a phototoxic potential if one or more concentrations +UVA (60 min with 6 J/cm<sup>2</sup>) results in a decrease in relative cell viability of  $\geq 30\%$ , when compared to the identical concentration –UVA. Tagetes essential oil and absolute were tested at concentrations ranging from 0.1% to 10% (v/v) in 1:3 ethanol:diethyl phthalate (EtOH:DEP). A confirmatory phototoxicity patch test was then conducted in a group of human volunteers, at a concentration identified to be non-phototoxic. In the EST1000 model, no phototoxicity was observed to Tagetes essential oil over the range of concentrations tested. However, within this same model, phototoxic effects were observed following exposure to Tagetes absolute at concentrations as low as 0.1%. Based on the dose-response in these *in vitro* assays, a concentration of 0.01% was identified as being non-phototoxic. This concentration (0.01% in 1:3 EtOH:DEP) of Tagetes essential oil and absolute was confirmed as having no phototoxic effects in humans following the phototoxicity patch test.

**PS 1311 Saponins from *Platycodon grandiflorum* and Its Constituent Platycodin D Regulates Fatty Acid Metabolism via an AMP-Activated Protein Kinase Dependent Signaling Pathway.**

H. Pil<sup>2,1</sup>, J. Choi<sup>1</sup>, H. Kim<sup>1</sup>, K. Tilak<sup>1</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

The saponins from the roots of *Platycodon grandiflorum* (CKS) have a variety of pharmacological properties, including antioxidant and hepatoprotective properties. This study was conducted to suggest the role of AMP-activated protein kinase (AMPK) pathway in the anti-obesity effect of CKS. We evaluated body weight, liver histology, and hepatic triglyceride content in high-fat diet (HFD)-fed mice treated with CKS. In addition, we characterized the underlying mechanism of CKS's effects in HepG2 cells by Western blot and RT-PCR analysis. CKS administration attenuated fat accumulation and induction of lipogenic genes such as sterol regulatory element binding protein-1c (SREBP-1c) and fatty acid synthase in the liver of HFD-fed mice. We also found that CKS suppressed high glucose-induced lipid accumulation in HepG2 cells. CKS inhibited the high glucose-induced fatty acid synthase (FAS) and sterol regulatory element binding protein-1c (SREBP-1c) expression. Blood biochemical analyses and histopathologic examinations showed that CKS prevented liver injury. Moreover, the using pharmacological AMPK inhibitor revealed that AMPK is essential to suppression of SREBP-1c expression in CKS-treated cells. These results indicate that CKS prevents high glucose-induced lipogenesis in HepG2 cells by blocking the expression of SREBP-1c, FAS through AMPK activation, suggesting that CKS is a novel AMPK activator with a potential role in the prevention and treatment obesity.

**PS 1312** *Platycodi radix* Attenuates Dimethylnitrosamine-Induced Liver Fibrosis in Rats.

J. Choi<sup>1</sup>, S. Jin<sup>1</sup>, Y. Hwang<sup>2</sup>, C. Choi<sup>3</sup>, Y. Chung<sup>2</sup>, Y. Lee<sup>4</sup> and H. Jeong<sup>1</sup>.  
<sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea;  
<sup>2</sup>International University of Korea, Jinju, Republic of Korea; <sup>3</sup>Natural Resources Research Institute, Jangheung-gun, Republic of Korea; <sup>4</sup>Jangsaeng Doraji Research Institute of Biotechnology, Jinju, Republic of Korea.

Liver fibrosis is a wound healing response to a variety of chronic stimuli, including alcohol intake, viral infection, drugs, and metabolic disease. This study investigated the anti-fibrotic effects of the aqueous extract of the *Platycodi Radix* root (Changkil: CK) on dimethylnitrosamine (DMN)-induced liver fibrosis in rats by inducing Nrf2-mediated antioxidant enzymes. Repeated DMN exposure causes chronic liver injury with necrosis, fibrosis, and nodular regeneration through metabolic activation of CYP2E1 in experimental animals. CK inhibited DMN-induced increases in serum ALT and AST activities, fibrosis score, and hepatic malondialdehyde and collagen content. CK also inhibited DMN-induced reductions in rat body and liver weights. CK inhibited DMN-induced increases in MMP-13, TIMP-1, and TNF- $\alpha$  mRNA, and collagen type I and  $\alpha$ -smooth muscle actin protein. DMN-induced COX-2 expression and NF- $\kappa$ B activation was reduced by CK treatment. Furthermore, CK induced activation of Nrf2-mediated antioxidant enzymes such as  $\gamma$ -glutamylcysteine synthetase ( $\gamma$ -GCS), heme oxygenase-1 (HO-1), NAD(P)H quinone oxidoreductase 1 (NQO1), and glutathione-S-transferase (GST) in HepG2 cells. These results demonstrated that CK attenuates DMN-induced liver fibrosis through the activation of Nrf2-mediated antioxidant enzymes.

**PS 1313** Protective Effects of Saponins Isolated from the Root of *Platycodon grandiflorum* against Ovalbumin-Induced Airway Inflammation in a Mouse Allergic Asthma Model.

Y. Chung<sup>2</sup>, J. Choi<sup>1</sup>, H. Kim<sup>1</sup>, Y. Lee<sup>3</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea; <sup>3</sup>Jangsaeng Doraji Research Institute of Biotechnology, Jinju, Republic of Korea.

Bronchial asthma is a chronic airway disorder characterized by airway inflammation, mucus hypersecretion, and airway hyperresponsiveness. This study investigated the protective effects of saponins isolated from the root of *Platycodon grandiflorum* (Changkil saponins: CKS) on airway inflammation induced by allergic reaction in mice. Mice were sensitized and challenged with ovalbumin (OVA) developed inflammation and remodeling in airway. CKS inhibited OVA-induced number of inflammatory cells and levels of TNF- $\alpha$ , INF- $\gamma$ , IL-4, IL-5, IL-13, monocyte chemoattractant protein-1 (MCP-1) and OVA-specific IgE in bronchoalveolar lavage fluid. Also, CKS attenuated OVA-induced mucus hypersecretion in lung histopathological studies. CKS inhibited OVA-induced mRNA expression level of MMP-2, MMP-9, and MUC5AC in lung tissues. Furthermore, CKS blocked NF- $\kappa$ B p65 nuclear translocation in the nuclear extracts from lung tissues of OVA-challenged mice. These results suggest that CKS ameliorates OVA-induced inflammation and remodeling in airway.

**PS 1314** Topical Application of Cultivated Ginseng Suppresses 2, 4-Dinitrochlorobenzene-Induced Atopic Dermatitis in NC/Nga Mice.

J. Choi<sup>2</sup>, J. Choi<sup>1</sup>, S. Jin<sup>1</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Atopic dermatitis (AD) has been known to be related with local and systemic immunologic dysfunction that leads to Th1/Th2 response as well as being related to environmental factors. This study examined the inhibitory effects of 1-chloro-2,4-dinitrobenzene (DNCB)-induced AD by cultivated ginseng (CG) (Panax ginseng C.A. Meyer) in NC/Nga mice. CG, an herb used in Korean herbal medicine, has been widely used in China and Japan to treat fatigue and to enhance resistance to many diseases. CG ameliorates DNBCB-induced skin dermatitis severity, serum level of IgE and TARC, and mRNA expression of T helper (Th)1 and Th2 cytokines in mice. In addition, CG reduced thickness of the dermis and dermal infiltration of inflammatory cells in histopathological examination. These results indicate that CG inhibits allergic contact dermatitis through the modulating of Th1 and Th2 responses and diminishing the inflammatory cells in the skin lesions in NC/Nga mice.

**PS 1315** *Pleurotus eryngii* Extracts Inhibits 2, 4-Dinitrochlorobenzene-Induced Atopic Dermatitis in NC/Nga Mice by the Regulation of Th1/Th2 Balance.

S. Chun<sup>2</sup>, J. Choi<sup>1</sup>, S. Jin<sup>1</sup>, J. Choi<sup>2</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Atopic dermatitis (AD) is a chronic, relapsing and inflammatory skin disease in humans and animals, caused by a complex interrelationship among genetic, environmental, pharmacologic, psychological, immunologic and skin barrier dysfunction factors. This study investigated the inhibitory effect of the *Pleurotus eryngii* extracts (PEE) on 2,4-dinitrochlorobenzene (DNCB)-induced atopic dermatitis (AD)-like skin lesions. *Pleurotus eryngii* has been used in traditional medicine for nutritional and medicinal food that enhances the host immune system as a response to various diseases. This study evaluated skin dermatitis severity, ear thickness, histopathological examination, and cytokines level in DNBCB-applied mice treated with PEE. Continuous treatment of PEE inhibited the development of the AD-like skin lesions. PEE attenuates DNBCB-induced skin dermatitis severity, serum level of IgE and TARC, and mRNA expression of TNF- $\alpha$ , INF- $\gamma$ , IL-4, IL-5, and IL-13 in mice. Also, PEE reduced thickness of the dermis and dermal infiltration of inflammatory cells and mast cells in histopathological examination. These results suggest that PEE inhibits allergic contact dermatitis through the modulating of T helper (Th)1 and Th2 responses and diminishing the inflammatory cells and mast cells infiltration in the skin lesions in NC/Nga mice.

**PS 1316** Chronic Oral Toxicity Study of the Extracts from Herbs in Phikud Navakot.

K. Kanchana<sup>1</sup>, K. Chaimongkolnukul<sup>1</sup>, S. Cherdyu<sup>1</sup>, S. Ampawong<sup>2</sup> and T. Ketjareon<sup>2</sup>. <sup>1</sup>Academic Services Office, National Laboratory Animal Center, Mahidol University, Nakorn Pathom, Thailand; <sup>2</sup>Veterinary Medical Office, National Laboratory Animal Center, Mahidol University, Nakorn Pathom, Thailand. Sponsor: - NA.

Phikud Navakot is commonly used as Thai traditional medicine for alleviation hyperlipidemia, cardiovascular diseases, and cerebrovascular diseases. Chronic toxicity effects of the extracts from herbs in Phikud Navakot were performed because there were no 6-month toxicological studies reported in the literature. The repeated dose as 10, 100, 1,000 mg/kg/day of the extracts were randomly administered to both male and female Sprague Dawley rats as described in the OECD code 452 guideline. 183 rats survived to the end of the study while 20 rats died. The cause of death was considered to be related to the gavage technical error which positively correlated to high dose concentration. Mean body weights of dosed rats were similar to those of the control group. No differences in feed consumption, relative organ weights, and hematology and blood clinical chemistry were noted. Significant proportionally increased incidences of transitional cell hyperplasia of the renal pelvis in both sexes dosed rats. Therefore our obtained results suggested that Phikud Navakot is a relatively nontoxic herb for repeated oral administration. However the contraindication of the usage of Phikud Navakot is related to induce transitional cell hyperplasia of the renal pelvis after prolong high dose oral administration.

**PS 1317** Plum Consumption Modulate Gut Microbiota and Obesity in Zucker Rats.

G. Noratto<sup>1</sup>, J. Garcia-Mazcorro<sup>2</sup>, H. Martino<sup>3</sup>, D. Byrne<sup>4</sup>, M. Markel<sup>5</sup>, J. Suchodolski<sup>3</sup>, J. Steiner<sup>3</sup> and S. U. Mertens-Talcott<sup>6</sup>. <sup>1</sup>School of Food Science, Washington State University, Pullman, WA; <sup>2</sup>Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Nuevo León, Monterrey, Mexico; <sup>3</sup>Department of Nutrition and Health, University of Vicos, Vicos, Brazil; <sup>4</sup>Horticulture, Texas A&M University, College Station, TX; <sup>5</sup>Gastrointestinal Laboratory, Texas A&M University, College Station, TX; <sup>6</sup>Nutrition and Food Science, Texas A&M University, College Station, TX.

The role of peach and plum polyphenols on the modulation of gut microbiota and the possible relationship with obesity is unknown. We investigated how peach and plum consumption can modulate metabolic syndrome and relative proportions of gut microbiota populations in feces of obese Zucker rats. Experimental groups received peach or plum juice ad libitum during 11 weeks, the control and lean groups received water with same amount of glucose than fruit juices. At the end of the study blood was analyzed for glucose, insulin triglycerides, cholesterol and LDL oxidation levels. DNA in feces was analyzed using 454-pyrosequencing and qPCR. Results showed that only plum juice consumption prevented weight gain and modulated microbiota populations in feces; this was related to the higher content of polyphenols in plum juice (3X of peach). However, both peach and plum juice exerted similar protective effects on metabolic syndrome and inflammatory markers

in blood as confirmed by a component score coefficient analysis in which peach and plum groups were overlapped and located in between the control and lean groups. Pyrosequencing data from DNA in feces showed that plum group had higher abundance of Bacteroidetes, Ruminococcaceae, and Lactobacillus. qPCR data showed that plum group had higher Faecalibacterium, Lactobacillus, and Turicibacter than all other groups. The abundance of Bifidobacterium in plum group was similar to the lean group and higher than peach and control groups ( $p < 0.05$ ). These results suggest that polyphenols-rich foods can alter the composition of the distal intestinal microbiota in obese rats and modulate metabolic syndrome and obesity.

**PS 1318 Kolaviron, a Biflavonoid of *Garcinia kola* Seed Offered Cardioprotection against Ischaemic/Reperfusion Injury by Up-Regulation of Prosurvival and Down-Regulation of Apoptotic Signaling Pathways.**

A. A. Oyagbemi<sup>1,2,3</sup>, J. D. Bester<sup>2,3</sup>, A. J. Esterhuyse<sup>2,3</sup> and O. E. Farombi<sup>3,2</sup>.  
<sup>1</sup>Veterinary Physiology, Biochemistry and Pharmacology, University of Ibadan, Ibadan, Nigeria; <sup>2</sup>Biochemistry, University of Ibadan, College of Medicine, Ibadan, Nigeria; <sup>3</sup>Department of Biomedical Sciences, Faculty of Health and Wellness Sciences, Cape Peninsula University of Technology, Bellville, Cape Town, South Africa.

Possible cardioprotective effect of Kolaviron (KV) administration and the molecular mechanism (s) involved in ischaemic/reperfusion injury of isolated rat hearts were assessed. Twenty rats were used for this study. They were grouped into ten rats of group of two. Rats in group I received 2ml/kg of corn oil (vehicle) while animals in groups II received 200 mg/kg body weight of Kolaviron (KV) for four weeks respectively. Isolated rat hearts were stabilized for 5 minutes on Langendorff, perfused on working heart model for 10 minutes and subjected to global ischaemia for 15 minutes followed by 25 minutes reperfusion. Antioxidant enzymes, markers of oxidative stress and western blot analyses were carried out on snap-frozen heart tissues. There was significant ( $p < 0.05$ ) increase in superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx), oxygen radical absorbance capacity (ORAC) and concomitant significant ( $p < 0.05$ ) decrease in malondialdehyde (MDA) and intracellular reactive oxygen species (ROS) in isolated rat hearts of animals that received KV compared to the control. Western blot analysis revealed significant up-regulation of Akt/PKB, p-Akt/PKB, HSP27, p-HSP27 and down-regulation of p38 MAPK, Caspase 3, cleaved Caspase 3 and cleaved PARP. Taken together, KV offered cardioprotection by enhancing the expression of pro-survival signaling pathway and abrogation of apoptotic pathway in isolated rat hearts subjected to ischaemic/reperfusion injury.

**PS 1319 Antimalarial Activity of Methanolic Fraction of *Clerodendrum violaceum* Leaf Extract.**

J. O. Adebayo, A. Zailani and E. A. Balogun. Biochemistry, University of Ilorin, Ilorin, Nigeria.

Malaria is a parasitic disease with devastating impact in Africa. Decoction of *Clerodendrum violaceum* leaf is indigenously used in Nigeria for the treatment of the disease. In this study, the methanolic fraction of *Clerodendrum violaceum* leaf extract was evaluated in *P. berghei*-infected mice in a 4-day suppressive test. Also, its effects on the activities of antioxidant enzymes in the infected mice were also evaluated. The results revealed that the methanolic fraction of *Clerodendrum violaceum* leaf extract possesses antimalarial activity, causing 42.69% and 79.42% reduction in parasitemia at the doses of 125 and 250 mg/Kg body weight on day 5 post-inoculation. It also caused 61.78% and 87.57% reduction in parasitemia at the doses of 125 and 250 mg/Kg body weight on day 8 post-inoculation. The extract fraction however caused a significant increase ( $P < 0.05$ ) in superoxide dismutase and catalase activities and a significant decrease ( $P < 0.05$ ) in glutathione peroxidase activity in erythrocyte and liver in a dose-dependent manner compared to controls on day 5 post-inoculation. The results of this study suggest that *Clerodendrum violaceum* leaf may be a potential source of cheaper antimalarial drug.

**PS 1320 Effect of Probiotics (*Lactobacillus* and *Bifidobacterium*) on Growth Performance and Haematological Profile of *Clarias gariepinus* Juveniles.**

S. O. Ayoola<sup>1</sup>, E. K. Ajani<sup>1,2</sup> and O. F. Fashae<sup>1</sup>. <sup>1</sup>Marine Sciences, University of Lagos, Akoka, Lagos, Nigeria; <sup>2</sup>Aquaculture and Fisheries, University Ibadan, Oyo State, Ibadan, Nigeria.

This study was carried out to evaluate the use of probiotic (a mixture of *Lactobacillus* and *bifidobacterium* species) on growth performance and haematological parameters of *Clarias gariepinus* juveniles. Fifteen tanks were used and 10

*Clarias gariepinus* juveniles (mean weight  $14.9 \pm 0.83$  g) per tank, each in triplicate. Five treatment tanks were fed a diet containing 40% crude protein supplemented with varying inclusion of probiotic comprising about 109 colony-forming units per gram of diet (the probiotic diet). Diet T0 contain 0g probiotic (control diet) while the other group contain 0.5 g, 1.0 g 1.5 g and 2.0 g probiotic diet. Results shows that Fish fed with diet T1 (0.5 g probiotic) had the best growth performance. There was no significant difference ( $P > 0.05$ ) in the Mean Corpuscular Volume, Mean Corpuscular Haemoglobin and Mean Corpuscular Haemoglobin Concentration, of fish fed different concentration of probiotic. All blood parameter obtained were between the range of recommended fish blood. It is concluded that using probiotic (especially at 0.5 g) as supplementary feed on *Clarias gariepinus* showed a slight increase in the haematological parameters compare with the control diet but it has no negative impact on the health status of the species. However, probiotic (*Lactobacillus* and *bifidobacterium*) can be used as a probiotic agent in aquaculture, to enhance fish health, survival and growth performance.

**PS 1321 Antifungal and Insecticidal Activities of Five Essential Oils from Plants of the Colombian Caribbean Coast.**

B. E. Jaramillo<sup>1</sup>, E. Duarte Restrepo<sup>1</sup> and W. Delgado Ávila<sup>2</sup>. <sup>1</sup>Chemistry Program, University of Cartagena, Cartagena, Colombia; <sup>2</sup>Chemistry Program, National University of Colombia, Bogotá, Colombia. Sponsor: B. Jaramillo.

Plants have developed chemical mechanisms of self-protection to avoid being attacked by insects fungi, bacteria and viruses. The diseases caused by these pests are controlled with fumigants, which have a high toxicity, and this necessitates the use of alternative compounds like essential oils. These are botanical sources of compounds potential alternative fumigants currently used, due to its low mammalian toxicity, high volatility and toxicity to stored grain pests and microorganisms.

**OBJECTIVE:** This study determined the insecticidal, antifungal, activities of essential oils isolated from *Chenopodium ambrosioides* L., *Triphasia trifolia*, *Eryngium foetidum*, *Bursera graveolens*, and *Swinglea glutinosa* collected in colombian caribbean coast.

**METHODS:** The essential oils (EO) were obtained from leaves of plants by hydrodistillation. The insecticidal activity assay was performed against *Sitophilus zeamais*. EO were also evaluated as fumigants against phytopathogenic fungi *Fusarium oxysporum* f. sp. *dianthi*.

**RESULTS:** *C. ambrosioides* was more active against *Fusarium oxysporum* than other EO evaluated, with a percentage of mycelial inhibition of 97.3% at 176.5  $\mu$ L EO/L air after 72 h of exposure; followed by *Eryngium foetidum* (65.4%); *Bursera graveolens* (60.0%); *Piper marginatum* (41.7%) and *Swinglea glutinosa* (14.7%). *C. ambrosioides* and *Eryngium foetidum* essential oils showed the best fumigant activity against *Sitophilus zeamais* (100% at 500  $\mu$ L/L air after 24 h of exposure); *Piper marginatum* oil had weak fumigant toxicity (86.7%  $\mu$ L/L air after 24 h of exposure).

**CONCLUSIONS:** This study demonstrated that essential oils exhibit important fungicidal activity on *F. oxysporum* and fumigant on *S. zeamais*, which could become an alternative to synthetic fungicides and insecticides.

**PS 1322 Protein Binding Effects the Cellular Uptake of Silver Nanoparticles in Human Cells.**

N. A. Monteiro-Riviere<sup>1,2,3</sup>, A. O. Inman<sup>1,2</sup>, M. E. Samberg<sup>2,3</sup>, S. Oldenburg<sup>4</sup> and J. E. Riviere<sup>1,2</sup>. <sup>1</sup>Nanotechnology Innovation Center of Kansas State, Kansas State University, Manhattan, KS; <sup>2</sup>Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC; <sup>3</sup>Joint Department of Biomedical Engineering at the University of North Carolina at Chapel Hill and North Carolina State University, North Carolina State University, Raleigh, NC; <sup>4</sup>nanoComposix, Inc, San Diego, CA.

Nanoparticles (NP) absorbed in the body will come in contact with blood proteins and form NP/protein complexes termed protein coronas, which may modulate NP cellular uptake. This study quantitated human epidermal keratinocyte (HEK) uptake of silver (Ag) NP complexed to different human serum proteins. Prior to HEK dosing, AgNP (20nm and 110nm citrate BioPure™; 40nm and 120nm silica-coated) were incubated for 2h at 37°C without (control) or with physiological levels of albumin (44mg/ml), IgG (14.5mg/ml) or transferrin (3mg/ml). HEK were exposed to the protein incubated AgNP for 3h, rinsed with medium and incubated for 48h, rinsed in buffer and lysed. Ag was assayed by inductively-coupled plasma optical emission spectrometry. Uptake of Ag in HEK was <4.1% of applied dose with proteins suppressing citrate, but not silica coated, Ag uptake into HEK two fold relative to controls. IgG dramatically reduced 110nm citrate AgNP uptake. In contrast, greatest uptake of 20nm silica AgNP was seen with IgG incubation, while 110nm silica AgNP showing similar uptake profiles across all exposures. Electron microscopy confirmed cellular uptake of all particles but showed differences in the

appearance and agglomeration state of the NP within HEK vacuoles. This suggests that NP association with serum proteins purportedly form different protein coronas that significantly modulates Ag uptake compared to native NP uptake, suggesting caution in extrapolating *in vitro* uptake data to predict behavior *in vivo* where the nature of the protein corona may determine patterns of cellular uptake, biodistribution, biological activity and toxicity. (Supported by NIH RO1 ES016138)

### PS 1323 Relationship between Silver Nanoparticle Intracellular Accumulation and Cytotoxicity in L-929 Fibroblasts.

B. E. Wildt<sup>1</sup>, E. I. Maurer<sup>2</sup>, G. Kumar<sup>1</sup>, H. A. Degheidy<sup>1</sup>, S. M. Hussain<sup>2</sup> and P. L. Goering<sup>1</sup>. <sup>1</sup>US FDA, Silver Spring, MD; <sup>2</sup>711 HPW/RHDJ, AFRL, Wright-Patterson AFB, Dayton, OH.

Medical devices containing silver nanoparticles (AgNPs) may release NPs or leach silver (Ag) ions, both of which are cytotoxic *in vitro* at high concentrations. Given the complexities of NP *in vitro* dosimetry, proper assessment of AgNP cytotoxicity requires a better understanding of intracellular Ag concentration and observed bio-effects. Therefore, the objective of this study was to measure time-dependent AgNP cell internalization in L-929 fibroblast cells, a cell line that is commonly used for medical device biocompatibility testing, while simultaneously assessing cell viability. These endpoints were assessed following exposure of cells to 50 µg/mL AgNPs (10, 50, 100 and 200 nm) and to equimolar Ag ions. Intracellular uptake of AgNPs and Ag concentrations in L-929 cells were assessed using time-lapse confocal microscopy, flow cytometry and ICP-MS at 4, 16 and 24 hrs after treatment. Metabolic activity and plasma membrane integrity of the cells were assessed at 4, 16 and 24 hrs after treatment using the MTT assay and ethidium homodimer-1 dead cell indicator, respectively. A time-dependent, linear increase in intracellular accumulation of AgNPs and Ag concentrations were observed using confocal microscopy and ICP-MS. Flow cytometric evidence of AgNP uptake and accumulation in cells was also observed from changes in side scatter characteristics vs. forward scatter characteristics dot plots. The results of the MTT assay suggest that Ag ions and 10 nm NPs are highly toxic, compared to 50, 100 and 200 nm NPs. Membrane integrity analysis of time-lapse images revealed that 10 nm AgNPs are cytotoxic within 1 hr after dosing and all cells are dead after 10 hrs. In contrast, equimolar concentrations of Ag ions kill all cells within an hour. This study demonstrated that the size-dependent *in vitro* cytotoxicity of AgNPs to L-929 fibroblasts correlated with intracellular Ag accumulation, and underscores the value of using multiple analytical methods when determining NP accumulation and cytotoxicity.

### PS 1324 Role of Sample Preparation in *In Vitro* Cytotoxicity Responses to Silver Nanoparticles.

A. N. Clendaniel<sup>2,1</sup>, G. Kumar<sup>1</sup>, H. A. Degheidy<sup>1</sup>, B. J. Casey<sup>1</sup> and P. L. Goering<sup>1</sup>. <sup>1</sup>CDRH, US FDA, Silver Spring, MD; <sup>2</sup>Richard Stockton College of New Jersey, Galloway, NJ.

Metallic nanoparticles readily agglomerate in aqueous media and this effect can influence their physical properties and *in vitro* biological responses. The goal of this study was to: 1) compare effects of cell culture medium containing 10% FBS and DI water as suspension vehicles on AgNP size and agglomeration, and 2) compare effects of pre-mixing of medium and AgNPs on their biological responses in L-929 fibroblasts compared to direct addition of nanoparticles to the cells. To assess the effects of premixing on agglomeration, AgNPs were pre-mixed with cell culture medium or DI water for 1 min, or 1, 5, 24, or 120 hr. Results of dynamic light scattering analysis showed that pre-mixing AgNPs with medium maintained particle dispersion better than DI water. The hydrodynamic diameter of AgNPs increased proportionally to the pre-mixing time. AgNP agglomeration was size-dependent; 10 nm AgNPs agglomerated more readily than 100 nm and 200 nm particles. To assess the effects of premixing on biological responses, AgNPs pre-mixed with cell culture medium for 1 min, or 1, 5, or 24 hr were added to L-929 fibroblasts, or were added to the cells without premixing. After 24 hr exposure, cell viability was assessed by using the standard MTT assay. After 4 and 24 hr exposures, the degree of cell necrosis (via 7-AAD dye) and apoptosis (via Annexin V dye) was assessed using flow cytometry. AgNPs produced a mass concentration (µg/ml) dependent decrease in MTT reduction. Pre-mixing of AgNPs with cell culture medium did not affect cell viability compared to controls; however, AgNPs added directly to the media without pre-mixing were cytotoxic. The degree of necrosis and apoptosis of L-929 cells when exposed to AgNPs depended on mass concentration, exposure time, and size of AgNPs. Cells treated with 10 nm particles at 50 µg/ml showed 22-fold and 33-fold increases in the percentage of apoptotic and necrotic cells, respectively, after 24 hr. Thus, the data show that different sample preparation for AgNPs can affect particle agglomeration and biological responses.

### PS 1325 Flow Cytometry Evaluation of Cell Cytotoxicity Induced by Silver Nanoparticles.

G. Kumar<sup>1</sup>, A. N. Clendaniel<sup>2,1</sup>, H. Degheidy<sup>1</sup>, B. E. Wildt<sup>1</sup> and P. L. Goering<sup>1</sup>. <sup>1</sup>CDRH, US FDA, Silver Spring, MD; <sup>2</sup>The Richard Stockton College of New Jersey, Pomona, NJ.

Particles possess unique properties in the nanoscale, e.g., enhanced catalytic activity, high surface area and surface energy, and light emission/absorption properties, which might result in interference with colorimetric *in vitro* cytotoxicity assays such as MTT, LDH release, and Neutral Red. Alternatively, assays that do not use spectrophotometric detection, such as trypan blue exclusion or flow cytometry (FC) based assays, are less likely to be influenced by nanoparticle interference. The aim of this study was to evaluate FC assays to assess the cytotoxicity of three different sizes (10, 100, or 200 nm) silver nanoparticles (AgNPs) at different mass concentrations (1, 25, or 50 µg/ml) in L-929 fibroblast cells. After 4 hrs and 24 hrs exposure, cell necrosis and apoptosis were assessed using 7-AAD and Annexin V dyes, respectively, with FC. Multiple FC controls (including cells alone, AgNPs alone, and single fluorophore controls and their combinations) were used to optimize the experiment and eliminate background autofluorescence and fluorochrome overlap. The data show that cell necrosis and apoptosis in AgNP-exposed fibroblasts depend on dose, exposure time, and AgNPs size. Cells treated with 10 nm particles at 50 µg/ml showed 7- to 22-fold increases in percentage of apoptotic cells and 2- to 33-fold increases in percentage of necrotic cells after 4 hrs and 24 hrs, respectively. Cells treated with 200 nm particles at 50 µg/ml showed only up to 6 fold increases in degree of apoptosis after 24 h. The data show that AgNPs produced a dose- and time-dependent decrease in cell viability; however, 200 nm AgNPs were significantly less toxic than smaller sized particles. Thus, standard FC assays can be utilized to assess apoptosis and necrosis in response to nanomaterial exposure.

### PS 1326 Incorporation of Silver Nanoparticles into a Degradable Poly(L-Lactide-Co-Epsilon-Caprolactone) Copolymer Scaffold for Skin Regeneration.

M. E. Samberg<sup>1</sup>, P. Mente<sup>1</sup>, T. He<sup>2</sup>, M. W. King<sup>2</sup> and N. A. Monteiro-Riviere<sup>1,3</sup>. <sup>1</sup>Joint Department of Biomedical Engineering at the University of North Carolina at Chapel Hill and North Carolina State University, North Carolina State University, Raleigh, NC; <sup>2</sup>College of Textiles, North Carolina State University, Raleigh, NC; <sup>3</sup>Nanotechnology Innovation Center of Kansas State, Kansas State University, Manhattan, KS.

The development of an antibacterial, degradable scaffold system that utilizes patient-derived cells would improve upon current skin grafting techniques which often result in severe scarring, aesthetically undesirable mismatches in skin tones, and are susceptible to surgical site infection. The objective of this study was to characterize and assess the toxicity of an electrospun scaffold of poly(L-lactide-co-epsilon-caprolactone) (PLCL) incorporating antibacterial 20nm silver nanoparticles (AgNP). The content and distribution of 20nm AgNP incorporated within the PLCL scaffold was optimized to maximize their biocompatibility and antimicrobial activity. The toxicity of the scaffold to human epidermal keratinocytes (HEK) was assessed using Live/Dead and alamarBlue viability assays following 7 days and 14 days. No significant decreases in cell viability were noted at either time point and cell proliferation increased 120% by 7 days and 200% by 14 days on both control and AgNP incorporated scaffolds. After 14 days, scanning electron microscopy revealed a confluent layer of HEK on the surface of the scaffolds, and fluorescent microscopy confirmed cell migration into the scaffold interior. The antibacterial efficacy of the scaffold was evaluated against *Escherichia coli* and *Staphylococcus aureus*. The mechanical properties of the PLCL scaffold were assessed via uniaxial tensile testing to failure. A slight decrease in the modulus of elasticity was observed following AgNP incorporation compared to control, while cellular attachment increased the modulus of elasticity significantly. (Supported by NIH RO1 ES016138)

### PS 1327 Formation of a Protein Corona on Silver Nanoparticles Mediates Cellular Toxicity via Scavenger Receptors.

J. Shannahan<sup>1</sup>, R. Chen<sup>2</sup>, T. Fennell<sup>3</sup>, C. J. Wingard<sup>1</sup>, P. Ke<sup>2</sup> and J. M. Brown<sup>1</sup>. <sup>1</sup>East Carolina University, Greenville, NC; <sup>2</sup>Clemson University, Clemson, SC; <sup>3</sup>RTI International, Durham, NC.

Addition of a protein corona (PC) on the surface of nanomaterials can modify their activity, bio-distribution, cellular uptake, clearance and toxicity. As silver nanoparticles (AgNP) are incorporated into many products as anti-bacterial/fungal agents, the risk of human exposure escalates. We hypothesize that AgNPs will associate with proteins commonly found in human serum and cell culture media forming PCs which will impact cell activation and cytotoxicity. Furthermore, we believe that

activation of scavenger receptor B (SR-B) mediates this toxicity. Citrate- or PVP-coated AgNPs were incubated with human serum albumin (HSA), bovine serum albumin (BSA), high-density lipoprotein (HDL), or water (control). AgNPs associated with each protein (HSA, BSA, HDL) forming PCs by TEM, UV-vis spectroscopy and altered Z-potential and hydrodynamic size. Rat aortic endothelial (RAEC) and rat lung epithelial (RLE) cells were exposed to increasing concentrations of AgNPs (0, 6.25, 12.5, 25 or 50 µg/ml) with or without PC for 3h or 6h. All PC-coated AgNPs demonstrated a dose-response relationship in cytotoxicity in both cell types. To determine the role of SR-B in the observed cytotoxicity, cells were exposed to AgNPs with or without PCs for 3h in the presence of a SR-B antagonist. Treatment with the SR-B antagonist inhibited cytotoxicity in RAEC but not RLE. Lastly, cell activation was assessed at 1h by measuring interleukin-6 (IL-6) mRNA expression. All PC-coated AgNPs induced IL-6 mRNA expression at 1h in both cell types whereas treatment with the SR-B antagonist was found to inhibit expression. Differences in the induction of IL-6 were found between PC-coated AgNPs based upon suspension (citrate or PVP). This study characterizes a PC on AgNPs using proteins found in human serum and cell culture media. The presence of these PCs influenced cytotoxicity and cell activation through SR-B leading to altered cell responses. This work was supported by the U19 ES019525 and R01 ES09311.

**PS 1328 Importance of p38MAPK and pmk-1 a *Caenorhabditis elegans* Homologue, in Silver Nanoparticles-Induced DNA Damage Response and Apoptosis.**

J. Choi, N. Chatterjee, H. Eom and J. Ahn. *Faculty of Environmental Engineering, College of Urban Science, Seoul, Republic of Korea.* Sponsor: D. Ryu.

Silver nanoparticles (AgNPs) have recently received much attention for their possible applications in new material design, biotechnology and other commercial purposes. Our previous studies conducted in Jurkat T cells and *Caenorhabditis elegans* displayed that AgNP exposure caused dose and time dependent increase in only p38MAPK and pmk-1 expression among all other stress responsive proteins and DNA damage in Jurkat T cells. These findings motivated to ask whether and how p38MAPK and pmk-1 is involved in AgNP induced DNA damage response and eventually in mode of cell death. Our approach was comparative and we used the wild type (wt) and p38MAPK knocked down Jurkat T cells (siRNA transfection) as in vitro model system and wild type (N2) and pmk-1 (KU25) mutant strains of *C. elegans* as in vivo model system. The result showed that p38MAPK siRNA knocked down (KD) Jurkat T cells and pmk-1 mutant worms were more sensitive to AgNP and posed higher DNA damage response by activating sensors (hus-1, γH2AX) and effectors (cep-1 and p53) but preferred necrosis rather than DNA damage mediated apoptosis which is attested by egl-1 and ced-3 expression in *C. elegans* and in the same way, Bax/caspases in KD cells. Moreover, loss of p38MAPK and pmk-1 displayed impairment with the expression and activation of DNA damage repair systems (Rad-51, Lig-4). The mode of choosing of cell death pattern ultimately affects longevity and survival which in turn, support the idea that apoptosis actually play a defense against AgNP induced toxicity. On the whole, p38MAPK and pmk-1 play an evolutionarily conserved role in AgNP induced DNA damage response and cell death.

**PS 1329 Cytotoxicity and Genotoxicity of Silver Nanoparticles and Silver Ions to CHO K1 Cells.**

X. Jiang<sup>1</sup>, R. Foldbjerg<sup>2</sup>, T. Mclaus<sup>3</sup>, C. Chen<sup>1</sup>, H. Autrup<sup>2</sup> and C. Beer<sup>2</sup>. <sup>1</sup>National Center for Nanoscience and Technology, Chinese Academy of Science, Beijing, China; <sup>2</sup>Environmental and Occupational Medicine, Aarhus University, Aarhus, Denmark; <sup>3</sup>Interdisciplinary Nanoscience Center (iNANO), Aarhus University, Aarhus, Denmark.

Silver nanoparticles (Ag NPs) are used in a variety of commercial products due to their antimicrobial activity. As both in vitro and in vivo studies have demonstrated toxic effects of Ag NPs, there is an urgent need to explore the toxicity of Ag NPs. Here we studied the cytotoxicity and genotoxicity of Ag NPs (BSA coated, 15.9±7.6 nm) and silver ions (Ag<sup>+</sup>) to Chinese hamster ovary (CHO K1) cells. To analyse the cytotoxic effects the mitochondrial activity was determined by the MTT assay, intracellular reactive oxygen species (ROS) and the cell cycle were analyzed by flow cytometry. Fluorescence microscopy and flow cytometry based micronucleus assays were applied to qualify and quantify the number of micronuclei induced by Ag NPs and Ag<sup>+</sup>. P32 postlabeling was performed to detect DNA adducts. In addition, inductively-coupled plasma mass spectrometry (ICP-MS) and transmission electron microscope (TEM) were applied to study the uptake and intracellular distribution of Ag NPs, respectively.

A time and dose dependent decrease in mitochondrial activity and increase of intracellular ROS level in CHO K1 cells was observed after exposure to Ag NPs and Ag<sup>+</sup> (0-20 µg/ml) for 24h and 48h. Ag NPs and Ag<sup>+</sup> induced a cell cycle arrest in the G2/M phase. Micronucleus assay and P32 postlabeling revealed that both Ag NPs and Ag<sup>+</sup> induced micronuclei and DNA adducts. Using TEM observations Ag NPs were found to be located in endosomes/ lysosomes suggesting that Ag NPs are taken up by receptor mediated endocytosis. However, no Ag NPs were found in the nucleus suggesting that Ag NPs are presumably dissolved into Ag<sup>+</sup> in the endosomes/ lysosomes and released to the cytoplasm. From here they can enter mitochondria and /or the nucleus leading to an increased intracellular ROS level and the induction of DNA damage.

**PS 1330 Chronic Exposure to Realistic Doses of Silver Nanoparticles Demonstrated Differential Cellular Responses Than Acute Exposure in Human Keratinocytes.**

K. K. Comfort<sup>1,2</sup>, L. Braydich-Stolle<sup>1</sup> and S. M. Hussain<sup>1</sup>. <sup>1</sup>Molecular Bioeffects Branch, Human Performance Wing, Air Force Research Laboratory, Wright-Patterson AFB, OH; <sup>2</sup>Chemical and Materials Engineering, University of Dayton, Dayton, OH.

One obstacle plaguing the field of nanotoxicology is the development of a mechanism to translate acute exposure data to an accurate prediction of real world implications of nanomaterials (NM). In an effort to enhance the efficacy of information gathered from an in vitro environment, a chronic NM exposure scenario was designed and implemented in which human keratinocyte cells (HaCaT) were dosed with 50 nm silver nanoparticles (Ag-NP) 8 h a day, 5 days a week, for 3 months. Working concentrations were based off the permissible exposure limits set by OSHA and were 0.4, 4, and 400 pg/ml. The HaCaT stress response of the chronically treated cells was directly compared to a 24 h acute exposure at a concentration equal to the cumulative Ag-NP dosage encountered over the 3 months. Cellular endpoints evaluated include activation of Heat shock protein-27 signal transduction, ki67 expression, pro-inflammatory cytokine secretion, actin inflammation, and alterations in gene regulation. Results indicated that the chronically dosed HaCaT cells were functioning under sustained, augment cellular stress: as seen with increased reactive oxygen species levels, HSP-27 signaling, cytosolic ki67 expression, and actin inflammation and disorganization. Furthermore, considerable IL-6 secretion was observed throughout the experiment, indicating a continuous inflammatory response. Most notably, these stress indicators were all significantly higher in chronically dosed cells vs. their acute counterparts, demonstrating a more severe response. Additionally, chronically dosed cells demonstrated a vastly higher modification to gene regulation, again representing the potential for a serious long-term impact. In conclusion, this study identified a significant variation in the HaCaT stress response following chronic exposure of Ag-NPs vs. an acute scenario and offers a novel approach to nanotoxicology research.

**PS 1331 Evaluation of Uptake and Cytotoxicity of Citrate Stabilised Gold Nanoparticles in Chinese Hamster Ovary (CHO) Cells prior to the *In Vitro* Mammalian Mutation Test.**

M. Vetten<sup>1,2</sup> and M. Gulumian<sup>1,2</sup>. <sup>1</sup>Toxicology and Biochemistry Section, National Institute for Occupational Health, Johannesburg, South Africa; <sup>2</sup>School of Pathology, University of the Witwatersrand, Johannesburg, South Africa.

The health risk assessment of engineered gold nanoparticles (AuNPs) requires the generation of hazard identification data. Currently the Organisation for Economic Co-operation and Development (OECD) has released a guidance manual for the testing of manufactured nanomaterials. Within this document various established toxicological endpoints have been proposed for study, including the *in vitro* mammalian cell gene mutation test (OECD TG476) for genotoxicity assessment. Prior to this mutation study, preliminary experiments were required to assess the cytotoxicity and uptake of the AuNPs into the cells. Chinese Hamster Ovary (CHO) cells were treated with 14 nm, 20 nm, and 40 nm citrate stabilised gold nanoparticles. The Roche xCELLigence RTCA system was used to determine cytotoxicity of the particles using cell impedance. The nanoparticles were non-toxic for the duration of the period tested. The use of this technology eliminated any potential interference of the nanoparticles with the assay. The uptake of the particles into the cells was visualised using the CytoViva Hyperspectral Imaging system and showed a time-dependent uptake of the particles into the cells. This preliminary data confirms lack of toxicity of the particles prior to use in the mutation assay, and confirms uptake of the particles into the cells. Mutagenicity studies using this cell line will be conducted to measure mutation at hypoxanthine-guanine phosphoribosyl transferase (HPRT). Although gold nanoparticles have been shown in literature to induce some DNA damage; to our knowledge, the genotoxicity of gold nanoparticles has not been assessed using the HPRT mutation assay to date.

**PS 1332 Bioavailability of Silver Nanoparticles in Artificial Physiological Fluids: Coating and pH Impact on Degree of Ionic Dissociation.**

L. Braydich-Stolle, E. Breitner, E. I. Maurer, B. Stacy and S. M. Hussain. 711 HPW/RHDJ, Wright-Patterson AFB, Dayton, OH.

The majority of studies have focused on nanoparticle (NP) fate and their induced damage with limited information on the physiological environment's role in altering NP properties. Artificial fluids (AFs) have been used to test the bioavailability of metallic compounds (difference between the amount of a substance a person is exposed to and the amount of substance the body receives). Literature has demonstrated that inhaled NPs accumulated in lungs and clearance was hindered during chronic exposure indicating the observed effects should become more pronounced over time due to impeded clearance. Based on these findings, this study examined the impact of artificial interstitial, alveolar, lysosomal, and gastric fluid on the physical properties of hydrocarbon coated silver (Ag-HC) and polysaccharide coated silver (Ag-PS) NPs and the associated changes in toxicity. Since inhalation exposure is of concern, the toxicity of the Ag-NPs exposed to the AFs was evaluated in alveolar macrophages and doses represent a week or year of exposure (0.5 ng/ml and 25 ng/ml) based on the concept that this delayed clearance will result in macrophages continually be recruited to engulf the NPs. For all the AFs, the Ag-HC NPs demonstrated large agglomeration, limited ionic dissociation, and no changes in cell viability. Ag-PS NPs exposed to alveolar and interstitial fluid demonstrated a similar trend, in addition to a loss of the PS coating. For the gastric fluid, large agglomerates were observed but these were rare and most likely due to the Ag NPs precipitating out as AgCl. Interestingly, the Ag-PS NPs exposed to lysosomal fluid demonstrated a loss of coating, less agglomeration, and significant decreases in cell viability. Since NPs are most likely taken up via endocytosis in cell cultures or by phagocytic cells in an in vivo system, the interactions of the NP with the lysosomal environment has critical implications on mediating the NP cellular consequences. Based on this study, the lysosomal environment has the potential to make a NP more toxic over time. (88ABW-2012-5185)

**PS 1333 Cytotoxic and Inflammatory Responses to Silver Nanoparticles in Hepatocyte-Kupffer Cell (HC-KC) Coculture and HepG2 Cells.**

M. W. Betz, B. E. Wildt, B. J. Casey and P. L. Goering. CDRH, US FDA, Silver Spring, MD.

Nanoparticles accumulate in several organs following in vivo exposure, notably the liver. Numerous studies have assessed effects of nanoparticles on liver cells *in vitro*, but it is unclear whether it is preferable to conduct these studies using a physiologically-relevant cell culture model or if using an established liver-derived cell line is adequate. To address this question, we compared cellular responses to AgNPs in a primary rat HC-KC coculture with those in HepG2 cells. Metabolic activity (MTT reduction) was assessed 24 hr after exposure of cells to 10, 50, or 100nm AgNPs administered at 1, 10, 25, or 50 µg/mL and 0.25, 0.5, 1, 2, 3, 4 cm<sup>2</sup>/mL. Calcium homeostasis and flux were investigated after exposure to AgNPs by mass concentration. Inflammatory responses were assessed by measuring TNF-α and IL-6 levels in HC-KCs and monocultures of hepatocytes and Kupffer cells after 6 and 24 hr exposure to 50nm AgNPs ± lipopolysaccharide. Metabolic activity results showed that HC-KCs are more sensitive to AgNPs than HepG2 cells on the basis of both mass and surface area. Calcium homeostasis and flux levels also demonstrated that HC-KCs were more sensitive to AgNPs than HepG2 cells. Using confocal microscopy, AgNPs appeared to localize in the cytoplasm of both HC-KC cell types; however, a greater density of particles was observed in Kupffer cells compared to hepatocytes. Kupffer cells and HC-KCs both produced strong inflammatory responses (TNF-α and IL-6) to AgNPs by 6 hr, which remained unchanged at 24 hr, while hepatocytes alone did not produce TNF-α or IL-6. Thus, the data show that inflammatory responses in HC-KCs are dependent on the presence of Kupffer cells. Additionally, with increasing AgNP concentrations, TNF-α and IL-6 levels remained constant in HC-KCs but decreased in Kupffer cells suggesting the KCs are more sensitive in monoculture and protected by hepatocytes in the coculture. This study demonstrates the value of using a more physiologically-relevant cell culture system for the *in vitro* investigation of nanoparticle toxicity on liver.

**PS 1334 Evaluation of Genotoxicity of Silver Nanoparticles with *In Vitro* and *In Vivo* Standard Assays.**

Y. Li<sup>1</sup>, J. Yan<sup>1</sup>, N. Mei<sup>1</sup>, Y. Chen<sup>1</sup>, M. G. Pearce<sup>1</sup>, W. Ding<sup>1</sup>, C. Candice<sup>2</sup>, P. C. Howard<sup>2</sup>, P. Rice<sup>3</sup>, T. Zhou<sup>4</sup>, R. K. Elespuru<sup>5</sup>, M. M. Moore<sup>1</sup> and T. Chen<sup>1</sup>. <sup>1</sup>Division of Genetic and Molecular Toxicology, US FDA/National Center for Toxicological Research, Jefferson, AR; <sup>2</sup>Nanotechnology Core Facility, US FDA/National Center for Toxicological Research, Jefferson, AR; <sup>3</sup>Center for Food Safety and Applied Nutrition, US FDA, College Park, MD; <sup>4</sup>Center for Veterinary Medicine, US FDA, Rockville, MD; <sup>5</sup>Center for Devices and Radiology Health, US FDA, Silver Spring, MD.

Many publications are available on genotoxicity of nanomaterials. However, it is difficult to compare these results objectively due to conflicting results from different test methods, most of which were not the standard assays. In this study, both *in vitro* and *in vivo* standard genotoxicity assays including the Ames test, the *in vitro* and *in vivo* micronucleus assay and the mouse lymphoma gene mutation assay were applied to assess the genotoxicity of 5 nm uncoated and PVP coated silver nanoparticles (AgNPs). Mutagenic evaluation of uncoated AgNPs with the Ames test showed negative results possibly due to lack of cell uptake of the nanoparticles and strong cytotoxicity of AgNPs to bacteria. The AgNPs, however, induced mutations in a dose-dependent manner in mouse lymphoma cells via an oxidative stress mechanism evidenced by the results from loss of heterozygosity analysis of the Tk mutants, oxidative Comet assay and gene expression analysis. Micronuclei in TK6 cells were also increased by AgNPs in a dose-dependent manner. At a concentration of 30 µg/ml, uncoated AgNPs caused around 50% cytotoxicity (relative population doubling) and induced a significant, 3.17-fold increase over the vehicle control while PVP-coated AgNPs induced 50% cytotoxicity and 2.25-fold increase of micronuclei over the control at only 1.75 µg/ml. Although AgNPs can reach the bone marrow, they were negative in *in vivo* micronucleus assay. Our results demonstrate that the AgNPs are genotoxicity in *in vitro* mammalian assays, but not in *in vivo* mouse micronucleus assay.

**PS 1335 DNA-Dependent Protein Kinase Reduces Toxicity of Silver Nanoparticles in Mammalian Cells through JNK and Telomerase Pathways.**

H. Lim and H. Manoor Prakash. *Physiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore.* Sponsor: S. Sawant.

Silver nanoparticles (Ag-np) are distinctively reported to be toxic to mammalian cells. Less is known about the signalling response triggered in cells to counteract such toxicity. This study was initiated to enhance our mechanistic insight on correlation between, DNA-dependent protein kinase catalytic subunit (DNA-PKcs) and toxicity of Ag-np. The toxicity of polyvinyl alcohol (PVA)-coated Ag-np was studied in normal human lung fibroblast and human breast cancer and brain cancer cells. DNA-PKcs inhibition was carried out to investigate impact of DNA-PKcs on influencing toxicity of Ag-np. The toxicity was evaluated using changes in cell survival, DNA damage and repair and telomeres length. We observed concurrent activation of DNA-PKcs and JNK pathway in cancer cells upon Ag-np treatment, which were anticipated as physiologic responses to DNA damage and repair. JNK pathway was insufficiently activated in DNA-PKcs inhibited cancer cells, abolishing the signalling events required for mediating DNA repair. Further investigation on genotoxic effect of Ag-np indicated that Ag-np causes telomere attrition and dysfunction in human cancer cells by disrupting shelterin complex integrity and telomerase expression. Recruitment of activated DNA-PKcs to damaged telomeres signifies the importance of DNA repair machinery at damaged telomeres. DNA-PKcs inhibition potentiates the damaging effect of Ag-np at telomeres in human cancer cells. Abrogation of JNK mediated DNA repair and substantial damages at telomeres lead to higher cell death in DNA-PKcs inhibited, Ag-np treated cancer cells. Altogether, presence of DNA-PKcs effectively reduces the toxic effects of Ag-np in human cancer cells by triggering the activation of JNK pathway and telomeres length maintenance. This study suggests that the potentially detrimental combination of Ag-np with DNA-PKcs inhibition can however be applied as a better strategy in cancer therapy.

**PS 1336 Determination of Nanosilver Dissolution Kinetics and Toxicity in an Environmentally Relevant Aqueous Medium.**

A. Harmon, A. J. Kennedy, A. R. Poda, A. J. Bednar, M. A. Chappell and J. A. Steevens. *US Army Corps of Engineers, Vicksburg, MS.*

The dissolution potential of citrate capped silver nanoparticles (AgNPs) in laboratory test media and in the environment is critical for determining toxicity. In the present study, the ion-release kinetics from citrate capped 20, 50, and 80 nm

AgNPs in dilutions of an environmentally relevant freshwater (30µS/cm and 150µS/cm reconstituted water) was examined and related to the associated impact on an aquatic organism (*Daphnia magna*). Diluted suspensions of nanoparticles were placed on a multi-tube vortexer and orbital shaker for 0, 1, 2, 3 and 7 days. The acute toxicity of the AgNPs suspensions was then assessed with *D. magna* at 0 and 7 days post interaction between the particles and test media. An increase in hydrodynamic diameter measured by dynamic light scattering and field flow fractionation over time was observed at a relatively higher specific conductivity of 150 µS/cm in 20nm particles (3.3 fold increase) and only a small increase in 50 and 80nm particles (1.4 and 1.2 fold increase, respectively). At a lower conductivity of 30 µS/cm a 1.7, 1.0, and 1.2 fold increase was observed in 20, 50 and 80nm, respectively. Results showed that although the total concentration of silver in solution decreased with time, there was a consistent spike in dissolved concentration after 2-3 days interaction, followed by a steady decrease in dissolved silver in 150µS/cm and 30 µS/cm medium. This suggests that the concentration of dissolved silver in environmentally relevant ionic strength media increases over time after the introduction of citrate capped AgNPs which may have implications on aquatic organisms. When exposed *D. magna* was exposed to 150µS/cm and 30µS/cm test media, 30µS/cm test media induced more toxicity than 150µS/cm test media. Toxicity increased with longer *nAg* interaction time with smaller particles inducing more toxicity than larger particles.

### PS 1337 Silver Nanoparticles Induce Mast Cell Degranulation via Scavenger Receptors.

A. Aldossari, J. Shannahan, S. Hilderbrand and J. M. Brown. *Pharmacology and Toxicology, East Carolina University, Greenville, NC.*

Silver nanoparticles (AgNPs) are increasingly incorporated into a variety of consumer and industrial products such as water filters and cosmetics for their antimicrobial properties. This has increased human exposures to AgNPs and therefore the possibility of adverse health effects. Mast cells are well known to orchestrate allergic immune responses through degranulation and release of pre-formed mediators such as histamine. Furthermore, mast cells have been shown to mediate pulmonary inflammation following exposure to nanoparticles in a murine model. We therefore examined whether AgNP could induce mast cell degranulation. Bone marrow derived mast cells (BMMCs) were generated from femoral bone marrow of C57BL/6 mice. BMMCs were exposed to either citrate- or polyvinylpyrrolidone (PVP)-coated AgNPs (20 nm or 110 nm diameter) at increasing concentrations (6.25, 12.5, 25, or 50 µg/ml) for 3, 6, or 24 h. Exposure to 20 nm AgNPs, but not 110 nm AgNPs, was found to cause concentration-dependent degranulation of BMMCs at 1 h. TNF-α gene expression was increased in BMMCs following AgNP exposure while TNF-α protein levels were increased only after exposure to citrate-coated AgNPs at 50 µg/ml. To determine the mechanism of BMMC degranulation following exposure to 20 nm AgNPs, we examined scavenger receptors which have been shown to mediate nanoparticle uptake in macrophages. PCR and flow cytometry demonstrated the presence of scavenger receptor class B1 (SR-B1) on the surface of cultured BMMCs. To determine the role of SR-B1, BMMCs were treated with two different SR-B1 antagonists (blt-1 or blt-2). Treatment with either SR-B1 antagonist was found to prevent AgNP-induced degranulation of BMMCs. These *in vitro* findings suggest that AgNPs may induce an inflammatory response via mast cell degranulation *in vivo*, which is dependent upon nanoparticle size and scavenger receptor activation. Therefore mast cell degranulation may be considered as an indicator of nanomaterial toxicity. This work was funded by NIEHS R01 ES019311 and U19 ES019525.

### PS 1338 High-Throughput Methods for Assessing the Molecular Toxicity of Nanomaterials in Bacteria.

C. Kaweeteerawat<sup>1,2</sup>, A. Ivask<sup>2</sup>, C. Low-Kam<sup>2,3</sup>, P. Holden<sup>2,4</sup> and H. A. Godwin<sup>1,2</sup>. <sup>1</sup>Molecular Toxicology, University of California Los Angeles, Los Angeles, CA; <sup>2</sup>University of California Center of Environmental Implication of Nanotechnology, University of California Los Angeles, Los Angeles, CA; <sup>3</sup>Department of Biostatistics, University of California Los Angeles, Los Angeles, CA; <sup>4</sup>Donald Bren School of Environmental Science and Management, University of California Santa Barbara, Santa Barbara, CA.

Synthesis and use of nanoparticles has skyrocketed during the past decade. To ensure that nanotechnology is safely and sustainably developed, rapid, cost-effective methods are needed to determine the toxicity of nanoparticles. Here, we report the application of a suite of sub-lethal assay as well as a growth inhibition assay to a series of silver and metal oxide nanoparticles in bacteria (*Escherichia coli*). Sub-lethal effects such as perturbation of membrane integrity (using PI/SYTO) disruption of membrane potential (using DiBAC) and reduction of respiration rate (using XTT) were used to identify toxic nanoparticles. To further look into mechanism of toxicity, intracellular Reactive Oxygen Species (ROS) and the intrinsic property of

nanoparticles to oxidize electron (abiotic ROS generation) were measure by using H2DCFDA and DCFH respectively. These studies revealed that toxicity of the silver particles studied correlates with size and surface charge, with smaller particles and particles with a more positive surface charge being more toxic. By contrast, the toxicity of the metal oxide particles studied correlates most significantly with their ability to oxidize biomolecules, although dissolution of some of the particles also plays an important role.

### PS 1339 Role of microRNA in Toxicity of Silver Nanoparticles in Jurkat T Cells.

H. Eom<sup>1</sup>, J. Choi<sup>1</sup> and J. Lee<sup>2</sup>. <sup>1</sup>Faculty of Environmental Engineering, College of Urban Science, Seoul, Republic of Korea; <sup>2</sup>National Instrumentation Center for Environmental Management, Seoul, Republic of Korea. Sponsor: D. Ryu.

In this study, in order to identify whether miRNAs are involved in toxicity of silver nanoparticles (AgNPs), we investigated miRNA expression in AgNPs treated Jurkat T cells using mRNA and miRNA microarrays. Surprisingly small numbers of genes were affected by both silvers exposure (19 up- and 2 down-regulated mRNA by AgNPs exposure, and 2 up- and 1 down-regulated mRNA by Ag ion exposure). More important numbers of differentially expressed (DE) miRNAs than DE mRNAs were revealed by miRNA microarray, such as, 31 up- and 51 down-regulated miRNAs by AgNPs exposure, whereas 11 up- and 27 down-regulated miRNAs by Ag ion exposure. The most dramatic alteration was observed in hsa-miR-1238 (a decrease of 67 folds) by AgNPs exposure. An integrated analysis of mRNA and miRNA expression was conducted on DE mRNA and DE miRNA by AgNPs and Ag ion exposure, which revealed that the expression of miRNA, hsa-miR-219-5p, was negatively correlated with that of mRNA, metallothionein 1F (MT1F) and tribbles homolog 3 (TRIB3), in the cells exposed to AgNPs; whereas, the expression of hsa-miR-654-3p was negatively correlated with the expression of mRNA, endonuclease G-like 1 (EDGL1) in the cells exposed to Ag ions. However no mRNA regulated by hsa-miR-1238 was identified. Individual validation was followed on these 3 miRNA-mRNA pairs using qPCR. Bioinformatics analysis was further conducted using Pathway Studio, which suggests hsa-miR-219-5p - MT1F and -TRIB3 pairs play an important role in AgNPs toxicity in Jurkat T cells by regulating the genes in important stress response pathways, such as, cell survival, cell death and oxidative stress. Overall results suggest that compared to serious toxicity, only limited genes were affected by AgNPs at transcriptomic level, whereas more important number of miRNAs were identified, which suggests fine regulation with miRNA may play important role in AgNPs toxicity.

### PS 1340 Assessing the Influence of Gold and Silver Nanoparticles on Conventional In Vitro Cytotoxicity Assays.

K. Boodhia<sup>1,3</sup>, L. Koekemoer<sup>1,3</sup>, C. Andros<sup>1,2</sup> and M. Gulumian<sup>1,2</sup>. <sup>1</sup>Toxicology, National Institute for Occupational Health, Johannesburg, South Africa; <sup>2</sup>Hematology and Molecular Medicine, University of Witwatersrand, Johannesburg, South Africa; <sup>3</sup>Biochemistry, University of Johannesburg, Johannesburg, South Africa.

Gold nanoparticles (AuNPs) and silver nanoparticles (AgNPs), due to their optical properties are used in optics and biomedical applications. A principal property of these NPs is their enhanced surface plasmon resonance which enables them to scatter and absorb light with great efficiency. When assessing NP toxicity, there are many challenges as conventional methods are optically based and make use of absorbance, luminescence and fluorescence. The objective of this work was to assess if AuNPs and AgNPs are capable of interfering with currently accepted *in vitro* cytotoxicity assays. Changes in the endpoints of the XTT, ATP, LDH and MitoPT-JC-1 assays was assessed in the absence and presence of cells, after the addition of AuNPs and AgNPs, to assess interference. Results obtained from XTT, ATP and LDH assays in the presence of cells showed toxicity. In the absence of cells, the XTT and ATP assays showed significant changes in their absorbance and luminescence; this could be explained by product adsorption to the NP or interference of NPs with the readings of the products assessed. On the other hand, the LDH assay showed little or no change in fluorescence. When using the MitoPT-JC-1, evaluation of cell treated with the NPs showed viable mitochondria, however in the absence of cells there is a decrease in the fluorescence which too can be explained by product adsorption to the NP. In conclusion, NPs have the ability to interfere in *in vitro* toxicity assays, skewing results. For this reason when assessing NP toxicity using these assay systems, their reliability and sensitivity needs to be determined. To overcome this interference of the gold and silver NPs a non invasive system such as the xCELLigence RTCA system, which does not use absorbance luminescence, and fluorescence, can be used to determine the viability of cells by measuring the cell index, a dimensionless parameter, which is an expression of cell adherence.

**PS 1341 Realistic Assessment of Nanomaterial Toxicity *In Vitro* Using a Nanoaerosol Exposure Chamber.**

C. Grabinski<sup>1,2</sup>, M. Sankaran<sup>2</sup> and S. M. Hussain<sup>1</sup>. <sup>1</sup>Molecular Bioeffects Branch, Air Force Research Laboratory, Wright-Patterson AFB, OH; <sup>2</sup>Department of Chemical Engineering, Case Western Reserve University, Cleveland, OH.

Traditional *in vitro* toxicology methods require dispersion of nanomaterials (NMs) in biological media for administration to cells, which does not depict realistic inhalation exposure. The objective of this work is to design and optimize a system to mimic inhalation exposure by delivering well-characterized NM aerosols to cells grown at the air-liquid interface. Gold or silver NMs were drawn into the gas phase from an aqueous dispersion using electrospray. The aerosolized NMs were introduced into a chamber and deposited onto cells using electrostatic deposition. The deposition of NMs in the chamber was assessed by evenly placing copper grids throughout the chamber and imaging particle deposition using transmission electron microscopy (TEM). NM deposition on cells grown in the chamber was quantified by digesting the samples and measuring gold or silver content using inductively coupled plasma – mass spectrometry (ICP-MS). A human nasal epithelial cell-line was grown in the chamber, and the viability was assessed using the Alamar Blue assay. Results showed that gold and silver NMs could be deposited uniformly in the chamber and that the dose could be controlled by varying the electric field strength and frequency used for electrostatic deposition. Additionally, the dose was found to be relevant compared to NM deposition in the respiratory tract predicted by the Multiple Path Particle Dosimetry model. The results of the Alamar Blue assay showed that the cells could be sustained in the chamber, and the application of electric fields did not have an effect on cell viability. This study demonstrates a promising step forward in the development of a standardized realistic exposure method for assessing NM toxicity *in vitro*.

**PS 1342 Influences of Capping Agent and Cell Type on Cellular Uptake of Silver Nanoparticles.**

F. Zhang, B. L. Lau and E. D. Bruce. *The Institute of Ecological, Earth and Environmental Sciences, Baylor University, Waco, TX.*

The usage of engineered silver nanoparticles (AgNPs) in catalysts, sensors, drug carriers, and personal care products is growing because of their unique physicochemical and biological activities. Consequently both occupational and consumer exposure to these AgNPs is likely to increase in proportion to the production and usage in the market. Meanwhile, there are increasing concerns that exposure to these NPs may cause potential adverse effects on human health as well as the environment. Capping agents are selected organic or inorganic material applied to the surface of nanoparticles as stabilizer to prevent aggregation. However, little is known about the effect of capping agents on the NPs-cell interaction and the mechanisms behind it. Experiments were carried out to quantitatively and mechanistically investigate the role of capping agents of AgNPs on cellular uptake by two different cell lines, human bronchoalveolar carcinoma derived cells (A549) and human colon adenocarcinoma derived cells (Caco-2). *In vitro* studies were used to quantify the uptake kinetics and the extent of internalized AgNPs and to investigate the uptake mechanism among five capping agents (citrate, polyvinylpyrrolidone (PVP), tannic acid, silica and penetratin) by two cell lines. Preliminary results on A549 cells showed that 34% of the penetratin-coated AgNPs were internalized, followed by tannic acid-coated AgNPs, 25%, while the silica-coated AgNPs showed the least uptake, only 4% internalized content. Penetratin is a cell-penetration peptide designed to translocate across the cell membrane, which explains why penetratin-coated AgNPs were more readily internalized than other capping agents. These results demonstrated that capping agents play an important role in cellular uptake of AgNPs. Further experiments on Caco-2 cell line are currently underway and will expand our knowledge on nanoparticle-cell interactions. The combined results can be applied to manage the risk associated with occupational and consumer exposure to AgNPs.

**PS 1343 Comparative Cytotoxicity of Silver Nanomaterials in a Murine Macrophage Cell Line.**

T. D. Green<sup>1</sup>, A. Badawy<sup>2</sup>, T. Tolaymat<sup>3</sup> and D. J. Thomas<sup>1</sup>. <sup>1</sup>ISTD, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Department Civil & Environmental Engineering, University of Cincinnati, Cincinnati, OH; <sup>3</sup>LRPCD, NRMRL, ORD, US EPA, Cincinnati, OH.

Manufactured silver nanomaterials (AgNPs) are used as antimicrobials in many consumer products. Although increased use of AgNPs increases risk of exposure by inhalation or ingestion, there are few data on human health risks associated with exposure. Here, we evaluated the toxicity of AgNPs in the murine macrophage J774A.1 cell line. Macrophages play a key role in the inflammatory response by

phagocytosis of pathogens, debris, and particles. Phagocytosis of AgNPs by macrophages could expose cells to Ag and alter cell structure and function. We used two *in vitro* cytotoxicity assays, lactate dehydrogenase (LDH) and reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), to compare cytotoxic effects of ionic Ag, polyvinylpyrrolidone PVP coated-AgNPs (MHD=13 nm), hydrogen reduced H<sub>2</sub>-AgNPs (14 nm), and citrate-AgNPs (12 nm). Cells were exposed to Ag, PVP-coated AgNPs, H<sub>2</sub>-AgNPs, or citrate-AgNPs, either in media alone or media supplemented with 1% fetal bovine serum (FBS) for 1, 4, or 24 hours before assessment. Each AgNP diminished MTT reduction capacity of J774A.1 cells with 50% reductions in activity in the low parts per million of Ag concentration range. Compared with AgNPs, Ag was a more potent cytotoxicant. LDH leakage increased after exposure to Ag and AgNPs indicated that all compounds produced damage to cell membranes. In MTT assays, addition of 1% FBS to media mitigated cytotoxic effects of all forms of Ag. In LDH assays, addition of FBS did not affect Ag-dependent membrane damage. These results indicate AgNPs affect integrity of cell membranes and metabolic competency of cells, although it is yet unclear whether these effects are mediated by phagocytosis of AgNPs or by accumulation of Ag solubilized from nanoparticles. Future studies that examine the disposition, fate, and effects of AgNPs will provide more information for assessment of bioavailability and potential human health risks. (This abstract does not reflect U.S. EPA policy.)

**PS 1344 Dispersion and Dissolution Behavior of Silver Nanoparticles in Artificial Biological Fluids.**

A. M. Mayo<sup>1</sup>, D. R. Johnson<sup>2</sup>, A. J. Bednar<sup>2</sup> and J. A. Steevens<sup>2</sup>. <sup>1</sup>Badger Technical Services, Vicksburg, MS; <sup>2</sup>Environmental Laboratory, US Army Engineer Research & Development Center, Vicksburg, MS.

Nano-sized silver (nAg) is the most widely used engineered nanoparticle in consumer products, so much attention is being given to environment, health, and safety (EHS) risk associated with nAg exposure. The purpose of this study was to evaluate the agglomeration and dissolution of engineered nAg in artificial biofluids to better understand nAg stability throughout the body. Twenty-four hour time-course evaluations of 1 mg/L nAg in artificial biological fluids (alveolar, interstitial, gastric [pH 1.5], and intestinal fluid) were conducted using field flow fractionation-inductively coupled plasma-mass spectrometry (FFF-ICP-MS), dynamic light scattering (DLS), spectrophotometry, and dissolution methods. Silver nitrate (AgNO<sub>3</sub>) was used as a positive control. Citrate- and PVP-Ag (20 nm) in alveolar fluid and intestinal fluid showed similar settling patterns, with absorbance levels decreasing only 10% from t=0 to t=24h, likely due to the presence of surfactants. In contrast, these same particles in interstitial fluid and gastric fluid (pH 1.5) show a 40% decrease in absorbance at 24 h. Rapid agglomeration of coated-nAgs appeared to be occur, as indicated by the sudden formation of black particulates upon addition of the coated-nAgs to all artificial biofluids tested. nAg showed marked size increases over 24 h in interstitial, intestinal, and gastric fluids. The decrease in surface area resulting from this agglomeration may also have an effect on Ag dissolution rates. Citrate- and PVP-coated nAg dissolution, as well as AgNO<sub>3</sub>, suggests the loss of Ag<sup>+</sup>, when compared with Ag<sup>+</sup> concentrations in water. The high concentration of chloride ions in many artificial biofluids may lead to the rapid formation of AgCl during nAg dissolution. These studies demonstrate that nAg is likely to undergo several dissolution and agglomeration changes as the particle moves through different organ systems. Furthermore, these data can be used to generate prediction models of nAg dispersion throughout the body.

**PS 1345 Correlating *In Vivo* Agglomeration State with Oral Bioavailability of Gold Nanoparticles.**

G. K. Hinkley<sup>1</sup>, S. M. Roberts<sup>1</sup> and K. W. Powers<sup>2</sup>. <sup>1</sup>Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL; <sup>2</sup>Particle Engineering Research Center, University of Florida, Gainesville, FL.

Particle size is thought to be a critical factor affecting the bioavailability of nanoparticles (NPs) following oral exposure. Nearly all studies of NP bioavailability focus on characterization of the primary particle size of the material as supplied or as dosed, and not on the effective particle size within the gastrointestinal tract (GIT), which is presumably most relevant for absorption. In the study reported here, agglomeration behavior of gold nanospheres was evaluated *in vivo* throughout the gastrointestinal tract (GIT) using transmission electron microscopy (TEM). Agglomeration state within the GIT was then correlated with bioavailability as indicated by tissue levels of Au detected using inductively coupled plasma mass spectrometry (ICP-MS). Mice were dosed (10mg/kg) with either 22nm PEG-coated or uncoated Au NPs. Previous work done by this group using dynamic light scattering in simulated gastric fluid (SGF) has shown that uncoated Au NPs quickly agglomerate in this environment while PEG-coated Au NPs remain well dispersed after 24 hours in SGF. Samples were taken from various regions of the GIT at varying times

after dosing for TEM analysis. Images from these samples are consistent with predicted agglomeration behavior in that PEG-coated Au NPs can be observed as primary (22nm), non-agglomerated NPs in the stomach, small intestine (SI), cecum, large intestine (LI) and feces of dosed animals. In contrast, uncoated Au NPs were observed to form agglomerates of several hundred nanometers in the stomach and remain agglomerated in the SI, cecum, LI and feces. At 12 hours post-gavage there was significantly more gold detected in the blood and liver ( $p < 0.05$ ) of animals dosed with PEG-coated vs. uncoated Au particles. The characterization of these particles in vivo supports our hypothesis that differences in ICP-MS tissue levels of Au between animals dosed with PEG-coated vs. uncoated Au NPs is due to the particle size being presented to absorptive surfaces in the GIT.

### PS 1346 Comparison of Acute and Chronic Toxicity and Effects of Nanoparticles *Ceriodaphnia dubia*.

A. J. Kennedy<sup>1</sup>, A. Harmon<sup>1</sup>, J. G. Laird<sup>1</sup>, A. J. Bednar<sup>1</sup>, C. Detzel<sup>2</sup> and J. A. Steevens<sup>1</sup>. <sup>1</sup>US Army Corps of Engineers, Vicksburg, MS; <sup>2</sup>NanoSafe, Blacksburg, VA.

In recent years, the usage of nanoparticles has grown tremendously, and their potential to exert toxicity in aquatic environments is an increasing concern. This study evaluated the toxicity of 20 and 100nm nanosilver and nanogold to *Ceriodaphnia dubia* in soft reconstituted water. The selected nanoparticles were chosen for nanosilver ability to dissolve in environmentally relevant solution and nanogold for its slow dissolution in environmentally relevant solution. Standard toxicity test have shown that *Ceriodaphnia dubia* are less sensitive to silver chronically than they are acutely. This is most likely a result of the addition of food binding to the silver reducing bioavailability. An altered testing procedure adding food after 8 hours from water renewal alongside standard testing procedures was evaluated acutely and chronically. This window of time will allow for the uptake of nanoparticles by the organisms that would otherwise not be available. In acute and chronic test *Ceriodaphnia dubia* were less sensitive to nanogold than nanosilver. When comparing acute and chronic 20nm nanogold tests, 100% mortality was shown in the highest concentration 75 mg/L chronically with 60% survival acutely in the highest concentration. This would suggest the possibility that toxicity is occurring by different mechanisms. In 20nm nanosilver chronic testing the altered testing procedure showed an increase in mortality and delayed reproduction compared to standard testing procedures confirming that the addition of food decreases sensitivity to the organism. Future work will include the testing of 100nm nanosilver and nanogold. Further studies are needed to indicate that toxicity is occurring by different mechanisms when comparing acute-to-chronic ratios and testing of different aquatic organisms.

### PS 1347 Silver Nanoparticles Impair Neuronal Synaptic Function and Alter Neurotransmitter Content in the Brain.

K. Sriram, J. R. Roberts, G. X. Lin, J. M. Antonini, A. Kenyon and A. M. Jefferson. CDC-NIOSH, Morgantown, WV.

Silver nanoparticles (AgNPs) find application in the manufacturing of industrial, household and diagnostic products, besides its extensive antimicrobial use. While the economic benefits of manufacturing such materials are highly promising, their adverse environmental and health effects are yet to be fully realized. The unique physico-chemical properties of AgNP influence its ability to aerosolize, and thus occupational or environmental exposure is of major concern. To determine if AgNPs pose a neurological risk, we evaluated its effects in a rodent model. Well characterized AgNP (primary particle size = 20-50 nm) suspensions were prepared in dispersion medium (DM; mean particle aggregate size in DM = 180 nm). Adult male Sprague-Dawley rats were intra-tracheally instilled with a single dose of either DM, 37.5, 112.5 or 450 µg AgNP. At 1, 7, 28, or 84d post-exposure, various indices of neural dysfunction were examined in discrete brain areas. By 7d post-exposure, AgNPs caused a partial loss (35-40%) of striatal synaptosomal-associated protein 25 (Snap25) and syntaxin binding protein 1 (Stxbp1), critical molecular regulators of synaptic neurotransmission. Levels of Snap25 decreased further (~85%) by 84d post-exposure. AgNP also decreased (~25%) striatal tyrosine hydroxylase (Th) protein content. Further, AgNP caused a time-dependent increase (16-45%) in striatal norepinephrine, while lowering (25%) serotonin content by 28d post-exposure. However, AgNP did not alter striatal dopamine content, although it reduced striatal Th. Reactive astrogliosis, as evidenced by increased (30%) expression of glial fibrillary acidic protein (Gfap) was observed in the striatum, 7d following exposure. The persistent reduction of synaptic proteins 84d following cessation of exposure suggests that AgNPs can potentially be neurotoxic. Whether such abnormalities can culminate in neurodegeneration remains to be investigated. Our findings call for extensive safety evaluation to better understand the risks associated with AgNPs and avert any adverse neurological health effects.

### PS 1348 A Study of Mice Inhalation Exposures to Silver Nanoparticles Generated by Nebulization and Electrospray Methods.

A. Lao<sup>1</sup>, M. Zhong<sup>1</sup>, K. Galdanes<sup>1</sup>, D. Chen<sup>2</sup>, T. Gordon<sup>1</sup> and L. Chen<sup>1</sup>.

<sup>1</sup>Environmental Medicine, New York University, Tuxedo, NY; <sup>2</sup>Energy, Environmental and Chemical Engineering, Washington University in St. Louis, St. Louis, MO.

Many forms of engineered nanomaterials are currently being used in industrial and medical applications in the advanced field of nanotechnology. One of the major routes of human exposure to nanomaterials is inhalation. Silver nanoparticles or nanosilver in particular, are prevalent in consumer products and many other applications as antibacterial agents, yet there are relatively limited nanosilver toxicity data in the literature. A series of rodent exposures were conducted to assess the lung inflammatory response. The nanoparticles were generated via a Collision nebulizer and an electrospray aerosol generator using suspensions composed of citrate stabilized nanosilver or polyvinylpyrrolidone (PVP) stabilized nanosilver. The primary size of both nanosilvers was 20 nm in diameter. Particle size distributions of aerosolized citrate stabilized nanosilver and PVP stabilized nanosilver were also characterized. Count median diameters (CMD) of citrate nanosilver and PVP nanosilver were between 50 and 60 nm, while their volume median diameters (VMD) were between 80 and 100 nm, respectively. The CMD and VMD of citrate stabilized nanosilver generated by electrospray were found to be about 2-fold and 3-fold lower, respectively, than that generated by Collision nebulizer. Acute nose-only exposures were conducted on male BALB/c mice using the nebulizer and lung inflammatory responses were examined following 4-h exposure to citrate stabilized nanosilver at a concentration of 1.0 mg/m<sup>3</sup>. At 24-h and 7-d post exposure, there were little change in the number of polymorphonuclear neutrophils and protein concentrations in bronchoalveolar lavage fluid as compared to filtered air control. Our results showed that citrate and PVP coated nanosilver elicited minimal pulmonary inflammatory response in mice at the concentration tested in this experiment.

### PS 1349 Estimation of Human Equivalent Exposure from Rat Inhalation Toxicity Study of Silver Nanoparticles Using Multipath Particle Dosimetry Model.

J. Ji and L. Yu. Institute of Nanoproduct Safety Research, Hoseo University, Asan, Republic of Korea.

Respiratory tract dosimetry is a useful tool to estimate the exposure concentrations of an inhaled substance that will produce the same result at a target site of the respiratory tract in both rats and humans. Thus, to enable the results of animal inhalation studies to be extrapolated to human equivalent exposure levels, the MPPD (multi-path particle dosimetry) model was used to estimate the differences in the respiratory dosimetry of rats and humans. In our previous study, when animals were subchronically exposed to silver nanoparticles over a period of 90 days, a no observable adverse effect level (NOAEL) of 100 µg/m<sup>3</sup> was suggested. Therefore, this study used results from a previous animal study, including the test aerosol information and estimated clearance rate of silver nanoparticles after a 90-day inhalation toxicity test. As a result, the human equivalent workplace exposure concentration of silver nanoparticles was estimated as 59 µg/m<sup>3</sup> compared to the rat NOAEL of 100 µg/m<sup>3</sup>.

### PS 1350 Alterations in Lung Host Defense after Pulmonary Exposure to Silver Nanoparticles in Rats.

B. M. Yingling<sup>1,2</sup>, C. McLoughlin<sup>2</sup>, J. M. Antonini<sup>2,1</sup>, R. I. MacCuspie<sup>3</sup>, V. A. Hackley<sup>3</sup>, B. T. Chen<sup>2</sup>, D. Schwegler-Berry<sup>2</sup> and J. R. Roberts<sup>2,1</sup>. <sup>1</sup>WVU, Morgantown, WV; <sup>2</sup>NIOSH, Morgantown, WV; <sup>3</sup>NIST, Gaithersburg, MD.

Silver nanoparticles (AgNP) are among the fastest growing categories of manufactured nanomaterials, and there is a need to investigate the risk for potential adverse effects of respiratory exposure in workers. The goal of the current study was to characterize susceptibility to lung bacterial infection following AgNP exposure *in vivo*. AgNP, 20 nm in diameter with a 0.3% wt polyvinylpyrrolidone coating (NanoAmor, Inc.), were suspended in a physiological dispersion medium (DM) and sonicated. On day 0, rats were intratracheally (IT) instilled with 37.6 (Ag Low) or 449 (Ag High) µg of AgNP in DM or DM alone. On day 3, rats were inoculated IT with 5x10<sup>5</sup> *Listeria monocytogenes* (LM). Rats were euthanized on day 3 (pre-infection), and on days 4, 6, 8, and 10. Bronchoalveolar lavage (BAL) was performed on the right lung. The left lung was cultured to assess LM burden, and the lung-associated lymph nodes (LALN) were harvested. BAL cells and fluid were retained for analysis of injury, inflammation and oxidant production, and LALN lymphocytes were counted to assess immune response. On day 3 pre-infection, increased BAL albumin levels (lung injury) neutrophil influx (inflammation), LALN lymphocytes, and

BAL cell oxidant production were measured in the Ag High group when compared to the Ag Low and DM groups. Following infection, LM lung burden increased significantly in the DM and Ag Low groups as compared to the Ag High group, peaking on day 6, with the highest burden in the DM group. LALN lymphocytes and BAL neutrophils, lymphocytes, and cellular oxidant production were elevated in the Ag High group on days 4 and 6 compared to DM and Ag Low groups. By day 8, LM lung burden, and BAL and LALN cell counts were similar for all groups. Induction of an early inflammatory response and oxidant burst in conjunction with increased lymphocyte proliferation in the lungs of the high dose AgNP group prior to infection enhanced the innate immune response and led to an increased clearance rate of bacteria from the lungs.

**PS 1351 Exposure to Inhaled Silver-Nanoparticles Results in the Induction of Gene Expression Alterations in Oxidative Stress Pathway Components, in a Time-Dependent Manner.**

M. A. Popovech, K. Galdanes, E. L. Saunders, M. N. Hernandez, L. Chen and T. Gordon. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

The use of silver nanoparticles (AgNPs) is ubiquitous, and they are now commonly employed in pharmaceuticals, medical imaging, medical devices, cosmetics, clothing, and other consumer products. Due to the commonality of AgNPs, along with a general lack of toxicity and safety testing, AgNPs have been deemed safe by default. However, legitimate concerns exist, and a number of recent studies suggest that AgNPs pose a threat to human health. This study was conducted in order to examine the hypothesis that inhaled nano-sized Ag particles cause lung and extrapulmonary organ dysfunction via oxidative stress pathways. Male and female FVB/NJ mice were exposed to either 0.5 mg/m<sup>3</sup> or 1 mg/m<sup>3</sup> of AgNPs generated from metal rods, using a Palas spark generator, via nose only inhalation for 4 hrs. An n=5 animals were used in each treatment group, and all treated animals were compared to air exposed controls. At 2hr, 24hr, 48hr, 72hr, and 7d post-exposure, animals were euthanized and blood, lavage and tissue were collected. RNA was isolated from lung and liver tissue and mRNA expression levels, of key oxidative stress genes, were quantified by real-time RT-PCR. A number of significant alterations in gene expression of key oxidative stress genes were observed in response to AgNP exposure. At 2 hours post exposure, Hmx1 and Keap1 expression increased ~2.75 fold in lung tissue, and modestly decreased to ~2.5 fold at 24 hours post exposure. Whereas in liver tissue, Keap1 expression changed from a 2.5 fold increase to a 3.5 fold increase in liver tissue, at 2 and 24 hours post exposure, respectively. Similarly, in liver tissue, Txnrd1 expression increased from 0.5 fold to a 2.5 fold increase at 2 and 24 hours post exposure, respectively. These experiments have suggested that exposure to inhaled AgNPs results in the induction of gene expression alterations in oxidative stress pathway components. Further, these alterations occur in a time-dependent manner.

**PS 1352 Genetic Influence of Pulmonary Response to Silver Nanoparticles Exposure.**

M. N. Hernandez, E. L. Saunders and M. Popovech. *Environmental Medicine, New York University, Tuxedo, NY.*

Within the last decade, nanotechnology has seen a boost in commercial, medical and industrial applications. However, there is great uncertainty in terms of the biomolecular activity nanoparticles (NPs) may have on biological systems. In particular, this study sought out to determine the genetic influence on the pulmonary response to silver NPs. Murine models were employed to evaluate the variation of inter-strain response. Differences were quantitated by measuring inter-strain variability in terms of polymorphonuclear neutrophil (PMN) infiltration in bronchoalveolar lavage fluid. Initially, three mouse strains (C57BL/6J, FVB/NJ, and BALB/cJ) representing resistant, moderate, and sensitive responders, respectively, were exposed to 0.5 µg/g body weight of 20 and 110 nm citrate or PVP stabilized silver NPs by oropharyngeal aspiration. Bronchoalveolar lavage was performed 24 hr post exposure to measure PMN number and protein concentration. All three strains were found to be more sensitive to 20 nm silver citrate (40-85% PMN response) and 20 nm silver PVP (15-85% PMN response). We then performed a similar exposure in 8 strains of mice (DBA/2J, C57BL/6J, AKR/J, 129SI/SvJ, A/J, FVB/NJ, C3H/HeJ, Balb/cJ) at a lower dose of 0.25 µg/g body weight of 20 nm silver citrate. PMN responses between 1.5% and 60% were observed. In addition, temporal pulmonary response was measured in C57BL/6J, FVB/NJ, and BALB/cJ mice at 24 hrs and 7 days. At 24 hours, PMNs were found to be strain dependent, between 14-46%, and the response at 7 days was found to be between 0-15% PMN response. Based upon these initial findings on inter-strain response variation, it can be concluded that these mouse models show a susceptibility pattern among strains, and can help to elucidate sensitivity mechanisms in terms of exposure assessment and innate inter-species responses.

**PS 1353 Short- and Long-Term Effects of Commercially Available Gold Nanoparticles in Rodents.**

J. Bahamonde<sup>1</sup>, B. Brenseke<sup>1</sup> and M. R. Prater<sup>1,2</sup>. <sup>1</sup>*Biomedical Sciences and Pathobiology, Virginia Tech, Blacksburg, VA;* <sup>2</sup>*Biomedical Sciences, Edward Via College of Osteopathic Medicine, Blacksburg, VA.*

Gold nanoparticles (GNPs) have physical and chemical properties that place them as top candidates for biomedical uses, including promising alternatives for targeted drug delivery, cancer therapy, and diagnostic contrast imaging. Their characteristics and behavior depend largely on their size, shape, and coating, making their uniformity an important aspect to consider, and making comparisons among studies a great challenge. We acquired 15 nm GNPs commercially available for *in vivo* contrast imaging, characterized them, and exposed female BALB/c mice, female F344 rats, and female and male C57BL/6 mice to either 1g/kg of GNPs, or phosphate buffered saline (PBS) via tail vein injection. Blood, urine, and feces collection, euthanasia and necropsy were performed at 24 hours, 1, 2, 3, 4, and 18 weeks post exposure. GNPs were found to be polydispersed, polyethylene glycol-coated, and varied in size from about 4 to 30 nm. Three out of the 19 rats exposed to GNPs died unexpectedly within 24 hours of exposure, with no deaths registered in any other group. GNPs were detected in urine for up to 1 week post exposure, and in feces for up to 2 weeks in mice and 4 weeks in rats. On gross inspection, GNPs caused immediate and persistent darkening of all tissues, and stayed in blood for up to 1 week. Histological examination demonstrated accumulation of GNPs in macrophages and endothelial cells of all tissues examined up to the end of the study, with increased numbers of activated macrophages in GNPs exposed animals compared to PBS exposed animals. Serum levels of interleukin-18, a pro-inflammatory cytokine secreted by macrophages, were significantly higher in animals exposed to GNPs in comparison to those exposed to PBS. Main conclusions of this study are that commercially available GNPs are not necessarily standardized, may cause acute death in rats, accumulate in macrophages and endothelial cells, incite granulomatous inflammation, and persist in the body indefinitely.

**PS 1354 Assessment of Genotoxicity of Silver Nanoparticles in Myh-Deficient and Wild Type Mice.**

R. Reliene, P. Kovvuru, P. E. Mancilla and A. Shirode. *University at Albany, State University of New York, Albany, NY.*

Silver nanoparticles (AgNPs) are extensively used in consumer products due to their antimicrobial properties. AgNPs are released from textile fabrics under regular wash conditions and were detected in sewage sludge of a municipal wastewater treatment plant, suggesting a potential for widespread exposures to AgNPs. However, genotoxicity and underlying molecular mechanisms of AgNPs are poorly understood. We studied DNA double strand breaks (DSBs) and chromosomal damage by γ-H2AX assay and micronucleus assay, respectively, in mice after 5-day treatment with AgNPs by oral application. AgNPs treatment resulted in a 2-fold induction in γ-H2AX foci in both bone marrow and peripheral blood. In addition, AgNPs increased the frequency of micronucleated cells in bone marrow erythroblasts and peripheral blood erythrocytes. Myh is a DNA glycosylase involved in both base excision repair and mismatch repair. We speculated that Myh is involved in AgNP-mediated DNA damage, which predisposes Myh deficient mice to DSBs and/or chromosomal damage. We observed a similar number of γ-H2AX foci and about 2-fold more micronuclei in AgNP treated Myh deficient compared to wild-type controls, suggesting a potential role of Myh in the repair of AgNP-mediated damage. We further investigated the effect of AgNPs on changes in the expression levels of 84 genes involved in DNA repair using PCR array profiler. In total, 25 genes were downregulated and 12 genes were upregulated as a function of AgNP treatment (1.5-fold cutoff). Most downregulated genes play a role in base excision and nucleotide excision repair, while upregulated genes are part of different DNA repair pathways. In summary, AgNP exposure by oral ingestion induces DSBs and chromosomal damage and alters expression of DNA repair genes, suggesting a potential hazard to genetic integrity. Further studies are needed to understand the effect of AgNP on DNA damage signaling, DNA repair efficiency, genomic instability and carcinogenicity.

**PS 1355 Comparative Hepatotoxicity Study of Two Different Diameter Size Silver Nanoparticles in Sprague-Dawley Rats.**

A. Patlolla<sup>1</sup> and P. Tchounwou<sup>2</sup>. <sup>1</sup>*Biology, Jackson State University, Jackson, MS;* <sup>2</sup>*Biology, Jackson State University, Jackson, MS.*

The antibacterial effect of silver nanoparticles (Ag-NPs) has resulted in their extensive application in health, electronic, and household products. Due to the intensive commercial application of Ag-NPs, their health risk assessment is of great importance. The previous *in vitro* studies demonstrated that AgNPs caused toxicity in

various cell-lines. However, the data on the toxicity of Ag-NPs in vivo is largely lacking. The main objective of this study was to determine the effect of two different diameter sizes (6nm, 10nm) silver nanoparticles on certain liver enzymes (alanine ALT, aspartate AST and alkaline phosphatase ALP) in serum and analysis of liver damage in Sprague-Dawley rats. Four groups of five male rats, each weighing approximately 80 + 2 g, were administered orally, once a day for five days with doses of 5, 25, 50, 100, mg/kg body weight (BW) of Ag-NPs. A control group was also made of five rats. Serum was collected following standard protocols, and the activity of the liver enzymes (ALT, AST and ALP) was determined by colorimetric method. The results demonstrated that Ag-NPs exposure increased the activities of the liver enzymes (ALT, AST, ALP) and damage in liver tissue in exposed groups compared to control. The increase in the activity was larger in 6nm size AgNPs compared to 10nm size. Only the highest two concentrations 50 mg/kg and 100 mg/kg showed statistically significant increases in ALT and ALP in both diameter size AgNPs compared to control. AST activity showed an increase; however, it was not statistically significant compared to control. Furthermore, the smallest sized AgNPs (6nm size) had a greater ability to induce hepatic damage in Sprague-Dawley rats than the other sized AgNPs (10 nm). These data suggest that the AgNPs-induced hepatotoxic effects against tissue cells are particle size-dependent, and thus, the particle size needs careful consideration in the design of the nanoparticles for biomedical uses.

### PS 1356 Increased Mucus Production and Histopathological Gill Alterations after Exposure to Nanosilver and Silver Nitrate.

A. D. Hawkins<sup>1</sup>, C. Thornton<sup>1</sup>, A. Harmon<sup>2</sup>, A. J. Kennedy<sup>2</sup>, J. A. Stevens<sup>2</sup>, N. G. Reyero Vinas<sup>2</sup>, K. Bu<sup>3</sup>, J. Cizdziel<sup>3</sup> and K. L. Willett<sup>1</sup>. <sup>1</sup>Pharmacology/Environmental Toxicology Research Program, University of Mississippi, Oxford, MS; <sup>2</sup>Environmental Lab, ERDC, Vicksburg, MS; <sup>3</sup>Chemistry, University of Mississippi, University, MS.

Silver nanoparticles are among the most widely used nanomaterials because of their antibacterial and antifungal properties. Despite their extensive use, information is now becoming available on the toxicity and fate of nanosilver formulations within living organisms. Mucus has both increased and decreased the toxicity of different xenobiotics by either concentrating the xenobiotic on the gills and body or encapsulating toxicants to prevent exposure. In order to understand the relationship between mucus, toxicity and silver exposure, zebrafish (ZF) and fathead minnows (FHM) were exposed for 36 or 96 hr to nominally 20 nm PVP- or citrate-coated silver nanoparticles (PVP-AgNPs; citrate-AgNPs) or silver nitrate (AgNO<sub>3</sub>) at 2 nominal concentrations (20 and 200 µg/L) or (2 and 6 µg/L), respectively. After 4 hr, ZF produced significantly more mucus secretion in every treatment than the control fish in a dose-dependent manner as measured by a phenol-sulfuric acid method. FHM gill RNA was extracted for microarray analyses. To quantitate distribution of silver, skin, liver and GI were digested for ICP-MS. FHM gills were also paraffin embedded, sectioned and examined for histopathological lesions to phenotypically anchor the molecular and chemical endpoints. The highest AgNO<sub>3</sub> and both citrate-AgNPs concentrations caused significant atrophy in gill mucus goblet cells. Every silver treatment also had a significantly higher histopathological alterations index compared to control. Citrate-AgNPs (20 and 200 µg/L) had the highest incidence of alterations (3.5 and 3.25 times higher than control, respectively). The results suggest that mucus production and mucus-related cells are impacted by silver exposure. This research is supported by US Army ERDC grant: W912HZ-09-C-0033.

### PS 1357 Impact of Silver Nanoparticles (AgNP) on Bacteria Species Isolated from Gastrointestinal (G.I.) Tract of Sprague-Dawley (SD) Rats.

M. S. Imam<sup>1</sup>, S. Khare<sup>2</sup>, A. M. Paredes<sup>3</sup> and M. D. Boudreau<sup>1</sup>. <sup>1</sup>Division Biochemical Toxicology, NCTR, Jefferson, AR; <sup>2</sup>Division of Microbiology, NCTR, Jefferson, AR; <sup>3</sup>Office of Scientific Coordination, NCTR, Jefferson, AR.

The food industry is incorporating AgNP into a growing number of products, which suggests that consumers are being exposed orally to increasing amounts of these nanoparticles. The absorption of AgNP from the G.I tract has been demonstrated; however the potential effects from the interactions of AgNP with bacteria of the G.I. tract are largely unknown. We investigated the bactericidal effects of AgNP on *Lactobacillus* sp. (G+) and *Bacteroides* sp. (G-) isolated from the G.I. tract of SD rats. Three sizes of AgNP (10, 75, and 110 nm) at (0.1, 0.5, 1, 2, 5, 10 µg/ml) were incubated with cultures of bacteria (in triplicate), and the bactericidal effects at 60, 120, and 180 min were assessed using colony forming unit (CFU) and adenosine triphosphate (ATP) release assays. There were no CFUs in cultures of *Lactobacillus* sp. or *Bacteroides* sp. when incubated for 120 min or longer in the presence of 75 or 100 nm AgNP at concentrations of ≥2 µg/ml or in the presence of 10 nm AgNP at concentrations of ≥1 µg/ml, suggesting enhanced bactericidal

effects by 10 nm AgNP. Both bacterial species showed a significant decrease in ATP release when exposed to AgNP (10, 75, or 107 nm) at concentrations > 1 µg/ml. At equivalent number of cells (10<sup>3</sup> cells/ml), *Bacteroides* sp. were more sensitive than *Lactobacillus* sp to the bactericidal properties of AgNP (10, 75, or 110 nm), likely reflecting differences in cell wall composition between species. Scanning electron microscopy showed that AgNP were attached to bacterial cells at the surface, suggesting that protein binding or cell wall distortion by AgNP might result in cellular toxicity or death. These results provide new insights into the bactericidal properties of AgNP and how the consumption of AgNP might disrupt the normal balance of microorganisms in the healthy G.I. tract. Supported by interagency agreements 224-12-0003 and AES12013 between the NCTRFDA and NIEHS/NTF

### PS 1358 Influence of Dose, Size and Chemical Composition on Persistence of Silver Nanoparticles in the Rat Lung.

D. S. Anderson, R. Silva, D. Lee, P. C. Edwards, K. E. Pinkerton and L. S. Van Winkle. University of California Davis, Davis, CA.

Silver nanoparticles (AgNPs) have antimicrobial activity and unique electrical properties, resulting in increasing use. While there have been studies of the biological effects of AgNPs, including persistence and clearance of AgNPs from the lung, an examination of the effect of AgNP size and surface coating (used to stabilize these materials when in solution) has not been fully investigated. We investigated lung deposition, retention and clearance of 20nm and 110nm spherical AgNPs coated with citrate or polyvinylpyrrolidone (PVP). Rats were instilled intratracheally with 0.1, 0.5 or 1.0 mg/kg of either one of the AgNP solutions or a vehicle control and were assessed at 1, 7 and 21-days post treatment. Ag was quantified in tissue using inductively coupled plasma mass spectrometry. At one day postinstillation, lungs dosed with 1.0 mg/kg AgNPs had 0.25 to 0.51 mg Ag/g dry tissue and these amounts did not differ by surface coating or particle size. Sham controls had no detectable Ag. Total leukocytes and neutrophils in bronchoalveolar lavage fluid increased in a dose dependent manner 1-day after exposure to all AgNPs with significant increases in the 1.0mg/kg dose compared to all other doses for all 4 particle types. This increase persisted at the 7-day time point in all AgNP groups except for 20nm PVP. Distribution of Ag in the lung was determined using autometallography and semiquantitative scoring on paraffin-embedded lung sections to demonstrate Ag was preferentially localized to the bronchoalveolar duct junction at the 1-day time point. At 7-days post exposure, Ag was localized to the subepithelial extracellular matrix of the terminal bronchioles. Uptake of Ag by alveolar macrophages was also observed. These findings suggest Ag can persist in the lungs over time and alveolar macrophages have a role in the clearance. Supported by U01ES02027 and P42ES004699. Nanomaterials supplied by the NIH NCNHR consortium.

### PS 1359 Subtle Surface Variations Influence Biological Compatibility of Gold Nanoparticles.

K. Kim<sup>1</sup>, T. Zaikova<sup>2</sup>, J. E. Hutchison<sup>2</sup> and R. L. Tanguay<sup>1</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR; <sup>2</sup>Chemistry, University of Oregon, Eugene, OR.

To better understand the nanoparticle physicochemical properties that influence biological compatibility, we investigated how subtle ligand variation on the surface of gold nanoparticles (AuNPs) influences biological responses. The zebrafish embryos were exposed to four distinct, well-defined ligand-stabilized 1.5 nm spherical AuNPs. The ligand shells for each AuNP contain: (1) only anionic 2-mercaptoethanesulfonic acid (MES), (2) only cationic N,N,N trimethylammoniumethanethiol (TMAT), (3) a mixed ligand shell containing MES and a small amount of triphenylphosphine (TPP), and (4) a mixed ligand shell containing TMAT and a small amount of TPP. Small-angle X-ray scattering (SAXS) confirmed the core size of the particles and that there was no agglomeration in the embryonic test medium. The only difference between partial and full functionalization was the P/Au ratio as determined by XPS analysis. The MES/TPP coated particles caused higher mortality and malformation than those fully functionalized with MES, and in TMAT/TPP coated particles a higher incidence of smaller size and pale gray eyes was observed. In the gene expression profiles of transcription factors for apoptosis (p53 and bax), eye development (pax6a, otx2 and rx1) and pigmentation (sox10 and mitfa), the gene expression of embryos were significantly disrupted in both mixed ligand particles in a concentration-dependent manner, consistently with the observed developmental toxicity. In addition, laser ablation ICP-MS analysis revealed that biological absorption and distribution of AuNPs in exposed embryos were closely related to the toxicity phenotype and gene expression caused by differential surface functionalization. These data provide new insights into the understanding of how subtle surface changes impact biological compatibility and further emphasize the importance of material characterization. This research is supported by NIEHS P3 ES000210, ES016896 and Air Force Research Laboratory #FA8650-05-1-5041.

**PS 1360 Gold Nanoparticles in Central Nervous System of Mice: Localization and Inflammatory Markers.**

F. Fallahi<sup>1,2</sup>, S. M. Hussain<sup>1,2</sup>, I. E. Pavel<sup>1</sup>, J. P. O'Callaghan<sup>3</sup>, M. Sharma<sup>1,2</sup>, R. Saadawi<sup>4</sup> and M. Morris<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, Wright State University, Dayton, OH; <sup>2</sup>711 HPW/RHDJ, AFRL, Wright-Patterson AFB, Dayton, OH; <sup>3</sup>CDC-NIOSH, Morgantown, WV; <sup>4</sup>Chemistry, University of Cincinnati, Cincinnati, OH.

Gold nanoparticles (GNPs) possess unique physicochemical properties that may facilitate entry into the central nervous system (CNS) where they may act therapeutically. There is little information on GNPs biodistribution in specific brain regions or extent of inflammation induction. Experiments determined the localization and neuroinflammatory response of spherical GNPs (10 nm) after IV injection in male C57Bl mice. As a supplement, a known inflammogen, lipopolysaccharide (LPS, 2 mg/kg, sc), was tested. To determine the optimal buffer concentration to maintain GNP solubility, we measured aggregation of GNPs using various PBS concentrations (10, 1, 0.1, 0.01 X). 0.01X PBS produced the least amount of GNP aggregation and was used in all studies. The next experiment verified entry of GNPs into CNS. Mice were IV injected using the tail vein (200 µg/ml 10 nm GNPs in 0.01X PBS). After 24 hrs mice were perfused transcardially with 2 % glutaraldehyde/paraformaldehyde and brains were collected. GNPs were measured using inductively coupled plasma mass spectrometry in whole brain homogenates. To specifically localize accumulation of GNPs in brain, septum, caudate, hippocampus, hypothalamus, cortex, frontal cortex, and spinal cord were dissected. Hypothalamus, hippocampus, and septum had the highest levels of GNPs (6.7, 6.2, and 4.6 µg Au/g, respectively). To evaluate brain inflammation, we used q-PCR analysis of frozen brain regions for study of pro-inflammatory mediators, LIF, CCL2 and IL1β. GNPs did not affect cytokine/chemokine expression in cortex, frontal cortex or hippocampus. LPS, as expected, caused a marked (100-fold) increase in the same cytokines. Results show that GNPs enter brain and concentrate in specific regions without eliciting an inflammatory response. Data raise the possibility of usefulness of GNPs in drug delivery and therapeutic treatment of CNS diseases.

**PS 1361 Dissolution Kinetics of Inhaled Metal Nanoparticles in a Murine Model.**

E. L. Saunders, E. Bartnick, K. Galdanes, M. Popovech, M. N. Hernandez, L. Chen and T. Gordon. *Environmental Medicine, New York University, Tuxedo Park, NY.*

Previous work has established that Ag, Ni, and Ce nanoparticle (NP) inhalation induces a defined dose/inflammatory-response relationship. Adverse responses to each metal were found to vary by size, shape (TEM analysis) and chemistry (XPS analysis). This study was conducted to delineate the inflammatory responses generated by exposure to Ag, Ni, and Ce NP's in a murine model, as marked by the polymorph neutrophil response (PMN), and examine absorbed kinetics associated with NP exposure. PMN response for the larger sized particles (100-130nm) did not exceed 4% across three doses (1mg/m<sup>3</sup>, 0.5mg/m<sup>3</sup>, and 0.25mg/m<sup>3</sup>), and ranged from 4% to 32% for smaller sized particles (30-45nm) in a concentration dependant manner. To further investigate the inflammatory response and extrapulmonary translocation, synthetic body fluids were used to establish dissolution rates; specifically, synthetic phagolysosomal fluid (PSF, pH 4.6), and synthetic lung surfactant (LS, pH 7.5). NP's were dispersed directly into the fluids using a fritted bubbler and the dissolved fraction was subsequently separated from the particles using centrifugation of spin column filters (1-2nm pore size). The metal concentrations were then analyzed using ICP-MS and expressed as percentage of dissolved vs. total. Surprisingly results of Ag showed similar trends in both fluid types, with larger particles dissolving more rapidly than smaller particles. The percent difference between 130nm and 30nm particles in LS was 18% at 15 min, 9% at 30 min, and 0% at 1 hr. In contrast, percent differences between these two Ag NP's in PSF were 42% at 15 min, 26% at 30 min, and 6% at 1 hr. To assess the effect of size on kinetics, mice were exposed to Ag NP's of 4 sizes (20, 30, 90, and 130nm) with liver, kidney, lungs, and brain, digested for ICP-MS analysis. Our results clearly showed that, for those NP's that dissolve within 48 hrs, the NP's with the lower dissolution rate (e.g., the smaller Ag NP's produce a greater inflammatory response.

**PS 1362 Utility of the Greenscreen™ for Nanoscale Hazard Assessments: Nanosilver Case Study.**

N. A. Linde, T. L. McGrath, B. J. Lampe and J. C. English. *NSF International, Ann Arbor, MI.*

A project employing GreenScreen™ methodology was undertaken to assess the chemical hazards of selected manufactured nanomaterials. The GreenScreen™ methodology provides a basis for clear and transparent communication of potential

human health and environmental hazards. It is being adopted by businesses, governments, and others seeking to identify safer chemical replacements. The purpose of the present investigation was to evaluate the utility of the GreenScreen™ for assessing the hazards of nanoscale substances and to recommend changes to the method to accommodate the properties specific to nanomaterials. An independent Science Advisory Team was assembled and tasked with providing technical guidance from project onset through ongoing implementation, including the selection of nanomaterials and identification of reliable data. In the initial stage of the project, chemical hazard assessments were undertaken for nanoscale silver and a silica-silver nanocomposite, AGS-20, used to confer antimicrobial properties to textile fabrics, thereby inhibiting the growth of odor-causing bacteria in the treated textile. The scope of each assessment was defined with respect to chemical entities, particle size and shape, use of ligands, stabilizers or capping agents, and potential transformation products. Modifications to the GreenScreen™ method and template to accommodate nanomaterial applications were developed and incorporated. Recognizing that the methodology fundamentally assesses only hazard, not risk, this exercise demonstrated that a GreenScreen™ assessment of nanoscale materials can reveal hazard characteristics and concern levels that differ among different nanoscale forms and conventional forms. The availability of data on adequately characterized materials and the identification and use of relevant analogs to address data gaps remains a challenge. Potential confounds in the application of the results for product comparisons are described. Hazard assessments for several additional nanoscale materials are planned or underway, to further evaluate the utility and limitations of this approach.

**PS 1363 The Role of Macrophage Scavenger Receptor A in the Disposition of Silver Nanoparticles.**

J. N. Smith<sup>1</sup>, M. H. Littke<sup>1</sup>, J. A. Klein<sup>1</sup>, C. W. Frevert<sup>2</sup>, B. D. Thrall<sup>1</sup> and J. G. Pounds<sup>1</sup>. <sup>1</sup>Systems Toxicology, Battelle Memorial Institute, Pacific Northwest Division, Richland, WA; <sup>2</sup>University of Washington, Seattle, WA.

The role of macrophage scavenger receptor A (SR-A) in the disposition and biological response of silver nanoparticles was investigated using cellular and animal models. Bone marrow derived macrophages from wild-type C57BL/6J and SR-A deficient mice were exposed to silver nanoparticles (20 and 110 nm, primary size) coated with citrate and polyvinylpyrrolidone (PVP). Macrophages from wild-type mice demonstrated higher rates of silver binding/uptake compared those from SR-A<sup>-/-</sup> mice (0.5 vs. 0.003 hr<sup>-1</sup>, respectively), which led to increased levels of cell associated silver (~10 fold at 24 hr) after exposure to 20 nm silver nanoparticles measured by inductively coupled plasma mass spectrometry (ICP-MS). In contrast, no significant differences in total cell binding/uptake or cytotoxicity with 110 nm silver particles were observed between wild-type and SR-A<sup>-/-</sup> macrophages. After administration of 20 nm particles by oropharyngeal aspiration *in vivo*, wild-type mice and SR-A<sup>-/-</sup> mice demonstrated similar silver clearance from lungs, bronchoalveolar lavage (BAL) fluid, and BAL cells (half-life: 15.5 vs. 23.8 d, respectively in lungs) after 28 d measured by ICP-MS. However, wild-type mice had increased levels of silver in liver (area under the curve [AUC]: 0.06 vs. 0.02 g<sup>-1</sup>xd, respectively) and spleen (AUC: 0.16 vs. 0.03 g<sup>-1</sup>xd, respectively) driven by higher silver levels in liver and spleen at day 7, indicating increased uptake of silver by wild-type mice. After retro-orbital injection, *in vivo* biokinetics of silver in wild-type and SR-A<sup>-/-</sup> mice were very similar. Overall, these results support the conclusion that SR-A plays a significant role in silver nanoparticle uptake at both the cellular and whole animal levels, but its role may be size-dependent.

**PS 1364 Nanosilver-Induced Lung Inflammation Is Mouse Strain Dependent.**

D. Botta<sup>1</sup>, S. C. Schmuck<sup>1</sup>, D. K. Scoville<sup>1</sup>, C. C. White<sup>1</sup>, C. M. Carosino<sup>1</sup>, C. M. Schaupp<sup>1</sup>, W. C. Griffith<sup>1</sup>, E. M. Faustman<sup>1</sup>, T. Gordon<sup>2</sup> and T. J. Kavanagh<sup>1</sup>. <sup>1</sup>Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA; <sup>2</sup>Department of Environmental Medicine, New York University, New York, NY.

Silver nanoparticles (NanoAg) have found many uses in electronics, medical diagnostics and as microbicides. While ionic silver (Ag<sup>+</sup>) is acknowledged to have relatively low toxicity toward mammals, the particulate nature of NanoAg has raised concerns, especially in the context of potential occupational exposures. Because human genetic variability can influence susceptibility to many toxicants, we used multiple inbred mouse strains to determine if genetics could influence NanoAg induced lung toxicity and inflammation. We exposed the Collaborative Cross (CC) parental mouse strains (C57BL/6J, 129S1/SvJ, A/J, NOD/LtJ, and NZO/HILtJ) and 3 wild derived strains (CAST/EiJ, PWK/PhJ, and WSB/EiJ) to citrate-stabilized 20 nm NanoAg at a dose of 0.25 µg/gm BW via oropharyngeal aspiration. Mice were sacrificed either 1 or 21 days after exposure. Lung injury and inflammation were assessed by examining total protein and lactate dehydrogenase activity,

and the presence of leukocytes and inflammatory cytokines in bronchoalveolar lavage fluid (BALF). One day after exposure, none of the strains exhibited differences in total protein or LDH activity compared to saline vehicle controls. However, there were marked strain-dependent differences in lung inflammation, with C57BL/6 mice showing a 3-6 fold lower response compared to other strains. Evidence to date indicates that neutrophilic inflammation was attenuated by 21 days, suggesting a transient effect for these nanoparticles. Because C57BL/6 mice were not very responsive, relying on this strain alone to assess NanoAG-induced inflammation may not adequately assess their safety. This work is done in collaboration with the NCNHR Consortium and supported by NIH/NIEHS grants U19ES019545, P30ES07033 and T32ES07032.

### PS 1365 Characterization and Toxicity of Silver Nanowires.

A. Tagmount<sup>1</sup>, B. Gilbert<sup>2</sup>, L. Scanlan<sup>1</sup>, C. Tran<sup>1</sup>, C. Clark<sup>1</sup> and C. Yulpe<sup>1</sup>.  
<sup>1</sup>Nutrition Science and Toxicology, University of California Berkeley, Berkeley, CA;  
<sup>2</sup>Earth Science Division, LBNL, Berkeley, CA.

Metal and semiconductor nanowires (NW) have a diverse range of anticipated applications in electrical devices, sensors, catalysts and composite materials but there is very limited information on the fate of NW in the environment or the effect of NW on organisms. We are studying the environmental fate and biological toxicity of silver nanowires (Ag NW), a representative metal NW, to (1) *Daphnia magna*, an aquatic eco-indicator and (2) cell lines of different species representing potential target organs, including a cell line from fathead minnow, another eco-indicator species. LC50 values were determined in *D. magna* exposed to Ag NW and different end-points of cytotoxicity were investigated using cell based imaging assays (high content screening) and other cell assays. Transcriptomic response to Ag NW was also studied in *Daphnia* and in a macrophage cell line using high throughput RNA sequencing. We characterized the physicochemical properties of Ag NW to determine how their chemistry relates to cytotoxicity. We studied the colloidal stability and oxidation rates of Ag NW with two lengths and two coatings in different aqueous solutions, including conditions relevant to studies of toxicity to *D. magna*, and cell media. While poly(vinylpyrrolidone) (PVP) and aluminosilica (SiO<sub>2</sub>) coatings prevent NW aggregation in ultrapure water, rates of aggregation and settling were greatly increased in the presence of dissolved inorganic and ionic ions. In stirred anaerobic solutions, morphological changes, including fusing of multiple nanowires, was the dominant transformation. In aerobic solutions, Ag oxidation to release dissolved Ag<sup>+</sup> occurred for all coating types. Rates of Ag<sup>+</sup> release cannot explain observed differences in Ag NW toxicity to *Daphnia*, suggesting that toxicity is controlled by a complex mixture of colloidal and chemical processes in solution. Also, in parallel to this physicochemical study, cell internalization, sub-cellular localization as well as in situ localization of Ag NW in *Daphnia* were carried out

### PS 1366 Examining Mechanisms of Toxicity and Uptake of Gold Nanoparticles to *Caenorhabditis elegans*.

O. Tsyusko<sup>1</sup>, J. M. Unrine<sup>1</sup>, R. M. Nass<sup>2</sup> and B. Collin<sup>1</sup>. <sup>1</sup>Plant and Soil Sciences, University of Kentucky, Lexington, KY; <sup>2</sup>Stark Neuroscience Research Institute, Indiana University, Indianapolis, IN.

Background: Gold nanoparticles (Au-NPs) have been used in previous studies as a particle-specific probe in nanotoxicity studies due to their resistance to oxidative dissolution. Objectives: To examine the particle-specific toxicity of Au-NPs to *C. elegans* using a toxicogenomic approach and to explore possible mechanisms of defense against toxicity of Au-NPs using gfp strains, mutants and RNAi. Methods: The LC10 of 5.9 mg/L Au-NPs was used for 12hr exposure in microarray experiments using Affymetrix whole genome microarrays. qRT-PCR was used to confirm results for six selected genes. Selected mutant and gfp *C. elegans* strains were used for toxicity testing to Au-NPs. Differences in distribution of Au in endocytosis mutants were examined using synchrotron-based X-ray microfluorescence spectroscopy. Results: 797 significantly differentially expressed genes identified from whole genome microarray analyses were linked to seven common biological pathways. Significant up-regulation was observed for 26 pgn/abu genes from non-canonical unfolded protein response (UPR) pathway and molecular chaperones (hsp-16.1, hsp-70, hsp-3 and hsp-4). There was significant increase in sensitivity to Au-NPs in non-canonical UPRs (pgn-5 and abu-11) knockouts. Au-NPs induce gfp expression of the vesicular GABA transporter homologue in GABA neurons. Significant up-regulation by Au-NPs of FOXO transcription factor daf-16 was confirmed by microarrays and through using daf-16::gfp strains. Differences in distribution of Au among endocytosis mutants (chc-1 and rme-2) and wild type nematodes were correlated with differences in toxicity. Conclusions: Our results suggest possible involvement of genes from endocytosis and UPR pathways in uptake and detoxification mechanisms, respectively. Au-NPs may also induce stress response through insulin signaling pathway. Support: US NSF EPA CEINT, University of KY microarray core Pilot grant.

### PS 1367 Mouse Neural Progenitor Cells As a Functional Model for Developmental Neurotoxicity Testing: Intracellular Calcium Signaling.

M. M. Dingemans, M. de Groot and R. H. Westerink. Neurotoxicology Research Group, Toxicology Division, Institute for Risk Assessment Sciences (IRAS), Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.

Developmental neurotoxicity (DNT) is often investigated in a traditional manner (*in vivo* using large numbers of experimental animals), while development of *in vitro* methods for DNT reduces animal use and increases insight into cellular and molecular mechanisms of DNT. Neural progenitor cells (NPCs) are particularly suited for the investigation of neurodevelopmental processes as they are pre-programmed to differentiate into nervous system-specific cell types: neurons and glia.

The intracellular calcium concentration ([Ca<sup>2+</sup>]<sub>i</sub>) plays an essential role in neurotransmission, plasticity and neurodevelopment and can therefore be used as a functional readout for DNT [1]. We therefore investigated changes in [Ca<sup>2+</sup>]<sub>i</sub> evoked by a set of neurotransmitters in primary mouse NPCs using the Ca<sup>2+</sup>-responsive dye Fura-2. Calcium responses were measured at a single-cell resolution at various differentiation durations. Calcium responses could be evoked by depolarization, acetylcholine, and adenosine triphosphate (ATP), indicating the expression and functionality of the respective neurotransmitter receptors and related calcium signaling pathways.

The data demonstrate that this model allows for the investigation of possible effects of (suspected) developmental neurotoxins on the development of neuronal characteristics, such as intracellular signaling in response to neurotransmitters. As investigation of chemical-induced effects on the development of functional neuronal characteristics is underrepresented in DNT testing, we argue that biochemical and morphological approaches should be complemented with investigations of neuronal (network) functionality, including network formation, inter- and intracellular signaling and neuronal network function.

Funding: EU (DENAMIC-FP7282957); ZonMW NL (85300003).

### PS 1368 Ketamine-Induced Neuronal Damage and Altered N-methyl-D-aspartate (NMDA) Receptor Function in Rat Primary Forebrain Culture.

N. Sadovova<sup>1</sup>, F. Liu<sup>2</sup>, M. G. Paule<sup>2</sup>, W. Slikker<sup>3</sup> and C. Wang<sup>2</sup>. <sup>1</sup>Toxicologic Pathology Associates, Jefferson, AR; <sup>2</sup>Division of Neurotoxicology, National Center for Toxicological Research/US FDA, Jefferson, AR; <sup>3</sup>Office of Director, National Center for Toxicological Research/US FDA, Jefferson, AR.

Ketamine, a noncompetitive NMDA receptor antagonist, is used in pediatric general anesthesia and causes neuronal cell death during the brain growth spurt. To understand the underlying mechanisms associated with ketamine-induced neuronal toxicity and search for approaches or agents to prevent such adverse effects, a primary cell culture system was utilized. Neurons harvested from the forebrain of newborn rats were maintained under control conditions or exposed to either ketamine (10 μM), or ketamine plus L-carnitine (1, 30 and 100 μM) for 24 hours, followed by a 24-hour withdrawal period. Ketamine exposure resulted in elevated NMDA receptor (NRI) expression, increased generation of reactive oxygen species (ROS) as indicated by higher levels of 8-oxoguanine production, and enhanced neuronal damage. Co-administration of L-carnitine significantly diminished ROS generation and provided near complete protection of neurons from ketamine-induced cell death. NMDA receptors regulate channels that are highly permeable to calcium. Calcium imaging data demonstrated that neurons exposed to ketamine had a significantly elevated influx of calcium and higher intracellular free calcium concentrations ([Ca<sup>2+</sup>]<sub>i</sub>) evoked by NMDA (50 μM), compared to control neurons. These findings suggest that prolonged ketamine exposure produces an increase in NMDA receptor expression (compensatory up-regulation) which allows for a higher/toxic influx of calcium into neurons once ketamine is removed from the system, leading to elevated ROS generation and neuronal cell death. L-carnitine appears to be a promising agent in preventing ketamine toxic effects on neurons at an early developmental stage.

### PS 1369 L-Carnitine Ameliorates Propofol-Induced Toxicity in Rat Embryonic Neural Stem Cells.

M. G. Paule<sup>1</sup>, F. Liu<sup>1</sup>, C. M. Fogle<sup>1</sup>, N. Sadovova<sup>2</sup>, W. Slikker<sup>1</sup> and C. Wang<sup>1</sup>. <sup>1</sup>Division Neurotoxicology, National Center Toxicological Research US FDA, Jefferson, AR; <sup>2</sup>Toxicology Pathology Associates, Inc., National Center Toxicological Research US FDA, Jefferson, AR.

Propofol is a widely used general anesthetic. A growing body of data suggests that perinatal exposure to general anesthetics can result in long-term deleterious effects on brain function. In the developing brain there is evidence that general anesthetics

can cause cell death, synaptic remodeling, and altered brain cell morphology. Acetyl-L-carnitine (aLc), an anti-oxidant dietary supplement, has been reported to prevent neuronal damage from a variety of causes. To evaluate the ability of aLc to protect against propofol-induced neuronal toxicity, neural stem cells were isolated from gestational day 14 rat fetuses and on the 8th day in culture were exposed for 24 hr to propofol at 10, 50, 100, 300 and 600  $\mu$ M, with or without aLc (10  $\mu$ M). Markers of cellular proliferation (EdU), mitochondrial health (MTT), cell death/damage (LDH) and oxidative damage (8-oxo-dG) were monitored to determine: 1) the effects of propofol on neural stem cell proliferation; 2) the nature of propofol-induced neurotoxicity; 3) the degree of protection afforded by aLc; and 4) to provide information regarding possible mechanisms underlying protection. After propofol exposure at a clinically-relevant concentration (50  $\mu$ M), the number of dividing cells was significantly decreased and oxidative DNA damage was increased. There was also a significant dose-dependent reduction in mitochondrial health as evidenced by decreases in MTT metabolism. No significant effect on LDH release was observed at propofol concentrations up to 100  $\mu$ M. The oxidative damage at 50  $\mu$ M propofol was blocked by aLc. Thus, clinically-relevant concentrations of propofol induce dose-dependent adverse effects on rat embryonic neural stem cells by slowing or stopping cell division/proliferation and causing cellular damage. Elevated levels of 8-oxo-dG suggest oxidative damage and aLc effectively blocks at least some of the toxicity of propofol, presumably by scavenging oxidative species and/or reducing their production.

### PS 1370 Determination of Neurotoxicity in the Developing Rat Induced by Dexmedetomidine.

J. Liu. *Anesthesia, Harvard Medical School, Boston, MA.*

Anesthetic, sedative and analgesic drugs are used for diagnostic studies and surgery procedures in infants and children, but little is known about their impact on the developing nervous system. Dexmedetomidine is a selective  $\alpha_2$ -adrenergic agonist, and has been used many clinical applications including the reduction of postoperative delirium and has many protective effects on cell damage in animal models. However, dexmedetomidine induced human neutrophil apoptosis by activation of caspases-3, 7, -8 and -9. Based on these, we hypothesize how dexmedetomidine affects neuroapoptosis in the developing rat brain.

**Material and Methods:** Sprague-Dawley postnatal day 7 (P7) rat pups were used for this study. Rats were divided into three doses of 10, 25, and 50  $\mu$ g/kg body weight of dexmedetomidine and one control group. Each rat pup received 5 intraperitoneal doses of either saline, or Dex at 90 minutes intervals over 6 hours. After the 6 hour treatment period, the animals were deeply anesthetized with pentobarbital (100 mg/kg, IP). Parts of the brain tissues were extracted and flash frozen in liquid nitrogen for western blotting analysis. The other parts were fixed in 4% paraformaldehyde for immunohistochemical assay. Apoptosis such as cleaved-caspase-3, TUNEL, and other protein expression such as GSK-3 $\beta$  were determined by immunohistochemistry and western blotting assays.

**Results and Conclusion:** Dexmedetomidine increased neuroapoptosis by increasing apoptosis and cleaved caspase-3 expression in the rat brain tissues. Dexmedetomidine also increased the p-GSK-3 $\beta$  / GSK-3 $\beta$  ratio, indicating a reduction in GSK-3 $\beta$  activity. These findings suggest that dexmedetomidine may induce neuroapoptosis by regulating GSK-3 $\beta$  in the developing rat brain.

### PS 1371 Nicotine-Induced Toxicity in Rat Embryonic Neural Stem Cells.

F. Liu<sup>1</sup>, N. Sadovova<sup>2</sup>, C. M. Fogle<sup>1</sup>, M. G. Paule<sup>1</sup>, W. Slikker<sup>1</sup> and C. Wang<sup>1</sup>.  
<sup>1</sup>Division of Neurotoxicology, National Center for Toxicological Research NCTR/US FDA, Jefferson, AR; <sup>2</sup>Toxicologic Pathology Associates, Jefferson, AR.

Maternal smoking substantially increases the risk of learning disabilities, behavioral problems, and attention deficit/hyperactivity disorder in offspring. Nicotine is the main pharmacologically active component of tobacco smoke. Prenatal exposure to nicotine is capable of causing fetal brain damage. To evaluate nicotine's effects on the developing nervous system and explore potential mechanisms underlying such toxicity, rat embryonic neural stem cells were used.

Brain cortices were collected from fetal rats (gestational day14, GD14) for neural stem cell isolation and subsequent culture in commercial rat growth medium. On the 8th day in vitro (DIV), confluent neural stem cells were exposed to nicotine at concentrations of 0.5, 1.0, 2.0, 5.0 and 10  $\mu$ M for 24 hours. Neural stem cells were identified using monoclonal anti-*nestin* antibody. Markers of cellular proliferation (EdU), mitochondrial health (MTT), cell death/damage (LDH) and immunohistochemical staining of activated caspase 3 were monitored to determine the nature of nicotine-induced neurotoxicity.

Nicotine treatment resulted in a substantial dose-dependent reduction in mitochondrial function as evidenced by significant decreases in the metabolism of MTT. No significant effect of nicotine on LDH release was observed. 1  $\mu$ M nicotine significantly increased the expression of activated caspase 3, suggesting that nicotine induced neural stem cell apoptosis.

These results suggest that nicotine decreased neural stem cell viability, and nicotine-induced cell death is probably apoptotic in nature.

### PS 1372 Consequences of Nicotine Exposure on Larval Zebrafish Circadian Rhythms.

M. E. Wolter and K. R. Svoboda. *Joseph J. Zilber, School of Public Health, UWM, Milwaukee, WI.*

Cigarette smokers often report having problems associated with disrupted sleep. One potential mechanism underlying sleep disruption could be related to alterations in an individual's circadian rhythm. Nicotine from cigarettes can activate neuronal nicotinic acetylcholine receptors (nAChRs) throughout the nervous system including structures important for maintaining the circadian rhythm. We have utilized oscillations in larval zebrafish locomotor activity as a model to study circadian rhythms. Initially, the circadian rhythm in embryos reared on a 14/10 light/dark (L/D) cycle was evaluated. Of 257 larvae examined, 76.6% exhibited a typical rhythm where locomotor activity was high in the initial hours of the cycle, declined to a minimum, and then became elevated again at the end of the cycle. We then determined the consequences of raising embryos in constant dark or constant light conditions from 0-127 hours post fertilization (hpf) as well as being exposed to nicotine. At 127 hpf, 23.5% of the larvae reared in constant dark exhibited a typical circadian rhythm and 12.5% of embryos reared in constant light exhibited a typical circadian rhythm. Moreover, the locomotor activity of larvae reared in constant light was reduced and remained at a constant level for the duration of the cycle. Since nAChRs are expressed in the zebrafish pineal gland and retina (two structures that influence circadian rhythms in fish) early in development, we hypothesized that nicotine exposed fish would have a pattern of activity similar to those reared in constant light. Zebrafish reared in 15  $\mu$ M nicotine from 36-96 hpf and then evaluated at 127 hpf indeed lacked the normal circadian rhythm. The locomotor activity pattern of the nicotine-exposed zebrafish was similar to the pattern of zebrafish reared in constant light; the activity was reduced and remained at constant level for the duration of the cycle. These results indicate that nicotine is capable of disrupting vertebrate circadian rhythms and could be involved with the disrupted sleep pattern of smokers.

### PS 1373 Ethanol Pretreated Astrocytes Increase Synapses in Hippocampal Neurons.

P. J. Roque<sup>1</sup>, G. Giordano<sup>1</sup>, A. Barria<sup>2</sup>, M. Guizzetti<sup>3</sup> and L. G. Costa<sup>1</sup>.  
<sup>1</sup>DEOHS, University of Washington, Seattle, WA; <sup>2</sup>Physiology & Biophysics, University of Washington, Seattle, WA; <sup>3</sup>Department of Psychiatry, University of Illinois, Chicago, IL.

In children exposed to alcohol *in utero*, problems with learning and memory suggest hippocampal involvement and effects on synapse formation and function. Astrocytes may contribute to synaptogenesis by releasing specific factors. The present study investigated how ethanol influences the ability of astrocytes to modulate synapse formation *in vitro*. Using immunocytochemical labeling of synaptic proteins, confocal imaging and 3-dimensional object analysis, we found that astrocytes pre-treated with ethanol (50 mM) and co-cultured with primary hippocampal neurons (14 days in culture) for 24 hours, induce a 4.5-fold increase in synaptic structure formation. To corroborate that this is reflected in increased functionality, we used whole cell patch clamp techniques to measure spontaneous miniature excitatory post-synaptic currents. In neurons co-cultured with ethanol pre-treated astrocytes, we observed a higher frequency of events, relative to neurons co-cultured with control astrocytes, suggesting more functional synapses in the ethanol group. However, a second population of neurons in the same treatment group was observed to have a lower frequency than control astrocytes. No amplitude differences were observed, suggesting no difference in the number of post-synaptic receptors between groups. Ethanol increases the efflux of cholesterol-containing lipoproteins (CCL) from astrocytes, and cholesterol appears to play a role in synapse formation. Direct treatment of hippocampal neurons with high-density lipoproteins induced a 3.2-fold increase in synaptic structures. When cholesterol release from astrocytes was induced by LXR/RXR agonists, through the over-expression of cholesterol transporters, this also resulted in an increase in synapses, suggesting a role for astrocytic CCLs in the observed synaptic increase after ethanol pre-treatment (Supported by F31AA019869, AA008154).

**PS 1374 PCB 95 and IFN-gamma Exert Opposing Effects on Dendritic Growth in Cultured Rat Sympathetic Neurons.**

P. E. Goines and P. J. Lein. *Molecular Biosciences, University of California Davis School of Veterinary Medicine, Davis, CA.*

There is credible evidence that environmental factors interact with genetic susceptibilities to determine risk for neurodevelopmental disorders such as autism spectrum disorders (ASD). PCBs and IFN $\gamma$  are implicated as environmental risk factors for ASD. Increased levels of both have been documented in ASD, and both interfere with neuronal connectivity in central neurons via effects on dendritic growth. Recent reports indicate that PCBs upregulate inflammatory cytokines, but the combined effects of these factors on neuronal connectivity have not been explored. Because of emerging awareness of autonomic dysfunction in ASD, which may link the triad of behavioral deficits, gastrointestinal disturbances, and immune dysfunction often observed in ASD, we are quantifying independent and combined effects of PCB95 and IFN $\gamma$  on dendritic morphology in cultured sympathetic neurons. Sympathetic neurons were dissociated from superior cervical ganglia of perinatal rat pups and grown in serum-free defined medium in the absence of glial cells. Under these conditions, these neurons do not extend dendrites unless treated with BMP7 (10 ng/ml). After 5 d of exposure to BMPs in the absence of presence of PCBs (1 pM-1  $\mu$ M) and/or IFN $\gamma$  (30 ng/ml), cultures were fixed and immunostained for MAP2b to visualize dendrites. PCB 95 increased the number and length of dendrites in a concentration-dependent manner in the absence or presence of BMP7 and these effects were inhibited by pharmacological block of ryanodine receptor calcium channels. IFN $\gamma$  reduced dendritic growth in PCB 95-treated cultures in the absence or presence of BMP7. These findings illustrate a novel interaction between PCBs and cytokines in the autonomic nervous system, and suggest that exposure to these factors during critical windows of neurodevelopment may interfere with normal patterns of neuronal connectivity in sympathetic neurons and contribute to neuronal, immune and GI dysfunction in ASD. Support provided by NIEHS (R01 ES014901 to PJJ) and a Hartwell Biomedical Research Fellowship (to PEG)

**PS 1375 PCB 95 Stimulates Synaptogenesis via Ryanodine Receptor-Mediated miR132 Upregulation.**

H. Chen<sup>1</sup>, A. Lesiak<sup>2</sup>, M. Zhu<sup>2</sup>, S. M. Appleyard<sup>2</sup>, S. Impey<sup>3</sup>, D. Bruun<sup>1</sup>, G. A. Wayman<sup>2</sup> and P. J. Lein<sup>1</sup>. <sup>1</sup>Department of Molecular Biosciences, University of California Davis, Davis, CA; <sup>2</sup>Program in Neuroscience, Washington State University, Pullman, WA; <sup>3</sup>Vollum Institute, Oregon Health and Sciences University, Oregon Health and Sciences University, Portland, OR.

Polychlorinated biphenyls (PCBs) are widespread environmental pollutants linked to developmental neurotoxicity in children. Recent evidence suggests that non-dioxin-like (NDL) PCBs interfere with neuronal connectivity via interactions with ryanodine receptors (RyRs) which are calcium release channels broadly expressed in the nervous system. NDL PCBs stabilize RyRs in the open configuration and this triggers a calcium-dependent signaling pathway that mediates activity-dependent dendritic growth via CREB activation. CREB activation is also linked to increased formation of dendritic spines and synapses via upregulation of miR132, which suppresses the translation of p250GAP, a negative regulator of synaptogenesis. This suggests the possibility that NDL PCBs modulate these signaling events to influence synaptogenesis. To test this, we quantified dendritic spine and synapse formation in primary dissociated hippocampal cultures and organotypic hippocampal slice cultures treated with PCB 95, a NDL congener with potent activity at the RyR. Nanomolar concentrations of PCB 95 significantly increased spine density and the frequency of miniature excitatory post-synaptic currents. These effects were coincident with upregulation of miR132 and were blocked by inhibiting RyR or CREB, suppressing miR132 or expressing a mutant p250GAP, translation of which is not suppressed by miR132. These data demonstrate that PCB 95 sensitization of the RyR modulates synaptogenesis via activation of a CREB-miR132-p250GAP signaling pathway, and provide further evidence of mechanisms by which NDL PCBs may interfere with normal patterns of connectivity in the developing brain. Supported by NIH grants R01 MH086032, R01 ES014901, P42 ES04699, and the Hope for Depression Research Foundation.

**PS 1376 Developmental PCB 95 Exposure Affects Spatial Memory in Weanling Mice.**

C. Barnhart<sup>1</sup>, D. Yang<sup>1</sup>, H. Chen<sup>1</sup>, L. Qi<sup>2</sup> and P. J. Lein<sup>1</sup>. <sup>1</sup>Molecular Biosciences, University of California Davis, Davis, CA; <sup>2</sup>Public Health Sciences, University of California Davis, Davis, CA.

Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants that have been linked to behavioral deficits in children and experimental animals. We previously reported that developmental exposure to Aroclor 1254 interferes with

spatial memory in weanling rats coincident with decreased experience-dependent dendritic plasticity. We hypothesize that non-dioxin-like (NDL) PCBs mediate this phenomenon via interactions with ryanodine receptor (RyR) Ca<sup>2+</sup> channels. To test this hypothesis, we are comparing the effects of developmental exposure to NDL PCB 95, a potent RyR sensitizer, on spatial memory in wildtype (WT) versus mice heterozygous (HET) for the human R163C-RyR1 mutation that enhances sensitivity to halogenated hydrocarbons. RyR1<sup>WT</sup> dams were exposed to 0, 0.1, 1, or 6 mg PCB 95/kg/day in the diet for 2 weeks prior to mating with RyR1<sup>HET</sup> males, and throughout gestation and lactation. Offspring were weaned at P21 and trained in the Morris water maze from P24-P29. Preliminary analyses shows that developmental PCB 95 exposure affects latency, percentage of time (PT) and distance (PD) in the training quadrant, and average distance to the target (ADT) during training and these effects are both sex- and genotype-dependent. Within dose groups, RyR<sup>HET</sup> weanlings have higher PT and PD and lower ADT than RyR<sup>WT</sup> littermates during the probe test. There are no treatment, sex or genotype differences in latency, time in walls, or path length during the visual cue test. There are also no differences in dam or pup body weight across experimental groups. These experiments suggest that developmental exposure to a RyR-active NDL PCB congener alters spatial learning and memory and the magnitude of this effect is influenced by sex and by expression of the R163C-RyR1 mutation. This work supported by NIH (grants R01 ES014901, T32 ES007059 and P42 ES04699) and the ARCS Foundation.

**PS 1377 Optimizing Methods to Quantify CYP1A Enzyme Activity in Mouse Brain following Developmental PCB Exposure.**

A. Ashworth and C. P. Curran. *Biological Sciences, Northern Kentucky University, Highland Heights, KY.*

Polychlorinated biphenyls (PCBs) are developmental neurotoxins and endocrine disruptors that remain widespread in the human food supply. Children exposed during gestation and lactation are at highest risk of neurotoxicity. Genetic differences can influence how these chemicals are metabolized, so we use a mouse model in an effort to identify genes which affect human susceptibility to developmental PCB exposure. Coplanar PCBs activate the aryl hydrocarbon receptor (AhR) in high-affinity AhR mice and increase cytochrome P450 (CYP1) expression, including CYP1A2 protein which can sequester PCBs in the liver. Our work and the work of others have shown that this sequestration is protective. However, our previous research also found an increase in CYP1A1 mRNA in the brains of our most susceptible mouse line with the AhR<sup>Cyp1a2(-/-)</sup> genotype at postnatal day 28 when PCB tissues levels were highest. Other researchers have reported differential expression and regulation of CYP1A1 and CYP1A2 in the brain. So, we are now assessing CYP1A protein levels and activity in various brain regions. We used the EROD assay as a test for CYP1A1 activity and the MROD assay for CYP1A2 activity. Liver from PCB-treated AhR<sup>Cyp1a2(+/-)</sup> was used as a positive control whereas Cyp1a1<sup>(-/-)</sup> and Cyp1a2<sup>(-/-)</sup> knockout mice served as the respective negative controls. We compared traditional methods used for liver tissue (microsome purification) and a modified EROD protocol assay developed for smaller tissue volumes which uses a whole tissue homogenate. Both methods yielded sufficient protein for enzyme activity assays in all tissues tested: cortex, cerebellum, and hypothalamus. We found that 100mM potassium phosphate was an optimal buffer to homogenize the tissue, compared with 50mM Tris buffer. As expected, we also found higher enzyme activity in microsomes compared with whole tissue homogenates. Confirming previous reports, we also detected significant MROD activity in liver microsomes from Cyp1a2<sup>(-/-)</sup> mice, indicating this is a non-specific test for CYP1A2 activity.

**PS 1378 Selective Dieldrin Toxicity to Differentiating Dopaminergic Neurons.**

S. Schildknecht, B. Zimmer and M. Leist. *University of Konstanz, Konstanz, Germany.*

Parkinson's Disease (PD) is characterized by the selective loss of dopaminergic neurons of the Substantia nigra. Epidemiological observations have suggested a causative role of environmental pollutants such as heavy metals and pesticides in idiopathic forms of PD. Dieldrin is an insecticide for which adverse effects on the dopaminergic system have been reported. However, the underlying selective neurotoxicity is not fully characterized yet. In a model of murine embryonic stem cell-derived neurons, we observed a selective degeneration of dopaminergic neurons while other types such as GABA neurons, were not affected by dieldrin. Based on these observations with mixed neuronal types, a human dopaminergic cell line (LUHMES) was used for all further studies. LUHMES cells are conditionally immortalized human fetal mesencephalic cells that acquire a dopaminergic phenotype following differentiation for 6 days. Exposure to dieldrin during early differentiation (day 0-2) lead to an inhibition of normal differentiation and ultimately cell death. The same concentrations of dieldrin (0.5-1  $\mu$ M) did not show any adverse

effect when added to fully differentiated LUHMES or other, non-neuronal cell types. By using an alternative differentiation protocol, LUHMES can be differentiated into neurons without tyrosine hydroxylase (TH), the central enzyme in dopamine synthesis. When exposed during early differentiation (day 0-2), these TH-negative cells were less sensitive to dieldrin compared with normally differentiated LUHMES, indicating that components of the dopaminergic phenotype are responsible for the selective degeneration observed.

**PS 1379 Differential Gene Expression in the Neonatal Rat Brain following Combined Maternal Exposure to Chlorpyrifos and Nicotine.**

T. V. Damodaran<sup>1,2</sup>, J. Bradley<sup>2</sup> and M. B. Abou-Donia<sup>2</sup>. <sup>1</sup>Biology, NCCU, Durham, NC; <sup>2</sup>Pharmacology and Cancer Biology, DUMC, Durham, NC.

Environmental exposure to toxic chemicals during early fetal development has been known to manifest long lasting adverse effects for several decades. We hypothesized that combined exposures to pesticides used in households and to nicotine in cigarettes may have adverse synergistic outcome in both the mother and developing fetus. We studied the effects of combined exposure to chlorpyrifos (0.2 mg/kg) and nicotine (1mg / kg) with appropriate controls on the developing rats. Following parturition from exposed mothers, the brains of the new born litters were dissected out to isolate different tissues from the brain. Total RNA from the cerebellum was isolated and global gene expression analysis was done using cell cycle specific super arrays from Qiagen, employing standard molecular techniques. Some of the major findings include the following: A) There were a number of cell cycle genes altered in various treatment groups. B) cdc25b was significantly up-regulated in nicotine treatment group, but was down-regulated in both chlorpyrifos and combined treatment groups. C) cdk5 was up-regulated in chlorpyrifos alone and combined treatment groups. D) Up-regulation of p27kit1 and p15ink4b were noted in combined treatment group and not in nicotine or chlorpyrifos alone groups. This data indicates complex pathways of inhibition and acceleration of cell cycle. Further studies with those genes identified as biomarkers from this study can be useful for developing molecular tools for diagnostics and therapeutics for toxicities involving chlorpyrifos and nicotine

**PS 1380 The Effect of Embryonic Exposure to Deltamethrin on the Dopaminergic System and Swim Activity in the Zebrafish.**

T. S. Kung, J. Richardson, K. R. Cooper and L. A. White. Rutgers University/UMDNJ, New Brunswick, NJ.

Pyrethroids are commonly used insecticides that are generally considered to pose little risk to human and environmental health. However, there is increasing concern that children are more susceptible to the adverse effects of pesticides. We developed the zebrafish model to test the hypothesis that developmental exposure to low doses of pyrethroid pesticide deltamethrin alters dopaminergic gene expression and leads to persistent behavioral alterations. Zebrafish embryos were treated with deltamethrin at doses below the LOAEL (0.25-0.5 µg/L), during the embryonic period (3-72hpf) using a static non-renewal water exposure. After 72hpf, embryos were either harvested for RT-qPCR or reared in pesticide free water until adulthood. At 72hpf, deltamethrin treated embryos had significant increased expression of the dopamine transporter (DAT) and dopamine receptors D1 and D2. We quantified the swim activity of 2-week old zebrafish (larvae) and 1-year old zebrafish (adults) using the Noldus Ethovision system and observed significant increases in swim activity in both larvae and male adults that had been developmentally exposed to deltamethrin. To determine if the increased swim activity at the 2-week stage is mediated by deltamethrin's effect on dopaminergic system, we treated deltamethrin exposed and control larvae to methylphenidate, a DAT agonist. Methylphenidate had a significant stimulating effect on control larvae and a significant suppressive effect on larvae developmentally exposed to deltamethrin. To further investigate the role of the DAT, embryos were injected with a DAT morpholino to transiently reduce mature DAT transcript levels during the developmental period. DAT knockdown alone results in significant increases in swim activity at 2-weeks of age which is significantly reduced in deltamethrin treated embryos. Our data suggest that exposure to deltamethrin during the embryonic period results in persistent behavioral changes and is likely due to an interaction between deltamethrin and the dopaminergic system. **PS 1381 Dysregulation of Redox Homeostasis by Paraquat in Rat Developing Brain.**

M. Rathinam, L. Chen, A. Fowler, A. Riar, M. Narasimhan, L. Mahimainathan and G. I. Henderson. Pharmacology and Neuroscience, Texas Tech University Health Sciences Center, Lubbock, TX.

Immature brain is susceptible to paraquat (PQ) induced oxidative stress resulting in neuron damage. We hypothesize that dysregulation of glutathione (GSH) homeostasis is a key factor in these neurotoxic responses. To test this, postnatal day 4 (PN4) rat pups were chosen as the period between birth and PN10 includes active brain development equivalent to that in the human 3rd trimester. Initially, LD50 levels on PN4 were evaluated. Sprague Dawley rat pups were grouped as control, vehicle control, and PQ was administered (I.P) at 10, 25 and 50 mg/kg. At 24h post-treatment, declines in viability by 45% and 100% were observed in the 25 and 50 mg/kg PQ groups, respectively. During the 24h period, a decline in motor activity was also noticed in these two high dose groups. For subsequent studies the 10 mg/kg dose was used for all time points (2-24 hours). Body weight was unchanged compared to both controls (p<0.05) Brain PQ levels peaked at 4h (140µg/mg protein) as assessed by HPLC. In brain, a significant (p<0.05) increase in reactive oxygen levels (ROS) was observed by DCF-DA fluorimetry as early as 6h which persisted to 24h. Increased oxidized form of GSH (GSSG) was observed at all time points (2, 4, 6, 8 and 24h) while decreased reduced glutathione (GSH) was noted only at 24h. These changes were reflected in decreased GSH/GSSG ratios with an associated increase in brain PARP-1 levels (50%) at 24h. These results indicate altered redox homeostasis and DNA damage in PQ exposed brain. The studies have established a role for oxidative stress in PQ induced neurotoxicity in developing brain and a model for studying PQ neurodevelopmental toxicity.

**PS 1382 Neonatal Bisphenol A (BPA) Exposure Alters Sex-Specific Estrogen Receptor 2 (ERβ) mRNA Expression in the Postnatal Rat Brain.**

J. Cao, L. Joyner and H. B. Patisaul. Biology, North Carolina State University, Raleigh, NC.

Perinatal life is a critical window for sexually dimorphic brain organization, which is profoundly influenced by endogenous steroids, most notably estrogen. Exposure to endocrine disrupting compounds may disrupt this process, resulting in compromised reproductive physiology and altered sociosexual behavior in adult life. To test the hypothesis that Bisphenol A (BPA) exposure specifically confined to the neonatal critical period impacts ESR expression through weaning, the present study assessed the impact of exposure (on the first three days of life) to 10 µg estradiol benzoate (EB), 50 µg/kg BPA (LBPA) or 50 mg/kg BPA (HBPA) on ESR2 expression in the bed nucleus of the stria terminalis (BNST), the paraventricular nucleus (PVN) and the anterior medial amygdala (MeA) in the postnatal rat brain. In unexposed animals, ESR2 expression decreased in the BNST and increased in the PVN from postnatal day (PND) 0 to 19 in both sexes. Sexually dimorphic ESR2 expression was transient in the neonatal BNST and PVN. EB decreased ESR2 expression in females in the BNST, and in both sexes in the PVN. In the BNST, ESR2 expression was decreased in males by LBPA and in females by HBPA on PND 10. LBPA increased ESR2 expression in females but decreased it in males on PND 10, thus reversing the sexually dimorphic expression pattern observed in the vehicle controls. In the MeA, BPA mimicked the EB effect and decreased ESR2 expression levels on PND 4. Collectively, these data demonstrate that the neonatal period is vulnerable to BPA exposure, and BPA does not simply mirror the impacts of EB, but rather, disrupted ESR2 expression in a dose, temporal, and region specific manner. The functional significance of this altered ESR2 expression may underlie reported disruptions of adult reproductive deficiencies and abrogated sex differences in sociosexual behavior across the lifespan. Further work will also be needed to establish if these effects can be induced via exposures which recapitulate human exposure conditions and doses.

**PS 1383 Effects of Different Endocrine Disruptor Mixtures on Gene Expression in Neonatal Rat Brain Regions: Focus on Developing Excitatory Synapses.**

W. Lichtensteiger<sup>1</sup>, C. Bassetti-Gaille<sup>1</sup>, O. Faass<sup>1</sup>, J. Boberg<sup>2</sup>, S. Christiansen<sup>2</sup>, U. Hass<sup>2</sup>, A. Kortenkamp<sup>3</sup> and M. Schlumpf<sup>1</sup>. <sup>1</sup>GREEN Tox and Institute of Anatomy, University of Zurich, Zurich, Switzerland; <sup>2</sup>National Food Institute, Technical University of Denmark, Søborg, Denmark; <sup>3</sup>Institute for the Environment, Brunel University, Uxbridge, United Kingdom. Sponsor: T. Slotkin.

Brain development is regulated by sex hormones. In mammals, estradiol is thought to control male sexual brain differentiation, but recent data also indicate a role for androgen receptor-mediated mechanisms. Female brain development is dependent

on estrogens. It is not known how these processes are affected by real-world mixtures of endocrine disruptors (EDCs). We investigated effects of a mixture of 13 EDCs (T-Mix) and of mixtures of its estrogenic (E-Mix) and anti-androgenic (A-Mix) components, administered by oral gavage to rat dams from gestational day 7 until weaning. The mixture ratio was chosen to reflect high end human intakes (S. Christiansen et al., 2012). At postnatal day 6, during the last part of sexual brain differentiation, exon microarray analyses were performed in medial preoptic area (MPO) of both sexes in the highest dose group, and real time RT-PCR of selected mRNA species in MPO and ventromedial hypothalamus (VMH) of all dose groups. Microarray analyses in MPO revealed sex-specific effects on gene expression patterns that differed between all three EDC mixtures. Real time RT-PCR of individual mRNA species demonstrated treatment- and sex-dependent differences between MPO and VMH; effects were dose-dependent. Prominent are effects of all three EDC mixtures on the expression of genes encoding for proteins involved in excitatory glutamergic synapse formation and function, including a number of genes identified as risk factors for autism spectrum disorders. Our study demonstrates differential responses of the developing brain to different types of EDC mixtures and points to excitatory synapse development as a new, potentially relevant focus. Supported by EU FP7 Framework Programme (CONTAMED).

### PS 1384 The Effect of Prenatal Exposure to Amorphous Nanosilica Particles on Neonatal Memory.

Nanomaterials (NMs) are increasingly being used in various fields for their unique functions. Therefore, it is important to ensure the safety of NMs to take advantage of their usefulness. Previously we identified the hazard that intravenous injection of several NMs to pregnant mice might induce intrauterine growth retardation (IUGR). IUGR children are known to have high risks of contracting some diseases, such as neurological disorders. Thus, it is important to assess postnatal effects of prenatal exposure to NMs. In this study, we examined neonatal memory after in utero exposure to amorphous nanosilica particles (nSP), as one of the typical NMs. Pregnant mice were intravenously injected nSP. The body weight of pups were measured weekly. Working memory, reference memory, and context memory of pups were measured by eight-arm radial maze test, Barnes maze test, and fear conditioning test. Pups of nSP treated mice (nSP pups) had smaller body weight than control mice from birth to 30 weeks old. On the other hand, no difference was found on the scores of memory tests between nSP pups and control mice. These results suggest that in utero exposure to nSP might result in growth disorder of pups but have little effect on memory of pups.

### PS 1385 Sex-Dependent Impairment of Learning due to Exposure to Concentrated Ambient Particles.

J. L. Allen, D. Weston, K. Conrad, G. Oberdorster and D. A. Cory-Slechta.  
*Environmental Medicine, University of Rochester Medical School, Rochester, NY.*

Multiple studies link air pollution to impaired cognition in humans and experimental animals. Our study sought to determine the effects of ultrafine (<100nm) concentrated ambient particles (CAPS) on learning in C57BL/6 mice exposed to CAPS or filtered air for 2 weeks during early postnatal life with and without CAPS re-exposure as adults. Behavioral testing begun at 2-3 mos of age using a repeated learning and performance paradigm that housed a series of three response levers (left, center, right) was located on the front wall of the chamber. During the repeated learning component of the paradigm, the required sequence changed with each session, whereas a constant sequence was used in the performance component. Both male and female mice showed significant sequence-dependent learning impairments, but no alterations in the performance component, consistent with selective learning deficits. Postnatal female CAPS-exposed mice showed significant learning impairment in sequences requiring a right-center-left order, whereas male adult CAPS-exposed mice were impaired on learning sequences requiring a left-center-right order. Assessment of brain pathology in non-behaviorally tested littermates showed CAPS-related evidence of sex and brain-region dependent microglial

activation, astrogliosis, and neurochemical changes even several months post termination of exposure, the importance of which will be determined by histopathological examination and neurochemical analysis of the brains from CAPS-exposed mice that underwent behavioral testing. Collectively, these findings demonstrate long-lasting brain and behavioral toxicity in response to CAPS exposures, with impairments on the repeated learning and performance paradigm that are sex-, sequence-, and exposure period-dependent. They support the need for broader assessment of the role of CAPS exposure in nervous system diseases and disorders. Supported by T32ES007026, R21ES019105, P30ES01247.

### PS 1386 Effects of Maternal Inhalation of Gasoline Evaporative Condensates on Sensory Function in Rat Offspring.

L. L. Degn<sup>1</sup>, D. F. Lyke<sup>1</sup>, T. E. Beasley<sup>1</sup>, P. A. Evansky<sup>2</sup>, S. A. Martin<sup>1</sup>, W. K. Boyes<sup>1</sup>, P. J. Bushnell<sup>1</sup> and D. W. Herr<sup>1</sup>. <sup>1</sup>TAD/INB, US EPA, Durham, NC; <sup>2</sup>EPHD, US EPA, Durham, NC.

In order to assess potential health effects resulting from exposure to ethanol-gasoline blend vapors, we previously conducted neurophysiological assessment of sensory function following gestational exposure to 100% ethanol vapor (Herr et al., *Toxicologist*, 2012). For comparison purposes, the current study investigated the same measures after gestational exposure to 100% gasoline evaporative condensates (GVC). Pregnant Long-Evans rats were exposed to 0, 3K, 6K, or 9K ppm GVC vapors for 6.5 h/day over GD9 – GD20. Sensory evaluations of male offspring began around PND106. Peripheral nerve function (compound action potentials, NCV), somatosensory (cortical and cerebellar evoked potentials), auditory (brainstem auditory evoked responses), and visual evoked responses were assessed. Visual function assessment included pattern elicited visual evoked potentials (VEP), VEP contrast sensitivity, and electroretinograms (ERG) recorded from dark-adapted (scotopic) and light-adapted (photopic) flashes, and UV and green flicker. Although some minor statistical differences were indicated for auditory and somatosensory responses, these changes were not consistently dose- or stimulus intensity-related. Scotopic ERGs had a statistically significant dose-related decrease in the b-wave implicit time. All other parameters of ERGs and VEPs were unaffected by treatment. All physiological responses showed changes related to stimulus intensity, and provided an estimate of detectable levels of change. The results show that gestational exposure to GVC vapors did not result in large decrements in peripheral nerve, somatosensory, auditory, or visual function when the offspring were assessed as adults. However, the alterations in ERG b-waves may indicate subtle changes in retinal function. Additional studies are in progress to evaluate the effects of exposure to the evaporative condensate vapors from a blend of ethanol (15%) and gasoline (85%). *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

### PS 1387 Abnormality in Fear-Related Emotional Function in Mice Perinatally Exposed to a Low Dose of TCDD.

S. Benner<sup>1</sup>, A. Haijima<sup>1</sup>, Y. Zhang<sup>1</sup>, R. Kobayakawa<sup>2</sup>, K. Kobayakawa<sup>2</sup>, M. Kakeyama<sup>1</sup> and C. Tohyama<sup>1</sup>. <sup>1</sup>Laboratory of Environmental Health Sciences, Center for Disease Biology and Integrative Medicine, Graduate School of Medicine, University of Tokyo, Tokyo, Japan; <sup>2</sup>Osaka Bioscience Institute, Osaka, Japan.

An increasing trend of prevalence of developmental disorders, psychiatric illnesses and associated pathological behaviors has been suspected of being induced at least partly by environmental chemical exposure during development. We have previously reported the lasting consequences of perinatal exposure to a low dose of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in brain functions, such as cognitive and social-emotional defects in mice. Nevertheless, the effects on emotional function have not yet been clearly defined. The current study thus aimed to examine whether a perinatal TCDD-exposure at an oral dose of 0.6 µg TCDD/kg on GD 12.5 in C57BL/6 dams affects emotional function in offspring. Eleven brain regions were microdissected by the punch out technique for determination of the basal monoamine contents using HPLC-ECD. Behavioral responses toward acquired and innate fear were analyzed using fear conditioning and olfactory-based fear stress tests. A depression-like behavior was assessed using forced swim test. It was found that the TCDD-exposure enhanced dopamine level in the ventral tegmental area and ventral hippocampus. These mesolimbic structures are thought to regulate behavioral responses toward external stimuli by processing internal information, such as memory and emotion. A mesolimbic dopaminergic balance is particularly sensitive to aversive stimuli such as fear. Accordingly, the TCDD-exposed mice exhibited abnormal behavioral responses to both acquired and innate fear. However, no apparent alterations in the basal serotonin levels were found in the examined regions. In correlation, no abnormalities associated with serotonergic emotional behavior emerged under the forced swim test. The present results suggest that a perinatal low-dose TCDD exposure persistently disrupts dopamine balance in brain regions involved in regulating fear-related emotion.

**PS 1388 Neonatal Exposure to Perfluorohexane Sulfonate (PFHxS) in Mice Alters Neuroprotein Levels Essential for the Developing Brain.**

I. Lee and H. Viberg, *Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Perfluorohexane sulfonate (PFHxS) is a perfluorinated compound (PFC) used as an industrial additive. The chemical properties of PFCs make them suitable as surfactants and oil- and water repellents, and they are frequently used in products for packaging and as protective coatings. However, the same properties account for their extreme physico-chemical stability, making them practically non-biodegradable, which has generated a worldwide environmental spread and concern. Since we recently have seen that other PFCs, like perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA), can induce developmental neurotoxic effects, the purpose of the present study was to explore if neonatal exposure to PFHxS can affect specific neuroprotein levels e.g. calcium/calmodulin-dependent kinase II (CaMKII), growth-associated protein-43 (GAP-43), synaptophysin and tau, in the mouse brain. Male and female NMRI-mice were exposed, on postnatal day 10, to a single oral dose of 6.1 or 9.2 mg PFHxS/kg bw and control animals received a 20% fat emulsion vehicle. The animals were euthanized 24h or 4 months after PFHxS exposure and the neuroprotein levels in hippocampus and cerebral cortex were analyzed. 24h after exposure there were significant differences seen in the neuroprotein levels compared with control and the neurotoxic effects differed between hippocampus and cerebral cortex. Increased levels of CaMKII, synaptophysin and tau in the hippocampus and decreased levels of GAP-43 in the cerebral cortex were measured for both sexes. The effects on the protein levels in adult animals were less pronounced than in the neonates. The results from the present study show that a single oral exposure to PFHxS during a critical period of brain development can cause developmental neurotoxic effects. The neurotoxic effects are similar to previous studies done with other PFCs such as PFOS and PFOA. Further investigations on the developmental neurotoxic effects of PFHxS are needed as there still is very limited knowledge about the neurotoxicity of PFCs.

**PS 1389 Prenatal Exposure to 1-Bromopropane Changes Basic Excitability of the Hippocampus and Inhibits the Behaviors Induced by Kainic Acid and Pentylenetetrazole in the Rat Offspring during Lactation Period.**

Y. Fueta<sup>1</sup>, S. Ueno<sup>1</sup>, T. Ishidao<sup>1</sup>, M. Kanemitsu<sup>2</sup> and H. Hori<sup>1</sup>. <sup>1</sup>University of Occupational and Environmental Health, Kitakyushu, Japan; <sup>2</sup>Kyushu Institute of Technology, Kitakyushu, Japan.

1-Bromopropane (1-BP), a substitute for specific chlorofluorocarbons, is mainly used for degreasing agents and spray adhesives. 1-BP exhibits central neurotoxicity in adult humans. Animal studies have shown reproductive/developmental toxicity as well as neurotoxicity. However, developmental neurotoxicity remains unclear. We aimed to clarify whether prenatal exposure to 1-BP affects development of neuronal excitability and behaviors in the juvenile offspring. 1-BP was inhalationally exposed to pregnant Wistar rats from day 1 to 20 (6 h/day) with the concentration of 0, 400, or 700 ppm. On the days of PND 13, 14 and 15, field potentials were recorded from the CA1 area of hippocampal slices obtained from the control and 1-BP groups. At PND14, kainic acid (KA, 0, 0.1, 0.5 and 2.0 mg/kg) or pentylenetetrazole (PTZ, 60 mg/kg) was injected to the control and 1-BP groups. Stimulation/response curves of field excitatory postsynaptic potential and those of population spike (PS) enhanced, and the ratios of paired-pulse responses of PS decreased in the 1-BP groups at PND14. PTZ or KA injection to the PND14 offspring resulted in a significant inhibition of the drug-induced behaviors in the 1-BP groups. Our results provide the evidence that prenatal exposure to 1-BP/metabolites affects the central nervous system (CNS) of the offspring during lactation period, suggesting developmental modification of neuronal networks and changes in the excitability of the CNS during the lactation period.

**PS 1390 Neonatal Exposure to a Single Low Dose of Ionising Radiation Causes Persistent Disruptions in Cognitive Abilities and Increased Levels of Tau in Mice.**

S. Buratovic<sup>1</sup>, B. Stenéröw<sup>2</sup>, S. Sundell-Bergman<sup>3</sup>, A. Fredriksson<sup>1</sup>, H. Viberg<sup>1</sup> and P. Eriksson<sup>1</sup>. <sup>1</sup>Environmental Toxicology, Organismal Biology, Uppsala, Sweden; <sup>2</sup>Radiology, Oncology and Radiation Science, Biomedical Radiation Sciences, Uppsala, Sweden; <sup>3</sup>Soil and Environment, Uppsala, Sweden.

Ionising radiation (IR) is extensively used in the medical field for treatment and diagnostics. Concern has been raised about possible negative consequences from low dose exposure to IR during critical phases of perinatal and/or neonatal brain devel-

opment. The brain growth spurt, which is characterized by maturation of axonal and dendritic outgrowth, establishment of neural connections and acquisition of new motor and sensory abilities, occurs perinatally in humans and neonatally in mice. By using the neonatal mouse as an animal model we are able to study the effect of IR during early periods of brain development and which consequences it has for the adult animal.

Neonatal NMRI mice were irradiated (0; 0.35 and 0.5 Gy) at one single occasion on postnatal day 10. At 2- and 4-months of age, spontaneous behaviour was tested in a novel home environment and parameters observed were locomotion, rearing and total activity. Analyses of important neuroproteins in cerebral cortex were performed 24h following irradiation (0 and 0.5 Gy) and at 6-months of age.

Observations of spontaneous behaviour revealed a significantly deranged behaviour in 2- and 4-month old mice of both sexes irradiated with 0.35 or 0.5 Gy in a dose response related manner. The observed reduced activity during the beginning of the test period and increased activity at the end of the test period indicates a lack of habituation capacity and disrupted cognitive functions. Neuroprotein analyses of cerebral cortex 24h after irradiation and at 6-months of age showed a significantly increased level of tau in mice irradiated with 0.5 Gy compared to controls. This demonstrates that a single dose of IR, given at a defined critical period during brain development, is sufficient to cause persistently reduced cognitive functions and increased levels of tau in mice.

**PS 1391 CYP1A1\_CYP1A2(-/-) Double Knockout Mice Exhibit Impaired Motor Function.**

A. Lang, H. Garber, C. Strohmaier, K. Taylor and C. P. Curran. *Biological Sciences, Northern Kentucky University, Highland Heights, KY.*

CYP1A1 and CYP1A2, members of the cytochrome P450 superfamily, are key detoxifying enzymes normally expressed in the liver. Though they are also reportedly expressed in the cortex and cerebellum of the brain, their physiological function in the brain remains unknown. Previous work in our lab uncovered motor deficits in Cyp1a2(-/-) knockout mice. To confirm those findings, we obtained Cyp1a1\_1a2 (-/-) double knockout mice which had the Cyp1a2 gene deleted using a different genetic strategy. We compared Cyp1a1\_1a2 (-/-) double knockout mice with wild-type Cyp1a1\_Cyp1a2 (+/+) mice using a battery of four behavior tests: The rotarod test primarily identifies deficits in cerebellar function related to balance and motor coordination. Gait analysis, adhesive removal, and pole climbing tests primarily identify impairments in the nigrostriatal pathway, which is a major dopaminergic pathway related to motor function. We found significant impairments in Cyp1a1\_1a2 (-/-) double knockout mice in rotarod testing and adhesive removal. Male knockouts demonstrated the greatest impairment in adhesive removal compared with females. Interestingly, Cyp1a1\_1a2 (-/-) double knockout mice had shorter latencies in the pole-climbing test. This might be explained by a difference in motivation or anxiety, because the animals climb down a 50cm pole to return to their home cage. There were no significant differences in the gait test for stride length, stride width or stride differential. Together, these data suggest a novel function for CYP1A2 in brain regions important to normal motor function.

**PS 1392 Aryl Hydrocarbon Receptor (AhR) Deletion in Cerebellar Granule Neuron Precursors Impairs Motor Function and Neurogenesis.**

D. P. Dever, K. Conrad, D. A. Cory-Slechta and L. Opanashuk. *Environmental Med, University of Rochester, Rochester, NY.*

The AhR is a ligand-activated member of the basic-helix-loop-helix (bHLH)/PER-ARNT-SIM transcription superfamily that regulates the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Increasing evidence suggests that AhR influences the development of many tissues, including the central nervous system. In particular, the AhR has been reported to be involved in regulating critical stages of neurogenesis. Our previous data suggest that inappropriate and/or sustained AhR activation by TCDD disrupted granule neuron precursor (GNP) development. Moreover, studies in AhR knockout mice suggested that GNP maturation was abnormal. This study tested the hypothesis that the AhR endogenously controls GNP maturation in the developing cerebellum. We created a GNP-specific AhR knockout mouse (AhR<sup>fx</sup>/Math1<sup>CRE</sup>/+) utilizing the Cre-LoxP conditional knockout strategy, then examined motor function and GNP maturation. GNPs in AhR<sup>fx</sup>/fx/Math1<sup>CRE</sup>/+ exclusively expressed Cre recombinase in the developing mouse cerebellum and the intrachromosomal recombination of AhR alleles by Cre recombinase resulted in decreased AhR protein expression. Behavioral studies revealed that AhR<sup>fx</sup>/fx/Math1<sup>CRE</sup>/+ mice displayed repetitive motor activity and abnormal rotarod performance. Additionally, DNA content, a surrogate measure of

cell number, was reduced at PND10, PND21, and PND60 in AhR $\alpha$ /f $\alpha$ /Math1CRE/+ mice compared to controls, suggesting that cell numbers were diminished. Following AhR excision, there were fewer proliferating GNP in the external germinal layer of the cerebellum at PND10, which resulted in a reduction of granule neurons reaching their final destination in the adult cerebellum. These results suggest that AhR activity plays a role in regulating granule neuron number, possibly by promoting GNP cell cycle activity, which ultimately impacts cerebellar function. These studies will provide novel insights for understanding mechanisms of dioxin-mediated neurotoxicity in the developing cerebellum.

**PS 1393 Assessment of Brain Morphometry Data Using Multivariate Statistical Analysis Methodology.**

W. Miner, T. J. Vidmar and L. Freshwater. *BioSTAT Consultants, Portage, MI.*

As required by EPA guidelines, brain morphometry is an area of interest in screening chemicals for developmental neurotoxicity. Brain morphometry data includes multiple measurements from the same animal such as brain weight, brain width, and brain length. These measurements are typically resource intensive and costly and therefore often made on a small subset of animals. Univariate statistical methodology (eg. ANOVA) treats these measurements as independent of one another and analyzes each separately. By contrast, using multivariate analysis of variance, the potential error resulting from conducting multiple univariate tests can be avoided. Multivariate statistical analysis evaluates all measurements simultaneously, taking advantage of the correlation between those measurements. In this simulated study, female brain morphometry data were generated in SAS® using the means, standard deviations, and correlations between measurements observed in an actual study. Three dose groups (control, low, and high) were created. The simulation was designed such that individual brain morphometry components suggested the presence of dose-related increasing trends. A univariate analysis of variance was performed on each of the components: brain weight, brain width, and brain length. The univariate analysis showed no significance for any of the three brain measurements at the 5% significance level. Performing a multivariate analysis of variance yielded an overall significant treatment effect ( $p < .05$ ). Pairwise comparisons provided evidence that brain morphometry for both the low and high dose groups was significantly higher when compared to the control group. In the simulated study, the univariate analysis of variance fails to detect biologically relevant treatment effects in brain morphometry measurements. The multivariate analysis, which addresses the measurements concurrently, identifies statistically significant differences among the dose groups. These results suggest a multivariate analysis should be used to analyze brain morphometry data.

**PS 1394 Mother's Environmental Tobacco Smoke Exposure during Pregnancy and Externalizing Behavior Problems in Children.**

J. Liu<sup>1</sup>, P. Leung<sup>2</sup>, L. McCauley<sup>3</sup> and J. Pinto-Martin<sup>1</sup>. <sup>1</sup>*School of Nursing, University of Pennsylvania, Philadelphia, PA;* <sup>2</sup>*Chinese University of Hong Kong, Hong Kong, China;* <sup>3</sup>*Nell Hodgson School of Nursing, Emory University, Atlanta, GA.*

**Background:** While the impact of active maternal smoking during pregnancy on child health has been well investigated, the association between maternal passive smoking, or environmental tobacco smoke (ETS), and behavioral development of offspring is less clear. This study examines the association between maternal ETS exposure during pregnancy and child behavior problems.

**Methods:** As part of the Jintan China Cohort Study, mother-child pairs ( $n=646$ ) were included in the analyses. Maternal ETS exposure at home, the workplace, and other places during pregnancy was retroactively assessed when children were 5-6 years old. Behavior was assessed via the Child Behavior Checklist when children were 5-6 years old. Logistic regression models were constructed to examine associations between maternal exposure to ETS during pregnancy and internalizing and externalizing behavior problems, adjusting for potential cofounders including child sex and parental characteristics.

**Results:** 37% of mothers reported ETS during pregnancy. Children of mothers exposed to ETS during pregnancy had higher scores for externalizing and total behavior problems with 25% of children whose mothers were exposed to ETS, compared to 16% of children of unexposed mothers. After adjusting for potential cofounders, ETS exposure was associated with a higher risk of externalizing behavior problems in offspring of exposed mothers (OR=2.08, 95% confidence interval [CI] 1.27-3.43). Analysis after multiple imputations and sensitivity analysis further verified the association, but no dose-response relationship was found. ETS exposure, however, was not associated with internalizing or total behavior problems.

**Conclusion:** This study suggests that maternal ETS exposure during pregnancy may impact child behavioral development, particularly externalizing behaviors.

**PS 1395 Patterns of Clinical Bioindicators in Rat Serum following Acute Exposure to Pesticides of Different Chemical Classes.**

D. W. Herr<sup>1</sup>, N. A. Stewart<sup>2</sup>, D. F. Lyke<sup>1</sup>, K. L. McDaniel<sup>1</sup> and V. C. Moser<sup>1</sup>. <sup>1</sup>*TAD/NB, US EPA, Durham, NC;* <sup>2</sup>*Contractor, Durham, NC.*

There is interest in bioindicators of adverse outcomes in safety assessment and translational research. Chemically-induced neurological effects may be reflected in specific neuronal changes and/or by general stress-like responses, and such bioindicators may be useful for measuring health impacts. We examined differential profiles of clinical bioindicators after acute treatment (po) with different pesticides (permethrin, deltamethrin, fipronil, imidacloprid, carbaryl, triadimefon). These same rats were evaluated for EEG changes (Lyke *et al.*, *Toxicologist*, 2010, 2011, 2012, 2013). Rats were sacrificed after EEG testing. Serum samples were processed by Myriad RBM using their RodentMAP® and Rat MetabolicMAP® assays. Depending on the pesticide, 2-18 of 78 analytes were altered, and each pesticide produced a different pattern of changes. Discriminant analysis indicated that these alterations differed in a dose-related manner for each chemical. The data show that acute exposure to different classes of pesticides produced different patterns of changes in clinical bioindicators, which may be analyzed for linkages to biological pathways. *This is an abstract of a presentation and does not necessarily reflect EPA policy.*

**PS 1396 Acute Triadimefon-Induced Changes in the EEG of Long-Evans Rats.**

D. F. Lyke, K. L. McDaniel, V. C. Moser and D. W. Herr. *TAD/NB, US EPA, Durham, NC.*

We have reported that the non-stimulus driven EEG is altered differently by acute treatment with deltamethrin, permethrin, fipronil, or imidacloprid (Lyke and Herr, Lyke *et al.*, *Toxicologist*, 2010, 2011, 2012) in non-restrained animals. In the current study, we examined the ability to detect changes in EEG activity produced by triadimefon, a triazole pesticide which inhibits sterol synthesis in fungal cell membranes and inhibits dopamine re-uptake in the mammalian nervous system. Adult male Long-Evans rats were implanted with epidural screw electrodes. After about 1 week recovery, non-restrained animals were gavaged with corn oil (vehicle) and tested for 2 days for acclimation. On day 3, the rats were dosed with 1 ml/kg corn oil, 75, or 150 mg/kg triadimefon and tested 1 h later. EEG was recorded as 30 segments of 2 s durations, transformed using a Fast Fourier Transformation, and the spectra averaged. These dosages have increased motor activity in Long-Evans rats in previous studies. Treatment with 150 mg/kg triadimefon increased the amplitude associated with Theta activity compared to controls (31% increase), and compared to 75 mg/kg triadimefon (27% increase), when recorded between the visual cortex and cerebellum. These results were different from the decreased gamma activity resulting from treatment with fipronil, increased gamma activity following treatment with permethrin, slightly decreased alpha activity with deltamethrin, and lack of changes after dosing with imidacloprid. The data show that triadimefon can alter CNS activity as measured by EEG, and the alterations may differ from some other pesticides. *This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.*

**PS 1397 In Vitro Assessment of Parkinsonian Neurodegeneration by Dinitrophenolic Herbicides in PC12 Cells.**

H. J. Heusinkveld<sup>1</sup>, A. C. van Vliet<sup>1</sup>, P. C. Nijssen<sup>2</sup> and R. H. Westerink<sup>1</sup>. <sup>1</sup>*Neurotoxicology Research Group, Institute for Risk Assessment Sciences, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands;* <sup>2</sup>*Department of Neurology, Elisabeth Hospital, Tilburg, Netherlands.*

Parkinson's disease (PD) is the most prevalent human neurodegenerative disorder after Alzheimer's disease affecting 1-2% of the population over 65 years of age. In several epidemiologic studies, chronic exposure to environmental pollutants, in particular pesticides, has been linked to neurodegeneration and the development of PD, though the underlying mechanisms are largely unknown.

Research directed by neurologist Dr Peter Nijssen encountered PD patients clustered in a remote rural area in the Netherlands, both occupationally and non-occupationally involved in agriculture, with relatively high exposure to pesticides. Among the pesticides, (dinitrophenolic) herbicides, were identified as common denominator. Since this class of herbicides is known as mitochondrial uncouplers, we assessed the potential role of dinitrophenolic herbicides in dopaminergic neurodegeneration.

Using a battery of in vitro tests, including measurements of cell viability, oxidative stress, single-cell fluorescence calcium imaging and protein analysis, the effects of dinitrophenolic herbicides on different pathways of neurotoxicity were assessed in PC12 cells as a model for mature dopaminergic neurons. Our results demonstrate

that dinitrophenolic herbicides induce moderate cytotoxicity via calcium-dependent activation of caspase-mediated apoptosis as well as activation of key proteins characteristic for Parkinsonian neurodegeneration in surviving dopaminergic cells. This leads to the hypothesis that human exposure to dinitrophenolic herbicides may be linked to the pathophysiology of PD. Funding: EU (ACROPOLIS, KBBE-245163) and the Dutch "International Parkinson Fonds" (PAGES).

### PS 1398 Protein Cysteine Oxidation and Dopaminergic Cell Death Induced by Pesticides.

J. Navarro-Yepes<sup>1,2</sup>, L. M. Del Razo<sup>1</sup>, R. Franco<sup>2</sup> and B. Quintanilla-Vega<sup>1</sup>.  
<sup>1</sup>Toxicology Department, CINVESTAV-IPN, Mexico City, Mexico; <sup>2</sup>Redox Biology Center, University of Nebraska-Lincoln, Lincoln, NE.

Parkinson's disease (PD) is characterized by the loss of dopaminergic neurons in the substantia nigra, which is linked to mitochondrial dysfunction, oxidative stress, protein aggregation and impairment in protein degradation pathways. Epidemiological studies suggest that chronic exposure to pesticides is associated with an increased risk of developing PD. However, the underlying mechanisms have not been precisely elucidated. Oxidative protein modifications can modulate the activation of cell death pathways. Thus, we explored the role of oxidative cysteine modifications in dopaminergic cell death induced by pesticides. Human neuroblastoma cells (SK-N-SH and SH-SY5Y) and the fetal human mesencephalic cell line (LUHMES, Lund human mesencephalic) were exposed to paraquat (PQ), rotenone and dieldrin. Compared to neuroblastoma cells, LUHMES cells exhibited greater sensitivity to all pesticides independent from their differentiation state. Apoptotic cell death induced by pesticides was paralleled to oxidative stress and a decrease in glutathione content. Cell death was prevented by glutathione ethyl ester. PQ induced protein alterations in both sulfenic acid (PSOH) and glutathionylation profiles (PSSG). Mass spectrometry of immunoprecipitated PSOH/PSSG proteins identified several proteins from the ubiquitin/proteasome degradation system and molecular chaperones as being modified by PSOH and PSSG in response to PQ, including E3 ubiquitin-protein ligases (SIAH1, TRIM13, RNF25, RNF139, HERC2, BRE1B), ubiquitin hydrolases (USP47, USP24), ubiquitin conjugating enzymes (UBE20), and Hsp40 co-chaperones (DNAJB4, DNAJC11). The expression of the protein DNAJC11 was down-regulated in a concentration dependent manner by PQ. Results suggest a role for protein cysteine oxidation (sulfenylation and/or glutathionylation) in the regulation of the ubiquitin/proteasome and chaperone-mediated folding systems in response to pesticide exposure. Supported by CONACYT-Mexico (Grant #104316).

### PS 1399 Aldehyde Dehydrogenase Dysfunction Increases Parkinson's Disease Risk via Gene-Environment Interactions.

A. G. Fitzmaurice<sup>1,2</sup>, S. L. Rhodes<sup>3</sup>, M. Cockburn<sup>4</sup>, B. Ritz<sup>3</sup> and J. M. Bronstein<sup>1,2,5</sup>. <sup>1</sup>Neurology, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA; <sup>2</sup>Molecular Toxicology, University of California Los Angeles, Los Angeles, CA; <sup>3</sup>Epidemiology, University of California Los Angeles Fielding School of Public Health, Los Angeles, CA; <sup>4</sup>Preventive Medicine, Keck School of Medicine of University of California Los Angeles, Los Angeles, CA; <sup>5</sup>Greater Los Angeles Veterans Administration Medical Center, Los Angeles, CA.

Parkinson's disease (PD) is a neurodegenerative disorder characterized by the loss of dopaminergic neurons in the substantia nigra. We recently reported that exposure to the fungicide benomyl resulted in dopaminergic neuronal loss, aldehyde dehydrogenase (ALDH) inhibition, and an epidemiologic association with increased PD occurrence. Since the dopamine metabolite 3,4-dihydroxyphenylacetaldehyde (i.e., DOPAL) is highly toxic and an ALDH substrate, ALDH inhibition might contribute to the particular vulnerability of dopaminergic neurons. To investigate the potential relevance of this mechanism, we developed a novel ex vivo neuronal assay to screen pesticides for ALDH inhibitory activity. All dithiocarbamates tested (e.g., mancozeb, maneb, ziram), two dicarboximides (captan, folpet), and two imidazoles (benomyl, triflumizole) inhibited ALDH activity, potentially via metabolic byproducts (e.g., carbon disulfide, thiophosgene). We developed a geographic information system method employing state-mandated commercial pesticide use reports to estimate patient exposures to specific pesticides from 1974-1999. Exposures to ALDH-inhibiting pesticides (i.e., from the screen) were associated with dose-dependent twofold to fourfold increases in PD risk. Patients were genotyped for variation in the mitochondrial ALDH2 gene, and haplotypic analyses of six single nucleotide polymorphisms revealed that ALDH2 variation potentiated PD risk for people working where ALDH-inhibiting pesticides were sprayed liberally. This ALDH model for PD etiology might help explain the selective vulnerability of dopaminergic neurons in PD and provide a potential new mechanism through which environmental toxicants contribute to PD pathogenesis.

### PS 1400 Pesticide-Linked Parkinson's Disease: Using *Drosophila* to Build a Novel *In Vivo* Model of Paraquat, Maneb and Ziram Exposure.

C. A. Martin<sup>1</sup>, A. Barajas<sup>2</sup> and D. Krantz<sup>1,2</sup>. <sup>1</sup>Molecular Toxicology, University of California Los Angeles, Los Angeles, CA; <sup>2</sup>Neurobiology, University of California Los Angeles, Los Angeles, CA.

The vast majority of Parkinson's disease (PD) cases are sporadic and environmental exposure to pesticides have long been suspected to contribute to PD development, though the disease etiology remains poorly understood. Recently, epidemiological data has supported this and revealed that individual exposures to the pesticides ziram, maneb, and paraquat increase PD risk. Interestingly, it appears that these pesticides interact synergistically and exposure to all three pesticides increases PD risk up to three-fold. We are using the model organism *Drosophila melanogaster* to study the connection between pesticide exposures and the neuronal dysfunction and dopaminergic cell loss characteristic of PD. We find that combined, but not individual, chronic exposures to maneb and paraquat leads to significant dopaminergic neuron loss. To understand how neuronal dysfunction may contribute to a PD phenotype, we complement this approach by utilizing the *Drosophila* neuromuscular junction. This powerful tool has allowed us to explore the way pesticide exposures may more subtly affect neuronal physiology and behavior in an intact synapse. We report that ziram exposure significantly alters synaptic vesicle fusion and reuptake, processes that are essential for proper neuronal signaling. Ziram has been shown to inhibit the E1 ligase, which is required for targeting proteins to the proteasome for degradation. We find that inhibiting the proteasome increases synaptic vesicle fusion in a similar manner to ziram, implying a shared mechanism of action. However, it remains unclear if it is ziram's inhibition of E1 itself or ziram's downstream effect on the proteasome that is responsible for this synaptic phenotype. Ongoing investigations are exploring these possible neurotoxic mechanisms of action and may help elucidate the interrelationship between ziram, neuronal dysfunction, and early neurotoxic mechanisms that could initiate a PD phenotype.

### PS 1401 High i.p. Doses of Paraquat Do Not Result in a Loss of Dopaminergic Neurons in the Substantia Nigra of the Mouse.

M. Butt<sup>3</sup>, P. Botham<sup>1</sup>, C. Breckenridge<sup>2</sup>, L. Smith<sup>1</sup>, N. Sturgess<sup>1</sup> and J. Wolf<sup>4</sup>.  
<sup>1</sup>Syngenta, Bracknell, United Kingdom; <sup>2</sup>Syngenta, Greensboro, NC; <sup>3</sup>Tax Path Specialists, Frederick, MD; <sup>4</sup>EPL, Sterling, VA.

A number of publications have reported that the i.p. administration of paraquat (PQ) to rodents (normally male C57Bl/6 mice; up to 3 x 10 mg/kg) results in a loss of dopaminergic neurones from the substantia nigra pars compacta (SNpc), which is the primary area of neuropathological damage in Parkinson's disease (PD). We have conducted studies in the male C57Bl/6 mouse examining the effect of high i.p. doses (up to the maximum tolerated dose of 3 x 25 mg/kg) of PQ looking not only for neuronal cell loss, but also for evidence of striatal neurochemical changes and pathological changes using stains to detect disintegrating neurones and neuronal processes and the expected astrocyte/microglial activation in response to neuronal cell damage. Mice were administered paraquat dichloride on 1, 2 or 3 occasions (separated by one week) at doses of 10, 15 or 25 mg/kg. A relatively low dose of N-1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP; 10 mg/kg administered i.p. 4 times in a single day at 2 hr intervals) was dosed to a separate group as a positive control. Studies were conducted to GLP and assessment of toxicological endpoints was by individuals blinded to treatment group. No consistent stereological evidence for a loss of tyrosine hydroxylase positive (TH+) dopaminergic neurones in the SNpc was observed in the PQ treated mice. PQ did not alter the concentration of striatal dopamine or its metabolites. Over a range of time points (4-168 hrs post-dose), there was no evidence of PQ-induced neuronal degeneration in the SNpc, degenerating processes in the striatum or apoptotic cell death; astrocytes and microglia were not activated. In the MPTP treated mice the number of TH+ dopaminergic neurones in the SNpc was reduced, striatal dopamine was reduced and significant pathological changes, including necrotic neurones and astrocyte/microglial activation in the SNpc, were consistently observed. These results bring into question the use of PQ mouse studies as a robust model for PD/parkinsonism.

**PS 1402 Repeated Exposure to Paraquat Affects the Neural Behavior in Male C57BL/6 Mice.**

D. Lou<sup>1</sup>, Q. Zhao<sup>2</sup>, M. Huang<sup>3,1</sup> and Z. Zhou<sup>1</sup>. <sup>1</sup>Department of Occupational Health Sciences and Toxicology, Fudan University, Shanghai, China; <sup>2</sup>Center of Disease Control in Minhang District, Shanghai, China; <sup>3</sup>Department of Environmental and Occupational Health Sciences, Ningxia Medical University, Yinchuan, China.

Epidemiological studies have revealed that neural degenerative diseases such as Parkinson disease are typically influenced by genetic and environmental factors, while little is known about the environmental factors. The broad application of paraquat (PQ) has given rise to wide public concern on its potential to damage the nigrostriatal dopaminergic (DA) system because its chemical structure closely resembles that of the well-known DA neural toxicant MPP<sup>+</sup>. We used male C57BL/6 mice (aged 8 weeks and weight 20 ± 2 g) to examine the effects of PQ oral exposure on neural behavior. The Society's criteria for the care and use of laboratory animals were used for all the experiments in this study. After treated with normal saline (vehicle) and PQ (5mg/kg, 10 mg/kg or 20mg/kg) daily for 30 consecutive days, no significant differences in the body weight gain as well as the brain coefficient were observed among different dose groups. The transmission electron microscope showed that the subcellular structures of DA neurons were impaired when exposed to the high dose of PQ. The Open Field test revealed reduced locomotor activity and exploratory drive with the increase of PQ concentrations. Cognitive assessments were conducted in all the groups of mice via Morris Water Maze, no statistically significant difference among treatment groups was shown in the avoidance latency, although a trend toward less learning can be observed. On probe trial, PQ-treated mice did show a significant preference for the correct quadrant. Together, the functional observational battery showed treatment-related, but not necessarily dose-related changes in the mice's reactivity and activity. Thus, we proposed that repeated exposure to PQ can induce neurochemical and persistent neurobehavioral changes.

(Supported by NSFC81072324)

**PS 1403 Protective Effect of Edaravone Pretreatment against Mancozeb Cytotoxicity in Rat Hippocampal Astrocytes.**

L. D. Trombetta and N. Ruparel. *Pharmaceutical Sciences, St. John's University, Queens, NY.*

Mancozeb [manganese-zinc ethylenebis(dithiocarbamate)] is a polymeric dithiocarbamate fungicide that has been used commercially for decades. A number of studies have shown this agent to cause neurotoxicity that is linked to oxidative stress. The purpose of this experiment was to study the protective effects of edaravone (3-Methyl-1-phenyl-2-pyrazoline-5-one) on rat hippocampal astrocytes after mancozeb insult. Edaravone has been demonstrated to be a free radical scavenger and inhibits cerebral edema and infarction after brain ischemia. Rat hippocampal astrocytes maintained in Dulbecco's modified Eagle's medium with 10% FBS were exposed to a range of concentrations of Mn-Zn dithiocarbamate for one hour at 37°C. Viabilities 23hrs post-treatment with 4uM, 8uM, 16uM, and 24uM doses were 94%, 82%, 34%, and 20%, respectively. The LC50 was found to be 14.7 uM. For further experiments, treatment with 12uM mancozeb was chosen. Cells pretreated with edaravone (10uM, 80uM, 160 uM, 320uM) for 24 hours, and then treated with 12uM mancozeb for 1 hour showed significant increases in viability at all doses of edaravone. The 320uM pretreatment of edaravone increased the viability by 63.7% when compared to the group treated with 12uM mancozeb alone. GSH studies showed that 12uM mancozeb treatment for 1 hr. decreased the GSH/GSSG ratio by 45.87%, however, when astrocytes were pretreated with 320uM Edaravone the GSH/GSSG ratio was significantly different from the group with mancozeb alone with a decrease of 36.84%. Edaravone pretreatment was shown to be protective against mancozeb cytotoxicity and this protection may involve a reduction in oxidative stress.

**PS 1404 Role of Alpha-Synuclein and Its Mutants on Dithiocarbamates Cytotoxicity.**

A. Stoll and S. Cheng. *Science, John Jay College of Criminal Justice, New York, NY.*

Mn-containing dithiocarbamates, such as maneb (MB) and mancozeb (MZ), often seen in the agricultural industry, have been known to increase the toxicity of neurotoxin MPTP on dopaminergic neurons, which can lead to cell death and Parkinson-like symptoms. Dopamine transporter (DAT) is a key protein in MPTP's toxicity by transporting the active metabolite (MPP<sup>+</sup>) into dopaminergic neurons; increasing the cell surface expression of DAT raises the uptake of MPTP. Alpha-synuclein, a protein that interacts with the dopamine transport, can regulate DAT trafficking and the DAT cell surface expression. Alpha-synuclein (wt) and its mutants (A30P and A53T) have been associated with Parkinson's disease.

The aim of this study is elucidate the role of the alpha-synuclein and its mutants on dithiocarbamate cytotoxicity. HEK 293 cells transfected with DAT and either alpha-synuclein or its mutants were treated with dithiocarbamates for 1hour. Cell lysates from these treated groups and the control group, treated with phosphate buffered saline (PBS), were used for co-immunoprecipitation using anti-DAT antibody. The co-immunoprecipitated proteins were subjected to Western blot analysis, probed with alpha-synuclein and DAT antibodies. The integrated density values (IDV) of the alpha-synuclein were normalized to the IDV of the DAT. The PBS control was taken as 1.

We report roughly a 30% decrease in the DAT/alpha-synuclein interaction in the presence of the A53T mutant versus wild-type, but not in the presence of the A30P mutant. With dithiocarbamates, the interaction of DAT and alpha-synuclein (wt) was enhanced, with increases ranging from 50% to 200%. Cells transfected with A53T mutants respond to pesticides more dramatically than cells transfected with A30P mutants in increasing the interaction between the DAT and the alpha-synuclein.

**PS 1405 The Role of RTP801 in Maneb and Mancozeb-Induced Cytotoxicity.**

S. Cheng, C. Ta, A. A. Calderone and S. Oh. *Sciences, John Jay College of Criminal Justice, New York, NY.*

Environmental factors, such as pesticide exposure, have been implicated in the pathogenesis of neurodegenerative diseases such as Parkinson's disease (PD). Manganese (Mn)-containing ethylene-bis-dithiocarbamate compounds, maneb (MB) and mancozeb (MZ) have been extensively used for pesticides over the past 50 years. Exposure to MB lowers the threshold for dopaminergic damage triggered by MPTP, which is a human Parkinson's disease inducing neurotoxin. Preliminary data from Cheng's lab demonstrate that MB and MZ enhance 1-methyl-4-phenylpyridium (MPP<sup>+</sup>)-induced cell death in rat pheochromocytoma (PC12) cells. However, the neurotoxic molecular mechanisms and the signal transduction pathways involved in the action of these dithiocarbamate toxins in PD are still not clear. Neuron death, regardless of initiating causes, generally requires proapoptotic gene activation. Studies showed RTP801 is dramatically increased by oxidative stresses. A sequential mechanism (induction of RTP801, suppression of mTOR signaling, and then depletion of phosphorylated/activated Akt) has been suggested to be the mechanism of neurotoxins-induced cell death. In this study we observed no change in RTP801 protein expression after 4 h diethyldithiocarbamate (DDC) and MB treatments. But for MZ, RTP801 was twice the PBS control. After 8 h treatment, all chemicals showed significant increase of RTP801 protein expression (about 3 to 4 fold). This observation proved that the RTP801 protein expression has been regulated by Manganese (Mn)-containing ethylene-bis-dithiocarbamate compounds. Then, the transcriptional activation was studied by real time RT-PCR for 2 h, 4 h, and 8 h treatments. At 2 h, the transcription of RTP801 was increased for MB and MZ (2 and 3.5 fold), but not very significant for DDC. At 2 h, the transcription appeared the highest comparing to other time periods, and gradually decreased at 4 h and 8h. This observation showed that the up-regulation of RTP801 is due to the increase in RTP801 mRNA transcript. RTP801 shRNA will be used to further confirm the involvement of RTP801 in MB and MZ induced cytotoxicity.

**PS 1406 Nrf2 Protects Hippocampus against Oxidative Stress Caused by Maneb.**

D. Kurzatkowski and L. D. Trombetta. *Pharmaceutical Sciences, St. John's University, Queens, NY.*

Maneb is an ethylene(bis)dithiocarbamate fungicide that has been used to treat diseases of vegetables, fruits, and field crops. This study investigated the neurotoxic effects of maneb on the hippocampus of C57BL/Nrf2 (-/-; knockout) and C57BL/Nrf2 (+/+; WT) mice. The mechanism by which maneb exerts its neurotoxicity is unclear; however, a number of effects have been observed both in vitro and in vivo, which suggest a link between exposure to maneb and an increase in oxidative stress. Genes that are regulated by the ARE help control the redox status of the cell and protect it against oxidative injury. The Nrf2-ARE pathway can be found in most tissue types and is responsible for the control of expression of many genes that are involved in the protection of cells such as γ-GCS light subunit, peroxiredoxin, glutathione peroxidase, glutathione reductase, superoxide dismutase, and heme-oxygenase 1. The activation of Nrf2 has been linked to neural cell protection against numerous toxicants; therefore, Nrf2-/- mice treated with pro-oxidants such as maneb would be expected to show increased neurologic damage. Animals were injected I.P., twice a week for 30 days, at 0, 15, 30 and 60 mg of maneb/kg body weight. Levels of TBARS were not increased in hippocampal tissue in Nrf2+/+ animals at any dose of maneb but were significantly increased in the Nrf2-/- animals at the 30 and 60 mg dose. The TUNEL technique demonstrated

the presence of positive cells in the hippocampus of Nrf2<sup>-/-</sup> mice treated with 60 mg/kg maneb. Of 84 antioxidant pathway genes included in an oxidative stress and antioxidant defense array, qPCR demonstrated that the only gene mediated by the Nrf2 transcription pathway significantly modulated by at least 1.5-fold was glutathione peroxidase 4 (GPX4). This enzyme was significantly upregulated in Nrf2<sup>+/+</sup> mice treated with 30 mg/kg maneb and significantly downregulated in Nrf2<sup>-/-</sup> mice treated with the same concentration. It was concluded that maneb exposure causes oxidative stress mediated by the Nrf2 pathway and that GPX4 plays an important role in this protection.

**PS 1407 Neurotoxicity of the Dithiocarbamate Fungicide Ziram Is Dependent on Synuclein in Zebrafish: Implications for Parkinson's Disease.**

A. Lulla<sup>1,2</sup>, L. Barnhill<sup>1,2</sup>, M. Stahl<sup>2</sup>, A. G. Fitzmaurice<sup>1,2</sup>, S. Li<sup>2</sup> and J. M. Bronstein<sup>2,1</sup>. <sup>1</sup>Toxicology, University of California Los Angeles, Los Angeles, CA; <sup>2</sup>Neurology, University of California Los Angeles, Los Angeles, CA.

Parkinson's disease (PD) is a neurodegenerative disorder characterized by dopaminergic (DA) neuronal death and  $\alpha$ -synuclein ( $\alpha$ -syn) accumulation. Epidemiological studies reveal that exposure to the dithiocarbamate fungicide ziram is associated with increased risk of PD. We have previously found that ziram causes selective toxicity to DA neurons, ubiquitin proteasome system (UPS) inhibition, and  $\alpha$ -syn accumulation in primary neuronal cultures. Here, we use developing zebrafish (ZF, *Danio rerio*) embryos as an in vivo model to investigate mechanisms of ziram toxicity and its dependence on endogenous synuclein.

ZF embryos exposed to environmentally relevant of ziram were deformed, had altered swimming behavior, and premature death with a LD50 of approx. 50 nM at 7 days post fertilization (dpf). Transgenic ZF expressing green fluorescent protein (GFP) driven by vesicular monoamine transporter protein (VMAT) were used to identify aminergic neurons in ZF embryos. Ziram exposure (50nM) resulted in a 35% reduction in VMAT-GFP-expressing neurons in anterior DA clusters and 26% reduction in posterior clusters (noradrenergic) but was not toxic to non-DA sensory neurons.

ZF express 3 synucleins similar to mammalian  $\beta$  and  $\gamma$  synucleins. Overexpression of ZF  $\gamma$ 1-syn in neurons led to ZF-syn aggregates and neuronal death in a similar manner as overexpression of human  $\alpha$ -syn. ZF embryos exposed to ziram also showed accumulation and aggregation of endogenous ZF  $\gamma$ 1-syn. This accumulation appears to confer some of ziram's neurotoxicity since knockdown of ZF  $\gamma$ 1-syn expression improved survival. Furthermore, treatment with CLR01, a molecular tweezer that mitigates  $\alpha$ -syn toxicity, also attenuated ziram toxicity. The mechanism/s by which ziram increases ZF  $\gamma$ 1-syn appear to involve inhibition of protein degradation since ziram at concentrations as low as 10 nM inhibited the UPS in ZF embryos. These studies add further insight into the mechanism of pesticide neurotoxicity relevant to the risk of PD.

**PS 1408 Linking Developmental Atrazine Exposure in Zebrafish to Long-Term Neurotransmission Alterations.**

C. Xiao, G. J. Weber, S. E. Watson, J. L. Freeman and J. R. Cannon. School of Health Sciences, Purdue University, West Lafayette, IN.

Atrazine is an agricultural herbicide widely used to prevent pre- and post-emergence of broadleaf and grassy weeds in major crops. It is a major environmental contaminant, commonly present in potable water supplies. Recent work has suggested that atrazine exposure may affect behavior and neurotransmitter systems in rodents. However, rodent studies have typically utilized exposures many magnitudes above environmentally relevant levels and produced conflicting data. The role of early-life exposures in the development of late-life neurodegenerative diseases has recently received much attention. In an effort to assess the immediate and late-life effects of atrazine on neurological function, zebrafish embryos were exposed to environmentally relevant doses of atrazine (0, 0.3, 3, 30ppb) from 1-72 hours post fertilization. Following the developmental exposure, larvae were changed to atrazine-free water and allowed to mature under normal conditions to assess lifespan impacts. Neurotransmitter levels were assessed using HPLC with electrochemical detection. Adult female zebrafish (9 months) exhibited statistically significant decreases in 5-hydroxyindoleacetic acid (5-HIAA), the primary metabolite of serotonin, as well as a reduction in 5-HIAA/serotonin turnover. Interestingly, larvae evaluated at 7 days post fertilization did not show significant alterations in neurotransmitters levels, indicating that deficits arise over time, many months after the initial exposure. In addition, microarrays performed on adult female brain tissue revealed alterations in genes that are enriched in neurological, psychological and developmental diseases. Thus, after short-term atrazine exposure during development, persistent neurotransmitter disruptions are observed, indicating long-term disruption of brain function. Future experiments are focused on elucidating mechanisms of neurologic dysfunction and neurodegeneration elicited by toxicant exposure during critical development stages.

**PS 1409 Effects of the Long-Term Coexposure to the Herbicide Atrazine and Inorganic Arsenic (IAs) in the Nigrostriatal Dopaminergic System of the Albino Rat.**

U. Bardullas, M. Giordano and V. Rodríguez. Departamento de Neurobiología Conductual y Cognitiva, Instituto de Neurobiología, Universidad Nacional Autónoma de México, Queretaro, México.

The herbicide atrazine (ATR) and the metalloid arsenic (As) are substances widely distributed in the environment. In recent years interest has grown regarding the toxicity of these substances on the nigrostriatal dopaminergic system. To date, no study has evaluated the effects of chronic and simultaneous exposure to ATR and As, substances that may share the same neuronal target. In order to study the effects of the coexposure As+ATR, six groups of rats were given atrazine (10 mg ATR/kg), arsenic (0.5 or 50 mg As/L of drinking water) or their combinations (ATR+0.5 mg As/L or ATR+50 mg As/L) daily for one year. Behavioral tests showed hypoactivity in the 50 mg As/L group, and hyperactivity in the ATR group. All treatments decreased motor coordination. Striatal DA content was significantly reduced in ATR, 0.5 mg As/L, ATR+0.5 mg As/L and ATR+50 mg As/L groups, compared to controls. The number of mesencephalic TH<sup>+</sup> cells was significantly reduced in ATR and ATR+0.5 mg As/L groups, compared to controls. Furthermore, the assessment of cell integrity in the substantia nigra showed decreases in cytochrome oxidase reactivity in all treatment groups, but no changes in malondialdehyde immunoreactivity. In summary, the nigrostriatal dopaminergic system appears to be a target for the toxic effects of As and ATR. Our results indicate that when combined, ATR + As act independently, and ATR has more severe effects on dopaminergic neurons. We appreciate the technical assistance of Biol. Soledad Mendoza. This work was sponsored by PAPIIT 214608-19 and CONACYT 60662, 103907 and 152842.

**PS 1410 Glyphosate Treatment Suggests Offspring and Reproductive Toxicity in *Caenorhabditis elegans*.**

R. Negga, M. B. Johnson, K. A. McVey, I. B. Snapp and V. A. Fitsanakis. Biology, King College, Bristol, TN.

Herbicides are widely used in both agricultural and residential areas; therefore, pesticide users, as well as family members, may be routinely exposed to these potentially harmful chemicals. Epidemiological studies have shown pesticide exposure may lead to decreased fetus viability in exposed versus non-exposed females. A significant gap in the literature exists as to whether these observations are applicable to exposures of glyphosate-containing herbicides. To further examine this question, we utilized the model organism, *Caenorhabditis elegans*, to test our hypothesis that exposure to the glyphosate-containing herbicide, TouchDown (TD), results in decreased numbers of offspring in wild-type (N2) worms. Furthermore, this exposure could render surviving offspring more susceptible to neurodegeneration. Based on concentrations (LC50 and LC75) from previous data, eggs were removed from gravid adults and chronically (24 hours) exposed to TD. The numbers of hatched offspring were counted to determine whether TD adversely affected embryo viability. One-way ANOVA indicated a statistically significant decrease ( $p < 0.05$ ) in the number of hatched eggs from treated compared to control worms. Our second study was designed to determine whether eggs exposed to TD would result in general neuronal degeneration. Eggs from NW1229 worms (a green fluorescent protein (GFP)::neuron construct) were treated as described. Data suggested potential neuronal degeneration in treated worms compared to control ( $p < 0.05$ ), as determined by fluorescence photomicrograph analysis. Lastly, we chronically exposed eggs from strain CL2166 (GFP::glutathione-S-transferase) to varying concentrations of TD. Fluorescence between control and treated groups, however, did not vary, suggesting that large increases in oxidative stress are not responsible for the observed changes in the nervous system. Taken together, these results suggest that TD decreases the number of viable offspring in the nematode, and that neurodegeneration may be present in those that survive.

**PS 1411 Effects of the Subchronic Exposure to the Herbicide Glyphosate on Behavior and the Nigrostriatal and Mesolimbic Dopaminergic Areas of the Albino Rat.**

I. Hernandez-Plata<sup>1</sup>, M. Diaz-Muñoz<sup>2</sup>, M. Giordano<sup>1</sup> and V. M. Rodríguez<sup>1</sup>. <sup>1</sup>Neurobiología Conductual y Cognitiva, Instituto de Neurobiología, Queretaro, México; <sup>2</sup>Neurobiología Celular y Molecular, Instituto de Neurobiología, Queretaro, México.

Glyphosate (Glyph) is the active ingredient of several herbicide formulations widely used to eliminate weeds. Although it has been described that the Glyph formulations are slightly toxic for mammals, reports of human exposure and studies using animal models suggest that Glyph formulations may be neurotoxic. In order to evaluate the effects of Glyph on the nervous system, male Sprague-Dawley rats received six i.p injections of 50, 100 or 150 mg Glyph/kg or saline (n=10) during 2

weeks (3 injections/week). We recorded locomotor activity 15 min before and 3 h immediately after each injection. Also, the locomotor activity was recorded during 24 h, 16 days after the last injection. The subchronic exposure to Glyph caused decreases in locomotor activity immediately after each injection, as well as 48 h after the Glyph injection. This hypoactivity was maintained until the 16th day post-treatment. We did not detect changes neither in monoamine concentrations nor in the levels of TH in NAcc or STR at 2 and 16 days after the last Glyph injection. However, specific binding to D1 dopamine receptors in NAcc decreased dose-dependently when measured 48-h after the last Glyph injection. These results indicate that subchronic exposure to Glyph has acute as well as long-term effects on locomotor activity, and that these effects may be related to a decrement in specific binding to D1 dopamine receptors in NAcc. We thank Soledad Mendoza for her technical assistance. Supported by CONACYT 60662, 152842 and 103907 and PAPIIT grants 214608-19 and 211709-21; IHP received a fellowship from CONACYT 164300.

**PS 1412 Relationship between Administered Dose, Target Tissue Levels and Thermoregulatory Response Alterations after Acute Oral Exposure to the Potent Tremor-Inducing Pyrethroid Bifenthrin in Rats.**

M. Mosquera-Ortega<sup>1</sup>, A. Pato<sup>3</sup>, C. Sosa-Holt<sup>3</sup>, A. Ridolfi<sup>2</sup>, M. J. Wolansky<sup>1</sup> and E. Villaamil Lepori<sup>2</sup>. <sup>1</sup>*Biological Chemistry, IQUIBICEN (CONICET); University of Buenos Aires, Buenos Aires, Argentina;* <sup>2</sup>*Toxicology, Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina;* <sup>3</sup>*Biological Chemistry, University of Buenos Aires, Buenos Aires, Argentina.*

In toxicological studies, potency estimates for pyrethroid insecticides (PYRs) in rats may depend on the exposure and testing conditions. This experimental factor may challenge present efforts to reconsider the health risks posed to humans by exposure to PYRs. We are using exposure-dose-effect studies to explore the influence of the testing conditions on the qualitative toxicological classification of, and relative potencies for, these insecticides. Four PYRs (tefluthrin, bifenthrin [BIF], deltamethrin, alpha-cypermethrin) are evaluated in Wistar adult rats. Body temperature is measured using microchip-like transponders implanted in rat backs 5-7 days before testing. Subcutaneous temperature (T-SC) is then monitored by radiotelemetry at 30 min intervals for 5 h after oral dosing of PYRs in corn oil. Basal T-SC is recorded before the test day, and 30 min before dosing (i.e., physiological T-SC). The maximal difference in T-SC compared to the pre-dosing baseline (i.e.,  $\Delta T_{\text{max}}$ ) is here used as a measure of peak response. Soon after the thermoregulation assay, target tissues are dissected out. Blood, liver and brain (striatum, cortex, cerebellum) are collected at 6 h post-dosing for posterior determination of PYR residues using a SPE-GC-ECD protocol. Results for BIF are shown in this first presentation. 0, 0.5, 3, 9 and 12 mg BIF/Kg (N=4-8) produced dosage-related increases in temperature and  $\Delta T$ . Dose-related increases in both BIF levels in target tissues and  $\Delta T_{\text{max}}$  were observed. R-squared values were +0.6 in all pairwise relationships. These results are mostly consistent with previous BIF studies carried out using motor activity and rectal temperature as endpoints (Wolansky et al., 2006, 2007), and a toxicokinetic study (Scollon et al., 2011).

**PS 1413 Interactions of a Promoter/Potentiator of Neuropathy and Esterases of Membrane and Soluble Fractions of Brain.**

I. Mangas, J. Estévez and E. Vilanova. *Unit of Toxicology and Chemical Safety Institute of Bioengineering, University Miguel Hernández, Elche, Spain.*

Phenylmethyl sulfonyl fluoride (PMSF) is a protease and esterase inhibitor causing protection or potentiation/promotion of the organophosphorus induced delayed neuropathy if dosed before or after the organophosphate inducer. The molecular target/s of potentiation/promotion has not yet been elucidated. The analysis of the kinetic of inhibition of PMSF on chicken brain esterases (using a kinetic model which considers the spontaneous hydrolysis of inhibitor) allowed to discriminate the following esterase components: In soluble fraction, a resistant component E $\alpha$  (28%) and two sensitive components, E $\beta$  (61%) and E $\gamma$  (11%) with I50 (20 min) of 70 and 447  $\mu$ M; in membrane fraction two resistant components EP $\alpha$  and EP $\delta$  (14%) and two sensitive, EP $\beta$  (41%) and EP $\gamma$  (44%) with I50 (20 min) of 138 and 23  $\mu$ M. The enzymatic components discriminated correspond to the previously observed in experiments with mipafox and paraoxon in these fractions. E $\alpha$  becomes 6-fold more resistant to mipafox after the pre-incubation with 5  $\mu$ M PMSF and 50-fold with 4000  $\mu$ M PMSF. E $\gamma$  becomes totally resistant after pre-incubation with 10  $\mu$ M PMSF or more and it becomes resistant to PMSF after pre-incubation with 20 nM mipafox. However none of the membrane esterases changed their sensitivity. The data suggest that these effects might be due to an irreversible interaction of PMSF and mipafox at sites other than the substrate catalytic center. Such interactions should be considered to interpret the potentiation/promotion phenomenon of PMSF and to understand the effects of multiple exposures to chemicals.

**PS 1414 In Vitro Inhibition and Aging of Neuropathy Target Esterase (NTE) Caused by Fenamiphos and Acephate.**

G. L. Emerick, L. S. Fernandes, N. G. Santos and A. C. Santos. *Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Universidade de São Paulo, Ribeirão Preto, Brazil.*

Organophosphorus-induced delayed neuropathy (OPIDN) is a neurodegenerative disorder characterized by ataxia progressing to paralysis with concomitant central and peripheral distal axonopathy. Symptoms of OPIDN in people include tingling of the hands and feet. These symptoms appear about 8–14 days after exposure. One of the criteria for acceptance of organophosphates pesticides (OPs) in Brazil is if the compound does not cause OPIDN. Guidelines for evaluating OPIDN require the observation of dosed animals over several days and the sacrifice of at least 48 hens. Adhering to these protocols in tests with analytical standards of OPs is difficult because large quantities of the compound are needed and many animals must be sacrificed. Thus, developing an in vitro screening protocol to evaluate if the OP is able to induce or not delayed neuropathy is important. This study aimed to evaluate in SH-SY5Y human neuroblastoma cell culture samples the potential of some OPs, which are widely used in Brazil, to induce delayed neurotoxicity. The relations between the inhibition and aging of neuropathy target esterase (NTE) by the fenamiphos and acephate were evaluated as indicator of the compound ability to induce OPIDN. Mipafox was used as inducer of OPIDN and paraoxon was used as non-inducer. The compounds were diluted in ethanol and the cells were incubated with the OPs for 24 hours in a 96-well microplate. Paraoxon exhibited an inhibitory concentration of 50% of enzyme activity (IC50) value approximately 47 times greater than that of the mipafox. Fenamiphos and acephate exhibited IC50 values 117 and 124 times, respectively, greater than that of the mipafox in the SH-SY5Y human neuroblastoma cells. Considering the esterases inhibition and aging results, fenamiphos and acephate would not be expected to have a great ability to induce OPIDN in humans compared with the ability of mipafox. Financial support: Fapesp grant # 2012/00168-6.

**PS 1415 Inhibition and Aging of Neuropathy Target Esterase (NTE) in SH-SY5Y Human Neuroblastoma Cells As Screening for Inducers of Delayed Neuropathy.**

L. S. Fernandes, G. L. Emerick, N. G. Santos and A. C. Santos. *DACTB, Universidade de São Paulo, Ribeirão Preto, Brazil.*

Organophosphorus-induced delayed neuropathy (OPIDN) is characterized by a central-peripheral distal axonopathy and Wallerian-type degeneration that develops 8–14 days after poisoning by a neuropathic organophosphate (OP). The current Organisation for Economic Co-operation and Development (OECD) guidelines for evaluating organophosphorus-induced delayed neuropathy (OPIDN) require the observation of dosed animals over several days and the sacrifice of at least 48 hens. Adhering to these protocols in tests with analytical standards of OPs is difficult because large quantities of the compound are needed and many animals must be sacrificed. Thus, developing an in vitro screening protocol to evaluate if the OP is able to induce or not delayed neuropathy is important. This study aimed to evaluate in SH-SY5Y human neuroblastoma cell culture samples the potential of some OPs, which are most utilized in Brazil, to induce delayed neurotoxicity. The relation between the inhibition and aging of neuropathy target esterase (NTE) by the trichlorfon was evaluated as a possible indicator of the compound ability to induce OPIDN. Mipafox was used as inducer of OPIDN and paraoxon was used as non-inducer. The compounds were diluted in ethanol and the cells were incubated with the OPs for 24 hours. Paraoxon exhibited an inhibitory concentration of 50% of enzyme activity (IC50) value approximately 47 times greater than that of the mipafox. Trichlorfon exhibited an IC50 value 48 times greater than that of the mipafox in the SH-SY5Y human neuroblastoma cells. Considering the esterases inhibition and aging results, trichlorfon would not be expected to have a great ability to induce OPIDN in humans compared with the ability of mipafox.

**PS 1416 Use of a Human Haploid Cell-Based Loss of Functional Genetic Screening Model to Identify Human Susceptibility Genes for Chlorpyrifos Toxicity.**

A. Dubois, J. R. Olson and X. Ren. *Pharmacology & Toxicology, University at Buffalo, The State University of New York, Buffalo, NY.*

Chlorpyrifos (CPF), one of the most widely used organophosphorus pesticides, has been known to cause neurotoxicity through the inhibition of cholinesterase activity. However, other neurobehavioral deficits, unrelated to cholinesterase inhibition, have been linked to chlorpyrifos exposure. The mechanisms behind these effects are not fully known or understood. High-throughput loss-of-function genetic

screening tools in yeast or other non-mammalian model systems have been successfully used to study human susceptibility to chemical exposure and decipher chemical compounds mode of action. We recently obtained a newly developed human haploid cell based loss of functional genetic screening model and adopted this haploid cell model in our laboratory. We treated the cells with 200  $\mu$ M CPF, a dose causing 30% death of haploid cells after 3 days of treatment. After 21-days of treatment, we were able to identify cells carrying genes with deficient functions that play a role in the resistance to CPF-induced toxicity. We are currently conducting functional tests to validate their association with CPF toxicity. Ultimately, this approach will help identify novel susceptibility genes and gain insight into potential mechanisms of CPF-induced toxicity. (This work was supported by Startup funds to X.R. provide by SUNY Buffalo).

**PS 1417 Pharmacological Modulation of Endocannabinoid Signaling Differentially Affects Acute Toxicity of Paraoxon and Chlorpyrifos Oxon in Rats.**

J. Liu and C. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Organophosphorus anticholinesterases (OPs) elicit acute toxicity by inhibiting acetylcholinesterase, increasing acetylcholine levels at cholinergic synapses throughout the nervous system. This leads to excessive/prolonged activation of cholinergic receptors and resulting signs of toxicity including increased parasympathetically-mediated secretions (SLUD signs) and involuntary movements (e.g., tremors). Endocannabinoids (eCBs, e.g., anandamide [AEA] and 2-arachidonoyl glycerol [2-AG]) are released from membrane lipids upon neuronal activation. AEA, 2-AG and potentially other putative eCBs can regulate neurotransmission by activating presynaptic CB1 receptors to inhibit neurotransmitter release. We hypothesized that pharmacological modulation of eCB signaling will influence the expression of anticholinesterase toxicity. The comparative effects of WIN 55,212-2 (WIN, a CB1 receptor agonist, 1.5 or 5 mg/kg), AM251 (a CB1 receptor antagonist, 3 mg/kg), URB597 (an inhibitor of AEA degradation, 3 mg/kg) and capsazepine (a TRPV1 endovanilloid antagonist, 10 mg/kg) on the toxicity of paraoxon (PO) and chlorpyrifos oxon (CPO) were evaluated. Involuntary movements were induced by both OPs in a dose-related manner (PO: 0.4,0.5,0.6 mg/kg, sc; CPO: 8,10,12 mg/kg, sc), whereas somewhat less consistent dose-related effects were noted with SLUD signs. WIN partially reduced signs of toxicity following PO exposure, but had little effect on toxicity following CPO. The CB1 receptor antagonist AM251 had no effect on CPO toxicity, but substantially increased lethality following PO exposure (6/12 vs 1/9). URB597 had no effect on PO toxicity, or on involuntary movements following CPO, but increased SLUD signs following CPO. Similar to effects of URB597, capsazepine had little effect on PO toxicity, but increased SLUD signs following CPO. These results suggest that pharmacological modulation of eCB and/or endovanilloid signaling may differentially influence selected toxic responses to anticholinesterases in an OP-related manner. (Supported by NIEHS R01ES009119).

**PS 1418 Hippocampal Changes Induced by Noncholinergic Diisopropylfluorophosphate (DFP) Exposure in Fischer 344 Rat Brain.**

D. A. Mahle<sup>1</sup>, A. Soto<sup>1</sup>, V. T. Chan<sup>1</sup> and N. V. Reo<sup>2</sup>. <sup>1</sup>711 HPW/RHDJ, Wright-Patterson AFB, OH; <sup>2</sup>Wright State University, Fairborn, OH.

The mechanism of organophosphate (OP) induced inhibition of acetylcholinesterase and subsequent excitotoxicity is well described. However, exposure to OPs at non-cholinergic doses has been reported to cause deficits in cognitive behavior and spatial memory, though little is known about the mechanisms of action. Here an integrated approach using both metabolomic and transcriptomic techniques was used to reveal some of the non-cholinergic effects of DFP in rat hippocampus. Adult male Fischer 344 rats were administered 1 mg/kg DFP or saline (control) via subcutaneous injection at 10 mL/kg. Time points for hippocampal collection were 0.5, 1, 2, 12, 24 and 48 hr post dose. AChE activity reached a minimum of 55% at 2 hr post dose. Total RNA was isolated from hippocampus for differential gene expression analysis using the Affymetrix 1.0 ST gene array at 1 hr post dose. Lipid and aqueous extracts were prepared from each hippocampus at 2 hr post dose, and profiles of small molecule metabolites, lipids and phospholipids were measured using multinuclear NMR spectroscopy. The amino acids valine, isoleucine and alanine were increased 4-5 fold, while cis-aconitate and fumarate were increased 2-3 fold after exposure to DFP. Succinate and  $\gamma$ -aminobutyric acid (GABA) were decreased approximately 57%. No change was detected in any of the

lipid metabolites measured. Differential gene expression and pathway analysis revealed that the I-kappaB/NF-kappaB and the Wnt signaling pathways were down-regulated. By evaluating the impact of low level OP exposure on the metabolic and transcriptomic profile of the hippocampus, we hope to gain a greater understanding of the noncholinergic mechanisms of action and sensitive target areas of OPs.

**PS 1419 Dose-Dependent Behavioral Deficits in Egyptian Agricultural Workers with Chronic Organophosphorus Pesticide (OP) Exposures.**

W. K. Anger<sup>1</sup>, F. M. Farahat<sup>2</sup>, P. J. Lein<sup>3</sup>, J. R. Olson<sup>4</sup>, M. Lasarev<sup>1</sup> and D. Rohlman<sup>1</sup>. <sup>1</sup>Oregon Health & Science University, Portland, OR; <sup>2</sup>Menoufia University, Shebin Elkom, Egypt; <sup>3</sup>University of California Davis, Davis, CA; <sup>4</sup>University at Buffalo, Buffalo, NY.

Chronic exposure to OPs is consistently associated with deficits on neurobehavioral tests in workers using pesticides. While years of work have correlated with degree of effect in a few studies, a dose-effect relationship has not been identified, leading some to doubt the association. We identified a population of pesticide application teams in Egypt primarily exposed to one OP, chlorpyrifos (CPF). Teams include engineers (who do not typically enter the fields during applications), technicians (who walk side-by-side with the applicators in the fields), and applicators (who are typically seasonal workers and have the highest exposures). TCPy levels in urine confirmed the pattern of lower to higher exposures across these job categories. Trailmaking, a test of complex visual scanning, motor speed and agility, consists of two test components, A and B that differ in complexity. The test was administered to 54 engineers, 59 technicians, 31 applicators, and 150 controls 3 times during the OP application season and 1.5 months after applications had ended. While time to complete Trailmaking A and B improved across sessions, a consistent dose-response relationship was seen in performance speed: Controls had the best (fastest) performance throughout the application season on Trailmaking A ( $p < 0.04$ ) and B ( $p < 0.001$ ). Applicators had slower performance than engineers ( $p = 0.015$ ) and technicians ( $p = 0.032$ ) on Trailmaking A. On the more complex Trailmaking B test, applicators and technicians had comparable performance that was significantly slower ( $p = 0.003$  and  $p = 0.012$  respectively) than performance of engineers. Test performance at 1.5 months after applications ended revealed that differences between the groups were persistent. Ongoing studies are evaluating relationships between neurobehavioral performance and genetic polymorphisms of enzymes that metabolize CPF. (NIH R01 ES016308; MPI: WKA & PJJ)

**PS 1420 Chlorpyrifos Exposure and Self-Reported Neurological Symptoms in Adolescent Pesticide Applicators.**

D. Rohlman<sup>1</sup>, K. Khan<sup>1</sup>, A. A. Ismail<sup>2</sup>, G. Abdel Rasoul<sup>2</sup>, M. R. Bonner<sup>3</sup>, M. R. Lasarev<sup>1</sup>, A. L. Crane<sup>4</sup>, S. T. Singleton<sup>4</sup> and J. R. Olson<sup>3,4</sup>. <sup>1</sup>Occupational and Environmental Health, University of Iowa, Iowa City, IA; <sup>2</sup>Community Medicine & Public Health, Menoufia University, Shebin El-Kom, Egypt; <sup>3</sup>Social & Preventive Medicine, State University of New York at Buffalo, Buffalo, NY; <sup>4</sup>Pharmacology & Toxicology, State University of New York at Buffalo, Buffalo, NY.

Although studies with adults have demonstrated associations between organophosphorus (OP) pesticide exposure and neurological symptoms, the change in symptom reporting across an application season and the relationship between symptoms and biomarkers of exposure is poorly understood and few studies have examined adolescents. The prevalence of neurological symptoms across the chlorpyrifos (CPF)-application season was examined in adolescent pesticide applicators ( $n = 57$ ) and environmentally exposed adolescents ( $n = 38$ ) in Egypt. Self-reported symptom data at 32 time points over a 7-month CPF-application season were collected. Associations of symptoms with the urine CPF biomarker, trichloro-2-pyridinol (TCPy) and blood cholinesterase inhibition were also investigated. Increased reporting of neurological symptoms were observed among both applicators and non-applicators after several weeks of repeated exposure. Applicators demonstrated a greater percentage of neurological symptoms relative to baseline than the non-applicators at all subsequent time intervals. Cumulative TCPy, an estimate of overall seasonal exposure, was positively associated with average percentage of symptoms only among the applicators in the adjusted models. No associations were found between acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) inhibition and self-reported symptoms after accounting for covariates. Results of the study demonstrate that adolescent applicators and non-applicators experience a greater percentage of neurological symptoms due to repeated exposure. Reduction of CPF exposure among the adolescent applicators should be a public health priority since neurological symptoms remained elevated even after the cessation of CPF application. Supported by NIEHS ES017223.

**PS 1421 Differential Antagonism of Tetramethylenedisulfotetramine-Induced Seizures by Agents Acting at NMDA and GABAA Receptors.**

M. Shkarjian<sup>1,2</sup>, J. Velíšková<sup>3,4,6</sup>, P. Stanton<sup>3,6</sup> and L. Velíšek<sup>3,5,6</sup>.  
<sup>1</sup>Environmental Health Science, New York Medical College, Valhalla, NY; <sup>2</sup>Medicine, UMDNJ-RWJMS, Piscataway, NJ; <sup>3</sup>Cell Biology & Anatomy, New York Medical College, Valhalla, NY; <sup>4</sup>Obstetrics & Gynecology, New York Medical College, Valhalla, NY; <sup>5</sup>Pediatrics, New York Medical College, Valhalla, NY; <sup>6</sup>Neurology, New York Medical College, Valhalla, NY. Sponsor: D. Heck.

Tetramethylenedisulfotetramine (TMDT) is a highly lethal neuroactive rodenticide responsible for many accidental and intentional poisonings in mainland China. Ease of synthesis, water solubility, potency, and difficulty to treat make TMDT a potential terrorist weapon. We characterized TMDT-induced seizures and mortality in male C57BL/6 mice. TMDT (ip) produced a syndrome of twitches, clonic, and tonic-clonic seizures decreasing in onset latency and increasing in severity with increasing dose; 0.4 mg/kg was 100% lethal. The NMDA antagonist, ketamine (KET, 35 mg/kg) injected ip after the first TMDT-induced seizure, did not reduce lethality, but increased the number of clonic seizures. Doubling the KET dose decreased tonic-clonic seizures and eliminated lethality through a 60 min observation period. Treating mice with another NMDA antagonist, MK-801, 0.5 or 1 mg/kg ip, showed similar effects as low and high doses of KET, respectively, and prevented lethality, converting continuous (status epilepticus) EEG activity to isolated interictal discharges. Treatment with these agents 15 min prior to TMDT administration did not increase their effectiveness. Post-treatment with diazepam (5 mg/kg; GABAA allosteric enhancer) reduced seizure manifestations and prevented lethality 60 min post-TMDT, but ictal events were evident in EEG recordings and, hours post-treatment, mice experienced status epilepticus and died. Thus, TMDT is a highly potent and lethal convulsant for which single-dose benzodiazepine treatment is inadequate in managing EEG seizures or lethality. Repeated benzodiazepine dosing or combined application of benzodiazepines and NMDA receptor antagonists are more likely to be effective in treating TMDT poisoning. Supported by NIH NS056093, NS072966, NS044421, DOD PR100634P1 & NYMC

**PS 1422 Postexposure Administration of Diazepam Blocks TETS-Induced Tonic Seizures and Death but Does Not Prevent Neuroinflammation.**

D. Bruun<sup>1</sup>, S. Vito<sup>2</sup>, B. Inceoglu<sup>2</sup>, B. D. Hammock<sup>2</sup> and P. J. Lein<sup>1</sup>. <sup>1</sup>VM Molecular Bioscience, University of California Davis, Davis, CA; <sup>2</sup>Entomology, University of California Davis, Davis, CA.

Tetramethylenedisulfotetramine (TETS) is a potent convulsant rodenticide that is considered a credible chemical threat agent. There is no approved therapy for TETS poisoning, although clinical reports suggest that generally-used anticonvulsants, including diazepam, keep patients alive when administered soon after exposure. Our goal was to identify the therapeutic window for diazepam when administered after TETS exposure, and to determine whether post-exposure administration of diazepam would attenuate the delayed neuroinflammation associated with acute TETS intoxication. In adult male mice administered a lethal dose of TETS (0.15 mg/kg, i.p.), a relatively high dose of diazepam (5 mg/kg, i.p.) blocked tonic seizures and death when administered 3 min after the second clonic seizure (approximately 20 min after TETS injection). Administration of diazepam at later times did not significantly reduce tonic seizures and death relative to TETS-exposed animals that did not receive diazepam. However, animals protected by diazepam from tonic seizures and death still exhibited significant and persistent region- and time-dependent activation of astrocytes and microglia, as determined by GFAP and Iba-1 immunoreactivity and microglia morphology. Thus, we next determined whether combined administration of diazepam with an anti-inflammatory agent would mitigate post-TETS neuroinflammatory responses. Inhibition of soluble epoxide hydrolase (sEH) has been shown to exert potent anti-inflammatory effects. Combined administration of diazepam and the sEH inhibitor 1709 (1 mg/kg, i.p. every 24 h after TETS injection) significantly decreased microglial activation but enhanced astrocyte activation. While the functional significance of this combined treatment has yet to be determined, these data suggest that combinatorial therapy may be necessary to mitigate long-term neurological sequelae of acute TETS intoxication. Support provided by the NIH NINDS CounterAct Program (R21 NS072094 and U54 NS072022).

**PS 1423 THC-Mediated Immunosuppression Leads to Decreased Th1 Response to Allogeneic Cells by Triggering Induction of MDSCs.**

J. M. Sido, M. Nagarkatti and P. Nagarkatti. Pathology, Immunology & Microbiology, University of South Carolina School of Medicine, Columbia, SC.

Host versus graft disease (HvGD) is a model for transplant rejection, wherein the recipient mounts an immunological response to donor cells causing T-cell driven destruction of the graft. The host immune response involves activation of T-cells, up-regulation of Th1 cytokines, and cellular proliferation in lymphoid organs. Δ-9-Tetrahydrocannabinol (THC) is a cannabinoid (CB) associated with anti-inflammatory and immunosuppressive properties, and is a known ligand for CB receptors 1 and 2 (CB1 and CB2). Our lab recently published that administration of THC recruits myeloid derived suppressor cells (MDSCs) which are innate regulatory cells, CD11b+Gr1+ in mice, that have been shown to reduce inflammation. To this end, we used THC (20mg/kg) pretreatment to ameliorate HvGD in C57BL/6 mice administered C3H/HeJ splenocytes (2.2x10<sup>7</sup> cells). Our studies show that THC treatment was able to reduce clinical symptoms of HvGD dependent on the presence of the CB1 receptor. THC-treated mice had significantly reduced lymphoid organ proliferation, Th1 cytokine levels, and T-cell activation. Using CB knockout mice as well as antagonists, we found that THC treatment was unable to reduce HvGD in the absence of CB1 receptor. Furthermore, THC treatment led to induction of MDSC resulting in a microenvironment that allowed graft cells to persist without eliciting graft versus host disease. The mechanism of CB1-dependent THC-mediated reduction in T cell proliferation and in Th1-mediated inflammation by induction of MDSCs, suggests a novel role for THC to induce a state of homeostasis that results in elevated host immunosuppression and reduced toxicity associated with transplantation (Support in part by NIH P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

**PS 1424 Mechanistic Comparison of Asbestos-Associated Autoantibodies.**

K. Serve, A. Santin and J. Pfau. Biological Sciences, Idaho State University, Pocatello, ID.

Chrysotile and amphibole asbestos are structurally distinct silicate fibers that cause a range of respiratory tract diseases, though Libby amphibole (LA) exposure is associated with diffuse pleural fibrosis and chrysotile with localized pleural plaquing. LA-associated disease seems to progress more rapidly, suggesting additional factors in disease manifestation. Examination of serum antibodies revealed mesothelial cell autoantibodies (MCAAs) in both LA and chrysotile exposed subjects. However, MCAA presence was significantly correlated with pleural disease only in LA exposed subjects, suggesting a role of MCAAs in driving pleural fibrosis on-set and/or progression. We hypothesized that LA and chrysotile associated MCAAs interact with mesothelial cells in mechanistically distinct ways, resulting in the different disease phenotypes observed within each asbestos-exposed cohort. We compared the ability of LA and chrysotile-associated MCAAs to induce cellular changes indicative of fibrotic disease, including collagen deposition and matrix metalloproteinase (MMP) expression. Results revealed that both LA and chrysotile MCAAs induce deposition of insoluble collagen proteins by cultured human pleural mesothelial cells. However, only LA MCAAs required MMP activity for collagen deposition. Immunoblot analysis revealed increased levels of MMP-8 in the supernatants of cells exposed to LA MCAAs whereas chrysotile MCAAs inhibited MMP-8 expression. These data, coupled with differences in cytokine profiles, indicate mechanistically distinct routes of MCAA-induced collagen deposition. We additionally determined that LA MCAAs are predominantly an IgG3 subtype whereas chrysotile MCAAs are mixed IgG1, 3, and 4 subtypes. This suggests that LA and chrysotile MCAAs differ in their potential for receptor binding and complement activation, which may contribute to distinct modes of pathogenicity. The mechanistic dissimilarities between LA and chrysotile MCAAs may help explain the disparate disease phenotypes and fibrosis progression noted in clinical observations of asbestos-exposed subjects.

**PS 1425 Cannabidiol-Induced Myeloid-Derived Suppressor Cells Lead to Amelioration of Experimental Autoimmune Encephalomyelitis.**

D. M. Elliott, P. Nagarkatti and M. Nagarkatti. Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.

Multiple sclerosis (MS) is an autoimmune disease of the CNS with heterogeneous symptoms and progression. According to the National Multiple Sclerosis Society, roughly 400,000 people are affected in the US today and current therapies include

immunosuppressive agents with harsh side effects. Cannabinoids, which are a group of compounds derived from the marijuana plant (*Cannabis sativa*), are known to mediate their signals through the cannabinoid receptors, CB1 and CB2, and have been effective as treatment for cancer associated pain, nausea and appetite loss. Recently, their anti-inflammatory properties have been studied. Moreover, the use of cannabinoid therapy for MS has also been exploited. However, the proposed mechanism of action needs to be explored further. We used experimental autoimmune encephalomyelitis (EAE), a murine model of MS, to explore the anti-inflammatory role of cannabidiol (CBD) and its effects on myeloid-derived suppressor cells (MDSCs). EAE disease paradigms were consistently reduced with CBD treatment, as a significant reduction in clinical scores of paralysis and decrease in cellular infiltration, marked improvement of CNS tissue integrity, and reduced demyelination via histopathological analysis were observed. In addition, CBD treatment led to a reduction in the percentage and absolute number of T cells particularly the CD4<sup>+</sup> T cells infiltrating the CNS (spinal cord and brain), which were significantly increased in the untreated EAE mice. However, there was a profound increase in MDSC induction in the spleens, CNS, and peritoneal wash of CBD treated EAE mice as compared to the untreated EAE controls. Both granulocytic and monocytic MDSCs were increased in CBD treated EAE mice. Together, these studies demonstrate that CBD treatment may ameliorate EAE via the induction of MDSCs which suppress the aberrant autoimmune response. (Supported by NIH grants R01 AT006888, R01 ES019313, R01 MH094755, P01 AT003961, P20 RR032684 and VA Merit Award BX001357).

### PS 1426 Attenuation of Trichloroethene-Mediated Autoimmune Response in iNOS-null MRL<sup>+/+</sup> Mice.

G. Wang<sup>1</sup>, M. Wakamiya<sup>2</sup>, J. Wang<sup>1</sup>, G. Ansari<sup>1</sup> and M. Khan<sup>1</sup>. <sup>1</sup>Pathology, University of Texas Medical Branch, Galveston, TX; <sup>2</sup>Institute for Translational Sciences and Animal Resource Center, University of Texas Medical Branch, Galveston, TX.

Exposure to trichloroethene (TCE), a ubiquitous environmental contaminant, is associated with an autoimmune response both in humans and animal models. However, mechanisms underlying TCE-mediated autoimmunity remain largely unknown. Previous studies from our laboratory in MRL<sup>+/+</sup> mice suggest that reactive oxygen and nitrogen species (RONS) may contribute to TCE-induced autoimmunity. The current study was undertaken to further assess the role of oxidative and nitrosative stress in TCE-induced autoimmunity by using iNOS-null MRL<sup>+/+</sup> mice. iNOS-null mice were backcrossed to MRL<sup>+/+</sup> mice for 10 generations and then N10 heterozygous mutants were intercrossed to obtain homozygous mutants. Female MRL<sup>+/+</sup> and iNOS-null MRL<sup>+/+</sup> mice were given TCE (10 mmol/kg, i.p., every 4th day) for 6 weeks; their respective controls received corn oil only. TCE treatment led to significant induction of anti-malondialdehyde (MDA)- and anti-4-hydroxynonenal (HNE)-protein adduct antibodies along with increased iNOS in sera, and increased nitrotyrosine (NT) in sera, livers and kidneys in MRL<sup>+/+</sup> mice, suggesting an overall increase in oxidative and nitrosative stress. The TCE-induced oxidative stress was also associated with significant increases in serum anti-nuclear antibodies (ANA) and anti-double stranded DNA antibodies (anti-dsDNA) levels. Interestingly, iNOS and NT levels were negligible in both controls and TCE-treated iNOS-null MRL<sup>+/+</sup> mice. However, TCE treatment in iNOS-null mice still led to significant increases in serum anti-MDA/HNE-antibodies along with increases in serum ANA and anti-dsDNA compared to controls. Remarkably, the increases in serum ANA and anti-dsDNA induced by TCE in the iNOS-null mice were significantly less pronounced compared to that in MRL<sup>+/+</sup> mice. Our results provide further evidence for a role of oxidative/nitrosative stress in TCE-induced autoimmune response, and iNOS elimination attenuates this autoimmune response. Supported by NIH ES016302.

### PS 1427 Mouse Model of Halogenated Platinum Salt Hypersensitivity.

W. Williams<sup>1</sup>, E. H. Boykin<sup>1</sup>, C. Copeland<sup>1</sup>, L. Copeland<sup>1</sup>, S. J. Quell<sup>3</sup>, S. H. Gavett<sup>1</sup>, M. Selgrade<sup>2</sup> and D. M. Lehmann<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>ICF International, Durham, NC; <sup>3</sup>Independent, Research Triangle Park, NC.

Occupational exposure to halogenated platinum salts can trigger the development of asthma. Concern for increased asthma risk exists for the general population due to the use of platinum (Pt) in catalytic converters and its emerging use as a diesel fuel additive. To investigate airway responses to Pt, we developed a mouse model of Pt hypersensitivity. Previously, we confirmed the dermal sensitizing potency of ammonium hexachloroplatinate (AHCP) using an ex vivo [3H]methyl thymidine labeling version of the local lymph node assay in BALB/c mice. Here, we investigated the ability of AHCP to induce airway responses in mice sensitized by the dermal route. Mice were sensitized through application of 100 µL 1% AHCP in DMSO to

the shaved back on days 0, 5 and 19, and 25 µL to each ear on days 10, 11 and 12. Unsensitized mice received vehicle. On day 24, mice were challenged by oropharyngeal aspiration (OPA) with 0 or 100 µg AHCP in saline. Before and immediately after dosing, airway responses were assessed using whole body plethysmography (WBP). A dose dependent increase in immediate airway responses (IAR) was observed in AHCP sensitized and challenged mice. On day 26, changes in ventilatory responses to methacholine (Mch) aerosol were assessed by WBP; dose-dependent increases in Mch responsiveness occurred in sensitized mice. Bronchoalveolar lavage fluid harvested from sensitized mice contained an average of 7.5% eosinophils compared to less than 0.5% in control mice ( $p < 0.05$ ); significant increases in total serum IgE was observed for all sensitized mice. This model will be useful for assessing both relative sensitizing potency and cross-reactivity between different halogenated Pt salts and for investigating the possible adjuvant effects of diesel exhaust particles. This abstract does not represent EPA policy.

### PS 1428 Effect of Analgesic Administration on the Guinea Pig Maximization Test.

D. W. Rice, L. C. Anderson and J. H. Gass. Department of Toxicology, Baxter Healthcare Corporation, Round Lake, IL.

Guinea pig maximization tests have been associated with inflammation at cutaneous induction sites due to the use of 1-chloro-2, 4-dinitrobenzene (DNCB) as a positive control and Complete Freund's Adjuvant (CFA). CFA enhances the sensitization potential of the test substances and its use is required by ISO 10993-10. To alleviate the potential for pain and distress, we evaluated the use of the analgesic, buprenorphine hydrochloride (HCl). Analgesics can modulate the inflammatory response and may interfere with the detection of contact sensitization. The purpose of this study was to determine if the administration of buprenorphine HCl, as a refinement to reduce the potential for pain and distress, would affect the results of the guinea pig maximization test. DNCB and Rubbercare® Gloves were used as the test articles. The experimental design was consistent with the procedures described in ISO 10993-10 and the guinea pig maximization test (Magnusson and Kligman), with additional parameters evaluated. The experimental design consisted of 10 groups with each group receiving different concentrations of the test articles with or without analgesic treatment. Twenty-four to 30 hours after topical induction, the groups treated with buprenorphine HCl were given 0.006 mg/kg every 12 hours for a total of three doses. Three animals per group were terminated on study day 10 for hematology, coagulation and histologic evaluation of treatment sites. The remaining animals were terminated after completion of the sensitization test. Body weight gain, clinical observations, pain assessment, and sensitization potential were evaluated. Clinical observations, hematology, coagulation or histopathology of treatment sites were similar in groups that received analgesics compared to groups that did not. At least 60% to 100% of animals in each group were sensitized with no difference between corresponding groups with or without analgesic treatment. Based upon the results of this study, the use of the analgesic, buprenorphine HCl, did not interfere with the evaluation of the results of the guinea pig maximization test.

### PS 1429 Chemical Assessment of "In-Use" Allergic Contact Dermatitis Patch Test Reagents from Dermatology Clinics.

P. D. Siegel<sup>1</sup>, J. F. Fowler<sup>2</sup>, B. F. Law<sup>1</sup>, E. M. Warshaw<sup>3</sup> and J. S. Taylor<sup>4</sup>. <sup>1</sup>NIOSH/CDC, Morgantown, WV; <sup>2</sup>University of Louisville, Louisville, KY; <sup>3</sup>University of Minnesota, Minneapolis, MN; <sup>4</sup>Cleveland Clinic, Cleveland, OH.

Epicutaneous patch tests (EPT) are commonly used to identify chemical agents of allergic contact dermatitis in dermatology patients. Test validity and assessment of allergic reaction severity are highly dependent on the use of reliable chemical allergen test reagents. The purpose of the present study was to measure the actual concentration of nickel sulfate (NiSO<sub>4</sub>), methyl methacrylate (MM), formaldehyde (FA) and glutaraldehyde (GA) compared to the labeled concentrations of commercial reagents found in dermatology clinics where patch testing is routinely performed. The commercial reagents, NiSO<sub>4</sub>, MM and GA are supplied either dissolved or suspended in petrolatum (usually in syringe, multiuse containers) while FA is diluted in water. Participating clinics submitted in-date and out-dated reagents to the laboratory for analyses. Both NiSO<sub>4</sub> and FA levels were at or above the labeled concentration. NiSO<sub>4</sub> particulate was uniformly distributed throughout the petrolatum. In contrast, MM was low and variable in commercial allergen reagents. "In-use" MM reagent syringes were all ≤56% of the 2% label concentration with no observable relationship to expiration date. One MM syringe purchased directly from the manufacturer was 70% of the labeled concentration. Lower MM levels in syringes were consistently measured at the tip vs. plunger end

of the syringe suggesting loss due to MM's volatility. GA patch test reagents concentrations ranged from 27 to 45% of the labeled (1% in petrolatum) amount, independent of expiration date. No GA concentration pattern between tip and plunger was observed. These data suggest that false negative EPT results may be due to instability of volatile or self-polymerizing chemical allergens in the test reagents.

#### **PS 1430 Adjuvant Effect of Dibutyl Phthalate (DBP) in an Animal Model of Contact Hypersensitivity.**

A. S. Lourenço<sup>2</sup>, R. M. Zaia<sup>2</sup>, A. Prudente<sup>2</sup>, M. F. Otuki<sup>2</sup> and A. J. Martino-Andrade<sup>1,2</sup>. <sup>1</sup>Fisiologia, Universidade Federal do Paraná, Curitiba, Brazil; <sup>2</sup>Farmacologia, Universidade Federal do Paraná, Curitiba, Brazil. Sponsor: E. Silbergeld.

Recent studies have demonstrated that certain phthalates can have adjuvant effects in contact hypersensitivity models, exacerbating inflammatory responses. According to human exposure estimates, perfumes containing DBP can result in topical applications as high as 0.4 mg DBP/day. The aim of the present study was to investigate the adjuvant effect of DBP in the oxazolone-induced contact hypersensitivity model using human relevant doses. Adult male Balb/c mice were divided into 5 different groups (n=6/group). These animals received oxazolone (75 µg/animal) in hairless abdomen (induction). After five days, mice received oxazolone (75 µg/ear; positive control and DBP exposed groups) or vehicle (negative control group) in the right ear (sensitization). In addition, in the sensitization day and in the two subsequent days, DBP groups received three different doses (0.04, 0.4 and 4 mg DBP/ear) twice a day, while positive and negative controls received vehicle (acetone). All exposures were topical. For three subsequent days after sensitization ear thickness (edema) was measured with the use of a micrometer. After the last measurement, animals were decapitated and the ears were collected for the determination of N-acetyl-β-D-glucosaminidase (NAG) and Myeloperoxidase (MPO) activity. The study was in accordance to the ethics committee of the Federal University of Paraná. Ear thickness was increased in positive control when compared to vehicle only (negative control) group. No difference was seen between positive control and the lowest DBP dose group. However, oxazolone-induced edema was increased in the groups treated with 0.4 and 4 mg DBP/ear when compared to positive control. Similar results were found in MPO and NAG activity. The groups treated with the two highest DBP doses displayed significantly higher enzymatic activity when compared to positive control group. These results indicate that human relevant doses of DBP can have adjuvant effects in the oxazolone-induced contact hypersensitivity in mice.

#### **PS 1431 Characterization of the Mouse Allergy Model to Understand Mechanisms of Drug Allergy.**

X. Zhu, S. Cole, T. Kawabata and J. Whritenour. Pfizer Inc. Immunotoxicology CoE, Drug Safety Research and Development, Groton, CT.

Developed as a modification of the Lymph Node Proliferation Assay, the mouse allergy model (MAM) appears to be a promising tool for predicting the potential of drug development candidates to produce hypersensitivity reactions (HR). In this model, drugs associated with HR in the clinic produce a marked increase (compared to controls) in the cellularity of the draining lymph nodes (LN). The objective of this study was to characterize the phenotype of draining LN cells to identify new parameters that can be used to enhance the sensitivity and specificity of the MAM and to better understand the mechanism(s) for the response. Drugs that are associated with HR in the clinic (abacavir and amoxicillin) were selected as positive controls for this study. Negative control drugs (metformin and cimetidine) were selected based on the low number of reported HR for these compounds. Groups of 5 mice per group were injected subcutaneously with drug (100 mg/kg) or vehicle once daily for three consecutive days. After a two day rest, cells from the draining brachial LN were isolated and analyzed by flow cytometry. A significant increase in total LN cell number (compared to vehicle) was observed for mice treated with the positive control drugs. Compared to vehicle and negative control animals, an increase in CD4+ and CD8+ T cells and B cells was observed in the draining LN of abacavir and amoxicillin treated animals. Positive control drugs produced significant decreases (~25% compared to control) in the percentage of naïve T cells and increases (~27% compared to control) in the percentage of L-selectin (CD62L) and CD44 double-negative T cells. The negative control drugs induced slight, but statistically insignificant, changes in the expression of these markers. Drugs associated with HR in the clinic produced changes in draining LN cellularity and phenotype that are not observed for negative control drugs. Changes observed in adhesion molecule expression may suggest an effect of positive control drugs on lymphocyte trafficking.

#### **PS 1432 Characterization and Comparison of Methylene Diphenyl Diisocyanate Haptenated Human Serum Albumin and Hemoglobin.**

M. Mhike<sup>1,2</sup>, J. M. Hettick<sup>1</sup>, I. Chipinda<sup>1</sup>, R. H. Simoyi<sup>2</sup> and P. D. Siegel<sup>1</sup>. <sup>1</sup>Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV; <sup>2</sup>Department of Chemistry, Portland State University, Portland, OR.

Methylene diphenyl diisocyanate (MDI) is widely used as a cross-linking agent in the manufacture of polyurethane products. Exposure to diisocyanates (dNCO), such as MDI, is known to cause occupational asthma. MDI haptenation of proteins is central to dNCO immunological sensitization, however, the resultant protein conjugates are complex and difficult to characterize. The objective of the present study was to characterize hemoglobin (Hb) and human serum albumin (HSA) following conjugation to different molar concentrations of MDI. MDI-protein conjugates were acid digested to obtain free methylene dianiline (MDA). MDA was extracted, derivatized with fluorescamine and analyzed by HPLC-fluorescence. MDI-Hb was also digested with trypsin and specific amino acid conjugation sites determined by ultra-performance liquid chromatography-quadrupole-tandem time-of-flight mass spectrometry. The trinitrobenzene sulfonic acid assay (TNBS) and denaturing gel electrophoresis were used to determine the extent of cross-linking. MDI conjugation was observed to be dependent on the MDI: protein ratio and the concentration of protein. Greater binding to HSA than Hb was observed and MDI bound to only eight binding sites on Hb compared to twenty for HSA (at 40:1 molar ratio of MDI: protein). Self-polymerization of MDI onto protein was observed on some amino acids at higher MDI concentrations. The TNBS assay was used to confirm cross linking in MDI-HSA with approximately 60% loss of amine reactivity at 40:1 MDI: HSA. More cross-linking was observed at 0.5 mg/ml HSA than at 5mg/ml at 40:1 MDI: HSA. It is concluded that MDI has a greater reactivity toward HSA than Hb with respect to the number of residues haptenated and amount of MDI bound per mole of protein.

This work was supported by an Interagency agreement with the NIEHS (Y1-ES-0001).

#### **PS 1433 Dimethylfumarate: Potency Prediction and Clinical Experience.**

I. R. White<sup>2</sup>, D. Basketter<sup>1</sup>, F. G. Burleson<sup>3</sup>, G. Burleson<sup>3</sup> and I. Kimber<sup>4</sup>. <sup>1</sup>DABMEB Consultancy Ltd., Sharnbrook, United Kingdom; <sup>2</sup>Department of Cutaneous Allergy, St. John's Institute of Dermatology, London, United Kingdom; <sup>3</sup>BRT - Burleson Research Technologies, Morrisville, NC; <sup>4</sup>Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

Dimethylfumarate (DMF) was the cause of a major outbreak of allergic contact dermatitis as a consequence of its use as an antifungal agent in leather products, particularly when used in furniture. This became known, as "toxic sofa dermatitis". However, what has not previously been established is why the risks to human health had not been assessed adequately for this chemical. The purpose of these investigations was, therefore, to determine whether the frequency and severity of reactions to DMF arose as a function of its intrinsic skin sensitizing potency and/or the nature and extent of exposure. The intrinsic sensitizing potency of DMF was measured using the standard local lymph node assay (LLNA) with determination of an EC3 value; the threshold in the LLNA and which serves as an indicator of relative skin sensitising potency in humans. The EC3 value for DMF was 0.35% when tested in dimethylformamide as a vehicle, indicating that this chemical is a strong, but not an extreme, skin sensitizer in this mouse model. DMF was found therefore to have a relative sensitising potency that is comparable with formaldehyde, also a strong human skin sensitizer. The conclusion is drawn that the frequency and intensity of allergic contact dermatitis reactions to DMF suggest that it was the prolonged, repeated and occlusive exposure over large skin areas to this chemical, combined with strong sensitising potency, that together generated the "perfect storm" conditions that caused the DMF epidemic.

#### **PS 1434 Characterization of the Allergenic Potential of Proteins: An Assessment of the Kiwifruit Allergen Actinidin.**

L. Beresford<sup>1</sup>, S. McClain<sup>2</sup>, I. Kimber<sup>1</sup> and R. J. Dearman<sup>2</sup>. <sup>1</sup>Faculty of Life Sciences, Manchester University, Manchester, United Kingdom; <sup>2</sup>Syngenta Crop Protection, Durham, NC.

Assessment of the potential allergenicity (IgE-inducing properties) of novel proteins is an important component of the overall safety assessment of foods. Resistance to digestion with pepsin is commonly measured to characterize allergenicity, although the association is not absolute. We have shown previously that the measurement of specific IgE antibody production induced by systemic (intra-peritoneal) exposure of BALB/c strain mice to a range of proteins correlates with

allergenic potential. The purpose of the present investigations was to explore further the utility of these approaches using the kiwifruit allergen, actinidin. During the past 10 years, kiwifruit has become an important allergenic foodstuff, coincident with its increased consumption, particularly as a weaning food. The ability of actinidin to stimulate antibody responses has been compared with the reference allergen ovalbumin, and with the non-allergenic protein bovine hemoglobin. Hemoglobin was rapidly digested by pepsin whereas actinidin was relatively resistant unless subjected to prior chemical reduction (conditions more closely reflecting intracellular digestion). Hemoglobin stimulated detectable IgG antibody production at relatively high doses (10%), but failed to stimulate IgE. In contrast, actinidin was both immunogenic and allergenic at relatively low doses (0.25% to 1%). Vigorous IgG and IgG1 antibody production and relatively high titer IgE antibody responses were recorded, similar to those provoked by ovalbumin. Thus, actinidin displays a marked ability to provoke IgE, consistent with allergenic potential. These data provide further encouragement that in tandem with analysis of pepsin stability, the assessment of IgE antibody production following systemic (intraperitoneal) exposure of BALB/c strain mice provides an informative approach for the prospective identification of protein allergens.

## PS 1435 Risk of Allergic Reaction to Undeclared Milk Proteins in a Dietary Supplement.

J. Fleischer and M. H. Whittaker. *ToxServices LLC, Washington DC.*

In food allergic individuals, the immune system is sensitized to food proteins and mounts a damaging inflammatory response. As a major food allergen, milk and milk-derived ingredients must be declared on food labels under the U.S. Food Allergen Labeling and Consumer Protection Act. Individuals with cow's milk allergy (CMA) may be at risk from a single exposure to undeclared milk, and may experience hives, swelling, vomiting, diarrhea, and/or asthma. Life-threatening anaphylaxis may occur.

We assessed the risk of allergic reaction due to consumption of undeclared milk proteins in a dietary supplement in adults with CMA by calculating acceptable daily intake (ADI) thresholds for the milk proteins lactoglobulin and casein. ADIs are the lowest exposures that would elicit only mild symptoms in adults with CMA. We compared these ADIs with estimated intake (EI) levels for the two proteins, based on analytical evaluation of the supplement and recommended serving size.

We conducted benchmark dose (BMD) modeling on data from published double- or single-blind, placebo-controlled milk challenge studies in individuals with CMA. Dichotomous modeling (presence/absence of allergic response) was conducted using EPA's BMD Software 2.1.2. BMDs and BMDLs (lower 95% confidence interval for the BMD) at a benchmark response (BMR) of 10% for allergic response to milk challenge were modeled. BMDLs were adjusted for milk lactoglobulin and casein content (10% and 83% of total milk protein, respectively) and divided by an UF of 10 (individual variation) to obtain the ADIs. ADIs were 0.3 mg/person for lactoglobulin and 2.1 mg/person for casein, compared to respective EIs of 0.47 mg/person and 0.02 mg/person. The ADI for lactoglobulin was exceeded at an EI of 0.47 mg/person, suggesting that levels of undeclared milk protein in a dietary supplement are sufficient to increase the risk of allergic reaction in adults with CMA. The potentially severe and life-threatening nature of allergic reaction suggests the need for immediate risk management action and highlights the importance of GMPs for dietary supplements.

## PS 1436 Allergenic Antibiotics (Blactams and Sulfonamides) Induce Oxidative Stress in Keratinocytes.

B. E. Lucas<sup>1</sup>, A. E. Asangba<sup>1</sup>, S. Mohammad<sup>1</sup>, M. Gande<sup>1</sup>, K. L. Voie<sup>2</sup>, K. L. Campbell<sup>2</sup> and S. N. Lavergne<sup>1</sup>. <sup>1</sup>Comparative Biosciences, University of Illinois, Urbana, IL; <sup>2</sup>Veterinary Clinical Medicine, University of Illinois, Urbana, IL.

Drugs can induce hypersensitivity reactions (drug allergies). Delayed drug hypersensitivity occurs after >5 days of drug exposure. Surprisingly, delayed reactions usually target the skin although most drugs are not administered per-cutaneously. "Danger" signals such as necrotic cell debris, oxidative stress or inflammation, are key elements in the events leading to the sensitization of the immune system against an environmental toxicant or a therapeutic drug. We hypothesized that allergenic antibiotics would induce oxidative stress in keratinocytes in vitro. We therefore measured levels of intracellular glutathione (reduced and total GSH) and reactive oxygen species (ROS) in a canine keratinocyte cell line (CPEK cells) exposed to 2 Blactams (amoxicillin or cephalixin) 2 sulfonamides (sulfamethoxazole and sulfadimethoxine). Amoxicillin, cephalixin, sulfadimethoxine and sulfamethoxazole decreased levels of GSH in CPEK cells after 2h compared to the negative control; at 8h, levels were similar to the negative control with the 2 Blactams, but higher with the 2 sulfonamides; there was no difference between conditions at 24h. These effects affected total GSH rather than reduced or oxidized GSH. Sulfadimethoxine

was the only antibiotics that increased hydrogen peroxide levels compared to the media control at 2h/8h/24h. When measuring a larger range of ROS (hydroxyl, peroxide, superoxide), amoxicillin started to increase ROS levels at 4h; these ROS levels were further increased by amoxicillin and cephalixin at 24h compared to the media control. The effects were dose-dependent over a 2-2000uM range. Our data on these canine keratinocytes confirm results published on sulfonamides and human keratinocytes; they also expand them to Blactams.

## PS 1437 Activities of Xenobiotic Metabolizing Enzymes in Cell Lines Used for Skin Sensitization Testing *In Vitro*.

D. Vogel<sup>1,3</sup>, E. Fabian<sup>1</sup>, T. Eltze<sup>1,2</sup>, T. Ramirez<sup>1</sup>, S. N. Kolle<sup>1</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety Paper Chemicals, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Food Chemistry and Toxicology, Technical University of Kaiserslautern, Kaiserslautern, Germany.

Skin sensitization is caused by repeated contact with an allergen. An early step in the sensitization process is the interaction of haptens with proteins. In some cases the hapten is formed from pro-haptens by enzymatic reactions in the skin (1). Several in vitro methods are currently in the validation process as alternative methods to test for skin sensitization (2,3).

The metabolic activities of selected enzymes were assayed in keratinocyte-like cells Keratinosens® (Givaudan, Switzerland) and LuSens (BASF, Germany) as well as in the dendritic-like cell U937 (used for the MUSST assay) and THP-1 (used for the h-CLAT). Protein and cytochrome c reductase contents as well as activities of oxidizing enzymes (CYP, FMO, ADH, AIDH), hydrolysing enzymes (esterase) and conjugating enzymes (NAT and UGT) were measured in subcellular fraction of the cells by monitoring metabolic transformation of model substrates. CYP, FMO, UGT and ADH activities were below the detection limit for all investigated cells. NAT1 and esterase activities were detectable in all cell lines. AIDH activities were detected in the keratinocyte-like cells Keratinosens® and LuSens but not in U937 or THP-1 cells.

These results demonstrate that potential pro-haptens can be metabolically activated during sensitization testing in vitro. The xenobiotic metabolizing enzymes of the respective cells need, however, to be compared to those of native skin.

## PS 1438 Interleukin 17 Expression by Chemical Allergen-Activated Lymph Node Cells: Selectivity for Contact Allergens.

I. Kimber, A. Metryka, M. D. Hayes and R. J. Dearman. *Faculty of Life Sciences, Manchester University, Manchester, United Kingdom.*

Chemical allergens can cause skin sensitization resulting in allergic contact dermatitis, or sensitization of the respiratory tract associated with occupational asthma. The immunological mechanisms resulting in sensitization, and the contributions made by the innate immune response are not fully understood. The interleukin (IL)-17 cytokine family, originally described as Thelper (Th)17 cytokines, are now known to be expressed by cells of the innate immune system. It has been shown previously that topical exposure of mice to 2,4-dinitrochlorobenzene (DNCB), a potent contact allergen, is able to provoke the rapid (within 6-16 hours) production of IL-17 by components of the innate immune system in regional lymph nodes. Here we have examined whether this rapid elaboration of IL-17 cytokines is selective for contact allergens. BALB/c mice were exposed on the dorsum of both ears to various allergens (DNCB, dinitrofluorobenzene, oxazolone, 2-methyl-4-isothiazolin-3-one and 5-chloro-2-methyl-4-isothiazolin-3-one, or  $\alpha$ -hexylcinnamaldehyde), to the irritants sodium lauryl sulfate and benzalkonium chloride or to the appropriate vehicle control. At various times thereafter cells from draining lymph nodes were isolated and cultured, and supernatants analyzed for IL-17A, IL-17F, IL-17A/F and IL-22 expression. Expression of IL-17 cytokines and IL-22 was selective for contact allergens with no significant increase in response to skin irritants. A chemical respiratory allergen (trimellitic anhydride; TMA) also induced IL-17 and IL-22, but with substantially delayed kinetics compared with contact allergens. Enhancing the dendritic cell migration kinetics in response to TMA to match those induced by contact allergens did not impact on the tempo of lymph node IL-17 expression. Collectively these data suggest that the rapid elicitation of IL-17 cytokines in draining lymph nodes is a potentially selective biomarker of exposure to contact allergens, and may provide a platform for the development of a novel approach to the characterization of skin sensitizing activity.

**PS 1439 Interleukin 17 Responses Induced in Mice by Chemical Allergens: A Functional Role for Gammadelta T Cells.**

R. J. Dearman<sup>1</sup>, M. D. Hayes<sup>1</sup>, B. Hunt<sup>2</sup>, A. Hayday<sup>2</sup> and I. Kimber<sup>1</sup>.

<sup>1</sup>Manchester University, Manchester, United Kingdom; <sup>2</sup>London Research Institute, London, United Kingdom.

Interleukin (IL)-17 cytokines, expressed by T helper (Th)17 cells, play pivotal roles in adaptive immune responses. They have been implicated in autoimmune and allergic diseases and have roles in bacterial and fungal clearance. Importantly, IL-17 is produced not only by adaptive immune cells but also by cells of the innate immune system including the nonconventional  $\gamma\delta$  T cell subset. It has been shown recently that IL-17 expressing  $\gamma\delta$  T cells are required for the development of adaptive Th17 responses that mediate experimental autoimmune encephalomyelitis, a murine model of multiple sclerosis. We have examined whether IL-17 influences sensitization to chemical allergens. BALB/c strain mice were exposed topically to the contact allergen 2,4-dinitrochlorobenzene (DNCB), the respiratory allergen trimellitic anhydride (TMA), or to vehicle alone. At selected time points single cell suspensions of draining lymph nodes were cultured and analyzed for cytokine secretion or for mRNA following enrichment/depletion using magnetic beads. A single exposure to either allergen resulted in transient up-regulation of IL-17 from  $\gamma\delta$  T cells. Maximal levels of secretion were observed at 6h and 48h following exposure to DNCB and TMA, respectively. After repeated exposure under conditions where DNCB and TMA stimulate polarized Th1 and Th2 cytokine phenotypes, respectively, DNCB, but not TMA, was shown to induce the expression of IL-17. IL-17 production by DNCB-activated cells was shown by complement depletion to reside only in the CD4<sup>+</sup> population. In subsequent experiments, responses were explored in  $\gamma\delta$  T cell null mice and C57BL/6 wild type (WT) controls. A similar pattern of IL-17 production to that provoked in BALB/c strain mice was seen in the WT mice following prolonged exposure to DNCB. However, in the  $\gamma\delta$  T cell null mice the adaptive Th17 response was completely abrogated. These data suggest strongly that the lack of IL-17 production by  $\gamma\delta$  T cells during the acute (innate) response affects the subsequent adaptive Th17 response to contact allergens.

**PS 1440 IL-18 Secretion in Human 3D Organotypic Skin Models for the Identification of Contact Sensitizers.**

E. Corsini<sup>1</sup>, S. Gibbs<sup>2</sup>, V. Galbiati<sup>1</sup>, S. Spiekstra<sup>2</sup>, H. Kandarova<sup>3</sup>, P. Hayden<sup>4</sup>, C. Seaman<sup>4</sup> and E. L. Roggen<sup>5</sup>. <sup>1</sup>DiSeFeB, Università degli Studi di Milano, Milan, Italy; <sup>2</sup>Vrije Universiteit Medical Center, Amsterdam, Netherlands; <sup>3</sup>MatTek Corporation, Ashland, MD; <sup>4</sup>GSK, Hertfordshire, United Kingdom; <sup>5</sup>3Rs Management and Consultancy, Kongens Lyngby, Denmark.

Over the last decade, several in vitro methods have been proposed to identify potential of contact sensitizers, but no accepted in vitro method yet available. Keratinocytes play a key role in all phases of skin sensitization. Interleukin-18 (IL-18) production in keratinocyte was identified as a potentially useful endpoint for determination of contact sensitizers. Limitations of traditional submerged cell culture include chemical solubility, stability in water and metabolic competence. To overcome these problems, experiments were performed to test the possibility to use commercially available 3D organotypic skin models to exploit the possibility to use the secretion of IL-18 for the identification of contact sensitizers. A protocol was developed using different 3D skin models, including EpiDerm TM, EST1000TM. Preliminary experiments were conducted to determine chemical toxicity profiles using the MTT viability assay. Additional doses were then chosen for IL-18 secretion experiments. Following topical exposure for 24 h to several contact allergens (including benzocaine, cinnamaldehyde, citral, DNCB, eugenol, isoeugenol, 2-mercaptobenzothiazole, oxazolone, etc.) and irritants (including chlorobenzene, lactic acid, octanoic acid, phenol, salicylic acid, SDS, Tween 20, etc.) a robust increase in IL-18 release was observed only after exposure to contact allergens. The method could be easily transferred to naïve laboratories. Using a cut-off of 2-fold increase of IL-18 above vehicle control and 40% cell viability, depending from the laboratory 85-100 % sensitivity and 88-100 % specificity were obtained. This model appears to be very promising, additional testing with a larger chemical set is required to fully evaluate the utility of this assay.

**PS 1441 Animal Strains Usable to the LLNA: brdU-ELISA (OECD 442B).**

T. Anzai<sup>1,2</sup>, Y. Nozaki<sup>3</sup>, M. Kaminishi<sup>1,2</sup>, H. Takagi<sup>3</sup>, T. Satoh<sup>1</sup>, R. Guest<sup>4</sup> and K. Sato<sup>2</sup>. <sup>1</sup>Harlan Laboratories Co., Ltd., Tokyo, Japan; <sup>2</sup>School of Medicine, Showa University, Tokyo, Japan; <sup>3</sup>Japan SLC, Hamamatsu, Japan; <sup>4</sup>Harlan Laboratories (UK), Derby, United Kingdom.

The murine local lymph node assay (LLNA) is a widely accepted alternative test to assess the skin sensitizing potential of chemical substances. The original LLNA was designed to quantify lymph cell proliferation in the draining auricular lymph nodes

by incorporation of radiolabeled thymidine analogues. To avoid use of the radioisotope in the tests, some modified LLNA protocols were developed. One of the modified methods utilizes the nucleus (uridine) analogue of 5-Bromo-2'-deoxyuridine (BrdU). In this method, the incorporated BrdU is measured by ELISA, using anti BrdU antibody. This modified LLNA:BrdU-ELISA has been validated and adopted as OECD test guideline 442B. In this guideline, the CBA/J or CBA/JN strains are recommended, since researchers had used these strains during the validation. Previously, we noted differences in response in the LLNA with different strains of mouse. In this study, we used mice of several CBA strains to compare the reactivity against several skin sensitizers and a non sensitizer. It is confirmed that the mouse strains, CBA/CaOlaHsd and CBA/N Slc showed similar but not equal response to CBA/JN.Crlj, the preferred strain in the LLNA:BrdU-ELISA.

**PS 1442 Elucidation of the Reason Underlying the Incorrect Sensitization Evaluation Results for Methyl Methacrylate, Methyl Salicylate and 2-Mercaptobenzothiazole by Nonradioactive Local Lymph Node Assay.**

W. Jang<sup>1</sup>, K. Jung<sup>1</sup>, Y. Lee<sup>2</sup>, Y. Yum<sup>2</sup>, Y. Heo<sup>3</sup> and K. Lim<sup>1</sup>. <sup>1</sup>Amorepacific R&D Center, Yong-in, Republic of Korea; <sup>2</sup>Korea FDA, Cheong-won, Republic of Korea; <sup>3</sup>Catholic University of Daegu, Daegu, Republic of Korea.

The non-radioisotopic local lymph node assay (LLNA) using bromodeoxyuridine (BrdU) with flow cytometry (FCM) has been developing as an alternative test for identifying skin sensitizers. We previously performed pre-validation with recommended reference substances in the OECD Test Guideline 429 using Balb/c mice. Our results by non-radioactive LLNA were similar to those of traditional LLNA. However, a weak sensitizer, methyl methacrylate (MM), a non-sensitizer, methyl salicylate (MS) and a moderate sensitizer, 2-mercaptobenzothiazole (MBT) were wrongly identified by non-radioisotopic LLNA:BrdU-FCM as a non-sensitizer, a weak sensitizer and a non-sensitizer, respectively. Therefore, we tried to clarify the reason underlying the wrong prediction by LLNA:BrdU-FCM. First, we compared strain difference of Balb/c mice from CBA mice that are recommended strain in the OECD Test Guideline 429 with several test materials including the 3 chemical substances described above. Mice received topical application of the test material or vehicle on both ears for consecutive 3 days. Mice were sacrificed 24 hr after intraperitoneal injection of BrdU. Ear thickness and ear weight were measured for evaluating irritation and auricular lymph nodes were used for determining BrdU incorporation into lymph node cells. All of test materials including positive control showed similar stimulation index and ear thickness between two mice strains suggesting that strain difference may not be the reason for the wrong prediction by LLNA:BrdU-FCM. Interestingly, MBT was correctly identified as a moderate sensitizer when AOO was used as a vehicle while it was a non-sensitizer when DMF was used as recommended in the OECD guideline suggesting that vehicle selection may profoundly affect the prediction for MBT by LLNA:BrdU-FCM.

**PS 1443 Polarized Immune Responses Induced by Chemical Allergens Display Differential DNA Methylation Patterns.**

V. Chapman<sup>1</sup>, J. Moggs<sup>2</sup>, R. Terranova<sup>2</sup>, T. Zollinger<sup>2</sup>, I. Kimber<sup>1</sup> and R. J. Dearman<sup>1</sup>. <sup>1</sup>Manchester University, Manchester, United Kingdom; <sup>2</sup>Novartis, Basel, Switzerland.

There is increasing evidence that epigenetic regulation of gene expression plays a pivotal role in the orchestration of immune responses. It has been demonstrated previously that chemical allergens can be divided into two categories; contact allergens (such as dinitrochlorobenzene; DNCB), that cause type 1/type 17 polarized responses and respiratory allergens (such as trimellitic anhydride, TMA) that induce a preferential type 2 response. Such polarization occurs upon repeated (13 day) topical exposure. In order to explore the regulation and maintenance of such responses at the molecular level, the genome wide pattern of DNA methylation following treatment with the reference allergens DNCB and TMA was characterized. Mice (n=5 per group) were exposed to DNCB, TMA or vehicle alone for 13 days, and draining auricular lymph nodes excised. DNA was extracted, sonicated and processed for methylated DNA immunoprecipitation (MeDIP) followed by hybridization to a high resolution DNA promoter array (Roche) representing 28,000 probe ranges, covering promoter regions and known CpG islands. Changes in DNA methylation profiles for allergen-activated tissues were compared with the vehicle-treated control samples, with a cut off of p<0.01. More differentially methylated regions (DMR) were recorded for DNCB tissue than for TMA tissue (6319 versus 2178), although approximately half those identified for TMA were in common with DNCB. Direct comparisons between DNCB and TMA-treated tissue revealed 268 DMR that were differentially regulated between the two different classes

of allergens. The 15 most significant genes identified were associated with hypermethylation and hypomethylation for DNCB and TMA exposure, respectively. Thus, topical exposure to different classes of chemical allergen under polarizing conditions results in characteristic patterns of DNA methylation indicative of epigenetic regulation of the developing allergic response. Furthermore, DNCB and TMA are associated with more silencing and activating epigenetic marks, respectively.

**PS 1444 Chemicals Acute Toxicity Testing and Evaluation Based on Nematode *Caenorhabditis elegans* Model.**

Y. Li, K. Yang, S. Gao, H. Jing, L. Qi, J. Ning, Z. Tan, C. Zhao, L. Ma and G. Li. *Institute for Toxicology, Beijing Centers for Disease Control and Prevention, Beijing Research Center for Preventive Medicine, Beijing, China.*

The toxicity assessment and risk management of chemicals is highly associated with the safety of human health. At present, the conventional model of which rodent tests were greatly characterized, can no longer meet the increasing requirements of chemical toxicological evaluation. Studies on the non-rodent in vivo assay by using model organisms are becoming a potential perspective and frontiers in the research field of chemicals toxicity risk assessment. Nematode *Caenorhabditis elegans* (*C. elegans*) has great potential value in the chemical rapid toxicity screening and complying with principles of "3R" for its short life cycle, easy operation and low cost. However, the fact that how the acute toxicity in rodents and even health risks in human being can be predicted through toxicity in *C. elegans*, is still a key scientific problem that remains to be solved. In this pilot study, we assayed 50% lethal concentration (LC50) and 50% lethal time (LT50) of 20 selected chemicals using *C. elegans* as an in vivo model organism in 96-well plate for 24h, analyzed the correlation between LC50 of *C. elegans* and LD50 of rat/mouse. The results indicated that the estimated toleration of chemical pH for *C. elegans* was greater than 2.75. There was a positive correlation between LC50 of *C. elegans* and LD50 of rat/mouse ( $R > 0.83$ ,  $P < 0.01$ ). LC50 and LT50 of chemicals in *C. elegans* have positive correlation as well. Taking together, there is an intrinsic relationship between LC50 of *C. elegans*, LD50 of rat/mouse. LC50 and LT50 are recommended as toxic effect index for further study on acute toxicity test of chemicals using *C. elegans*. *C. elegans* will be a potential valuable in vivo pre-screening toxicity model in the new chemical's predictive toxicity test and assessment prior to the conventional rodent model (partly supported by NSFC Grant in China #81273108, Capital Development Project 2011-1013-03, and Beijing Health Bureau Project-2011. Corresponding author: Guojun J. Li: guojunli88@yahoo.com).

**PS 1445 Predicting Developmental Neurotoxicity in Rodents from Larval Zebrafish—and Vice Versa.**

V. C. Moser, R. C. MacPhail, P. M. Phillips, M. E. Culbreth, K. L. McDaniel, K. A. Jarema and S. Padilla. *TAD & ISTD, NHEERL, US EPA, Research Triangle Park, NC.*

The complexity of standard mammalian developmental neurotoxicity tests limits evaluation of large numbers of chemicals. Less complex, more rapid assays using larval zebrafish are gaining popularity for evaluating the developmental neurotoxicity of chemicals; there remains, however, a pressing need to determine the utility of the model for predicting adverse neurobehavioral outcomes. We are undertaking studies to compare the developmental effects of chemicals in both larval zebrafish and rats. Zebrafish studies show that transitions between light and dark periods can produce robust changes in activity that may be differentially altered by chemicals; an analogous behavior pattern is being studied in rats. Developmental heptachlor in rats increased motor activity in addition to altering righting reflex ontogeny, and impairing learning and memory in adult offspring. In zebrafish, developmental heptachlor produced marked increases in dark-induced activity and dysregulation of the light-dark patterning of activity. Preliminary studies with dimethyl phthalate (DMP) in zebrafish showed reduced habituation only during the dark period, perhaps reflecting changes in anxiety or cognitive behaviors. We evaluated developmental effects of DMP in rats using light-dark transition activity measures in addition to standard neurobehavioral toxicity tests including anxiety. Alterations were observed on several of these endpoints; however, the results were not always dose-related and were confounded by maternal toxicity at high doses. While these results suggest concordance between outcomes of two chemicals from different classes, considerably more comparisons with positive and negative controls are needed to understand the predictability of the larval zebrafish assay. Further exploration of analogous/homologous behavioral tests in both species may be beneficial in evaluating neurotoxic outcomes from developmental exposures, and in assessing the conformity of results.

This is an abstract of a proposed presentation and does not reflect US EPA policy.

**PS 1446 Developmental and Reproductive Toxicity of Fusarium Mycotoxins in the Nematode *Caenorhabditis elegans*.**

Z. Yang<sup>2,1</sup>, L. Tang<sup>1</sup>, G. Qian<sup>1</sup> and J. Wang<sup>1</sup>. *Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Developmental and reproductive toxic effects of some naturally occurring Fusarium mycotoxins were shown in certain animal models. In this study we used the nematode *Caenorhabditis elegans* (*C. elegans*), as an alternative model for mechanistic studies, to investigate the developmental and reproductive toxic effects of T-2 toxin (T-2), zearalenone (ZEN), and deoxynivalenone (DON). *C. elegans* (N2) at 1-day or 3-day old were exposed to various concentrations of these toxins for up to 72 hrs. The development arrested rate (DAR) and the reproduction arrested rate (RAR) were outcomes used to assess the overall effects on the development and reproduction of the exposed *C. elegans*. T-2 has the most potent suppressive effects on the development and growth, concentrations from 0.5- to 8-mg/L caused averaged DAR from 12.01% to 41.6%; exposure to ZEN from 5- to 80-mg/L caused averaged DAR from 11.14% to 35.56%; exposure to DON from 50- to 800-mg/L caused averaged DAR from 12.71% to 32.77%. The concentration ratio for inducing significant DAR (10%) is approximate to 1:10:100 for T-2, ZEN, and DON, respectively. T-2 also has the most potent toxic effect on the reproduction, concentrations from 0.5- to 8-mg/L caused averaged RAR from 28.97% to 72.43% with an EC50 at 3.57-mg/L; exposure to ZEN from 5- to 80-mg/L caused averaged RAR from 26.15% to 90% with an EC50 at 12.02-mg/L; exposure to DON from 50- to 800-mg/L caused averaged RAR from 23.83 to 52.33% with an EC50 at 585.85-mg/L. The concentration ratio for EC50 is approximate to 1:3.4:164.1 for T-2, ZEN, and DON, respectively. These results suggest that T-2 and ZEN have more significant toxic effects than DON on development and reproduction in *C. elegans* and that *C. elegans* is an excellent model, due to its short life cycle and easy genetic manipulation of genes, for studying molecular mechanisms of developmental and reproductive toxic effects caused by food-borne mycotoxins.

**PS 1447 Zebrafish As a Complementary Model in Toxicology.**

A. Menke<sup>2</sup>, A. Wolterbeek<sup>1</sup>, A. Beker<sup>1</sup>, C. Snel<sup>2</sup> and D. de Groot<sup>1</sup>. <sup>1</sup>TNO, Zeist, Netherlands; <sup>2</sup>TNO Triskelion BV, Zeist, Netherlands. Sponsor: R. Woutersen.

Growing awareness to apply the principles of Replacement, Refinement and Reduction (3Rs) of animals in regulatory testing drives the need for alternatives identifying potential toxic agents with accuracy, speed, reliability and respect for animal welfare. So far, for complex endpoints like reproduction and developmental toxicology, animal-free in vitro models are limited and cover only a restricted part of the reproductive cycle. Various characteristics warrant the Zebrafish (embryos and/or larvae) as an ideal non-mammalian whole organism model that could bridge gaps between in vitro cell systems and complex reproduction studies in mammals, e.g. small size, ease of obtaining high number of progeny, external fertilization, transparency and rapid development of embryo, and a basic understanding of its gene function and physiology.

Macroscopical examination of zebrafish embryos/larvae predicted toxicity of chemical and pharmaceutical agents with high certainty and proved to form a reliable total organism approach to study embryo- and developmental (neuro)toxicity. More in depth analysis and interpretation of the locomotor data in the developing zebrafish larvae relative to (nervous system) development increases the use of the zebrafish model in developmental neurotoxicity research. A full histopathological survey of the embryo's combined with high-end analytical methods appeared to further increase the applicability domain of zebrafish into toxicity screening studies. Further refinement with respect to the physical and chemical properties of test compounds that determine the body burden and tissue distribution increases the predictability of the assay. For translation to other toxicity models and man, there is an urgent need to research on responsible toxicity pathways.

This research is supported by the Dutch Ministry of Health, Welfare and Sport and the Dutch Ministry of Social Affairs and Employment.

**PS 1448 Using Yeast Functional Toxicogenomics to Decipher the Toxicity of the Dieldrin Organochlorinated Pesticide.**

B. Gaytan<sup>1</sup>, A. Loguinov<sup>1</sup>, S. Lantz<sup>1</sup>, N. Denslow<sup>2</sup> and C. Vulpe<sup>1</sup>. <sup>1</sup>University of California, Berkeley Berkeley, CA; <sup>2</sup>University of Florida, Gainesville, FL.

Exposure to organochlorinated pesticides (OCPs) has been linked to neurotoxicity, endocrine disruption, and cancer, but the cellular mechanisms of toxicity remain largely unknown. It was hypothesized that a chemical genomics approach using a *Saccharomyces cerevisiae* gene deletion library could help elucidate the cellular mechanisms by which various OCPs induce toxicity. In this study, pools of deletion

strains were exposed in triplicate for five and fifteen generations to the IC20, 50% IC20, and 25% IC20 dieldrin OCP concentrations. The oligo sequences unique to each deletion strain were PCR-amplified and hybridized to TAG4 arrays to identify sensitive, unaffected, and resistant strains. The overrepresented biological terms within the data assisted in the selection of individual deletion strains for confirmation experiments. Analyses indicate that amino acid sensing and components of the pyruvate dehydrogenase complex are critical for cell survival under dieldrin exposure. Exogenous amino acids rescue dieldrin toxicity, while lower concentrations of amino acids in the media exacerbate toxicity. Finally, it was demonstrated that dieldrin inhibits amino acid uptake in yeast cells. Future investigations will examine whether amino acid status is tied to dieldrin toxicity in human cell lines. Additionally, the development of an automated high-throughput system to screen the yeast deletion library for altered growth in various toxicants may be discussed.

**PS 1449 Evaluation of Epigenetic and Developmental Effects in *Danio rerio* Zebrafish Embryos following Diethylstilbestrol, 17 $\beta$ -Estradiol And/or 5-Azacytidine Treatment.**

R. G. Ellis-Hutchings, R. A. Alyea, V. A. Marshall, M. J. LeBaron, R. Sura, N. P. Moore, B. Gollapudi and R. J. Rasoulpour. *Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

The fundamental mechanisms that regulate epigenetic modifications as well as embryo development are highly conserved amongst vertebrates. *Danio rerio* (zebrafish) potentially may be used to examine epigenetic alterations during stages of early development. Zebrafish embryos were treated with estrogenic molecules (17 $\beta$ -estradiol (E2) or diethylstilbestrol (DES) (0.001, 0.01, 0.1, 1, 1.5, 2, 2.5, 3, 5, 7, and 10 $\mu$ M) in the presence or absence of a DNA methyltransferase inhibitor 5-azacytidine (5-azaC, 1-100 $\mu$ M) and evaluated daily for lethality. On test day 5, morphological abnormalities were assessed using a quantitative scoring system: somites, notochord, tail, fins, heart, face, brain, arches and jaw. Treatment with 25 $\mu$ M 5-azaC prior to the period of DNA re-methylation (2-cell stage) caused >80% lethality whereas starting treatment shortly after the onset of DNA re-methylation ( $\geq$  16 cell stage) resulted in <10% lethality. Regardless of developmental stage, treatment with 50 and 100 $\mu$ M 5-azaC caused >90% lethality. Treatment with >2 $\mu$ M DES caused significant mortality whereas treatment with 1 or 1.5 $\mu$ M increased the incidence of developmental variations. Treatment with >7 $\mu$ M E2 significantly impacted survival, while 5 $\mu$ M caused a generalized slight increase in developmental abnormalities; however, 1, 1.5, 2, 2.5 and 3 $\mu$ M E2 caused slight developmental effects on the heart, face and brain. Overall, E2 had a wide developmental dose response curve while DES caused significant mortality within a narrow region. Morphological characterization of embryos and larvae following exposure to these compounds indicated that within the chosen dose response range, clear apical end point no-observed-adverse-effect levels (NO(A)ELs) and lowest-observed-adverse-effect levels (LO(A)ELs) can be determined thereby providing a useful model to establish associations between apical and epigenetic end points.

**PS 1450 A High-Throughput Mechanism-Based Toxicity Screen Using *C. elegans*.**

R. B. Goldsmith<sup>2</sup>, J. R. Pirone<sup>3</sup>, W. A. Boyd<sup>2</sup>, M. V. Smith<sup>3</sup> and J. H. Freedman<sup>1</sup>. <sup>1</sup>NIH, Research Triangle Park, NC; <sup>2</sup>NTP, NIEHS, Research Triangle Park, NC; <sup>3</sup>SRA International, Durham, NC.

To quantitatively assess the effects of chemical exposures on transcription, an automated high-throughput *in vivo* toxicity assay was developed to measure changes in the levels and cell-specificity of specific gene expression in *C. elegans*. Transcriptional responses were measured in individual strains of transgenic *C. elegans* that express fluorescent proteins under the control of archetypal stress-inducible genes: *ced-3*, *cyp-35A2*, *gcs-1*, *gst-38*, *gst-4*, *hsp-16.2*, *hsp-16.41*, *hsp-17*, *hsp-4*, *hsp-6*, *hsp-60*, *mtl-2*, *ugt-1* and *ugt-13*. As part of assay development, transgenic nematodes with large dynamic ranges (i.e., low constitutive levels of expression) and sensitivity (high response at low concentrations) were identified following exposure to juglone, an oxidative stressor; N-methyl-N'-nitro-N-nitrosoguanidine, a DNA damaging agent; cadmium, a heavy metal; chlorpyrifos, an organophosphate neurotoxin; tunicamycin, an endoplasmic reticulum stressor; and heat shock, a protein denaturant. Concomitant with chemical exposure, fluorescence data were measured from images acquired using a high content imager and subsequently analyzed using CellProfiler's WormToolbox, a high-throughput imaging analysis program designed for use with nematodes. For some of the stress-inducible genes high levels of constitutive expression limited their dynamic range and utility in this assay. As expected, not all of the chemicals affected all of the genes; however, the chemicals generally affected the stress-inducible genes that corresponded to their known mechanisms of action. For example, nematodes containing the *hsp-4* transgene, which responds to endoplasmic reticulum stress, showed increased fluorescence after tunicamycin treatment. In addition, strong correlations were observed between chemical concentration and fluorescent signal. The results obtained using the

transgenic *C. elegans* were verified by measuring changes in the cognate steady-state mRNA levels by qRT-PCR. These results show that this assay can be used to assess the effect of toxicants on gene expression *in vivo*.

**PS 1451 The Effects of Microcystin-LR on the Chemotaxis Indexes of *Caenorhabditis elegans***

C. Moore and B. Puschner. *Molecular Biosciences, University of California Davis School of Veterinary Medicine, Davis, CA.*

The blue green algae toxins microcystins (MCs) are known ubiquitous hepatotoxins found in fresh and marine waters. The World Health Organization has established a drinking water guideline of 1  $\mu$ g/L total MCs based on MC-LR liver toxicity data after oral exposure. MCs inhibit serine/threonine protein phosphatases (PP1 and 2A), a mechanism extensively studied in the liver; yet the effects of MCs on the nervous system are poorly understood. To study MCs' effects on the nervous system, a 24-hour exposure assay using the neurotoxicity model *Caenorhabditis elegans* (*C. elegans*) was established. *C. elegans* have remarkable genetic and neurobiochemical conservation with humans, and with all 302 neurons extensively studied, key sensory neurons have been linked to specific behaviors. It is well known the AWA and AWC sensory neurons detect diacetyl and benzaldehyde, respectively, and sensory neuron function can be quantified using a chemotaxis index (CI). Wildtype (N2) adult nematodes were exposed for 24 hours to 0, 1, 10, 40, 80, 160 and 320  $\mu$ g/L MC-LR before determining CIs. No significant changes in CIs for benzaldehyde were observed. At MC-LR concentrations of 40  $\mu$ g/L and above, CIs for diacetyl decreased significantly. The unchanged CIs for benzaldehyde suggest that AWC is not affected. The decreased CIs for diacetyl suggest that AWA is targeted by MC-LR. PP2A inhibitor okadaic acid and PP1 inhibitor autamycin were used in the same 24-hour exposure model to evaluate whether PP1 or PP2A inhibition result in changes in AWA function. Results of CI indexes suggest that the AWA chemosensory neuron is affected by MC-LR resulting in neurotoxicity.

**PS 1452 Quantitative Assessment of Phase II ToxCast™ Chemical Toxicity in *C. elegans*.**

W. A. Boyd<sup>1</sup>, M. V. Smith<sup>2</sup>, J. R. Pirone<sup>2</sup>, J. R. Rice<sup>1</sup> and J. H. Freedman<sup>1,3</sup>. <sup>1</sup>DNTP, NIEHS, NTP, Research Triangle Park, NC; <sup>2</sup>SRA International, Research Triangle Park, NC; <sup>3</sup>LTP, NIEHS, NIH, Research Triangle Park, NC.

The Tox21 community is working to prioritize thousands of chemicals for further toxicity testing and to develop prediction models for human toxicity. To integrate the large amounts of high throughput *in vitro* and *in vivo* toxicity and develop these models, better quantitative methods are necessary. To develop quantitative assessments of *in vivo* toxicity data, the U.S. EPA's ToxCast Phase II library, which contains 676 unique chemicals including failed drugs, food additives and industrial products, was screened using the *C. elegans* growth assay. This assay uses the COPAS Biosort to measure size changes in individual nematodes after 48-h exposures. Over the seven concentrations tested (0.5-200  $\mu$ M), >50% of the chemicals caused a decrease in growth. To rank their toxicity in *C. elegans*, a concentration-response curve for each chemical was described using isotonic regression and the statistical significance of the curve assessed. For significant concentration-response curves, the fitted isotonic regression model calculated three parameters that characterized the efficacy and potency of each chemical: 1) change in response between control and highest concentration (R); 2) concentration of chemical at which half of R is reached (ECR50); and 3) slope of the curve at the ECR50. Chemicals were also ranked by computing a toxicity score, which is a weighted sum of the change in response at each dose relative to the control. The top 5% most active compounds included several organic pollutants (e.g., DDT, PFOS), which have been banned from use due to their toxicity and bioaccumulation. Excellent reproducibility was observed for eight chemicals replicated in the library: seven were active and one was inactive for all replicates. The application of this new method for the quantitative assessment of chemical toxicity in *C. elegans* could be applied to other *in vitro* and *in vivo* toxicity screens, thus allowing for better comparisons among various assays, and the development of predictive models of toxicity.

**PS 1453 Triazole-Induced Gene Expression Changes in the Zebrafish Embryo.**

S. A. Hermesen<sup>1,2</sup>, T. E. Pronk<sup>1</sup>, E. van den Brandhof<sup>1</sup>, L. T. van der Ven<sup>1</sup> and A. H. Piersma<sup>1,3</sup>. <sup>1</sup>Health Protection, RIVM, Bilthoven, Netherlands; <sup>2</sup>Toxicogenomics, University, Maastricht, Netherlands; <sup>3</sup>IRAS, University, Utrecht, Netherlands. Sponsor: H. van Loveren.

The zebrafish embryo is a promising alternative test for developmental toxicity. The classical read-out is via morphological assessment. Microarray analyses may increase sensitivity and predictability of the test by detecting more subtle and mechanistic

responses. We have shown earlier that with transcriptomics data we could discriminate between two chemical classes, glycol ethers and triazoles, in a concentration-response design. It is time-consuming and expensive to perform concentration-response analysis for many compounds. Thus, we studied the possibility of relating gene expression profiles of structurally related chemicals tested in a single concentration, to a complete transcriptomic concentration-response of the triazole antifungal flusilazole (FLU). We tested five other triazoles, hexaconazole (HEX), cyproconazole (CYP), triadimefon (TDF), myclobutanil (MYC), and triticonazole (TTC) at equipotent concentrations based on morphological evaluation. Results showed that compounds differed in their regulation of major anti-fungal and developmental toxicity pathways, steroid biosynthesis and retinol metabolism, respectively. Assuming that the ratio between these pathways is relevant for efficacy compared to developmental toxicity, we found TTC was more efficacious and CYP was more toxic compared to the other triazoles. MYC showed a different response similar to the high toxic concentrations of FLU. We here demonstrated that gene expression data allow more comprehensive assessment of compound effects by discriminating relative potencies using these specific gene sets. The zebrafish embryo model can therefore provide information on relative pathway sensitivity related to intended mechanism of action and toxicological activity of compounds.

**PS 1454 Early-Life Exposure to Methylmercury and Multiple Stressors: *Daphnia pulex* As an Alternative Model System to Evaluate Long-Term Effects.**

D. Doke and J. M. Gohlke. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

While human populations are exposed simultaneously to chemical stressors and physical factors including temperature and differing nutrition, safe limits of exposure are based primarily on tests using single chemicals. Due to the high cost and time required to test mixtures in traditional animal models, development of novel model systems are of critical importance. We are currently evaluating *Daphnia pulex*, a standardized USEPA and OECD ecotoxicology model system and an NIH model organism for biomedical research, as a tool for assessing long-term effects of early life exposures to multiple stressors. As a case study, we are examining the interaction between MeHg exposure and varying temperature regimes and nutrition. We hypothesize that: Early life exposures in high temperature or a low food regime will increase MeHg toxicity as measured by reproduction and lifespan in *Daphnia pulex*. *D. pulex* were exposed to a matrix of three temperature regimes emulating standard laboratory conditions versus natural environment daily fluctuations, three feed rates and five concentrations (200ng/l to 1000ng/l) of MeHg as methylmercury (II) chloride. Data evaluating lifespan and fecundity across the temperature regimes suggest that although there are no significant differences in time to first reproduction, *D. pulex* lifespan and fecundity were increased in daily fluctuating versus constant temperature regimes. This indicates that subtle differences in lifespan can be detected across standard laboratory thermal conditions and those that would be experienced in a natural environment. Subsequent work will evaluate interactions. Since current alternative model systems are not designed to evaluate long-term effects of early life exposures, our research is designed to evaluate the utility of *D. pulex* as a complementary model system.

**PS 1455 A Rapid Chemical Screening Platform in *C. elegans* for Assessing Environmental Germline Disruption.**

P. Allard<sup>1</sup>, N. Kleinstreuer<sup>3</sup>, T. B. Knudsen<sup>3</sup> and M. Colaiacovo<sup>2</sup>. <sup>1</sup>*Environmental Health Sciences, UCLA, Los Angeles, CA;* <sup>2</sup>*Genetics, Harvard Medical School, Boston, MA;* <sup>3</sup>*NCCT, US EPA, Research Triangle Park, NC.*

Despite the developmental impact of errors in chromosome segregation, we lack the tools to comprehensively assess environmental effects on meiotic integrity in animals. Here, we report the development of an assay in *C. elegans* that fluorescently marks aneuploid embryos following chemical exposure. We qualified the predictivity of the assay against chemotherapeutic agents as reference compounds, as well as environmental compounds with comprehensive mammalian in vivo endpoint data. The assay was highly predictive of mammalian reproductive toxicities with a maximum specificity of 78%. Finally, we validated selected compounds from the screen by analyzing germline maintenance following exposure. With this novel approach, we provide the first high-throughput screening strategy for the assessment of environmental effects on the germline.

**PS 1456 Cytotoxic Effects of Methyl-Mercury in Whole Worms and Pan-Neuronal GFP-Expressing Embryonic Cultures of *Caenorhabditis elegans*.**

K. Breithaupt<sup>1</sup>, R. K. Hajela<sup>1,2</sup> and W. D. Atchison<sup>1,2</sup>. <sup>1</sup>*Neuroscience Program, Michigan State University, East Lansing, MI;* <sup>2</sup>*Pharm/Tox, Michigan State University, East Lansing, MI.*

*Caenorhabditis elegans* (*C. elegans*) strain KC136 was used to study whole worm viability in response to methylmercury (MeHg) toxicity in a semifluid gellan gum medium. Stage L3 KC136 whole worm viability is reduced by exposure to 0.5-25  $\mu$ M MeHg ( $p=0.0001$ ) for 24-48 hrs. At the highest [MeHg] tested, cytotoxicity was 54% and time of exposure (24 and 48 hrs) did not have an effect ( $p=0.15$ ). *C. elegans* strain NW1229, which expresses pan-neuronal Green Fluorescent Protein (GFP), was used to prepare primary cell cultures from eggs to test the ability of the nemadipine-A to reduce the cytotoxicity of MeHg in worm neurons. Nematodipine-A is a novel dihydropyridine (DHP) L-type voltage gated  $Ca^{2+}$  channel antagonist and we hypothesize it has a similar effect as we have previously reported for the non-DHP-type antagonist verapamil. At [MeHg] of 0.4-1.2  $\mu$ M, cytotoxicity in neurons was both concentration and time dependent as determined by ethidium homodimer viability assay. Thus the results obtained in whole worms differ somewhat from those of isolated neurons relative to time-dependence of cytotoxicity. As previously reported, verapamil reduced MeHg-induced cytotoxicity by ~10% at 1 hr of exposure, however, lost its protective effect at 3 hrs ( $p=0.08$ ). Similarly, nemadipine-A (0.25-1  $\mu$ M) protected neurons against MeHg toxicity at 1 hr ( $p=0.033$ ), but not 3 hrs of exposure. The reduction of MeHg-induced cytotoxicity by L-type  $Ca^{2+}$  channel antagonists at early stages of exposure suggests that L-type  $Ca^{2+}$  channels contribute to MeHg mediated neuronal cell death in *C. elegans*, just as they do in mammalian neurons. The lack of correlation between time and exposure to MeHg may result from upregulation of genes for proteins involved in metal detoxification. Using *C. elegans* neuronal cultures as a model system for MeHg neurotoxicity may help uncover why certain neurons are more susceptible to MeHg-induced cell death furthering our understanding of the underlying mechanisms.

**PS 1457 MTBE Disrupts HIF1-Vegf Regulated Angiogenesis in Zebrafish (*Danio rerio*).**

J. A. Bonventre<sup>1,2</sup>, T. S. Kung<sup>2</sup>, L. A. White<sup>2</sup> and K. R. Cooper<sup>2</sup>. <sup>1</sup>*EMT, Oregon State University, Corvallis, OR;* <sup>2</sup>*JGPT, Rutgers University, New Brunswick, NJ.*

Understanding the sensitivity of developing vascular networks to toxic insult is important to advancing vascular biology. Methyl tert-butyl ether (MTBE) induces vascular lesions in the zebrafish embryo, including pooled blood in the common cardinal vein (CCV), cranial hemorrhages (CH), and abnormal intersegmental vessels (ISV). The transcript levels of two isoforms of vascular endothelial growth factor, *vegfa* and *vegfb*, as well as a primary receptor, *vegfr2*, are significantly decreased during the critical period (6-somites to Prim-5). The vascular lesions were hypothesized to be a result of the MTBE-induced down-regulation of *vegfa*. An over-expression study was conducted to rescue MTBE-induced vascular lesions. Over-expression of zebrafish *vegfa* resulted in 46% fewer animals exhibiting MTBE-induced CH and 35% fewer embryos exhibiting abnormal ISV, while no rescue was observed for the CCV lesion. Global gene expression changes during the critical period, assayed with the Affymetrix GeneChip® and analyzed with Ingenuity Pathway Analysis®, identified the cardiovascular system as a primary pathway altered by MTBE exposure, as well as other pathways associated with hypoxia inducible factors (HIFs). Two further rescue studies were designed to block HIF1 $\alpha$  degradation to test the hypothesis that MTBE toxicity was HIF1 $\alpha$ -dependent. Chemical inhibition of HIF1 $\alpha$  degradation, by blocking prolyl-4-hydroxylase activity with N-oxalylglycine, rescued both the CCV lesion (24%) and CH (32%). Knockdown of a ubiquitin ligase component, von Hippel-Lindau protein, with an anti-sense morpholino rescued only the CCV lesion (35%). Rescue of MTBE-induced vascular lesions by over-expression of *vegfa* and inhibition of HIF degradation demonstrated that MTBE toxicity is mediated by a down-regulation of HIF driven Vegf at a critical period during the developing cardiovascular system. Chemicals with anti-angiogenic properties, such as MTBE, can be used to advance the science of angiogenesis in both a disease state and during development. Funding: ES07148, ES05022

**PS 1458 An In Vitro Placental Model Using BeWo Cells for the Prediction of Placental Transfer of Compounds.**

H. Li<sup>1</sup>, B. van Ravenzwaay<sup>1,2</sup>, I. Rietjens<sup>1</sup> and J. Louisse<sup>1</sup>. <sup>1</sup>*Division of Toxicology, Wageningen University, Wageningen, Netherlands;* <sup>2</sup>*Experimental Toxicology and Ecology, BASF SE, Ludwigshafen, Germany.*

The use of reverse dosimetry for in vitro-in vivo extrapolation (IVIVE) enhances the use of in vitro toxicity data for risk assessment (Louisse et al., 2010). With reverse dosimetry, in vitro toxic effect concentrations are translated to in vivo doses using physiologically based kinetic (PBK) modelling. For the PBK models needed for reverse dosimetry, parameter values for kinetic processes need to be obtained, such as for intestinal absorption, metabolism and placental transfer. The present study aims to assess whether an in vitro model for the placental barrier, consisting of human placental BeWo cells, could be used to predict the placental transfer kinetics of compounds. To this end, BeWo cells were grown on transwell inserts to form a confluent monolayer, thereby separating an apical maternal compartment from a basolateral fetal compartment. For a set of 9 compounds the transport velocity from the apical to the basolateral compartment was determined in this model. Relative transport rates obtained in this model were compared with the relative transport rates of these compounds calculated from data of ex vivo human placental perfusion studies reported in the literature (Hewitt et al., 2007). The relative transport rates in the BeWo model were in good correlation ( $R^2=0.95$ ) with the relative transport rates calculated for the ex vivo model (Li et al., submitted). This indicates that the BeWo model can be useful in the prediction of the transplacental transfer of compounds and for obtaining model parameter values for PBK that can be used for reverse dosimetry.

**PS 1459 Controlled Hemodynamics and Transport in Primary Hepatocytes Shift Induction and Toxic Responses to Drugs Closer to In Vivo Concentrations.**

A. Dash, T. Deering, J. Thomas, B. R. Blackman and B. R. Wamhoff. *Liver Surrogate Systems, Ajit Dash, Charlottesville, VA.*

Preclinical in vitro drug screening systems exhibit efficacy and toxicity responses to concentrations very different from corresponding clinical or in vivo plasma C<sub>max</sub> levels, contributing to poor in vitro-in vivo correlations. We established a primary hepatocyte system using controlled hemodynamics and transport that retains polarized morphology and metabolic function more stably than traditional static cultures. We tested the hypothesis that restoring these critical parameters could achieve in vitro hepatocyte drug response at concentrations closer to in vivo levels. Fresh rat hepatocytes were cultured under controlled hemodynamics alongside static controls for 5 days before treating with various concentrations of test drugs (dexamethasone, acetaminophen, chlorpromazine) for 2 days. Cytotoxic response was evaluated by MTT and ATP assays and cytochrome p450 activity by standard kits. Under controlled hemodynamics, dexamethasone was significantly more toxic to primary hepatocytes at concentrations used for induction studies in static cultures ( $93.31 \pm 5.26\%$  vs.  $32.8 \pm 9.5\%$  at  $50 \mu\text{M}$ ,  $p < 0.01$ ). Induction responses of Cyp3A activity equivalent to  $50 \mu\text{M}$  of dexamethasone in static cultures were seen at  $2.5 \mu\text{M}$  under controlled hemodynamics. Cytotoxic dose response curves of acetaminophen demonstrated a leftward shift with IC<sub>50</sub> values at  $10 \mu\text{M}$  in devices compared to  $30 \mu\text{M}$  in static cultures. A similar shift in cytotoxic response was seen with chlorpromazine with induction of Cyp1A activity in a dose dependent manner at sub lethal concentrations. We demonstrate that control of transport and hemodynamics in a primary hepatocyte system results in induction and toxicity responses to drugs at concentrations significantly lower than static systems and closer to in vivo levels. The retention of in vivo-like hepatocyte phenotype and metabolic function coupled with drug response at more physiological concentrations emphasizes the importance of restoring in vivo physiological transport parameters in vitro.

**PS 1460 Validation of In Vitro Systems to Explore Mechanisms of Striated Muscle Toxicity.**

W. Dott<sup>1</sup>, J. Wright<sup>2</sup>, P. Mistry<sup>2</sup> and K. Herbert<sup>1</sup>. <sup>1</sup>*Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom;* <sup>2</sup>*Product Safety, Syngenta, Bracknell, United Kingdom.* Sponsor: P. Botham.

The validation of in vitro cardiac and skeletal muscle models of toxicity may find a utility in predicting toxicity early within the research and development process. The primary aim of this project was to investigate the extent of translation from an in vivo to an in vitro, system, using a toxicogenomics approach. Female Han Wistar rats were dosed daily via the diet with sulfonyl isoxazoline (SI) chemistries for 4 or 28 days. Histopathological evaluation revealed a dose-dependent myositis and myodegeneration in striated muscle. Gene expression profiling of cardiac and skeletal

muscle tissues taken from sub-toxic doses identified a number of perturbed cellular pathways including: mitochondrial dysfunction, altered energy metabolism, oxidative stress, cell cycle and apoptosis. This data provided a plausible hypothesis which suggested mitochondrial toxicity as a principle mechanism of SI-induced striated muscle toxicity. To investigate the translation of this toxicity to an appropriate in vitro system cardiac (H9c2) and skeletal muscle (L6) cell lines were selected. A cell based assay was developed in which the cardiac and skeletal muscle cells were adapted to use mitochondrial oxidative phosphorylation rather than glycolysis. This system identified the SI compounds as mitochondrial toxicants. In addition there was a significant increase in mitochondrial reactive oxygen species, which provided further evidence of mitochondrial perturbation. SI treatment also induced cellular hypertrophy, accompanied by cell cycle arrest, and subsequent caspase-mediated apoptosis. These in vitro results were consistent with the transcriptomics data, providing further validation that the cell systems models may have utility for predicting striated muscle toxicity. Future work will be aimed at exploring tissue-specific toxicity using higher tier in vitro models (liver, muscle bioreactor flow through systems) which might better represent the in vivo system.

**PS 1461 3D Liver Models for Investigating Drug-Induced Hepatotoxicity.**

E. Jain<sup>1</sup>, M. Ehrlich<sup>2</sup>, T. Murali<sup>3</sup> and P. Rajagopalan<sup>1</sup>. <sup>1</sup>*Department of Chemical Engineering, Virginia Tech, Blacksburg, VA;* <sup>2</sup>*Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA;* <sup>3</sup>*Department of Computer Science, Virginia Tech, Blacksburg, VA.*

Testing the toxic effects of chemicals has traditionally relied on large-scale animal studies. In addition to being extremely expensive, this strategy has come under scrutiny for its over-reliance on laboratory animals, and the need to extrapolate results from animals to humans. In vitro tissue mimics are a promising avenue for studying the effects of toxicants. Such systems can serve as reliable models of in vivo structures and can be systematically probed with a wide range of cues. Since they are engineered, experimentation on these mimics is considerably less complex than those needed to probe tissues and organisms in vivo. We have designed a novel 3D organotypic liver model assembled with three cell types (hepatocytes, liver sinusoidal endothelial cells and Kupffer cells) and a polyelectrolyte multilayer (PEM) that mimics the Space of Disse. We have established a dose range ( $20\text{--}40\text{mM}$ ) for acetaminophen in 3D liver models that is non-lethal yet is capable of perturbing hepatic function. When acetaminophen was administered 4 days after hepatocytes were obtained from rat livers, conventional monolayer, collagen sandwich and 3D liver model cultures showed a small decrease in cell viability. When the drug was administered at day 12, only the 3D liver models showed a decrease in viability. All cultures exhibited a decrease in albumin production and urea secretion. The 3D liver models exhibited better urea secretion than monolayer and collagen sandwich cultures. Intracellular glutathione levels were measured for all three cultures. 3D liver models exhibited approximately 40% decrease in glutathione in comparison to monolayer and collagen sandwich cultures that exhibited greater than 60% decrease. These trends suggest that the inclusion of non-parenchymal cells in the 3D liver model may impart cytoprotective effects and present an in vivo like environment.

**PS 1462 In Vitro Cell Models: Moving from Tumor Cell 'Monsters' to Differentiating Immortalized- or Stem Cells.**

D. Gerhold, D. Kuo, Z. Tong, J. Braisted, M. Xia, A. Simeonov and C. P. Austin. *Tox21 Consortium, NIH-National Center for Advancing Translational Sciences (NCATS), Rockville, MD.*

The Tox21 Consortium aims to develop in vitro quantitative High Throughput Screening (qHTS) using human cells and targets to replace animal testing. In screening for cytotoxicity, primary human cells make useful models, but results from primary cells are irreproducible and the cells are problematic to obtain. At the other extreme, transformed cell lines are readily available and reproducible, but are often poor representations of normal human tissues. Between these extremes, immortalized cells or differentiated stem cells provide reliable phenotypic models for neurons, kidney proximal tubule epithelial cells or podocytes, cardiomyocytes, vascular endothelial cells, and hepatocytes. We are evaluating cell models for these cell types by evaluating susceptibilities to toxicants that are organ-selective in vivo. Efforts are also underway to adapt such cells that require differentiation to qHTS in 1536-well plate format. Gene expression profiling is being leveraged to dissect the modes of cytotoxicity, and to determine why in vitro models succeed for some compounds and fail for others. We will present the evaluation of several such toxicological models vis-à-vis: differentiated phenotypes, cytotoxicity assays, and gene expression profiling.

**PS 1463 Potential Cholestatic Compounds Assessed by Membrane Transport Vesicle Assays As Well As Bile Canaliculi Inhibition in Primary Hepatocytes in Both Human and Rat.**

L. Qiu<sup>1</sup>, M. Taimi<sup>2</sup>, C. Strock<sup>2</sup>, J. Gilbert<sup>2</sup> and Y. Will<sup>1</sup>. <sup>1</sup>Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT; <sup>2</sup>Apredica, Watertown, MA.

BSEP (Bile Salt Export Pump) inhibition has been proposed as a mechanism for drug-induced cholestasis, a subtype of drug induced liver injury (DILI). Screening systems for BSEP inhibition have been established in membrane vesicles from Sf9 insect cells over-expressing rat or human BSEP transporter. However, as any cell-free assay, the data from vesicle assays might not reflect true BSEP inhibition profile due to lack of biotransformation and metabolism. In addition, the contribution of MRP2 (Multidrug resistance-associated protein 2) to drug induced liver cholestasis also needs to be considered.

In this study, we examined 18 potential cholestatic compounds, which were either known to be BSEP inhibitors, dual inhibitors for BSEP and MRP2 or glutathione depleters, in both human and rat BSEP and MRP2 vesicle assays. Moreover, a high-content imaging assay using fluorescent selective substrates for BSEP and MRP-2 transporters including CMFDA and CLF, was used to examine these compounds in inhibition of bile canaliculi excretion in both human and rat sandwich-cultured hepatocytes. In addition, CMFDA and CLF were characterized for their ability as uptake substrates for BSEP and MRP2 transporters.

We found that both, CMFDA and CLF were not selective for BSEP transport since they were also potent MRP2 substrates. Vesicle and hepatocyte canaliculi inhibition data showed no substantial species difference between human and rat, for either transporter.

Furthermore the vesicle data correlated well with the hepatocyte canaliculi data. However, for a few compounds the vesicle data did not translate into hepatocyte canaliculi data probably due to impact of cell-based effects such as metabolism or permeability.

In conclusion, to better predict drug-induced cholestasis, a larger set of compounds with known clinical DILI outcomes need to be tested in both vesicle and hepatocyte canaliculi assays in order to elucidate the mechanisms involved in liver toxicity.

**PS 1464 Development of Alternative *In Vitro* Methods to Screen for Pulmonary Toxicities—Characterization of Epithelial-Macrophage Coculture and *In Vitro* Assay Conditions at the Air-Liquid Interface (ALI).**

S. P. Ng and D. B. Warheit. DuPont Haskell Global Centers for Health & Environmental Sciences, Newark, DE.

The successful development of *in vitro* assays with cultured pulmonary cells and aerosols is instrumental for creating toxicity/screening tests for use during product development. To optimize for future *in vitro* aerosol exposures using the Nano-Aerosol Chamber for In Vitro Toxicology system, rat lung epithelial L2 cells and NR8383 macrophages (MØ) were co-cultured on an ALI system and cell metabolism (XTT), cytotoxicity (LDH), and cytokine (IL-6) release assays were developed as endpoints to assess cell toxic effects following particle exposures. Co-cultures were exposed to 0-80 µg/cm<sup>2</sup> ZnO fine particles in supplemented growth medium for 2 hrs followed by 24-hr maintenance of cultures at ALI. Results showed that both XTT and LDH assays performed with cells co-cultured at the ALI were able to detect toxicity in a dose-response manner. Cytotoxic effects measured following 20 µg/cm<sup>2</sup> ZnO particle exposures (i.e., -LC<sub>50</sub>) increased with epithelial cell:MØ (L2:NR8383) ratios, revealing that the seeding ratio strongly affects the assay sensitivity. In a separate study, optimization for cytokine release assay performed with different cell seeding densities and L2:NR8383 ratios showed the highest IL-6 release (~2.5 ng/mL) from cultures seeded at 0.5E5/cm<sup>2</sup> in a 2:1 ratio and maintained at ALI for 1 day. Maximum stimulation of IL-6 release was detected from the optimized cultures 4- and 24-hr post-exposure to low dose (2.5 µg/cm<sup>2</sup>) ZnO (200-300% of medium-exposed controls); IL-6 release was suppressed to 0-50% of controls after relatively high-dose ZnO (>10 µg/cm<sup>2</sup>) exposures. In conclusion, these studies are useful in characterizing and optimizing the co-culture and *in vitro* assay conditions with ALI which could better simulate *in vivo* exposure of lung cells to inhaled materials (when compared to a submerged exposure system) and ultimately should facilitate the development of reliable *in vitro* cell exposure systems and cell-based lung toxicity/screening tests.

**PS 1465 Predicting Heart-Specific Toxicity Using Two Cell Models: Human iPS-Derived Cardiomyocytes and Human Liver Cells (HepaRG).**

P. C. Wilga, D. Keller, B. Franz and J. M. McKim. CeeTox, Inc., Kalamazoo, MI.

A major reason for the failure of new drugs is due to adverse effects in the cardiovascular system. An *in vitro* model capable of identifying heart-specific liabilities would be of considerable value. To differentiate heart toxicity from liver toxicity, a dual cell model was developed that utilizes changes in cell health and function following exposure to a test drug. Human cardiomyocytes and normal human liver cells were used as the test system. Cardiomyocytes were derived from induced pluripotent stem cells (iPS) obtained from Cellular Dynamics International. Terminally differentiated bi-potent HepaRG cells were from Life Technologies. Each cell type was established in a 96-well format and prepared in triplicate wells for each concentration. Markers of cell health (ATP, LDH leakage, and GSH) were monitored in both cell types. Additional information was collected for beat rate (BR) in heart cells and endpoints were monitored over concentration and time. The concentration-response curves were compared using mean IC<sub>50</sub> values. Beat rate (BR) was measured using the xCelligence RTCA Cardio system (ACEA). To test the model, hepatotoxic (camptothecin (CAMP), rotenone (ROT)) or cardiotoxic (doxorubicin (DOX), mitoxantrone (MTX)) compounds were used. These were added to cells at concentrations of 0, 0.1, 1, 10, and 100 µM and exposed for 24 hr. In addition, drugs known to produce QT prolongation (Terfenadine (T) and verapamil (V)) were included and the BR determined. T and V significantly reduced BR at a concentration of 0.3 µM. To determine heart (H) or liver (L) specificity, average IC<sub>50</sub> values were obtained for each cell type and the H-to-L ratio calculated. H-to-L ratios were MTX = 0.5, DOX = 2.6, ROT = 0.02 and CAMP undetermined. Ratios < 1.0 indicate cardiotoxicity, those >1.0 but < 3 indicate toxicity in both models, while ratios >3 indicate hepatotoxicity. BR data was used to improve these predictions. The combined data provided better resolution and enabled cardiac toxicity to be determined with greater confidence.

**PS 1466 Predicting Respiratory Sensitization Using Activation of Nrf2/ARE Genes in a Human Reconstructed Airway Model.**

J. A. Willoughby, D. Keller, P. C. Wilga and J. M. McKim. CeeTox, Inc., Kalamazoo, MI.

Current *in vitro* methods for determining sensitization have focused on skin sensitization and provide data on hazard, but are unable to predict potency. The aim of this study was to determine if a new method known as SenCeeTox®, originally developed to detect skin sensitizers, could also identify respiratory sensitizers and provide potency. The EpiAirway™ model from MatTek Corp. was used as the test system. Viability, test article reactivity, and the expression of genes controlled by Nrf2/ARE (NADPH Quinone oxidoreductase (NQO), aldoketoreductase (AKR), interleukin-8 (IL8), aldehyde dehydrogenase (ADH), heme oxygenase-1 (HMOX1), and glutamate cysteine-ligase catalytic subunit C (GCLC)) were monitored. CYP1A1 was monitored to identify proallergens. Test solutions of p-benzoquinone (BQ), benzoic acid (BA), glycerol (Gly), cinnamic aldehyde (CA), toluene diisocyanate (TDIC), and oxazolone (OX) were prepared in DMSO. Each test agent was evaluated in a glutathione depletion assay (GSH) and then applied apically to the tissue at concentrations of 0, 100, 250, 500, and 2500 µM. Following 24 hr incubation, total RNA was isolated and changes in gene expression determined by qRT-PCR. Tissue viability was monitored by MTT. BQ reduced viability to 73% at 2500 µM, depleted GSH by 70% and induced NQO, AKR, CYP1A, ADH, HMOX1 and GCLC. Oxazolone reduced viability to 56% at 2500 µM, depleted GSH by 92% and induced GCLC. TDIC had no effect on viability, depleted GSH by 26% and induced GCLC. CA had no effect on viability, depleted GSH by 22% and induced GCLC. Glycerol and benzoic acid had no effect on viability or GSH depletion, but did produce a positive response on GCLC. These data provided a rank order of potency from highest to lowest of BQ > OX > TDIC > CA >> BA and Glycerol. This ranking is consistent with reported sensitization potency categories for these chemicals. In conclusion, Nrf2/ARE signaling pathways are intact in the EpiAirway™ tissue and that this model may provide a means of accurately identifying respiratory sensitizers.

**PS 1467 Measurement of Phagocytic Activity in Rats with the Phagotest® Kit.**

J. Legrand<sup>1</sup>, C. Mimouni<sup>1</sup>, M. Valin<sup>1</sup>, N. Pearson<sup>1</sup>, R. Forster<sup>1</sup> and J. Descotes<sup>2</sup>. <sup>1</sup>CiToxLAB, Evreux, France; <sup>2</sup>Poison Center, Lyon, France.

Very few tools are available to assess phagocytosis, a major functional component of the innate immune system, during nonclinical immunotoxicity studies. The objective of the present study was to evaluate the feasibility of the Phagotest® in rats.

Phagotest® (Glycotope Biotechnology, Berlin, Germany) is routinely used in clinical immunology laboratories to assess phagocytosis in humans. It allows the quantitative determination of leukocyte phagocytosis by measuring the percentage of phagocytes that have ingested bacteria and the number of ingested bacteria per cell. In the present study, 2 ml samples taken from 6 male and 6 female Sprague-Dawley rats onto heparin lithium tubes were incubated with FITC-labeled *E. coli* bacteria at +37°C. Thereafter, phagocytosis was stopped by placing the samples on ice and adding a quenching solution. After washing and erythrocyte lysis, a DNA staining solution was added prior to flow cytometry analysis using a XL MCL flow cytometer with the Expo 32 ADC software (Beckman Coulter, France). The percentage of phagocytizing cells (granulocytes and monocytes, differentiated by side scatter and forward scatter) and their mean fluorescence intensity (number of ingested bacteria) were determined in four independent runs. The mean  $\pm$  SD of the percentage of phagocytizing granulocytes was found to be  $84.4 \pm 5.0$  for males and  $86.2 \pm 11.02$  for females, and the mean  $\pm$  SD of the percentage of phagocytizing monocytes,  $51.6 \pm 8.3$  for males and  $55.5 \pm 11.7$  for females. Intra-individual precision (CV%) was between 10.4% and 13.6% for males, and between 18.1% and 24.2% for females. These results demonstrate that the Phagotest® kit can be used to assess phagocytosis in rats as it is in humans.

### PS 1468 Thirdhand Smoke: Extraction and Cytotoxicity.

V. Bahl<sup>1,2</sup>, P. Jacob<sup>3</sup>, C. Havel<sup>3</sup>, S. Schick<sup>3</sup>, T. Mao<sup>3</sup> and P. Talbot<sup>1</sup>. <sup>1</sup>Department of Cell Biology and Neuroscience, University of California Riverside, Riverside, CA; <sup>2</sup>Environmental Toxicology Graduate Program, University of California Riverside, Riverside, CA; <sup>3</sup>University of California San Francisco, San Francisco, CA.

Thirdhand smoke (THS) consists of chemicals that remain in indoor environments after secondhand smoke has cleared. The purpose of this study was to develop an extraction protocol for THS and evaluate its cytotoxicity using terrycloth exposed to cigarette smoke for 110 hours over 334 days and stored at room temperature (RT). THS was extracted in DMEM culture medium at different temperatures and for different lengths of time, and concentrations of nicotine, and related chemicals in the extracts were measured. Highest concentrations of nicotine, cotinine, nicotilline, anataline, N-formynornicotine, 2,3'-bipyridine, N'-nitrosornicotine (NNN) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) were present in the extracts made at RT for 1 hr. However, highest concentrations of 1-(N-methyl-N-nitrosamino)-1-(3-pyridinyl)-4-butanal (NNA) and myosmine were in the 1 hr extract made at 4°C. The 1 hour, RT extract had 144 µg of nicotine per gram of terrycloth. A terrycloth bathrobe, weighing 450 g and similarly exposed to smoke, would contain 64 mg of nicotine, which is higher than the LD50 dose for humans. Cytotoxicity was assayed using mouse neural stem cells. The extract made at RT for 1 hr was more cytotoxic than that made for 2 hrs. However, when extracted at 4°C, the 2 hr extract was more cytotoxic. Prolonging the extraction time to 24 hours at RT caused complete loss of cytotoxicity, whereas extracting for 24 hours at 4°C helped to preserve some activity. Extracts made with lower headspace volume were more cytotoxic than when the headspace volume was large, presumably due to better preservation of volatile chemicals. In general, the extract made for 1 hr at RT was most cytotoxic, killing cells at the full strength and 30% dose. These data are consistent with the interpretation that cytotoxicity of THS extracts resides in the volatile fraction and that extraction conditions are critical when quantifying chemicals in THS.

### PS 1469 Prevalidation of the Ex Vivo Model Precision Cut Lung Slices (PCLS) for the Prediction of Respiratory Toxicology.

K. Sewald<sup>1</sup>, L. Lauenstein<sup>1</sup>, S. Vogel<sup>2</sup>, A. Hess<sup>2</sup>, X. Schneider<sup>3</sup>, C. Martin<sup>3</sup>, R. Pirow<sup>4</sup>, M. Liebsch<sup>4</sup>, R. Landsiedel<sup>2</sup> and A. Braun<sup>1</sup>. <sup>1</sup>Fraunhofer ITEM, Hannover, Germany; <sup>2</sup>BASF Ludwigshafen, Germany; <sup>3</sup>RWTH, Aachen, Germany; <sup>4</sup>BfR ZEBET, Berlin, Germany. Sponsor: C. Dasenbrock.

**Introduction:** For acute inhalation toxicity studies, animals inhale chemicals. At the beginning it is difficult to estimate non-toxic doses for *in vivo* inhalation. In the context of REACH and the principle of 3Rs, there is a public demand for alternative methods. The goal of this BMBF-funded project is the pre-validation of PCLS as a suitable *ex vivo* alternative model to replace pre-studies of inhalation toxicology. The project is conducted in three independent laboratories. BfR provides support in biostatistics.

**Methods:** In all participating laboratories, PCLS were prepared and exposed to 5 concentrations of industrial chemicals in DMEM under standard culture conditions for 1 hour. After post-incubation, chemical-induced toxicity was assessed by LDH and WST-1 assay. In addition, PCLS protein content and pro-inflammatory cytokine IL-1 $\alpha$  were measured by BCA assay and ELISA, respectively. For all endpoints a sigmoid dose-response model was fitted to the data and EC<sub>50</sub> values were calculated. Test acceptance criteria were established for each endpoint.

**Results:** This study shows the results of the first 6 tested substances out of 20. In all laboratories, concentration dependent toxicity could be shown for aniline, glutaraldehyde, triton X-100 and paracetamol, but not for lactose and methyl methacrylate. EC<sub>50</sub>-values obtained for the WST-1, LDH and BCA data were very similar in all participating laboratories. No increase in IL-1 $\alpha$  was observed for these chemicals.

**Conclusion:** Local respiratory toxicity induced by chemicals could be tested with comparable results in the PCLS model without *in vivo* experiments in three independent laboratories. The standardization of the PCLS method was successful and the reproducibility of the results is very promising after testing of the first 6 substances.

### PS 1470 High-Content Analysis of Drug-Specific Neurotoxic Effects on Rat Dorsal Root Ganglion Cells.

H. P. Behrsing<sup>1</sup>, F. M. Cutuli<sup>1</sup>, M. Davis<sup>2</sup> and R. E. Parchment<sup>1</sup>. <sup>1</sup>Laboratory of Investigative Toxicology, Applied/Developmental Research Directorate, SAIC-Frederick, Frederick National Lab. for Cancer Research, Frederick, MD; <sup>2</sup>Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD.

The incidence of chemotherapy-induced peripheral neuropathy (CIPN) is increasing because more neurotoxic drugs are being developed and these are increasingly administered in combinatorial regimens to longer living cancer patients. To evaluate neurotoxic drugs, a high content analysis (HCA) strategy was developed to assess response differences of exposed rat dorsal root ganglion cells (DRG). DRG microculture wells were exposed to CIPN-inducing drugs (up to 1 µM) for 24 hr. After exposure, treatment medium was removed and cells were fixed, or were given fresh culture medium and allowed to "recover" for 24 or 72 hr prior to fixation. DRG were fluorescently stained for nuclei, acetyl- $\alpha$  tubulin, and Nissl bodies. Four of the six drugs evaluated caused concentration-specific changes in acetyl- $\alpha$  tubulin staining (AATS) and total neurite area (TNA) after 24 hr exposure. Eribulin and colchicine were most potent, reducing TNA by 50% at <10 nM, but only colchicine effects were reversible after drug removal (AATS intensity doubled in value and TNA increased >5-fold during the 72 hr recovery period). Taxol moderately decreased TNA (~65% of control), but increased AATS intensity to >150% at 1 µM. Initially, bortezomib notably increased AATS intensity but a later effect included loss of AATS, TNA, and increased cell loss after drug removal. Evaluation of Nissl staining areas also showed drug-specific changes in response to exposure and "recovery". Cisplatin and thalidomide had no effect on the parameters measured. Evaluating cellular response is confounded by low level cytotoxicity and loss of viability over time. The use of HCA has identified several morphological endpoints and biomarkers of rat DRG that may serve as indicators of drug-specific neurotoxic risk. Funded by NCI Contract No. HHSN261200800001E.

### PS 1471 Testing Nanomaterials in Precision-Cut Lung Slices: In Vitro-In Vivo Comparisons.

S. Vogel<sup>1</sup>, A. Aumann<sup>1</sup>, W. Wohlleben<sup>3,1</sup>, S. Treumann<sup>1</sup>, U. G. Sauer<sup>4</sup>, K. Wiench<sup>2</sup>, S. Gröters<sup>1</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Polymer Physics, BASF SE, Ludwigshafen am Rhein, Germany; <sup>4</sup>Scientific Consultancy - Animal Welfare, Neubiberg, Germany.

The usefulness of precision-cut lung slices (PCLuS) in assessing nanomaterial (NM) respiratory toxicity was investigated. The data from testing 16 OECD reference NM (rutile and anatase TiO<sub>2</sub>, CeO<sub>2</sub>, SiO<sub>2</sub>, Ag, coated and uncoated ZnO NM, and different multi-walled carbon nanotubes) in rat PCLuS were related to published *in vivo* acute inhalation toxicity data, and the influence of different test system parameters on test results was evaluated.

After 24-hour exposure to the test substances indicators of oxidative stress (glutathione levels), inflammatory reactions (induction of cytokines: CINC-1/IL-8, MCSF, OSP, TNF alpha, MCP-1 and intracellular IL-1 alpha), cytotoxicity (membrane integrity by LDH release, mitochondrial activity by WST-1 metabolism), and apoptosis (caspase 3/7 activity) were measured in the PCLuS. No concentration-dependent oxidative stress or apoptosis was observed with any NM. Cytokines were induced by most of the NM, with varying. ZnO and Ag induced severe cytotoxicity, whereas the remaining NM induced no or only slight cytotoxicity in the tested concentrations. Histopathological evaluation of the PCLuS revealed only particle uptake into macrophages for most of the NM.

The observed effects in PCLuS by most of the NM not always reflected NM size, NM class, or pulmonary inflammatory reactions *in vivo*. The relevance of the different effects measured in PCLuS for respiratory toxicity *in vivo* needs further investigations.

**PS 1472 A Transcriptomic Comparison between the Neural and Cardiac Embryonic Stem Cell Tests (ESTn and ESTc).**

P. T. Theunissen<sup>1,2</sup>, J. L. Pennings<sup>1</sup>, D. A. van Dartel<sup>3</sup>, J. F. Robinson<sup>1,2</sup>, J. C. Kleinjans<sup>2</sup> and A. H. Piersma<sup>1,4</sup>. <sup>1</sup>Health Protection, RIVM, Bilthoven, Netherlands; <sup>2</sup>Toxicogenomics, University, Maastricht, Netherlands; <sup>3</sup>Human and Animal Physiology, University, Wageningen, Netherlands; <sup>4</sup>IRAS, University, Utrecht, Netherlands.

In vitro screening assays may increase testing efficiency and reduce animal use in developmental toxicity testing. The cardiac mouse embryonic stem cell test (ESTc) is a promising in vitro assay in this field, in which the effect of developmental toxicants on cardiomyocyte differentiation is assessed. To increase prediction of the EST approach, we developed a neural differentiation variant of the stem cell test (ESTn). In both ESTn and ESTc, we performed a series of transcriptomic studies to characterize gene expression changes 1) across time during normal differentiation and 2) in response to a series of developmental toxicants in the ESTn and ESTc. In the present study, gene expression profiles of ESTn and ESTc over time as well as model-specific changes induced by seven compounds are compared. Time-related gene expression profiles showed that specific genes changed over time differently in each model, related to the two specific lineages of differentiation. Interestingly, compound-induced gene-expression changes were generally model-specific, particularly for methylmercury and flusilazole, which were predicted better in ESTn and in ESTc, respectively. Valproic acid-induced gene expression changes were most comparable between ESTn and ESTc. Direct transcriptomic comparisons between the ESTn and ESTc models indicate that both assays support and complement each other. Therefore, a combined transcriptomics approach, incorporating ESTc and ESTn, may result in improved developmental toxicant detection over individual assays.

**PS 1473 In Vitro Proliferation in Human and Rat Urothelial Cells.**

E. L. Bowen<sup>1</sup>, J. Southgate<sup>1</sup>, S. Baker<sup>1</sup> and P. Rawlinson<sup>2</sup>. <sup>1</sup>Jack Birch Unit for Molecular Carcinogenesis, University of York, York, United Kingdom; <sup>2</sup>Syngenta, Bracknell, Berkshire, United Kingdom. Sponsor: R. Peffer.

Despite the regular use of the rat in toxicity studies, which are used for human risk assessment, the extrapolation from rat to humans is often difficult. This study set out to explore the utility of cell culture systems to better understand species differences. As urine is a main route of chemical excretion from the body, the epithelial barrier lining of the bladder (urothelium) may be exposed to higher concentrations of xenobiotics, with the potential for adverse findings. Methods have been successfully developed to culture normal human urothelial (NHU) cells in vitro, with subsequent differentiation to form a functional barrier. With this in mind, equivalent normal rat urothelial cell culture systems were grown from Wistar (NRU-W) and Homozygous Scottish (NRU-HS) rats. They were compared to human cell cultures by exploring their regulation and capacity for proliferation. NHU cells could be propagated beyond passage 6 in serum-free medium, whilst NRU-W could only be maintained up to passage 1, and NRU-HS cells required serum to grow to passage 1. By immunofluorescence, NHU cells were shown to express nuclear Ki67 and cyclin D1, but the same proliferation markers were cytoplasmic in NRU cells. In contrast, Ki67 was virtually negative in histological sections of human and HS rat urothelium, but strongly expressed (nuclear) in Wistar. The results for human urothelium reflect the fact it is mitotically-quiet, and has a low rate of turnover in vivo, but has a large capacity for regeneration, which can be seen in culture. It appears that there may be fundamental differences in the way in which rat urothelium is regulated, with cells maintained in the cell cycle in vivo and with a less proliferative phenotype observed in vitro. Future work will aim to further characterise these differences, and to understand the consequence of these findings for the development of a comparative model.

**PS 1474 In Vivo-In Vitro Comparison of Respiratory Tract Toxicity Using Human 3D Airway Models and Human A549 and Mouse 3T3 Monolayer Cell Systems.**

U. G. Sauer<sup>3</sup>, S. Vogel<sup>1,2</sup>, A. Hess<sup>1</sup>, S. N. Kolle<sup>1</sup>, L. Ma-Hock<sup>1</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Performance Chemicals - Master Data, Product Safety, Product Stewardship, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Scientific Consultancy - Animal Welfare, Neubiberg, Germany.

Four in vitro systems to predict acute inhalation toxicity were evaluated. 19 substances (lactose, paracetamol, methylmethacrylate, aniline, acetic- and trimellitic anhydride, N-hexylchloroformate, octanoyl chloride, isophorone and toluene diisocyanate, zinc oxide, paraquat, glutar- and formaldehyde, acetone, ethanol, dimethylformamide, ammonium hexachloroplatinate and sodiumdodecylsulfate)

were tested in 3D human airway epithelial models, EpiAirway™ and MucilAir™, and in A549 and 3T3 monolayer cell cultures. Cytotoxicity was assessed by determining LDH release and MTT or WST reduction.

IC50 values were compared to literature rat 4-hour LC50 values classified according to the US EPA and GHS hazard categories. Best results were achieved with a prediction model identifying non-toxic substances (determination of LDH release in 3T3 cells: sensitivity 1.00 and specificity 0.89).

Further predictions of in vivo hazard categories based on four in vitro hazard categories resulted in mediocre correlations: 9 of 19 test substances were classified concordantly in the MucilAir™ system determining MTT reduction and 8 of 19 in A549 cells determining WST reduction. Concordance could be improved by excluding substances leading to pulmonary edema and emphysema in vivo.

None of the test systems was outstanding; and there was no evidence that the use of 3D or monolayer systems using respiratory tract cells provide an added value to simple 3T3 monolayers. However, the test systems only reflected bronchiole epithelia and alveolar cells and only investigated cytotoxicity so that effects occurring in other cells by other mechanisms were not recognized.

**PS 1475 Neurotoxicity In Vitro: Assessment of the Predictivity of Neuronal Networks Coped to Microelectrode Arrays for Identification of Neurotoxicants.**

H. Hüner, T. Ramirez, T. Weisschu, N. Stein, B. van Ravenzwaay and R. Landsiedel. *Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany.*

A challenging aspect to assure the safety of a product is the assessment of its neurotoxic hazard potential. Currently, only in vivo methods are regulatorily accepted and so far, no in vitro model has been fully validated. The majority of the test systems are reduced to the analysis of cytotoxicity in immortalized cell lines, without including unique characteristics of the nervous system, such as axonal transport, synaptic transmission or its electrophysiology. Recently, with the advance in technology and the ability to maintain neuronal models for prolonged periods, a test system emerged, combining the use of microelectrode arrays (MEAs) and in vitro culture of 2D neuronal networks (NN). Herein, we report on the in-house validation of the NN MEA assay using a set of 43 compounds with known neurotoxic and non-neurotoxic potential with the aim to use it for screening of compounds under development. The results demonstrate that the methods presents a sensitivity of 71%, while the specificity is still an aspect for optimization, since in its current status, it cannot distinguish specific neurotoxicity from unspecific cytotoxicity. In order to increase the sensitivity and predictivity, we are currently working on the combination of the electrophysiological assessment with a panel of cytotoxicity assays.

**PS 1476 A Human 3D Myocardial Microtissue Model for Cardiotoxicity Testing.**

C. Zuppinger<sup>1</sup>, I. Agarkova<sup>2</sup>, W. Moritz<sup>2</sup> and J. M. Kelm<sup>2</sup>. <sup>1</sup>University of Bern, Bern, Switzerland; <sup>2</sup>InSphero, Zürich, Switzerland. Sponsor: A. Wolf.

Cardiomyocytes (CMs) are terminally differentiated cells in the adult organism and regeneration is limited. This is a worrisome fact, since insults such as ischemia and cardiotoxic compounds can lead to cell death and irreversible reduction of cardiac function. As testing platform, isolated organs and primary cells from rodents have been the standard in research and toxicology so far, but due to a very limited cell supply there is a strong need for better in vitro models. Hence, an in vitro model comprising the advantages of 3D cell culture and the availability of induced pluripotent stem cells (iPSC) from human origin was developed and characterized. Myocardial microtissues (MTs) were generated by self-assembly in multi-well hanging drop cultures. iPSC-derived CMs were evaluated regarding cardiac features and toxicological response. Prior use of the iPSC-derived cells, CMs were characterized after 10 days in standard culture which showed highly differentiated myofibrils positive for sarcomeric proteins such as myomesin, myosin, cardiac actin and desmin. The cells showed spontaneous contractile activity and connexin-43 positive gap junctions. In the hanging drop cultures, iPSC-derived CMs formed MTs within 4 days, contracting up to 3 weeks recorded by optical motion tracking. Excited by electrical field pacing they complied to the external stimulus up to 2Hz. Effects of a cardiotoxic cancer therapeutics such doxorubicin on iPSC-derived CMs in 2D- and 3D-culture were further evaluated with respect to caspase activation, LDH release and cellular ATP levels. Adult human CMs are a very rare and hard to handle cell source. New concepts have to be developed to create cardiac models systems to be used for cardiotox testing, ideally in a standard multi-well format. Within this "proof-of-concept" study a novel 3-dimensional human myocardial MT model was developed and characterized based on iPSC-derived CMs. Morphological and functional characterization underline that this model might become a valuable tool for substance safety testing in the future.

**PS 1477 Use of An *In Vitro* Flow Cytometric Method As a Replacement for Live Animal Experimentation.**

J. Godin-Ethier<sup>1</sup>, S. Th  baud<sup>1</sup>, J. Leiva<sup>1</sup>, C. L  vesque<sup>1</sup>, A. Nelson<sup>1</sup> and W. Lee<sup>2</sup>.  
<sup>1</sup>Immunology, ITR International, Baie d'Urfe, QC, Canada; <sup>2</sup>Toxicology, ITR International, Baie d'Urfe, QC, Canada.

**Scope:**

Animal welfare guidelines place more and more emphasis on the 3 Rs principle as a way to achieve excellence in animal care and use. In that objective, we have developed an *in vitro* flow cytometry method that allows us to quantify the immune response to IL-2 stimulus in a lymphocyte population thus replacing the use of live monkeys.

We have evaluated the potency of test items to phosphorylate stat5 in lymphocyte subsets expressing or not the IL-2 high affinity receptor subunit (CD25).

**Experimental Procedures and Results:**

Cynomolgus monkey peripheral blood mononuclear cells (PBMC) were stimulated with increasing doses of the test items under evaluation. The PBMCs were then stained using conjugated monoclonal antibodies specific to different lineage markers such as CD3, CD4, CD8 and CD25 to allow distinction between the different T lymphocyte subsets. In addition, in order to evaluate the potency of the test items to differentially stimulate CD25+ and CD25- lymphocytes, we have evaluated the activation of a downstream mediator of the IL-2 receptor signaling by measuring the phosphorylation of the Signal Transducer and Activator of Transcription (Stat5). Intracellular staining using a Phospho-Stat5 (pStat5) specific antibody was thus performed and data was acquired by flow cytometry. The pStat5 signal fold-increase was plotted against the test items concentration and the half maximal effective dose (EC50) was determined. The results obtained showed that the calculated EC50 for the CD4+CD25+ was of approximately 100 to 1000 times lower compared to CD4+CD25- cells and CD8+ cells. In addition, when comparing the potency to the two test articles to stimulate CD4+CD25+ cells, a 2-log difference was observed between calculated EC50.

**Conclusions:**

This innovative approach enables us to replace animal experimentation by an *in vitro* assay. Our method assesses the potency of test items to signal through the IL-2 receptor in different lymphocyte subsets.

**PS 1478 The Role of Facilitated Transport by Serum Protein in *In Vitro* Intrinsic Clearance.**

B. J. Blaauwboer, J. Moulin and N. Kramer. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

When a chemical is exposed to an *in vitro* cell assay in culture medium with serum protein, the effect (e.g. clearance) observed may be lower than when the chemical is exposed in culture medium without serum protein. This is because the chemical can bind to serum protein, which reduces the unbound free concentration of the chemical available for uptake into cells. Therefore, it is better to determine *in vitro* intrinsic clearance (CL<sub>int</sub>) based on unbound fractions of chemicals. However, a few studies have suggested that serum protein may also facilitate the transport of chemicals through aqueous media (facilitated transport). Thus the presence of serum protein may increase the uptake rate of chemicals into cells and solid phase microextraction (SPME) fibers. If the uptake rate determines clearance, then the presence of serum protein may increase clearance, thus hampering the extrapolation of *in vitro* CL<sub>int</sub> to *in vivo* clearance when clearance assays use varying concentrations of serum. Therefore, the uptake rate and clearance of the strongly-albumin bound, quickly cleared chemical testosterone was measured in HepaRG, HepG2 and H4IIE hepatoma cell lines at varying concentrations of bovine serum albumin using the substrate depletion approach. To measure the free fraction, mimic uptake of testosterone in cells, and facilitate the modeling of the transport into cells, a SPME method was developed for extracting the unbound chemical from the exposure medium. Results indicate that *in vitro* CL<sub>int</sub> of testosterone increases with increasing albumin concentration when using the unbound fraction. SPME was successfully applied to determine the free concentration and study the uptake rate of unbound testosterone into cells.

**PS 1479 Screening of Cosmetics Ingredients for Phototoxic Potential Using the *In Vitro* 3T3 Neutral Red Uptake Phototoxicity Test.**

R. Labib<sup>1</sup>, E. Gilberti<sup>1</sup>, S. Gettings<sup>1</sup> and H. Raabe<sup>2</sup>. <sup>1</sup>Product Safety & Integrity, Avon Products, Suffern, NY; <sup>2</sup>Institute for *In Vitro* Sciences, Gaithersburg, MD.

Phototoxicity is an acute toxic response after exposure to a phototoxicant and either UV radiation or visible light (UV/VIS). Phototoxicity from substances applied topically typically occurs at the site of photo-irradiation. Phototoxicity is the result of

direct cellular damage caused by a nonimmunological inflammatory response. Clinically, phototoxicity resembles an exaggerated sunburn (erythema, increased skin temperature, pruritis and edema). Phototoxicity reactions have been reported for both synthetic substances and those which occur naturally (eg., botanical extracts). Although symptoms generally subside quickly, the potential for substances used in topical products to cause phototoxicity is clearly of concern for manufacturers of cosmetics, personal care and other consumer products. Historically, the potential to cause phototoxicity from substances applied topically was evaluated by utilizing various animal models; however in 1997 the 3T3 Neutral Red Uptake Phototoxicity Test (3T3 NRU PT) was validated by ECVAM's Scientific Advisory Committee as an *in vitro* method for evaluating the phototoxic potential of chemicals shown to absorb in the UV/VIS range. To illustrate the utility of the 3T3 NRU PT as a useful screening tool in the safety evaluation of potential cosmetic ingredients, the results of the evaluation of 42 botanical extracts and 25 synthetic chemicals found to absorb in the UV/VIS range are reported. Most substances evaluated were found not to be phototoxic *in vitro*; however, 9 substances were identified as potentially/probably phototoxic in the 3T3 NRU PT and were eliminated from further consideration for use as cosmetic ingredients. Several substances found to be non-phototoxic in the 3T3 NRU PT were formulated with other ingredients in a prototype cosmetic formulation and subject to clinical testing. No manifestations of phototoxicity were observed in any of the test subjects in the prototype formulation containing any of the substances identified as non-phototoxic *in vitro*.

**PS 1480 Validation of a Cell Microelectronic Sensing Technique for Semi-Quantification of Cyanobacterial Toxins (Microcystins) in Recreational Water.**

V. Charoensuk<sup>1</sup>, D. Y. Huang<sup>1</sup>, W. Zhang<sup>2</sup>, S. Gabos<sup>3</sup> and D. W. Kinniburgh<sup>1</sup>.  
<sup>1</sup>Physiology & Pharmacology, Alberta Centre for Toxicology, Calgary, AB, Canada;  
<sup>2</sup>Protection Branch, Family and Population Health, Alberta Health, Edmonton, AB, Canada; <sup>3</sup>Office of the Chief Medical Officer of Health, Alberta Health, Edmonton, AB, Canada.

Microcystins (MCYSTs) are hepatotoxins produced by cyanobacteria (blue-green algae) commonly found in fresh water. There are a few semi-quantitative and quantitative detection methods available including protein phosphatase inhibition assay (PPI), enzyme-linked immunosorbent assay (ELISA) and liquid chromatography tandem mass spectrometry (LC/MS/MS).

Our laboratory recently developed a novel assay using a cell microelectronic sensing technology known as RTCA (Real-Time Cell Analyzer, Roche xCELLigence system) for detecting MCYSTs cytotoxicity. The assay is based on the fact that MCYSTs toxicity requires the active uptake of MCYSTs into the cytoplasmic membrane which is mediated by the organic anion transporting polypeptides (OATPs). By comparing the 48-hour cytotoxic effects of MCYSTs in wild type Chinese hamster ovarian cells (CHO/WT) and in CHO with OATP1B3 expression (CHO/OATP1B3), we semi-quantified MCYSTs cytotoxicity in recreational water using standard curves prepared from MCYST-LR, the most common MCYST analogue. MCYSTs levels in water samples were compared with results from PPI, ELISA and LC/MS/MS. The RTCA directly demonstrated MCYSTs total toxicity and the semi-quantitative results have high correlation to those from other methods (p-value < 0.0001), particularly at the Canadian recreational water guideline level (20 µg/L) or greater.

In summary, we have validated a semi-quantitative assay for cytotoxic testing of MCYSTs in recreational water by observing real-time toxic response at microgram per litre concentrations.

**PS 1481 Human Intestinal Microflora Reduces Butyl Paraben Toxicity in HepG2 Cell Cultures.**

W. Kang<sup>2</sup>, T. Khanal<sup>1</sup>, H. Kim<sup>1</sup>, T. Jeong<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea.

Parabens are alkyl esters of p-hydroxybenzoic acid, including methyl paraben, ethyl paraben, propyl paraben, and butyl paraben. In the present study, possible role of metabolism by fecalase in BP-induced cytotoxicity was investigated in HepG2 cell cultures. As an intestinal bacterial metabolic system for butyl paraben, human fecal preparation containing intestinal microflora (fecalase) was employed. Initially, among the parabens tested, cytotoxicity of butyl paraben was most severe. When butyl paraben was incubated with fecalase, it rapidly disappeared, in association with reduced cytotoxicity in HepG2 cells. In addition, butyl paraben-incubated with fecalase reduced cytotoxicity of HepG2 cells in a concentration-dependent manner. Moreover, butyl paraben-incubated with fecalase significantly caused an increase in Bcl-2 expression together with a decrease in Bax expression and cleaved Caspase-3. Furthermore, anti-apoptotic effect by the incubation of butyl paraben

with fecalase was also confirmed by the terminal deoxynucleotidyltransferase-mediated dUTP-biotin nick-end labeling assay. Taken all together, the findings suggested that metabolism of butyl paraben by human fecalase might have protective effects against butyl paraben-induced toxicity in HepG2 cells.

## **PS 1482 Characterization of Cellular and Molecular Markers of Toxicity in C6-Glioma Cells Exposed to Modern Pyrethroids.**

D. M. Romero, M. J. Wolansky and M. L. Kotler. *Biological Chemistry, IQUIBICEN (CONICET); School of Sciences, University of Buenos Aires, Buenos Aires, Argentina.*

Pyrethroids (PYRs) are insecticides increasingly used in various pest control applications. Low levels of PYR residues have been detected in diverse environmental samples, food and human urine. In vitro systems may be useful to characterize the diversity of primary and secondary toxicogenic pathways that may account for the pyrethroid-type specific divergence in clinical syndromes observed in small rodents. We use C6-glioma cell cultures to identify toxicologically relevant PYR exposures that may require cumulative risk assessment efforts in animals in vivo. Four compounds (bifenthrin, tefluthrin,  $\alpha$ -cypermethrin, deltamethrin) were examined after 24 h of PYR exposure. We also evaluated pyrethroid actions in C6 cells treated with sodium butyrate (NaBu) which induce an astrocyte-like phenotype. Threshold dose and EC15(24h) estimates were obtained after modeling MTT test data. In order to study subcellular integrity and signaling pathways with greater specificity and sensitivity, Mitotracker-Red and Neutral Red staining (informing on mitochondrial and lysosomal status, respectively), caspases and p53 (cell death related markers), AchE (an insecticide neurotoxicity related target) and GFAP (glia-specific xenobiotic response) were then examined. Low  $\mu$ M exposures induced dose-related declines in cell viability in both cell systems. We further found dose-related increases in fragmented mitochondria and mitochondrial membrane potential disruption in C6 cells. Increase in cell death related proteins and drop of GFAP levels were also observed in NaBu-treated cells. In addition, cholinesterase inhibition was not evident below EC15 levels for general cell viability for any test chemical. These results confirm that  $\mu$ M exposures affect cell viability markers unrelated to the proposed primary mode of action of pyrethroids, and that the classically proposed target cell for pyrethroids, the neuron, is not the only cell type that may be susceptible of cytotoxicity and severe cell damage in mammals.

## **PS 1483 DNA Damage-Induced by Goldenseal Constituents.**

S. Chen<sup>1</sup>, L. Wan<sup>1,2</sup>, H. Lin<sup>1</sup>, L. Couch<sup>1</sup>, N. Mei<sup>1</sup> and L. Guo<sup>1</sup>. <sup>1</sup>NCTR, Jefferson, AR; <sup>2</sup>Shanghai Institute for Food and Drug Control, Shanghai, China.

Goldenseal is used for the treatment of gastrointestinal disturbances, urinary disorders and inflammation. The major alkaloid constituents in goldenseal are berberine, hydrastine, and canadine. Because it is one of the most widely used herbal dietary supplements in the United States and the lack of carcinogenicity data, goldenseal was nominated to the National Toxicology Program (NTP). The NTP conducted 2 year bioassay on goldenseal and reported that goldenseal increased the incidence of liver tumors in rodents. However, the mechanisms of goldenseal-associated liver carcinogenesis are unclear. In this study, we compared genotoxicity of five goldenseal constituents and studied the underlying mechanisms. Five goldenseal constituents tested (berberine, palmatine, hydrastine, hydrastinine, and canadine) did not induce mutagenicity in the salmonella mutation assay. Berberine and palmatine at high concentrations showed positive results in the mouse lymphoma assay. Berberine and palmatine also caused DNA strand breaks in cultured hepatic cells whereas the rest three did not. The expression of the  $\gamma$ -H2AX, a biomarker of double strand breaks, was induced in a dose-dependent manner in response to berberine treatment. In addition, berberine and palmatine suppressed that activities of both topoisomerase I and II, indicating that the inhibitory effect may contribute to berberine- and goldenseal-induced genotoxicity and tumorigenicity.

## **PS 1484 DNA Adduct Formation and Mutation Induction by Aristolochic Acid in Rat Spleen.**

N. Mei, X. Guo, P. McDaniel and T. Chen. *Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, Jefferson, AR.*

Aristolochic acid (AA) is a potent human nephrotoxin and carcinogen. We previously reported that AA treatment resulted in DNA damage and mutation in the kidney and liver of rats. In the present study, we have determined the DNA adducts and mutations induced by AA in rat spleen. Big Blue transgenic rats were gavaged

with 0, 0.1, 1.0 and 10.0 mg AA/kg body weight 5-times/week for 3 months. Three DNA adducts, [7-(deoxyadenosin-N6-yl)-aristolactam I, 7-(deoxyadenosin-N6-yl)-aristolactam II and 7-(deoxyguanosin-N2-yl)-aristolactam I], were identified by P32-postlabeling. Over the dose range studied, there were strong linear dose-responses for AA-DNA adduct formation in the treated rat spleens, ranging from 4.6 to 217.6 adducts/ $10^8$  nucleotides. Spleen cII mutant frequencies (MFs) also increased in a dose-dependent manner, ranging from 32.7 to 286.2  $\times 10^{-6}$  in the treated animals. Mutants isolated from the different treatment groups were sequenced; there were significant differences between the spectra of 1 mg/kg AA-treated and control groups, and between the 10 mg/kg AA-treated and control groups. A:T  $\rightarrow$  T:A transversion was the major type of mutation in AA-treated rats, while G:C  $\rightarrow$  A:T transition was the main type of mutation in the vehicle controls. These results indicate that AA is genotoxic in the spleen of rats exposed under conditions that result in DNA adduct formation and mutation induction in kidney and liver.

## **PS 1485 In Vitro Genotoxicity of Ginkgo biloba Extract and Two of Its Major Components, Quercetin and Kaempferol.**

H. Lin, X. Guo, S. L. Dial, C. E. Schulte, M. G. Manjanatha, M. M. Moore and N. Mei. *DGMT, NCTR/US FDA, Jefferson, AR.*

Ginkgo biloba (ginkgo), one of the world's oldest living tree species, has been used for many years for a variety of medicinal purposes. The NTP 2-year bioassays on ginkgo extract found an increased incidence of liver cancer in mice and thyroid gland cancer in both mice and rats. In this study, the mouse lymphoma assay (MLA) was used to evaluate the in vitro mutagenicity of ginkgo extract and two of its major constituents, quercetin and kaempferol. L5178Y/Tk+/-3.7.2C mouse lymphoma cells were treated with different concentrations of ginkgo extract (0.2-1.2 mg/ml), quercetin (3-30  $\mu$ g/ml) and kaempferol (2.7-57.2  $\mu$ g/ml) in the absence of metabolic activation. Ginkgo extract, quercetin, and kaempferol significantly increased the mutant frequency in the MLA. Loss of heterozygosity (LOH) analysis for mutants induced by quercetin and kaempferol were also examined at five microsatellite loci spanning the entire mouse chromosome 11. The results indicated that the mutational spectrum from the quercetin and kaempferol treatment were significantly different from that of the negative control. In addition, the neutral comet assay conducted in the mouse lymphoma cells with quercetin and kaempferol also demonstrated a dose-dependent increase in the DNA double-strand breaks (DSBs). Western blot analysis showed that quercetin increased the phosphorylation of ATM, and consequently increased expression of  $\gamma$ -H2AX, phosphorylated Chk1 and Chk2 in the cells; while kaempferol increased expression of  $\gamma$ -H2AX and phosphorylated Chk1. These results suggest that ginkgo extract and two of its major constituents, quercetin and kaempferol, are genotoxic in the mouse lymphoma cells.

## **PS 1486 Loss of Heterozygosity Analysis of the Tk Mutants Induced by Cigarette Smoke Condensates in Mouse Lymphoma Cells.**

X. Guo, M. M. Moore and N. Mei. *Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, Jefferson, AR.*

Cigarette smoke condensate (CSC) is a set of sticky particles comprised of thousands of chemicals created by burning cigarette. Our previous study on 11 cigarette smoke condensates (CSCs) using the mouse lymphoma assay (MLA) has demonstrated that all these CSCs resulted in a dose-dependent increase of both cytotoxicity and mutagenicity in the mouse lymphoma cells. To elucidate the underlying mutagenic mechanism, we examined the mutational types of CSC-induced Tk mutants by analyzing loss of heterozygosity (LOH) using the allele-specific PCR at five microsatellite loci (Tk1, D11Mit42, D11Mit36, D11Mit20 and D11Mit74) spanning the entire chromosome 11. For each CSC treatment, 48 large and 48 small mutant colonies were randomly collected from the cultures of the highest acceptable concentrations. The statistical analysis demonstrated that the mutational spectra of all colonies induced in CSC-treated mouse lymphoma cells were significantly different from those of the vehicle control, although the most common type of all the mutations including CSC-treated and control samples was LOH involving the Tk and D11Mit42 locus. A larger proportion of LOH at Tk and D11Mit 42 loci was observed in the CSC-induced small colonies, whereas the large colonies showed different LOH patterns among the 11 CSCs. These results suggest that CSCs are mutagenic in mouse lymphoma cells with a clastogenic mode-of-action, and the induction of large and small colony mutants may result from different mechanisms.

**PS 1487 Evaluation of Genotoxicity of Cyproterone Acetate in Both Sexes of Rats.**

W. Ding<sup>1</sup>, M. E. Bishop<sup>1</sup>, M. G. Pearce<sup>1</sup>, G. A. White<sup>2</sup>, L. Lyn-Cook<sup>1</sup> and M. G. Manjanatha<sup>1</sup>. <sup>1</sup>Division of Genetic and Molecular Toxicology, FDA/NCTR, Jefferson, AR; <sup>2</sup>Toxicology Pathology Associates, FDA/NCTR, Jefferson, AR.

Cyproterone acetate (CPA), a hormone therapy drug with anti-androgenic activity, is commonly used for androgenisation symptoms in women and treatment of prostate cancer in men. CPA is known to produce liver tumor in rats, with a higher incidence in females. In standard genotoxicity assays, such as Ames test, HGPRT assay, chromosomal aberration assay and *in vivo* micronucleus assay, negative responses were observed. However, more recent studies have demonstrated that CPA induces a sex-specific genotoxicity, forming DNA adducts in female rats but not in male rats. To investigate the genotoxicity of CPA, and to answer the question if it is sex-specific, we evaluated the genotoxicity of CPA through *in vivo* Comet assay in both sexes of rats. hOGG1- and Endo III-modified *in vivo* Comet assay were performed to measure CPA induced oxidative DNA damage. Groups of 5 seven-week old male F344 rats were treated with olive oil or 10, 25, 50 or 100 mg/kg bw CPA in olive oil at 0, 24, and 48 hr. Animals were sacrificed at 48 hr, 3 hr after the last treatment. Liver, testis, kidney and blood were collected for Comet assay. CPA treatment resulted in an increase in DNA strand breaks in the liver of male rats with significant ( $p \leq 0.05$ ) increases detected in rats treated with 50 and 100 mg/kg CPA. There were near-linear dose responses for EndoIII-sensitive and hOGG1-sensitive DNA damages in CPA-treated rat livers, both with significant ( $p \leq 0.05$ ) increases detected in all the dose groups, suggesting a possible role of reactive oxygen species for CPA-induced genotoxicity. To evaluate the genotoxicity of CPA in female rats, groups of 5 seven-week old female F344 rats will be treated identically with CPA. Liver, mammary gland, uterus, ovary, kidney and blood will be collected for Comet assay and the responses will be compared with the males. This study will provide a further understanding of the cancer mode of action of CPA and if there is any sex-specific genotoxic response in rats.

**PS 1488 Assessment of Dosimetry and Biological Responses *In Vitro* Using a Vitrocell® Smoke Exposure System.**

D. Thorne<sup>1</sup>, J. Kilford<sup>2</sup>, B. Payne<sup>2</sup>, K. Scott<sup>1</sup>, J. Adamson<sup>1</sup>, A. Dalrymple<sup>1</sup>, C. Meredith<sup>1</sup> and D. M. Dillon<sup>1</sup>. <sup>1</sup>Group R&D, British American Tobacco, Southampton, United Kingdom; <sup>2</sup>Covance Laboratories Ltd., Harrogate, United Kingdom.

Routine toxicological assessment of tobacco smoke commonly uses the particulate fraction of the smoke aerosol. The particulate phase of cigarette smoke makes up a small percentage of the total aerosol, approximately 5-9% by weight. The remaining ~91% is associated with the vapour phase of cigarette smoke and is not routinely evaluated. Whole smoke exposure systems are capable of capturing the full interactions of both the particulate and vapour phase together and offer unique potential for toxicological assessment.

In this study we used a Vitrocell® VC10 smoking robot to expose cell cultures at the air-liquid interface to ISO mainstream 3R4F cigarette smoke. All experiments were independent and completed a minimum of three times. For biological assessment we developed the Neutral Red Uptake (NRU) assay with a Balb/c cell line, and the Ames assay using bacterial strain YG1042. We also used a novel quartz crystal microbalance (QCM) tool for real-time *in situ* deposition analysis. For the Ames assay we observed a mean fold increase of 5.9 at the highest concentration of smoke tested (1L/min), which correlated with a  $2.29 \mu\text{g}/\text{cm}^2$  increase in particulate deposition. Clear differences were seen at all doses; for example, 12, 8 and 4L/min produced a 2.1, 2.3, 3.8 and 0.04, 0.09, 0.50 fold increase and deposited mass ( $\mu\text{g}/\text{cm}^2$ ) respectively. The NRU assay showed a complete cytotoxic dose response (12-1L/min), with a calculated dilution  $\text{IC}_{50}$  and deposited mass  $\text{IC}_{50}$  of approximately 6.5 L/min and  $1.7 \mu\text{g}/\text{cm}^2$  respectively.

We conclude that the VC10 can be used in conjunction with routine toxicological assays for the assessment of cigarette smoke toxicity, as demonstrated by consistent responses in two independent *in vitro* test systems. Furthermore, QCM measurements *in situ* of exposure have enabled us to present biological data as a function of deposited mass. QCMs have also acted a important QC tool for smoke exposure and provide valuable information on the exposure system itself.

**PS 1489 Evaluation of the Results of Several Genotoxicity Tests in Carvacrol and Thymol.**

J. Scognamiglio, V. T. Politano and A. Api. Research Institute for Fragrance Materials, Woodcliff Lake, NJ.

Carvacrol (CAS499-75-2) and thymol (89-83-8) are fragrance ingredients that have been studied in bacterial and mammalian genotoxicity assays *in vitro* and in an *in vivo* chromosome aberration test. These materials have antibacterial and anti-

fungal properties and are cytotoxic. Their cytotoxicity needs to be considered when evaluating the results of genotoxicity assays using mammalian cell cultures because cytotoxicity is the most important confounding factor in analyzing these results. To avoid the occurrence of secondary (indirect) modes of clastogenic activity, the highest concentrations tested in these assays should lead to sufficient levels of cytotoxicity within the guidelines, but not cause extreme cytotoxicity. In published literature, there are inconsistent results of the genotoxicity tests on these two materials, where positive results correlate with cytotoxicity, indicating that positive results can be explained by secondary effects. An SOS Chromotest was less prone to false positives than the Ames test and was negative with both carvacrol and thymol. A positive chromosomal aberration test in rats on both carvacrol and thymol was further evaluated to clarify the cause of the chromosomal aberration observed. Thus an *in vitro* micronucleus test in human peripheral blood lymphocytes was conducted with careful selection of doses based on cytotoxicity to determine if these materials were potential clastogens or a spindle poison. Both assays yielded negative results, supporting the hypothesis that the previous positive genotoxic outcomes were the result of high cytotoxic activity in the test system and that carvacrol and thymol are likely not genotoxic agents.

**PS 1490 No Direct Genotoxic Potential of Different Radiofrequency Electromagnetic Fields in MRC-5 Cells and B6C3F1 Mice.**

C. Dasenbrock<sup>1</sup>, T. Tillmann<sup>1</sup>, A. Oertel<sup>1</sup>, H. Brockmeyer<sup>1</sup>, M. Murbach<sup>2</sup>, M. Capstick<sup>2</sup>, N. Kuster<sup>2</sup> and C. Ziemann<sup>1</sup>. <sup>1</sup>Fraunhofer ITEM, Hannover, Germany; <sup>2</sup>IT'IS Foundation, Zurich, Switzerland.

Public exposure to electromagnetic fields in the radiofrequency spectrum (RF-EMF) has increased dramatically, attracting notice to health risk evaluation. RF-EMF was classified as possibly carcinogenic to humans (Group 2B) by the IARC in 2011. But clear risk assessment is still limited by data gaps and contradictory data, not only for mobile phones but also for wireless network devices. As there are some indications for disturbance of DNA-integrity by RF-EMF exposure, we evaluated the *in vitro* and *in vivo* genotoxic potential of different RF-EMF signals by using well established and standardized genotoxicity.

*In vitro*, normal human MRC-5 lung fibroblasts were exposed intermittently (5 min ON, 10 min OFF) in a 1950 MHz exposure system for 1, 4, and 24 h to various RF-EMF signals (continuous wave (CW), UMTS, WiFi, GSM-basic, RFID) at specific absorption rates (SAR) up to  $4.92 \text{ W}/\text{kg}$ . DNA-strand break (SB) induction and oxidative DNA-damage were subsequently evaluated in an enzyme (hOGG1)-modified comet assay.

*In vivo*, male B6C3F1 mice were whole-body exposed to CW, UMTS, WiFi, or RFID signals at SAR of 1.6, 4.0 and  $10 \text{ W}/\text{kg}$  for 14 d, 20 h/d (5 min ON, 10 min OFF) using a reverberation chamber. Micronucleus (MN) frequency was determined in peripheral blood, immature bone marrow erythrocytes and keratinocytes. Irrespective of signal type, SAR-value, and exposure duration RF-EMF did not mediate significant cytotoxicity, induction of DNA-strand breaks, or oxidative DNA-damage in MRC-5 cells, compared to concurrently sham-exposed cells. In addition, no increase in MN formation was observed in B6C3F1 mice. In conclusion, none of the tested signal modulations revealed evidence for a direct DNA-damaging or cytotoxic potential of RF-EMF.

This study was part of the SEAWIND project, funded by the European Union's Seventh Framework Programme ([FP7/2007-2013]) under grant agreement No. 244149.

**PS 1491 *In Vitro* Evaluation of Cytotoxic and Genotoxic Effects of Ofloxacin.**

V. Sekeroglu<sup>1,2</sup>, Z. Atli Sekeroglu<sup>1,2</sup>, M. Aksoy<sup>2</sup> and S. Kontas<sup>2</sup>. <sup>1</sup>Applied Medical Sciences, University of Southern Maine, Portland, ME; <sup>2</sup>Biology, University of Ordu, Ordu, Turkey. Sponsor: J. Wise Sr.

Ofloxacin (OFX), the second-generation of quinolones, is a broad-spectrum fluoroquinolone antibiotic used in the treatment of various bacterial infections. In this study, the genotoxic and cytotoxic effects of OFX in cultured human peripheral blood lymphocytes were investigated by measuring chromosome aberrations (CAs), sister chromatid exchange (SCE) assay, mitotic index (MI) and proliferation index (PI). Cultures were treated with three doses of OFX (30, 60 and  $120 \mu\text{g}/\text{ml}$ ) at 48 h exposure period for all assays. An untreated culture (negative control) and a positive culture treated with MMC (positive control) were established, as well. Although the frequency of SCE slightly increased in a concentration-dependent manner, dose-dependent increases were not observed in the CAs. But, these increases were statistically not significant, compared to negative control ( $P < 0.05$ ). With respect to the cytotoxic effects of the test compound on lymphocyte cultures, as measured by MI and PI, a concentration-dependent reduction in cell proliferation was also observed. The highest dose of OFX ( $120 \mu\text{g}/\text{ml}$ ) significantly reduced the MI values compared to negative control ( $P < 0.05$ ), whereas decreases in PI values were not found significant compared to negative control.

The results of this study indicate that OFX can exert a cytotoxic effect especially at the higher doses because of statistically significant decreases in MI, but has no genotoxic activity in both CA and SCE assays in human peripheral blood lymphocyte cultures.

## PS 1492 Genotoxic Effects in Children Environmentally Exposed to Particulate Matter.

M. Sánchez-Guerra<sup>1,2</sup>, A. Araujo<sup>3</sup>, L. Serrano-García<sup>3</sup>, L. Hernández-Cadena<sup>4</sup>, R. Montero-Montoya<sup>1</sup>, I. Alvarado-Cruz<sup>1</sup>, A. De Vizcaya-Ruiz<sup>1</sup>, L. Rafael-Vázquez<sup>1</sup>, E. Jiménez-Mendoza<sup>1,5</sup>, J. Torres-Arellano<sup>1,5</sup>, V. Mugica<sup>6</sup> and B. Quintanilla-Vega<sup>1</sup>. <sup>1</sup>Toxicology Department, CINVESTAV-IPN, Mexico City, Mexico; <sup>2</sup>Exposure Epidemiology and Risk Program, Harvard School of Public Health, Boston, MA; <sup>3</sup>Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico; <sup>4</sup>INSP, Cuernavaca, Mexico; <sup>5</sup>FÉZ-Iztacala, UNAM, Mexico City, Mexico; <sup>6</sup>UAM-Azcapotzalco, Mexico City, Mexico.

Ecatepec County is considered one of the most contaminated counties in the Metropolitan Area of Mexico City. There are reports about the high levels of particulate matter (PM) in this area related to the high traffic and industrial activity. PM is associated with several health problems including genotoxic effects. Children are considered one of the most susceptible populations to air pollution. The aim of this study was to evaluate the DNA damage related to the exposure to PM in the air. We conducted an air monitoring study and an epidemiological survey in schoolchildren from 6 to 10 years (n=86) of both genders in an area of Ecatepec County and the following was evaluated: concentrations of PM<sub>10</sub> and PM<sub>2.5</sub> in the air, as well as the organic and elemental carbon content (CO and CE, respectively), the presence of micronucleus (MN), apoptotic cells (AC) and necrotic cells (NC), and the nuclear division index (NDI) in peripheral lymphocytes by the cytokinesis-block micronucleus test in 1000 cells. The geometric average age was 8.4 years; 41% of children showed at least 1 MN (range 1-6), 27% showed 1-49 AC and 16% had 1-9 NC, some children showed exceptionally high AC or NC values. We found a significant association between CO-PM<sub>10</sub> and the presence of MN, AC and NC, and a decrease in the NDI, while CE-PM<sub>10</sub> was associated with MN and NC. Regarding PM<sub>2.5</sub>, the CO content was associated only with the presence of MN. These preliminary data suggest that both the CO and CE contents of PM from Ecatepec County are involved in the genotoxic effects observed in schoolchildren. Study supported by CONACYT-México (Grant #106034).

## PS 1493 Bariatric Surgery Reduces Intestinal Toxicity in Man.

A. Alkandari, Q. Wu, H. Ashrafian and N. J. Gooderham. *Surgery and Cancer, Imperial College London, London, United Kingdom.*

Obesity is a global epidemic. Worldwide 500 million people are classified as obese with a global prevalence that continues to rise. Obesity and its co-morbidities are amongst the leading causes of global mortality and morbidity and pose substantial socioeconomic burdens on health services worldwide. Bariatric surgery is a form of gastrointestinal surgery that leads to sustained weight loss, resolution of type 2 diabetes and a decrease in cancer risk. These operations alter gut microbial composition which is reflected in the bacterial composition of faeces. We hypothesise that the protective effect of bariatric surgery is due to a decrease in diet-derived intestinal toxic burden. Here, we determined the effect of bariatric surgery on intestinal cytotoxicity and genotoxicity in man. Aqueous dimethyl sulfoxide faecal extracts were obtained from preoperative and 2 month postoperative samples from 5 individuals undergoing Roux-en-Y gastric bypass. Human MCL5 cells, a lymphoblastoid cell line expressing CYP1A1, 1A2, 2E1 and 3A4 and epoxide hydrolase, were used to assess faecal extract toxicity and genotoxicity was determined at the TK and HPRT loci using benzo(a)pyrene as a positive control. We found a trend of decreased cytotoxicity postoperatively, as assessed by relative total growth (20% decrease compared to preoperative faecal extracts). Furthermore, the genotoxicity of the faecal extracts decreased postoperatively at both the TK and HPRT loci (30% and 70% respectively, whereas the BaP control induced mutation frequency more than 50 fold). These results support the hypothesis that bariatric surgery leads to a decrease in diet-derived intestinal toxicity burden, which in turn may contribute to the health beneficial effects associated with surgery.

## PS 1494 The Tobacco-Specific nitrosamine 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) Induces Mitochondrial and Nuclear DNA Damage in *Caenorhabditis elegans*.

R. K. Bodhicharla<sup>1</sup>, P. Gaddamanugu<sup>2</sup> and J. N. Meyer<sup>1</sup>. <sup>1</sup>Nicholas School of the Environment, Duke University, Durham, NC; <sup>2</sup>R.J. Reynolds Tobacco Company, Winston-Salem, NC.

The metabolites of the tobacco-specific carcinogen NNK form DNA adducts in animal models. One report indicates that NNK could cause damage to the mitochondrial as well as nuclear genome in rats (Stepanov and Hecht, 2009 *Chem. Res. Toxicol.* 22: 406-414). Using a different DNA damage detection technology, we tested whether this could be repeated in the nematode *Caenorhabditis elegans*; we also evaluated whether mitochondrial function would be affected. We treated N2 strain (wild-type) nematodes with NNK in liquid culture. Quantitative PCR was applied to analyze NNK-induced nuclear and mitochondria DNA damage. This assay has the advantage of measuring all DNA lesions that inhibit the DNA polymerase, and normalizes results to mitochondrial DNA copy number (Hunter *et al.*, 2010 *Methods* 51:444-451). Our results confirm that NNK causes both nuclear and mitochondrial DNA damage, but surprisingly nuclear DNA damage was greater than mitochondrial DNA damage in *C. elegans*. To test whether the mitochondrial DNA damage was associated with mitochondrial dysfunction, we used a transgenic nematode strain that permits *in vivo* measurement of ATP levels and found lower levels of ATP in NNK-exposed animals when compared to the unexposed controls. To test whether the lower levels of ATP were due to the inhibition of respiratory chain components we investigated oxygen consumption in whole *C. elegans* and found reduced oxygen consumption in exposed animals when compared to the unexposed controls. Our data suggest a model in which NNK causes damage to both nuclear and mitochondrial genomes, and support the hypothesis that the mitochondrial damage is functionally important. These results also represent a first step in developing this genetically tractable organism as a model for assessing NNK toxicity.

## PS 1495 Meta-Analysis Evaluating the Association between Diseases Linked to Asbestos and Genetic Polymorphisms.

L. Lievense<sup>1</sup>, C. J. Ronk<sup>2</sup>, S. A. Gross<sup>3</sup> and C. A. Barlow<sup>3</sup>. <sup>1</sup>ChemRisk LLC, Chicago, IL; <sup>2</sup>ChemRisk LLC, San Francisco, CA; <sup>3</sup>ChemRisk LLC, Boulder, CO.

Asbestos is a ubiquitous, naturally occurring mineral fiber that has been linked to the development of malignant and fibrotic lung diseases. Numerous studies have shown that a polymorphism in the genes involved in xenobiotic and oxidative metabolism or in DNA repair processes may play an important role in the pathogenesis of many, if not most, diseases. Unlike some other neoplastic diseases, no association with mesothelioma risk has been consistently demonstrated for polymorphic genes involved with oxidative stress, metabolism, or DNA repair. To evaluate the association between diseases linked to asbestos and genetic variability, we performed a meta-analysis combining the available data on the presence of polymorphisms in GSTM1, GSTT1, NAT2, mEH, XRCC1, and XRCC3 from Italian (n = 57) and Finnish (n = 48) populations with pleural mesothelioma in which the relative magnitude of asbestos exposure was classified. Meta-relative risk statistics were estimated through fixed effects modeling using SAS software. Our analysis found that the GSTM1 null genotype, NAT2 fast acetylator genotype, mEH low activity genotype, and the T/M variant allele of XRCC3-T241M were significantly associated with having an increased risk of pleural mesothelioma. When mesothelioma patients were stratified by asbestos exposure (high vs. low), the association between mesothelioma and GSTM1, NAT2, and mEH was not statistically significant for the high exposure group. The association between the T/M variant allele of XRCC3-T241M and mesothelioma was significantly increased, regardless of asbestos exposure. The R/Q variant allele of XRCC1-R399Q appeared to be confined to those mesothelioma patients with a history of high exposure to asbestos, although the confidence interval includes parity. The results from the present analysis strengthen the hypothesis that intensity of asbestos exposure combined with the presence of certain genetic polymorphisms may increase individual mesothelioma risk.

## PS 1496 Evaluation of the Mutagenicity of Dyed Fabrics with Direct Black 38.

G. A. Oliveira<sup>1</sup>, D. M. Leme<sup>1</sup>, T. C. Santos<sup>2</sup>, M. B. Zanoni<sup>2</sup> and D. P. Oliveira<sup>1</sup>. <sup>1</sup>Faculty of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo (USP), Ribeirão Preto, Brazil; <sup>2</sup>Institute of Chemistry, University Estadual Paulista (UNESP), Araraquara, Brazil.

There are several information on toxicity of textile dyes, but data of colored fabrics are still limited. Although a dye itself may be toxic, its presence in the finished material may not be harmful. Direct Black 38 (DB38) is a benzidine-based azo dye,

commonly used in textile industry. It is known that, under conditions of perspiration, dyes migrate from colored fabrics and penetrate into human skin. Objective: Evaluate the mutagenicity of DB38 extracted from dyed cotton fibers using artificial sweat solutions. Methodology: Pieces of cotton fabric were dyed with DB38 and washed with and without rinsing (bath with a colloid dispersant). DB38 was extracted from the dyed fabric with artificial sweat solutions (pH 5.5, 6.5, 8.0) at 37°C and 42°C for 2, 8 and 12 h. HPLC-DAD analysis was performed to determine the concentration of dye extracted in each sweat extract. Both original dye and sweat extracts were evaluated by the Salmonella/microsome assay using the strains TA98 and TA100 with and without S9 mix in order to compare with the higher dye concentration extracted with sweat. Results: Original DB38 dye showed positive mutagenic response for TA98 and TA100 with S9. The migration of DB38 dye into artificial sweat resulted in 5.9 µg/mL (dyeing without rinsing, pH 8.0, 42°C, 8 h). Sweat extracts with DB38 did not induce mutagenic effects under the conditions tested. Discussion: Original dye induces mutagenicity by both base-pair substitution and frameshift mutations in presence of S9. However, these effects could no longer be observed after its extraction from dyed fabric using artificial sweat as extracting agent. Our findings showed that DB38 dye can migrate from colored fabrics to artificial sweat, however the concentration of dye extracted does not cause mutagenicity. Thus, as important as the toxicological information of textile dyes, is an investigation of the toxic effects of fabrics which contain these dyes in order to avoid human health problems.

**PS 1497 Characterizing the Genotoxicity of the Trichloroethylene Metabolite Dichlorovinyl Cysteine.**

J. B. Asfaha, V. De La Rosa and C. Vulpe. *University of California Berkeley, Berkeley, CA.*

Trichloroethylene (TCE) is an industrial solvent and common environmental contaminant. TCE is metabolized via the glutathione conjugation (GSH) pathway where the reactive metabolite, dichlorovinyl cysteine (DCVC) is formed. Previous work in the field has shown DCVC as the penultimate metabolite resulting in renal toxicity. Our studies using a functional genomics approach in yeast suggest DNA damage and repair pathways play a role in DCVC toxicity. Specifically, we identified the error-prone translesion synthesis (TLS) repair pathway and nucleotide excision repair (NER) as important for response to DCVC exposure. Preliminary work in human fibroblast cells shows initiation of translesion synthesis repair after DCVC exposure. Studies to identify potential DCVC-DNA lesions were conducted using liquid chromatography mass spectrometry (LCMS) analysis. Results indicate the potential for DCVC to cause direct DNA damage via DNA adducts with specific nucleotides. Our data suggests DCVC is genotoxic and has the potential to lead to cell death.

**PS 1498 Coexposure to LA Sweet Crude Oil and Dispersant Alters Genomic DNA Damage Occurrence in the Gulf Killifish.**

K. E. Germ and G. D. Mayer. *Environmental Toxicology, The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.*

The BP-Deepwater Horizon event in the Gulf of Mexico unleashed an unprecedented environmental disaster where more than 650 miles of Gulf coastline was littered with Louisiana Sweet Crude oil. During this event Corexit 9500, a surfactant designed to disperse and emulsify crude oil and expedite microbial breakdown, was used to mitigate damage. However, surfactant additives can increase membrane permeability and biological uptake of exogenous compounds including components of crude oil. Recent studies indicate that although visible traces of weathered crude oil have long been absent in the estuarine environments, particular toxic mutagens persist in organisms and sediments that were once co-exposed to oil and dispersant. This research focuses on the notion that toxic components of crude oil may persist and adversely affect genomic integrity. We examined genomic DNA coding sequences, cytochrome c oxidase-subunit I and cystic fibrosis transmembrane conductance receptor for lesion analysis. Here we show that killifish, *Fundulus grandis*, exposed to crude oil and dispersant have increased amounts of genetic damage in both mitochondrial and nuclear templates, relative to killifish exposed to each individual compound. Additionally, DNA lesion formation in the mitochondrial genome was increased in the co-exposures, compared to singular exposures of contaminants.

**PS 1499 Absence of Genotoxicity in a Series of 2'-O-Methyl Phosphorothioate Oligonucleotides.**

Y. Ponstein, C. den Besten and S. de Kimpe. *Prosenza, Leiden, Netherlands.*  
Sponsor: E. van Doesum-Wolters.

PRO044, PRO045 and PRO053 are 2'-O-methyl phosphorothioate RNA antisense oligonucleotides (AON) that are in development for the treatment of Duchenne Muscular Dystrophy (DMD), a lethal orphan disease for which no disease modifying therapy exists. The fundamental cause of this disease is mutations in the dystrophin gene leading to out of frame transcripts for the corresponding muscle protein. AON-induced exon skipping of exon 44, 45 and 53, respectively, in human dystrophin pre-mRNA results in the restoration of the reading frame and an internally deleted but functional dystrophin protein. The mutagenic and clastogenic potential of PRO044, PRO045 and PRO053 was assessed using in vitro tests in bacteria and mammalian cells and an in vivo rodent assay. The bacterial reverse mutation assay (i.e. Ames test using *Salmonella typhimurium* TA98, TA100, TA102, TA1535 and TA1537) showed that the mentioned AONs have no mutagenic activity at concentrations up to 5,000-10,000 µg per plate, in the presence or absence of an in vitro metabolic activation system (S9-mix). The Chinese hamster ovary (CHO) chromosomal aberration assay showed that PRO044, PRO045 and PRO053 did not induce structural aberrations in the presence or absence of S9-mix, with tested concentration up to 5,000 µg/mL. In addition, PRO044, PRO045 and PRO053 did not induce any polyploidy or give indications of mutagenic properties in the presence or absence of S9-mix at 5,000 µg/mL. In the in vivo micronucleus assay, no genotoxic effect was observed in the bone marrow of mice following repeated subcutaneous administrations of PRO044, PRO045 and PRO053 at dose levels ranging between 80 and 1,000 mg/kg on days 1, 3, 5, and 8, resulting in a weekly dose of 320 to 4,000 mg/kg. In conclusion, results from these experiments demonstrate that PRO044, PRO045 and PRO053 are not mutagenic nor clastogenic. This is in accordance with the EMA's reflection paper indicating that phosphorothioate nucleotides (as potential degradation products/metabolites of phosphorothioate oligodeoxynucleotides) are unlikely to pose a genotoxic hazard.

**PS 1500 Different Extraction Strategies to Evaluate the Genotoxicity of the Water Soluble Fraction of Air Particulate Matter.**

I. C. Palacio<sup>2,1</sup>, R. L. Franklin<sup>1</sup>, C. F. Suzuki<sup>1</sup>, I. F. de Oliveira<sup>1</sup>, D. A. Roubicek<sup>1</sup> and S. B. Barros<sup>2</sup>. <sup>1</sup>*Departamento de Análises Ambientais, Companhia de Tecnologia de Saneamento Ambiental, São Paulo, Brazil;* <sup>2</sup>*Departamento de Análises Clínicas e Toxicológicas, Universidade de São Paulo, São Paulo, Brazil.*

Exposure to contaminated airborne particulate matter (PM) as a consequence to urban air pollution has adverse effects on human health and the ecosystem. In most air pollution studies, only the genotoxic potential of the organic fraction is evaluated and the toxic effects of the soluble metals are not usually verified. In order to determine an appropriate extraction method for assessing the mutagenicity of the water-soluble fraction of PM, we performed microwave assisted (MW) and ultrasonic bath (UT) extractions, using water as the only solvent, in 10 different air samples (Total particulate matter-TPS- and PM10- fraction of particles with diameter of 10µm or less), from the state of São Paulo, Brazil. Mutagenicity and extraction performances were evaluated using the Salmonella/microsome assay with strains TA98 and TA100, followed by chemical determination of soluble metals (ICP). Except for one sample, the mutagenic potential of TPS was significantly higher in the samples extracted with MW than those with UT. The PM10 samples extracted with MW showed mutagenic activity only with TA98, with and without metabolic activation, and in those with UT there was no biological response. Of the metals analyzed (Ni, Cu, Zn, Cr, Fe, Pb, Mn, Co, V and Ti), only vanadium (in the samples extracted with MW) and copper (in the UT extracted samples) were above detectable levels. Our results demonstrate the importance in determining an efficient extraction method for evaluating genotoxicity, especially at low concentrations of water-soluble contaminants in the air particulate matter. The MW represented a powerful tool to evaluate the genotoxicity of those samples, and additionally has methodological advantages against UT, allowing more reproducibility of the test conditions and improving the analysis precision. Supported by CAPES Ph.D. fellowship Isabel Palacio

**PS 1501 Time Course Study of Sulphur Mustard-Induced DNA Damages in Hairless Skh-1 Mice.**

M. Batal<sup>1,2</sup>, I. Boudry<sup>2</sup>, C. Cléry-Barraud<sup>2</sup>, S. Mouret<sup>2</sup> and T. Douki<sup>1</sup>. <sup>1</sup>CEA, Grenoble, France; <sup>2</sup>IRBA, La Tronche, France. Sponsor: J. McDonough.

A major target for sulphur mustard (SM) is DNA. DNA alkylation leads to the formation of monoadducts, mainly at the N7 position of guanine (HETE-N7Gua: N7 hydroxyethylthioethyl-guanine) and in a lesser extent at the N3 position of adenine (HETE-N3Ade: N3 hydroxyethylthioethyl-adenine), and biadducts (N7Gua-ETE N7Gua: bis[N7guanin-ethyl]sulphide). It is a critical step to explain SM cytotoxicity. Therefore, we have developed a high performance liquid chromatography coupled to tandem mass spectrometry (HPLC-MS/MS) method to quantify the three main SM-DNA adducts. The assay was applied to SKH-1 mice exposed to liquid SM on the dorsal skin at 2, 6 and 60 mg/kg during 4h and were sacrificed at 6h, d1 (day 1), d3, d7, d14 and d21 after exposure. SM exposed skin, skin adjacent to exposed skin and skin being located at 2 cm apart of this latter were removed. The maximum of DNA lesions in SM exposed skin was obtained at 6h post-exposure. The contribution of HETE-N3Ade to SM DNA adducts in skin was much lower than that found in isolated and cellular DNA in previous experiments. Adducts frequencies decreased from d1 likely as the result of DNA repair. Yet a relatively important persistence of SM-DNA adducts was observed since HETE-N7Gua and N7Gua-ETE N7Gua were still detected at d21 after 60 mg/kg exposure. For each exposure dose, SM-DNA adducts were also measured, in skin adjacent to the exposed zone, although in lower amounts. They were quantified until d14 after 60 mg/kg exposure. For the highest dose, SM-DNA adducts were detected at 2 cm of the burn but only at d1. These results show a limited radial diffusion of SM in skin but a significant persistence in time. They also demonstrate the reliability of our method to quantify SM-DNA adducts which could be monitored as part of therapeutic tests.

**PS 1502 Accurate Assessment for the *In Vitro* CB Micronucleus Test by Comparison of Two Different Protocols Using Human Lymphocytes.**

S. Bohnenberger, A. Poth and W. Voelkner. *Genotoxicity and Alternative Toxicology, Harlan Cytotest Cell Research, Rosdorf, Germany.*

The OECD Guideline 487 for the *In Vitro* Mammalian Cell Micronucleus Test (MNvit) became effective in July 2010. The objective of the test is to identify micronucleus formation via clastogenic and aneugenic mechanisms in cells that have completed mitosis. This work presents the assessment of various test parameters for the performance of the assay with human lymphocytes with regard to the above mentioned Guideline. With respect to the *In Vitro* Mammalian Cell Micronucleus Test (MNvit) aneugenic and clastogenic reference chemicals (colcemid/demecolcin, mitomycin C (MMC) and cyclophosphamide (CPA). were tested for their potential to induce micronuclei in cultured human peripheral blood lymphocytes. The protocol given by the current OECD Guideline 487 was compared to a slightly modified protocol allowing the cells to have a recovery period between end of treatment and addition of the cytokinesis blocker cytochalasin B. Lymphocyte proliferation was studied in response to stimulation with phytohemagglutinin and the normal cell cycle time was assessed by bromodeoxyuridine uptake. The presented data show difficulties in the detection of an aneugenic compounds in binucleate cells and marked differences in the induction of micronuclei in the micronucleus *in vitro* by the two different test protocols employed by using the four different reference chemicals. Reproducible results were obtained with the clastogenic reference chemical MMC, regardless of the protocol used. With both aneugenic compounds robust and adequate results could be obtained by including the evaluation of micronucleated cells and using the pulse treatment. Robust data were obtained with CPA when using a time schedule including a recovery period.

**PS 1503 Clastogenicity and Mutagenicity Testing of Gaseous Compounds.**

C. S. Farabaugh<sup>1</sup>, J. Randazzo<sup>2</sup>, M. M. Wells<sup>1</sup>, M. L. Moy<sup>1</sup> and M. J. Schlosser<sup>1</sup>. <sup>1</sup>WIL Research, Skokie, IL; <sup>2</sup>WIL Research, Ashland, OH.

WIL Research evaluated methods for genetic toxicology testing with gaseous compounds in both the *In Vitro* Chromosome Aberration (CA) assay using human peripheral blood lymphocytes (HPBL) and the Bacterial Reverse Mutation assay (Ames assay). In the CA assay, 10 mL HPBL cultures were initiated with S9 (3-hour exposure) and without S9 (3- and 22-hour exposures) in flasks and were sealed in airtight Tedlar bags using a heat sealer. The air was evacuated and a mixture of ambient air, ~5% CO<sub>2</sub>, and the appropriate concentration of Chloroethane (CE) up to 30% v/v for the 22-hour exposure or Propylene Oxide (PO) up to 10% v/v

for the 3-hour exposures were added via a septum into the bag. The cultures in the bags were then incubated at 37°C in a humidified atmosphere with 5% CO<sub>2</sub>. For the 3-hour exposure periods, cultures were removed from bags and washed before being returned to the humidified incubator until a single harvest time of ~22 hours. Statistically significant, dose related increases in cells with aberrations when compared to the vehicle control cultures were observed with responses of up to 42% of cells for the 22-hour exposure (at a dose level of 5% v/v), 14.5% for the 3-hour exposure with S9 (2.5% v/v), and 30% for the 3-hour exposure without S9 (2.5 % v/v).

In the Ames assay, *Salmonella* tester strains TA98, TA100, TA1535, and TA1537 and *E. coli* tester strain WP2uvrA were exposed using the preincubation method to various concentrations of CE up to 25% v/v and incubated at 37°C for ~30 minutes in sealed Tedlar bags. The air was evacuated and a mixture of ambient air and the appropriate concentration of CE were added via a septum into the bag. Following exposure, the cultures were removed from the bags, plated, and incubated at 37°C for ~48 hours. Dose related increases in the mean number of revertants when compared to the vehicle control cultures were observed.

Results indicate that gaseous exposures using Tedlar bags are appropriate for producing positive responses with and without S9 with known clastogenic and mutagenic compounds in the CA and Ames assays.

**PS 1504 Quantitative Analysis of Specific DNA Adducts and *In Vivo* Mutagenicity following Exposure to the Hepatocarcinogen Estragole.**

Y. Ishii<sup>1</sup>, S. Takasu<sup>1</sup>, K. Matsushita<sup>1</sup>, K. Kuroda<sup>1</sup>, T. Nohmi<sup>2</sup>, K. Ogawa<sup>1</sup>, A. Nishikawa<sup>1</sup> and T. Umemura<sup>1</sup>. <sup>1</sup>Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Research and Development Promotion, National Institute of Biomedical Innovation, Osaka, Japan.

DNA modifications are considered a trigger for somatic mutations. However, factors such as DNA repair and cell proliferation are known to contribute to DNA modification processes, promoting gene mutations. We previously reported that specific DNA adducts are formed in the livers of rats following treatment with estragole (ES), a hepatocarcinogen in rodents. ES caused formation of the DNA adducts, ES-3'-N<sup>2</sup>-dG, ES-3'-C8-dG, and ES-3'-N<sup>6</sup>-dA, in rat livers, as determined by LC-MS/MS analysis. To clarify associations between the number of modified bases and the mutant frequencies (MFs) in the same animal and organ, we quantified ES-specific DNA adducts and performed reporter gene mutation assays in livers, kidneys, and lungs of 6-week-old F344 *gpt* delta rats given ES at doses of 0, 3, 30, and 300 mg/kg/day by gavage for 4 weeks. Relative liver and kidney weights were significantly increased in rats given high-dose ES. Mitosis, single-cell necrosis in hepatocytes, and oval cell proliferation were seen in high-dose group livers. Three ES-specific DNA adducts were detected in a dose-dependent manner beginning with the low-dose group. *gpt* MF was significantly increased only in the high-dose group. In lungs and kidneys, DNA adducts were detected only in the high-dose group, but their frequencies were almost identical to those in the low-dose group livers. These results suggest that the site specificity observed in ES carcinogenicity may depend on the number of modified bases. In addition, the fact that ES-specific DNA adducts were detected to some extent in the livers of rats treated with moderate doses, despite *gpt* MF being unchanged, suggests involvement of micro-environmental factors, such as cell proliferation and DNA repair enzymes, in the progression from DNA modification to gene mutation. Some of these factors will be presented, along with results of *gpt* mutation assays in the lungs and kidneys.

**PS 1505 Mutagenic Activity of Allura Red AC and Tartrazine in *Salmonella typhimurium*.**

R. Narayananeni, S. Sharma, S. Visram, G. Lo and R. D. Mehta. *Genetic Toxicology, PBR Laboratories Inc, Edmonton, AB, Canada.*

Allura Red AC (Red 40) and Tartrazine (Acid yellow 23) are two of the most commonly used artificial color additives (azo dyes) in food, drug and cosmetic industries. Allura Red and Tartrazine are nitrous derivatives which are the focus of studies on mutagenesis and carcinogenesis because of their transformation into aromatic amines after being metabolized by the gastrointestinal microflora. We investigated the mutagenic activity of Tartrazine and Allura Red against TA98, TA100, YG1041 and YG1042 strains of *Salmonella Typhimurium* using the protocol described by Prival and Mitchell (1981). Both YG1041 and YG1042 strains, derived from TA98 and TA100, respectively carry a plasmid with genes for higher levels of nitroreductase and O-acetyltransferase involved in the break down of azo dyes to mutagenic aromatic amines. These strains have been shown to detect mutagenic activity of azo dyes in the effluents from textile industries, eliciting a higher mutagenic response compared to TA98 and TA100 (Umbuzeiro et al, 2003). We used six dose levels (4mM, 2mM, 1mM, 0.5mM, 0.25mM, 0.125mM) of Allura Red and Tartrazine for testing the mutagenic activity. The assay was performed

under hamster S9-activated and non-activated conditions. In our study, none of the four tester strains showed toxicity or an increase in the mutation frequency at the dose levels tested. Whereas, Tartrazine has been reported to have cytotoxic effect in mammalian cells (Patterson and Butler, 1982) and Allura Red has been found to cause DNA damage when tested with the comet assay (Shuji et al, 2001). European Food Safety Authority (2009) has also reported that Allura Red was negative in *in vitro* genotoxicity as well as long term carcinogenicity studies. Our results demonstrate that the salmonella strains even with high level of nitroreductase and O-acetyltransferase activities failed to show mutagenic activity in both, Tartrazine and Allura Red.

## PS 1506 Genotoxicity of 2-Bromo-3'-Chloropropiophenone.

F. Meng<sup>1</sup>, J. Yan<sup>1</sup>, Y. Li<sup>1</sup>, P. Fu<sup>2</sup>, L. Fossum<sup>3</sup>, R. Sood<sup>3</sup>, D. Mans<sup>3</sup>, P. Chu<sup>3</sup>, M. M. Moore<sup>1</sup> and T. Chen<sup>1</sup>. <sup>1</sup>Division of Genetic and Molecular Toxicology, NCTR/FDA, Jefferson, AR; <sup>2</sup>Division of Biochemical Toxicology, NCTR/FDA, Jefferson, AR; <sup>3</sup>CDER, FDA, Silver Spring, MD.

Impurities are generally an integral part of any drug substance or drug product. They can be either process-related impurities that are not completely removed during purification or formed due to the degradation of the drug substance over the product shelf-life. Unlike the drug, they do not provide health benefits. Therefore, their amount should be minimized. 2-Bromo-3'-chloropropiophenone (BCP) is an impurity of bupropion, a second-generation antidepressant and a smoking cessation aid. The US Pharmacopeia recommends an acceptable level for BCP that is not more than 0.1% of the maximum dose of bupropion. Recently a qualitative structure-activity analysis (DEREK for Windows version 13) has shown that BCP is likely genotoxic. The genotoxicity of BCP, however, has not been tested based on a search of the available public literature. Because the US FDA limits genotoxic impurities to much lower levels than non-genotoxic impurities, it is important to determine whether or not BCP is genotoxic. Therefore, in this study the Ames test and the *in vitro* micronucleus assay were conducted to evaluate the genotoxicity of BCP. BCP was mutagenic with S9 metabolic activation, increasing the mutant frequencies in a concentration-dependent manner, up to 22- and 145-fold induction over the controls in Salmonella strains TA100 and TA1535, respectively. BCP was also positive in the *in vitro* micronucleus assay, resulting in up to 3.3- and 5.1-fold increase of micronucleus frequency for treatments in the absence and presence of S9, respectively; and 9.9- and 7.4-fold increase of hypodiploids without and with S9, respectively. The addition of N-acetyl-L-cysteine, an antioxidant, reduced but not eliminated the genotoxicity of BCP in both assays. The results suggest that BCP is mutagenic, clastogenic, and aneugenic, and these activities are possibly mediated via generation of reactive metabolites.

## PS 1507 Comparison of Mainstream Smoke (Mss) Cytotoxicity and Clastogenicity from Filtered Cigars with the Corresponding Data for the Mss from the KY3R4F Reference Cigarette.

J. H. Lauterbach<sup>1</sup>, E. Z. Sheabar<sup>2</sup>, D. Muldoon<sup>2</sup>, G. Nelluru<sup>2</sup>, T. Oshunwusi<sup>2</sup> and D. Powell<sup>2</sup>. <sup>1</sup>Lauterbach & Associates, LLC, Macon, GA; <sup>2</sup>Arista Laboratories, Richmond, VA.

Filtered cigars, dimensionally similar to 100s cigarettes, have become popular smoking articles. Unlike cigarettes, the tobacco column is wrapped with a single ply of paper-type reconstituted tobacco. The blends in filtered cigars range from light-air cured tobaccos to tobaccos with more cigar-like character. Since filtered cigars have been reported to be popular with younger smokers, concern has been raised about the toxicity of the smoke relative to cigarette smoke. Rickert et al., 2011, reported that on a per unit smoke nicotine basis the toxicity of the mainstream smoke (MSS) from filtered cigars was no less than that of the MSS from cigarettes. However, the Rickert work used the Health Canada Intensive (HCI) smoking regimen and used king-size like products that are no longer popular or available commercially. In this research, we have used ISO smoking regimen and three contemporary 100 mm filtered cigars, one of which (FC1) had a more traditional cigar blend than did the other two (FC2, FC3). On a unit TPM basis, there was little difference in the Neutral Red cytotoxicity of the MSS from the three filtered cigars and the cytotoxicity of the MSS of the KY3R4F reference cigarette. However, when the results were put on a per unit smoke nicotine basis, the MSS from two of the three filtered cigars (FC2, FC3), which had low MSS nicotine concentrations, were more cytotoxic than the MSS from the KY3R4F. On a per unit nicotine basis, the cytotoxicity of the MSS from FC1 was similar to that of the MSS of the KY3R4F. Genotoxicity was determined with the *in vitro* micronucleus assay. On a unit TPM basis, toxicity rankings (-S9) were FC1=FC3>FC2>>KY3R4F and (+S9) were FC3>FC2>FC1>>KY3R4F. On a unit nicotine basis, toxicity rankings (for both -S9, +S9) were FC3>FC2>FC1>>KY3R4F. Our results were similar to those reported by Rickert et al. and showed that the ISO smoking regimen was better able to show product differences than was the HCI regimen.

## PS 1508 Effects of Obesity on Spontaneous Reporter Gene Mutations in *Gpt* Delta Mice Fed a High-Fat Diet.

S. Takasu<sup>1</sup>, Y. Ishii<sup>1</sup>, K. Matsushita<sup>1</sup>, K. Kuroda<sup>1</sup>, Y. Kodama<sup>2</sup>, K. Ogawa<sup>1</sup>, A. Nishikawa<sup>3</sup> and T. Umemura<sup>1</sup>. <sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Division of Toxicology, National Institute of Health Sciences, Tokyo, Japan; <sup>3</sup>Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.

Epidemiologically, obesity has been suggested to be associated with increased risk of several human cancers, including cancers of the liver, kidneys, and colon. In several rodent models, genetically induced obesity or high-fat diet (HFD) induced obesity has been shown to enhance carcinogenesis in the liver and colon after treatment with a regimen of respective tumor initiators. However, the factors responsible for the obesity-related progression of carcinogenesis, especially the initiation phase, are not fully elucidated. To reveal the effects of obesity induced by an HFD on spontaneous gene mutations, we performed reporter gene mutation assays in liver, kidney, and colon tissues from obese mice fed an HFD. Six-week-old male and female C57BL/6 *gpt* delta mice were fed either an HFD or a standard diet (STD) for 13 or 26 weeks. At the end of the experimental period, all mice were sacrificed, and reporter gene mutation assays were performed. Final body weights of male and female mice fed an HFD for 13 weeks were significantly increased compared with those fed an STD. *gpt* and *Sp1* mutant frequencies in the liver, kidneys, and colon of male mice fed an HFD for 13 weeks were not significantly different from those fed an STD. These results implied that HFD-induced obesity does not influence the spontaneous frequencies of somatic gene mutations, indicating that obesity may affect the tumor promotion phase rather than the tumor initiation phase to enhance carcinogenesis. Further data from the organs of mice fed an HFD for 26 weeks will be presented to evaluate the effects of long-term consumption of an HFD on spontaneous mutagenicity *in vivo*.

## PS 1509 Community Lead (Pb) Domains and Exposure Disparities: Case Study of Pre- and Post-Katrina New Orleans.

H. W. Mielke<sup>1,2</sup>, C. R. Gonzales<sup>3</sup>, E. T. Powell<sup>3</sup> and P. W. Mielke<sup>4</sup>. <sup>1</sup>Pharmacology, Tulane University School of Medicine, New Orleans, LA; <sup>2</sup>Chemistry, Tulane University, New Orleans, LA; <sup>3</sup>Lead Lab, Inc., New Orleans, LA; <sup>4</sup>Statistics, Colorado State University, Fort Collins, CO.

We sought to gain insight into the Pb toxicity characteristics of communities in New Orleans. Based on previous soil Pb mapping we divided New Orleans census tracts into two soil Pb domains, high (median  $\geq 100$  mg/kg) and low (median  $< 100$  mg/kg). Soil samples from four locations represented each of the domains: busy streets, residential streets, house sides, and open spaces (away from streets and houses). Blood and soil Pb concentrations within the high and low Pb domains of New Orleans were analyzed by permutation statistical methods (Multi-Response Permutation Procedures). The children's blood Pb prevalence  $\geq 5$   $\mu\text{g/dL}$  for the high and low Pb domains were 58.5% and 24.8%, respectively, pre-Katrina vs. 29.6% and 7.5% in post-Katrina New Orleans. In the high Pb domain median soil Pb was 367, 313, 1228, and 103 mg/kg, respectively, busy streets, residential streets, house sides, and open space locations; in the low Pb domain median soil Pb was 64, 46, 32, and 28 mg/kg, respectively (p-Values  $< 10E-16$ ). After Katrina relatively small decreases in soil Pb were observed, and elevated soil Pb permeates the high Pb domain; children living there generally lack Pb safe areas for outdoor play. The low Pb domain was safer by factors ranging from 3 to 38 depending on specific location. Patterns of lead deposition from decades of Pb accumulation have not been transformed by renovations conducted post-Katrina. We expect that all large cities will exhibit the same characteristics as observed in New Orleans. Low Pb soils are available outside of cities to remedy soil Pb contamination. Mapping soil Pb delineates Pb deposition and assists with planning to improve primary prevention of Pb exposure.

## PS 1510 Portable XRF Technology to Quantify Lead and Strontium in Bone *In Vivo*—Calibration and Validation.

A. J. Specht<sup>1</sup>, M. Weisskopf<sup>2</sup> and L. Nie<sup>1</sup>. <sup>1</sup>Health and Human Sciences, Purdue University, West Lafayette, IN; <sup>2</sup>Public Health, Harvard University, Boston, MA.

Concentrations of lead and strontium in bone can serve as a long-term indicator of exposure levels, and can be more easily correlated to their respective health effects. Lead adversely affects almost all the systems in the body. High levels of strontium, on the other hand, have been correlated to skeletal abnormalities in animal and human populations. We have previously shown the viability of a portable XRF system in detection of lead in bone *in vivo*. This system has since been improved to include a larger detector with an improved geometry. In this project, the new instrument was calibrated and validated to quantify lead and strontium in bone *in vivo*.

The system was effectively calibrated for bone lead quantification with lead doped bone-equivalent phantoms. However, it is difficult to calibrate the system for bone strontium quantification using strontium doped phantoms because most of the bone equivalent materials are severely contaminated with strontium. Therefore, a new calibration method was developed, which made use of a Monte Carlo (MC) simulation model developed specifically for this instrument. In this new method, net strontium signals were obtained for different soft tissue thicknesses using MC simulations and the signals were plotted against corresponding concentrations of the strontium. The concentrations of strontium for in vivo measurements can then be calculated from the calibration lines generated from MC simulation. Three main results were obtained from this study: a) An agreement between the experimental and simulated spectra of approximately 13% were shown with the MC simulation model; b) the detection limit for bone lead and strontium is improved by a factor of 2 with the improved instrument; c) it is valid to calibrate the system with the calibration lines created by MC simulations. In conclusion, the new system with improved detection limit, combined with the use of Monte Carlo simulations for calibration can be applied to accurately quantify lead and strontium in bone in vivo.

## PS 1511 The Effect of Environmental Exposure to Lead on Blood Pressure in Korean Adults.

J. Park<sup>1</sup>, S. Choi<sup>1</sup>, S. Eom<sup>2</sup>, D. Kim<sup>1</sup>, H. Kim<sup>2</sup>, B. Choi<sup>1</sup>, K. Park<sup>3</sup>, H. Pyo<sup>3</sup>, Y. Hong<sup>4</sup>, S. Sohn<sup>5</sup> and H. Kwon<sup>6</sup>. <sup>1</sup>Chung-Ang University, Seoul, Republic of Korea; <sup>2</sup>Chungbuk National University, Cheongju, Republic of Korea; <sup>3</sup>Korea Institute of Science and Technology, Seoul, Republic of Korea; <sup>4</sup>Dong-A University, Busan, Republic of Korea; <sup>5</sup>Chonnam National University, Gwangju, Republic of Korea; <sup>6</sup>Dankook University, Cheonan, Republic of Korea.

General population is exposed to chronic and low level of lead (Pb). Previous studies reported that blood Pb is possibly related to the blood pressure. However, the effect of environmental exposure to Pb on blood pressure is not clear yet. This study was performed to estimate the representative blood Pb level and to assess whether blood pressure is affected by chronic and low Pb exposure in Korean adults. The total study subjects of 2,090 people (male: 908, female: 1,182) were nationwide sampled by multi-staged, sex- and age- stratified probability method, who had not been exposed to Pb occupationally. The geometric mean concentration of Pb in blood was 2.22 ug/dL. The level of blood Pb was significantly higher in males (2.60 ug/dL) than in females (1.97 ug/dL). The level of blood Pb was increased with age-dependent pattern which was the highest in the group of 50-59 years old. Also, blood Pb level was affected by individual behavioral patterns such as smoking and drinking. The mean concentration of blood Pb was higher in rural or urban inhabitants than in metropolitan, respectively. The positive relations were observed between blood Pb concentrations and systolic/diastolic blood pressure in males and in females, both. However, blood Pb was significantly correlated with systolic and diastolic blood pressure after adjustment for covariates in males, but not in females. In summary, the findings from this study suggest that chronic Pb exposure under the environment might be increase blood pressure, systolic and diastolic, both, in males.

## PS 1512 Induction of Autophagy and Aberrant MHC Class II Surface Expression in Lead-Exposed Murine Macrophage Raw 2674 Cells: Dysregulation in Mhc-II<sup>+</sup> Compartment Exocytosis.

R. M. Gogal<sup>1</sup>, R. P. Kerr<sup>1</sup>, T. M. Krunkosky<sup>1</sup>, D. J. Hurley<sup>2</sup>, B. S. Cummings<sup>3</sup> and S. D. Holladay<sup>1</sup>. <sup>1</sup>Department of Biosciences and Diagnostic Imaging, University of Georgia, Athens, GA; <sup>2</sup>Department of Population Health, University of Georgia, Athens, GA; <sup>3</sup>Department of Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Aberrant major histocompatibility complex class II (MHC-II) surface expression on antigen presenting cells (APCs) is associated with dysregulated immune homeostasis. Lead (Pb) is known to increase MHC-II surface expression on murine peritoneal macrophages ex vivo at concentrations exceeding 25  $\mu$ M. Little data exist examining this effect at physiologically relevant concentrations. To address this deficit, we examined the effects of Pb on MHC-II surface expression, secondary T-cell activation markers (CD80, CD86, CD40), cell viability, cellular metabolic activity, and  $\beta$ -hexosaminidase activity in RAW 267.4 macrophage cell lines, with changes in cell ultrastructure evaluated by electron and confocal microscopy. Pb induced a bi-phasic, dose dependent increase in MHC-II, CD86, and lysosome-associated LAMP-1 and LAMP-2 surface expression during one cell doubling cycle (17 hr), which was mirrored by increased  $\beta$ -hexosaminidase activity. Although cell viability was unaffected, cellular metabolism was inhibited. Electron microscopy revealed evidence of lipid vacuolization, macroautophagy and myelin figure formation in cells cultured with either Pb or LPS. Confocal microscopy with antibodies

against LC3B showed a punctate pattern consistent with the presence of mature autophagosomes. Collectively, these data suggest that 2.5-5.0  $\mu$ M Pb increased MHC-II surface expression by inhibiting metabolic activity, inducing autophagy, and increasing MHC-II trafficking in a macrophage cell line.

## PS 1513 Exposure to Cobalt Causes Changes in Gene Expression and Protein Abundance in Two Rat Liver-Derived Cell Lines.

M. Permenter<sup>2</sup>, W. E. Dennis<sup>1</sup>, J. A. Lewis<sup>1</sup> and D. A. Jackson<sup>1</sup>. <sup>1</sup>USACEHR, Fort Detrick, MD; <sup>2</sup>Excet, Inc., Fort Detrick, MD.

Cobalt is an essential component of the diet, but in large doses it is acutely toxic, and chronic exposures can injure multiple organ systems. While the toxic effects of cobalt have been widely studied, the exact mechanisms of toxicity remain unclear. In order to further elucidate these mechanisms in liver, we exposed two rat liver-derived cell lines, H4-II-E-C3 and MH1C1, to sublethal concentrations of cobalt chloride to eliminate cell-line specific effects. We chose the treatment concentrations based on a novel qPCR assay using a panel of genes developed from previous metal toxicity studies, as opposed to traditional cytotoxicity assays, to more accurately predict gene expression endpoints at sublethal concentrations. We examined changes in gene expression using DNA microarrays and also examined changes in secreted and cytoplasmic protein abundance using mass spectrometry. We performed both gene-level and functional analyses of the results and observed changes in pathways that are involved in the Nrf2-mediated response, protein degradation, glutathione production, Hif-1 signaling, and energy metabolism. These results are consistent with the known effects of cobalt toxicity, including oxidative stress and hypoxic responses. The changes in protein abundance closely resemble and validate our conclusions drawn from the microarray analysis. This work offers key insights into the role specific genes, proteins, and pathways play in cobalt toxicity mechanisms, and provides leads, which upon validation, may characterize novel toxic effects.

Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the U.S. Army. The research described herein was sponsored by the U.S. Army Medical Research and Materiel Command, Military Operational Medicine Research Program.

## PS 1514 Dose-Response Relationships for Blood Cobalt Concentrations and Associated Health Effects.

A. Monnot, S. Gaffney, D. J. Paustenbach and B. L. Finley. ChemRisk, San Francisco, CA.

Cobalt (Co) is an essential component of vitamin B12. As with all metals, at sufficiently high doses, Co can have detrimental effects on different organ systems, and adverse responses have been observed in patients on Co therapy, workers handling Co-containing powders, and other Co-exposed groups. Although blood Co concentrations are thought to be the most accurate indicator of ongoing Co exposure, little is known regarding the dose-response relationships between blood Co concentrations and adverse health effects. In this analysis, we reviewed the animal toxicology and epidemiology literature to identify blood Co concentrations at which effects have, and have not, been reported. Where necessary, a biokinetic model was used to convert oral doses to blood Co concentrations. Our results indicate that blood Co concentrations in humans of approximately 300  $\mu$ g/L and higher have been associated with certain hematological and reversible endocrine responses (polycythemia and reduced iodide uptake, respectively), while blood Co concentrations of 700-800  $\mu$ g Co/L and higher have been consistently associated with a risk of more serious neurological, reproductive, or cardiac effects. Although there are some anecdotal reports to the contrary, the weight of evidence from the many available studies suggest that blood Co concentrations of 300  $\mu$ g/L and less have not been associated with adverse responses in healthy humans. This suggests that certain populations known to have blood Co concentrations of < 100  $\mu$ g/L, such as some patients with Co-containing hip implants and those who ingest Co vitamin supplements, are unlikely to be at risk due to Co exposure.

## PS 1515 Loss of Hypoxia-Inducible Factor (HIF)-1 $\alpha$ , and Not HIF-2 $\alpha$ , in the Lung Alveolar Epithelium of Mice Leads to Enhanced Eosinophilic Inflammation in Cobalt-Induced Lung Injury.

S. P. Proper, K. Greenwood, J. Harkema and J. J. LaPres. Michigan State University, East Lansing, MI.

Cobalt is a known hypoxia mimic and stabilizer of hypoxia-inducible factors (HIFs). HIF-1 $\alpha$  contributes to cobalt toxicity in vitro and previous work in our lab has shown that loss of HIF-1 $\alpha$  in the alveolar epithelial cells led to a switch from a

neutrophilic to eosinophilic response. While HIF-1 $\alpha$  and HIF-2 $\alpha$  have known overlapping gene targets, HIF-2 $\alpha$  is the predominant HIF isoform in the adult lung, and little is known about HIF-2 $\alpha$  in the context of cobalt-induced lung injury. We therefore hypothesized that HIF-2 $\alpha$  could be playing a more active role in cobalt toxicity. To compare the roles of HIF-1 $\alpha$  and HIF-2 $\alpha$  in cobalt-induced lung injury, we used mice deficient in either HIF-1 $\alpha$  (HIF-1 $\alpha$  $\Delta/\Delta$ ), HIF-2 $\alpha$  (HIF-2 $\alpha$  $\Delta/\Delta$ ) or both HIF-1 $\alpha$  and HIF-2 $\alpha$  (HIF-1/2 $\alpha$  $\Delta/\Delta$ ) in alveolar type II epithelial cells. Mice were exposed to cobalt (60  $\mu$ g/day) or saline via oropharyngeal aspiration for five consecutive days, and sacrificed on day six. Bronchoalveolar lavage (BAL) cellularity, qRT-PCR, and histopathologic analyses were performed. Results confirm previous data showing that loss of HIF-1 $\alpha$  leads to enhanced eosinophilic inflammation, and an enhanced T-helper type 2 (Th2) response. In contrast, inflammation in HIF-2 $\alpha$  mice resembled that of control mice following cobalt exposure. HIF-1/2 $\alpha$  $\Delta/\Delta$  mice showed similar cobalt-induced eosinophilic inflammation seen in HIF-1 $\alpha$  $\Delta/\Delta$  mice. Together, data suggest that loss of HIF-1 $\alpha$  in lung epithelium plays the dominant role in determining the response to cobalt-induced lung injury, and that HIF-2 $\alpha$  does not play an active role in cobalt-induced lung injury. Coupled with other experiments performed in our lab, this indicates that epithelial HIF-1 $\alpha$  in the postnatal developmental period plays a central role in guiding immune responses in the airway.

**PS 1516 Can Zinc Reverse Uranium Toxicity? Potential for a Community-Based Intervention.**

L. G. Hudson, K. L. Cooper, R. Tsosie, D. Begay and J. L. Lewis.  
*Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.*

Many Navajo people have been, and continue to be, exposed to uranium through the legacy of uranium mining. 1100 abandoned Cold War uranium waste sites remain within Navajo communities and numerous wells exceed maximum contaminant levels for uranium and other metals such as arsenic. Certain metals can disrupt protein function by interacting with zinc finger structures and thus inhibit important cellular processes including DNA repair. Based on this mechanism, many metals are now viewed as co-carcinogens and amplify the DNA damaging capacity and tumorigenicity of other carcinogens even at levels where the metals alone are not carcinogenic. The carcinogenicity of uranium is well established in the literature, but there is little known regarding uranium interaction with zinc finger protein structures. Published reports demonstrating that uranium exposure leads to deficiency in DNA repair processes suggest that uranium may interfere with zinc finger DNA repair proteins. Our work with arsenic demonstrates that very low levels of arsenic causes zinc depletion from target zinc finger DNA repair proteins leading to increased DNA damage and mutagenesis that can be reversed by zinc. Based on these findings, we investigated the effect of uranium on DNA repair and the activity of a specific zinc finger DNA repair protein target (PARP-1). Uranium in the form of uranyl acetate (UA) demonstrated little cytotoxicity in an immortalized human embryonic kidney cell line (HEK293) at concentrations at or below 10  $\mu$ M. UA at concentrations of 10 or 100  $\mu$ M inhibited the DNA repair protein PARP-1 and caused retention of ultraviolet radiation-induced DNA lesions (CPDs and pH2Ax). The addition of zinc ameliorated PARP-1 inhibition and partially decreased the retention of DNA damage. These findings suggest that one mechanism of uranium toxicity may rely on disruption of zinc finger protein function, so this work will inform a planned assessment of the potential for zinc to block uranium toxicity as an additional component of the Navajo Birth Cohort Study.

**PS 1517 Toxicological Properties of PM<sub>1</sub> from Pellet Combustion—Role of Zn.**

O. Uski<sup>1,2</sup>, P. Jalava<sup>2</sup>, M. Happonen<sup>2</sup>, T. Kaivosoja<sup>2</sup>, H. Lamberg<sup>2</sup>, J. Leskinen<sup>2</sup>, T. Torvela<sup>2</sup>, J. Tissari<sup>2</sup>, O. Sippula<sup>2</sup>, J. Jokiniemi<sup>2,3</sup> and M. Hirvonen<sup>2,1</sup>.  
<sup>1</sup>*Department of Environmental Health, National Institute for Health and Welfare, Kuopio, Finland;* <sup>2</sup>*Department of Environmental Science, University of Eastern Finland, Kuopio, Finland;* <sup>3</sup>*Technical Research Centre of Finland, Espoo, Finland.*

Biomass combustion is important source of ambient air fine particulate matter (PM<sub>2.5</sub>), which has been associated with a substantial health burden. Thus, it is important to reveal the effect of used fuel in induced adverse health effects. In search for causative constituents, we studied the role of Zn on toxicity of combustion emission PM<sub>1</sub>. PM<sub>1</sub> samples were produced in complete combustion using a pellet boiler (25 kW). Untreated reference pellet fuel (including 11 mg/kg Zn) was used as control sample. The same pellets were doped with Zn in different concentrations; 170, 480 and 2300 mg Zn/kg fuel. PM<sub>1</sub> samples were collected on PTFE-filters from diluted flue gas by using Dekati® gravimetric impactor, and subsequently extracted from filters

by using methanol. Mouse macrophages (RAW264.7) were exposed for 24 h to four doses (15, 50, 150 and 300 mg/ml) of emission samples. Markers for cytotoxicity (MTT), inflammation (MIP-2 and TNF- $\alpha$ ) and cell cycle analysis (DNA content analysis) were measured.

All the studied emission samples induced significant dose-dependent decrease in cell viability when compared to control. However, with the samples where Zn was added the toxicity was more severe. Moreover, significant increase in S-G<sub>2</sub>/M-phase in the cell cycle was detected after exposure to emissions from all Zn doped pellets, but not with reference pellet. Instead, only minor inflammatory responses were seen by all the samples.

The present results indicate that in very good combustion conditions, high Zn content of fuel induces significant changes in the cell cycle and increases cytotoxicity of PM<sub>1</sub>. Combustion particles toxicity is affected not only by the appliances design or the combustion conditions but also of the fuel and fuel quality.

**PS 1518 A Preliminary Study on Analytical Methodology for Determination of Zinc in Liver of Laboratory Rats, by ICP-QMS.**

L. V. Saldivar<sup>1</sup>, H. Garcia<sup>1</sup>, R. Leon<sup>1</sup>, T. Rodríguez Salazar<sup>1</sup>, M. G. Espejel<sup>1</sup> and T. I. Fortoul<sup>2</sup>. <sup>1</sup>*Analytical Chemistry, UNAM Faculty of Chemistry, Mexico City, Mexico;* <sup>2</sup>*Cellular and Tisular Biology, UNAM Faculty of Medicine, Deleg Coyoacán, México City, Mexico.* Sponsor: D. Acosta.

Zinc is an essential micronutrient for living organisms. It plays a specific role in the synthesis and stabilization of proteins. Its deficiency is characterized by growth retardation, and impaired immune function. While the excess of Zn results in fever and pathological changes in some tissues. Excessive absorption of zinc suppresses copper and iron absorption. Therefore Zn, Cu and Fe can be utilized as pathological indicators. The determination of these elements is of interest in the biomedical area, where laboratory rats are used as model animals, because of their physiological similarities to the human body.

The Inductively Coupled Plasma-Quadrupole Mass Spectrometry (ICP-QMS) has been applied to the analysis of trace elements in biological samples due to its characteristics: low detection limit, multielemental analysis and low sample volume. In this work, analytical methodology was optimized to determine total Zn concentration in livers of laboratory rats. Samples were dried and homogenized, and digested in a microwave oven using HNO<sub>3</sub> and H<sub>2</sub>O<sub>2</sub> mixture. Analytical quantification of the isotopes <sup>66</sup>Zn using <sup>74</sup>Ge as internal standard, was performed using an Elan DRC-e spectrometer (Perkin-Elmer). The dynamic reaction cell was not employed. Results for three replicates of certified reference material (NIST SRM 1577c, National Institute of Standards and Technology) were in good agreement with certified values: 0.21 % (mean relative error, accuracy), and 0.2 % RSD (precision). The range of Zn total concentrations found in samples of livers of rats were: 37-163 mg/kg. This study belongs to a research where it is included the determination of Zn/Cu ratio in several tissues.

The authors thank the financial support of DGAPA-PAPIIT IN229911 and PAL 3400-02.

**PS 1519 Effects of Tungsten Chemical Species on Biochemical Pathways and Mineralization in Bone.**

C. Y. Ang<sup>1</sup>, D. R. Johnson<sup>2</sup>, J. M. Seiter<sup>2</sup>, A. R. Osterburg<sup>3</sup>, G. F. Babcock<sup>3</sup>, P. G. Allison<sup>2</sup> and A. J. Kennedy<sup>2</sup>. <sup>1</sup>*Badger Technical Services, Vicksburg, MS;* <sup>2</sup>*Environmental Laboratory, US Army Engineer Research & Development Center, Vicksburg, MS;* <sup>3</sup>*Cincinnati Shriners Hospital for Children and the University of Cincinnati, Cincinnati, OH.*

Tungsten (W) is a metal that has numerous civil and military applications. When W enters the environment, it is rapidly oxidized and speciates based on the environmental matrix it is embedded in. Bone is the long-term storage organ for W—and presumably W chemical species if present—when taken up by organisms. It is unknown what long-term effects W has in bone, therefore, we evaluated the effects of W species on biochemical pathways in hFOB 1.19 osteoblastic cells exposed to water (control) or W chemical species (sodium tungstate, phosphotungstate [PW], poly tungstate [polyW], and tungstosilicic acid [TSA]) at 0-10,000  $\mu$ M for 24 h at 37 degrees C. W species did not affect adenosine triphosphate (ATP) concentrations except at the highest concentration. PW, polyW, and TSA, but not tungstate, significantly increased protein tyrosine kinase activity at 10,000  $\mu$ M after 4 h exposure. Tungstate and PT increased cellular cyclic adenosine monophosphate (cAMP) at  $\geq$  100  $\mu$ M, while TSA decreased cellular cAMP at 10,000  $\mu$ M. Preliminary analyses also demonstrate an effect on alkaline phosphatase, the enzyme involved in bone mineralization. Synchrotron analysis of bone from female rats exposed to 200

mg/kg/d sodium tungstate in drinking water ad libitum for 90 d showed W incorporation into bone as calcium poly-tungstate (77% total W in bone) and calcium tungstate (23%). These data demonstrate that W chemical species generally only affect phosphate-dependent cell signaling and secondary messenger pathways in hFOB 1.19 cells, and may also affect bone mineralization enzymes, resulting W species incorporation into bone in animals. Follow-up studies will analyze the effects on bone mineralization and strength associated with W incorporation due to chronic exposure.

**PS 1520 Accumulation of Manganese (Mn) in Rat Brain Ventricular Region following *In Vivo* Subchronic Mn Exposure: Effect on Copper (Cu) Status.**

S. L. O'Neal, L. Hong and W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Welders and smelters occupationally exposed to high levels of Mn have an increased risk for developing manganism, a disease similar to Parkinson's. Existing human and animal studies indicate that Mn accumulates mainly in the striatum, the area adjacent to the brain ventricular region (BVR) which houses cells implicated in adult neurogenesis. The neural stem cells in BVR are capable of migrating to striatum and hippocampus en route to the olfactory bulb. This group has previously shown Mn exposure results in Mn accumulation in the choroid plexus (CP), cerebrospinal fluid (CSF) and increases intracellular Cu concentration. This study was undertaken to test the hypothesis that a high Mn level in the CP and CSF may influence the surrounding ventricular structure and interfere with the homeostasis of other essential elements. Adult male rats received daily ip injections of MnCl<sub>2</sub> at the doses of 6 and 15 mg Mn/kg as the low and high dose groups, respectively, or saline as the control, 5 days per week for 4 weeks. Twenty-four hr after the last injection, BVR, femur bone and liver tissues were dissected and quantified by atomic absorption spectroscopy for concentrations of Mn, Cu, iron (Fe) and zinc (Zn). Data analysis by Student's t-test showed that levels of Mn in BVR of the low- and high-dose groups increased by 94.8% and 218.5%, respectively, as compared to controls (n=4-6, p < 0.01). In femur, Mn concentration increased by 278.2% and 1237.4% in the low- and high-dose groups, respectively (p < 0.01). Interestingly, Cu concentrations in BVR decreased significantly for low- and high-dose groups (p < 0.05). In contrast, Cu levels in bone increased by 23.2% and 51.2% for low- and high-dose groups, respectively (p < 0.05). Taken together, our data provide the initial evidence that Mn accumulates in brain ventricular area following *in vivo* exposure. Mn's potential impairment of this region in the disease progression of Mn Parkinsonism deserves further investigation. (Supported in part by NIH RO1 ES008146)

**PS 1521 Methylmercury-Induced Dopaminergic Neurotoxicity in *Caenorhabditis elegans*.**

E. Martinez-Finley and M. Aschner. *Vanderbilt University Medical Center, Nashville, TN.*

Mercury is a persistent environmental contaminant that exerts its toxic effects on the nervous system through molecular mechanisms that remain unknown. Parkinson's disease (PD) is a neurodegenerative disorder characterized by the slow progression and irreversible loss of the dopaminergic (DAergic) neurons. The etiology of PD remains elusive, with aging, environmental toxicant exposure and genetic mutations contributing to the disease. Epidemiological studies have pointed to the contribution of methylmercury (MeHg) to DAergic vulnerability and the predisposition to PD. We examined the impact of early-life exposure to MeHg on DAergic neurodegeneration in *Caenorhabditis elegans* (*C. elegans*) with emphasis on gene-environment interactions. SKN-1, orthologue of mammalian Nrf2, is a major stress-activated cytoprotective transcription factor. We hypothesized that MeHg's toxicity is dependent on an intact SKN-1 response and skn-1 knockout (KO) worms would show heightened toxicity compared to wildtype (N2). We also tested the effect of MeHg in a pdr-1KO worm, ortholog to the human parkin gene (mutated form found in juvenile PD), under the premise that these worms would show heightened sensitivity to MeHg. We identified the impact of early-life MeHg exposure on MeHg content, stress reactivity and measures of DAergic neurodegeneration in N2, skn-1KO and pdr-1KO worms exposed to 0-30μM MeHgCl for 30 minutes following synchronization. Our data suggests that skn-1KO (LD50=19μM) and pdr-1KO (LD50=17μM) are more sensitive to MeHg than N2 controls (LD50=25μM). MeHg uptake was higher in the pdr-1KO strain compared to the N2 strain. DAergic morphology observed via fluorescent analysis at adult life-stage revealed presence of puncta at 20μM MeHg in skn-1KOs and loss of cell body fluorescence in pdr-1KO. Dopamine (DA)-dependent behavioral

analysis revealed alterations in DA following MeHg exposure, corroborated by decreased DA levels, measured via HPLC. Taken together this data suggests that exposure to MeHg early in the lifespan can have detrimental effects on DAergic neurons. Supported by RO1ES07731 and EST32007028.

**PS 1522 Lactational Exposure to Mercury (Hg) and Evidence of Oxidative Stress.**

I. Al-Saleh, M. Abdel Jabbar, R. Al-Rouqi, R. Elkhatib, A. Alshabbaheen and N. Shinwari. *Environmental Health Section, Biological & Medical Research Department, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia.*

The objective of this work was to assess exposure to Hg in mothers and their breast-fed infants. We also evaluated urinary 8-hydroxy-2-deoxyguanosine (8-OHdG) and malonaldehyde (MDA) in both the mothers and infants as biomarkers of oxidative stress. The mean urinary Hg (UHg) levels in 155 mothers and 102 infants was 1.47 and 7.9μg/g-Cr, respectively with significant correlation between the two (r=0.36, P=0). UHg levels > 5μg/g-Cr (background level in unexposed population) found in 3.3% mothers and 50.1% infants. The mean concentration of Hg in breast milk was 1.19μg/L (range: 0.012-6.44μg/L) with only one mother had Hg > 4μg/L, the ATSDR upper limit. This corresponds to approximately a daily intake of 1.02μg Hg (0.13-5.47μg). Based on the average infant's body weight in this study (7.7Kg) and the EPA reference dose of Hg (0.3 μg/Kg/day), this brings the highest daily intake to 2.31μg. There were 7 infants exceeded this limit. None of the mothers had total blood Hg > the EPA reference dose of 5.8μg/L. Probably, this might be due to the low exposure to organic in comparison to inorganic Hg. Furthermore, no correlation was noted between UHg in infants and Hg in breast milk (P>0.05). On the other hand, Hg in breast milk was associated with total Hg in blood (r=0.53, P=0) suggesting the efficient transfer of organic form of Hg from blood to milk. Both urinary MDA (r=0.2, P=0.015) and 8-OHdG (r=0.24, P=0.003) levels increased with the mother's UHg levels. Infant's UHg levels in infants were positively associated with urinary levels of MDA (r=0.31, P=0.003) and 8-OHdG (r=0.43, P=0) in infants. There was also an association between Hg in breast milk and increased urinary MDA levels in infants (r=0.35, P=0). Our results clearly showed the transfer of Hg from the mother to infant through breastfeeding, and its role in inducing oxidative stress, that can be of potential health risk. Nevertheless, breastfeeding should not be discouraged; and instead efforts should be made to identify and eliminate the source of Hg exposure in the present population.

**PS 1523 Methylmercury Toxicity in KK-Ay Obese Type 2 Diabetic Mice.**

M. Yamamoto<sup>1</sup>, R. Yanagisawa<sup>1,2</sup>, E. Motomura<sup>1</sup>, M. Nakamura<sup>1</sup>, M. Sakamoto<sup>1</sup>, M. Takeya<sup>3</sup> and K. Eto<sup>4</sup>. <sup>1</sup>National Institute Minamata Disease, Minamata, Japan; <sup>2</sup>National Institute Environment Studies, Tsukuba, Japan; <sup>3</sup>Kumamoto University, Kumamoto, Japan; <sup>4</sup>Jushindai, Tamana, Japan.

We examined the toxic effects of methylmercury (MeHg) exposure on the brain, kidney, pancreas and spleen of KK-Ay type 2 diabetic mice to clarify how the metabolic changes associated with type 2 diabetes mellitus (T2DM) affect MeHg toxicity. MeHg (5 mg Hg/kg/day p.o.) was given to male KK-Ay and C57BL/6J (BL/6) mice three times per week for 6 weeks beginning at 4 weeks of age. Average of body weights (BW) of vehicle-treated BL/6 and KK-Ay mice were 16.3 g and 16.4 g on the first day, and 24.8 g and 42.3 g on the last day of the experiment, respectively. BW gain in MeHg-treated KK-Ay mice stopped 4 weeks after MeHg-administration, and these mice began to lose weight around 5 weeks. Six of 7 MeHg-treated KK-Ay mice showed neurological symptoms such as hind limb crossing in the final stage of the experiment. Alternatively, no obvious symptoms and decrease in body weight were observed in vehicle-treated and MeHg-exposed BL/6 mice. The mean blood mercury level of KK-Ay mice administered MeHg increased constantly throughout the administration of MeHg and reached a maximum of about 8 μg/ml. On the other hand, the average blood mercury level of BL/6 mice administered MeHg was 2.8 μg/ml after 10 days of MeHg administration. The average kidney weights of vehicle-treated and MeHg-exposed KK-Ay mice were 542 mg and 408 mg, and those of BL/6 mice were 357 mg and 413 mg, respectively. The average spleen weights of vehicle-treated and MeHg-exposed KK-Ay mice were 91 mg and 135 mg, and those of BL/6 mice were 65 mg and 71 mg, respectively. The average total mercury concentrations in the cerebrum, kidney, pancreas, spleen and epididymal fat pad of KK-Ay mice were 27, 51.7, 40.9, 32 and 1.6 μg/g, respectively. The average total mercury concentrations in these organs of BL/6 mice were 7.4, 51.9, 10.4, 6.9 and 0.57 μg/g, respectively. These results indicate that body fat gain in T2DM and low accumulation of mercury in adipose tissue can increase organ accumulation of MeHg accompanied by toxicity in KK-Ay mice.

**PS 1524 The Palmitoylation of Meh1, a Component of EGO Complex, Has an Important Role in the Reduction of Methylmercury Toxicity in Budding Yeast.**

G. Hwang, Z. Zhang and A. Naganuma. *Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.*

Methylmercury (MeHg) is an environmental pollutant that causes the severe central nervous system disorder. However, the molecular mechanism underlying MeHg toxicity remains to be clarified. We have found that deletion of the Akr1, one of palmitoyl transferase, causes hypersensitivity to MeHg in budding yeast.

In this study, we found that yeast cells lacking Meh1, one of substrates for Akr1, exhibit hypersensitivity to MeHg. Palmitoylation of Meh1 was not detectable by a deletion of Akr1, suggesting that Akr1 is the main palmitoyl transferase for Meh1. We also found that the palmitoylation of Meh1 by Akr1 is essential for the protective effect of Meh1 against MeHg toxicity. Meh1 has been identified as a component of the EGO complex that is involved in the regulation of microautophagy. We found an increased susceptibility to MeHg in yeast cells with deletion of Meh1 or the other EGO complex components (Gtr2 and Ego3). Moreover, Meh1/Gtr2- or Meh1/Ego3-double deletion mutants did not exhibit further increase in the susceptibility to MeHg when compared to Meh1 deletion mutant. These results suggest that Meh1 might reduce MeHg toxicity as a component of the EGO complex. It has been reported that Meh1 forms an EGO complex by binding with Ego3 on vacuole membrane. Interestingly, Meh1 with a mutation in the palmitoylation site was defective in its ability to bind with Ego3. Moreover, normal Meh1-GFP was localized in the vacuolar membrane, but the mutant Meh1-GFP was widely distributed in the cytoplasm and not in the vacuolar membrane. These phenomena proposed that the palmitoylation of Meh1 has an important role in its cellular distribution and formation of the EGO complex.

As for our result, the palmitoylation of Meh1 by Akr1 is related to the formation of the EGO complex through its localization into the vacuolar membrane, and this action is important for the reduction of MeHg toxicity.

**PS 1525 Involvement of AAT Transporters in Methylmercury Toxicity in *Caenorhabditis elegans*.**

S. W. Caito and M. Aschner. *Department of Pediatrics/Pediatrics Toxicology, Vanderbilt University Medical Center, Nashville, TN.*

*Caenorhabditis elegans* (*C. elegans*) is a powerful genetic model for the investigation of neurotoxicity of metals, such as methylmercury (MeHg). MeHg has been shown to accumulate in *C. elegans*, leading to decreased survival, reproductive and developmental defects, and neurodegeneration. It is unknown how MeHg is transported in the worm. In mammals, MeHg complexes with cysteine, which functionally resembles methionine; and the complex is transported into cells via a molecular mimicry mechanism involving the large neutral amino acid transporter LAT1. It is unknown if MeHg can enter cells without being complexed to cysteine or if there are additional uncharacterized MeHg transport mechanisms. *C. elegans* can be used to quickly identify MeHg transport mechanisms due to their ease of genetic manipulability and high degree of homology to mammals. Herein we tested the hypothesis that LAT1 homologues (AATs) are responsible for MeHg transport in *C. elegans*. Worms were pre-treated with 1 mM methionine to assess whether MeHg toxicity could be attenuated by increasing a competitor for AAT transporters. Treatment with MeHg resulted in decreased survival of *C. elegans* (LD50 = 22.91  $\mu$ M), however methionine pre-treatment showed significantly less toxicity to MeHg (LD50 = 47.54  $\mu$ M,  $p < 0.0001$ ), implicating the AAT amino acid transport systems in MeHg toxicity. Using RNAi feeding protocols we selectively knocked down expression of the *aat-1*, *aat-2* and *aat-3* genes, and assayed for MeHg induced-lethality. Knockdown of each gene individually resulted in a significant right hand shift in the dose-response lethality curve (*aat-1*: LD50 = 118.1  $\mu$ M,  $p < 0.001$ ; *aat-2*: LD50 = 102.1  $\mu$ M,  $p < 0.001$ ; *aat-3*: LD50 = 44.65  $\mu$ M  $p < 0.001$ ), suggesting these genes may be involved in MeHg transport. As lethality of MeHg was not completely blocked by methionine pre-treatment or *aat* gene knockdown, there is a possibility that additional MeHg transport mechanisms may be identified in *C. elegans*.

**PS 1526 Effects of Methylmercury on Heart Rate Variability in the Rat.**

M. Sasaki, M. Yamamoto and M. Fujimura. *Department of Basic Medical Sciences, National Institute for Minamata Disease, Minamata, Japan.*

Analysis of heart rate variability (HRV) in humans has revealed that methylmercury (MeHg) exposure decreases parasympathetic nerve function or increases sympathetic nerve function. However, limited information is available on such effects in

experimental animals. In the present study, 5 rats were treated 2 times per week for 5 weeks with MeHg (4 mg/kg) or vehicle orally. Several weeks before and after treatment, telemetry recordings of ECG were acquired. HRV and its power spectrum parameters were determined from 1-hour segments (approximately 16,000 to 20,000 beats) of ECG data during the day by LabChart and its HRV Module. With 4 mg/kg MeHg treatment, a decrease in body weights and the hind limb crossing sign and an increase in the heart rate (HR) were observed from the analysis of the ECG. HRV analyses showed a decrease in the coefficient of HRV (CVRR) and low frequency (LF) and high frequency (HF) HRV. A slight increase in the LF/HF ratio was observed due to the decrease in HF. These results suggest that a decrease in the CVRR, LF, and HF and an increase in the HR indicate the suppression of parasympathetic nervous system activities after repeat treatments with MeHg in rats. These findings also suggest similar effects of MeHg on the autonomic nervous system of humans and animals.

**PS 1527 Sex Differences in Paraoxonase Activity in Subchronic Inorganic Mercury Exposure.**

A. D. Wusu<sup>1</sup>, O. Ademuyiwa<sup>1</sup>, O. O. Ogunrinola<sup>1</sup>, O. K. Afolabi<sup>1</sup>, E. O. Abam<sup>1</sup>, D. O. Babayemi<sup>1</sup>, E. A. Balogun<sup>1</sup> and O. O. Odokoya<sup>2</sup>.

<sup>1</sup>Biochemistry, University of Agriculture, Abeokuta, Nigeria; <sup>2</sup>Chemistry, University of Agriculture, Abeokuta, Nigeria.

Epidemiological evidences suggest an increased risk of cardiovascular diseases (CAD) as a result of inorganic mercury exposure. The underlying mechanisms underpinning this risk, as well as sex differences in response to mercury exposure, are not yet understood. Paraoxonase (PONase), an enzyme located in the high-density-lipoprotein (HDL) has been shown to protect against CAD. In order to investigate the association between inorganic mercury exposure and CAD, male and female rats were exposed to mercury (0.5, 1.0 and 1.5mg/kg) for 12 weeks. PON activities towards paraoxon (PONase) and phenylacetate (AREase) in plasma, lipoproteins, hepatic and brain microsomal fractions were determined using standard methods. Inhibition of PONase and activation of AREase in plasma and HDL characterised the effects of inorganic mercury in both sexes. Inorganic mercury exposure inhibited PONase by 63% (plasma) and 67% (HDL) respectively in male animals, whereas the female enzyme was inhibited by 80 and 47% respectively. AREase activity was activated by 55 and 53% in male, whereas the activation in female amounted to 25 and 49% respectively. In the VLDL, inorganic mercury inhibited PONase in both sexes whereas AREase was activated in female animals but inhibited in male. In the hepatic microsomal fractions, only the PONase enzyme was inhibited in male animals whereas in female, activation was observed in both enzymes at the highest dose of inorganic mercury. Brain microsomal cholesterol was increased in male but decreased in female by inorganic mercury resulting in altered cholesterol/phospholipid ratios. Our findings indicate that inorganic mercury exposure exerts an inhibitory effect on PONase but activated AREase. Modulation of PON activity may be an early biochemical step in the induction of CAD by mercury. This may also be mediated through changes in membrane fluidity brought about by changes in the concentration of cholesterol in the microsomes.

**PS 1528 Ethylmercury Induces ER Stress and Mitochondria Dysfunction Mediated Autophagy.**

M. Dong and J. Choi. *School Lifesciences and Biotechnology, Korea University, Seoul, Republic of Korea.* Sponsor: B. Lee.

Mercury is one of the most important environmental and industrial pollutants throughout the world. Exposure to mercury causes strong damage to organs including the brain, blood, liver, bone and kidneys. Renal proximal tubular cells represent the primary target site. We previously investigated the cytotoxicity of seven kinds of mercury compounds in human renal proximal tubule (HK-2) cells. Ethylmercury chloride (EMC) was shown the strongest cytotoxicity among them with 2.4 and 0.76  $\mu$ M of IC50 values exposed for 24 h and 48 h in HK-2 cells, respectively. In this study, we explored the mechanism of EMC induced cytotoxicity in HK-2 cells. EMC was increased the accumulation of JC-1 monomers in mitochondria from 0.5 to 2  $\mu$ M concentrations in a dose-dependent manner. The expression of MT-I and Hic-5, which were related to oxidative stress, was also induced by EMC treatment. In addition, calcium is a well-known regulator of many intracellular processes, including apoptosis and autophagy. Interestingly, EMC was increased in cytosolic [Ca<sup>2+</sup>], which was the tendency appears unlikely that the increased after 2  $\mu$ M A23187 treatment. EMC was up-regulated the expression of UPR target genes and proteins such as transcription factor, CHOP, XBP-1, ERdj4 and GRP 78. After the exposure of EMC to cells, LC3II formation was dose- and time-dependently increased. When cells were treated with ER inhibitor 4-Pheylbutyric acid, they blocked the formation of autophagosome compared with untreated cells. However, cleaved of caspase-9, caspase-12 and PARP were weakly activated. To test whether ER stress by EMC can occur in vivo, EMC was treated to

male C57BL/6 mice with 1, 2, 5 and 10 mg/kg/day. The expression of ER stress related marker genes were increased by immunoblot analysis. LC3-II was significantly increased in the kidneys of EMC treated mice. Together, these results suggest that EMC induced autophagy via ER stress and mitochondrial dysfunction not only in human renal proximal tubule (HK-2) cells but also in mice kidneys.

## PS 1529 Protective Role of Quercetin against Mercury-Induced Nephrotoxicity in Sprague-Dawley Rats.

J. Kim<sup>1</sup>, Y. Kim<sup>2</sup>, W. Kim<sup>3</sup>, Y. Shin<sup>4</sup>, A. Won<sup>4</sup>, E. Park<sup>4</sup>, E. Lee<sup>4</sup>, M. Yoo<sup>4</sup>, Z. Lan<sup>4</sup>, T. Kim<sup>4</sup> and H. Kim<sup>4</sup>. <sup>1</sup>College of Pharmacy, Pusan National University, Busan, Republic of Korea; <sup>2</sup>Gorton School, Farmers Row, Groton, MD; <sup>3</sup>The Hockaday School, Dallas, TX; <sup>4</sup>Sehwa High School, Seoul, Republic of Korea.

Mercury chloride (HgCl<sub>2</sub>) is a well-known nephrotoxicant. HgCl<sub>2</sub> preferentially accumulates in the kidneys and causes nephrotoxicity as a result of oxidative stress. The aim of this study was to investigate the possible protective role of quercetin against HgCl<sub>2</sub>-induced acute renal damage. Quercetin, a naturally occurring phenolic compound found in fruits and vegetables, has gained considerable attention for its antioxidant properties. In this study, quercetin (250 mg/kg) was administered orally to Sprague-Dawley male rats for 3 days prior to HgCl<sub>2</sub> (20 mg/kg) treatment. All animals were sacrificed 24 h after the last treatment and various urine or blood biomarkers associated with renal damage were measured. Significant increases in urinary volume and decreases in urinary pH were observed in the HgCl<sub>2</sub>-treated group. Blood urea nitrogen (BUN) and serum creatinine (sCr) levels were significantly increased in the HgCl<sub>2</sub>-treated group when compared to control group. In the HgCl<sub>2</sub>-treated group, the urinary excretion of BUN, sCr, lactate dehydrogenase (LDH) and total protein were all markedly lower than those of the control group. These adverse effects were ameliorated by pretreatment with quercetin. Compared to the HgCl<sub>2</sub>-treated group, quercetin pretreatment led to a significant decrease in the amounts of KIM-1, NAGL, HMGB1, and Netrin-1 in the urine. Furthermore, histopathological examinations indicated that quercetin had a protective effect against HgCl<sub>2</sub>-induced proximal tubular damage. These results suggest that quercetin may be a promising agent to protect against HgCl<sub>2</sub>-induced acute kidney injury.

## PS 1530 Selenium Protects against the Toxic Effects of Methylmercury in Sperm Whale (*Physeter macrocephalus*) Skin Cells.

L. C. Savary<sup>1,2,4</sup>, A. Holmes<sup>1,2,3</sup>, M. Braun<sup>1,2</sup>, D. Evers<sup>5</sup>, I. Kerr<sup>2,4</sup>, R. Payne<sup>2,4</sup>, W. Thompson<sup>2,3</sup>, C. Perkins<sup>6</sup>, T. Zheng<sup>7</sup>, C. Zhu<sup>7</sup> and J. Wise<sup>1,2,4</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Sciences, University of Southern Maine, Portland, ME; <sup>4</sup>Ocean Alliance, Gloucester, MA; <sup>5</sup>Biodiversity Research Institute, University of Southern Maine, Portland, ME; <sup>6</sup>Center for Environmental Sciences and Engineering, University of Connecticut, Mansfield, CT; <sup>7</sup>Yale School of Public Health, New Haven, CT.

Mercury (Hg) persists, bioaccumulates and is toxic to the marine environment posing risks to the marine ecosystem. Selenium (Se), an essential element, antagonizes Hg toxicity when present in equimolar amounts. The sperm whale, a toothed whale, is a sentinel of ocean health. We biopsied skin from 343 free-ranging sperm whales in 17 regions around the globe during the voyage of the Odyssey, between 2000-2005 analyzing them for total Hg and Se levels. Hg was detected in 340 samples with a global mean of 2.4 ug/g ww ranging from 0.1 to 16 ug/g. Se was detected in all samples with a global mean of 33.0 ug/g ww ranging from 2.5 to 179.0 ug. The global mean Se:Hg molar ratio was 59:1 ranging from 3:1 to 1719:1. This excess Se may mitigate the toxic effects of Hg. Hg is known to cause cytotoxicity, altered mitotic index and aneuploidy in cells. The aim of this study was to determine if Se protects sperm whale skin cells from Hg-induced toxicity at similar concentrations found in the skin biopsies. Sperm whale skin cells developed from the biopsies were cotreated with 72 h exposure to 2, 3, 4 or 5 uM methylmercury (MeHg) and 10 uM sodium selenite, and cytotoxicity, mitotic index and genotoxicity was measured. Our findings show MeHg induces cytotoxicity, alters mitotic index and causes aneuploidy in sperm whale skin cells, and Se protects against MeHg induced toxicity compared to control.

## PS 1531 Selenium Compounds Cause Apoptosis and GSH Depletion in Rat Hippocampal Astrocytes.

S. Roy and D. Hardej. Pharmaceutical Sciences, St. John's University, Queens, NY.

Selenium (Se) is a required trace element in mammalian systems. While generally accepted to play a protective role, exposure to high levels of Se have been associated with neurotoxicity. Previous work in our laboratory has demonstrated toxicity of Te

and Se compounds in rat hippocampal astrocytes. The purpose of this study was to evaluate the mechanism of cell death of diphenyl diselenide (DPDS) and selenium tetrachloride (SeCl<sub>4</sub>) and to investigate their effects in the functioning of mitochondrial complexes III and IV and depletion of the antioxidant GSH. Rat hippocampal astrocytes were used as a model system. The LC50 of both compounds had been previously found to be 7.8 μM. For the present study, concentrations of both compounds ranging from 1.9-15.625 μM were tested. Phase-contrast microscopy was used to study the morphological changes in the cells following treatments. Micrographs of cells exposed to high concentrations of either compound (15.625 and 7.8 μM) showed decreases in cell number and increases in rounded cells with loss of processes. Micrographs of cell exposed to low concentrations (3.9 and 1.9 μM) appeared similar to control astrocytes. Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES) demonstrated that treatments with both compounds resulted in a dose-related increase of Se in the cells that is significantly greater than amounts seen in the controls. Caspase 3/7 activities were assessed and significant increases in activity were observed at the 7.8 μM and 15.625 μM concentrations with both Se compounds confirming apoptotic activity. ELISA assays were used to investigate the activities of complexes III and IV of the mitochondrial respiratory chain. There were no significant changes in the activities of the two enzymes in any treatment group. GSH/GSSG ratios were significantly decreased at 7.8 and 15.625 μM of each compound indicating oxidation of sulfhydryl groups. These results suggest that selenium compounds cause cytotoxicity in rat hippocampal astrocytes resulting in apoptosis but mitochondrial complexes III and IV are not involved.

## PS 1532 Heavy Metal Hazards of Smokeless Tobacco in Nigeria.

O. Orisakwe<sup>2</sup>, Z. N. Igweze<sup>1</sup> and K. O. Okoro<sup>1</sup>. <sup>1</sup>Department of Pharmacology College of Health Sciences, University of Port Harcourt, Rivers State, Nigeria, Nigeria; <sup>2</sup>Toxicology Unit, Department of Experimental Pharmacology & Clinical Pharmacy, University of Port Harcourt, Rivers State, Nigeria, Nigeria.

Smokeless tobacco (ST) or snuff prepared by grinding tobacco leaves into a very fine powder with addition of salt petre and other ingredients has been in use in Nigeria for a very long time. ST is marketed for oral and nasal use. Recently there has been an upsurge in the use of ST even amongst the younger generation. Information on the public health implication and heavy metal hazards of ST in Nigeria is sparse. This study was carried out to determine the extent of heavy metal contamination in ST used in Nigeria. Concentration of five heavy metals, Lead(Pb), Cobalt(Co), Cadmium(Cd), Nickel(Ni), and Chromium(Cr) were determined in smokeless tobacco by wet digestion using HNO<sub>3</sub> and analysis with AAS 205A Spectrophotometer. Thirty samples of smokeless tobacco sourced from six geographical regions in Nigeria were used. Our results showed that the level of contamination with all the metals was ≤10 μg/g, 11-30 μg/g, ≤10 μg/g, 20-70 μg/g and 2770-11400 μg/g for Pb, Co, Cd, Ni and Cr. These concentrations are higher than acceptable limits. Health risks associated with ST snuffing have received little or no attention in Nigeria in spite of wide spread use. This study underscores the importance of elaborate human risk assessment of ST in Nigeria and indeed Sub Saharan Africa.

## PS 1533 Tobacco Cigarettes: A Source of Metals (Al, Cd, Co, Cr, Mn, Ni, Pb, Sr) for Humans.

C. Rubio<sup>1</sup>, T. Garcia<sup>1</sup>, A. Soler<sup>1</sup>, D. Glez-Weller<sup>1</sup>, A. J. Gutiérrez<sup>1</sup>, A. Hardisson<sup>1</sup> and A. Anadon<sup>2</sup>. <sup>1</sup>Toxicology, Universidad de La Laguna, La Laguna, Spain; <sup>2</sup>Farmacología y Toxicología, Universidad Complutense de Madrid, Madrid, Spain.

Every six seconds a smoker dies, the victim of an addiction that causes a high degree of toxicity.

Al, Cd, Co, Cr, Mn, Ni, Pb and Sr were determined in 33 tobacco samples randomly obtained in Tenerife using Inductively Coupled Plasma Spectrometry by previously treating the samples according to the standard procedure, that is, by adding HNO<sub>3</sub> at 65% to the sample and burning it in a muffle oven for 50 hours at 450 degrees Celsius.

With respect to results, 428 mg Al/kg, 0.810 mg Cd/kg, 0.558 mg Co/kg, 1.442 mg Cr/kg, 112.026 mg Mn/kg, 2.238 mg Ni/kg, 0.602 mg Pb/kg and 82.206 mg Sr/kg. Al was the metal with the greatest concentration while Co had the lowest. The tobacco was also classified according to the type of tobacco (Virginia vs Dark), type of cigarette (Normal vs Light) and manufacturer. The amount of Al in Virginia tobacco was 423 mg/kg while in Dark this was 478 mg/kg. Cd concentrations were 0.807 mg/kg for Virginia and 0.844 mg/kg for Dark, Co values were 0.56 mg/kg for Virginia and 0.533 mg/kg for Dark, Cr values were 1.487 mg/kg for Virginia and 1 mg/kg for Dark, Mn was determined to be 113.362 mg/kg for Virginia and 98.667 mg/kg for Dark, Ni values were 2.242 mg/kg for Virginia and 2.199 mg/kg

for Dark, Pb afforded 0.607 mg/kg for Virginia and 0.556 mg/kg for Dark, and Sr gave values of 77.982 mg/kg for Virginia and 124.444 mg/kg for Dark. Regarding the differences between Light and Normal tobacco, the following values were obtained in Light: 412.4 mg Al/kg, 0.873 mg Cd/kg, 0.553 mg Co/kg, 1.64 mg Cr/kg, 120.02 mg Mn/kg, 2.4 mg Ni/kg, 0.873 mg Pb/kg and 78.627 mg Sr/kg; while in Normal tobacco the values determined were 434.783 mg Al/kg, 0.783 mg Cd/kg, 0.559 mg Co/kg, 1.366 mg Cr/kg, 108.56 mg Mn/kg, 2.168 mg Ni/kg, 0.484 mg Pb/kg and 83.762 mg Sr/kg.

Exposure to metals through the inhalation of cigarette smoke represents a significant source of metal contamination to smokers, adding to the dietary intake of these same metals.

**PS 1534 Metal Mobilization from Retained Embedded Fragments in a US Veteran: Biomonitoring Correlates with Fragment Content.**

J. Gaitens<sup>1,2</sup>, K. Squibb<sup>1,2</sup>, J. Centeno<sup>3</sup>, M. Condon<sup>1</sup> and M. McDiarmid<sup>1,2</sup>.  
<sup>1</sup>VA Medical Center, Baltimore, MD; <sup>2</sup>School of Medicine, University of Maryland, Baltimore, MD; <sup>3</sup>Joint Pathology Center, Silver Spring, MD.

Recent clinical findings implicate the potential for local and systemic long-term health effects from embedded metal fragments associated with injuries from improvised explosive devices in soldiers serving in military conflicts. In the past, fragments embedded in muscle tissue were thought to be relatively inert; however, evidence has shown that soldiers with embedded depleted uranium fragments have elevated urine U levels 20 years after exposure. To understand the potential health risks associated with embedded fragments from blast injuries, the Department of Veterans Affairs has established a medical surveillance program which integrates fragment composition data, surrounding tissue analyses, and urine biomonitoring results that characterize systemic and local tissue exposure to: Al, As, Cd, Cr, Co, Cu, Fe, Mn, Ni, Pb, U, W and Zn. These metals were chosen based on available fragment composition data and known toxicity of individual metals. We present here results from a Veteran who had 3 fragments removed several years after injury. Using EDXRF, the removed fragments were determined to be an Al-Cu alloy. Chemical analysis of adherent tissue showed levels of Al and Cu consistent with mobilization of these elements from the fragment to the surrounding tissue. Histology showed focal foreign body-type giant cell reaction and chronic inflammatory cell infiltrates, but no evidence of neoplastic changes. Prior to fragment removal, biomonitoring results showed a urine Al level 1.5 fold higher than the reference range, but below levels associated with adverse health effects. Concentrations of all other metals were within established reference ranges. These results provide further evidence that metal fragments in the body are not inert and materials released from fragments can enter systemic circulation over time, thus warranting long-term biomonitoring and medical surveillance of Veterans with embedded fragments. Supported by the Department of Veterans Affairs.

**PS 1535 Baseline Blood Levels of Manganese (Mn), Lead (Pb), Cadmium (Cd), Copper (Cu), and Zinc (Zn) in Residents of Beijing Suburb.**

L. Zhang<sup>1</sup>, L. Lu<sup>1</sup>, Y. Pan<sup>2</sup>, C. Ding<sup>2</sup>, D. Xu<sup>1</sup>, J. Zhao<sup>1</sup>, W. Zheng<sup>3</sup> and H. Yan<sup>2</sup>.  
<sup>1</sup>Occupational Disease Control, Fengtai CDC, Beijing, China; <sup>2</sup>Institute of Occupational Health, China Center for Disease Control and Prevention, Beijing, China; <sup>3</sup>School of Health Science, Purdue University, West Lafayette, IN.

The baseline blood concentrations of heavy metals are important for monitoring metal exposure in the general population. The data can be used to evaluate the current environmental pollution and also serve as the references for exposure assessment in local residents as well as in occupational settings. The purpose of this study was to determine the blood levels of Mn, Pb, Cd, Cu, and Zn among the residents (aged 12-60 years old) living in the suburb southwest of Beijing, China. Blood samples were drawn from a total of 648 subjects from March 2009 to February 2010. Metal concentrations in the whole blood were measured by ICP-MS. The geometric means of the blood levels of Mn, Pb, Cd, Cu and Zn were 11.4, 42.6, 0.6, 802.4 and 4,665 ug/L, respectively. Blood Mn level of all participants is similar to the reports by Korean (Lee et al. Int J Hyg Env Health 2012;215:449) and Canadian (Clark et al. Chemosphere 2007;70:155) studies in literature. Blood Pb level was higher in Chinese residents than those of Korea's and Czech's (Batarlova et al. Int J Hyg Env Health 2006;209:359). Blood Pb levels in the all participants were higher among Chinese than those of Korean and Czechs; the magnitude of increase became more evident when compared with Korean data. Blood Cd levels in this Chinese cohort were within the same range as Czech's, but were significantly higher

than German's (Heitland & Koster J Trc Elem Med Biol 2006;20:253). Blood Cu levels were significantly lower in Chinese than those of Germany and Canadian, while blood Zn levels were significantly lower than those of Czechs. Based on the data of the 95th percentile, we estimate the normal reference values for the whole blood Mn to be 21.7 ng/mL, Pb 10.3 ug/dL, Cd 5.3 ng/mL, Cu 1.36 ug/mL, and Zn 9.03 ug/mL in Chinese resident living in Beijing suburb. These baseline values will be useful for occupational and environmental exposure assessment.

**PS 1536 Effect of Long-Term Exposure of Heavy Metals on the Expression Profile of Cytoprotective Genes among Individuals Living in Mining Areas.**

I. M. Attafi, S. A. Albakheet and H. M. Korashy. *Pharmacology and Toxicology, King Saud University, Riyadh, Saudi Arabia.*

Environmental exposure to heavy metals is one of the most global concerns, particularly among whom living around the polluted areas. These heavy metals are known to generate oxidative stress species, and induce of oxidized DNA adduct formation, and DNA repair genes causing disease induction. The aim of this study is to evaluate the effects of long-term exposure to environmental heavy metals in the expression profile of some cytoprotective genes and the level of oxidized DNA adduct formation among individuals living around mining areas. Sixty healthy volunteers were divided to two groups; exposed group consisted of 40 male residents in a heavy metal-polluted area, whereas the control group consisted of 20 male residents in a non-polluted area. Whole blood concentrations for heavy metals, particularly lead, cadmium, and mercury, were determined using ICP-MS. Total RNA was isolated using PAXgene Blood RNA kits and the mRNA levels of heavy metals biomarker genes: NQO1, HO-1, and MT-1 and DNA repair genes: OGG1 and APE1 were determined by RT-PCR. Plasma levels of 8-OHdG were evaluated by ELISA technique. The results showed a significant increase in blood levels of heavy metals among exposed group. RT-PCR results revealed significant inhibitions of NQO1 mRNA level in group which were highly contaminated with lead, whereas the group of highly contaminated with cadmium showed the highest inhibitory effect on MT-1 mRNA level and significant induction of OGG1 mRNA level. Furthermore, mercury contaminated group showed a significant inhibition of APE1 mRNA level. The level of 8-OHdG was well correlated with the level of OGG1 mRNA. We conclude that long-term exposure to environmental heavy metals differentially altered the expression of cytoprotective and DNA repair genes. Therefore, they may be used as biomarkers for early prediction of disease risk among individuals living around polluted areas.

**PS 1537 Phytotoxicity and Trace Metal Accumulation from Long-Term Chicken Litter Amendment in Wilkes County, North Carolina: A Field Study.**

A. K. Hastings, S. Mouro, M. Brower and S. Tuberty. *Biology, Appalachian State University, Boone, NC.* Sponsor: G. LeBlanc.

Arsenic, zinc and copper are commonly integrated in chicken feeds to ensure increased weight gain in chickens and prevent chicken house diseases. These metals ultimately become part of the litter that is spread by farmers over crop fields as an alternative to expensive fertilizers. Massive growth in industrial chicken production across Wilkes County, NC has resulted in increased concentrations of phytotoxic metals in farmland soils and loss of copper sensitive crops such as peanuts. Using *Zea mays* as a representative crop species, our research objective was to evaluate the long-term sustainability of this practice by measuring adverse effects on corn in fields that have received a varied number of poultry litter amendments. Three agricultural fields receiving chicken litter amendment ranging from less than 10 yrs to more than 30 yrs within Wilkes County were selected as sampling areas for trace metal analysis. Soils were collected prior to and after annual litter application dates and corn tissue samples were collected in thirty day intervals (30, 60 & 90 days post planting) from each field. Nearly 400 corn tissue and soil samples were lyophilized and homogenized; 0.5g samples were nitric acid digested with a microwave reactor (USEPA Method 3051); and analyzed using ICP-OES to quantify levels of Cu and Zn. ICP-OES analysis indicated that industrial broiler chicken litter contains considerably elevated Cu (~388 ppm) and Zn (~481 ppm) concentrations. Thirty day corn seedling Cu and Zn burdens correlate closely with soil metal levels and with significantly delayed seedling emergence time and reduced growth rates (e.g., mean leaf height and area). No correlation was observed between soil metal levels and mature plant burdens. Continued chicken litter application may result in significantly reduced *Zea mays* productivity due to elevated Cu and Zn levels and therefore is not sustainable at the maximum application rates currently practiced in NC.

**PS 1538 Association of 25-Hydroxyvitamin D and 1, 25-Dihydroxyvitamin D with Metals in a Cohort of Adolescents in Torreon, Mexico.**

R. D. Zamoiski<sup>1</sup>, E. Guallar<sup>2,3</sup>, G. G. Garcia-Vargas<sup>4</sup>, M. Rubio-Andrade<sup>4</sup>, P. J. Parsons<sup>5</sup>, A. J. Steuerwald<sup>5</sup>, S. J. Rothenberg<sup>6</sup>, A. Navas-Acien<sup>1,2</sup>, C. Resnick<sup>1</sup>, V. Weaver<sup>1</sup> and E. K. Silbergeld<sup>1</sup>. <sup>1</sup>*Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*; <sup>2</sup>*Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*; <sup>3</sup>*Cardiovascular Epidemiology and Population Genetics, National Center for Cardiovascular Research, Madrid, Spain*; <sup>4</sup>*Facultad de Medicina, Universidad Juárez del Estado de Durango, Gómez Palacio, Mexico*; <sup>5</sup>*Inorganic and Nuclear Chemistry, Wadsworth Center, Albany, NY*; <sup>6</sup>*Centro de Investigación en Salud Poblacional, Instituto Nacional de Salud Pública, Cuernavaca, Mexico*.

**Background:** Data suggest that nephrotoxic metals may disrupt vitamin D metabolism and inhibit production of 1,25(OH)2D, the active vitamin D metabolite, from 25(OH)D in the kidney. Prior studies support this but are few in number and limited by small sample sizes. We sought to describe this association in a much larger sample.

**Methods:** Cross-sectional study of 512 adolescents in Torreon, a smelter town in Mexico. BPb was measured using atomic absorption; urine As, Cd, Mo, W, Sb, Tl, and U using ICP-MS. Vitamin D was measured using radioimmunoassay and chemiluminescent assay. Multivariate linear models with vitamin D as the outcome measured effect of metal on vitamin D level, controlling for age, sex, smoking, SES, and time outdoors.

**Results:** 25(OH)D was positively associated with Mo, Tl, and U ( $\beta=2.25, 1.46$ , and  $0.89$ , respectively). 1,25(OH)2D was positively associated with As and U ( $\beta=3.64, 2.25$ ), even after controlling for 25(OH)D ( $\beta=3.45, 1.90$ ).

**Conclusions:** No evidence that metals are inhibiting production of 1,25(OH)2D. Exposure to U or As may upregulate 1,25(OH)2D, perhaps in response to proximal tubule damage. Nephrotoxic metals such as U and As may cause a sub-threshold Fanconi syndrome, wasting phosphorus, and upregulating 1,25(OH)2D to maintain homeostasis.

**PS 1540 Broad Spectrum Safety of LOWAT: A Novel Weight Management Ingredient.**

E. Lau<sup>1</sup>, Z. M. Saiyed<sup>1</sup>, J. Lugo<sup>1</sup>, G. Trimurtulu<sup>2</sup>, A. V. Krishnaraju<sup>2</sup> and K. Sengupta<sup>2</sup>. <sup>1</sup>*R&D, Interhealth Nutraceuticals, Benicia, CA*; <sup>2</sup>*Laila Nutraceuticals, Vijayawada, India*.

LOWAT is a novel formulation consisting of extracts from Piper betle leaves and Dolichos biflorus seeds. Clinical research demonstrated that LOWAT is effective and well-tolerated in weight management. The current study evaluated the broad spectrum safety of LOWAT in a battery of animal and in vitro studies including acute oral, acute dermal, primary dermal irritation, primary eye irritation, mammalian erythrocyte micronucleus and chromosomal aberration tests. A sub-chronic repeated-dose 28-day toxicity study was conducted to determine the no-observable-adverse-effect-level (NOAEL) of LOWAT.

The LD50 levels of LOWAT in Sprague-Dawley (SD) rats, as determined by the acute oral and acute dermal toxicity studies, were  $>5,000$  and  $>2,000$  mg/kg body weight, respectively. Primary skin and eye irritation studies done on New Zealand rabbits classified LOWAT as non-irritating to the skin and as mildly irritating to the eye. Genotoxicity studies showed that LOWAT was non-mutagenic.

In a repeated-dose 28-day oral toxicity study, SD rats were administered orally with LOWAT at 0, 50, 250 or 2,500 mg/kg body weight daily dose. Rats were sacrificed at 28 days after supplementation. Body weight, food and water consumption, select organ weights, ocular health, hematology, blood chemistry, clinical chemistry and histopathology were assessed. No morbidity, mortality, or significant adverse events were observed at 28 days. Based on these findings, NOAEL of LOWAT was determined to be at least 2,500 mg/kg body weight in male and female SD rats.

These results, combined with the tolerability of LOWAT in the human clinical trial, demonstrate the broad spectrum safety of LOWAT.

**PS 1541 Evaluation of Nose-Only Inhalation Exposure to Aerosolized Linalool in Sprague-Dawley Rats.**

J. Randazzo<sup>1</sup>, D. Vitale<sup>2</sup>, D. Kirkpatrick<sup>1</sup>, F. G. Burleson<sup>3</sup> and M. Singal<sup>2</sup>. <sup>1</sup>*WIL Research, Ashland, OH*; <sup>2</sup>*Research Institute for Fragrance Materials, Woodcliff Lake, NJ*; <sup>3</sup>*Burleson Research Technologies, Morrisville, NC*.

Linalool is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized linalool when administered to rats by nose-only inhalation at 0.1, 1, and 10 ppm (0.63, 6.3, 63 mg/m<sup>3</sup>) for 2 weeks (6 hours/day, 5 days/week). Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) analysis for cellular markers of inflammation (i.e., cytokines). As a positive control to validate the utility of cytokine measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m<sup>3</sup> amorphous silica (0, 1, 2, 5 or 10 exposures). At all exposure levels, linalool was well tolerated with test substance-related effects limited to non-adverse microscopic findings in the nasal cavity. Therefore, the no-observed-adverse-effect level (NOAEL) was considered to be 10 ppm (equivalent to 63 mg/m<sup>3</sup>), the highest exposure concentration tested.

**PS 1542 Evaluation of Nose-Only Inhalation Exposure to Aerosolized Cinnamal in Sprague-Dawley Rats.**

D. Vitale<sup>1</sup>, J. Randazzo<sup>2</sup>, D. Kirkpatrick<sup>2</sup>, F. G. Burleson<sup>3</sup> and M. Singal<sup>1</sup>. <sup>1</sup>*Research Institute for Fragrance Materials, Woodcliff Lake, NJ*; <sup>2</sup>*WIL Research, Ashland, OH*; <sup>3</sup>*Burleson Research Technologies, Morrisville, NC*.

Cinnamal is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized cinnamal when administered to rats by nose-only inhalation at 1, 10, and 100 ppm (5.4, 54.1, 540.5 mg/m<sup>3</sup>) for 2 weeks (6 hours/day, 5 days/week). Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) and serum analysis for cellular markers of inflammation (i.e., cytokines). As a positive control to validate the utility of cytokine measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m<sup>3</sup> amorphous silica (0, 1, 2, 5 or 10 exposures). Exposure to cinnamal at 100 ppm was not tolerated as evidenced by adverse clinical observations and substantial body weight loss coupled with histologic changes in the upper and lower respiratory tract and clinical chemistry alterations suggestive of hepatotoxicity. Exposures were terminated for the 100 ppm group following the 5th exposure and the animals were sacrificed on study day 7. Exposures at 1 and 10 ppm (equivalent

**PS 1539 Is Genotoxic Metal Exposure Part of the Toxic Legacy of the Deepwater Horizon Oil Crisis?**

J. J. Wise<sup>1,2,4</sup>, J. Wise<sup>1,2,4</sup>, W. Thompson<sup>2,3</sup>, C. Perkins<sup>5</sup> and J. Wise<sup>1,2,4</sup>. <sup>1</sup>*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME*; <sup>2</sup>*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME*; <sup>3</sup>*Department of Applied Medical Science, University of Southern Maine, Portland, ME*; <sup>4</sup>*Ocean Alliance, Gloucester, CT*; <sup>5</sup>*Center for Environmental Sciences and Engineering, University of Connecticut, Storrs, CT*.

In the wake of the Deepwater Horizon oil disaster of 2010, we collected tissue samples from sperm whales in order to determine the effects of the oil and chemical dispersants on their population. We focused on whales because they are at the top of the food chain and they are biologically similar to humans. Sperm whales live and feed at the same depth as the Deepwater Horizon well head, placing them at high risk to this disaster. After it became apparent the spewing oil was going to be the worst incident in US history, concern largely focused on oil and dispersants while the potential threat of genotoxic metals in the oil has gone largely overlooked. Genotoxic metals, such as chromium and nickel, damage DNA and bioaccumulate in organisms resulting in longer exposures. Analysis of sperm whale skin samples showed mean levels of Ni and Cr at significantly higher levels than those found in whales collected around the world prior to the spill. We found Cr and Ni levels ranged from 0.4-94.63 ppm in tissue collected from Gulf of Mexico whales in the wake of the crisis, with mean Ni and Cr levels of 14.9 and 12.00 ppm, respectively. In addition, we found Cr and Ni levels ranged from 0.24-8.46 ppm in crude oil from the riser, oil slicks from surface waters and tar balls from Gulf beaches. Maps of where we collected our samples showed the highest metal levels in whales closest to the epicenter. Given the capacity of these metals to break DNA, their presence in the oil and their elevated levels in whales, we believe metal exposure is an important overlooked concern for the Deepwater Horizon oil disaster. Further analysis is underway to determine the impact of this disaster on the genetic health of the whales and the long term impact in years following.

to 5.4 or 54.1 mg/m<sup>3</sup>, respectively) did not result in any adverse findings and show a clear threshold of response for lung and liver. Therefore, the no-observed-adverse effect concentration (NOAEC) was determined to be 10 ppm (equivalent to 54.1 mg/m<sup>3</sup>).

## PS 1543 Evaluation of Nose-Only Inhalation Exposure to Aerosolized Isoeugenol in Sprague-Dawley Rats.

M. Singal<sup>1</sup>, J. Randazzo<sup>2</sup>, D. Kirkpatrick<sup>2</sup>, F. G. Bursleson<sup>3</sup> and D. Vitale<sup>1</sup>.  
<sup>1</sup>Research Institute for Fragrance Materials, Woodcliff Lake, NJ; <sup>2</sup>WIL Research, Ashland, OH; <sup>3</sup>Bursleson Research Technologies, Morrisville, NC.

Isoeugenol is a commonly used fragrance material that has been associated with skin sensitization. The study objective was to understand the effects of inhalation exposure in Sprague-Dawley (SD) rats when aerosolized when administered to rats by nose-only inhalation at 0.15, 1.5, and 14.9 ppm (1, 10, and 100 mg/m<sup>3</sup>) for 2 weeks (6 hours/day, 5 days/week). Prior to the main study, a preliminary 3-day exposure (6 hours/day) was run at 89.4 and 44.7 ppm to allow selection of appropriate doses. At both concentrations, the animals were observed to have decreased body weight over the 3 day exposure period. Therefore, a third of the lowest dose tested, 14.9 ppm, was chosen as the high exposure level for the main study. Standard endpoints evaluated included: clinical observation; body and organ weights; hematology and serum chemistry evaluation; macroscopic/microscopic examination of selected organs; and bronchoalveolar lavage fluid (BALF) and serum analysis for cellular markers of inflammation (i.e., cytokines). As a positive control to validate the utility of cytokine measures as indicators of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m<sup>3</sup> amorphous silica (0, 1, 2, 5 or 10 exposures). Exposure of SD rats to  $\geq 0.15$  ppm isoeugenol resulted in adverse histologic changes indicative of dose dependent epithelial irritation. These were the only findings noted following isoeugenol exposure up to 14.9 ppm. There were no test substance-related microscopic effects in the lower respiratory tract tissues (lungs, trachea or larynx), liver, or kidneys. There were no toxicologically significant effects on BALF or serum cytokine levels. Therefore, neither a no-observed-adverse-effect level (NOAEC), nor a no observed effect level (NOEC) could be determined for this study regarding upper airway irritation. For the lower airway the NOEL was considered to be 14.9 ppm.

## PS 1544 Toxicological Evaluation of 4, 4, 5, 5, 6, 6, 7, 7, 8, 8, 8-Undecafluoro Octanoic Acid (5:3 Acid).

S. MacKenzie<sup>1</sup>, T. L. Serex<sup>1</sup>, C. Carpenter<sup>1</sup>, D. L. Nabb<sup>1</sup>, R. Hoke<sup>1</sup>, S. A. Gannon<sup>1</sup>, D. Hoban<sup>1</sup>, M. Donner<sup>1</sup> and R. C. Buck<sup>2</sup>. <sup>1</sup>DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE; <sup>2</sup>E.I. du Pont de Nemours & Company, Inc., Chemicals and Fluoroproducts, Wilmington, DE.

Studies were conducted to evaluate mammalian and aquatic toxicity of 4,4,5,5,6,6,7,7,8,8,8-undecafluoro octanoic acid (5:3 acid) (CAS# 914637-49-3). 5:3 acid is a metabolite of 6:2 fluorotelomer alcohol (6:2 FTOH). 6:2 FTOH is a raw material for fluorotelomer-based products. Rat oral and dermal LD50 values were 2950 mg/kg and >5000 mg/kg, respectively. 5:3 acid produced no dermal irritation but irreversible eye irritation in rabbits, while a weak dermal sensitization response was observed in mice (LLNA), with an EC3 of 23%. A bacterial reverse mutagenicity assay and an in vivo rat micronucleus assay were negative. A 2-week rat gavage study identified red blood cells (anemia), liver (hypertrophy, focal necrosis, and increased beta-oxidation), kidney (tubular vacuolation), stomach (ulceration), and thyroid (follicular hyperplasia; of questionable relevance to humans) as target organs. Rats dosed at 600/900 mg/kg/day were euthanized in extremis. The NOAEL was <30 and 30 mg/kg bw/day in males and females, respectively. In vitro metabolism was evaluated in male and female rat hepatocytes and predicted half-life in males and females of 430 and 2573 min., respectively, and identified several metabolites. Preliminary evaluations (single dose and repeat dose exposures) demonstrated that 5:3 acid exhibits biphasic pharmacokinetics. Studies demonstrated low to moderate toxicity in aquatic organisms with the following results: 72-hour EbC50 in *Pseudokirchneriella subcapitata* was 22.5 mg/ml; 90-day NOEC in rainbow trout was 9.14 mg/L; 48-hour EC50 in *Daphnia magna* was >103 mg/L; 21-day NOEC in *Daphnia magna* was 1.25 mg/L. The 90-day bioconcentration factor (BCF) measured in rainbow trout was 2.25-5.85, which supports a lack of predicted bioaccumulation in fish. 5:3 Acid is not expected to be harmful to human health or the environment at environmentally relevant concentrations.

## PS 1545 A 28-Day Toxicity Study of PSOA by Oral Gavage in Rats Followed by a 14-Day Recovery Period.

T. O'Brien<sup>1</sup>, N. Pechacek<sup>1</sup>, W. Aulmann<sup>2</sup> and K. Laidlaw<sup>3</sup>. <sup>1</sup>Ecolab, St. Paul, MN; <sup>2</sup>Ecolab, Düsseldorf, Germany; <sup>3</sup>Charles River, Edinburgh, United Kingdom.

The objective of this study was to determine the potential repeat dose toxicity and reversibility of any findings over a 14 day recovery period for a peroxy sulfonated fatty acid (PSOA). The study design followed OECD Guideline 407. Sprague-Dawley (CrI:CD(SD)) rats were given PSOA once daily via gavage for 28 days at doses of 0, 5, 15 and 50 mg/kg/day. The highest PSOA concentration used was 0.5%. On completion of the dosing period, designated recovery animals were retained for a 14 day recovery period. The following parameters and end points were evaluated in this study: clinical signs, body weights, body weight changes, food consumption, ophthalmology, functional observations, clinical pathology parameters, gross necropsy findings, organ weights, and histopathology. No early deaths were observed in the dose groups. At the end of the treatment period, gross and microscopic findings observed were of the nature and incidence commonly seen in rats of this age and strain for studies of this type, and/or were of similar incidence in control and treated animals. Differences in the incidence of dark foci in the lungs, observed in male rats sacrificed on Day 29, were shown to correlate with alveolar hemorrhage which showed no biologically significant difference in incidence between treated animals and controls. The increased incidence of minimal hemorrhage in the thymus of treated animals which were sacrificed after the recovery period on Day 43 is considered incidental, as this is a common background lesion. Overall, no test article-related findings were observed for this study. Also no impairment of the mucous membranes of the gastrointestinal tract was observed up to the highest concentration of 0.5 %, which can be regarded as a No-Observed-Effect-Concentration (NOEC) in terms of local toxicity after 28 days repeated exposure. In conclusion, administration of PSOA by once daily oral gavage was well tolerated in rats at levels of 5, 15 and 50 mg/kg/day. Based on these results, the No-Observed-Effect Level (NOEL) was considered to be 50 mg/kg/day.

## PS 1546 Smokeless Tobacco (Guthka)-Induced Toxicological Effects in a Mouse Model: A Nicotine Twist.

D. Willis<sup>1</sup>, M. A. Popovich<sup>1</sup>, E. Gany<sup>2</sup>, C. Hoffman<sup>1</sup>, J. L. Blum<sup>1</sup> and J. T. Zelikoff<sup>1</sup>. <sup>1</sup>Environmental Medicine, New York University, Tuxedo Park, NY; <sup>2</sup>Memorial Sloan Kettering Cancer Center, New York, NY.

The popularity of smokeless tobacco (ST), usually placed within the mouth to be chewed, sucked, or swallowed, is growing rapidly and its prevalence of use is rising globally, due (in part) to greater convenience and stricter smoking laws. Guthka, an addictive form of ST that contains areca nut, catechu, cardamom, lime, flavored chewing tobacco, and natural and artificial flavoring materials, is particularly common amongst Southeast Asian communities throughout the world, including the US. This study seeks to determine the generalized toxic effects of Guthka and to determine the role of nicotine in producing Guthka-associated toxicity. Ten-week-old B6C3F1 male mice were divided randomly into three groups and treated for 3-wk (5 d/wk) via the oral mucosa with equal volumes of water (control), a water-soluble nicotine solution, containing 0.24 mg of nicotine, or a water-soluble, 21 mg lyophilized Guthka solution. Serum cotinine, used as the exposure metric, was measured weekly in all three groups and was similar in both the Guthka- and nicotine-treated mice (36 vs. 48 ng/mL, respectively). At sacrifice, liver, heart, spleen, tongue, kidneys, thymus, and testes were collected, weighed, and evaluated histologically; serum testosterone (T) and hepatic CYP 2A5 (equivalent to human CYP2A6 in humans and the major nicotine and cotinine oxidase in mouse liver) was also measured. Heart weight (relative to body weight) was significantly decreased following either nicotine or guthka exposure, while normalized liver/body weight and serum T levels were significantly decreased in the Guthka-treated group only. These findings suggest that repeated Guthka use adversely impacts body weight, organ weight, and circulating T levels and that Guthka toxicity may be driven by toxic components other than nicotine. As the use of Guthka rapidly increases worldwide, future studies are needed to further delineate its toxicological implications. MSK Cancer Center and NIEHS Center Grant ES000260.

## PS 1547 Safety Assessment of Dicamba Monooxygenase from the Biotechnology-Derived Soybean MON 87708.

M. Koch, L. Burzio, J. Finnessy, T. Kaempfe, H. Kang, A. Silvanovich, C. Wang and E. Bell. Monsanto Company, St. Louis, MO.

Monsanto has developed a soybean, MON 87708, which is tolerant to dicamba herbicide. It contains a gene, *dmo*, that expresses dicamba monooxygenase (MON 87708 DMO). A safety evaluation of the MON 87708 DMO protein was conducted, it examined: 1) the source of the gene; 2) its function and a history of safe use for structurally similar proteins; 3) its homology to known allergens, toxins, or

other proteins known to have adverse effects in mammals; 4) its stability to heat treatment; 5) its digestibility in simulated gastrointestinal fluid; and 6) its potential toxicity *in vivo*. The *dmo* gene was obtained from a strain of *Stenotrophomonas maltophilia*, a bacterium that is found in a variety of foods (i.e., "ready to eat" salads, vegetables, frozen fish, milk, and poultry), is widespread in the home environment, and has not been reported to be allergenic. Accordingly, the gene was considered to come from a safe source. Structurally, MON 87708 DMO is classified as a Rieske-type non-heme iron oxygenase (RO), as such it shares structural and functional similarities with related proteins in plants - including crops like corn, rice, and soybean. Thus, there is a history of safe use of RO proteins that are structural homologs of MON 87708 DMO. Similarly, protein homology searches conducted with MON 87708 DMO indicate no biologically relevant sequence similarities to allergens (including 8 amino acid epitopes), toxins, or other proteins with adverse biological activities. When subjected to temperatures approximating soybean processing, MON 87708 DMO demonstrates a loss of enzymatic activity and a change in structural stability. The protein also rapidly digests in simulated GI fluids. As well, field trial data indicates low MON 87708 DMO expression levels *in planta*. Taken together, dietary exposure to intact/active MON 87708 DMO is anticipated to be negligible. MON 87708 DMO was also administered to mice in acute and 28-day toxicity studies, and the protein was not associated with signs of toxicity. The weight of evidence demonstrates that MON 87708 DMO is safe for food and feed.

## PS 1548 A 14-Day IV Infusion Exploratory Toxicity Study of Hydroxylamine in Rats.

J. Zhou, R. Giovannelli, W. J. Reagan and M. D. Aleo. *Drug Safety R&D, Pfizer Worldwide Research and Development, Groton, CT.*

Hydroxylamine (HA) is an important industrial reducing agent with little therapeutic value. However, it may be formed as a by-product when drugs containing hydroxamic acid functional groups are used, and thus exhibit hemotoxicities. As many of these compounds are developed as intravenously (IV) administered (infusion) drugs, understanding the dose-toxicity relationship of HA by IV infusion becomes important in risk mitigation and management. In this study, we investigated if, at the same daily doses (12, 24 or 36 mg/kg/day), either by continuous infusion (CI) or by twice daily 1-hour intermittent infusions (II), HA produced the same level of toxicity. As systemic toxicities of HA are well-known, the focus of this study was on toleration and hematologic effects. Clinical signs, body weight and quantitative food consumption were assessed. Blood samples were taken at various times to evaluate methemoglobin (metHb) and total hemoglobin (Hb) levels. Hematology parameters and morphology were evaluated in blood samples taken on Days 3, 9 and 15. Dose-dependent increases in the metHb level were observed in both CI- and II-treated animals, however, a higher level of metHb was generally observed in II animals at the same daily doses. The metHb level increased within the first 4-6 days of dosing and then declined in the remaining course of study. Clinically, administration of HA up to 36 mg/kg/day (CI or II) was well-tolerated, with only pale appearance observed in the high-dose animals (CI and II) during the second week. No significant effect of HA on the body weight was observed although food consumption at 36 mg/kg (CI and II) was significantly reduced. Multiple hematology parameters demonstrated HA induced a dose- and time-dependent hemolytic anemia with the formation of Heinz bodies in both CI and II animals. The reduction of total Hb worsened with daily dosing and appeared to reach a plateau after 6-9 days of dosing. These data provided useful information on the choice of infusion regimen and risk management of some hydroxamic acids by infusion.

## PS 1549 Increased Hypothalamic Dopaminergic Neuron Tyrosine Hydroxylase Expression in Lean Wistar Rats.

S. M. Plummer<sup>1</sup>, M. Beltran<sup>2</sup>, M. Millar<sup>2</sup>, R. Wiegand<sup>3</sup> and J. Wright<sup>4</sup>. <sup>1</sup>MicroMatrices Associates Ltd., Dundee, United Kingdom; <sup>2</sup>MRC Centre for Reproductive Health, Edinburgh, United Kingdom; <sup>3</sup>MRC Centre for Inflammation Research, Edinburgh, United Kingdom; <sup>4</sup>Syngenta Ltd., Bracknell, United Kingdom.

Caloric restriction in Wistar rats has been reported to show a decrease in mammary and pituitary tumours and an increase in uterine tumours (1, 2) associated with delayed hypothalamic dopaminergic neuronal senescence (3). This study was designed to assess the effects of reduced body weight gain on hypothalamic dopaminergic neurons using FFPE tissue obtained from 100 female Wistar rats (50 controls; 50 with >30% body weight gain reduction) from a 2 year bioassay. A combination of immunostaining (IHC) and RNAscope™ *in situ* hybridisation (ISH) was used to examine expression of tyrosine hydroxylase (TH), a rate limiting enzyme for dopamine synthesis.

TH protein expression was detected in both the paraventricular (PVH)/periventricular (PeVH) nuclei and the median eminence (ME). TH RNA expression was also detected in these regions, but there was a disparity in the strength and location of

TH RNAscope™ staining compared to TH protein staining. TH protein staining was strongest in the ME, whereas TH RNA staining was strongest in the PVH/PeVH nuclei. To examine the relationship between TH protein vs RNA staining in more detail dual fluorescence IHC/ISH was performed. This analysis showed coincident TH protein and RNA staining in some neuronal cell bodies and axons; however, some neurons displayed TH protein staining in the absence of TH RNA staining and vice versa. Qualitative assessment indicated that rats with reduced bodyweight gain showed an increase in the number and intensity of TH RNA and TH protein positive neurones in the PVH/PeVH nuclei and the ME, respectively. These results indicate a disparity between the expression of TH RNA and TH protein in the rat hypothalamus, and suggest that chronic reduction in bodyweight gain may alter regulation of TH expression at the RNA and protein levels in hypothalamic nuclei.

## PS 1550 Proposition 65 and Cancer Incidence in California.

L. Haighton, H. Fikree, A. Pais, S. Prasad and J. W. Card. *Intertek Cantox, Mississauga, ON, Canada.*

Proposition 65 has been in effect in California (CA) for 25 years. It requires businesses to notify consumers if products they buy contain chemicals that are known to the State of CA to cause cancer and birth defects or other reproductive harm. This study determined the tumor types reported to be associated with the 71 carcinogens that were first added to the Proposition 65 list in 1987 and evaluated the incidence rates for these tumor types in males (M) and females (F) in CA through to 2009. Corresponding incidence rates in Washington State (WA; geographically similar) and New York State (NY; as a diverse East coast regional control) were evaluated as comparators. Of the 71 chemicals added as carcinogens to the Proposition 65 list in 1987, >10 have each been reported to be associated with urinary bladder and breast tumors and >20 each with liver and lung tumors. Between 1988 and 2009, there was a modestly decreased trend in bladder cancer incidence in CA [linear slope = 0.19 (M) and 0.06 (F); R<sup>2</sup> = 0.75 (M) and 0.77 (F)]. Less robust decreases were observed in WA [slope = 0.05 (M and F); R<sup>2</sup> = 0.01 (M) and 0.18 (F)], while a modestly increased trend was observed in NY. Over the same time period, there was a modestly increased trend in breast cancer incidence (slope = 0.15 to 0.41; R<sup>2</sup> = 0.02 to 0.18) and an approximate doubling of liver cancer incidence in both sexes in all 3 states (slope = 0.07 to 0.41; R<sup>2</sup> = 0.80 to 0.99). A substantial and comparable decrease in lung cancer incidence was observed in males in all 3 states (slope = 1.18 to 1.80; R<sup>2</sup> = 0.90 to 0.99). For females, lung cancer incidence decreased in CA (slope = 0.36; R<sup>2</sup> = 0.79) but increased in WA and NY. The results of this preliminary assessment indicate that since Proposition 65 came into effect 25 years ago, liver cancer incidence in CA has approximately doubled but consistent and robust decreases in incidence rates have been observed for bladder cancer in both sexes and for lung cancer in females. The contribution of Proposition 65 to these observed changes is unclear and warrants further investigation.

## PS 1551 Alternatives to Bisphenol A in Thermal Paper: Analysis of Substitution Options and Trade-Offs.

C. Baier-Anderson<sup>1</sup>, J. Rhoades<sup>2</sup>, M. Kawa<sup>2</sup> and J. Tunkel<sup>2</sup>. <sup>1</sup>US EPA, Washington DC; <sup>2</sup>SRC, Inc, Syracuse, NY.

The U.S. Environmental Protection Agency (US EPA) Design for Environment (DfE) Program undertook a chemical alternatives assessment for the use of bisphenol A (BPA) in thermal paper, including cash register receipts, as part of the Action Plan for BPA in March 2010. The purpose of the alternatives assessment is to identify and compare alternative chemicals to inform decision-making. The alternatives assessment was conducted via a multi-stakeholder partnership that identified 19 functional alternatives to BPA. The hazard assessment for BPA and the alternatives used the DfE hazard evaluation criteria to assign hazard designations for human health toxicity, ecological toxicity and environmental fate endpoints. Some alternatives were well characterized for all endpoints. Other alternatives were poorly characterized, wherein analog data, predictive models, structural alerts and expert judgment were used to make hazard designations for data gaps. Trends for human health, ecological toxicity and fate characteristics were indicated in a number of the alternatives due to particular molecular size ranges and/or molecular structures. In general, all alternatives have important trade-offs although if used with appropriate control measures, some of the alternatives could provide incremental benefits. Effective hazard assessment approaches, coupled with decision-making protocols that are practical tools for businesses to use in materials selections, will lead to more sustainable product development when human health or ecological toxicity concerns exist. The resulting hazard profiles should be of value to manufacturers making substitution decisions and facilitate reductions in environmental releases and subsequent exposures.

**PS 1552 Body-Residue Based Environmental Safety Assessment of Personal Care Product Ingredients: A Case Study with Benzophenone-3.**

F. Liu<sup>1</sup>, V. Tu<sup>1</sup> and N. Y. Wang<sup>2</sup>. <sup>1</sup>Revlon Research Center, Edison, NJ; <sup>2</sup>Environmental Assessment Scientist Serving in a Personal Capacity, Cincinnati, OH.

Personal care product (PCP) ingredients are released into aquatic ecosystem via wastewater discharge and potentially affect environmental health. The environmental safety assessment (ESA) is an important component of overall ingredient safety evaluation. We presented here an exploratory effort in applying the body-residue based approach in ESA of PCP ingredients. The traditional water-concentration based ESA has been used to evaluate the environmental impact of PCP ingredients. Compared with the water-based concentration, body residue concentration represents an internal dose, takes chemical disposition into account and provides an integrated assessment of the exposure an organism receives over space and time. With advancement of computational toxicology, critical body residues (CBRs) corresponding to toxicity endpoints and chemical bioaccumulation levels can be modeled as an alternative to animal testing. Organic UV filters are widely used in PCPs to offer sunscreen benefit. Environmental occurrence of various organic UV filters has been documented in both abiotic and biotic media. As a lipophilic UV filter, benzophenone-3 bioaccumulates in fish and concerns have been raised due to its *in vitro* antiestrogenic and antiandrogenic activities. The CBR and body residue level of benzophenone-3 were predicted using QSAR models. Information on environmental occurrence of benzophenone-3 was compiled and analyzed. The modeled tissue levels were comparable with the measured tissue levels in the environment. Our ESA analysis indicated that the CBR was significantly higher than the tissue level of benzophenone-3 in various fish species habituated in different aquatic ecosystems. The result was in good agreement with water-concentration based approach obtained by comparing the measured water concentration with the predicted no effect concentration (PNEC). As a result of this work, an alternative approach based on available *in silico* methods was developed for conducting screening level ESA of PCP ingredients.

**PS 1553 Evaluation of the Potential for Establishing a Threshold for Chemical Ocular Irritation Using a Model of Repeated Topical Ocular Administration in Albino Rabbits.**

K. G. Eckles, J. Amin, K. Krenzer and M. E. Richardson. *Nonclinical Safety, Bausch & Lomb, Rochester, NY.*

**Rationale:** The qualification of low levels of impurities in topical ophthalmic products is often hampered by a lack of ocular safety data at levels relevant to the products; establishing a threshold would be valuable in safety assessments. Therefore, the goal of this study was to explore the possibility of a threshold level for ocular irritation from repeated topical exposure to agents in solution.

**Methods:** Ten compounds from 8 chemical families (acids, acrylates, alcohols, aldehydes, alkalis, amines, anionic surfactants, and cationic surfactants), were identified which resulted in severe ocular irritation or corrosive effects when administered as a single drop on the rabbit eye at high concentrations. Each chemical was prepared in an appropriate vehicle (saline or sesame seed oil) to give concentrations of 20 and 100 ppm. One eye of albino rabbits (5/dose group) was administered 50  $\mu$ L of the test article 4 or 6 times daily (oil- or saline-vehicle, respectively) for 3 days. The contralateral eye served as a vehicle control. Draize scoring was performed before the first daily dose and after the final daily dose and biomicroscopy was performed pre-dose and on Days 2 and 3.

**Results:** None of the 10 chemicals resulted in notable ocular irritation at either 20 or 100 ppm after repeated ocular administration.

**Conclusion:** Despite being severe irritants or corrosives when dosed as a single drop at high concentrations, the favorable ocular irritation results observed with up to 100 ppm concentrations of severe irritants or corrosives suggest that it may be possible to establish a threshold for ocular irritation.

**PS 1554 Human Health Assessment of Scented Candle Emissions.**

T. Petry<sup>2</sup>, D. Vitale<sup>1</sup>, L. Cruse<sup>3</sup>, F. J. Joachim<sup>4</sup>, R. Mascarenhas<sup>5</sup>, S. Schneider<sup>6</sup>, B. Smith<sup>7</sup> and M. Singal<sup>1</sup>. <sup>1</sup>Research Institute for Fragrance Materials, Woodcliff Lake, NJ; <sup>2</sup>ToxMinds BVBA, Brussels, Belgium; <sup>3</sup>Procter & Gamble, Cincinnati, OH; <sup>4</sup>SC Johnson & Son, Racine, WI; <sup>5</sup>Reckitt-Benckiser, Hull, United Kingdom; <sup>6</sup>Firmenich SA, Princeton, NJ; <sup>7</sup>Firmenich SA, Geneva, Switzerland.

Airborne compounds in the indoor environment arise from a wide variety of sources such as environmental tobacco smoke, heating & cooking, dusts, emissions from furniture and construction materials as well as outdoor sources. One product

category which has received recent attention as a source of indoor airborne substances is scented candles. The potential impact of airborne candle emissions on the quality of the indoor air is highly dependent on the type and concentrations of chemical substances released. To better understand the potential of scented candles to contribute to the indoor load of airborne substances, a comprehensive candle emission testing program initiated by the consumer products and fragrance industry was undertaken to investigate the emissions of volatile and semi-volatile organic compounds (VOC; SVOC) and particulate matter (PM). Associated human exposures scenarios were derived and computer models used to estimate exposure of these materials to consumers. Measured chamber concentrations of VOC, SVOC and PM were used to predict their respective, cumulative indoor air concentrations in a standard EU-based dwelling using 2 models - the well-known and widely accepted ConsExpo 1-Box inhalation model and the recently developed, refined RIFM 2-Box indoor air dispersion model. The output from both models has been used to estimate realistic yet conservative consumer exposure to scented candle emissions measured under this program. The potential consumer health risks associated with the exposure to these materials was compared to existing air quality guideline values and established safe exposure levels. This investigation concluded that even under the conservative assumptions, potential human exposures are a minimum of one order of magnitude below established regulatory indoor air guideline values and/or published safe exposure levels.

**PS 1555 Cobalt Whole Blood Concentrations in Healthy Adult Volunteers following Two Weeks of Ingesting a Cobalt Supplement.**

B. L. Finley<sup>2</sup>, B. E. Tvermoes<sup>1</sup>, K. M. Unice<sup>3</sup>, J. M. Otani<sup>2</sup>, D. J. Paustenbach<sup>2</sup> and D. A. Galbraith<sup>2</sup>. <sup>1</sup>ChemRisk, Boulder, CO; <sup>2</sup>ChemRisk, San Francisco, CA; <sup>3</sup>ChemRisk, Pittsburgh, PA.

Recently, there has been an increase in the marketing and sales of dietary supplements, energy drinks, muscle builders and other consumer products that may contain relatively high concentrations of essential elements. Cobalt-containing supplements are readily available in the U.S. and have been marketed to consumers as energy enhancers. However, little information is available regarding cobalt (Co) body burden and steady-state blood concentrations following the intake of Co dietary supplements. We assessed Co whole blood concentrations in four healthy adult male volunteers who ingested a commercially available Co supplement (0.4 mg Co/day) for 15 or 16 days. Pre-supplementation blood Co concentrations were less than the reporting limit of 0.5  $\mu$ g/L, consistent with background concentrations reported to range between 0.2 to 0.4  $\mu$ g/L. The mean whole blood Co concentration in the volunteers after 15 or 16 days of dosing was 3.6  $\mu$ g Co/L and ranged from 1.8 to 5.1  $\mu$ g Co/L. The mean observed concentration in the study group was approximately 9 to 18 times greater than background concentrations. Further studies of Co whole blood concentrations following supplementation over longer time periods with additional monitoring of physiological parameters may provide useful information for evaluating the health of persons who take various doses of Co.

**PS 1556 Multiparameter *In Vitro* Toxicity Testing of Crizotinib, Sunitinib, Erlotinib, and Nilotinib in Human Cardiomyocytes.**

K. Doherty<sup>1</sup>, R. L. Wappel<sup>1</sup>, D. R. Talbert<sup>1</sup>, P. B. Trusk<sup>1</sup>, D. M. Moran<sup>1</sup>, J. W. Kramer<sup>2</sup>, A. M. Brown<sup>2</sup>, S. A. Shell<sup>1</sup> and S. Bacus<sup>1</sup>. <sup>1</sup>Quintiles, Westmont, IL; <sup>2</sup>ChanTest, Cleveland, OH.

Targeted therapy has greatly improved the treatment and prognosis of multiple types of cancer. However, unexpected cardiotoxicity has arisen in a subset of patients for some of the tyrosine kinase inhibitors (TKi). For these TKi, the cardiotoxicity was not wholly predicted by pre-clinical testing, which centers around the inhibition of the *human Ether-à-go-go-Related Gene* (hERG) channel. Therefore, we sought to determine whether a multi-parameter panel of tests that assesses a drug's effect on cellular, molecular, and electrophysiological endpoints would more accurately predict cardiotoxicity. To do so, we examined how 4 FDA-approved drugs impacted cell viability, apoptosis, reactive oxygen species (ROS) generation, metabolic status, impedance, and ion channel function in human cardiomyocytes. The 3 drugs with known associated cardiac adverse events (crizotinib, sunitinib, and nilotinib) all proved to be cardiotoxic in our series of *in vitro* tests while erlotinib, a cardiac-safe drug, did not show any indications of toxicity. Crizotinib, an ALK/ MET inhibitor, was the most cardiotoxic by our panel, leading to increased ROS production, caspase activation, cholesterol accumulation, and a significant disruption in cardiac cell beat rate and blockage of ion channels. The multi-targeted TKi sunitinib also demonstrated severe cardiotoxicity in our tests, showing decreased cardiomyocyte viability, inhibition of AMPK, increased lipid droplet accumulation, disrupted beat pattern, and hERG block. Nilotinib, a second

generation Bcr-Abl inhibitor, led to increased ROS generation, caspase activation, hERG block, and an arrhythmic beat pattern. Thus, each drug showed a unique toxicity profile, demonstrating that a multi-parameter approach allows for a more complete assessment of the potential for drug-induced cardiotoxicity and may allow for earlier detection in the drug development process.

## PS 1557 Safety Assessment of Chemicals in Toys.

M. Whitehead, J. Doran, G. Goodfellow and J. Daniels. *Intrinsic Health Sciences Inc., Mississauga, ON, Canada.*

Numerous countries have enacted laws and regulations to protect children from the potential health hazards associated with exposures to chemicals used in the manufacture of toys, including the United States, Canada and the member states of the European Union. Assessing the risk posed to children from exposure to chemicals in toys poses a special challenge, due to the particular vulnerability of this population to both adverse effects and chemical exposure. Examples of chemical categories used in toys that may be of concern include metals, boron-containing substances, pigments and colorants, preservatives, and allergenic fragrances. The aim of this study was to evaluate the risk of substances flagged as potential chemical hazards when included as ingredients in child-intended products in various jurisdictions. Results of toxicological studies indicate that metal-containing pigments, certain azo dyes, and boric acid and its salts are associated with toxicity concerns such as reproductive, developmental, mutagenic, and carcinogenic effects. Product formulation data collected in a proprietary database over a two-year period was analyzed in order to determine the levels and frequency of use of these substances in various categories of toys. Exposure considerations and scenarios designed to specifically address the enhanced risk to children from chemical exposures as a result of the intentional use and reasonably anticipated misuse of different categories of toys were developed. Using the results of the toxicological studies and exposure scenarios developed by our group, we analyzed the margin of safety for the use of these chemicals of concern with respect to toxicity effects in toys. The results of our studies suggest that restricted chemicals are still being used to formulate toys at levels that indicate potential concern for this sensitive population.

## PS 1558 Health-Based Framework for Evaluating the Safety of Hydraulic Fracturing Products.

D. Wikoff<sup>1</sup>, L. Fitzgerald<sup>1</sup>, L. C. Haws<sup>1</sup> and M. Harris<sup>2</sup>. <sup>1</sup>ToxStrategies, Austin, TX; <sup>2</sup>ToxStrategies, Houston, TX.

Hydraulic fracturing has made it possible to extract natural gas from dense shale rock formations and has become the fastest-growing source of gas in the U.S. Because the process involves drilling through groundwater formations, there has been concern that drinking water aquifers could become contaminated – a concern compounded by a lack of information regarding the composition and safety of the products used. In an effort to address these concerns, we developed a quantitative framework to characterize potential safety of hydraulic fracturing products. The framework consists of four evaluation criteria that are applied to each of the product components: composition and use, toxicity, exposure, and risk of release. Each of the criteria has specific requirements associated with scores ranging from 1-5 (with 1 being the best and 5 being the worst) that are based on USEPA guidelines and standard risk assessment practices. A final composite product score is calculated based on scores for each of the criteria for each of the components and this score is used to place the product into a category of use relating to its safety (not recommended for use, use with caution/specialized conditions, or acceptable for designated use). Importantly, if any component of the hydraulic fracturing product does not achieve a score below the STOP point for any of the four criteria (indicative a minimum level of knowledge or safety), the product is automatically placed into the not recommended for use category. This framework allows health experts to tailor the evaluation to any type of product used in the fracturing process and can be consistently conducted by independent parties. Because this process focuses on human health risk and environmental exposures, it is different than those currently available in the natural gas industry and is more in line with standard risk assessment practices. Most importantly, this framework allows for transparency in the evaluation process and provides a quantitative method upon which experts can make decisions.

## PS 1559 Novel Methodology in Hazard Assessment: Chemical Clustering for Read Across—The Phthalate Alternatives Case Study.

M. Kawa<sup>1</sup>, J. Rhoades<sup>1</sup>, C. Baier-Anderson<sup>2</sup>, T. Webb<sup>1</sup>, K. Mayo-Bean<sup>3</sup> and J. Tunkel<sup>1</sup>. <sup>1</sup>SRC, Inc., East Syracuse, NY; <sup>2</sup>US EPA, DFE, Washington DC; <sup>3</sup>US EPA, OPPT, Washington DC.

Phthalates are a class of compounds produced in high volume in the U.S. and are found in many products, primarily as plasticizers. The U.S. EPA published an initial Action Plan for eight phthalates in 2010 due to concern about the toxicity of phthalates and the evidence of pervasive human and environmental exposure. As indicated in the Action Plan, a Design for the Environment (DfE) alternatives assessment (AA) will be performed for these chemicals. The DfE Program publishes AAs to help industries identify safer chemicals and provide a comparison of potential human health and environmental impacts of chemical alternatives. DfE hazard criteria are used to assign hazard designations for human health toxicity, ecological toxicity and environmental fate endpoints. Over 70 substances were identified as potential alternatives to the eight action plan phthalates. Some alternatives are well characterized for all endpoints, while others are data poor. In the absence of experimental data, DfE assessment methodology designates hazards based on a read across approach to structurally similar compounds. This poster describes a novel technique for green chemistry and hazard screening that uses the EPA's Office of Pollution Prevention and Toxics ChemACE program to cluster the alternatives based on common structures, functional groups, and molecular architectures. The ChemACE program automates chemical clustering based on structural similarities and generates reliable and organized results. Using this methodology, read across (analog) data from data-rich chemicals was used to assist in assigning and justifying hazard designations for data poor chemicals within a cluster. This allows for the determination of hazard designations for as many endpoints as possible including human health endpoints that often lack experimental data and methods for estimation. The resulting AAs should be of value to manufacturers making substitution decisions and facilitate reductions in potential human health impacts.

## PS 1560 Transdermal Toxicity of the Phorbol Ester Isolated from Biodiesel Feedstock, Jatropha Curcas.

M. Nakao, S. Kinoshita and Y. Ishihara. *Kurume University, Kurume, Japan.*

[Purpose] *Jatropha curcas* attracts rising attention as a biodiesel feedstock in the world. However, *Jatropha* contains various toxic components, generating concerns about its health effects. One of toxic components is potential tumor promoter, phorbol esters. Toxicity of *Jatropha* phorbol esters has not been fully described. In this study, transdermal toxicity of main component of *Jatropha* phorbol esters was assessed in mice.

[Experimental procedures] One of the *Jatropha* phorbol esters, 12-deoxy-16-hydroxyphorbol-4'-[12',14'-butadienyl]-6'-[16',18',20'-nonatrienyl]-bicyclo [3.1.0] hexane-(13-*O*)-2'-[carboxylate]-(16-*O*)-3'-[8'-butenoic-10'] ate (DHPB) (1 – 10 µg), was applied onto skin of mice. As a positive control, 12-*O*-Tetradecanoylphorbol 13-acetate (TPA) (1 – 10 µg) a known tumor promoter was applied. Transformation activity of test compound was assayed using Bhas42 cells. Autopsy was conducted on the dead mice to observe the lesions. All survived mouse were sacrificed at 8 weeks from the beginning of the study and hematological tests and splenic lymphocyte measurement using flow cytometer were carried out.

[Results] 2.5 µg of DHPB led to weight loss and over 5 µg of DHPB caused death during 3 weeks observation. There were no such symptoms in the mice treated with the same dose of TPA. Gastrointestinal bleeding and splenic atrophy was observed in the dead mice. The NOAEL of DHPB was considered to be 2 to 2.5 µg. No papilloma on the skin was observed in DHPB group in contrast to TPA which developed papilloma when the dose exceeded 1 µg. There was no significant difference in splenic lymphocyte composition among DHPB, TPA, and control groups. Hematological analyses showed that the number of red blood cells, platelet, and lymphocyte was markedly decreased in DHPB treated mice at 8 weeks.

[Conclusion] DHPB, on the contrary to TPA, showed no tumor promotion in this experiment but showed acute toxicity which was not seen in the mice treated with TPA. These results suggest that DHPB has different characteristics in transdermal toxicity in comparison with those of TPA.

**PS 1561 Identifying No Observed Effect Levels (NOEL) and No Observed Adverse Effect Levels (NOAEL) through Metabolomics.**

G. Montoya<sup>1</sup>, V. Strauss<sup>1</sup>, H. G. Kamp<sup>1</sup>, W. Mellert<sup>1</sup>, T. Walk<sup>2</sup>, R. Looser<sup>2</sup>, M. Herold<sup>2</sup>, G. Krennrich<sup>2</sup>, E. Peter<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>metanomics, Berlin, Germany.

A key quantitative element in toxicity studies is the identification of the NO(A)EL – no observed (adverse) effect level. With the introduction of omics into toxicology, questions have been raised concerning the sensitivity of these methods. BASF's Experimental Toxicology and Ecology unit and metanomics developed the MetaMap® Tox database with more than 500 reference compounds obtained from rat studies (OECD 407 design). Metabolome analysis in plasma was performed after 7, 14 and 28 days and relative levels of endogenous metabolites in treated rats versus controls were analyzed. We have obtained metabolome data at toxicological NO(A)EL doses.

Recent advances in metabolic profiling technologies together with expert judgment offer the possibility of identifying whether differences from control values are treatment related and to discriminate between those that are adverse and those that are not. To obtain a measure of sensitivity of metabolomics vs. classical toxicology, we have used these data to analyze metabolomics changes at toxicological NO(A)EL doses. We have done this considering the number of statistically significant metabolite changes ( $p < 0.05$ ), the false-positive rate and the correlation with defined patterns for diverse modes of action (approximately 100 defined in MetaMap®Tox). Results show that in most cases where there are no toxicological effects (NOEL) there are also only few metabolomics changes (at/below the level of the false positive rate and without a match to the predefined MoA patterns). In some cases in which the study demonstrated a NOAEL (only effect noted being liver weight increase) metabolomics changes are often present and identify the liver as target organ. Following this analysis, it would seem that metabolomics is generally not more sensitive than classical toxicology, with respect to the identification of a NO(A)EL.

**PS 1562 Metabolic Profile of Rats in Repeated Dose Toxicological Studies after Oral and Inhalative Exposure.**

E. Fabian<sup>1</sup>, N. Bordag<sup>2</sup>, M. Herold<sup>2</sup>, H. G. Kamp<sup>1</sup>, G. Krennrich<sup>2</sup>, R. Looser<sup>2</sup>, L. Ma-Hock<sup>1</sup>, W. Mellert<sup>1</sup>, E. Peter<sup>2</sup>, A. Prokoudine<sup>2</sup>, M. Spitzer<sup>2</sup>, V. Strauss<sup>1</sup>, T. Walk<sup>2</sup>, J. Wiemer<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Metanomics, Berlin, Germany.

BASF and metanomics, in a joint effort, developed the MetaMap®-Tox application containing metabolic profiles attained from administration of over 500 toxicants. The toxicants were administered to five Wistar rats for each sex and each of the two dose levels for a total duration of four weeks following a standardized protocol, in accordance with OECD 407. Metabolome analysis of plasma samples was performed after one, two and four weeks. The ratios of the metabolites from treated rats versus untreated rats (control) were transferred to MetaMap®-Tox for data assessment.

In this study, metabolic profiles after oral and inhalative exposure were compared for six selected model compounds: aniline (A), chloroform (CL), ethylbenzene (EB), 2-methoxyethanol (ME), N,N-dimethylformamide (DMF) and tetrahydrofuran (THF). The toxicants were dosed inhalatively for six hours/day, five days a week and orally each day via the feed (DMF) and by gavage (A, CL, EB, ME, THF). Statistical evaluation (pairwise comparison in MetaMap®-Tox as well as principle component analyses) showed similar metabolic changes for DMF, EB, CL and ME, indicating a comparable systemic toxicity after oral and inhalative exposure. In contrast, metabolic profiles of A and THF showed differences between the tested exposure routes. Metabolic profiles were sufficient for the identification of test substance related toxicological modes of action using MetaMap®Tox. In conclusion, our results indicate the potential of metabolic profiling for generating fingerprints of systemic toxicity following different exposure scenarios.

**PS 1563 Percellome Toxicogenomics Application to Sick Building Syndrome-Level Inhalation Toxicity.**

J. Kanno, K. Aisaki, K. Igarashi, Y. Taquahashi and S. Kitajima. *Division of Cellular and Molecular Toxicology, National Institute of Health Sciences, Tokyo, Japan.*

Toxicity of low concentration formaldehyde (FA) corresponding to the level of Sick House/Building Syndrome (SHS) is difficult to assess by the ordinary inhalation animal studies; histopathological endpoints are negative for toxicity at such concentration. However, transcriptomic responses are captured at this exposure level.

Here we applied our Percellome Toxicogenomics Project. This project has been launched to develop a comprehensive gene network for the mechanism-based predictive toxicology. For this purpose, a normalization method designated as "Percellome" is developed (BMC Genomics 7:64, 2006) to generate mRNA expression values in "copy numbers per one cell" from microarrays and Q-PCR. The time- and dose-dependent alteration of gene expression induced by various exposure protocols in mice (4 time points x 4 dose levels, triplicate) are studied on more than 100 chemicals. Data are expressed in 3-D graphs (time x dose x mean copies per cell +/- sd); 45,000 surfaces corresponding to the probe sets of the Affymetrix Mouse Genome 430 2.0 Array.

FA at concentrations close to the "Indicative indoor exposure value of SHS (Ministry of Health Labour and Welfare, Japan)" of 0.08 ppm was applied to the 22hr/day x 7 day exposure protocol (0, 0.1, 0.3 and 1.0ppm, 4 time points, triplicate). C57Bl/6J mice were exposed and lung, liver and hippocampus were analyzed. As a result, strong suppression of gene expression related to neuronal activity in hippocampus, i.e. the immediate early genes including Arc, Nr4a1, Fos, Junb and Egr4 were shown. This study indicated that the comprehensive transcriptomic analysis will become useful for prediction of the effect on central nervous system of the very low concentration of toxicants. Our finding may be considered as a first substantial data that would explain the indefinite or unidentified complaint by this SHS-level exposure of FA. (Supported by Health Sciences Research Grants from the Ministry of Health, Labour and Welfare, Japan)

**PS 1564 Ten-Year Retrospective Assessment of the Food Contact Notification Program.**

A. P. Neal-Kluever, J. Cooper, T. Zebovitz and K. Butts. *Division of Food Contact Notifications, US FDA, College Park, MD.*

The Food Contact Notification (FCN) Program is FDA's premarket review system for evaluating the safety of packaging and other materials that contact food. Additionally, FCN notifiers can take advantage of a pre-notification consultation (PNC) program designed to provide guidance in advance of FCN filing. To assist program development and improve program transparency we performed a retrospective assessment of the FCN program. We analyzed the first 10 years of program performance, which included 924 FCNs and 980 PNCs. Overall, 76% of FCNs become effective, 23% were withdrawn, and 1% received not-accepted status. Some trends were observed which influenced the likelihood of an FCN becoming effective, such as whether the FCN was a resubmission, received a time extension, proposed a new use, or proposed the use of a novel or polymeric FCS. Company size as determined by the Small Business Association influenced whether an FCN was likely to become effective, with larger companies exhibiting a higher effective outcome rate. Smaller companies were more likely to withdraw FCNs, but experienced very high effective outcome rates with resubmitted and extended FCNs. There were some differences between the outcomes of notifiers utilizing and not utilizing the PNC program. Interestingly, 78% of the PNCs in the study period were not associated with an FCN.

**PS 1565 Development of a Regulatory Value for the Carcinogenic Potential of Isoprene via Inhalation Exposure.**

T. D. Phillips<sup>1</sup>, R. L. Sielken<sup>2</sup> and C. Valdez-Flores<sup>2</sup>. <sup>1</sup>Toxicology Division, Texas Commission on Environmental Quality, Austin, TX; <sup>2</sup>Sielken & Associates Consulting, Inc., Bryan, TX.

Isoprene is the 2-methyl analogue of 1,3-butadiene, a known human carcinogen. While isoprene is synthesized and used in the manufacturing of substances such as synthetic rubber, it is also produced naturally by plants, animals, and bacteria and is one of the main endogenous compounds found in human breath. Following the Texas Commission on Environmental Quality (TCEQ) Guidelines for the development of toxicity factors, a preliminary review and characterization of the carcinogenic potential of isoprene was conducted. Three key studies provided adequate data for the dose-response assessment of isoprene's carcinogenic potential. In order to determine URFs for study endpoints assuming exposure for 24h/d, 7d/wk, for a lifetime, the dose levels and numbers of animals at risk in the data sets were adjusted for differences between the exposure durations and times of response observation. The doses were adjusted to the constant lifetime environmental dose that is equivalent to the time-dependent doses in the studies, based on the multistage theory of carcinogenesis using the Armitage and Doll (1954) mathematical description of carcinogenesis with the number of stages being  $m = 1, 2, \text{ or } 3$ . Similarly, the number of subjects at risk of developing the specified response by necropsy time in the study was adjusted to the equivalent number of animals at risk if the time to necropsy were equal to the nominal animal lifetime. The adjusted parameters were used to carry out 171 model fits. The EC10 for each endpoint was identified using the estimated multistage models, and from there a URF for each endpoint was calculated. Based on the TCEQ Guidelines, only malignant endpoints considered relevant to humans and showing a statistical significance were considered for the draft

URF. The chosen draft URF was  $9.1\text{E-}04$  per ppm for liver carcinoma in a one stage carcinogenic process ( $m=1$ ). From the draft URF, a draft air concentration at the  $1\text{E-}05$  excess cancer risk level is calculated to be 11 ppb.

**PS 1566 Evaluation of Selected Nitrosamines As Candidates for Regulatory Determination Using a Group Approach.**

J. Donohue<sup>1</sup>, M. Simic<sup>1</sup>, Z. Bain<sup>1</sup>, A. Gebhart<sup>2</sup>, S. Goldhaber<sup>2</sup> and R. Howd<sup>2</sup>.  
<sup>1</sup>Office of Water, US EPA, Washington DC; <sup>2</sup>ToxServices, Washington DC.

In May 2011, EPA Administrator, Lisa Jackson announced the Drinking Water Strategy, a new cost-efficient approach to protecting public health that included broadening the traditional regulatory framework for chemicals by addressing groups of contaminants. Common physical and/or toxicological properties are features to be considered in determining group composition. The six nitrosamines, recently monitored nationally at public water systems (PWSs) under the Second Unregulated Contaminant Monitoring Rule (2009–2011), meet the grouping criteria based on a common mutagenic mode of action plus their chemical, and metabolic properties. Their toxicological data and co-occurrence at PWSs have been integrated to evaluate the practicality of considering a group of toxicologically similar chemicals in a Regulatory Determination context. The nitrosamines evaluated include N-Nitrosodi-n-butylamine, N-Nitrosodiethylamine, N-Nitrosodimethylamine, N-Nitrosodi-n-propylamine, N-Nitrosomethylethylamine, and N-Nitrosopyrrolidine. [The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.]

**PS 1567 Key Decisions in Establishing National Ambient Air Quality Standards.**

L. Fraiser<sup>1</sup> and L. J. Bradley<sup>2</sup>. <sup>1</sup>Environment, AECOM, Austin, TX; <sup>2</sup>Environment, AECOM, Chelmsford, MA.

This paper provides an evaluation of key decisions made by the US Environmental Protection Agency (EPA) in establishing more stringent short-term National Ambient Air Quality Standards (NAAQS) and provides an opinion on whether the supporting science suggests that their implementation will result in additional public health protection. Although EPA states that the NAAQS are based on evaluation of all relevant scientific evidence, they routinely are not. Despite many epidemiology studies that found no association between particulate matter (PM) exposure and mortality, EPA based the recent 24-hr PM<sub>2.5</sub> NAAQS on only two studies reporting associations between PM<sub>2.5</sub> reductions and health benefits. Only one controlled sulfur dioxide (SO<sub>2</sub>) study caused a significant response in the range used as the point of departure in establishing the 1-hr SO<sub>2</sub> NAAQS and neither clinical nor epidemiological studies support clinically-relevant lung decrements at this level. EPA used a consistent definition for moderate decrements in the lung function of asthmatics in establishing 1-hr NAAQS for nitrogen dioxide (NO<sub>2</sub>) and SO<sub>2</sub> but used a slightly different categorization in the latest review of the 8-hour ozone NAAQS. EPA included human exposures to NO<sub>2</sub> by mouthpiece in establishing the NO<sub>2</sub> NAAQS, but excluded mouthpiece exposure studies in developing the 1-hr SO<sub>2</sub> NAAQS because of the potential for increased pollutant delivery and altered distribution/deposition of pollutant that can occur. This evaluation of recently promulgated NAAQS reveals inconsistency in the way that EPA uses health effects studies to support its decisions, emphasizing the need to define key criteria/concepts, such as "adverse" effect, "sensitive" populations and principles of cause-effect relationships. It also highlights the need for guidelines on incorporating negative study results into weight-of-evidence evaluations. When all relevant data are considered, particularly in the context of other contributing factors, they do not support that the recent ratcheting down of NAAQS will result in additional health public protection.

**PS 1568 Development of a Proposed 24-Hour Health-Protective Air Monitoring Comparison Value for Formaldehyde for Comparison to 24-Hour Monitoring Data in the Barnett Shale Area.**

A. L. Curry, J. T. Haney and D. McCant. Toxicology Division, Texas Commission on Environmental Quality (TCEQ), Austin, TX.

The Barnett Shale is a large natural gas reserve encompassing more than 5,000 square miles and covering approximately 26 counties in North Texas. Due to public concern that natural gas compressor stations emit high formaldehyde concentrations, formaldehyde has been of increased public and regulatory interest in recent years. It has also been detected in 24-h carbonyl samples collected by the TCEQ in

the Barnett Shale. However, use of these data for evaluating potential health effects is typically limited to calculating long-term annual means for comparing to chronic, health-protective air monitoring comparison values (AMCVs). For evaluation of acute exposures, the agency generally uses 1-hr AMCVs, which are not designed to evaluate 24-h results. Thus, the development of a 24-h AMCV would allow the TCEQ to evaluate 24-h formaldehyde data for possible health concerns. Critical effect dose-response data for irritation (e.g., eyes, upper respiratory tract) from acute (~400 ppb) and chronic (~200 ppb) human studies suggest a narrow range for the lowest reported effect levels, indicating these irritant effects are primarily concentration dependent. The TCEQ conservatively used the same point of departure (POD) that its chronic noncarcinogenic AMCV is based on (NOAEL of 70 ppb) because the exposure duration (8 h/d) is more similar to the 24-h duration of interest than the 2–4 h exposure durations for the acute studies. Because the 8 h/d exposure was repeated 5 d/wk for 10 yrs, and irritation appears to be primarily concentration dependent, an 8-to-24-h exposure duration adjustment was judged not to be necessary. Dividing the POD of 70 ppb by an intrahuman uncertainty factor of 3 results in a proposed 24-h, health-protective AMCV of 23 ppb. The 24-h AMCV falls between TCEQ's 1-h (41 ppb) and chronic (8.9 ppb) noncarcinogenic AMCVs. To date, there has been only 1 exceedance in 1999 of the proposed formaldehyde 24-h AMCV when compared to Barnett Shale monitored data.

**PS 1569 Use of Other Scientifically-Relevant Information to Satisfy Tier 1 Testing Requirements in US EPA's Endocrine Disruptor Screening Program.**

P. L. Bishop<sup>1</sup> and C. Willett<sup>2</sup>. <sup>1</sup>People for the Ethical Treatment of Animals, Norfolk, VA; <sup>2</sup>The Humane Society of the United States, Washington DC.

The Endocrine Disruptor Screening Program (EDSP) has been designed to determine whether certain substances may have effects on the estrogen, androgen and thyroid hormonal systems. EPA is using an initial Tier 1 screening battery consisting of five in vitro and six in vivo assays to evaluate a chemical's potential to interact with the hormone systems in mammals and other animals. By order of the Office of Management and Budget, EPA must also consider Other Scientifically Relevant Information (OSRI) that is directly or functionally equivalent to data gathered in Tier 1, in lieu of developing new test data. This study characterizes the types of OSRI submitted by recipients of the first 67 test orders issued by EPA and reviews EPA's approach to acceptance of OSRI. It also assesses the impact of OSRI acceptance on reducing the number of animals used in screening this first round of chemicals. Companies submitted OSRI in lieu of some or all Tier 1 assays for 47 chemicals and sought waivers for 412 assays. EPA granted only 94 waivers, an overall acceptance rate of 23%; of these, 50 were for in vivo tests. For 20 of the 47 chemicals, EPA denied all OSRI and required the entire battery of assays to be performed. In most instances, the OSRI accepted was either identical to data that would have been generated by the Tier 1 test or indicated a positive response by the chemical in question. Although identified as potential sources of OSRI in EPA's guidance to test order recipients, guideline studies for pesticide registration, such as the mammalian two-generation reproductive toxicity study and 90-day rodent or dog studies, were all consistently rejected by EPA as satisfying Tier 1 data requirements. The 50 in vivo waivers EPA granted saved about 2,800 animals; however, nearly 26,000 were killed in the Tier 1 assays EPA required. The study concludes with a discussion of the implications for future use of OSRI in the EDSP.

**PS 1570 A New Approach to Academic and Guideline Research: The CLARITY-BPA Research Program.**

A. F. Johnson<sup>2</sup>, J. Aungst<sup>4</sup>, J. R. Bucher<sup>3</sup>, C. Luisa<sup>5</sup>, K. Delclos<sup>5</sup>, J. J. Heindel<sup>1</sup>, P. C. Howard<sup>5</sup>, D. Keefe<sup>4</sup>, R. Newbold<sup>3</sup>, W. Nigal<sup>3</sup> and T. T. Schug<sup>1</sup>. <sup>1</sup>Division of Extramural Science, NIEHS, Durham, NC; <sup>2</sup>Program Evaluation, MDB, Durham, NC; <sup>3</sup>NTP, NIEHS, Durham, NC; <sup>4</sup>Office of Food Safety, US FDA, College Park, MD; <sup>5</sup>Division of Biochemical Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR.

Recently, medical research has seen a strong push toward translational research, or "bench to bedside" collaborations, which strive to enhance the utility of laboratory science for improving medical treatment. The success of that paradigm supports the potential application of the process to other fields, such as risk assessment. Close collaboration among academic, government, and industry scientists may facilitate the application of scientific findings to regulatory decision making. The National Toxicology Program (NTP), National Institute of Environmental Health Sciences (NIEHS), and U.S. Food and Drug Administration (FDA) developed a consortium-based research program to more effectively link academic and guideline-compliant research. An initial proof-of-concept collaboration, the Consortium Linking Academic and Regulatory Insights on BPA Toxicity (CLARITY-BPA), uses bisphenol A (BPA) as a test chemical. The CLARITY-BPA program combines a core perinatal guideline-compliant 2-year chronic toxicity study with mechanistic

studies/endpoints led by academic investigators. Twelve extramural grantees were selected by NIEHS through an RFA-based initiative to participate in the overall study design and conduct disease-relevant investigations using tissues and animals from the core study. While the study is expected to contribute to our understanding of potential effects of BPA, it also has ramifications beyond this specific focus. Through CLARITY-BPA, NIEHS has established an unprecedented level of collaboration among extramural grantees and regulatory researchers. The CLARITY-BPA represents a potential new model for filling knowledge gaps, informing chemical risk assessment, and identifying new methods or endpoints for regulatory hazard assessments.

## PS 1571 How Consistent Are the Derived No-Effect Levels (DNELs) in the European REACH Legislation?

L. Schenk<sup>1,2</sup>, U. Deng<sup>1</sup> and G. Johanson<sup>1</sup>. <sup>1</sup>Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden; <sup>2</sup>Division of Philosophy, Royal Institute of Technology, Stockholm, Sweden.

The new European REACH regulation places more responsibility than hitherto on manufacturers and importers of chemicals ("industry") to provide safety information. An important part of the development of a REACH Chemical Safety Report is derivation of Derived No-Effect Levels (DNELs) which represent "the level of exposure above which humans should not be exposed". In order to study the consistency, we compared DNELs presented by industry at the website of the European Chemicals Agency (ECHA) with those derived by us in our interpretation of the REACH guidance (Chapter R.8: Characterisation of dose [concentration]-response for human health, [http://echa.europa.eu/documents/10162/13632/information\\_requirements\\_r8\\_en.pdf](http://echa.europa.eu/documents/10162/13632/information_requirements_r8_en.pdf)). There are various DNELs, e.g. representing short-term, long-term, inhalation and dermal exposure, as well as workers and the whole population. We limited our study to "worker-DNELs long-term" for inhalation route as they resemble occupational exposure limits (OELs). We found 24 substances for which (1) such DNELs were given in the ECHA chemical database (<http://echa.europa.eu/web/guest/information-on-chemicals/registered-substances>) and (2) a scientific basis for OEL had been published by the Swedish Criteria Group within the last 15 years in the serial Arbete och Hälsa (<https://gupea.ub.gu.se/handle/2077/3194?locale=en>). The results were startling, as the DNELs given by industry were 2.4 to 1,100 times higher than ours for 23 substances and 260,000 times higher for trimellitic anhydride. Some of the discrepancy is explained by different choice of key studies/points of departure (PODs). However, the choice of assessment factors (AFs) also differed markedly, as industry's total AFs (calculated implicitly from the POD and the DNEL) were 1-230 times lower than ours. We conclude that although the REACH guidance is relatively detailed, many arbitrary choices remain that will influence the DNEL. A major problem is that little advice is given on when and how to depart from default AFs.

## PS 1572 Animal Use for Testing Involving Unrelieved Pain and Distress.

M. Paris<sup>1</sup>, L. Rinckel<sup>1</sup>, W. Casey<sup>2</sup> and W. Stokes<sup>2</sup>. <sup>1</sup>ILS, Inc., Research Triangle Park, NC; <sup>2</sup>NTP/NICEATM, NIEHS, Research Triangle Park, NC.

Each facility in the United States that uses live animals for research, tests, experiments, or teaching must submit an annual report to the U.S. Department of Agriculture (USDA) that includes "the common names and the numbers of animals upon which experiments, teaching, research, surgery, or tests were conducted involving accompanying pain or distress to the animals and for which appropriate anesthetic, analgesic, or tranquilizing drugs were (or were not) used" (9 CFR, Chapter 1 Part 2, Section 2.36). In accordance with the definitions in §2132 of the Animal Welfare Act (7 U.S.C. 54), it is not necessary to report birds, rats of the genus *Rattus* and mice of the genus *Mus* bred for use in research, or fish, amphibians and livestock or poultry used in agricultural research. In the 2010 USDA annual report on animal usage, a total of 1,134,693 animals were reported, with 97,123 of those reported as experiencing unrelieved pain and distress. Based on an analysis of these data by the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM), 95% (91,997/97,123) of the animals reported to the USDA as experiencing unrelieved pain and distress were used for testing. Of these animals, 57% (54,889/97,123) were used for vaccine testing, and 38% (37,108/97,123) were used for toxicity testing. Most of the animals used for toxicity testing were used for safety testing and drug efficacy testing. NICEATM is currently investigating and promoting alternative test methods to further reduce the number of animals used in painful procedures. Supported by ILS staff under NIEHS Contract N01-ES-35504.

## PS 1573 A Reference Database for the Evaluation of Alternative Tests for Acute Dermal Systemic Toxicity.

J. Strickland<sup>1</sup>, F. Stack<sup>1</sup>, M. Paris<sup>1</sup>, L. Rinckel<sup>1</sup>, W. Casey<sup>2</sup> and W. Stokes<sup>2</sup>. <sup>1</sup>ILS, Inc., Research Triangle Park, NC; <sup>2</sup>NTP/NICEATM, NIEHS, Research Triangle Park, NC.

Alternatives for acute systemic toxicity testing are one of the highest priorities of ICCVAM and NICEATM. These are the most commonly performed product safety tests worldwide and are required by multiple U.S. Federal agencies. Acute toxicity testing can involve large numbers of animals and result in significant unrelieved pain and distress to test animals. High quality reference data are needed to evaluate alternative toxicity tests that may reduce, refine (enhance animal well-being and lessen or avoid pain and distress), and replace the use of animals for acute dermal systemic toxicity testing. To identify appropriate reference data for the acute dermal systemic toxicity test, NICEATM collected and analyzed data for 1897 substances. Rabbits were used for 28% (526) of the studies, and rats were used for 72% (1371). Of the 1897 substances, 84% (1598/1897) had data for both male and female animals, and 98% (1561/1598) of those substances were in the same GHS dermal hazard category. For the 37 substances that showed a different dermal hazard category between the sexes, female values were more often in a higher hazard category (21 for females vs. 16 for males). Two hundred forty six studies reported day of death. Approximately two thirds of the deaths (67% of male deaths [513/761]; 63% of female deaths [463/733]) occurred by Day 2 after a 24-hour dermal treatment on Day 0. Eighty-five substances had sufficient data to calculate dermal dose-mortality slopes. Dose-mortality slopes did not vary by species, sex, or GHS hazard category. As expected, the dermal dose-mortality slopes were lower than acute oral dose-mortality slopes. These data were used to design a proposed sequential test for acute dermal systemic toxicity, the dermal up-and-down procedure, to reduce the number of animals tested for acute dermal hazard classification. Supported by ILS staff under NIEHS Contract N01-ES-35504.

## PS 1574 Regulatory Acceptance of the BG1Luc Estrogen Receptor Transactivation Test Method.

W. Casey<sup>1</sup>, P. Ceger<sup>2</sup>, J. Strickland<sup>3</sup>, L. Rinckel<sup>2</sup>, E. Grignard<sup>3</sup>, S. Bremer<sup>3</sup>, H. Kojima<sup>4</sup>, S. Han<sup>5</sup> and W. Stokes<sup>1</sup>. <sup>1</sup>NTP/NICEATM, NIEHS, Research Triangle Park, NC; <sup>2</sup>ILS, Inc., Research Triangle Park, NC; <sup>3</sup>EUROL ECVAM, Ispra, Italy; <sup>4</sup>JaCVAM, Tokyo, Japan; <sup>5</sup>KoCVAM, NIFDS/KFDA, Cheongwon-gun, Chungcheongbuk-do, Republic of Korea.

NICEATM coordinated an international interlaboratory validation study of the BG1Luc estrogen receptor transactivation test method (BG1Luc ER TA, LumiCell®) developed by Xenobiotic Detection Systems, Inc. In 2010, the validation study completed its goal to evaluate the usefulness and limitations of the BG1Luc ER TA test method to screen for substances with in vitro ER agonist or antagonist activity. The international validation study was sponsored by NICEATM, with participation from the European Centre for the Validation of Alternative Methods, and the Japanese Center for the Validation of Alternative Methods. In 2012, NICEATM-ICCVAM released a test method evaluation report on the usefulness and limitations of the BG1Luc ER TA test method. ICCVAM recommended the use of the BG1Luc ER TA as a screening test to identify substances with in vitro ER agonist and antagonist activity and recommended that the BG1Luc ER TA test method could be considered as an alternative to the existing ER TA test guideline (EPA OCSP 890.1300/OECD TG 455). All 15 ICCVAM member agencies, including the US Environmental Protection Agency, concurred with the ICCVAM recommendations. NICEATM sponsored the new method for evaluation by the Organisation for Economic Co-operation and Development (OECD), which approved the BG1Luc test method and added the BG1 agonist protocol to the existing Test Guideline 455. The BG1 antagonist method has been adopted as OECD Test Guideline 457. Acceptance of the BG1Luc ER TA test method by U.S. and international agencies is an example of increased cooperation and collaboration to support the international adoption of scientifically valid test methods that will protect people, animals, and the environment while reducing, refining, and replacing animal use. Supported by ILS staff under NIEHS Contract N01-ES-35504.

## PS 1575 Quantitative Risk Assessment As the Basis for a Proposed NIOSH Recommended Exposure Limit for Hexavalent Chromium Compounds.

K. MacMahon, R. Park, F. Rice and K. Ashley. NIOSH, Cincinnati, OH. Sponsor: D. Dankovic.

To update the National Institute for Occupational Safety and Health (NIOSH) recommendations for protecting workers with occupational exposure to Cr(VI) compounds, all aspects of occupational exposure to and control of hexavalent

chromium compounds (Cr(VI); e.g., chromic acid, CAS No. 1333-82-0; sodium dichromate, CAS No. 7789-12-0) were evaluated including epidemiology, toxicology, risk assessment, analytical methods, and industrial hygiene practices. Derivation of a proposed Recommended Exposure Limit (REL) was one component of the updated risk management recommendations. The NIOSH proposed REL was derived based on the results of a quantitative risk assessment (QRA) of lung cancer in chromate production workers. The NIOSH REL was previously based on the quantitative limitation of the 1975 analytical method; at that time NIOSH recommended that occupational carcinogens be controlled to the lowest feasible concentration. Data from a cohort of Baltimore chromate production workers were selected for analysis due to the availability of extensive exposure assessment data, information about smoking histories, strong statistical power, and relative lack of confounding exposures. Excess lifetime risk at the REL of 1 µg Cr(VI)/m<sup>3</sup> was estimated as 6 (95% confidence limits=3-12) lung cancer deaths per 1000 workers. Based on these results, NIOSH proposed a REL of 0.2 µg Cr(VI)/m<sup>3</sup> 8-hour time-weighted average exposure during a 40-hour workweek. The proposed REL has an estimated working lifetime (45 years) excess risk of lung cancer mortality of approximately one in 1000. NIOSH, Occupational Safety and Health Administration, and international consensus standard analytical methods can accurately quantify workplace exposures at the proposed REL. Recommending the control of occupational Cr(VI) exposures to below the proposed REL is intended to reduce the incidence of work-related lung cancer.

### PS 1576 The Dermal Up-And-Down Procedure: An Alternative Test Method for Acute Dermal Systemic Toxicity Testing.

W. Stokes<sup>1</sup>, J. Strickland<sup>2</sup>, R. Morris<sup>3</sup>, L. Ho<sup>3</sup>, J. Wilkerson<sup>3</sup>, F. Stack<sup>2</sup>, M. Paris<sup>2</sup>, L. Rinckel<sup>2</sup> and W. Casey<sup>1</sup>. <sup>1</sup>NTP/NICEATM, NIEHS, Research Triangle Park, NC; <sup>2</sup>ILS, Inc., Research Triangle Park, NC; <sup>3</sup>SRA International, Research Triangle Park, NC.

Acute dermal systemic toxicity testing is required to identify chemicals and products that have the potential to cause life-threatening or fatal toxicity following skin exposures. Such testing is one of the five most commonly conducted safety tests and requires up to 20 or more animals per test. A dermal up-and-down procedure (UDP) was developed to estimate acute dermal toxicity hazard classification categories with fewer animals. The UDP incorporates an efficient experimental design using sequential testing to estimate LD50 rather than the simultaneous testing of multiple groups of animals at multiple doses, as specified by current regulatory test guidelines. In the dermal UDP, individual animals are dosed sequentially, and the response of each animal after 48 hours is used to determine the dose applied to the next animal. If a dose produces significant toxicity, the next animal is tested at a lower dose. Conversely, if no significant toxicity is observed, the next animal is tested at a higher dose, with the highest dose not to exceed a pre-specified limit dose. Unless there is a basis for a lower starting dose, the initial dermal UDP starting dose is the appropriate limit test dose (2000 or 5000 mg/kg). The default dose-progression factor for subsequent doses is 4.2. If the expected LD50 is less than the default starting dose, testing is started at one dose below the closest default dose. Using a starting dose of 5000 mg/kg, default doses are 5000, 1200, 300, 70, 15, and 4 mg/kg, while the default doses for a starting dose of 2000 mg/kg are 2000, 500, 100, 25, and 5 mg/kg. The dermal UDP provides LD50 point estimates and confidence limits for dermal hazard classifications while using up to 85% fewer animals. The proposed dermal UDP can support accurate hazard identification while significantly reducing animal use. Supported by ILS staff under NIEHS Contract N01-ES-35504 and SRA staff supported by NIEHS Contract GS-23F-9806H.

### PS 1577 Fatal Misuse of Humidifier Disinfectants in Korea: Importance of Screening Risk Assessment and Implications for Management of Chemicals in Consumer Products.

J. Lee<sup>1</sup>, J. Kwon<sup>2</sup> and Y. Kim<sup>3</sup>. <sup>1</sup>Institute of Environmental Safety and Protection, NeoEnBiz Co., Bucheon, Republic of Korea; <sup>2</sup>Department of Environmental Engineering, Ajou University, Suwon, Republic of Korea; <sup>3</sup>Korea Institute of Toxicology, Daejeon, Republic of Korea. Sponsor: K. Park.

The Korea Centers for Disease Control and Prevention (KCDC) reported on August 31, 2011 that the unidentified fatal lung disease found in Korea might have been caused by chemical disinfectants used with household humidifiers. Among them, four patients passed away because of the rapid development of pulmonary fibrosis after long exposure to the disinfectants over several months. A provisional conclusion by an epidemiological investigation that active ingredients of disinfecting products (polyhexamethyleneguanidine (PHMG) and oligo(2-(2-ethoxy)ethoxyethyl guanidinium chloride (PGH)) caused this disease was reinforced by a subsequent inhalation toxicological study using rats. In Korea, humidifier disinfectants have been put in the water tanks of humidifiers for the prevention of germs, mold, and/or algae. The disinfectants were manufactured and

sold on the market without any data on inhalation toxicity being submitted and without risk evaluation on an industrial or government level. We conducted a screening-level risk assessment for the disinfectants. With these high values of the risk quotients for PHMG and PGH containing the guanidine moiety, it should have been possible to screen the chemicals with potential health concerns before their introduction to the market. Precautionary measures such as "premarket registration and evaluation" and "significant new use notice and re-evaluation" need to be complemented by post-market control systems such as product recall and health surveillance systems to screen the health hazards of chemicals.

### PS 1578 Multiple Federal Hazard Assessment Programs—A Relevant Information or Redundant Efforts?

N. B. Beck<sup>1</sup>, B. A. Richard<sup>1</sup> and A. Twardowski<sup>2</sup>. <sup>1</sup>American Chemistry Council, Washington DC; <sup>2</sup>Concordia College, Moorhead, MN.

Much interest, at both the Executive and Legislative levels, is currently directed towards evaluating how to reform and streamline government to improve efficiencies and decrease costs. In Jan. 2010, President Obama, acknowledging challenging economic times, began an effort to decrease waste and inefficiencies in the government. Similarly, Public Law 111-139 (2010) required the Government Accountability Office to identify federal programs with duplicative goals and activities. Regarding the evaluation of hazards associated with environmental contaminants, there are at least three Federal programs that have seemingly overlapping, although not perfectly aligned goals. Our question was: Do these government programs provide novel information or are the efforts redundant? While the EPA Integrated Risk Information System (IRIS) evaluates risk information for chronic non-cancer and cancer effects, the Agency for Toxic Substances and Disease Registry (ATSDR), in its Toxicological Profiles, evaluates non-cancer effects at acute, sub-chronic and chronic exposures. The National Toxicology Program's Report on Carcinogens (RoC) provides cancer descriptors, as does the IRIS Program, although NTP does not develop quantitative risk values. The IRIS Reference Values and the ATSDR Chronic Minimal Risk Levels were examined. Additionally, the IRIS and NTP cancer classifications for substances were also reviewed. If the same substance was evaluated by two programs, we also compared the final Agency recommendations. Significant findings will be presented. For example, the analyses show that even though the IRIS program has evaluated over 550 chemicals there are only 85 chemicals with Reference Concentrations (RfC) and since 1995 EPA releases, on average, 3 new RfCs a year. Similarly, although ATSDR has evaluated over 170 chemicals, there are only 42 with chronic inhalation values and approximately half of these chemicals are the same ones EPA evaluated. The full analysis of results will help the agencies and stakeholders assess the value in supporting three separate programs.

### PS 1579 Utilization of Benzene Chromosomal Biomarkers by US Courts in Adjudicating Causation.

G. E. Marchant. College of Law, Arizona State University, Tempe, AZ.

This study evaluates the utilization of chromosomal biomarkers in court cases that involved benzene exposure, one of the first major set of cases to rely on biomarker data. The methodology involved searching the Westlaw database for all toxic tort cases involving plaintiffs allegedly injured by benzene exposure in which evidence of chromosomal aberrations was offered. The judicial decisions in these cases were evaluated to determine whether the judges properly understood and applied the scientific information on biomarkers, and to determine how useful the biomarker data was to the ultimate outcome of the case. A standardized multi-criteria analysis sheet was used to evaluate each case. A total of 17 U.S. court cases decided in the period from 1995 to 2012 that involved benzene chromosomal biomarker evidence were identified and evaluated in this study. The analysis identifies several problems in how judges and juries in these cases dealt with biomarker evidence, including: (i) some courts treat the evidence as deterministic rather than probabilistic, incorrectly concluding that biomarker evidence alone proves or disproves causation, or in other cases holding that the biomarker data is completely irrelevant and thus inadmissible; (ii) different courts treated the same biomarker evidence differently, resulting in inconsistent decisions; and (iii) individual judges made statements in specific cases indicating a poor understanding of biomarkers. Notwithstanding these limitations, the overall results of using chromosomal biomarker evidence in these toxic tort cases was beneficial, as the evidence was instrumental in helping to prove or disprove causation in appropriate cases. This analysis demonstrates that biomarker data can provide effective and useful evidence in toxic tort litigation, and are likely to be used increasingly frequently in such cases. At the same time, the problems identified in this analysis with handling of biomarker data by some courts provide important lessons for judges, attorneys, and scientific experts.

**PS 1580** **In Vitro Episkin Skin Corrosion As a Reference Test Method in OECD TG431 for the Assessment of Skin Corrosion in Subcategories 1A, 1B, and 1C.**

N. Alépée, M. H. Grandidier and J. Cotovio. *L'Oréal Research & Innovation, Aulnay sous Bois, France.* Sponsor: *E. Dufour.*

Skin corrosion or irritation refers to the production of irreversible or reversible damage to the skin following the application of a test substance, respectively. An effective way of predicting test substance toxicity is to make use of testing strategies which incorporate a range of alternative test methods. For the determination of skin irritation and corrosion, hazard assessments for both endpoints could be conducted using in vitro test methods that have been regulatory accepted (OECD TG431 & TG439). In the present study, skin irritation and corrosion evaluations were performed on Reconstructed human Epidermis (RhE) models i.e. EpiSkin and SkinEthic RHE. In the case of skin corrosion, GHS guidelines differentiate between non corrosive (NC) to corrosive (C) substances with 3 subcategories: 1A, 1B and 1C. The current evaluation of the test method was performed on 81 test substances from a wide range of chemical for each subcategory class (38 NC, 31 Cat1B/1C and 12 Cat1A) enlarging the evidence base associated with this method. Using the EpiSkin test method, within-laboratory variability (>87%) was assessed in 3 runs. Therefore a sensitivity of 98% and overall accuracy of 89% (with an accuracy of 1A, 1B/1C, NC of 79%) were obtained. The test method able to discriminate 1A, from 1B and 1C classes with the highest well -prediction rate for sub-categorize the substances in comparison with the others validated methods, was submitted to OECD for scientific review and adoption. Adoption of the EpiSkin seems sufficient to fill the gaps in terms of sub-categorisation predictions leading to a significant impact on the sub-group transport package labeling.

**S 1581** **Application of Systems Biology to Identify Molecular Mechanisms and Biomarkers of Lead (Pb) Neurotoxicity: Implications in a Developmental Origin of Alzheimer's Disease.**

*J. L. Freeman. Health Sciences, Purdue University, West Lafayette, IN.*

The heavy metal lead (Pb) can induce a wide-range of adverse health effects depending on dose and duration of exposure. During development the nervous system is most sensitive to Pb toxicity with epidemiological studies linking neurological deficits at and below the previous CDC blood Pb level of concern. Although the toxicity of Pb is extensively studied, the underlying genetic, epigenetic, and molecular mechanisms of Pb neurotoxicity are not completely understood. Moreover, recent studies link developmental Pb exposure with latent effects that do not appear until late in life, indicating a developmental origin of adult neurodegenerative disorders. More specifically, the latent overexpression of hallmark genes and proteins in Alzheimer's disease (AD) are reported in these studies. This session brings together a group of investigators that are actively applying systems biology (transcriptomics and epigenomics) and targeted approaches to define the mechanisms and identify biomarkers of both the developmental and late-life neurological alterations associated with a developmental Pb exposure in a variety of model systems and in human populations. Topics cover a study with the zebrafish model on the genetic mechanisms of developmental Pb neurotoxicity with an emphasis on transcriptomic alterations to a human comparative transcriptomic study in young adults aiming at establishing biomarkers between early-life Pb exposure and AD. The session also addresses the transcriptomic and epigenomic pathways of the developmental origin of Pb-induced neurodegenerative alterations with a specific focus on AD in rodent and primate models. Furthermore, the mechanism by which Pb increases the formation of amyloid  $\beta$  plaques in a transgenic mouse model is discussed. Overall, this session highlights the latest findings on the genetic, epigenetic, and molecular mechanisms of Pb neurotoxicity linking neurodevelopmental and later life impacts to further deduce the developmental origin of Pb-induced neurodegenerative disease with a specific focus on AD.

**S 1582** **Genetic Mechanisms of Developmental Lead Neurotoxicity and Links to Adult Neurodegenerative Disease Pathogenesis.**

*J. L. Freeman. Health Sciences, Purdue University, West Lafayette, IN.*

It is well established that lead (Pb) exposure is detrimental to neurological development, but the underlying mechanisms of Pb developmental neurotoxicity are not clearly elucidated. Furthermore recent evidence supports the hypothesis that a developmental Pb exposure results in later lifespan effects including pathological features characteristic of Alzheimer's disease (AD) proposing a developmental origin of Pb-induced adult neurological disease. The genetic and epigenetic mechanisms underlying and linking the immediate adverse effects of the developmental Pb exposure and the lasting impacts of the developmental exposure throughout the lifespan

are yet to be determined. In this study, global gene expression analysis using the zebrafish vertebrate model system demonstrated that developmental Pb exposure results in immediate altered expression of genes associated with axon guidance, neurogenesis, and neurodegeneration. Furthermore, gene expression alterations were correlated to functional changes in the form of altered protein levels and a delay in axonal growth. While being an established developmental model, characterization of the adult zebrafish is limited and is just beginning to be explored for application in neurodegenerative disease pathogenesis research. Studies utilizing zebrafish embryos show that many genes with direct roles in AD are highly conserved in terms of sequence and function supporting the application of the adult zebrafish brain as a model to investigate the role of a developmental Pb exposure in the pathogenesis of neurological disease. To further our understanding of these genes, protein sequence analysis and gene expression characterization was conducted. This study demonstrates that a strong degree of conservation occurs in regards to the presence and orientation of specific functional domains and in expression patterns. This study provides a framework for assessment of the influence of a developmental Pb exposure on late life neurological disease pathogenesis.

**S 1583** **Prenatal Lead Exposure and Biomarkers for Alzheimer's Disease in Humans.**

*M. Mazumdar<sup>1,2</sup>. <sup>1</sup>Environmental Health, Harvard School of Public Health, Boston, MA; <sup>2</sup>Neurology, Children's Hospital Boston, Boston, MA.* Sponsor: *J. Freeman.*

Animal studies suggest that early life lead (Pb) exposure influences gene expression and production of proteins associated with Alzheimer's disease (AD). This presentation will discuss recent studies in humans implicating early-life Pb exposure in the pathogenesis of AD. Aggregation of  $\beta$ -amyloid (A $\beta$ ) is a hallmark of AD pathology and plasma concentrations of A $\beta$  are biomarkers that potentially could predict the risk of AD prior to the clinical manifestation of dementia. To evaluate the association between early-life Pb exposure and AD risk, the mean plasma A $\beta$  concentration was measured in young adults and compared among those that had high umbilical cord blood Pb concentrations and those with lower cord blood Pb concentrations. Expression of genes whose products affect A $\beta$  production and deposition was evaluated and was inversely correlated with umbilical cord blood Pb concentrations. Gene network analysis suggested enrichment in gene sets involved in nerve growth and general cell development. These data suggest that prenatal Pb exposure may influence A $\beta$ -related biological pathways that are implicated in AD. Challenges in designing studies that investigate the contribution of early-life environmental exposures to adult disease will also be reviewed in this presentation.

**S 1584** **Do Epigenetic Pathways Initiate Late Onset Alzheimer's Disease (LOAD)?: Towards a New Paradigm.**

*N. H. Zawia. Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Cognitive decline and many of the hallmark pathological features of Alzheimer's disease (AD) such as amyloid plaques and tau tangles are present in normal aging individuals and pose a challenge for distinguishing AD from normal aging. The majority of AD cases occur in the elderly; however, it is still unresolved whether AD is a disease of old age or whether it has earlier beginnings. The development of early onset AD (EOAD) seems to be largely genetic; however, late-onset AD (LOAD) may be influenced by epigenetic factors acquired during early developmental stages. LOAD exhibits numerous non-Mendelian anomalies that suggest an epigenetic component in disease etiology. The sporadic nature of >90% of AD cases, the differential susceptibility and course of illness, as well as the late age onset of the disease suggest that epigenetic and environmental components play a role in the etiology of LOAD. In this presentation, the evidence derived from primates and rodents (genomic and epigenomic as well as biomarker-specific) that AD has a developmental origin and that early life exposure can reprogram gene expression in old age through epigenetic pathways rendering the brain more susceptible to neurodegenerative diseases will be provided.

**S 1585** **CNS Homeostasis of  $\beta$ -Amyloid, Plaque Formation, and Lead Toxicity.**

*W. Zheng. Health Sciences, Purdue University, West Lafayette, IN.*

The hallmark of Alzheimer's disease (AD) pathology is aggregation of  $\beta$ -amyloid (A $\beta$  or A $\beta$ ). Previous studies in this laboratory have established that the brain barrier systems are actively engaged in regulation of the homeostasis of A $\beta$  in

brain extracellular milieu (Crossgrove et al., *Exp Biol Med* 2005;230:771) and that lead (Pb) exposure can alter the property of the Abeta transport protein (LRP1) leading to abnormal accumulation of Abeta in brain tissues (Behl et al., *TAAP* 2009;240:245; *Neurotox* 2010;31:524). In the current study, we used transgenic PDAPP mice which over-express amyloid precursor protein (APP) and exhibit amyloid plaques in brain tissues to investigate if in vivo Pb exposure shortened the onset of amyloid plaque formation and increased the plaque aggregation. Our data show that in vivo Pb exposure resulted in an increased deposition of amyloid plaques in these transgenic mouse brains. Mechanistic investigation revealed that Pb reduced Abeta clearance from the central nervous system by inhibiting LRP1 at brain barriers. Pb also directly participated in physiochemical reaction with Abeta molecules in the test tube. Moreover, Pb increased the concentrations of other metals (i.e., Fe, Zn) in amyloid plaques in the mouse brain by synchrotron X-ray fluorescent (XRF) quantitation. Within the plaques, Pb concentrations were found to be significantly correlated with those of Fe and Zn. Our data support a role of Pb in the formation of amyloid plaques; how these findings may relate to human AD etiology deserves further investigation (Supported in part by NIH/NIEHS ES008146 and ES017055).

## **S 1586 Bone As a Target Tissue for Environmental Toxicants.**

J. Schlezinger, *Environmental Health, Boston University School of Public Health, Boston, MA.*

Bone brings to mind the strong, but light, organ that provides the skeleton for vertebrates. However, bone is more than just inert, osseous tissue. The bone marrow is a multifunctional organ that supports not only ongoing bone remodeling, but also provides the microenvironmental niche for hematopoiesis and regulates whole body energy homeostasis and as such, represents a significant target for environmental toxicants. Critical cell types in the bone marrow include multipotent mesenchymal stromal cells (MSCs) and hematopoietic stem cells (HSCs). MSCs are the source of both adipocytes and osteoblasts. HSCs are the source of all blood cell lineages and the bone-resorbing osteoclasts. The interaction between osteoblasts and osteoclasts creates a balance of bone formation and resorption, which is essential for maintenance of bone quality. There also is essential crosstalk between the mesenchymal and hematopoietic compartments that supports lifelong blood cell generation. Lymphocyte development, in particular, requires stromal cell support/interaction. Understanding how environmental toxicants disturb the interplay of bone marrow compartments requires attention given the rapidly aging population who are already at risk for loss of bone quality and immune suppression. We will explore new data suggesting that bone is responsive to many environmental toxicants, which may perturb the delicate balance between bone marrow cell types. A series of presentations will define interactions within both the mesenchymal and hematopoietic compartments and how exposure to toxicants may impact bone biology. Presentations will move from a broad, multispecies analysis of the effects of persistent organic pollutants on bone to more focused analyses of effects of ethanol and metals (lead, organotin, and tungsten) on bone and the bone marrow microenvironment.

## **S 1587 Bone Tissue As a Target for POPs Acting As EDCs (an Overview from Wild Animals to Humans).**

M. Lind, *Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden.*

Since World War II, there has been an increase in age-standardized incidence rates of osteoporotic bone fractures in industrialized countries, with the Nordic countries taking the lead. The reason for this increase is unknown but the idea that exposure to endocrine-disrupting chemicals (EDCs) could be involved has been put forward. The consequences of environmental contaminant-induced bone toxicity is evident across many species. Exposure to persistent organic pollutants (POPs) acting as EDCs, has been shown to negatively affect the bone tissue (e.g. leads to an osteoporotic phenotype) in laboratory models (monkeys, rats, mice, frogs, goat, sheep, bone cells), as well as wild-life (polar bears, seals, alligators and herring gulls). Important signaling pathways such as the estrogen receptor and aryl hydrocarbon receptor pathways have been suggested to contribute to the observed effects. Importantly, epidemiological studies on humans also support this hypothesis since they show a relationship between exposure to endocrine disrupting POPs and decreased bone mineral density or increased risk of bone fractures. The literature on this topic is, however, rather small and prospective studies on in utero or early EDC exposure and future osteoporotic bone fractures do not exist. The mechanisms behind the deleterious effects of EDCs on bone tissue also need to be a focus of study.

## **S 1588 Lead Exposure and Skeletal Dysregulation: A Molecular Mechanism of Toxicity That Contributes to Osteoporosis and Other Bone Diseases.**

J. Puzas and E. Beier, *Center for Musculoskeletal Research, University of Rochester, Rochester, NY.*

**Rationale and Scope:** Lead exposure and osteoporosis represent two of the most widespread health issues affecting humans. Our recent investigations provide evidence that these entities are linked. We have also identified a molecular mechanism by which lead can adversely affect bone forming cells.

**Experimental Procedures:** We used a small animal rodent model as well as isolated cell experiments to evaluate the effect of lead exposure. The animals were treated with lead in their drinking water. The cell studies were performed in culture media with added lead acetate. All treatments achieved lead levels relevant to human exposures. Bone mass parameters were measured with micro CT analysis, histology and Raman infrared spectrometry. Cell effects and signaling pathways in osteoblasts were measured with molecular methods for mRNA and protein.

**Results:** Our findings indicate that lead exposure induces an osteoporotic-like phenotype in the animal model. Bone volume, bone formation rates, bone quality and bone cell number were all significantly depressed in the treated animals. Lead also induced a strong adipogenic response in the marrow space. Data from exposure of cells to lead indicate that all parameters of osteoblastic bone formation were also markedly inhibited. Immunohistochemical assays as well as a molecular analysis of in vitro cell signaling pathways indicate that the effect of lead is, at least partially, due to a strong depression of the TGFbeta and Wnt pathways. The mechanism for this depression appears to be related to an up regulation of the bone formation inhibitor, sclerostin.

## **S 1589 Role of NADPH Oxidases and Reactive Oxygen Species in Regulation of Bone Turnover and the Skeletal Toxicity of Alcohol.**

M. Ronis<sup>1,2</sup>, K. Mercer<sup>1</sup>, L. Suva<sup>2</sup>, T. M. Badger<sup>1,2</sup> and J. Chen<sup>1,2</sup>. <sup>1</sup>*Arkansas Children's Nutrition Center, Little Rock, AR;* <sup>2</sup>*University of Arkansas for Medical Sciences, Little Rock, AR.*

Recent studies with genetically modified mice and dietary antioxidants have suggested an important role for superoxide derived from NADPH oxidase (NOX) enzymes and other reactive oxygen species (ROS) such as hydrogen peroxide in regulation of normal bone turnover during development and also in the responses of the skeleton to toxicants such as ethanol (EtOH) which generate excess ROS in bone tissue. We have shown that EtOH causes bone loss as a result of NOX generated ROS, reduced bone formation via impaired Wnt-β catenin signaling and increased RANKL-dependent osteoclastogenesis. Buffering of anti-oxidant capacity through administration of the glutathione precursor N-acetylcysteine, completely prevented EtOH-induced loss of bone mineral density, inhibiting both suppression of bone formation and increases in bone resorption. There was no apparent bone phenotype associated with genotype at age 3 mo., in mice lacking the NOX co-factor p47<sup>phox</sup> and thus with impaired capacity to generate excess superoxide in response to EtOH. However, these mice were only protected from alcohol-stimulated increases in bone resorption. This was accompanied by inhibition of EtOH-associated increases in osteoclastogenesis and induction of RANKL. In mice where hydrogen peroxide concentration in bone is reduced as a result of transgenic expression of catalase, whereas 6 wk old mice had increased trabecular bone, 3 mo. old mice had reduced trabecular bone and impaired osteoblastogenesis compared to wild type mice and were unprotected against ethanol actions. These data suggest that ROS signaling involving hydrogen peroxide is important in regulation of adult bone formation but that excess production of superoxide via NOX as a result of exposure to toxicants such as EtOH can stimulate RANKL-dependent increases in bone resorption. Supported in part by R01 AA018282 (M.J.R.).

## **S 1590 Organotins: Unique Modulators of Bone Quality and the Bone Marrow Microenvironment.**

J. Schlezinger<sup>1</sup>, A. Baker<sup>2</sup> and L. Gerstenfeld<sup>3</sup>. <sup>1</sup>*Environmental Health, Boston University School of Public Health, Boston, MA;* <sup>2</sup>*Medicine, Boston University School of Medicine, Boston, MA;* <sup>3</sup>*Orthopaedic Surgery, Boston University School of Medicine, Boston, MA.*

Bone marrow multipotent mesenchymal stromal cells (BM-MSC) are critical for osteogenesis, as well as for creating the supportive niche for lymphopoiesis. PPARγ is a central mediator of BM-MSC differentiation, traditionally thought to promote adipogenesis while suppressing osteogenesis. A growing number of environmental contaminants (e.g. phthalates, organotins) have been shown to activate PPARγ and increase adipogenesis, and thus recently have been termed environmental obesogens. Organotins are unique in their ability to bind and activate both PPARγ and

RXR, opening the possibility that they may activate multiple permissive nuclear receptor pathways. We investigated the hypothesis that tributyltin (TBT) is a potent modifier of BM-MSC differentiation and thus a negative regulator of bone quality and lymphopoiesis. *In vivo* TBT exposure results in decreased cortical bone and increased marrow adiposity without significantly altering bone resorption. B cell populations are altered in both the bone marrow and the spleen of TBT-treated mice. In primary BM-MSC cultures, TBT potently induces adipogenesis and suppresses osteogenesis. Surprisingly, female-derived BM-MSCs are significantly more sensitive to TBT-mediated suppressive effects than male-derived cells. In addition to activating a PPAR $\gamma$ -mediated gene expression pathway (FABP4 and adiponin) and suppressing a Runx2-mediated pathway (osterix and osteocalcin), TBT activates the LXR *in vivo* and *in vitro*, another nuclear receptor that contributes to bone homeostasis. Finally, TBT completely suppresses the development of hematopoietic cells in culture. Given its potency and ubiquitous environmental presence, TBT presents a risk to bone health and may accelerate the accumulation of adipocytes and loss of lymphopoiesis that occurs during aging.

## **S** 1591 **Tungsten: Effects on Bone Marrow and Lymphocyte Development.**

K. K. Mann. *Oncology, McGill University, Montréal, QC, Canada.*

Very little is known about the toxicity of tungsten. Recently, increased environmental tungsten levels were found near sites of pediatric leukemia clusters. These leukemia cases were predominantly of the preB lymphocyte subtype of acute lymphocytic leukemia. While no data link tungsten exposure to leukemogenesis, tungsten is known to accumulate within the bone, the site of B cell development. This important hematopoietic compartment is likely the site where leukemogenic events occur. We have explored the effects of tungsten exposure on developing B lymphocytes using *in vitro* and *in vivo* models. *In vitro*, B lymphocytes are more sensitive to tungsten-induced DNA damage and growth inhibition than the supporting mesenchymal stromal cells. In wild-type mice, we have shown that tungsten concentrations rapidly increase in the bone and reach a plateau after approximately 4 weeks of exposure. Removal of tungsten results in a slow release of tungsten from the bone with a much slower "off" rate. In addition, we see alterations in bone mineral content and density following tungsten exposure. Tungsten exposure alters B lymphopoiesis, increases DNA damage within the bone marrow B cells, and increases preB-colony forming units. Any of these could provide a leukemogenic hit, and thus, tungsten could act as a tumor promoter. Although we did not observe development of leukemia in wild-type mice, current data in pre-leukemic mouse models, as well as murine breast cancer models, will be discussed.

## **S** 1592 **Nonmonotonic Dose-Response Curves and Endocrine-Disrupting Chemicals: Fact or Falderal?**

L. E. Gray<sup>1</sup> and P. M. Foster<sup>2</sup>. <sup>1</sup>RTB, US EPA, Research Triangle Park, NC; <sup>2</sup>NTP, NIEHS, Research Triangle Park, NC.

"All substances are poisons. It's the dose that makes the poison," (Paracelsus, 1493–1541) is a fundamental tenet in toxicology: the severity of a response to a toxicant increases proportionally to the dose. Furthermore, it is generally assumed that dose-response curves for noncancer effects display a threshold below which there is no effect. Currently these assumptions are being challenged by claims that endocrine-disrupting chemicals (EDCs) often display U-shaped or inverted U-shaped nonmonotonic dose-response curves (NMDRCs) at low, environmentally-relevant exposure levels; levels below traditional NOAELs ("Current Chemical Testing Missing Low-Dosage Effects of Endocrine-Disrupting Chemicals" Endocrinology Society, 2012). In addition, the US EPA's Endocrine Disruptor Screening program (EDC program) has been severely criticized, sometimes unfairly. This symposium will review the state of the science on EDCs concerning the shape of the dose-response curve in the low-dose range and the prevalence of NMDRCs. Talks will initially discuss mechanisms of action, the biological plausibility for NMDRCs, and then focus on chemicals that disrupt the estrogen and androgen signaling pathways and the prevalence of *in vitro* and *in vivo* NMDRCs. Presentations will also discuss the shape of the dose-response curves from "case studies" of estrogenic chemicals. These "case studies" are robust, multigenerational studies conducted in a government laboratory using a protocol that had been "enhanced" to include several estrogen-sensitive endpoints in addition to the standard endpoints. Finally, we will discuss how some governmental agencies are addressing the NMDRC-low dose issue and views on how this might impact the risk assessment of EDCs and other chemicals. Changing how EDCs are tested to accommodate NMDRCs would significantly increase the resources need for testing as it would require the addition of several "low" dose groups and if NMDRCs are prevalent, then this would significantly impact several of the default assumptions used in risk assessment, including noncancer health effects displaying a threshold, and that adverse effects do not occur below the NOAELs.

## **S** 1593 **Molecular Pharmacology of Steroid Hormone Action: Nonmonotonic Dose-Responses.**

W. R. Kelce. *Nonclinical Development, Novan Therapeutics, Durham, NC.*

The basic biology of steroid hormone (SH) synthesis and action is reviewed to provide a molecular pharmacology basis for typical monotonic and nonmonotonic dose-response observations. Examples illustrate the molecular pharmacology basis for observed *in vitro* and *in vivo* effects. As the level of biological organization increases (from cell-free binding to transcription to *in vivo* adverse effects), the opportunity for complex nonmonotonic dose-responses emerge. Full strong receptor agonists and antagonists *in vitro* provide the highest level of predictability whereas weak agonists and antagonists are affected by ambient ligand levels. Agonist or antagonist activity can be passive (competition for receptor binding and subsequent direct receptor activation or inactivation) or active (influenced by co-activator and/or co-repressor preference and/or availability which can be cell type and tissue specific). *In vitro* cytotoxicity, cofactor squelching and substance metabolism can confound data interpretation. SH ligands can also have rapid nongenomic effects leading to receptor/co-regulator phosphorylation and nonmonotonic responses. Similar to SH receptors, inhibition of rate limiting steroidogenic enzymes (delivery of cholesterol to the inner mitochondrial membrane and P45017 $\alpha$ ) are more predictive than enzymes whose activity can be reduced by 95% or more without altering the rate of SH production. The intact animal leads to an even higher order of biological complexity where interactions with the hypothalamic-pituitary-gonadal axis can logically lead to nonmonotonic dose responses. Exogenously administered androgens and the maintenance of spermatogenesis will be used as an example. Low levels of testosterone have little effect, physiological levels reduce GnRH and LH production leading to reduced intratesticular levels of testosterone and the consequent inhibition of spermatogenesis and supraphysiological levels restore intratesticular testosterone and maintain spermatogenesis. Discussion of the molecular pharmacology of SH action will provide the mechanistic basis for examples discussed by the other speakers.

## **S** 1594 **Mechanistic Requirements for Nonmonotonic Dose-Response.**

R. B. Conolly<sup>1</sup>, L. E. Gray<sup>1</sup> and G. T. Ankley<sup>2</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>US EPA, Duluth, MN.

Conolly and Lutz (Toxicol. Sci. 77, 151-157, 2004) noted that "Dose-response curves for the first interaction of a chemical with a biochemical target molecule are usually monotonic; i.e., they increase or decrease over the entire dose range." Nonmonotonic dose response (NMDR) thus reflects more complex behaviors. Examples of such complexity include the regulation of cAMP levels in the striatum of the rat brain by the combined action of adenosine A1 and A2 receptors, dimerization of ligand-bound steroid hormone receptors prior to the promotion of gene expression, and induction of DNA repair in response to a DNA damaging xenobiotic, where the repair activity acts on previously formed endogenous adducts and on exogenous adducts due to the xenobiotic. Computational models will be used to illustrate how these relatively simple systems can give rise to NMDR. Interestingly, for each example, the models show that quantitative adjustments of key parameters allow for transitions from nonmonotonicity to monotonicity, with an intermediate, threshold-like behavior. The models that will be described are supported to varying degrees by relevant data. Full consideration of the ecotoxicological and human health significance of NMDR will require, among other things, understanding of the extent to which (1) the frequency with which NMDR occur is a function of the level of biological organization involved, (2) the nonmonotonic behaviors are wholly or partially aspects normal homeostatic regulation and, (3) the dose ranges over which NMDR occur in the laboratory are relevant to actual exposures in the real world. This work was reviewed by the U.S. EPA and approved for publication but does not necessarily reflect Agency policy.

## **S** 1595 **Nonmonotonic Dose-Response Curves (NMDRCs) Are Common after Estrogen or Androgen Signaling Pathway Disruption—Fact or Falderal?**

L. E. Gray. *Reproductive Toxicology Branch, NHEERL, US EPA, Research Triangle Park, NC.*

The shape of the dose response curve in the low dose region has been debated since the 1940s, originally focusing on linear no threshold (LNT) versus threshold responses for cancer and noncancer effects. Recently, it has been claimed that endocrine disruptors (EDCs), which act via high affinity, low capacity receptors, commonly induce adverse effects displaying NMDRCs at low doses. Effects that would be missed in standard EDC screening and multigenerational testing protocols.

Case studies of chemicals that disrupt reproductive development and function via the androgen and estrogen signaling pathways were reviewed, including in vitro and in vivo multigenerational studies for LNT, threshold and NMDRCs responses. In vivo studies selected included comprehensive, robust, well designed studies that administered the chemical via a relevant route of exposure over a broad dose response range, including low doses. The chemicals include ethinyl estradiol, estradiol, genistein, bisphenol A, trenbolone, finasteride, flutamide, phthalate esters, selective estrogen receptor modulators and inhibitors of aromatase.

Current conclusions are: 1) EDCs appear to induce some LNT effects. 2) NMDRCs are biologically plausible and occur frequently in vitro, but the points of inflection occur at high concentrations that are not relevant in vivo. 3) NMDRCs appear to be more common a) in short- versus long-term exposures and b) with upstream, mechanistic events vs. downstream phenotypic effects. 4) A few adverse effects of EDCs are non-monotonic, but other effects in these studies displayed monotonic responses at lower dose levels. 5) A number of robust multigenerational studies of estrogens and antiandrogens showed NMDRCs were uncommon at low dose levels. 6) Multigenerational Test guidelines can be enhanced on a case-by-case basis to improve the sensitivity to low dose effects of some EDCs. 7) Additional data needs to be examined from robust, multigenerational studies using a broad range of dosage levels for other toxicity pathways. This abstract does not reflect USEPA policy

## **S 1596 Comprehensive Studies Addressing Critical Questions in the Dose-Response Assessment of Endocrine-Active Compounds.**

K. Delclos, D. R. Doerge, S. M. Lewis, M. M. Vanlandingham and L. Camacho. *NCTR, US FDA, Jefferson, AR.*

It has been strenuously argued that standard guideline-compliant screening and testing protocols used to assess reproductive and developmental toxicants are inadequate to detect endocrine-active agents due to unique characteristics of the dose response. In particular, it has been proposed that potentially adverse effects may be missed by not including low doses that are closer to exposures in the general human population. Over the past decade, our laboratory has been conducting studies, including both multigenerational and chronic exposures, in Sprague Dawley rats that attempted to address this and other issues (e.g., long term cross generational effects). Articles tested include the potent estrogen ethinyl estradiol (EE<sub>2</sub>), the soy isoflavone genistein, *p*-nonylphenol, and the weak and ubiquitous estrogen bisphenol A. In addition to covering a range of doses within or close to human exposure ranges, these studies covered a broad range of endpoints and, importantly, included measures of internal doses. Knowledge of the serum levels of the test article and its metabolites allows better understanding of the relationship between the method and window of exposure and the observed effects. Clear effects on estrogen-sensitive endpoints were observed, but were largely confined to the high end of the dose range and there was no evidence for unique effects at low doses. Genistein induced estrogenic effects at an internal dose range achievable in humans. In the case of EE<sub>2</sub>, there appeared to be opposite effects on the age of vaginal opening, a marker of puberty, due to low (acceleration) or high (delay) neonatal doses. These studies were largely focused on endpoints that are typically considered as indicative of adverse effects for risk assessments. However, questions of whether molecular or other non-standard endpoints are altered at lower doses or with a different dose response are also being explored with the goal of evaluating whether such endpoints can enhance safety assessments of endocrine-active agents. Support: NIEHS/FDA IAG # 224-12-0003(FDA)/AES12013(NIEHS).

## **S 1597 Low Dose and Nonmonotonic Dose-Response Curves for Endocrine Disruptors.**

L. S. Birnbaum. *NIEHS, Research Triangle Park, NC.*

The incidence of conditions such as diabetes, obesity, asthma, neurodevelopmental, and reproductive problems has increased substantially in the past 20 years. The human genome has not changed in that period of time, which leads to the hypothesis that the environment is likely the cause of much of this increase. The endocrine system is a highly organized system of glands and hormones that regulates vital functions such as growth, response to stress, sexual development and behavior, production and utilization of insulin, metabolism, intelligence and behavior, and the ability to reproduce. This system can be perturbed by environmental chemicals that were designed for one effect but have been shown to interfere with endocrine signaling.

To date, there are over 800 identified endocrine disrupting chemicals (EDCs) and they are found in many everyday products. Recent evidence shows that the mechanisms by which EDCs, as well as endogenous hormones, act are much more intricate than originally recognized.

One aspect of endocrine disruptors is their ability to cause effects at low doses. Just as tiny amounts of hormones can have large effects on physiological systems, tiny amounts of chemicals that mimic hormones can have similar large effects. A feature related to low dose effects is the non-monotonic dose-response behavior of EDCs. In the past, basic toxicology focused on the simple dichotomy of toxic versus nontoxic, which implies that all substances can be harmful at high doses while at some lower dose, no harm is done. However, we now know that EDCs can create physiologically relevant effects at low doses, and these effects can have a substantial impact on our health. These effects may be beneficial at certain doses and deleterious at others. This modern understanding of non-monotonic effects is critical to understanding the behavior of chemical agents and also how resulting health effects may differ based on various exposures.

## **S 1598 Understanding Toxicities of Abnormal Lipid Metabolism: Alcoholic, Nonalcoholic, and Toxicant-Induced Fatty Liver Disease.**

M. S. Mitra<sup>1</sup> and M. You<sup>2</sup>. <sup>1</sup>*Drug Safety Evaluations, Bristol-Myers Squibb, Mt. Vernon, IN;* <sup>2</sup>*Department of Molecular Pharmacology and Physiology, University of South Florida, Tampa, FL.*

Accumulation of excess neutral lipids in the liver, referred to as fatty liver disease (FLD), is a major metabolic disorder and risk factor for development of hepatotoxicity. It is a progressive disease that initially manifests as reversible fatty liver, which upon infliction of inflammation advances to a nonreversible steatohepatitis, and finally leading to hepatic cirrhosis. FLD is generally categorized on the basis of its etiology, the two main types being alcohol-induced steatohepatitis (ASH) and obesity-induced (nonalcoholic steatohepatitis, NASH). Another class of FLD, drug/toxicant-induced FLD (TASH), is a major cause of pharmaceutical candidate attrition. The underlying pathogenic mechanisms of hepatic lipid accumulation and their implications are not completely understood. In this symposium, recent advances in the pathogenic role of microRNAs in the development of FLD will be introduced. The molecular mechanisms by which fatty liver promotes liver injury will be discussed using examples of drug overdose, hepatic ischemia-reperfusion, and obstructive cholestasis. Further, the implications of excess hepatic lipid accumulation in regards to altered drug metabolism and cellular uptake will be presented. The symposium will end with a comparative analysis of novel clinical biomarkers of ASH, NASH, and TASH. Students, as well as toxicologists working in academia, federal, and pharmaceutical industries interested in animal models, pathogenic mechanisms, biomarkers, and drug metabolism and toxicity of ASH, NASH, and TASH will benefit from this symposium.

## **S 1599 Symposium Introduction—Pathogenesis of Hepatic Fat Accumulation.**

M. S. Mitra. *Drug Safety Evaluations, Bristol-Myers Squibb, Mt. Vernon, IN.*

The introductory talk will focus on presenting a high level overview of FLD by providing background information on its pathogenesis. This will include presentation of epidemiology of FLD and the mechanisms of development of FLD that includes two stage model of development and progression of fatty liver to steatohepatitis to cirrhosis. Further, the molecular mechanisms of pathogenesis of FLD in regards to hepatic lipid uptake and esterification, de novo lipogenesis, fatty acid oxidation, and export of VLDL-triglyceride will be presented. The presentation will also include pathology of FLD and review the current scoring systems. The presentation will also describe the available biomarkers for diagnosis and monitoring FLD.

## **S 1600 miR-217-SIRT1 Signaling and Alcoholic Fatty Liver Disease.**

M. You. *Department of Molecular Pharmacology and Physiology, University of South Florida, Tampa, FL.* Sponsor: M. Mitra.

Alcohol-mediated inhibition of hepatic sirtuin 1 (SIRT1) plays a central role in the pathogenesis of alcoholic fatty liver disease. Our group has investigated the underlying molecular mechanisms of this inhibition by identifying a new hepatic target of alcohol, microRNA-217 (miR-217). We have found that, in cultured hepatocytes and in mouse livers, chronic alcohol administration dramatically and specifically induced miR-217 levels and caused excess fat accumulation. Our studies have further revealed that overexpression of miR-217 in hepatocytes promoted ethanol-mediated impairments of SIRT1 signaling. More importantly, miR-217 impairs lipin-1, a vital lipid regulator, in hepatocytes. Taken together, our novel findings suggest that miR-217 is a specific target of alcohol in the liver and may present as a potential therapeutic target for treating human alcoholic fatty liver disease. This presentation will discuss the results and implications of these novel findings in the pathogenesis of alcoholic fatty liver disease.

**S 1601 Enhanced Susceptibility of Fatty Livers to Drug Hepatotoxicity and Innate Immune Responses.**

H. Jaeschke. *Department of Pharmacology, Toxicology & Therapeutics, The University of Kansas Medical Center, Kansas City, KS.*

Steatosis is a risk factor for enhanced liver injury during drug hepatotoxicity and sterile inflammation. However, the mechanisms of this aggravated liver damage can vary dependent on the degree of steatosis and the pathophysiology. Steatosis can trigger microcirculatory disturbances, mitochondrial dysfunction and cause inflammation, which are important contributing factors for the increased susceptibility to liver cell death. The molecular mechanisms by which fatty liver promotes liver injury in genetic versus diet-induced steatosis models will be discussed in detail using examples of drug overdose (acetaminophen), hepatic ischemia-reperfusion and obstructive cholestasis.

**S 1602 Increased Risk of Drug Toxicity due to Altered Pharmacokinetics in Nonalcoholic Steatohepatitis.**

N. J. Cherrington. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Many severe adverse drug reactions occur when a patient is unable to metabolize and eliminate the standard dose of a drug due to alterations in drug metabolizing enzymes or transporters. Sources for this inter-individual variability include genetic polymorphisms or environmental factors such as inflammatory diseases that directly or indirectly alter the function of the enzymes and transporters that determine the pharmacokinetics of the drug. This presentation will discuss obesity-related and other possible sources of inter-individual variation in the transcriptional regulation, post-translational modification, and sub-cellular localization of specific drug metabolizing enzymes and transporters, thereby altering the pharmacokinetics and toxicity of drugs in patients that are at greater risk of adverse drug reactions

**S 1603 Biomarkers and Mechanisms for Steatohepatitis.**

C. McClain. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Steatohepatitis may be caused by toxicants (TASH), obesity (NASH), or alcohol (ASH) among other causes. Mechanistic similarities and differences appear to exist between different types of steatohepatitis. We compared serum adipocytokines, cytokerin 18 (CK18), and antioxidants in human subjects with ASH, NASH, and TASH. All forms of steatohepatitis were associated with reduced serum antioxidants and insulin resistance (although adipokine levels differed by etiology). ASH and TASH were characterized by higher levels of pro-inflammatory cytokines. Likewise, ASH and TASH were associated with increased hepatocellular necrosis:apoptosis ratios compared with NASH which had a similar ratio to healthy controls. Lastly, complementary studies in mice showed major interactions between diet (high fat) and environmental toxins. This presentation will describe these findings and highlight the similarities and differences of novel clinical biomarkers of TASH, NASH, and ASH.

**W 1604 "Air"-ing on the Side of Caution: Anticipating Impacts of Emerging Issues in the Health Effects of Air Pollution.**

A. K. Farraj. *EPHD, NHEERL, US EPA, Durham, NC.*

Dramatic reductions in air pollution over the last three decades have largely been driven by the enactment of federal regulations (e.g., the Clean Air Act in the United States). Today, policymakers and air quality managers rely on cutting-edge science to reduce and control air pollution. Toxicology is at the fore-front of this effort providing critical input on health effects of air pollution including dose-dependence, the role of constituents and size, mode of action, and relative toxicity of air pollution sources. Despite these advances, serious adverse health effects including cardiopulmonary mortality are still measurable at ambient air levels to which millions of people are currently exposed. Risk assessment of these air sheds is likely to get further complicated in light of the uncertainty posed by several emerging issues that intersect air quality and health. Climate change is one such issue that may affect health via direct effects of weather (i.e., heat and precipitation) and indirectly through increasing concentrations in ground-level ozone and particulate matter, two key air pollutants linked to adverse health effects. The burgeoning increase in obesity and associated metabolic disorders, groups with exaggerated sensitivity to the adverse effects of air pollution, is likely to aggravate health outcomes. With the implementation of new fuel standards and increasing popularity of alternative fuels, it is unclear what impact these changes may have on health effects of traffic-related emissions. Finally, several methods of power generation, including modern coal

technology, nuclear energy, and hydrofracking have recently captured public interest, yet their impacts on air quality are unknown. This workshop discusses the current state of the science including key toxicological findings and recent innovations as well as challenges in the study of these emerging issues. The workshop concludes with a prospective look at air pollution research with a discussion session that engages the audience in an effort to define data gaps and potential mitigation strategies.

**W 1605 Health Impacts from Climate Change through Atmospheric Systems: Recent Findings and Challenges.**

M. Bell. *Environmental Health, Yale University, New Haven, CT* Sponsor: [A. Farraj](#).

Climate change is anticipated to exacerbate many existing human health burdens such as through an increase in the duration and intensity of heat waves and through accelerated formation of tropospheric ozone. However, many questions on the nature of these impacts remain. This presentation discusses case studies of research on how atmospheric systems (air pollution, weather) could be impacted by climate change, thereby affecting human health, and will explore the challenges of this type of research. The case studies involve linking air quality, meteorological, and climate modeling to estimate the health consequences from changes in ozone levels in 50 U.S. cities and the mortality impacts from changes in heat waves in Chicago, Illinois, U.S. Challenges and assumptions of approaches to estimate health impacts from a changing climate include uncertainty in the various modeling systems (e.g., air quality models, climate change models), the use of current day relationships for weather or pollution and health for future scenarios, the changing distribution of susceptible subpopulations (e.g., elderly), and adaptive measures (e.g., air conditioning).

**W 1606 Environmental Factors and Cardiometabolic Disease: Signals in the Air.**

S. Rajagopalan. *Cardiovascular Medicine, Ohio State University, Columbus, OH.* Sponsor: [A. Farraj](#).

Cardiometabolic diseases represent a pandemic, with the World Health Organization (WHO) projecting that more than 2.3 billion people will be overweight/obese by 2015. Technology innovations, globalization with its free movement of food and services, seismic shifts in agrarian practices coupled with rural-urban migration, nutritional transition to freely available high-caloric diets have irrevocably altered energy expenditures during work and leisure. These and other factors are helping to foster the continued "epidemiological transition" occurring across the globe. Scientific effort over the last few decades has focused on components of urbanization such as inactivity and dietary factors. More recent observations provide additional links between chronic exposure to environmental factors in air/water and propensity to diseases. This issue is of importance given the extraordinary confluence of high levels of airborne and water pollutants in urbanized environments. Multiple studies in China, India and other rapidly urbanizing economies demonstrate a steep gradient in urban-rural prevalence. This presentation summarizes recent evidence on how air pollution may represent an under-appreciated yet critical linkage between urbanization and the emergence of cardiometabolic diseases, with a focus on diabetes mellitus.

**W 1607 Implications of New Fuel Standards and Alternative Fuels on Traffic Emissions: Insight from the Chemistry and Health Effects of Soy Biodiesel Emissions.**

M. S. Hazari. *Environmental Public Health Division, US EPA, Research Triangle Park, NC.*

The environmental impacts of combustion-derived vehicular emissions are well-established. In an effort to reduce greenhouse gas (GHG) emissions, improve fuel economy, and expand the nation's renewable fuel sector, new standards detailing the minimum volume of renewable fuel, which includes cellulosic biofuel, biomass-based diesel, advanced biofuel and total renewable fuel, contained in transportation fuel sold in the United States were recently proposed. Although it is assumed that these alternative energy sources will provide a "greener" fuel option, it is still largely unknown how their combustion emissions will impact human health, particularly when combined with traditional sources such as gasoline or diesel. Each biofuel has a unique chemical makeup, which will impact emissions characteristics and potential toxicity. Thus, this presentation highlights the new 2012 standards for renewable fuel, addresses the complexity of emissions arising from the combustion of various biofuel types, and examines the potential human health implications of incorporating biofuels into the transportation fuel sold in the U.S. For this last point, many of the health effects of vehicular air pollution in the last 10 years have

focused on particulate matter (PM). Recent studies suggest that certain biodiesel blends contain less PM and may be less toxic. Hence, a recent soy biodiesel study is discussed with respect to chemical composition and component analysis, and toxicological effects, including cardiovascular, pulmonary and carcinogenic endpoints, in several rodent models.

**W 1608 Fracking, Coal, and Nuclear Energy: Impacts of Contemporary Methods of Power Generation on Air Quality and Remediation Efforts.**

J. D. McDonald. *Toxicology, Lovelace Respiratory Institute, Albuquerque, NM.*

The complexity of the world's power production needs requires that a number of approaches be used to generate and distribute power. Natural gas, coal, nuclear, and other sources are all in play. Each of these energy sources are subject of intense regulation targeted at mitigating potential air and other contamination, recently including mitigation of carbon dioxide. The increase in demand for natural gas has led to new methods for harvesting and obtaining it, including the controversial techniques such as fracking. Carbon capture and sequestration offers a number of engineering challenges, and methods for capturing include potential approaches that may initiate additional environmental concerns. Of course nuclear energy, especially considering the recent events in Fukushima, has its own environmental concerns. This presentation focuses on emerging considerations related to the impact of power generation on air quality. The emphasis will be on coal emissions (modern vs traditional), carbon capture and sequestration (CCS), and natural gas (including fracking). Some mention of nuclear concerns will be considered. The presentation includes recent toxicology data on the health effects of inhaled amines and their degradation products used in CCS, and data on emissions from coal after they are atmospherically transformed in the environment and on air contaminants associated with fracking.

**W 1609 Predicting the Future: Getting Ahead of Problems—A Presentation and Discussion.**

D. L. Costa. *Office of Research & Development, US EPA, Research Triangle Park, NC.*

Despite dramatic reductions in air pollution since 1970, the impact of pollutants on health and the environment remains a concern to both regulators and the general public. Studies have not been able to show thresholds of effect for prominent "criteria" pollutants like particulate matter (PM) and ozone (O<sub>3</sub>) and much uncertainty remains with air toxic air pollutants that vary across sources. Millions of people are exposed to the criteria pollutants, but there are subpopulations which are at risk due to unusual exposure circumstances or underlying biologic susceptibility or increasing age. Science continues to chip away at these concerns through human population studies, and human and animal toxicological studies. But as we look to the future with increasing national demand for energy and global population and industrial growth, there is increasing pressure on resources and the atmospheric reservoir for pollutants. Climate change with its impacts on air pollution chemistry as well as regional weather is widely thought to be undermining the gains we've seen in reducing the national air pollution burden through challenging environmental complexities. New technologies, fuels, and ambient pollutant profiles require systematic assessments and innovative tools if we are to dissect these many interrelated issues to ensure optimal strategies to protect human and environmental health. This presentation attempts to draw on what we know and speculate on what we need to know from our science to forecast both emerging issues and solutions—preferably preventative—that have been discussed in this workshop. The audience will be engaged to embellish and enhance this discourse.

**W 1610 Breaking the Routine: Is There Room for Modern Techniques of Neuropathology Assessment in Routine Preclinical Safety Studies?**

C. D. Toscano<sup>1</sup> and J. P. O'Callaghan<sup>2</sup>. <sup>1</sup>FDA/CDER/OND/DNP, Silver Spring, MD; <sup>2</sup>CDC/NIOSH/Neurotoxicology Laboratory, Morgantown, WV.

Neurotoxicity in routine preclinical safety studies is traditionally assessed with three H&E-stained brain sections; an approach that is not optimal, considering the brain's complex neuroanatomy. The need to increase the sensitivity of this approach is supported by the finding that routine neuropathology assessments would fail to detect MPTP, ethanol and carbonyl sulfide induced-CNS lesions. Increasing the number of brain sections sampled and inclusion of additional histology stains have been recommended but there is no expert consensus on the feasibility of incorporating modern methods of assessment into routine preclinical safety studies. We will explore and comment on the adequacy of the traditional approach to neuropathology assessment in routine preclinical safety studies. We will also examine

the current regulatory guidance on neurotoxicity assessment in routine preclinical safety studies and discuss the feasibility of changing the current approach. Examples of emerging methods, such as MRI-directed histology and detection of circulating biomarkers of CNS damage, along with strategies for incorporating these techniques into standard preclinical safety studies will also be discussed. Finally, we will attempt to build consensus on appropriate approaches for improving the sensitivity of neurotoxicity assessment in routine preclinical safety studies by fostering a discussion between the audience and panel members. This discussion will focus on the feasibility of employing the proposed new markers, endpoints, and approaches and potential issues with interpretation of results of these studies. In conclusion, we believe that by examining the adequacy of current approaches of neuropathology assessment, discussing possible improvements to regulatory guidance and presenting emerging approaches of neurotoxicity assessment that this workshop will allow for a much needed dialogue on the need and feasibility of improving the current methods of neuropathology assessment in routine preclinical safety studies.

**W 1611 Routine Neuropathology Analysis for Nonclinical General Toxicology Studies.**

B. Bolon. *Veterinary Biosciences, Ohio State University, Columbus, OH.*

Microscopic neuropathological evaluation in Good Laboratory Practice (GLP)-type nonclinical general toxicology studies is one component of a battery of assays performed to assess potential nervous system toxicity of new chemical entities. Strategies for neuropathological assessment in such studies vary by species and among different industries and regulatory bodies. A Society of Toxicologic Pathology (STP) Working Group has recommended the following neuropathological strategy as suitable for all GLP-type nonclinical general toxicology studies. Selected brain areas should be examined routinely: caudate / putamen; cerebellum; cerebral cortex; hippocampus; hypothalamus; medulla oblongata; midbrain; olfactory bulb (in rodents only); pons; and thalamus. In rodents, these regions can be assessed in 6-7 full coronal sections on 2 standard-size slides; in non-rodents, they may be evaluated unilaterally in 6-7 standard slides each bearing 1 coronal hemisection. Spinal cord (cervical, thoracic, and lumbar regions) and peripheral nerve (sciatic and/or tibial) should be viewed in longitudinal / oblique and transverse sections. Current neurohistology practices—immersion fixation in 10% formalin, embedding in paraffin, and initial analysis only of H&E-stained sections—is acceptable for nonclinical general toxicology studies. These recommendations slightly expand current practice (i.e., analysis of 3-4 transverse brain sections in rodents) to improve sampling consistency using available technology. These recommendations affirm the importance of consistent routine neuropathological evaluation in GLP-type nonclinical general toxicology studies while acknowledging that histopathology is only one component of neural safety testing in such studies. Therefore, institutions should retain flexibility in devising the neuropathology portion of GLP-type nonclinical general toxicology studies as long as major nervous system regions are evaluated systematically.

**W 1612 A Regulatory Perspective on the Current State of Neuropathological Assessments in Drug Development.**

R. Mellon. *FDA/CDER/OND/DAAAP, Silver Spring, MD.* Sponsor: C. Toscano.

Neurotoxicological assessment of drug products is currently accomplished in preclinical studies by evaluation of central nervous system (CNS) safety pharmacology studies and general toxicology studies, which include simple behavioral observations and histopathological evaluation of the brain. Histopathological assessments in routine toxicology studies have identified adverse findings not detected by behavioral observation and therefore generate critical safety data. The scientific community has raised concern that histopathology in routine toxicology studies lacks adequate granularity for such a complex organ as the brain and therefore may not be appropriate for initial evaluations nor do they adequately identify when detailed "second tier" neurotoxicology studies are necessary. For example, the standard sampling and staining approach used in general toxicology studies may not be sufficient to detect certain CNS lesions (e.g. "Olney" lesions associated with NMDA receptor antagonists). Adopting an expanded sampling routine, such as the recently proposed Society of Toxicologic Pathology recommendations for the sampling and assessment of the brain in routine safety into Tier 1 testing, would increase the sensitivity of these studies. As there is currently no official CDER guidance on the assessment of the neurotoxicity of drug candidates, many approaches have been taken to addressing and reviewing the neurotoxicity of drug candidates; examples of these approaches and the level of success of such approaches will be provided. A regulatory perspective of the limitations of the current standard approach and feasibility of including modern methods of neuropathology assessment will be discussed. Overall, incorporation of modern methods of neuropathology assessment and improving the documentation of procedures used into the final study reports would provide greater confidence in the quality of the assessment. Such changes have the

potential to impact the safety assessment of a drug candidate prior to first-in-human clinical studies, throughout drug development and as part of post-market-ing safety assessments.

## **W** 1613 Utilization of MRI Imaging to Optimize the Selection of Brain Sections for Assessment by Classical Neurohistopathology.

J. P. Hanig<sup>1</sup>, M. G. Paule<sup>2</sup>, J. Ramu<sup>2</sup>, L. Schmued<sup>2</sup> and S. Liachenko<sup>2</sup>. <sup>1</sup>OTR, FDA/CDER, Silver Spring, MD; <sup>2</sup>Neurotoxicology, NCTR/FDA, Little Rock, AR.

Sampling of 3 coronal brain sections for morphological assessment in routine pre-clinical toxicology studies is clearly insufficient to reliably characterize all potential neuropathologies that may be caused by new drug candidates. It has been estimated that 60 coronal sections would be required to adequately insure that this can be accomplished. This is never done in routine safety studies. Using a panel of classical neurotoxins, including kainic acid, trimethyltin, domoic acid and nitropropionic acid that target different brain areas and structures and that exhibit effects varying from the massive to the subtle, a method has been developed for using MRI imaging to complement routine preclinical toxicology studies by allowing for a focused targeting and selection of candidate sections for histology in the rat. Proof of concept involves in-vivo MRI scanning to create files that can be compared and registered with coronal sections of the same brain sample after it has been fixed and stained appropriately for traditional neuropathology. Validation involves the establishment of concordance between the loci of pathological manifestation in each of these imaging approaches. Issues of comparability with respect to sensitivity, temporal equivalence of damage detection and whether MRI signals always predict morphological damage will be discussed. Successive in vivo MRI scans also allow subjects to be used as their own controls and for establishing time of onset, development and repair of morphologic damage. The MRI information may be used to optimize time of sacrifice for maximal visualization of traditional neurohistopathology. Most importantly, this method, when qualified, could provide guidance on where in the brain 3 "smart" sections should be taken for classical neuropathology in support of preclinical drug safety studies. Overall, we show that low resolution MRI imaging in the intact rat, may represent a powerful biomarker that can inform classical neurohistopathology assessment, but is not a substitute for it.

## **W** 1614 Translational Safety Biomarker Assessment of Neurotoxicity.

A. Jeromin. *NextGen Sciences DX, Boston, MA.* Sponsor: *C. Toscano.*

Neurotoxic effects of drugs pose a significant hurdle in the drug development process. Traditionally, neurotoxicity is assessed pre-clinically by classical histopathology, which has limited translational value for clinical development. Recent advances in imaging, functional assessment and the identification of fluid-based biomarkers of neurotoxicity might allow for the nomination of novel translational safety in neurotoxicity. Ideally, fluid based biomarkers of neurotoxicity detected in either CSF or blood could be combined with histopathology, high-resolution structural MRI and PET imaging, and other methods to assess neurotoxicity. We have assessed protein-based biomarkers of necrosis and apoptosis in addition to glial fibrillary acid protein (GFAP), ubiquitin C-terminal hydrolase L1 (UCH-L1), a biomarker of cell body injury and member of the ubiquitin proteasome system, myelin basic protein (MBP), a demyelination marker, and microtubule-associated protein (MAP-2), a biomarker of dendritic injury, in pilot studies with known neurotoxins, including kainate. We developed and employed sensitive and qualified ELISAs to assess this panel of biomarkers. In addition, this data will be supplemented by existing multiplexed solutions for cytokines to incorporate inflammatory components in addition to these brain injury biomarkers. Along with the ELISAs, we have developed and applied multiple-reaction monitoring (MRM)-based panels of brain biomarkers. These MRM-type assays have shown significant improvement in sensitivity and allow for the multiplexed assessment of hundreds of proteins for targeted discovery with a follow-up verification studies on validated assays. These multiplexed biomarker panels comprise markers of different pathways, ranging from inflammation to synaptic changes and have proven to be useful in identifying neurotoxicity.

## **W** 1615 Drug Safety Assessment and Regulatory Landscape in Emerging Markets.

P. Mu<sup>1</sup> and G. Krishna<sup>2</sup>. <sup>1</sup>TeamedOn LLC, Rockville, MD; <sup>2</sup>Supernus Pharmaceuticals, Inc., Rockville, MD.

With 85% of world's population and rapid economic growth, the emerging market countries are up and coming, and are now actively courted by large global pharmaceutical industries. Within the next decade, Asia is expected to overtake Europe in

pharmaceutical sales. For example, China is predicted to be the second largest pharmaceutical market after the United States by 2015 (Nature Reviews Drug Discovery, 2010). Many large pharmaceutical companies have increased their presence in emerging markets for research and discovery, and are seeking to market their products locally. Due to the short history of innovative pharmaceutical research and development, many of the emerging countries have limited experience of first hand review of new drugs applications, hence rely mostly on the review decisions taken elsewhere to grant the approval in local markets. However, regulatory agencies of the emerging countries are working diligently to catch up with the international standards and in the process establishing the regulations that address their country specific needs to promote innovation and bring drugs that are appropriately tested to demonstrate safety for their own population. The establishment and expansion of regulatory agencies functions is creating local job opportunities for people with specialized skills, to help with the review of various components of the new drug applications while at the same time presenting challenges never experienced before due to the nature of innovation. This has sometimes led to regulations that are not well defined and open to interpretation. The drug safety assessment and regulatory landscape in China, India, Korea, and Brazil will be introduced during the presentations. The similarity and difference of the regulatory environment in the emerging countries will be compared with the major ICH guidelines. The challenges and possible solutions for companies seeking regulatory approval in emerging markets will be discussed. This will also provide an open forum for regulators from emerging markets to exchange ideas on how to tackle unique situation they experience.

## **W** 1616 Framing the Workshop Theme.

S. Goel. *Supernus Pharmaceuticals, Inc., Rockville, MD.*

Countries in emerging markets are gaining increased focus regarding research and development activities and regulatory filings to market drugs due to an increase in consumer demand and rapid growth of their economies. To this end, it is essential to understand the progress and the intricacies in the regulatory filings among emerging markets. The speakers of this workshop will address several common questions on regulatory filing in their respective countries, including 1) The overall structure of the regulatory agencies and divisions under which various classes of drugs applications are submitted for reviews, 2) Comparison of various milestones in regulatory review process, preIND meeting, IND, SPA, end of Phase 2 meeting, and NDA, 3) Discovery and nonclinical safety studies required to support various stages of drug development and general comparison with ICH guidelines, 4) Requirements for country of origin of data, 5) Expertise and composition of non-clinical reviewers, 6) State of GLP compliance in contract research organizations within their countries, 7) Language used in regulatory submissions, 8) Regulatory outcomes and issue resolution.

## **W** 1617 Current Status of Preclinical Safety Assessment of Drugs in China.

J. Jiang. *State FDA (SFDA), Beijing, China.* Sponsor: *P. Mu.*

In China, Ministry of Health had regulated new drug registration and evaluation from 1949 to 1998. Starting from 1998, State Food and Drug Administration (SFDA) took over this function. There are three laws in China regulating the drug evaluation and registration process. In addition, SFDA has published 17 technical guidance for safety assessment of chemical drugs or biologics and 12 for traditional Chinese herbal medicines. Currently, in China chemical drugs or biologics are divided into 6 different registration categories. They are (1) investigational drug never marketed in any country, including synthesis or semi-synthesis; natural sources or by fermentation; optical isomer; new combination of products, (2) drug with changed administration route, not marketed both domestically and internationally, (3) drug marketed outside of China, but not in Chinese market, (4) raw materials and formulations of drugs with changed acid or alkaline radicals or metallic elements, but no changes of pharmacology, (5) drug with changed dosing form, but not administration route, and (6) raw materials and formulations of drugs fitting in Chinese national standard. Moreover, there are 11 registration categories for traditional Chinese herbal medicines. Preclinical safety assessments vary according to the registration categories of new drugs. During early development, investigator develops strategies to determine safety of investigational drug according to the registration category. In 2003, SFDA officially issued the "Good Laboratory Practice (GLP) for Non-clinical Laboratory Studies" and required all preclinical safety assessments of drug to be conducted in GLP accredited labs. China has developed its own unique drug evaluation system, which ensures safe and effective drug products for patients.

## **W** 1618 Regulations and Developments in Safety Assessment of New Drugs in India.

Y. K. Gupta. *All India Institute of Medical Sciences, New Delhi, India.* Sponsor: G. Krishna.

India is emerging as a major center for research and development of new chemical entities for therapeutic use. The Drug and Cosmetic Rules, 1945 and all its amendments set the foundation for manufacture and sale of drugs. The "Schedule Y" of the above rule specifies the studies that must be done in animals to establish safety and efficacy of new drugs prior to trials in humans. However, until recently India has been a center for manufacture of generic drugs. The Government of India Ministry of Health and Family Welfare established the Office of Central Drugs Standard Control Organization (CDSCO) headed by the Drugs Controller General (India) [DCG(I)] to regulate drug development. The current and up to date information on CDSCO can be found at <http://www.cdscn.in>. In March 2011, the DCG(I) formed 12 New Drug Advisory Committee (NDAC) based on broad categorization of use of drugs on various systems in the body, such as Reproductive & Urology, Cardiovascular & Renal, Ophthalmology, Vaccines, Dermatology and Allergy, etc. The NDAC's consists of expert members to advise on the matters of review and regulatory approval of clinical trials & new drugs. The charter for NDACs specifies that the drugs under development should consider relevance to population, innovation, and un-met medical need in India. India is unique in that it officially recognizes the development and marketing of traditional medicines (Ayurvedic, Siddha, and Unani drugs) for therapeutic use. India also prohibits certain drugs for manufacture and sale that it considers detrimental to its populations health. In India, the regulatory compliance of non-clinical studies is monitored by National Good Laboratory Practices (GLP) Compliance Monitoring Authority in Department of Science and Technology of Government of India. The Indian GLPs are based on the OECD guidelines due to initial close working relation between OECD countries in audit and GLP certification of Indian CROs.

## **W** 1619 Safety Assessment and Regulatory Landscape in Korea.

S. Han<sup>1</sup> and I. J. Yu<sup>2</sup>. <sup>1</sup>Korea FDA, Osong, Republic of Korea; <sup>2</sup>Hoseo University, Asan, Republic of Korea.

Korea is another major emerging center for research and development of new pharmaceuticals. The 2011 Pharmaceutical Affairs law had changed the regulations for manufacture, application, review, and approval of drugs. Korea Food and Drug Administration (KFDA), similar to US FDA, is a sole regulatory agency governing manufacture, application, review, approval, and surveillance of drugs. Within KFDA, the Pharmaceutical Safety Bureau with the Drug Evaluation Department is responsible for establishment of safety control system for drugs, promotion/support of the pharmaceutical industry, establishment of standards for the production of drugs and quality management, approval screening for drugs, and collection and evaluation of information on the side effects of drugs. Biopharmaceutical & Herbal Medicine Bureau and Medical Device Safety Bureau have similar roles in the relevant areas. As the research and development institute under KFDA, NIFDS (National Institute of Food and Drug Safety Evaluation) has played the key role in comprehensive research that is necessary for food and drugs regulation in Korea. It has been instrumental in the development and evaluation of toxicological and pharmaceutical methods. Center for Drug Development Assistance in KFDA supports for new drug R&D and regulatory affairs. The nonclinical safety studies at various stages of development are required according to ICH guidelines. Korean GLPs are based on the OECD GLP principles as a member country of OECD and Korean CROs have been frequently monitored jointly by three GLP authorities: KFDA, Rural Development Administration (RDA), and National Institute of Environmental Research (NIER).

## **W** 1620 Regulatory Developments in Brazil to Address Market Needs.

D. Barbano. *Brazilian Health Surveillance Agency (ANVISA), Brasilia, Brazil.* Sponsor: S. Goel.

In Brazil, for registration purposes, the medicines are classified in different categories, such as synthetics, biologics, phytotherapeutics. Synthetic medicines are classified as new, generic and similar. Each category of medicine is regulated by specific resolution, and its registration is granted for five years. The registration must be renewed by resubmitted the drug for evaluation at the end of each five year period. The registration of biological products is regulated by ANVISA since 2002. Due to the recent expiration of several patents for innovative biotechnology products, the interest in the production and sale of copies of these products is growing in Brazil. The regulatory framework for registration of biological products, (including new molecules or copies), was established in Brazil in December 2010 with the

publication of RDC No. 55/2010. For development of this technical regulation, the regulatory frameworks and guidance's of different agencies in the world were considered, including Health Canada (Canada), European Medicines Agency (EMA, Europe), CECMED (Cuba), and WHO Similar Biotherapeutic Products (SBP) guidelines. New Biological Products must be registered by the classic and regular manner, with the presentation of complete dossier, containing all the production, quality, non-clinical and clinical data. The non-innovative biological products can be registered with reduced information. ANVISA is actively developing new resolutions to fill old regulatory gaps to support development of biological products. The regulatory developments at ANVISA in relation to emerging needs of Brazil will be presented.

## **W** 1621 Workshop Summarization and Question and Answer Session.

G. Krishna. *Supernus Pharmaceuticals, Inc., Rockville, MD.*

Drug safety assessment around the globe is evolving. With the introduction of International Conference on Harmonization (ICH) guidelines, most emerging regions are trying to learn and adapt to the new expectations and processes. Drug industry scientists and the regulatory agencies are coming together and working diligently in the hopes of making a difference in the "waiting" patient. To this end, the workshop on Drug Safety Assessment and Regulatory Landscape in Emerging Markets is expected to answer multiple questions on the dynamics of evolving science, regulations, and processes based on the experiences from the more established markets/regions versus the individual interpretation and application of guidelines in the emerging markets. The Question and Answer session would provide an opportunity to deliberate current thinking on the subject and summarize the thoughts.

## **PL** 1622 Cell-Level Model of Morphogenetic Tissue Fusion for Computational Toxicology.

M. Hutson<sup>1</sup> and T. B. Knudsen<sup>2</sup>. <sup>1</sup>Physics & Astronomy, Vanderbilt University, Nashville, TN; <sup>2</sup>NCCT, EPA, Research Triangle Park, NC.

Vertebrate development is replete with instances of tissue fusion in which two tissues – each with its own complement of mesenchymal and epithelial cells – meet, adhere and eventually fuse into a seamless mesenchyme and epithelium. Such fusion is critical for proper morphogenesis of multiple organs, with failure implicated in several developmental defects: cleft lip/palate; closure defects of the neural tube; omphalocele (body wall); coloboma (optic cup); and hypospadias (urethra). Some of these defects are context-dependent – e.g., instances of cleft palate caused by failure of the palatal shelves to elevate, or hypospadias concomitant with impaired growth of the genital tubercle. Nonetheless, there is mounting evidence for fusion-specific defects (e.g., Pallister-Killian syndrome and VACTERL association). Furthermore, a predictive model built from ToxCast Phase-I data and ToxRefDB mapped cleft palate to Gene Ontology terms for diverse biological processes (balanced accuracies of 0.66-0.76): negative regulation of epithelial cell proliferation; epithelial-mesenchymal transitions (EMT); TGFβ2 production and type-II TGFβ receptor binding; and neural crest migration. We have thus constructed a cell-level computational model of tissue fusion that incorporates cellular adhesion and viscoplasticity with paracrine/juxtacrine control of proliferation, apoptosis, EMT and cell migration. The model includes three growing tissues – only two of which normally fuse – to explicitly model failures of both fusion competence and specificity. As a first demonstration, we model secondary palate fusion by tuning the relative contributions of apoptosis, EMT and cell migration to match dissolution of the midline epithelial seam. This flexible model is a platform for computational toxicology that can elucidate the varying interplay of such cell behaviors in the normal course of different tissue fusion events and their role in differential susceptibility to chemical disruption. [This work does not reflect EPA policy].

## **PL** 1623 Investigating Adverse Outcome Pathway Models for Mitochondrial Toxicity.

M. L. Patel, S. Canipa and D. Portinari. *Lhasa Limited, Leeds, United Kingdom.* Sponsor: C. Marchant.

Adverse Outcomes Pathways (AOPs) are used to describe the steps of a chemical interacting with a biological system from the subcellular to population level of observation. We investigated the published literature to develop qualitative AOPs for oxidative phosphorylation by mitochondria. Literature searches were carried out to identify chemicals and potential mechanisms of inhibition for each of the complexes of the electron transport chain (ETC) and for ATP synthase. Compounds for which sufficient experimental data could be located were then used to build plausible mechanistic pathway maps.

A dataset of over 200 compounds covering experimental data in a number of relevant screens (measuring individual complex activity, cellular ATP levels, reactive oxygen species (ROS) generation, oxygen consumption, mitochondrial membrane potential and cytotoxicity) was constructed. Seven model compounds were identified as having sufficient data and plausible mechanistic evidence to construct AOPs. The compounds used were: Rotenone, Thenoyltrifluoroacetone, 3-Nitropropionic acid, Antimycin A, Myothiazol, and Cyanide for mapping the ETC pathway, and Oligomycin A for ATP synthase. Using these representative model compounds an AOP was mapped for each complex from the molecular initiating event (MIE) to effects at the cellular level. The AOPs for inhibition of complexes of the ETC were then combined to create a single pathway.

We report the construction of AOPs for oxidative phosphorylation in mitochondria and their speculative extrapolation to in vivo endpoints such as cardiotoxicity, neurotoxicity and hepatotoxicity. The AOP maps are described in terms of the normal physiological pathway processes and potential intervention points, with reference to experimental in vitro assays which were used to support the elucidated steps. Not all compounds with mitochondrial effects may go on to display in vivo toxicology. An AOP view of such pathways is an useful construct in providing information in a form suitable for assessing outcomes relevant to risk assessment.

**PL 1624 Interactive Data Mining of Toxicogenomics and In Vivo Toxicity Databases Using Chemotypes to Improve Chemical-Disease Prediction Inferences and Mode-of-Action QSAR Models.**

A. Mostrag-Szlichtyng<sup>1</sup>, C. Yang<sup>1</sup>, J. Rathman<sup>1,2</sup>, C. Mattingly<sup>3</sup>, A. Davis<sup>3</sup>, A. Planchart<sup>3</sup> and A. M. Richard<sup>4</sup>. <sup>1</sup>Altamira, LLC, Columbus, OH; <sup>2</sup>The Ohio State University, Columbus, OH; <sup>3</sup>North Carolina State University, Raleigh, NC; <sup>4</sup>US EPA, Research Triangle Park, NC.

The Comparative Toxicogenomics Database (CTD, <http://ctdbase.org>) aims to shed light on the connection between chemical exposures and human health outcomes by inferring relationships via integration of curated chemical-gene, gene-disease and chemical-disease data from the scientific literature. Independent of CTD, structural knowledge via chemotypes, features linking chemicals to phenotypes, has been developed based on in vivo studies from toxicity databases, including regulatory sources at the US EPA and the US FDA. A chemotype is defined as a chemical substructure annotated with atom/bond properties that carry biological activity information. We explored whether the chemical-disease links in CTD could contribute to the further development of chemotypes, and whether mode-of-action Quantitative Structure Activity Relationship (QSAR) models for toxicity endpoints built around chemotypes could be used to validate CTD disease inferences or further delineate phenotypic effects. We applied a set of previously developed MOA models and chemotypes, e.g., for cleft palate, to the data found in CTD. Many of the same chemotypes (representing attributes of glucocorticoids, retinoids, conazoles, dioxanes, and phthalic esters) were found to be associated with cleft palate in CTD, either by direct curation or inferred via common interacting genes. The structural feature space enriched with cleft palate chemotypes was highly populated by the chemicals deemed associated with this condition in CTD. This work demonstrated how interactive data mining between CTD and in vivo toxicity databases with chemotype probes can improve the predictive power of gene-disease and chemical-disease associations, as well as the MOA models; also described is how these associations can be tested experimentally. This abstract does not reflect EPA policy.

**PL 1625 Cheminformatics Analysis of Compound-Cytochrome P450 Interaction Profiles.**

D. Fourches<sup>1</sup>, M. Elias<sup>2</sup>, E. Muratov<sup>1</sup>, L. Sheppard<sup>3</sup>, P. Bradley<sup>3</sup>, J. Reed<sup>3</sup> and A. Tropsha<sup>1</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>The Hebrew University of Jerusalem, Jerusalem, Israel; <sup>3</sup>Instem Scientific, Cambridge, United Kingdom. Sponsor: L. Rusyn.

Only five isoforms (1A2, 2C9, 2C19, 2D6, and 3A4) of Cytochrome P450 (CYP) enzymes are responsible for the metabolism of the vast majority of drugs. Beyond knowing what drugs are metabolized by a specific isoform and the subsequent metabolites, it is of critical importance to evaluate the CYP inhibition potency of a compound for predicting its most likely CYP-related adverse effects. In this study, our objective was to integrate, analyze, and model the growing compendium of publicly-available CYP-related datasets for these five isoforms using cheminformatics approaches: INSTEM (4,676 compounds) was obtained as assertional meta-data generated from MEDLINE abstracts; SUPERCYP (678 compounds) extracted from the online webportal; NCGC (16,142 compounds) is a compilation of qHTS screening results released by the NIH Center for Translational

Technologies. After chemical curation and duplicates' analysis, we have analyzed these datasets using cheminformatics approaches and addressed questions pertaining to: (i) the chemical concordance between the different isoforms illustrating the singularity of 1A2 and the tight 2C9:2C19 coupling, (ii) the identification of compounds being simultaneously potent and selective for a particular CYP isoform; compounds with selective CYP profiles found in the INSTEM database were experimentally confirmed in the NCGC screening, and (iii) the detection of erroneous database entries by performing neighborhood analysis using chemical similarity calculations. We have aimed to achieve and test robust predictors of CYP interaction profiles by building Quantitative Structure-Activity Relationships (QSAR) models for each isoform. To further benchmark our QSAR models (solely based on two-dimensional structures of chemicals), we docked our integrated CYP database into the CYP binding pockets using their crystal structures. We show how QSAR models and docking approaches can be used in synergy to predict CYP interaction profiles of drug candidates.

**PL 1626 Mechanistic Analysis of Welding Aerosol Toxicity Using Ingenuity Pathway Analysis (IPA).**

S. Tugendreich<sup>1</sup>, N. Ng<sup>1</sup>, P. C. Zeidler-Erdely<sup>2</sup>, J. M. Antonini<sup>2</sup>, M. L. Kashon<sup>2</sup> and A. Erdely<sup>2</sup>. <sup>1</sup>Ingenuity Systems, Redwood City, CA; <sup>2</sup>NIOSH, Morgantown, WV.

Welding involves occupational exposure to an aerosol containing gases and metal-rich particulates that induce adverse physiological effects including inflammation, immunosuppression, and cardiovascular dysfunction. To develop a deeper mechanistic understanding of these adverse effects, mice were exposed by inhalation to gas metal arc-stainless steel (GMA-SS) welding fume at 40 mg/m<sup>3</sup> for 3 hr/d for 5 d a week for 2 weeks followed by gene expression analysis of whole blood cells, aorta, and lung at 4 hr and 28 d post-exposure. New features in Ingenuity Pathway Analysis (IPA) were used to analyze the expression data. The analysis results establish the importance of interferons and the IRF-family of transcription factors, predicting that they are activated at 4 hours and maintained through 28 days in both blood and lung. The IPA Upstream Regulator Analysis also predicted involvement of several toxicants, such as nickel and ozone, which have been detected in welding aerosol thereby highlighting the utility of Upstream Regulator Analysis for toxicogenomics applications. In addition, as an important drug discovery tool, IPA predicted several compounds that might be useful to ameliorate the inflammatory phenotype. One such compound was LY294002, a PI3K inhibitor that has already been shown to be efficacious in a mouse model of asthma. The new Mechanistic Network Analysis in IPA was used to computationally construct a plausible hypothesis that TRIM24 inactivation may lead to activation of IRF7 and STAT1 and other upstream regulators to drive the gene expression profile after the first exposure. Finally, Downstream Effects Analysis in IPA predicted large increases in proliferation, chemotaxis, and trafficking of immune cells in the lung after 4 hours. In summary, IPA has a unique new set of capabilities to enhance the mechanistic understanding of toxicological datasets and to provide support for new hypotheses that can be tested in the lab.

**PL 1627 Insights into the TBX2 Role in Cellular Senescence in COPD: A Bayesian Structure Learning Approach.**

U. Tran and G. Acquaaah-Mensah. Massachusetts College of Pharmacy and Health Sciences, Worcester, MA.

COPD ranks among the top leading causes of death worldwide. The transcriptional factor T box 2 (TBX2) plays an important role in the COPD molecular etiology. A senescence hypothesis for the etiology of COPD has emerged. TBX2 and related genes have anti-senescence activity. Their expressions are suppressed in COPD, but elevated in many cancers. The purpose of this study was to identify the directionality of regulatory relationships between TBX2 and other genes involved in cellular senescence. From a compendium of lung epithelium cell microarrays generated using the Robust Multi-Array Average procedure, a subset of genes of interest was used for structure learning. The Bayesian Network Structure Learning approach was then used to learn the regulatory relationships. The Bayesian Network Inference with Java Objects toolkit (Banjo) was used, in each instance, to generate the single best-scoring direct acyclic network, given the gene expression data. In order to focus the large search space, an initial network of genes that TBX2 interacts with including ANF, NKX2-5, NDRG1, CDKN1A, PML, E2F, CDKN2A, and CDKN2B was identified. Simulated Annealing and Greedy Search were the network search algorithms used. The results predicted that TBX2 regulates both COL4A3 and PML. Reports in the literature confirm that TBX2 interacts with both COL4A3 and PML. Subsequently, the original known network was updated with these two interactions, and a new iteration of the learning procedure initiated.

As part of this new iteration, the compendium subset with expression data of genes of interest was updated to include senescence related genes. The results identified new TBX2 interaction partners including WNT3, WNT6, WNT7B, WNT11, IL12RB1, IL13, IL13RA1, IL27RA, CTNND1, E2F4, and FOXO3. The published literature, a functional map scoring relationships based on microarrays from over 15000 publications (HEFaLMP), as well as entries in a cis-regulatory elements database (cREMag) were utilized to validate the results. Thus, the results affirm the importance of TBX2 in the COPD etiology.

## PL 1628 Prediction of Metabolites Using Computational Approaches.

M. Kansy<sup>1</sup>, L. T. Anger<sup>1</sup>, U. Gundert-Remy<sup>2</sup> and A. Brigo<sup>1</sup>. <sup>1</sup>Non-Clinical Safety, F. Hoffmann-La Roche Ltd., Basel, Switzerland; <sup>2</sup>Institute of Clinical Pharmacology and Toxicology, Charité University Medical School Berlin, Berlin, Germany.

An increasing number of computational tools are nowadays available, which are claimed to predict drug metabolism. Those tools could most probably be used in an extended way to consider potential drug metabolites earlier in toxicity prediction of for example genotoxicity or carcinogenicity. Therefore it's important to understand the quality and limitations of metabolism prediction tools if applied in a broader context. However, to date, the software packages used in metabolism prediction have only been validated with relative small datasets containing limited number of compounds. Hence, they require a more comprehensive and explorative evaluation. Aim: Meteor (Lhasa Ltd., Leeds, UK), an available prediction tool, has been used to predict the metabolites of 325 drugs in therapeutic use. The results of the prediction were compared to the known human metabolites.

Methods: The WHO ATC index was used to extract drugs for the therapeutic classes of anti-infectives (A07E, M01A, S01BA, G02CC, M02AA, S01BC), central nervous system drugs and muscle relaxants (N, M03), cardiovascular drugs (C), oncologic substances (L01) and virostatics (J05, D06BB, S01AD). Additional information was received by queries in the DrugBank database. PharmaPendium and DrugBank were the sources to obtain information on the human metabolites of the therapeutic drugs observed in clinical studies.

Meteor (version 13.0.0, Lhasa Ltd.) is a so called knowledge-based expert system. As such it uses structured expert knowledge and its output offers the structures of metabolites with a guess on the probability of the occurrence of the metabolite.

The evaluation shows that the reliability of the prediction of human metabolites is presently limited. Hence, further development is necessary to improve the prediction potential.

## PL 1629 Comparison of Microarray and RNA-Seq for Gene Expression Analyses of Dose-Response Experiments.

M. B. Black<sup>1</sup>, E. Healy<sup>1</sup>, B. B. Parks<sup>1</sup>, L. Pluta<sup>1</sup>, T. Chu<sup>2</sup>, R. D. Wolfinger<sup>2</sup> and R. S. Thomas<sup>1</sup>. <sup>1</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>SAS Institute, Cary, NC.

Relative to microarrays, differential gene expression analysis using RNA-Seq data has been reported to offer higher precision estimates of transcript abundance, a greater dynamic range of transcript detection, and detection of novel transcripts. However, appropriate methods of analyzing RNA-Seq data and the number of reads required to match the sensitivity of microarrays are still a subject of debate. Moreover, comparisons of the two technologies have not covered dose-response experiments that are relevant to toxicology. Male F344 Rats were exposed for 13 weeks to 5 concentrations of bromobenzene. RNA was extracted from livers of five animals per dose level and used for measuring gene expression changes using both Affymetrix HT RG-230 PM microarrays and ABI SOLiD 50bp single read RNA-Seq. Sequencing produced an average of 9.3M reads per sample mapping to exons. The sequencing data was normalized using RPKM (Reads Per Kilobase per Million) and the microarray data was normalized using RMA. A standard one-way ANOVA was used to analyze the data across doses. Results were compared based on statistical significance (FDR < 0.05) and fold change (FC  $\geq \pm 1.5$ ) for 5,906 genes which had read counts > 10 and matched unambiguously to genes on the microarray. The results showed that paired fold-change values were highly correlated between microarrays and RNA-Seq, while the -log p-values showed little correlation. Random sampling at different read depths showed that RNA-Seq and microarrays produced similar numbers of significant genes based on fold-change (FC  $\geq \pm 1.5$ ) at ~6-8M mapped reads per sample. However, RNA-Seq produced significantly less significant genes based on p-value (FDR < 0.05) at even the highest read depth of 9.3M mapped reads per sample. Among the significant genes, ~50% overlapped between RNA-Seq and microarrays at each dose. The results highlight the need for additional studies examining the use of RNA-Seq data in toxicology.

## EC 1630 The Symbiosis of Mentoring: Getting the Most out of the Mentor-Mentee Relationship.

B. Hannas<sup>1</sup>, N. J. Walker<sup>2</sup>, S. H. Safe<sup>3</sup>, E. W. Carney<sup>4</sup> and O. Olivero<sup>5</sup>. <sup>1</sup>Reproductive Toxicology Branch, US EPA, Research Triangle Park, NC; <sup>2</sup>NTP, NIEHS, Research Triangle Park, NC; <sup>3</sup>Molecular & Cellular Medicine, Texas A&M University, College Station, TX; <sup>4</sup>The Dow Chemical Company, Midland, MI; <sup>5</sup>Laboratory of Cancer Biology & Genetics, National Cancer Institute, Bethesda, MD.

Mentoring is a critical element in the career development of all toxicologists, both in terms of making the most of potential mentors and developing effective mentoring skills. Whether through involvement in academia, or helping to develop the expertise of an early-career scientist, most toxicologists will provide mentoring at some point in their career. The mentor role serves to transfer knowledge, give advice and provide support to a trainee or developing scientist, while the mentee is relied upon by the mentor to provide active participation and input into the relationship. According to national polls, as well as SOT-specific surveys, one of the resounding topics of interest for developing scientists is mentoring from the broad perspectives of choosing the right mentor, down to developing the skills to become a sound mentor. Therefore, this session was designed to complement existing mentor matching opportunities offered through SOT. Speaker presentations will focus on: (1) the fundamentals of mentoring, including the different situations and roles in which the mentee-mentor dynamic may be encountered; (2) an introduction to the most commonly used mentoring techniques; (3) identifying characteristics of a strong mentor-mentee relationship; and (4) mentoring towards the future of science and the challenge to overcome more complex scientific problems. Speaker perspectives will address the mentorship role within academia, government, and industry. Attendees of this session will learn to identify a healthy mentor-mentee relationship and understand the benefits to each member of the collaboration. Mentoring topics discussed in this session will be applicable to scientists at every career stage through highlighting the basics behind a strong, mutually-beneficial mentoring relationship.

## S 1631 Role of Systems Biology in Characterizing Risk of Developmental Origins of Disease.

D. T. Szabo<sup>1</sup> and T. L. Palenski<sup>2</sup>. <sup>1</sup>National Center for Environmental Assessment, US EPA, Arlington, VA; <sup>2</sup>Molecular and Environmental Toxicology, University of Wisconsin Madison, Madison, WI.

Systems biology is the study of complex interactions of biological components, such as nucleic acids, proteins, chemical reactions, cells, and whole organisms, at multiple levels of organization. The National Research Council recommends implementing the use of systems biology approaches in the risk assessment process. While recent advances have been made to prioritize chemicals for further screening, to better understand mode of action, strengthen weight-of-evidence, and eventually replace traditional *in vivo* animal model data with *in vitro* and *in silico* methods, these data have not been systematically considered in mainstream approaches for risk assessment which also largely focuses on adult populations. The goal of this symposium is to consider emerging knowledge and information from systems biology to inform risk assessment and decision making in the arena of developmental origins of disease. Growing evidence suggests that chemical exposures in early life can have immediate and long-term effects on the structure and function of organ systems, leading to the development of disease later in life. Systems biology approaches can aid in understanding molecular, cellular, metabolic, and morphological changes resulting from such exposures. These approaches, which include analysis of complex data sets from multiple experimental sources, interdisciplinary 'omics tools, and computer simulation modeling, are increasingly being applied to better understand developmental origins of disease. We will present current systems biology approaches on how to better identify developmental origins of disease and its implications to the risk assessment process through several case studies.

## S 1632 Predictive Models of Developmental Toxicity.

N. S. Sipes and T. B. Knudsen. National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

Environmental chemical exposure during development can lead to birth defects which can have lasting effects through adulthood. *In vivo* data from both rodent and non-rodent species gathered using standardized prenatal guidelines are used in risk assessments to determine developmental toxicity potential; however these studies may not indicate the underlying complex mechanisms which lead to developmental toxicity. We used a systems biology approach to develop predictive models

that link in vivo outcomes (including malformations, fetal weight reductions, and prenatal loss) with potential mechanisms of toxicity. This approach uses in vivo data from guideline and literature studies and over 3 million in vitro data points from high-throughput and high-content screening techniques on chemical-biological interactions. Specifically, these assays are obtained from biochemical, cell-free and cell culture assays, along with embryonic stem cells and zebrafish embryos. The predictive models developed confirm known pathways, such as retinoic acid receptor and transforming growth factor, and suggest novel pathways such as G-protein-coupled receptors and inflammatory pathways to be important pathways involved in developmental toxicity of environmental chemicals. These models have the potential to aid in the prioritization of chemicals for further targeted toxicity testing and risk assessment, to generate hypotheses about mechanistic pathways leading to adverse developmental outcomes, and to reduce cost and increase throughput of chemical testing.

### **S** 1633 Multiple Organ-Omic Integration for HBCD Developmental Neurotoxicity Hazard Identification.

D. T. Szabo<sup>1</sup> and L. S. Birnbaum<sup>2</sup>. <sup>1</sup>National Center for Environmental Assessment, US EPA, Arlington, VA; <sup>2</sup>NIEHS/NCI, Research Triangle Park, NC.

Exposure to environmental chemicals during critical windows of development has shown to disrupt adult neurobehavioral function; however, the mode-of-action is not always well understood. A systems biology approach was taken to identify toxicity pathways after exposure to the major brominated flame retardant mixture, hexabromocyclododecane (HBCD), along with the individual chemicals that make up the commercial mixture to better characterize developmental neurotoxicity, strengthen its overall weight-of-evidence, and support its hazard identification for risk assessment. Short-term disruptions to the developmental profile of genes, proteins, and metabolites in the hippocampus, liver, and systemic circulation were identified after exposure to the commercial mixture and individual stereoisomers. Different molecular pathway profiles generated in several organs suggest the necessity to assess the effects from the individual isomers as well as the mixture when evaluating HBCD and can be used as a model for other environmental mixtures for chemical risk assessment. This presentation will demonstrate the utility of an omics and systems biology strategy to capture information on various facets of brain development that can be altered after environmental exposures and to provide focus for further toxicity studies in determining possible modes-of-action including methods to prioritize individual chemicals in mixtures for chemical risk assessments.

### **S** 1634 Assessing Antiandrogenic Effects of *In Utero* Exposure to Dibutyl Phthalate and Other Xenobiotics.

D. Spade and K. Boekelheide. Department of Pathology and Laboratory Medicine, Brown University, Providence, RI.

The rates of male reproductive tract malformations such as cryptorchidism and hypospadias have increased in the United States throughout the latter half of the 20th century. These disruptions in androgen-sensitive development may be influenced by early life exposures to environmental anti-androgens. However, determining the impact of exposure on human fetal development is hindered by species differences and a lack of human data. Using a fetal testis xenograft model, we have shown that human fetal testis is more resistant than fetal rat testis to the anti-androgenic effects of dibutyl phthalate (DBP). We are expanding this analysis to determine how environmental anti-androgens affect human fetal testis, particularly through alterations in gene expression and DNA methylation. To provide a baseline for this analysis, 12 unimplanted human fetal testis samples aged 14 to 23 weeks gestation have been evaluated using Affymetrix Human Gene 1.0 ST gene expression microarrays and the Illumina Infinium 450k methylation arrays to reveal developmental trends in fetal testis gene expression and DNA methylation. This will provide a baseline for ongoing analysis of xenografted tissues after exposure to anti-androgens. During this window, global testis DNA methylation increases significantly, although not at all genes. DNA methylation at imprinted sites consistently increases throughout this time frame, and there are significant changes in DNA methylation of genes related to testosterone biosynthesis, cell cycle, and transcriptional control. Therefore, reprogramming of testis DNA methylation during this developmental time period aligns with the existing data in mouse, and suggests that this window may be sensitive to disruption by xenobiotics. Assessing the anti-androgenic effect of various environmental compounds in human systems is essential for determining the risk that environmental chemicals pose for the in utero development of the male reproductive system, including understanding the fetal origins of disorders of the male reproductive tract.

### **S** 1635 Mechanistic Pathways Underlying Low-Dose PFOA Effects on Mammary Gland Growth.

M. B. Macon<sup>1</sup> and S. E. Fenton<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

Perfluorooctanoic acid (PFOA) is a synthetic surfactant and, in areas of high contamination in the US, has recently been found to have a probable link to several human diseases. Prenatal exposure to PFOA causes delayed mammary gland growth in female mice. Exposure to low levels of PFOA throughout gestation results in persistent mammary gland abnormalities in female offspring that remain until late in life. Although activation of peroxisome proliferator activated receptor alpha (PPAR $\alpha$ ) is thought to mediate PFOA-induced liver toxicity, the role of this transcription factor in the mammary gland is unclear. Genome-wide microarray analysis, protein expression approaches, and morphological analysis were used to identify molecular mechanisms involved in mammary gland delays following prenatal PFOA exposure. Our studies followed female mice exposed to environmentally relevant levels of PFOA in utero spanning neonatal time-points to late adolescence. Through analysis of whole mammary tissues and isolated cell types, it was found that PFOA altered pathways involved in epithelial-stromal interactions, including endocrine disruption, leaving the mammary gland more susceptible to the development of disease. The dosing levels of PFOA used in our studies produce body burdens in mice that are similar to those found in humans living in highly contaminated areas, therefore, these findings have implications related to the human risk assessment of PFOA.

### **S** 1636 Molecular Mechanisms Linking Maternal Diet-Induced Obesity to Offspring Metabolic Syndrome.

M. Alfaradhi and S. Ozanne. Metabolic Research Laboratories, University of Cambridge, Cambridge, United Kingdom. Sponsor: D. Szabo.

Population studies have suggested that the maternal nutritional status during key stages of development is able to influence offspring risk of metabolic diseases. Recent focus has been on maternal over-nutrition and obesity in programming metabolic disorder in offspring. This stems from human data which has correlated maternal body-mass index (BMI), maternal weight gain during pregnancy, and gestational diabetes to offspring BMI and risk of metabolic disorders such as type 2 diabetes. A large number of studies have reported dysregulation of key organs involved in glucose homeostasis and feeding regulation in the offspring of obese mothers. We have utilized a mouse model in which dams are fed a western-style diet (highly palatable, high-fat, high-sugar diet) during gestation and lactation and taken a whole systems approach to establish mechanisms through which metabolic disease in the offspring arises. Our studies incorporate analysis at the whole body, tissue and cellular level. Offspring of these dams are hyperphagic from a young age, leading to increased body weight and the development of type 2 diabetes later in life. Hyperinsulinaemia is an early observation in these offspring compared to offspring in the control group fed regular chow and we have associated this with impaired insulin signaling protein expression, especially in adipose tissue. We have employed both candidate and genome-wide mRNA and microRNA array approaches to explore the mechanisms by which the programmed changes in insulin signaling protein expression occurs and to identify novel genes and regulatory elements that are associated with metabolic disorders in the offspring. These findings have important implications for the identification of markers of disease risk and identification of susceptible populations to adverse effects resulting from sub-optimal early life exposures.

### **S** 1637 Toxicopigenomics, Disease Susceptibility, and Implications for Risk Assessment.

K. Kutanzi<sup>1</sup> and M. Verma<sup>2</sup>. <sup>1</sup>Biochemical Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>Division of Cancer Control and Population Sciences, National Cancer Institute, NIH, Bethesda, MD.

In the past, classical toxicology has largely focused on the genotoxic effects of environmental toxicants and chemicals. Recent studies have clearly indicated that environmental chemicals, along with their genotoxic abilities, can cause epigenetic alterations that, in concert, may lead to the development of a number of pathological states. The field of toxicopigenomics has since emerged from the combination of epigenetics, which studies the methylation of DNA, histone modifications, and chromatin condensation, and toxicology. During the last few years, excellent progress has been made in detecting altered epigenomic profiles in response to various chemical insults. Future investigations, however, are needed to link chemical

exposure to epigenetic alterations which develop over time, and, in turn, may increase the risk of disease. Although whole populations may be exposed to toxic substances, only a few people develop the disease, which may, in part, be due to the different epigenomic backgrounds of individuals. That is why the potential role of epigenetics in disease susceptibility, along with the potential opportunities for epigenetic biomarkers in the assessment of toxicity and carcinogenicity of chemicals have received a lot of attention recently. Specifically, the following key aspects need to be addressed: 1) How stable are the epigenetic alterations induced by environmental toxicants?; 2) What periods of development across the lifespan are windows of vulnerability and/or opportunity for an altered epigenome?; 3) How can exposure to toxicants *in utero* affect the epigenome and predispose individuals to various diseases throughout life?; 4) Are there methodological and measurement gaps to be filled to advance our understanding of toxicopigenomics?; and 5) How can we develop risk prediction models? Evidence that epigenetic alterations can be potentially reversed may be helpful in developing treatment and preventative strategies.

### **S 1638 Epigenetic Alterations in Response to Exposure to Environmental Toxicants.**

I. Koturbash. *Department of Environmental and Occupational Health, College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR.*

Epigenetics is the study of heritable changes in gene expression that are not associated with alterations in DNA sequence. Epigenetic mechanisms include DNA methylation, post-translational histone modifications, and nucleosome positioning along DNA, and are important for maintenance of normal cellular homeostasis. Disruption of epigenetic mechanisms may compromise the balance of the cellular epigenome and lead to development of various pathological states, including cancer. Accumulating evidence clearly indicates that various environmental toxicants, independently of their genotoxic abilities, can cause epigenetic alterations. These changes in the cellular epigenome are exhibited as decreases in global DNA methylation, aberrant gene-specific DNA methylation, changes in histone modifications, as well as associated alterations in chromatin status. Importantly, epigenetic alterations can be detected long before the occurrence of genetic changes; and are stable, persisting after the initial exposure-related DNA damage has been repaired. These findings highlight the significance of epigenetic alterations in the mechanisms of toxicity and carcinogenicity.

### **S 1639 Application of Cancer Toxicopigenomics in Identifying High-Risk Populations.**

M. Verma. *National Cancer Institute, NIH, Rockville, MD.* Sponsor: K. Kutanzi.

The epigenome is dynamic and very susceptible to environmental changes. Toxicopigenomic studies are conducted to explain the epigenetic effects of environmental exposures. Epigenetic programming occurs during development and reflects altered gene expression in disease states. This programming differs from genetic polymorphisms or mutations because genetic changes are reflected in all cells, whereas epigenetic changes are cell- and tissue-specific. Studies that involve the measurement of epigenetic changes that occur at the genome-wide level and their association with disease are called epigenome-wide association studies (EWAS). Epigenetic alterations respond quickly to environmental changes, and technologies are available to measure these changes. During the last 5 years, excellent progress has been made in the field of altered epigenomic profiling in response to toxins and environmental. It now is possible to use high-throughput technologies to measure epigenetic patterns that are altered by toxin exposure. Different environmental exposures, including toxins, affect different components of the epigenetic machinery and alter the methylation and acetylation equilibrium. Epidemiologic studies help to identify the etiology of a disease, especially factors that contribute to disease development. In the case of cancer, such factors include toxic substances, radiation, infectious agents, specific dietary components, tobacco, alcohol, and environmental factors. It makes sense to identify epigenetic markers in normal and exposed populations. The advantages of identifying epigenetic biomarkers of exposure include improved exposure assessment, documentation of early alterations preceding cancer development, and identification of high-risk populations. Examples of interaction between toxic substances and cancer initiation and progression will be discussed.

### **S 1640 Changes in Histone Tail Modifications and Gene Expression in PBMC from Subjects Exposed to Nickel and Arsenic.**

M. Costa. *Environmental Medicine, New York University School of Medicine, Tuxedo Park, NY.*

A major target of Nickel (Ni) ions in cells is the iron- and ascorbic acid-dependent dioxygenase enzymes. The family of histone H3 demethylases is an example of these enzymes. Since Fe binding is required for catalytic activity and Ni ions readily displace the Fe from all of these enzymes, Ni exposure results in inactive enzyme which increases global levels of the activating mark H3K4 trimethylation (H3K4me3) and the silencing mark H3K9 dimethylation (H3K9me2). Arsenic (As) induces oxidative stress in cells and will deplete reduced ascorbate which is required for the activity of these histone demethylases. *In vitro* exposure to Ni or As increases the levels of posttranslational modifications of histone tails. Here we show changes in global levels of histone modifications in peripheral blood mononuclear cells (PBMCs) of subjects with occupational exposure to Ni by inhalation in a Nickel refinery in China and subjects from Bangladesh exposed to As in their drinking water. Occupational exposure to Ni was associated with an increase in H3K4me3 and decrease in H3K9me2. A global increase in H3K9me2 and decrease in H3K9ac was found in subjects exposed to As. Additionally, exposure to As resulted in opposite changes in a number of histone modifications in males compared to females in the As exposed population. We also analyzed the gene expression changes in PBMC in a smaller subset of individuals exposed to Ni and As. Hierarchical clustering revealed that several thousand genes were similarly changed across subjects highly exposed to Ni, and there was similar clustering with low Ni exposure and with controls. With As the results were more complex because of the strong effect of gender. With As there were genes that changed in a gender dependent manner and also with As exposure independent of gender. The results of these two studies suggest that exposure to Ni or As compounds, and possibly other carcinogenic metal compounds, can induce changes in global levels of posttranslational histone modifications and gene expression in PBMC.

### **S 1641 Chromatin Remodeling As a Driver and Target for Lung Cancer.**

S. A. Belinsky. *Lovelace Respiratory Research Institute, Albuquerque, NM.* Sponsor: K. Kutanzi.

Epigenetic silencing of genes and microRNAs (miRs) via chromatin remodeling and cytosine methylation has emerged as a major mechanism in lung cancer etiology. The reversal of gene and miR silencing using pharmacological agents and potentially dietary supplements (e.g., omega-3 polyunsaturated fatty acids [n-3 PUFA]) by affecting cytosine-DNA methyltransferases (DNMTs), histone methyltransferases (HMTs), or histone deacetylases (HDACs) offers new strategies for prevention and intervention for lung cancer. We have developed an *in vitro* model using hTERT/cdk4 immortalized human bronchial epithelial cell lines (HBECs) that identifies molecular changes driving transformation of preneoplastic lung epithelial cells during exposure to carcinogens found in mainstream and environmental tobacco smoke. Our studies provided a mechanistic link between increased DNMT1 protein, *de novo* methylation of genes, and reduced DNA repair capacity that together seemed causal for transformation. Our recent studies show that the exposure of HBECs to carcinogens for 4 wks induces a persistent and irreversible, multifaceted dedifferentiation program characterized by the epithelial-to-mesenchymal transition (EMT). EMT induction was epigenetically driven, initially by chromatin remodeling involving H3K27me3 enrichment, with ensuing DNA methylation sustaining the silencing of miR-200b, -200c, and -205 implicated in this developmental program and persisting in malignant tumors. Overexpression of these miRs reversed transformation. Genome-wide profiling has identified >300 genes with a promoter CpG island whose expression is reduced after only 4 wks of treatment. The polycomb repressive complex PRC2 regulated many of these genes. While ensuing promoter methylation after 8 wks of further exposure to the carcinogens is seen in a small subset of these genes, many of these genes show dense methylation in tumor-derived cell lines and primary tumors. These findings implicate chromatin remodeling mediated by HMTs whose expression increases during carcinogen exposure and in primary tumors, as important initiators of epigenetic gene silencing (Supported by R01 ES008801).

### **S 1642 Molecular Basis for Dioxin-Induced Cardiovascular Disease.**

A. Puga. *Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH.*

Interactions between genetic and environmental factors are responsible for several forms of human congenital cardiovascular malformations. Of these, valvular stenosis and hypoplastic left heart syndrome are the most common forms of birth defects

in humans, occurring in eight newborns from every 1000 live births and constituting 25–30% of all cases of human cardiovascular malformation. These two congenital heart defects are the leading cause of neonatal and infant death and, underscoring the fetal origin of adult disease concept, are also a major cause of adult cardiac insufficiency, linking fetal and adult cardiovascular disease. The main known risk factors for these abnormalities in cardiac development are genetic inheritance and maternal exposure to hazardous chemicals, but their precise molecular etiology remains elusive. We have recently found that treatment of differentiating mouse ES cells with dioxin represses Nkx2.5 gene expression and other cardiac markers as a consequence of AHR activation. By following the expression trajectories of cardiomyocyte markers during ES cell differentiation we found that dioxin silenced the expression of Nkx2.5 and other cardiomyocyte-specific genes, including the genes coding for cardiac troponin-T and  $\alpha$ - and  $\beta$ -myosin heavy chains, and inhibited the formation of beating cardiomyocytes, a characteristic phenotype of differentiating mouse ES cells. The key mediator of these effects was the aryl hydrocarbon receptor (AHR), epigenetically silenced in pluripotent ES cells and activated during differentiation. Our work with ES cells may unravel molecular and epigenetic mechanisms responsible for human cardiac malformations due to environmental (organochlorinated compounds) or genetic (NKX2.5 mutations) causes. NKX2.5 repression by dioxin-mediated AHR activation may help us identify the regulatory loops controlling the NKX2.5 functions that determine embryonic identity and progression of cardiac tissue differentiation, and how these functions are silenced by the activated AHR. (Supported by NIH grants 5R01ES006273 and 5P30ES06096).

### **W** 1643 Dietary Arsenic—Forms, Hazards, and Risks.

P. M. Bolger. *Exponent, Annapolis, MD.*

Arsenic, particularly inorganic arsenic, is a well known and ubiquitous environmental contaminant, particularly in drinking water, and it originates from both anthropogenic and natural sources. It demonstrates a myriad of toxicological effects across a broad spectrum of organ systems. It has generally been believed that arsenic in food occurs in organic forms that demonstrate minimal, if any, toxicological activity. This is particularly the case with the forms found in seafood (e.g., arsenosugars). However, there has been concern for some time that organic forms may not be the predominant forms in certain foods, like rice, where concentrations of inorganic forms in certain cultivars may be significant. In addition, other organic forms, like tri- and penta- mono- and dimethyl forms, may be found, and at levels that are not insignificant, and could potentially pose a health hazard. These organic forms may not be as innocuous as the organic forms found in seafood. This session will explore the current state of knowledge regarding the occurrence of various forms of arsenic found in foods, as well as their potential exposures, hazards (e.g., toxicological, epidemiological) and risks to public health, and what risk management options may be available.

### **W** 1644 Noncancer Disease Risk Promoted by Low Level Arsenic Exposures.

A. Barchowsky. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Exposure to arsenic through drinking water and diet increases risk for a number of cancers and non-cancer diseases. Cardiovascular diseases contribute to a large portion of non-cancer arsenic-promoted morbidity and mortality, and may occur at relatively low levels of arsenic exposure that were considered safe based on cancer risk. While epidemiological studies have established the disease risk to low level exposures, basic studies have lagged in demonstrating mechanism for disease. However, recent low level exposure studies in mice and cultured human cells suggest novel receptor mediated and reactive oxygen species-dependent modes of action for arsenic induced pathogenic vascular and tissue remodeling, as well as metabolic dysfunction. This talk will review the current state of understanding of arsenic-induced cardiovascular disease risk and potential modes of action.

### **W** 1645 Exposure Assessment Methods for Dietary Arsenic.

L. Barraj and N. Tran. *Exponent, Washington DC.*

A brief overview of types of dietary exposure assessments and discusses the associated data requirements will be presented. Existing food consumption data sources that can be used for estimating dietary exposure to arsenic are reviewed and their strengths and limitations are discussed. Algorithms and models typically used are presented and their applicability to the various exposure scenarios (e.g., short term versus long term) are discussed.

### **W** 1646 Recent Epidemiologic Studies of Arsenic and How They Apply to the Health Evaluation of Arsenic in Food.

H. J. Gibb. *Tetra Tech Sciences, Arlington, VA.* Sponsor: P. Bolger.

The association of arsenic in drinking water with an increased risk of skin, lung, bladder, and kidney cancer has been known for several decades. In addition to the association of arsenic with increased risks of various forms of cancer, studies have found an association of arsenic in drinking water with a variety of noncancer effects including skin lesions, cardiovascular disease, diabetes, liver damage, and kidney disease. Some of these effects have been reported to occur at drinking water concentrations lower than 100  $\mu\text{g As/L}$ . Several studies indicate that exposures at younger ages have a disproportionately greater effect than exposures at older ages. Recent reports of arsenic in brown rice syrup and apple juice have raised concern whether arsenic in food products may also present a health problem, particularly for infants. The development of an epidemiologic database that focuses primarily on recent studies and how such studies may affect the risk assessment of arsenic in food will be presented.

### **W** 1647 Potential Risks to Human Health from Arsenic in the Diet: A European Food Safety Authority (EFSA) Perspective.

J. R. Schlatter. *Federal Office of Public Health (retired), Zurich, Switzerland.*

In 2010, the Panel on Contaminants in the Food Chain (CONTAM Panel) of the European Food Safety Authority (EFSA) assessed the risks to human health related to the presence of arsenic in food. More than 100,000 occurrence data on arsenic in food were considered with approximately 98 % reported as total arsenic. Making a number of assumptions for the contribution of inorganic arsenic to total arsenic, the inorganic arsenic exposure from food and water across 19 European countries was estimated for average consumers, for 95th percentile consumers and for children. The CONTAM Panel modeled the dose-response data from key epidemiological studies and selected a benchmark response of 1 % extra risk. A range of benchmark dose lower confidence limit (BMDL01) was identified for cancers of the lung, skin and bladder, as well as skin lesions. The estimated dietary exposures to inorganic arsenic for average and high level consumers in Europe as well as for children are within the range of the BMDL01 values identified, and therefore there is little or no margin of exposure and the possibility of a risk to some consumers cannot be excluded.

### **W** 1648 Pulmonomics, the Exposome, and Microbiomes in Immunotoxicology.

M. A. Williams. *US EPA, Research Triangle Park, NC.*

The exposome has revealed itself to be a powerful approach for assessing environmental exposures and their influences on human diseases. As we explore the origins of human disease, and the contributions made by environmental pollutants, a comprehensive understanding of systems biology is needed. This requires an integrated understanding of how environmental chemicals and other stressors of gene and protein expression are not only linked to a toxicological outcome but which may impact on chronic inflammatory diseases such as allergic asthma, COPD, and even lung cancer. Perturbations in normal cell cycle kinetics, apoptotic cell-death pathways, immune dysfunction, and a recent appreciation of the consequences of inadvertent dysregulation of the gut and lung microbiomes collectively distort normal systems biology homeostasis and the advent of adverse health effects. For the first time, this symposium presents emerging critical issues and paradigms that discuss the contributions and interplay of systems biology, the exposome, and microbiomes as they relate to immunotoxicology, dysregulation of inflammatory pathways, and chronic diseases. Invited speakers will place in context and share state-of-the-art approaches for advancing our understanding of the interplay of gene and environment and of the exposome in initiating and prolonging chronic inflammatory disease.

### **W** 1649 Breath Biomarkers from Viable Pulmonary Aerosols: Discovery of Human Microbiome Contributions.

J. Pleil. *Methods Development and Applications Branch, National Exposure Research Laboratory (NERL), US EPA, Research Triangle Park, NC.*

Exhaled breath and exhaled breath condensate (EBC) are two human biological fluids collected non-invasively to assess previous exposures to exogenous compounds and to evaluate metabolic (or health) effects. Although expression of volatile organic compounds (VOCs) in exhaled breath is considered a window into the circulating blood representing external exposures and human metabolism, it also represents contributions from the life cycles of the human microbiome. We have

developed methodology for distinguishing between human and bacterial contributions via collection of human generated aerosols in EBC, culturing them in growth media, and analyzing headspace with gas-chromatography – mass spectrometry. We have cataloged a series of VOCs from both aerobic and anaerobic conditions to inform human biomonitoring efforts for the assessment of in-vitro and in-vivo studies of the safety of manufactured chemicals.

## **W** 1650 Experimental Exposure of Mice to House Dust Alters Gut Microbiome and Attenuates Allergic Pulmonary Responses.

N. Lukacs. *Pathology, University of Michigan Medical School, Ann Arbor, MI.*

Sponsor: M. Williams.

Atopic asthma is more common in clean Western countries and its prevalence has increased greatly during the last century, along with improved hygiene and housing conditions. Exposure to a more diverse microbiome during childhood correlates with a lower risk of developing asthma during later life. Recent data has suggested that a diverse microbiome is associated with growing up with older siblings and pets. Dietary sampling from the environment can directly impact the gut microbiome. Interaction between intestinal microbiome and Gut Associated Lymphoid Tissue (GALT) not only directs local immune responses but also appears to affect the outcome of antigen-driven responses in the respiratory system. Using 2 different mouse models of allergic asthma (using the model-antigen ovalbumin –OVA – and the clinically relevant cockroach allergen – CRA), we set out to study pulmonary immune responses after dietary supplementation with household dust collected from homes with or without pets. Daily dosing of sieved dust administered to 6-8 week old BALBc mice via oral gavage for 2 weeks was used for controlled exposure. Following the dust treatment, mice were sensitized and challenged with CRA, or alternatively received a transfer of OVA-specific DO11.10 T-cells and a subsequent OVA challenge. In the dust exposed animals a significant decrease in Th2 cytokine protein expression and total IgE levels was observed in pet dust-treated animals exposed to allergen. Moreover, these mice showed reduced mucus hypersecretion in the lung, as determined by PAS staining and RT-PCR for gob5. Interestingly, phylochip analysis of the cecal content of these mice revealed that the pet dust treatment altered the microbiome in favor of *Lactobacillus* species. Altogether these data demonstrate that short-term oral sampling of dust from homes with pets, but not without pets, significantly alters the gut microbiome and can subsequently attenuate pulmonary allergen-induced immune responses.

## **W** 1651 Translating the Airway Transcriptome into Biomarkers of Tobacco-Related Lung Disease.

A. Spira. *The Pulmonary Center, Boston University School of Medicine, Boston, MA.*

Sponsor: M. Williams.

While cigarette smoke exposure is associated with lung cancer, COPD and a number of chronic inflammatory diseases of the lungs, only a fraction of smokers develop these diseases and there are currently no effective tools for identifying those smokers at highest risk for disease. Furthermore, we lack biomarkers for measuring the host response to inhaled toxins like cigarette smoke. This talk will focus on applying whole-genome gene-expression studies to airway epithelial cells in order to gain insights into the physiological responses to tobacco smoke exposure. The goal of the presentation will be to explore how individual variability in the airway genomic response to tobacco smoke associates with risk of tobacco-related lung diseases and how this information can be leveraged to serve as clinically-relevant biomarkers of disease activity in both lung cancer and COPD. This talk will be of broad interest to the biomedical research community including those with expertise in genomics, molecular biology, and epidemiology related to tobacco exposure and pulmonary disease.

## **W** 1652 Immune-Mediated Adverse Effects of Drugs and Environmental Agents.

J. Uetrecht. *Pharmacy, University of Toronto, Toronto, ON, Canada.*

Many adverse effects of drugs and environmental agents are immune-mediated. Exposure to drugs is easier to determine than most environmental agents, and most drugs can cause idiosyncratic (i.e. specific to an individual) adverse reactions (IDRs) such as skin rash, liver injury, bone marrow injury, and autoimmunity, most of which are immune-mediated. This provides a clear example of how different people can be affected by agents in different ways. Most drugs associated with a significant risk of IDRs form chemically reactive metabolites, which suggests that a major factor is the ability of the drug to form a hapten. However, this observation

is also consistent with the danger hypothesis because reactive metabolites can also cause cell injury leading to the release of danger signals that promote an immune response. There are also environmental agents that form reactive intermediates and lead to an immune response, e.g. poison ivy and hair dyes can cause contact hypersensitivity. However, not all drugs that cause IDRs form reactive metabolites so there must be other possible mechanisms. Other apparent mechanisms involve epigenetic changes, reactivation of viruses and direct binding to MHC. One example of an environmental agent that binds to MHC leading to an immune response is beryllium, which binds to HLA-DPB1 that has a glutamic acid at AA 69, and very low exposures to beryllium can lead to severe chronic lung disease in patients with this genotype. Other agents such as vinyl chloride can lead to autoimmunity. Although IDRs are frequently referred to as dose independent, this is not true; drugs given at a dose of 10 mg/day are associated with a very low risk of IDRs. This may reflect a threshold in hapten density required to induce an immune response. This suggests that most environmental agents are unlikely to cause immune-mediated adverse reactions; however, beryllium is an exception, and this threshold may be significantly lower for agents that act more directly to modulate immune responses. Environmental agents such as benzene can also lead to immunosuppression. Funded by grants from CIHR.

## **W** 1653 Targeted 'Omics Research in the Regulatory Environment.

J. Sobus. *Exposure Measurements and Analysis Branch, US EPA, Research Triangle Park, NC.*

The US EPA's Office of Research and Development (ORD) has recently implemented the "Chemical Safety for Sustainability" (CSS) research program. Much of this program is dedicated to "facilitating faster, more efficient, more certain, and sustainable chemical assessments and management decisions". Achieving these goals will require high-throughput and multi-chemical assessments of environments, living intact organisms, and surrogate (in vitro) systems. Single chemical assessment strategies alone cannot support these requirements, and will be supplemented using 'omic-based approaches to exposure- and health-based assessments. This presentation will highlight opportunities to integrate cutting-edge 'omics approaches into existing regulatory-based research frameworks. Special attention will be given to biomarker-based 'omics tools that can be used to link across environmental, biological (in vivo), and in vitro sample environments.

## **W** 1654 Standard and Nonstandard Animal Models for Evaluation of Drug Abuse Potential for Pharmaceutical Compounds with Novel Mechanisms.

C. G. Markgraf<sup>2</sup> and M. Guha<sup>1</sup>. <sup>1</sup>*Drug Safety Evaluation, Bristol-Meyers Squibb Co., Mt Vernon, IN;* <sup>2</sup>*DSS, Merck, Kenilworth, NJ.*

Preclinical assessment of abuse liability potential for new drugs with central nervous system (CNS) activity has been a recent focus of both regulatory and industry interest. The standard animal models used for evaluation of abuse potential for these pharmaceutical candidates are self-administration and drug discrimination. These models have been well characterized in both rats and monkeys with known drugs of abuse. However, unique challenges encountered when evaluating drugs with novel mechanisms or with difficult pharmaceutical properties raise questions: How can reinforcing properties be evaluated if there is no acceptable IV formulation? What comparator drug is appropriate for a candidate compound with a novel CNS-active mechanism? In these situations, using a nonstandard model may offer an attractive alternative. The promise of such alternative animal models is balanced by the challenge in data interpretation and in incorporation of the data into a comprehensive risk assessment. This workshop will start with a discussion of the regulatory requirements and standard data collected for a preclinical abuse potential assessment, followed by presentations on conditioned place preference (CPP) and intracranial self stimulation (ICSS)—both nonstandard animal models of drug abuse potential in a regulatory setting. The scientific rationale for their use, how each compares to standard animal models, and the use of their data in risk assessment and in an abuse potential package for submission to health authorities will be discussed.

## **W** 1655 Current Challenges in Abuse Liability Assessment of Drugs with Novel Mechanisms of Action.

K. H. Horn. *Drug Safety Evaluation, Bristol-Meyers Squibb, Mt Vernon, IN.*

Preclinical data from abuse liability assessments are required to support the registration and scheduling of new drugs with central nervous system activity. Despite the availability of a standard set of well characterized animal models (self administration and drug discrimination), there may be circumstances for compounds with

novel mechanisms of action where the standard models are not suitable or cannot be utilized for the lack of suitable comparators for training or due formulation issues. In these cases, investigators may wish to turn to alternative approaches to understand the abuse liability potential for drugs under development. The purpose of this presentation is to highlight the complexity and challenges associated with designing an abuse liability package for drugs with novel or unknown mechanisms of action where the use of standard assays may not be appropriate or when pharmaceutical properties prevent the use of standard assays. The first part of the presentation will focus on the standard pre-clinical models of abuse liability (self-administration, drug discrimination, and withdrawal/dependence). Following this introduction, the presentation will discuss specific circumstances, situations, and/or challenges that investigators may encounter during drug development which may require consideration of unconventional approaches.

#### **W 1656 The Assessment of Abuse Liability: The Regulatory Perspective.**

S. N. Calderon-Gutkind. *CDER, FDA, Silver Springs, MD.* Sponsor: M. Guha.

The assessment of the abuse liability of a drug is part of the evaluation performed by FDA, according to the requirements of the Federal Food, Drug and Cosmetic Act.

Issues concerned with the assessment of potential for abuse and with scheduling a drug under the U.S. Controlled Substances Act (CSA) are the responsibilities of the Office of the Center Director, Controlled Substance Staff.

When a new drug has structural or pharmacological similarity to a known drug of abuse, sponsors are required to thoroughly characterize its abuse potential and submit study results for scientific review. A drug's abuse potential is determined relative to a pharmacologically similar or other appropriate comparator drug. The abuse liability assessment is based upon comprehensive evaluation of chemistry, pharmacology (preclinical and clinical), pharmacokinetics, and pharmacodynamic profiles of the drug, and adverse events observed in clinical trials, as well as anticipated public health risks that may follow introduction of the drug on the market.

This presentation will focus on the current guidance for industry on the assessment of the abuse potential of drugs, and on the particular challenges encountered when assessing the abuse potential of drugs with novel mechanisms of action or pharmacological profiles.

#### **W 1657 Conditioned Place Preference As a Tool for Assessing Abuse Liability.**

C. L. Cunningham. *Behavioral Neuroscience, Oregon Health & Science University, Portland, OR.* Sponsor: C. Markgraf.

The conditioned place preference (CPP) procedure is commonly used to assess the rewarding and aversive effects of drugs in laboratory animals. This procedure is also used to study the role of learning in the control of drug seeking and relapse as well as the brain mechanisms underlying drug-induced learning and reward. However, the CPP procedure has not been used systematically in the assessment of abuse potential. This presentation will focus on important issues that should be considered when using the CPP procedure for such assessments. The basic procedure and its parametric determinants will be briefly described, followed by a review of its advantages and limitations as a tool for assessing abuse potential. This review will focus on relevant theoretical, methodological, empirical and practical issues that arise when comparing the CPP procedure to the most commonly used tool for assessing abuse potential, i.e., drug self-administration. For example, consideration will be given to the use of these procedures for assessing "reinforcement" vs. "reward" and to the conceptual issue of whether these procedures simply offer different strategies for measuring a common biological process. Literature showing similarities and differences in drug effects between these procedures will be briefly reviewed along with examples showing a positive effect of a known abused drug in one procedure but not in the other. Although a more systematic evaluation of its utility for predicting drug abuse liability in humans is needed, CPP might have significant value as an additional tool for assessing abuse potential in laboratory animals.

#### **W 1658 Use of Intracranial Self-Stimulation for Abuse Liability Assessment.**

T. J. Hudzik. <sup>1</sup>*Neuroscience Research, Abbott, Ludwigshafen, Germany;* <sup>2</sup>*Institute of Pharmacology, Pavlov Medical University, St. Petersburg, Russian Federation.* Sponsor: C. Markgraf.

All drugs entering the CNS may initially be viewed as having a potential risk for abuse. As there is no single test or assessment procedure likely to offer an ultimate characterization of abuse liability, preclinical abuse liability assessment is based on

using several experimental approaches that focus on establishing pharmacological equivalency to known drugs of abuse, ability to induce physical dependence, and reinforcing effects. This report discusses intracranial self-stimulation (ICSS; brain stimulation reward) as a tool that could complement existing assessment strategies. Many drugs of abuse facilitate ICSS in laboratory animals prepared with electrodes implanted into brain "reward" areas. In addition to fairly robust predictive validity, ICSS has a number of important advantages in studying: i) drug-drug interactions; ii) quantitative comparisons among drugs; iii) complex drug formulations, especially those intended to be abuse-resistant; and iv) multiple, repeated drug exposures. This report limits a review of the ICSS literature to that pertinent to its usefulness as a procedure predictive of the abuse liability of drugs, and argues for the standardization of experimental protocols to enable a more final assessment of its usefulness in this regard.

#### **W 1659 Impact of Nonstandard Animal Models on Preclinical Study Design for Meeting Regulatory Requirements.**

M. Kallman. *Discovery and Translational Services, Covance, Greenfield, IN.*

Although most pharmaceutical companies have transitioned to provide non-clinical data to address regulatory requirements for scheduling decisions on new drugs these studies have typically been the traditional dependence, drug discrimination, and self-administration studies. Alternative models of conditioned place preference and intracranial self-administration have been available as scientific tools for sometime but they have only rarely been conducted to support the regulatory environment. The reasons for the emphasis on the traditional models will be considered. In addition, a discussion of the advantages and potential applications of the non-standard models for scheduling decision making may provide insight into the utility of these models. The emphasis of the talk will be what the future environment might be and how we can develop scientific data packages using these non-standard models to meet the future decisions for scheduling.

#### **W 1660 The Placenta in Toxicology: Target or Travel Agent?**

C. J. Bowman<sup>1</sup> and W. Foster<sup>2</sup>. <sup>1</sup>*Developmental & Reproductive Toxicology, Pfizer Inc., Groton, CT;* <sup>2</sup>*Department of Obstetrics & Gynecology, McMaster University, Hamilton, ON, Canada.*

The placenta is a fascinating organ in its dynamic form and function appearing as a transient and critical tissue in the reproductive cycle. It is a collaboration of maternal and zygotic cellular layers whose major function is a conduit between mother and fetus focused on the growth and viability of the next generation whilst preserving maternal well-being. The unique physiology of biodistribution and metabolism of the placenta also render it sensitive as a target of toxicity. The human placenta is a complicated organ and understanding the comparative physiology of nonclinical species can be a critical component for drug and chemical safety assessment; both as a potential target of toxicity and as a presumed barrier to undesirable xenobiotics. As in much of toxicology, it is important to appreciate different perspectives including clinical, epidemiological, basic research, industry, and regulatory. It is only when this information is integrated and applied that we can appreciate the value and importance of basic research and the views of regulatory and industrial sciences.

#### **W 1661 How Predictive Are Animal Studies in Detecting Fetal Risks in Humans?**

G. Koren<sup>1,2</sup>. <sup>1</sup>*The Hospital for Sick Children, The University of Toronto, Toronto, ON, Canada;* <sup>2</sup>*Molecular Toxicology, The University of Western Ontario, Toronto, ON, Canada.* Sponsor: C. Bowman.

Every year scores of new molecules enter the market. Because half of all pregnancies are unplanned, fetal exposure to these drugs is inevitable. Unfortunately, due to wide variability and differences between and human placenta in anatomy and physiology, making animal models of placental transfer difficult to interpret. There is an urgent need for non human models to predict human risk/safety. The placenta is the only human organ that can be ethically harvested and kept alive *ex vivo* for 4-6 hr. By cannulating maternal and fetal vessels, the perfusion model can be used to study rates and extent of drug transfer across the human placenta, as well as placental functions such as oxygen consumption, hCG secretion etc. Using placental perfusion, we have established a model of predicting *in vivo* drug transfer, correlating it with results of *in vivo* fetal and neonatal sampling (Hutson et al, Clin Pharmacol Ther, 2011). Implementation of this model can revolutionize the prediction of fetal exposure to drugs *in vivo*.

## **W** 1662 Environmental Factors in Placental Toxicology and Women's Health.

M. M. Veras<sup>1,2</sup> and P. Saldiva<sup>1,2</sup>. <sup>1</sup>*Pathology, University of São Paulo, São Paulo, Brazil;* <sup>2</sup>*National Institute of Integrated Analysis of Environmental Risk, São Paulo, Brazil.* Sponsor: C. Bowman.

Environmental pollution is shown to affect reproductive functions in humans. In some situations exposures are unavoidable, such as traffic-derived air pollution in urban areas. The relationship between gestational exposure to air pollution and fetal outcomes is receiving progressively greater attention. Epidemiological findings correlate low birth weight, higher frequency of preterm birth, neonatal mortality and compromised specific reproductive endpoints such as infertility with air pollution. The limitations of epidemiological studies are associated with difficulties of identifying individual exposure levels as well as the presence and management of many cofounder factors such as nutritional and social status and smoking that challenges the establishment of causal relationships. To overcome these factors our group conducted experimental studies (murine model) using realistic concentrations of air pollutants, which "mimic" human exposures. Experimentation using real-world exposures to air pollutants provided corroboration of epidemiologic data and was used to identify the pathophysiological mechanisms involved. Changes in estrous cyclicity, fertility, number of ovarian follicles, embryonic implantation index, fetal development and placentation were some of the outcomes observed. In summary this session will provide an overview of the effects of environmental air pollution on reproductive functions; in particular, adverse effects on pregnancy outcome and placentation.

## **W** 1663 The Placenta As Therapeutic Border Patrol for Unintended Populations.

C. J. Bowman. *Developmental & Reproductive Toxicology, Pfizer Inc., Groton, CT.*

For most bio/pharmaceuticals the placenta and developing conceptus is not the target of therapy so effects on these tissues would generally be undesirable and should be addressed in the safety assessment and benefit-risk considerations of the intended therapy. In addition to direct placental toxicity and/or altered placental function, placental transfer of bio/pharmaceuticals may permit direct effects on the developing embryo, including teratogenicity. The most important placental transfer mechanism of small molecule pharmaceuticals is simple passive diffusion, but there are other mechanisms such as facilitated and active transport, phagocytosis/pinocytosis, membrane discontinuity and electrochemical gradient. The emerging class of large molecule therapies have brought new attention to the currently held dogma that all drugs cross the placenta to some extent (some more than others). These large molecule biopharmaceuticals are generally too big to passively cross plasma membranes and thus may offer a safety advantage (lower risk of teratogenicity) due to limited exposure to the unintended embryo. Antibody-like biopharmaceuticals have a unique placental transfer mechanism that is normally reserved for transport of maternal antibodies to protect the conceptus before and after birth. There is limited data regarding this mechanism of transfer and its timing as it pertains to antibody-like biopharmaceuticals and how it may impact the interpretation of nonclinical developmental toxicity data for human risk assessment to minimize the potential for birth defects. Recent data in the rodent indicates that antibody-like biopharmaceuticals cross the placenta during organogenesis in this species. This potential for embryo exposure during rat organogenesis, even at low levels, merit additional attention to placental transfer in nonclinical species and their concordance to human and how best to use nonclinical data to inform human developmental toxicity risk assessment.

## **W** 1664 The Placenta As a Target Organ in Toxicology—A Case Study.

B. van Ravenzwaay. *Experimental Toxicology and Ecology, BASF SE, Ludwigshafen, Germany.*

Triazole fungicides are known to cause changes in the placenta and they are known to cause late post implantation losses in prenatal studies in rats. Studies were initiated to investigate if there is a connection between these effects and the general mode of action of triazole fungicides, aromatase inhibition, causing a reduction of circulating estradiol. In prenatal studies, estradiol was co-administered with the triazole fungicide during rat prenatal development to test whether estrogen could prevent triazole late fetal resorptions. Co-treatment with estradiol reduced post implantation loss to 9%, compared to 48% without estradiol. Placental changes (labyrinth and trophospongium degeneration) were also less severe with estradiol treatment, indicating that these changes are secondary to reductions in estradiol. Thus, placental pathology may be the cause of late fetal resorptions. Expert pathological evaluation indicated that placental pathology could not support late fetal development; a quantitative evaluation suggested that degeneration of at least 70% of

the labyrinth correlated well with late fetal resorption. As rat placenta is histologically and biochemically different from human placenta, while guinea-pig placentas are quite similar, we studied the effect of the triazole fungicide using guinea-pigs. In this model, prenatal triazole treatment did not result in an increase in the incidence of late fetal resorptions, despite a profound reduction in circulating estradiol levels. Similarly, no placental changes were noted. These differences can be explained by the fact that the rat placenta is unable to produce estradiol whereas the placenta is the main source of estradiol maintaining pregnancy following implantation in guinea-pigs and humans. Despite the triazole fungicide-induced decrease in total circulating estrogen production, the local concentration of estradiol in the guinea pig placenta is sufficiently high to support normal maintenance and development in the fetal compartment. Therefore, the guinea-pig is a better model to assess prenatal toxicity of compounds inhibiting aromatase activity.

## **W** 1665 Regulatory Perspectives on Embryo-Fetal Developmental Studies: The Placenta in Pharmacological Studies and Toxicological Assessments.

L. Leshin. *US FDA, Silver Spring, VA.* Sponsor: C. Bowman.

In the safety assessment of bio/pharmaceuticals, a gross examination of the placenta is included as part of the *in vivo* embryo-fetal developmental toxicity study. Data from this study contribute to the risk assessment of drugs for use by patients of childbearing potential and during pregnancy. A more thorough evaluation of the placenta has the potential to contribute mechanistic information that could substantially inform the interpretation of study outcomes. Our knowledge of placental transport, metabolism, and immunology has increased dramatically since the development of the currently used regulatory practices and requirements. Closer examination of the placenta using various *in vitro* and *in vivo* approaches could provide a more complete understanding of drug effects on embryo-fetal development. With the progress made in understanding placental biology this critical multifunctional tissue can take on a more prominent role for improved pregnancy risk assessment.

## **IS** 1666 K-12 Toxicology Outreach Activities: Regional Chapter Successes and Resources.

C. E. Sulentic<sup>1</sup> and R. Ponce<sup>2</sup>. <sup>1</sup>*Pharmacology & Toxicology, Wright State University, Dayton, OH;* <sup>2</sup>*Amgen Inc, Seattle, WA.*

K-12 activities are a vital component in our mission to educate the community regarding hazards and hazard communication. Several regional SOT chapters have very active K-12 community outreach programs and others are interested in establishing these programs within their communities. Facilitating this type of outreach across all regional chapters is a tactical goal of the Regional Chapter Collaboration and Communication Committee (RCCCC) and the Education Committee. This goal ties directly into the SOT strategic plan of promoting recognition of toxicology and communicating the benefit of toxicology to external audiences. The 2011 Education Summit sponsored by SOT underscored the need for enhancing the perception of toxicology as a valuable discipline among scientists and nonscientists alike, which is vital to maintaining the discipline of toxicology and the pipeline of future toxicologists. Community outreach at the K-12 level is an important component in increasing the visibility and perceived importance of toxicology. Regional SOT chapters can be and have been a vital resource in facilitating outreach activities among the membership-at-large. This session will highlight some of the successful K-12 outreach activities supported by regional chapters and will include hands-on demonstrations, one organized and implemented by graduate students, as well as an overview of efforts to update website resources for K-12 activities. This session will also provide pedagogical insights helpful to those new to educational outreach. Promoting and facilitating K-12 activities by regional chapters has the added potential of greater graduate student and postdoc engagement and therefore increased opportunities for skill development and pedagogical background for those trainees considering academic careers.

## **IS** 1667 Totally Toxic! A K-12 Outreach Program Based on the 5E Model of Science Education.

C. P. Curran. *Biological Sciences, Northern Kentucky University, Highland Heights, KY.*

The Ohio Valley SOT (OVSOT) chapter developed an outreach program called "Totally Toxic!" to introduce middle and high school students to the fundamentals of toxicology. The program uses the Biological Sciences Curriculum Study (BSCS) 5E Model to Engage, Explore, Explain, Elaborate and Evaluate student understanding. Working in teams, students identify common toxins and toxicants in

their homes, learn about historic and recent poisonings then solve a toxic mystery. The "Strange Case of Jennifer Strange" is based on the true story of the water intoxication death of a California mother. The activities will be demonstrated, and the pedagogical advantages of the 5E model for science education will be discussed.

### **IS** 1668 Inspector Tox Outreach Activity.

D. Hardej<sup>1</sup> and A. Schatz<sup>2</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY; <sup>2</sup>Merck & Co., Whitehouse Station, NJ.

Inspector Tox was developed by the Mid-Atlantic SOT (MASOT) chapter as a means of introducing the basic concepts of toxicology to school aged children. This program includes Inspector Tox an investigator of harmful or toxic events and helps guide the audience through determining if several "toxic scenes" set in the house, backyard, and at the beach are relatively safe or dangerous. The various scenes are devised to introduce a mix of potentially toxic compounds including chemicals (pesticides), natural toxins (bee sting, poison ivy), UV radiation (sunlight), social/behavioral toxicants (alcohol, cigarette smoking, and poor diet), and even includes components that the audience might not initially recognize as toxic, such as food allergies (peanuts) and dust.

### **IS** 1669 Silly Science and Other Activities for K-12 Outreach.

M. M. Bourgeois. EOH, University of South Florida, CPH, Tampa, FL.

Activities to explore dose, toxicity and therapeutic windows of drugs will be demonstrated and include describing dosages using familiar measurements (i.e. tablets, teaspoons, medicine cups, glasses, buckets and kiddie pools) that are toxic by showing children the different amounts of specific household substances (water, salt, sugar, baby aspirin, etc.) necessary to do them harm.

### **IS** 1670 Exploring Toxicology: Designing Learning Goals and Evaluation Strategies for Outreach Activities.

E. Shanle and K. L. Blanke. Molecular and Environmental Toxicology Center, University of Wisconsin Madison, Madison, WI.

Molecular & Environmental Toxicology Center (METC) graduate students at the University of Wisconsin-Madison participate in toxicology outreach events to promote a better understanding of toxicology to the local community. METC currently has 37 graduate students, and 15 students (41%) have participated in at least one educational outreach activity over the past year. Two activities graduate students use to teach about toxicology are Carnation Intoxication and Tox Land. Carnation Intoxication uses colored dye added to the water of white carnations to show that plants can take up toxins from their environment along with water and nutrients. Learning goals for this activity are age dependent and include a basic understanding of toxicology and the concepts of bioaccumulation and experimental design. Tox Land is a game that takes participants on a path through global events related to toxicology while also highlighting local daily activities that have positive or negative effects on people, animals, and the environment. The learning goals for Tox Land are that participants are informed about global/local toxicologically relevant events. Both Carnation Intoxication and Tox Land are evaluated using survey questions that reflect the learning goals to assess what participants learn. Evaluations are used to improve activities in order to better inform the public about toxicology.

### **IS** 1671 Resources for Toxicology K-12 Education Outreach: Updating the SOT K-12 Website.

M. R. Gwinn. Office of Research & Development, US EPA, Washington DC.

The Society of Toxicology's Education K-12 Sub-Committee is updating the SOT website to increase support for K-12 education activities, share resources across the membership and with the public, and increase effectiveness in interacting with educators, parents and students. One main goal is to work with the Society membership to create the most useful resource website to help support excitement for toxicology through K-12 education outreach. Ideally, this website would be accessible to the public, easily searchable and contain hands-on activities, PowerPoint presentations and recommendations for increasing K-12 education outreach. Many SOT members are active in toxicology outreach, and many more would like to be but

don't know where to start. Working with Society members, the K-12 Sub-Committee will include links to successful activities, including past Annual Meeting activities and ongoing Regional Chapter outreach activities. This resource website will serve as a tool for those interested in getting involved in K-12 education outreach, as well as for those interested in learning more about what toxicologists do.

### **IS** 1672 The Regulatory Framework for Cosmetics: Current Status, Recent Science, and Future Prospects.

P. Wexler. Toxicology and Environmental Health Information Program, National Library of Medicine, Bethesda, MD.

Cosmetic products represent an immense global industry. It has been estimated that the \$60 billion cosmetics industry uses some 12,500 unique chemical ingredients in personal care products. These products and their chemical components are subject to varying degrees of regulation globally. In the US, the US FDA's regulatory authority over cosmetics is relatively minimal and different from that of other products regulated by the Agency, such as drugs, biologics, and medical devices. Although the US FDA can inspect cosmetic manufacturing facilities, respond to complaints of adverse reactions, and conduct research on cosmetics and their ingredients to address safety concerns, the Food, Drug, and Cosmetic Act does not subject cosmetics to US FDA premarket approval. The regulation of cosmetics in the European Union is considerably more stringent. A Safe Cosmetics Act of 2011 was introduced in the US House of Representatives in June, 2011, with the aim of ensuring that all personal care products are safe. It would establish labeling requirements and a safety standard, and issue guidance prescribing good manufacturing practices for cosmetics and ingredients. People, largely though not exclusively women, are exposed to vast quantities of cosmetics over their lifetimes. Compared with the safety of most other products, cosmetics are commonly believed to present a minimal, if any, risk, and are overlooked in discussions of hazardous substances. Are the regulations currently in place adequate? What is the US government's viewpoint? What is the stance of industry and advocacy groups on the cosmetics regulatory framework? How does the European Union handle issues involving the safety of cosmetics? Recent scientific issues surrounding production, safety, and testing of cosmetics could well influence the regulatory arena in years to come. These include 1) the increasing use of nanomaterials in cosmetic products and 2) computational and high-throughput alternative test methodologies. Both these topics will offer a backdrop to current and future regulatory approaches.

### **IS** 1673 Safety Evaluation of Nanoparticles and Skin.

N. A. Monteiro-Riviere. Anatomy and Physiology, Kansas State University, Manhattan, KS.

This presentation will review the physicochemical properties such as size, shape, coatings, vehicles and charge on skin penetration of nanoparticles (NP) that may enhance or prevent toxicity. There are properties of a chemical/ NP that determines its propensity to cause dermatotoxicity, which is the ability to penetrate skin and subsequently interact with biological components that could elicit a toxicological response. Recent advances of NP in consumer products such as cosmetics indicate safety concerns. Penetration of NP in skin is a controversial subject, partly because many factors that influence absorption were not studied and opinions of some investigators were generalized and based on limited studies of a few NP, many on large particles and not nanosize. Discrepancies may relate to differences in NP composition, surface chemistry, vehicles or solvents, techniques and methods of exposure, and analytical analysis, and duration of the experiment. This review will show how formulation, surface chemical alterations and mechanical stressing of skin and species can modulate the results.

### **IS** 1674 US EPA Computational Toxicology Predicting Cancer and Noncancer Outcomes for Cosmetics and Industrial Chemicals.

N. Kleinstreuer. National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

EPA's Computational Toxicology Research Program (CompTox), part of the broader Chemical Safety for Sustainability Research Program, is at the forefront of a major transformation in the field of toxicology in how chemicals are evaluated for potential effects on human health and the environment. EPA is partnering with the cosmetics company L'Oréal, pharmaceutical companies, European regulatory authorities, and other U.S. government agencies to research ways CompTox can decrease the cost of testing large numbers of chemicals, reduce animal use, identify

targeted testing strategies, and understand potential mechanisms of toxicity. Broad compound libraries may be screened and prioritized using rapid, automated high-throughput screening (HTS) assays with human gene and protein targets. Multiple HTS assay targets, e.g. chemokine expression in human primary skin cells, are highly relevant to cosmetics safety assessments. CompTox has already screened more than 1,000 chemicals in over 650 HTS assays in the ToxCast ("toxicity forecaster") research program, including many key ingredients in personal care products, fragrances, and cosmetics. The L'Oréal partnership provides collaborative research funding and access to existing cosmetics ingredients safety data, which are compared to the ToxCast results to determine the utility of CompTox tools in the safety assessment of chemicals in cosmetics. CompTox research has also developed predictive models for cancer and non-cancer toxicity endpoints, with a focus on the molecular and cellular pathways that are the targets of chemical interactions. Using computational approaches, EPA is building decision support tools based on ToxCast in vitro HTS results to help prioritize cosmetics chemicals for further investigation, as well as applying and refining predictive models for a number of adverse health outcomes. This abstract does not necessarily represent EPA policy.

## **IS 1675 Cosmetics—US FDA Regulatory Perspectives.**

P. A. Hansen. *Office of Cosmetics and Colors, US FDA, College Park, MD.* Sponsor: P. Wexler.

The two most important laws pertaining to cosmetics marketed in the United States are the Federal Food, Drug, and Cosmetic Act (FD&C Act) and the Fair Packaging and Labeling Act (FPLA). The presentation will cover the specific legal authorities granted to FDA under these two laws and the regulatory tools FDA uses to implement them. These regulatory tools include regulations, guidance, inspections, import monitoring, and other programs. The presentation will also cover other activities important to the oversight of cosmetic safety, such as FDA's Voluntary Cosmetic Registration Program, the agency's adverse event monitoring systems, outreach to consumers and health professionals, and more. The role of FDA's research and other scientific efforts will be discussed. Examples of recent activities in areas important to cosmetic safety will be highlighted. Additional authorities that have been suggested for strengthening FDA's monitoring of cosmetic safety and labeling will also be presented.

## **IS 1676 Assessing the Safety of Cosmetics in the US.**

H. Breslawec. *Personal Care Products Council, Washington DC.* Sponsor: P. Wexler.

Cosmetics in the United States have been regulated under the same legal framework for almost 75 years. The Cosmetic Safety Amendments Act of 2012 proposes to modernize the existing regulatory framework, and the proposed provisions in that legislation will be discussed. The responsibility for the pre-market assessment of the safety of cosmetics prior in the US, as in the EU, rests with the manufacturers. This presentation compares the US regulatory system with that in the EU and discusses how the industry assesses the safety of cosmetic ingredients and products. The Cosmetic Ingredient Review (CIR) Expert Panel, an independent group of dermatologists, toxicologists and other scientists who have, for over 35 years, assessed the safety of cosmetic ingredients in an open and public manner. The CIR is funded by the industry, but operates independently in a transparent manner. Current issues of interest in safety evaluation of cosmetic ingredients and products, will be discussed.

## **IS 1677 Safety Evaluation of Cosmetics and Their Ingredients in Europe: New Challenges Ahead.**

V. Rogiers. *Toxicology, Dermato-Cosmetology and Pharmacognosy, Vrije Universiteit Brussel, Brussels, Belgium.* Sponsor: P. Wexler.

Cosmetic products present on the European market must be safe for the consumer. In Europe, product safety is based on the safety of the ingredients (chemical structure, toxicological profile, exposure) and is the responsibility of the manufacturer, first importer or marketer. In July 2013, the EC Regulation n°1223/2009 will replace in all Member States the well-known Cosmetic Directive 76/768/EEC with its important sixth and seventh amendments. Under this RECAST, a so-called responsible person gets a key function in the follow-up of the safety of the products under consideration. This is not an easy task as the safety of cosmetics and their ingredients has to be guaranteed by the use of in vitro methods, replacing experimental animal testing. In the EU, during the last years the 3R principle (Refinement, Reduction, Replacement) of Russell and Burch has been implemented in the specific legislation of several types of products, including chemicals, pesticides, pharmaceuticals, food additives, ... but the cosmetics legislation is the only one in the world allowing only replacement methods, which additionally need to be validated.

Therefore, complete banning of animal testing of cosmetics and their ingredients has a tremendous impact with far reaching consequences. This presentation will cover the safety assessment process of cosmetics and their ingredients and the changes that have been introduced by shifting from legislation to a regulation (including special considerations for CMRs, nanomaterials...). Also, the actual status of validated in vitro methods will be given and the prospective for the near future will be discussed.

## **IS 1678 Cosmetics: Health Risks, Choices, and Opportunities for Change.**

S. Lunder. *Environmental Working Group, Washington DC.* Sponsor: P. Wexler.

The \$60 billion cosmetics industry relies on over 8,000 unique ingredients to produce tens of thousands of products sold in the U.S. Women use an average of 12 products daily, with an average of 167 ingredients, and men use about half that. Products go on skin, lips, hands and around eyes. Consumers ingest, inhale, and dermally absorb ingredients, in various amounts. Biomonitoring studies have established that cosmetic chemicals are common pollutants in blood and urine. Are these exposures safe? FDA regulates the cosmetic industry, but lacks the authority to require premarket testing, review products before they are sold, or recall products known to pose risks. Lacking a mandatory safety standard for cosmetics, the industry makes its own determinations about what is safe enough for consumers. But recent studies have detected lead, formaldehyde and other hazardous compounds in some everyday cosmetic products. And many other ingredients are poorly tested, or show no toxicity information at all in the public scientific literature. With the industry under growing scrutiny and pressure, change is in progress. Consumer awareness is on the rise, some companies are removing ingredients of greatest concern, and Congress has introduced legislation to modernize cosmetics safety regulations.

## **PL 1679 The DNT-EST: A Predictive Embryonic Stem Cell Test for Developmental Neurotoxicity Testing In Vitro.**

A. E. Seiler, K. Gulich, K. Hayess, R. Pirow, B. Slawik, M. Steinfath, C. Riebeling, A. Visan and A. Luch. *ZEBET, Federal Institute for Risk Assessment, Berlin, Germany.* Sponsor: E. Fritsche.

Disturbances and diseases of the brain and nervous system such as attention-deficit hyperactivity disorder, dyslexia, sensory deficits, mental retardation, autism-like disorders, learning disabilities, and cerebral palsy has also put the vulnerability of the developing human brain to environmental chemicals exposure into the focus of public awareness. Most of the chemicals on the market have not been evaluated for their toxic potency, an issue now being addressed by the registration, evaluation and authorization of chemicals (REACH) legislation of the European Union. In order to answer the increasing need for toxicity testing, the development of reliable methods ensuring a higher throughput than the currently available test guidelines became a main issue of risk assessment. One of the key aspects in this context is the application of alternative, non-animal approaches including in vitro test methods. Recently, we developed a new in vitro assay using mouse embryonic stem cells (mESC) to predict adverse effects of chemicals and other compounds on neural development - the so-called DNT-EST. After treatment of differentiating stem cells for 48 h or 72 h at two key developmental stages, endpoints for neural differentiation, viability and proliferation were assessed. As a reference we treated undifferentiated stem cells 2 days after plating for 48 h or 72 h in parallel to the differentiating stem cells, also measuring viability and proliferation. Here, we show that chemical testing of a training set comprising nine substances (six substances of known developmental toxicity and three without specific developmental neurotoxicity) enabled a mathematical prediction model to be formulated that can discriminate positive from negative DNT compounds with an in vivo - in vitro concordance of 100%. Thus, the mESC model introduced here might represent a useful tool for predicting adverse health effects of exogenous agents that affect brain development.

## **PL 1680 Identification of Pathways of Developmental Neurotoxicity for High-Throughput Testing by Metabolomics.**

H. T. Hogberg<sup>1</sup>, M. Bouhifd<sup>1</sup>, T. Dao<sup>1</sup>, A. Kleensang<sup>1</sup>, S. J. Nolan<sup>1</sup>, S. Odwin-DaCosta<sup>1</sup>, L. Smirnova<sup>1</sup>, E. van Vliet<sup>2</sup>, H. Welles<sup>1</sup>, L. Zhao<sup>1</sup> and H. Thomas<sup>1</sup>.  
<sup>1</sup>The Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD;  
<sup>2</sup>University of Barcelona, August Pi i Sunyer Biomedical Research Institute, Barcelona, Spain.

Tox-21c proposed a paradigm shift in the field of toxicology. Instead of relying on traditional animal experiments, the report proposes the application of the latest advances in science and technology to develop more relevant test strategies. An area of

toxicology where Tox-21c could have a significant impact is developmental neurotoxicity (DNT). There is concern that exposures to environmental chemicals contribute to the increasing incidence of neurodevelopmental disorders in children. However, due to lack of DNT studies only very few substances have been identified as developmental neurotoxicants.

This study aimed to develop an *in vitro* approach using metabolomics and gene expression for DNT assessment. A 3D rat primary neuronal organotypic model was exposed from day 7 up to 21 to suspected (developmental) neurotoxicants including pesticides (carbaryl, chlorpyrifos, lindane maneb), drugs (fluconazole, isotretinoin, phenytoin, terbutaline, valproic acid) and metals (CaCl<sub>2</sub>, PbCl<sub>2</sub>). Mass spectrometry based metabolomics measurements and quantitative measurement of genes expressed in different cell types (neural precursor cells, neurons and glial cells) were performed. Treatment with the different compounds significantly modified the expression of selected genes, related to the different stages of neuronal and/or glial cell development and maturation. Moreover, the mass spectrometry analysis showed differences in metabolite levels between control and treated cells. Further analysis of the altered metabolites could give mechanistic insight into the DNT of these compounds. This study demonstrates that gene expression and metabolomic analysis can be sensitive endpoints for DNT assessment. Funded by the Swedish Research Council and the FDA

#### **PL 1681 Reduced Nrf2 Signaling Contributes to Human Neuroprogenitor Cell (hNPC) Aging.**

E. Fritsche, J. Schuwald, S. Giersiefer and K. Gassmann. *IUF, Duesseldorf, Germany.*

During the normal brain aging process, neural progenitor cells (NPC) lose their capacities to proliferate and differentiate into neurons, which is associated with age-related impairment of cognitive functions. Molecular mechanisms causing NPC aging are unknown and also effects of chemicals, which might induce extrinsic brain aging are so far enigmatic. One common mechanism, however, well known to be involved in cellular aging processes, is oxidative stress. As a wide variety of toxicants cause cell damage through their ability to elicit oxidative stress, this study tests the hypothesis if changes in the oxidative stress response contributes to NPC aging. Therefore, young (1-2 months in culture (MIC)) and aged (3-9 MIC) human NPCs, which grow as neurospheres, were studied for their abilities to proliferate and differentiate into neurons. Moreover, their capabilities to activate the nuclear factor erythroid 2-related factor2 (Nrf2) pathway and thus respond towards oxidative stress were investigated. Finally, Nrf2 was knocked down via lentiviral transduction.

Our data indicate that aged neurospheres reproduce the aging phenotype observed in brains *in vivo*: NPC proliferation and the potential to differentiate into neurons is decreased. Moreover, 'old' NPC accumulate beta-galactosidase, which is an established aging marker. With regard to the antioxidant defense, young and old NPCs express mRNA for the transcription factor (Nrf2). However, Nrf2 protein is not induced in old NPCs challenged with H<sub>2</sub>O<sub>2</sub> or tetrachlorohydroquinone (TCHQ) like it is in young cells. As a consequence, the Nrf2 downstream targets superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) are not up-regulated in aged NPCs either. Knocking down Nrf2 indicates that NPC proliferation and neuronal differentiation are dependent on sufficient Nrf2 signaling.

#### **PL 1682 Effect of Organophosphorus Flame Retardants on Neuronal Development *In Vitro*.**

W. Mundy<sup>1</sup>, T. Freudenrich<sup>1</sup>, K. Wallace<sup>1</sup> and M. Behl<sup>2</sup>. <sup>1</sup>ISTD, US EPA, Research Triangle Park, NC; <sup>2</sup>Kelly Government Solutions, NTP/NIEHS, Research Triangle Park, NC.

The increased use of organophosphorus compounds as alternatives to brominated flame retardants (BFRs) has led to widespread human exposure. There is, however, limited information on their potential health effects. This study compared the effects of nine organophosphorus flame retardants (OPFs) with the BFR tetrabromobisphenol A and the known developmental neurotoxicants Pb and t-retinoic acid on neuronal proliferation and neurite outgrowth *in vitro*. Proliferation was assessed in human stem cell-derived neuroprogenitor (hNP1) cells after a 24 hr exposure by counting the number of cells incorporating BrdU. Neurite outgrowth was assessed in human stem cell-derived (hN2) neurons and rat primary cortical neurons after 48 hr of exposure by measuring the length and branching of neurites labeled with  $\beta$ III-tubulin antibody. Cytotoxicity was estimated by total cell counts. Cells were cultured and exposed to chemicals (0.003 to 30  $\mu$ M) in 96-well plates and endpoints quantified using the Cellomics ArrayScan high content imager. In hNP1 cells, Pb, t-retinoic acid, tetrabromobisphenol A and a majority of the OPFs were cytotoxic at concentrations > 3  $\mu$ M; however, tricresyl phosphate and triphenyl phosphate both decreased proliferation at 30  $\mu$ M in the absence of cytotoxicity. In

hN2 cells OPFs, tetrabromobisphenol A and t-retinoic acid decreased neurite outgrowth only at cytotoxic concentrations, while Pb decreased neurite outgrowth in the absence of cytotoxicity. Rat neurons were less sensitive than hN2 cells in that no chemical was cytotoxic at the concentrations tested; however, tricresyl phosphate, t-butylphenyl diphenyl phosphate, isodecyl diphenyl phosphate, and isopropylated phenyl phosphate decreased neurite outgrowth at 30  $\mu$ M. These data suggest that some OPFs have the ability to affect neurodevelopmental processes *in vitro* at micromolar concentrations, and that human neurons may be more sensitive compared to rats. *This abstract does not necessarily reflect U.S. EPA policy.*

#### **PL 1683 PCB 95-Induced Dendritic Growth in Primary Cultures of Rat Hippocampal Neurons Is Dependent on mTOR Activation.**

G. W. Miller, H. Chen and P. J. Lein. *Molecular Biosciences, University of California Davis, Davis, CA.*

Despite being banned since the late 1970s, polychlorinated biphenyls (PCBs) remain persistent environmental toxicants that pose significant risk to the developing nervous system. We recently demonstrated that the non-dioxin-like PCB 95 alters neuronal connectivity by promoting dendritic arborization in cultured hippocampal neurons via ryanodine receptor (RyR)-mediated, transcriptionally driven mechanisms. PCB 95 sensitizes RyR and this interaction requires FKBP12. Interestingly, FKBP12 also regulates mammalian target of rapamycin (mTOR), and the mTOR signaling pathway enhances dendritic growth via increased protein synthesis. Based on these observations, we hypothesize that mTOR signaling contributes to the dendrite promoting activity of PCBs. To test this hypothesis, primary cell cultures dissociated from hippocampi of wildtype (Sprague Dawley) postnatal rats were plated at high density and exposed to PCB 95 (2,2',3,5'-pentachlorobiphenyl, 20 pM – 2 nM) in the absence or presence of rapamycin. Exposure to PCB 95 from days 7 to 9 *in vitro* increased dendritic growth in pyramidal hippocampal neurons in a concentration-dependent manner. Simultaneous exposure to rapamycin at 20 nM, a concentration that inhibits mTOR activation, ameliorated the dendrite promoting activity of PCB 95. Ongoing studies are confirming that PCB 95 activates the mTOR signaling pathway implicated in dendritic growth, and determining whether these effects are RyR-dependent. These findings identify a novel mechanism by which low level exposures to non-dioxin-like PCBs cause developmental neurotoxicity, and perhaps dysfunction of other cell types, such as immune cells, whose function is heavily dependent on mTOR signaling. Supported by NIH grants R01 ES014901 and P42 ES04699.

#### **PL 1684 Diazinon and Diazoxon Impair Glial-Neuronal Interactions and Production of Neuritogenic Proteins in Primary Astrocytes.**

D. M. Pizzurro<sup>1</sup>, G. Giordano<sup>1</sup> and L. G. Costa<sup>1,2</sup>. <sup>1</sup>Department of Environmental and Occupational Health Sciences, University of Washington Seattle, Seattle, WA; <sup>2</sup>Department of Neuroscience, University of Parma Medical School, Parma, Italy.

Many organophosphorus insecticides (OPs) are increasingly recognized as developmental neurotoxicants. However, the mechanisms by which they exert their neurotoxicity remain unclear. This project focuses on a widely-used OP, diazinon (DZ), and its active metabolite, diazoxon (DZO), and their potential to impair astrocytes' ability to foster neuronal development. We have previously shown that astrocytes play a major role in fostering neurite outgrowth in neurons; in this project, a 50% decrease in the longest neurite length was observed in primary hippocampal neurons incubated with primary astrocytes previously exposed to 10  $\mu$ M DZ or DZO. We have also shown that this effect is largely mediated by increased oxidative stress in astrocytes that results from exposure to DZ or DZO. To further elucidate how these compounds adversely affect astrocytes and disrupt normal glial-neuronal interactions, levels of the pro-neuritogenic extracellular matrix proteins fibronectin and laminin were evaluated by Western blot analysis and confocal microscopy. Fibronectin and laminin have been extensively shown to play a vital role in a variety of neurodevelopmental processes, including neurite outgrowth and differentiation. At the same concentrations that significantly inhibit neurite outgrowth, both DZ and DZO cause a 30-40 % decrease in fibronectin and laminin protein levels in astrocytes. These decreases are prevented by astrocyte pre-treatment with the antioxidants melatonin and N-t-butyl-alpha phenylnitron (PBN), further supporting the role of oxidative stress in the mechanism of neurotoxicity. These findings were confirmed by confocal microscopy analysis of extracellular fibronectin expression, which showed a 40% decrease after exposure to DZ or DZO. These results suggest that DZ and DZO impair neuronal development by adversely affecting astrocyte production and secretion of important neuritogenic factors.

**PL 1685 Increased Oxidative Stress and Mitochondrial Dysfunction in a PARK2-Mutant iPSC Model of Environmental Risk in Parkinson's Disease.**

A. Aboud<sup>1</sup>, A. M. Tidball<sup>1</sup>, K. K. Kumar<sup>1</sup>, B. Han<sup>1</sup>, G. G. Li<sup>1</sup>, K. M. Erikson<sup>2</sup>, P. Hedera<sup>1</sup>, M. Neely<sup>1</sup>, K. C. Ess<sup>1</sup> and A. B. Bowman<sup>1</sup>. <sup>1</sup>Neurology, Vanderbilt University, Nashville, TN; <sup>2</sup>University of North Carolina Greensboro, Greensboro, NC.

Interactions of environmental and genetic risk factors for Parkinson's disease (PD) are believed to modify disease onset and progression in a patient-specific manner. We sought to examine such interactions by assessing sensitivities of neural progenitor cells (NPCs) differentiated from human induced pluripotent stem cells (iPSCs) to PD-relevant environmental toxicants. These iPSCs were derived from a patient (SM) with biallelic PARK2 mutations and preclinical PD as assessed by DaTScan, and from healthy control subjects (CA and CB). Mn exposure resulted in significantly higher ROS generation in SM than CA NPCs, but no difference in cytotoxicity or mitochondrial fragmentation was observed. Moreover, we found that SM NPCs accumulate significantly less intracellular Mn than CA NPCs. These results indicate heightened susceptibility of SM NPCs to Mn given the higher rate of ROS generation and the comparable cytotoxicity and mitochondrial fragmentation in the presence of significantly less intracellular Mn. While the accumulation of Cu was not different between SM and CA NPCs, it induced significantly greater ROS generation, loss of mitochondrial function and cytotoxicity in SM than CA NPCs. These differences in Cu exposure-associated phenotypes were not observed in the primary fibroblasts used to generate the iPSC lines. Given the role of PARK2 in mitochondrial integrity, heightened sensitivity of SM NPCs to manganese and copper may be due to suboptimal mitochondrial function in cells that lack functional PARK2. Our results support the hypothesis that genetic alterations may increase sensitivity to specific toxicants. We demonstrate here that iPSC technology can detect patient-specific and cell type-specific differences in vulnerability to PD environmental risk factors. Support: NIH ES016931 and NS078289

**PS 1686 Evaluation of the Ames II and 96-Well *In Vitro* Flow Micronucleus (MN) Assay Using 25 ToxCast™ Chemicals.**

M. Aardema<sup>1</sup>, A. D. Kligerman<sup>2</sup>, K. Houck<sup>1</sup>, R. R. Young<sup>3</sup>, L. F. Stankowski<sup>3</sup>, K. Pant<sup>3</sup> and T. E. Lawlor<sup>3</sup>. <sup>1</sup>Marilyn Aardema Consulting; Chief Scientific Advisor Toxicology BioReliance by SAFC, Fairfield, OH; <sup>2</sup>US EPA Office of Research and Development, Research Triangle Park, NC; <sup>3</sup>BioReliance by SAFC, Rockville, MD.

ToxCast™ is a multi-year effort to develop a cost-effective approach for the US Environmental Protection Agency to prioritize thousands of chemicals that need toxicity testing. Initial evaluation of more than 650 high-throughput, robotic, microwell-based endpoints with little or no metabolic activation showed that most of these assays lacked specificity and sensitivity for detecting direct-acting genotoxins. In an attempt to understand how to improve this approach for genotoxicity testing, we evaluated the specificity and sensitivity of 25 selected Phase I and Phase II chemicals from the ToxCast™ program using standard genotoxicity endpoints. These chemicals were chosen because of their known genotoxicity, their responses in specific ToxCast™ assays, or available data from the literature and databases. The tests used were the medium throughput Ames II and in vitro flow MN assays conducted ±S9. Results to date indicate that, as expected, the Ames II assay showed an excellent correlation with published data and industry submissions. Overall concordance was 89 and 82% (with and without S9, respectively). The MN assay also had good concordance of 78 and 73% (with and without S9, respectively); however, the number of conclusive calls was significantly smaller mainly due to concentrations limits and cytotoxicity. Chemicals were also tested in a 96-well in vitro single cell gel electrophoresis (Comet) assay though there were insufficient data from the literature to evaluate performance of this assay. Taken together, these studies offer a promising approach to higher throughput genotoxicity testing. [This is an abstract of a proposed presentation and does not necessarily reflect US EPA policy.]

**PS 1687 The Role of DNA Polymerase Eta in Oxidative Stress Response and Mutagenesis.**

K. N. Herman and S. D. McCulloch. Toxicology, North Carolina State University, Raleigh, NC.

Oxidative stress is induced by exposure to chemicals and radiation such as heavy metals, pesticides and ultraviolet exposure from sunlight. Oxidative stress leads to elevated levels of reactive oxygen species (ROS), which in turn can produce DNA lesions including 8-oxoguanine (8-oxoG). 8-oxoG has been linked to mutagenesis, cancer and aging. One way cells respond to this damage is translesion synthesis

(TLS), most often by Y family DNA polymerases. Y-family polymerases have open active sites, allowing them to copy past DNA adducts that otherwise block replication. DNA polymerase eta (pol η) is known to bypass cyclobutane pyrimidine dimers (CPD); more recently, pol η has been shown to bypass 8-oxoG. Intriguingly, while in vitro bypass of 8-oxoG by pol η appears to occur with nearly 50% error rate, in vivo experiments suggest it acts to suppress mutagenesis, similar to CPD. This apparent discrepancy has not been fully explained.

Due to the ability of pol η to bypass 8-oxoG very efficiently but with poor fidelity in vitro, we investigated pol η response in cells to oxidative-stress-induced DNA damage. We have demonstrated that pol η acts as a suppressor of oxidative stress-induced mutagenesis, likely due to bypass of 8-oxoG. We examined both pol η-expressing and -deficient cells and evaluated cell responses to various ROS-inducing treatments. We evaluated the cytotoxicity of these treatments and found that while pol η did not greatly alter cell survival, the mutation rate of surviving cells was markedly decreased when measured using hypoxanthine phosphoribosyl transferase (HPRT) mutation assay; showing the presence of pol η suppresses mutations compared to deficient cells. The measured mutation rates varied depending on the treatment used, possibly due to variation in the types and levels of different lesions generated by each. In total, the results demonstrate that pol η acts to suppress oxidative stress-induced mutations, suggesting that polymerase fidelity in vitro data is only part of the larger picture of lesion bypass.

**PS 1688 Different Micronucleus Induction of Mice Exposed to N-Ethyl-N-Nitrosourea at Light and Dark Dosing Times.**

K. Ito<sup>1,2</sup>, S. Masumori<sup>1</sup>, M. Nakajima<sup>1</sup>, M. Hayashi<sup>1</sup>, H. Sakakibara<sup>3</sup> and K. Shimoi<sup>2,4</sup>. <sup>1</sup>Public Interest Incorporated Foundation Biosafety Research Center, Iwata, Japan; <sup>2</sup>Graduate School of Integrated Pharmaceutical and Nutritional Sciences, University of Shizuoka, Shizuoka, Japan; <sup>3</sup>Graduate School of Agriculture, University of Miyazaki, Miyazaki, Japan; <sup>4</sup>Institute for Environmental Sciences, University of Shizuoka, Shizuoka, Japan.

Mammals, including human beings, have a circadian clock system to regulate behavioral and physiological processes. In this study, we investigated the effect of dosing time on micronucleus induction in the bone marrow by evaluating the frequencies of micronucleated peripheral reticulocytes (MNRETs) in mice exposed to N-ethyl-N-nitrosourea (ENU) to assess any difference in genotoxic sensitivity to chemicals between light and dark periods (inactive phase/sleep phase for rodents and active phase/awake phase for rodents). Nine-week-old male C3H/HeJ mice were treated intraperitoneally with ENU (12.5 or 25 mg/kg body weight) at zeitgeber time (ZT) 3 in the light period or ZT15 in the dark period, and then the time courses of the frequencies of the MNRETs were determined. The frequencies of the MNRETs induced by ENU increased time-dependently and peaked at 48 hr after treatment for ZT3 and ZT15, and were obviously higher in the ZT15 treatment group than the ZT3 treatment group. The MNRETs were measured at 48 hr after treatment with ENU (25 mg/kg body weight) at various dosing times (ZT0, 3, 6, 12, 15 and 18). The frequencies of the MNRETs in mice treated at ZT0, 15 and 18 were significantly higher than those in mice treated at ZT3, 6 and 12. These results suggest that genotoxic sensitivity to ENU in mouse bone marrow is different between light and dark periods maybe due to different biological responses (detoxification, cell cycle, DNA repair, etc.) related to circadian rhythms. The results in this study also suggest that varying treatment time points may change the toxicological activity of chemicals.

**PS 1689 The Use of Immunofluorescent Techniques in the CB Human Lymphocyte Micronucleus Test for Discrimination of Clastogenic and Aneugenic Compounds.**

A. Poth and S. Bohnenberger. Genotoxicity and Alternative Toxicology, Harlan Cytotest Cell Research, Rossdorf, Germany.

The micronucleus assay in human lymphocytes was developed as a short term screening test for the detection of both clastogenic and aneugenic chemicals. For human lymphocytes it is recommended to score micronuclei by the cytokinesis block (CB) method using cytochalasin B. The original method developed by Fenech and Morley, 1985, focusses exclusively on binucleated cells. However, recent studies suggest that micronuclei in mononucleated cells could provide complementary information. Results obtained with aneugenic compounds show a dose-dependent increase of micronuclei in mononucleated cells. At present, the underlying mechanism has not been clearly identified. In order to obtain more information a immunofluorescence technique was employed involving CREST analysis for detection of kinetochore proteins. As reference positive controls, Ethylmethanesulfonate (EMS) and Mitomycin C (MMC) were used as clastogenic

compounds and Colcemide as an aneugenic compound. Both, MMC and EMS exert a clastogenic activity which lead to a dose-dependent increase in micronucleus-positive binucleates only. In contrast treatment with colcemide resulted in an increase in micronuclei in both mononucleated and binucleated cells. The high level of CREST+ micronuclei in mononucleated cells suggest that polyploid cells which have undergone an incomplete endomitosis might be the case. Our results suggest that micronuclei in mononucleated cells can be used to investigate the aneugenic activity of chemicals in a fast and easy way, and can be included in the CB assay with human lymphocytes.

## PS 1690 Induction of Nucleotide Excision Repair Is Diminished in Heterozygous p53 Knockout Mice following Chronic Dietary Exposure to Aflatoxin B<sub>1</sub>

J. E. Mulder<sup>1</sup>, R. Mehta<sup>2</sup>, G. S. Bondy<sup>1</sup> and T. E. Massey<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Queens University, Kingston, ON, Canada; <sup>2</sup>Toxicology Research Division, Health Canada, Ottawa, ON, Canada.

Aflatoxin B<sub>1</sub> (AFB<sub>1</sub>) is produced by *Aspergillus* species, moulds that grow on grains, oilseeds and spices. AFB<sub>1</sub> is biotransformed *in vivo* into a highly reactive metabolite that binds to DNA, forming DNA adducts that may induce cancer if not repaired. p53 is a tumour suppressor gene implicated in both AFB<sub>1</sub> carcinogenesis and the regulation of DNA repair. Male heterozygous p53 knockout mice (p53 (+/-); B6.129-*Trp53*<sup>tm1Brd</sup>/N5, Taconic) and their wild type controls were exposed to 0, 0.2 or 1.0 ppm AFB<sub>1</sub> in AIN 93M semi-purified diet for 26 weeks. Nucleotide excision repair (NER) activity of lung and liver nuclear protein extracts was assessed with an *in vitro* assay, using adducted plasmid DNA as a substrate. In wild type mice, repair of AFB<sub>1</sub>-N<sup>7</sup>-Gua adducts was 124% and 96% greater than control in lung extracts from mice exposed to 0.2 ppm or 1.0 ppm AFB<sub>1</sub> respectively, and 224% greater than control in liver extracts from mice exposed to 0.2 ppm AFB<sub>1</sub> (p<0.05). In p53(+/-) mice, repair of AFB<sub>1</sub>-N<sup>7</sup>-Gua was only 45% greater than control in extracts from lungs of mice exposed to 0.2 ppm AFB<sub>1</sub> (p<0.05), and no difference was observed in extracts from lungs of mice treated with 1.0 ppm AFB<sub>1</sub> or extracts from livers of mice treated with either AFB<sub>1</sub> concentration. When comparing AFB<sub>1</sub> effects on NER activity after normalizing to untreated tissue, the induction of NER activity was significantly attenuated in p53(+/-) mice compared to wild type controls in both lung and liver, and AFB<sub>1</sub> dose had a significant effect in p53(+/-) mice. In conclusion, the increase in NER activity seen in wild type mice following chronic AFB<sub>1</sub> exposure indicates a homeostatic response to DNA damage. This homeostatic response was diminished or lost in p53(+/-) mice, which is consistent with p53 having a key role in regulating NER. (Supported by CIHR Grant No. MOP- 89698 and GRDI)

## PS 1691 XPC Haplotypes Alter Nucleotide Excision Repair and Levels of UV-Induced Genetic Damage.

C. M. Rondelli<sup>1,2</sup>, C. J. Etzel<sup>3</sup>, C. E. Cross<sup>2</sup>, M. Xu<sup>2</sup> and S. Z. Abdel-Rahman<sup>2</sup>. <sup>1</sup>Cell Biology & Environmental Toxicology, University of Texas Medical Branch, Galveston, TX; <sup>2</sup>Obstetrics and Gynecology, University of Texas Medical Branch, Galveston, TX; <sup>3</sup>Epidemiology, MD Anderson Cancer Center, University of Texas, Houston, TX.

The XPC protein encoded by the polymorphic XPC gene is essential for initiating global genome nucleotide excision repair (NER). Over 90 single nucleotide polymorphisms (SNPs) have been reported in XPC, but only a few were evaluated as disease risk modifiers with conflicting results. SNPs do not exist as independent variants in the genome but as combinations forming specific haplotypes due to linkage disequilibrium (LD) between them. The impact of XPC haplotypes on DNA repair capacity (DRC) is not known. Using bioinformatics, we recently determined the haplotype structure of XPC and found a correlation between XPC haplotypes and genetic damage in smokers. In this study we test the hypothesis that XPC haplotypes influence DNA damage by altering NER capacity through modifying transcription and/or translation. To test this hypothesis, we exposed human lymphoblastoid cell lines representing different XPC haplotypes to low UV dose to induce pyrimidine-6-4-pyrimidone photoproducts (6-4PPs) and cyclopuridine dimers (CPDs) formation. Levels of these adducts (reflecting DNA damage) and their rate of removal over time (representing DRC of the cells) were determined to evaluate the effect of XPC haplotypes on NER. We found that XPC haplotypes do not only influence NER, but that the haplotype influence is affected by the adduct being repaired. To provide a mechanistic explanation to our findings, we determined XPC mRNA and protein expression levels in different cell lines as a function of time after exposure. Our data indicate that XPC haplotypes significantly influence the rate of translation and transcription. Additional in-depth mechanistic

studies examining the effects of haplotypes on XPC transcription, translation, and function are currently in progress to clarify the role of XPC haplotypes in disease risk. (Supported by F31-019053; T32-07454; P30-006676; K07-CA093592; CA123208.)

## PS 1692 Evaluation of High-Throughput Mutation Test with Proprietary Pharmaceutical Candidates.

H. Adachi, K. Kijima, T. Yamada, J. Kimura and H. Funabashi. Dainippon Sumitomo Pharma Co., Ltd., Osaka, Japan.

[Background] High-Throughput Fluctuation Test (HTFT) is a bacterial gene mutation assay in *Salmonella typhimurium* with the same endpoint as that of the Ames assay. HTFT requires only a few mg of a test sample for the assay, which makes it possible to incorporate the assay into an early drug developmental stage. It is reported that the results in HTFT have a high concordance with the Ames assay results for well-known positive and negative control compounds. In the present study, to assess the availability of the test to early drug screening, we tested our proprietary pharmaceutical candidates in HTFT.

[Method] HTFT was performed for 47 our proprietary pharmaceutical candidate compounds in TA100 and TA98 with and without metabolic activation system prepared from rat liver (S9). Most of the compounds tested in this study were predicted as not having any obvious structural alerts for mutagenicity by a commercially available *in silico* system, DEREK for Windows. Microplates were used during the pre-incubation and incubation period, and mutation was detected with a pH indicator, which reflects the bacterial growth in medium. All the test compounds were also evaluated in the conventional Ames assay using five strains and the results were compared with HTFT results.

[Results and Discussion] The sensitivity (the proportion of positives in Ames assay correctly identified by HTFT), specificity (the proportion of negatives in Ames assay correctly identified by HTFT) and the concordance between the both assay results for a total of 47 test compounds were 88% (23/26), 86% (18/21) and 87% (41/47), respectively. In conclusion, the results of the present study indicate that HTFT is a reliable assay with a high sensitivity and specificity for detecting genotoxic compounds even among pharmaceutical candidates without obvious mutagenic structural alerts as well. Considering the advantages with respect to the amount of required sample and potential throughput capacity, HTFT is therefore thought to be a good screening tool for genotoxicity in the earlier drug screening.

## PS 1693 Establishment of the Comet Assay and Micronucleus Test Using Chimeric PXB-Mice® with Humanized Liver.

C. Tateno<sup>1,2</sup>, Y. Ishida<sup>1,2</sup>, M. Kakuni<sup>1</sup>, M. Fukumuro<sup>3</sup>, J. Tanaka<sup>3</sup>, S. Masumori<sup>3</sup>, M. Nakajima<sup>3</sup> and M. Hayashi<sup>3</sup>. <sup>1</sup>PhoenixBio Co., Ltd., Higashihiroshima, Japan; <sup>2</sup>Liver Research Project Center, Hiroshima University, Hiroshima, Japan; <sup>3</sup>Public Interest Incorporated Foundation, Biosafety Research Center, Iwata, Japan.

Genotoxicity studies have been performed as *in vitro* screening tests to predict carcinogenesis and genetic disorders in humans. Notably, the comet assay and micronucleus test may be used to detect the *in vivo* genotoxicity of test compounds and their metabolites in rodents. However, metabolic activities differ between humans and rodents. Thus, we developed humanized chimeric PXB-mice®—whose liver retains human-type metabolic activities—by using albumin enhancer/promoter-driven urokinase plasminogen activator transgenic/severe combined immunodeficiency disease (uPA/SCID) recipient mice. Using the PXB-mice, we performed a comet assay and micronucleus test of N-ethyl-N-nitrosourea (ENU). At the SOT 2012 Annual Meeting, we presented that a dose-dependent increase in the number of positive cells was observed (i) in the comet assay using liver, (ii) in the micronucleus test using bone marrow, but not (iii) in the micronucleus test using liver, which is probably because of insufficient mitotic condition in the liver. In the present study, we established a new type of PXB-mice by using cDNA-uPA/SCID recipient mice, which would be expected to supply a higher mitotic condition for human hepatocytes. Cryopreserved human hepatocytes from a 2-year-old Hispanic were transplanted into cDNA-uPA/SCID mice. The 7- or 9-week-old male new PXB-mice were orally treated daily with ENU at 25 mg/kg body weight for 2 or 4 weeks. The liver and femur bone marrow were collected from the PXB-mice and employed in the comet assay and micronucleus test. The number of positive cells significantly increased (i) in the comet assay using hepatocytes and also in the micronucleus test using (ii) bone marrow or (iii) hepatocytes from the 7-week-old male PXB-mice treated orally with ENU for 4 weeks. In conclusion, we established comet assays and micronucleus tests using a new type of PXB-mice to predict human genotoxicity *in vivo*.

**PS 1694 Reconstructed 3D Human Skin Micronucleus Assay: Preliminary Prevalidation Results.**

R. Fautz<sup>1</sup>, S. Pfuhler<sup>2</sup>, M. Aardema<sup>3</sup>, G. Ouedraogo<sup>4</sup>, B. Barnett<sup>2</sup>, B. Faquet<sup>4</sup>, G. Mun<sup>5</sup>, N. J. Hewitt<sup>6</sup>, S. Hoffmann<sup>7</sup>, R. Curren<sup>5</sup> and J. Barroso<sup>8</sup>. <sup>1</sup>Kao Germany GmbH, Darmstadt, Germany; <sup>2</sup>Procter & Gamble Company, Cincinnati, OH; <sup>3</sup>Marilyn Aardema Consulting LLC, Fairfield, OH; <sup>4</sup>L'Oréal, Paris, France; <sup>5</sup>IIVS Inc., Gaithersburg, MD; <sup>6</sup>Hewitt Consulting, Erzhhausen, Germany; <sup>7</sup>seh Consulting+Services, Koeln, Germany; <sup>8</sup>Cosmetics Europe, Brussels, Belgium.

The skin is the main route of exposure of many chemicals and cosmetic ingredients; therefore, Cosmetics Europe (formerly COLIPA) has funded projects to establish and evaluate more realistic models for genotoxicity using 3D reconstructed skin (RS) tissues. The aim is to use these to follow-up on positive results from the in vitro genotoxicity battery[1], which has been criticized for its low specificity. The RS model, EpiDerm™, was combined with the micronucleus (MN) assay and the resulting "RSMN" assay exhibited good intra- and inter-laboratory reproducibility[2], and correctly identified 3 coded chemicals as being either positive or negative[3]. A detailed protocol for the RSMN assay was published, together with a harmonized scoring atlas for micronuclei[4]. We have extended the number of coded chemicals to 29 as part of the pre-validation process. Eight of these were true positives, 11 were false positives and 10 were negatives. There was an excellent specificity (88%), demonstrating that the RSMN has a good potential to improve the specificity of in vitro genotoxicity assays as a whole. Of the 8 carcinogens with a suggested genotoxic mode of action, 5 were correctly predicted. While this indicates that the model shows decent sensitivity, the total number of true positives was considered too low to draw a final conclusion about the sensitivity of this assay. Therefore more coded compounds will be tested in a next project phase with a focus on genotoxic carcinogens. Overall, these data support the use of the 3D skin EpiDerm™ model for genotoxicity testing of dermally applied chemicals. [1] Pfuhler et al. 2010, Reg Pharm Tox; [2] Hu et al. **PS 1695 Reduction of Ataxia telangiectasia Associated Death Rates in ATM KO Mice with Yel002.**

M. J. Davoren and R. H. Schiestl. *Environmental Health Science, University of California Los Angeles, Los Angeles, CA.*

Ataxia Telangiectasia is a devastating disease that affects 1 in every 40,000–100,000 individuals worldwide. 1% of Americans carry a copy of a compromised Ataxia Telangiectasia Mutated (ATM) gene, an important signaling protein involved in both DNA repair and apoptosis. Having two copies of defective or null alleles leads to the disease, symptoms including motor defects (ataxia), extreme sensitivity to ionizing radiation, immunodeficiency, and predisposition to cancer. Lymphoma rates, in particular, occur at nearly 100 times the normal. Despite all of the defects, patients with AT are mentally normal, and many promising young high school and college graduates have their lives cut short by 22, the median age of death. The only treatments are palliative, focused on treating infections that result due to the compromised immune system.

The Schiestl Lab investigates the nature of DNA damage and its repair. During a yeast based high-throughput screen for agents that mitigate the damaging effects of radiation, the candidate drug Yel002 was identified. In later trials on healthy mice subjected to lethal radiation doses, Yel002 was found to significantly increase survival, even when administered a day after the insult. As radiation induces damage largely via strand breaks in DNA, it was thought to act by upregulating the DNA repair process. As AT patients symptoms result from DNA repair deficiency, we decided to treat ATM KO mice with the drug weekly in a long term study to cut death rates. Previous data on this same mouse strain showed that these mice usually die of cancer in the sterile facility by 50 weeks on average. Mice treated with a weekly injection of 75mg/kg Yel002 show far lower death rates – over 80% are still alive at week 60, and survival looks promising as it continues.

**PS 1696 Classification of Genotoxic Mode of Action in TK6 Cells via a High Content, Flow Cytometric In Vitro Micronucleus Assay.**

S. Bryce, S. Avlasevich, J. Weber, E. Beha and S. Dertinger. *Litron Labs, Rochester, NY.*

This laboratory has previously described a high content flow cytometric method for scoring micronuclei (In Vitro MicroFlow®) in CHO-K1 cells that is capable of discriminating aneugenic from clastogenic modes of action (MoA). It would be useful to capture MoA information when studying other cell lines, for instance the human

cell line TK6. Previous reports suggested that the proportion of metaphase cells represents a signature that can effectively discriminate between clastogenic and aneugenic MoA. We therefore set out to combine a flow cytometric micronucleus scoring method with a technique for enumerating metaphase cells and evaluate the multiplexed assay's ability to differentiate clastogenic and aneugenic responses. In order to accomplish metaphase scoring, the fluorescent reagent anti-histone H3 (pS28) antibody (anti-H3-P), which recognizes the phosphorylated form of the histone, was incorporated into the flow cytometric micronucleus assay procedure. TK6 cells were treated in a continuous exposure design with each of ten reference clastogens and seven reference aneugens. At the time of harvest (24 to 27 hrs after treatments were initiated), cells were processed according to In Vitro MicroFlow kit instructions; with the exception that anti-H3-P was incorporated into the sample processing. Data acquisition occurred for 4 mins per sample and provided approximately 2,000 metaphase cells per replicate. Each of the genotoxins was observed to cause increased MN frequencies and relative survival values to decrease in a concentration-dependant manner. Whereas the proportion of metaphase cells to total cells (as well as the proportion of metaphase cells to G2/M cells) were decreased by each of the ten reference clastogens, they were elevated by each of the seven aneugens. These data indicate that automated and multiplexed micronuclei and metaphase cell-scoring of TK6 cells provide strong aneugenic versus clastogenic MoA signatures that effectively discriminate between these classes of genotoxic agents.

**PS 1697 Qualification of 96-Well High-Throughput In Vitro Micronucleus and Comet Assays.**

T. E. Lawlor<sup>1</sup>, K. Pant<sup>1</sup>, M. Aardema<sup>2</sup> and L. F. Stankowski<sup>1</sup>. <sup>1</sup>BioReliance by SAFC, Rockville, MD; <sup>2</sup>Marilyn Aardema Consulting, Fairfield, OH.

We recently qualified 96-well high throughput versions of the in vitro micronucleus (MN) assay in CHO cells, and the Comet assay in TK6 cells. The MN assay evaluated the ten reference compounds in OECD TG 487 using MicroFlow™ kits (Litron Laboratories; 10 independent trials), while the Comet assay evaluated six reference compounds using the Japanese Center for Validation of Alternative Methods (JaCVAM) Comet validation protocol (version 6.2; four independent trials). All trials were performed, using 7-10 concentrations in duplicate cultures with and/or without exogenous metabolic activation (S9), to assess inter- and intra-experimental variability, as well as sensitivity and specificity. Using an empirical analysis of the results, it was possible to reduce the criteria for a positive response for micronuclei and hypodiploidy to 2- and 6-fold concurrent vehicle control values, respectively, thereby increasing sensitivity without an appreciable loss of specificity. Mitomycin C and cytosine arabinoside were reproducibly positive without S9, as were benzo(a)pyrene and cyclophosphamide with S9; all four compounds produced a clastogenic signature. Colchicine and vinblastine were positive with and/or without S9, and both produced a significant increase in micronuclei and hypodiploid cells, indicative of an aneugenic mechanism of action. In contrast, di(2-ethylhexyl)phthalate, nalidixic acid, pyrene and sodium chloride were all negative in all trials and at all dose levels with and without S9 except for one concentration of pyrene in one trial +S9. Reproducible positive results were observed in the Comet assay for the genotoxins 2-aminoanthracene +S9, and 9-aminoacridine, ethyl methanesulfonate and methyl methanesulfonate –S9, while reproducible negative results were observed for the nongenotoxins cycloheximide and triton-X ±S9. These results support the utility of these high throughput assays for genotoxicity screening in general and are being employed in the US EPA ToxCast program.

**PS 1698 Integration of Pig-a and Micronucleus Endpoints into a 28-Day Rodent Toxicity Assay with Urethane.**

L. F. Stankowski<sup>1</sup>, M. Aardema<sup>2</sup>, T. E. Lawlor<sup>1</sup>, S. E. Miller<sup>1</sup>, S. Roy<sup>1</sup>, Y. Xu<sup>1</sup> and R. H. Elbekai<sup>1</sup>. <sup>1</sup>BioReliance by SAFC, Rockville, MD; <sup>2</sup>Marilyn Aardema Consulting, Fairfield, OH.

Urethane is a rodent carcinogen (by po, ip, sc and inhalation routes) and is mutagenic and clastogenic in vivo, but generally considered non-genotoxic in vitro. Thus, it is an important chemical to evaluate the utility of the Pig-a in vivo gene mutation assay. As part of the Pig-a international validation trial, we examined the induction of CD59-negative reticulocytes and total red blood cells (RET<sup>CD59-</sup> and RBC<sup>CD59-</sup>) in the peripheral blood of male Sprague Dawley® rats treated with urethane for 29 consecutive days (25.0, 100 and 250 mg/kg/day, po). Animals also were evaluated for micronucleated reticulocytes (mnRET) in peripheral blood on Days 4, 15 and 29. Ethylmethane sulfonate (EMS; 200 mg/kg/day on Days 3, 4, 13, 14, 15, 27, 28 and 29) and sterile saline (daily) were evaluated as positive and vehicle controls, respectively (all n = 6). All animals survived to Day 29, no animals exhibited overt signs of toxicity due to urethane, and there were no significant differences in body weight gain between urethane and control groups. Significant,

dose dependent increases ( $p < 0.05$ ) were observed for urethane, up to 74- and 24-fold vehicle control values for RET<sup>CD59</sup>, up to 4.2- and 8.1-fold for RBC<sup>CD59</sup> (each on Days 15 and 29), and up to 6.6-, 4.0- and 5.3-fold for mnRET (Days 4, 15 and 29). EMS also induced significant 31- and 18-fold increases in RET<sup>CD59</sup>, 4.5- and 5.7-fold increases in RBC<sup>CD59</sup> (Days 15 and 29), and up to 2.8-, 11- and 16-fold in mnRET (Days 4, 15 and 29). These results compare favorably with earlier in vivo observations, and demonstrate the utility and sensitivity of the Pig-a in vivo gene mutation assay. Samples also were collected for evaluation of chromosome aberrations in peripheral blood lymphocytes; micronucleus induction in bone marrow; and DNA damage in peripheral blood and various organs using the Comet assay (the 29th dose being required for the Comet endpoint at terminal sacrifice). However, these latter analyses are ongoing.

## PS 1699 Reconstructed Skin Micronucleus (RSMN) Assay in Normal Human 3-Dimensional (NHu-3D) Skin Model.

M. Klausner, Y. Kaluzhny, V. Karetsky and J. DeLuca. *MatTek Corporation, Ashland, MA*. Sponsor: P. Hayden.

Safety assessment of new products for human use requires genotoxicity testing. Current in vitro assays have low specificity resulting in a high rate of false positives that may be due to use of transformed cell lines, non-physiological exposures, and lack of normal metabolism. Furthermore, the 7th amendment to the Cosmetics Directive banned in vivo genotoxicity testing in 2009.

EpiDerm is a 3D normal human cell-based epidermal model that is highly reproducible, contains a skin-like barrier, and possesses biotransformation capabilities including CYP450, GST, and UDP enzymatic activity. The RSMN assay utilizes topical application of test materials in a similar fashion to actual human contact. Test materials are dosed 2 to 4 times every 24 h in the presence of Cytochalasin-B and cells are harvested from the EpiDerm tissues 24 hours after the last dose. Altogether, 50 materials (24 direct genotoxins, 14 non-genotoxins, and 12 genotoxins that require metabolic activation) have been analyzed in the RSMN assay. Analysis of the complete set of chemicals resulted in 93.3% Sensitivity, 100% Specificity, and 95.5% Accuracy. In addition, a co-culture system that utilized a lymphoblast cell line TK6 cultured beneath of the EpiDerm tissues was used as a target to expand the relevance of dermally applied compounds to systemic carcinogenicity. Micronucleus induction in TK6 cells was assessed after treatment of the EpiDerm with MitomycinC,  $\beta$ -Propiolactone, and Ethyl Methanesulfonate. The TK6 cells, as well as the EpiDerm tissue itself, were found to be positive. However, exposure to the genotoxin, Benzidine, was negative in EpiDerm but positive in TK6 cells.

In conclusion, the RSMN assay that utilizes the EpiDerm skin model is more specific in identifying dermal human carcinogens than existing in vitro assays. The approach of using the human reconstructed skin together with a human lymphocyte target cell line appears to be a good method of detecting genotoxic effects for hard to predict chemicals and expanding the relevance of dermally applied compounds to systemic carcinogenicity.

## PS 1700 The Use of 3D Human Dermal Equivalents to Assess Genotoxicity of Textile Dyes.

D. M. Leme<sup>1</sup>, F. L. Primo<sup>2</sup>, A. Tedesco<sup>2</sup> and D. P. Oliveira<sup>1</sup>. <sup>1</sup>*Faculdade de Ciências Farmacêuticas de Ribeirão Preto (FCFRP/USP), Ribeirão Preto, Brazil;* <sup>2</sup>*Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto (FFCLR/USP), Ribeirão Preto, Brazil.*

**Introduction:** The use of 3D-human reconstructed skin seems to be promising for safety assessment of chemicals. Compared to traditional 2D in vitro systems, which basically represent one cell type, this model can provide organ-specific toxicity, mechanical/biochemical signaling and cell-cell communication. Humans are daily exposed to textile dyes through skin contact with colored garments. Studies have pointed that some textile dyes can be hazard to human beings. Considering that dyes, under conditions of perspiration, can migrate from clothes and penetrate into human skin, identification of safe textile dyes, related to dermal exposure, is relevant to avoid human health problems. **Objective:** Genotoxicological assessments of Reactive Green 19 (RG19), Reactive Blue 2 (RB2) and Disperse Red 1 (DR1) using the Comet assay with in vitro human dermal equivalents. **Methodology:** The dermal equivalent models were constructed in 3D-collagen matrix, using human gingival fibroblasts isolated from adult donors, at a density of  $3 \times 10^5$  cell/cm<sup>2</sup>, into 60 mm cell culture dishes, containing collagen type-I and D-MEM supplemented with 10% BFS and other nutrients (Primo et al., 2011). The alkaline Comet assay was carried out according to Tice et al. (2000), with slight modifications. **Results:** RB2 and DR1 did not induced DNA damage, whereas RG19 showed weak genotoxic response. **Discussion:** Our data are not in agreement with previous genotoxicological assessments of these dyes using 2D cell cultures. Genotoxicity was reported to DR1 using in vitro hepatocarcinoma cells. However, here this dye showed

to be non-genotoxic. RG19 did not induce DNA damage in in vitro human dermal fibroblasts, but a weak genotoxicity was here observed. **Conclusion:** This difference might be related to the test systems used in each study (2D and 3D cell cultures). 3D-human reconstructed skin affords better cellular environment, which could provide more reliable data of the genotoxicity of chemical (e.g. textile dyes).

## PS 1701 Comparison of Two High-Throughput Methods for In Vitro Micronucleus Assessment Comparison of Two High-Throughput Methods for In Vitro Micronucleus Assessment.

B. Goodwin<sup>1</sup>, J. Bemis<sup>2</sup>, Z. Liu<sup>3</sup>, S. Bryce<sup>2</sup>, K. Luu<sup>3</sup>, K. L. Witt<sup>4</sup>, C. P. Austin<sup>1</sup>, R. R. Tice<sup>4</sup> and M. Xia<sup>1</sup>. <sup>1</sup>*NCGC, NCATS, NIH, Rockville, MD;* <sup>2</sup>*Litron Laboratories, Rochester, NY;* <sup>3</sup>*IntelliCyt Corporation, Albuquerque, NM;* <sup>4</sup>*Division of the National Toxicology Program, NIEHS/NIH, Raleigh, NC.*

Identification of compounds with the potential to induce DNA damage is an important component of the chemical safety evaluation process. Micronuclei (MN), a frequently used endpoint for genotoxicity studies, are formed by clastogens inducing acentric chromosome fragments or aneugens disrupting anaphase during cell division. The traditional in vitro micronucleus (IVMN) test uses trained individuals to manually count MN, which is both labor intensive and time consuming. Here, we compare the performance of two automated high throughput methods for MN detection using CHO-k1 cells in 384-well format. Method 1 is a high-content MN assay using the Thermo Scientific ArrayScan VTi. Method 2 is the IntelliCyt Corp high capacity flow (HCF)-based High Throughput Flow Cytometry (HTFC) Screening System® using the In Vitro MicroFlow® kit (Litron Laboratories). For this comparison, cells were exposed to 10 compounds (20 dilutions, selection based on solubility, cytotoxicity, dose range finding, or 100  $\mu$ M limit concentration) for 24h, and processed on both systems, or incubated with cytochalasin B (CB) for another 24h prior to Arrayscan analysis. The compounds used included clastogens (etoposide, camptothecin, methyl methanesulfonate, bleomycin), aneugens (colchicine, griseofulvin, vincristine, geldanamycin), and non-genotoxic ones (nalidixic acid, sodium chloride). Both platforms correctly identified the known MN-inducing compounds and the 2 non-genotoxic compounds. Scoring of a 384-well plate required ~3h for the ArrayScan and 30m for the HTFC; the latter platform was also able to distinguish aneugens from clastogens. These data show that the throughput of the IVMN assay can be increased dramatically to permit screening large chemical libraries on a robotic platform. Supported by NIEHS Interagency Agreement Y3-ES-7020-01.

## PS 1702 Genome Profiling of Carcinogen Resistance in Budding Yeast Expressing Human P450 Genes.

M. Fasullo<sup>1,3</sup>, P. Egner<sup>2</sup> and T. Begley<sup>1,3</sup>. <sup>1</sup>*Nanobiosciences, College of Nanoscale Sciences and Engineering, Albany, NY;* <sup>2</sup>*Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD;* <sup>3</sup>*Biomedical Sciences, State University of New York, Albany, NY.*

Human susceptibility to environmental carcinogens is highly variable. Epidemiological studies have identified genes that confer resistance; however, these studies are limited due to small sample sizes. We use *Saccharomyces cerevisiae* (yeast) to profile eukaryotic genes that confer resistance to environmental carcinogens, such as the potent hepatocarcinogen, aflatoxin B1 (AFB1). A yeast collection is available containing ~5,000 diploid strains homozygous for individual gene knock-outs. Each gene knock-out is bar-coded and can be identified by high-throughput DNA sequencing. Since many carcinogens require P450-mediated activation, we introduced human CYP1A2, constitutively expressed on a high-copy expression vector, in the yeast diploid collection. We verified P450 expression in selected mutants by Western blots. To identify which strains are AFB1 sensitive, cells were inoculated in 96 well plates and growth was measured in a plate reader. To expedite results, we switched to high-throughput DNA sequencing of bar code sequences using an illumina platform. Results indicate the importance of the recombinational and excision repair pathways in conferring AFB1 resistance, and the accumulation of AFB1-N7-guanine DNA adducts in nucleotide excision repair (NER) mutants. The functional importance of recombination is further indicated by the presence of carcinogen-associated DNA repair foci that appear in AFB1-exposed cells, and the extreme sensitivity of double mutants lacking both recombinational and nucleotide excision repair. **Conclusions:** We have modified the yeast diploid strain collection to profile the genome resistance to P450-activated carcinogens, and identified genes in the recombinational and NER pathways that confer resistance. Further studies will identify orthologous human genes that confer carcinogen resistance. The yeast strain collection will be valuable in monitoring resistance to additional P450-activated chemicals and drugs.

**PS 1703 Roles for Telomeric Proteins in Regulating Nucleotide Excision Repair at Telomeres.**

D. Parikh and P. Opresko. *University of Pittsburgh, Pittsburgh, PA.*

Ultra-violet (UV) irradiation is the most ubiquitous environmental inducer of skin cancer and melanomas. UV exposure creates DNA photoproducts primarily cyclobutane pyrimidine dimers (CPD) and 6-4 photoproducts (6-4 PP). These cause mutations and block DNA replication, unless repaired by nucleotide excision repair (NER). Thymine repeats (TT) on G-rich strands of telomeric DNA are hotspots for CPD formation. Telomeres are DNA-shelterin protein complexes at ends of chromosomes, reported to lack a defined NER pathway for CPD repair. Diminished binding or loss of shelterin proteins TRF1 and TRF2 at telomeres cause telomere deprotection and end-to-end fusions directly leading to genomic instability. Also TRF2 binds to the key NER protein XPF-ERCC1 and recruits it to telomeres. Our working hypothesis is that telomeric photoproducts are repaired at slower rates compared to genomic lesions and that this repair inhibition involves interactions between XPF-ERCC1 with TRF2.

We measured photoproduct formation and repair in telomeres purified from human osteosarcoma (U2OS) cells exposed to UVC via a novel dot blot assay. We report a method for direct quantification of photoproducts formed *in vivo* and ensuing repair based on a standardized qPCR assay for DNA damage. Photoproducts were detected in genomic and telomeric DNA using specific antibodies following exposure of cells to 10 J/m<sup>2</sup> UVC and after recovery times of 0 to 12 hours. CPDs decreased in genomic DNA after 12 hours but persisted in telomeric DNA. Southern blot assays using radio-labeled oligonucleotides that bind to telomeric DNA confirmed enrichment of telomeres in purified fractions. To investigate possible mechanisms for repair inhibition, we tested directly effect of TRF2 on NER protein XPF-ERCC1 via enzyme activity assays. We discovered that nuclease cleavage activity of purified XPF-ERCC1 on a stem-loop DNA substrate was completely abolished by TRF2. Our results provide the first direct biochemical evidence towards quantifying critical UV damage at telomeres and elucidating NER pathway regulation by shelterin.

**PS 1704 Oxidative Stress-Induced PIGO Mutations in DT40 Cells: Critical Role of NHEJ and TLS Repair Pathways in ROS-Induced Mutations.**

V. Sharma<sup>1</sup>, L. B. Collins<sup>1</sup>, J. A. Swenberg<sup>1,2</sup> and J. Nakamura<sup>1</sup>. <sup>1</sup>*Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

A major mechanism resulting in the genetic alterations that can lead to cancer is through the induction of mutations in genes controlling vital cellular functions. Genotoxic chemicals cause chemically specific DNA adducts that can result in gene mutations, whereas non-genotoxic carcinogens can exert their effects through oxidative stress. The cells in animals, humans, and cell culture are subjected to continuous endogenous DNA damage arising mainly from oxidative stress and depurination. To understand mechanisms by which oxidative stress causes mutations, hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) was chosen as a model compound. 8-oxo-dG, a major DNA lesion generated during oxidative DNA damage showed non-linear increases following H<sub>2</sub>O<sub>2</sub> treatment. Similarly, H<sub>2</sub>O<sub>2</sub> caused a significant increase in PIGO gene mutations in parental DT40 cells. In addition, to study the critical DNA repair pathways associated with the oxidative stress, DNA damage response analyses were performed in different repair protein deficient DT40 cells. Hypersensitivity of RAD18, REV1, Rad54, RAD51c, Fen1, POLK, POLη, Ku70, Lig4 deficient cells to H<sub>2</sub>O<sub>2</sub> suggests that homologous recombination (HR), non-homologous end joining (NHEJ), translesion synthesis (TLS), and base excision repair (BER) are essential for tolerance to oxidative DNA damage. Due to the error prone nature of NHEJ and TLS repair pathways, we hypothesize that H<sub>2</sub>O<sub>2</sub> induced mutation levels may be decreased in NHEJ and TLS deficient cells. As we expected, Ku70 (NHEJ) and REV1 (TLS) deficient cells revealed a significant decrease in PIGO mutation frequency which might be due to the lack of these error prone pathways in the cells. This indicates that NHEJ and TLS pathway may play an important role in the mutagenesis observed during oxidative stress.

**PS 1705 Evaluating the Role of p53 in Cellular Fate and Micronucleus Induction following Exposure to Etoposide and Mms.**

R. A. Clewell<sup>1</sup>, B. Sun<sup>1</sup>, S. M. Ross<sup>1</sup>, A. Scott<sup>2</sup>, Y. Adeleye<sup>2</sup> and M. E. Andersen<sup>1</sup>. <sup>1</sup>*The Hammer Institutes, Research Triangle Park, NC;* <sup>2</sup>*Unilever, Colworth, United Kingdom.*

Etoposide (ETP) and methyl methanesulfonate (MMS) represent genotoxic chemicals with direct and indirect mechanisms of DNA damage. ETP inhibits binds topoisomerase II, leading to double strand breaks (DSBs). MMS is an alkylating agent that induces single strand breaks and DSBs. To evaluate the role of p53 in downstream protein response and cell fate with ETP and MMS exposure, we generated p53 knockdown (KD) HT1080 cells and utilized HCT116 p53 knockout (KO) cells for comparison with wild-type human HT1080 fibrosarcoma and HCT116 colon carcinoma cells. In WT cells, MMS and ETP induce DSBs (p-H2AX), (s15)p-p53, and p53 protein at 100 μM and 0.2 μM, respectively. Despite similar induction of p53, cellular response was different for the chemicals: ETP induced apoptosis, M-phase arrest, and a large increase in micronuclei (MN), while MMS induced S-phase arrest and showed little induction of apoptosis or MN. p53 regulated protein MDM2, p21 and Wip1 responses were reduced in KD HT1080s and completely abolished in KO HCT116s. Apoptosis was also significantly reduced in p53 KD/KO cells. Cell cycle arrest, however, was similar in WT and p53 KD/KO cells. Basal MN levels were approximately 1.8-fold higher in p53 KO cells than WT cells at 27 and 40 hr. However, chemical induction of MN in WT and p53 KO HCT116 cells showed notable time-dependencies. MN were slower to form in p53 KO cells; only the 40 hr time point showed a strong increase in MN induction in KO cells compared to WT cells after ETP or MMS treatment. While the total frequency of MN 40 hours after treatment was higher in KO cells than WT. Interestingly, the ratio of MN in p53 KO cells to WT cells remained constant across doses (KO:WT ~ 2:1) and chemicals. It appears that the efficiency of DSB break repair is similarly affected by p53 in the naïve and chemical treated cell at the tested doses (≤ 1 μM ETP, ≤ 200 μM MMS). Mechanistic studies of the relationship between DSBs, p53 function and MN are important in assessing the value of MN as functional marker of DNA damage.

**PS 1706 AZT-Induced Aneuploidy Is Mediated by Aberrant Sathmin1 Expression.**

A. Rivera-Rodriguez, M. Poirier, O. Olivero and V. Sanchez. *NCI, NIH, Bethesda, MD.*

Previous studies have shown that the antiretroviral nucleoside reverse transcriptase inhibitor (NRTI) zidovudine (AZT) causes cell cycle anomalies resulting in aneuploidy. In addition, we demonstrated a decrease in β-tubulin polymerization in normal human mammary epithelial cells (NHMECs) exposed to 100 μM AZT for 24 hours. Polymerized β-tubulin is a critical component of normal chromosome segregation, the lack of which causes improper spindle formation and chromosome misalignment. MicroRNA analysis of AZT-exposed NHMECs revealed downregulation of hsa-miR-770-5p, which has multiple cellular targets including Sathmin 1 (STMN1). Active STMN1 (non-phosphorylated) inhibits the polymerization of α- and β-tubulin required for normal cellular functions. Because hsa-miR-770-5p is downregulated in AZT-exposed cells, we hypothesized that AZT exposure would produce upregulation of STMN1, and result in decreased levels of polymerized/functional tubulins. Here we exposed human breast MCF-10A cells to 100 μM AZT for up to 3 passages (p), and quantified total STMN1 (tSTMN1) and phosphorylated (inactive) pSTMN1 by Western Blot. At p1 there was an increase in tSTMN1 (1.49 ± 0.3 fold) and a decrease in pSTMN1 (0.66 ± 0.3 fold) in AZT-exposed cells compared to unexposed cells. At p2 a consistent increase in tSTMN1 (1.46 ± 0.0003 fold), and an increase in pSTMN1 (1.78 ± 0.05 fold) was observed. At p3, no change was detected for tSTMN1 while a decrease was observed in pSTMN1 (0.51 ± 0.5 fold). The data are consistent with the conclusion that AZT induces aneuploidy by inhibition of hsa-miR-770-5p followed by upregulation of STMN1, decreased polymerization of tubulin, spindle abnormalities, and misdistribution of chromosomes into daughter cells at replication.

**PS 1707 Dose Response and Temporality of Ethylene Oxide-Induced Macromolecular Changes and Genotoxicity in Mice.**

M. R. Schisler<sup>1</sup>, M. J. LeBaron<sup>1</sup>, F. Zhang<sup>1</sup>, Y. C. Jeong<sup>1</sup>, M. Bartels<sup>1</sup>, R. Sura<sup>1</sup>, J. A. Hotchkiss<sup>1</sup>, D. R. Geter<sup>1</sup>, B. Gollapudi<sup>1</sup> and N. P. Moore<sup>2</sup>. <sup>1</sup>Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI; <sup>2</sup>Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Horgen, Switzerland.

Ethylene oxide (EO), a reactive industrial chemical, induced alveolar/bronchiolar adenomas and carcinomas in the lungs of B6C3F1 male mice at atmospheric concentrations of 50 and 100 ppm. The purpose of the current study was to characterize the mode of action (MoA) for lung tumors induced by EO. Male B6C3F1 mice were exposed by inhalation (6 hours/day, 5 consecutive days/week) to 0, 10, 50, 100, or 200 ppm (4 weeks) or 0, 100, or 200 ppm (8 or 12 weeks) and examined for incidence of micronuclei in the peripheral blood (MNT), DNA damage (Comet assay), histopathology of the lung, and characterization of DNA- and glutathione-adducts and lipid peroxidation in the tumor target and non-target tissues. In general, reactive oxygen species-related adducts (8-OHdG, CrotondG, M1dG) were only minimally affected, whereas alkylated DNA adducts (O<sup>6</sup>-HEdG, N1-HEdA, N6-HEdA, and N7-HEG) were increased more robustly. There was a dose-dependent increase in glutathione adducts (HESG) in all tissues, although severe GSH depletion was not noted. There were no treatment-related changes in the MN-RET (reticulocyte) frequency or %RET. Comet analysis of the lung revealed a dose-dependent, statistically significant increase in DNA damage at 50 ppm and above. There was no treatment-related histopathology in the lung, although a slight decrease in the proportion of Ki-67 positive cells was observed at 4 and 8 weeks in the terminal bronchioles. In summary, these observations reveal a complex sequela of biomarkers of exposure and effect following inhalation exposure to EO with a clear NOEL for all apical endpoints studied.

**PS 1708 Cii Mutant Frequencies and Types of Mutations in the Lung of Big Blue Mice Exposed to Ethylene Oxide for up to 12 Weeks by Inhalation.**

M. G. Manjanatha<sup>1</sup>, S. D. Shelton<sup>1</sup>, Y. Chen<sup>1</sup>, B. L. Parsons<sup>1</sup>, B. Gollapudi<sup>2</sup>, N. P. Moore<sup>3</sup>, L. T. Haber<sup>4</sup> and M. M. Moore<sup>1</sup>. <sup>1</sup>Genetic and Molecular Toxicology, FDA/NCTR, Jefferson, AR; <sup>2</sup>Toxicology & Environmental Research and Consulting, Midland, MI; <sup>3</sup>Dow Europe GmbH, Horgen, Switzerland; <sup>4</sup>TERA, Cincinnati, OH.

Ethylene oxide (EO) is a direct acting mutagen and many in vitro and in vivo data in rodents support its role as a mutagen and carcinogen, but whether EO is carcinogenic through a mutagenic mode of action remains unclear. To investigate this question, male Big Blue B6C3F1 mice (10 mice/group) were exposed to EO by inhalation, six hours/day, five days/week for 4 (0, 10, 50, 100, or 200 ppm EO), 8 or 12 weeks (0, 100, or 200 ppm EO). Lung DNAs were analyzed for induction of *cII* mutant frequencies (MFs) at 4, 8 and 12 weeks of exposure and 428 mutants derived from 4-12 wk control and 200 ppm EO treatments were analyzed to determine the mutational spectra. The background *cII* MFs increased with age from  $17.4 \pm 2.2 \times 10^{-6}$  at 4 weeks to  $29.6 \pm 4.1 \times 10^{-6}$  at 12 weeks. Although EO-induced *cII* MFs were 1.5-2.75-fold higher than the concurrent controls, significant increases in the *cII* MF were found only after 8 and 12 weeks of exposure to 200 ppm EO ( $p \leq 0.05$ ). DNA sequencing of *cII* mutants showed a significant shift in the mutational spectra between control and 200 ppm EO following 8 and 12 wk exposures ( $p \leq 0.035$ ), consistent with the significant increases in the EO-induced MFs at these weeks. The predominant types of EO-induced mutations in lung were G→T and A→T transversions; the role of EO-induced DNA adducts in the etiology of these mutations needs further elucidation. These results indicate that EO is likely to be a weak mutagen at high exposure concentrations in the lung, a tumor target tissue.

**PS 1709 Gain and Loss of K-Ras Mutations in Mouse Lungs following Inhalation Exposure to Ethylene Oxide.**

B. L. Parsons<sup>1</sup>, M. G. Manjanatha<sup>1</sup>, M. B. Myers<sup>1</sup>, K. L. McKim<sup>1</sup>, Y. Wang<sup>1</sup>, B. Gollapudi<sup>2</sup>, N. P. Moore<sup>3</sup>, L. T. Haber<sup>4</sup> and M. M. Moore<sup>1</sup>. <sup>1</sup>Division of Genetic and Molecular Toxicology, US FDA-NCTR, Jefferson, AR; <sup>2</sup>Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI; <sup>3</sup>Dow Europe GmbH, Horgen, Switzerland; <sup>4</sup>TERA, Cincinnati, OH.

K-ras codon 12 GGT→GAT mutation is the most prevalent K-ras mutation in spontaneous mouse lung tumors, whereas K-ras codon 12 GGT→GTT mutation was detected in 21/23 (91%) of mouse lung tumors induced by ethylene oxide (EO) [Hong et al. (2007) Toxicologic Pathology 35:81-85]. To investigate whether EO drives G→T transversion through a mechanism involving oxidative damage

and induction of 8-oxo-2'-deoxyguanosine at the second position of K-ras codon 12, allele-specific competitive blocker PCR (ACB-PCR) was used to measure the levels of three different K-ras codon 12 mutations (codon 12 GGT→GAT, GGT→GTT, and GGT→TGT) in lung DNAs of male Big Blue B6C3F1 mice exposed to EO. Ten mice per group were exposed to EO by inhalation, six hours/day, five days/week for 4 (0, 10, 50, 100, or 200 ppm EO), 8 or 12 weeks (0, 100, or 200 ppm EO). Four weeks of exposure to 100 ppm EO caused a significant increase in K-ras codon 12 GGT→GTT mutant fraction (MF) relative to controls, and 50, 100, and 200 ppm EO caused significant increases in K-ras codon 12 GGT→GAT MF. Surprisingly, 8 weeks of exposure to 100 and 200 ppm EO caused significant decreases in K-ras codon 12 GGT→GAT and GGT→GTT MFs relative to controls. The increases and subsequent decreases in K-ras MF may be interpreted as mutant cell proliferation, followed by selective killing of K-ras mutant cells, mediated by EO dose-dependent production of reactive oxygen species. Therefore, the shift in K-ras mutation spectrum observed in EO-induced mouse lung tumors may be due to effects on intracellular signaling pathways and selection of preexisting mutant cells, rather than direct mutagenesis of the K-ras gene by EO.

**PS 1710 Genotoxic and Epigenetic Effects of Tamoxifen Exposure in Mouse Liver.**

A. de Conti, V. Tryndyak, M. Churchwell, F. A. Beland and I. P. Pogribny. FDA-NCTR, Jefferson, AR.

Tamoxifen is a widely used non-steroidal anti-estrogenic drug for treatment and prevention of breast cancer in women; however, there is sufficient evidence that tamoxifen is hepatocarcinogenic in rats, but not in mice. Currently, there is insufficient knowledge to clarify the absence of hepatocarcinogenic effect of tamoxifen in mice. In light of this, the goal of the present study was to investigate the mechanism of mouse resistance to tamoxifen-induced liver carcinogenesis. Feeding female WSB/Eij mice a 420 p.p.m. tamoxifen-containing diet for 12 weeks resulted in substantial accumulation of tamoxifen-DNA adducts, e.g., (E)-α-(deoxyguanosin-N<sup>2</sup>-yl)-tamoxifen (dG-Tam) and (E)-α-(deoxyguanosin-N<sup>2</sup>-yl)-N-desmethyltamoxifen (dG-DesMeTam), in the livers as assessed by electrospray ionization tandem mass spectrometry coupled with high-performance liquid chromatography. The levels of hepatic dG-Tam and dG-DesMeTam DNA adducts in tamoxifen-treated mice were 261 adducts/10<sup>8</sup> nt and 340 adducts/10<sup>8</sup> nt, respectively. In contrast, the degree of global DNA methylation and extent of histone modifications, including trimethylation of histone H4 lysine 20 and histone H3 lysine 9 and lysine 27 in the livers of tamoxifen-exposed mice did not differ from their values in control mice. Previously, we demonstrated that hepatocarcinogenic activity of tamoxifen in rats is associated with its ability to induce, in addition to genotoxic alterations, extensive epigenetic abnormalities. In contrast, in mice tamoxifen-treatment induced only genotoxic alterations without affecting the cellular epigenome. These results provide additional evidence that carcinogenic process requires genotoxic and non-genotoxic alterations and latter are indispensable events in carcinogenesis.

**PS 1711 Acinar Cell Autophagy in Experimental Pancreatic Injury: Immunolocalization and Response of Relevant Proteins.**

L. W. Zhang, J. Zhang, K. I. Shea, G. A. Tobin, A. Knapton and R. L. Rouse. CDER, US FDA, Silver Spring, MD.

Drug-induced pancreatitis (DIP) is an under-diagnosed condition that lacks sensitive and specific biomarkers. In vivo and in vitro studies were designed to identify models and potential biomarkers for DIP. As a part of these studies, experimental pancreatitis was created in male C57BL/6 mice by intraperitoneal injection of caerulein (10 or 50 µg/kg) at one hour intervals for a total of seven injections. Pancreata from caerulein-treated mice exhibited consistent acinar cell autophagy and apoptosis with sporadic necrosis. Both serum amylase and lipase showed significant caerulein dose-dependent increases. TUNEL staining detected significant dose-dependent acinar cell apoptosis. By light microscopy, autophagy was characterized by the formation of autophagosomes and autolysosomes within the cytoplasm of acinar cells. Immunohistochemical (IHC) studies with specific antibodies for proteins related to autophagy and pancreatic stress were used to evaluate the role of acinar cell autophagy in the response to pancreatic injury. Western blots were used to confirm IHC results using pancreatic lysates from control and treated animals. Autophagy was identified as a contributing process in caerulein-induced pancreatitis and proteins previously associated with autophagy were impacted by caerulein treatment. Autophagy identified by autophagosomes and autolysosomes was found to be a common pathway, in which cathepsins, LAMP2, VAMP1, LC3, ATG9, Beclin1, and pancreatitis-associated proteins were simultaneously engaged. Regenerating islet-derived 3 gamma (Reg3γ), a pancreatic acute response protein, was dose-dependently changed in caerulein-treated mice and co-localized with the autophagosomal marker, LC3. These data suggest a role for autophagy in DIP and supports Reg3γ as an IHC marker of pancreatic injury.

**PS 1712 Deciphering the Role of Trail in Altering Spermatogenesis by Controlling Germ Cell Apoptosis.**

Y. Lin and J. Richburg. *The University of Texas at Austin, Austin, TX.*

TRAIL (TNFSF10/Apo2L) is a member of the tumor necrosis factor (TNF) superfamily of proteins, expressed in human and rodent testis. TRAIL is known to induce apoptosis via binding to its receptors DR4 (TRAIL-R1/TNFRSF10A) and DR5 (TRAIL-R2/TNFRSF10B) in humans, and TRAIL-R (MK/mDR5) in mice. TRAIL is found in Leydig cells and germ cells during development and TRAIL-R is predominantly expressed in post-meiotic germ cells in the rat. The major role of TRAIL in male reproduction is still unclear. In this study, we investigated TRAIL-/- mice and evaluated the possible role of TRAIL in germ cell development by measuring testis weight, germ cell apoptosis, and spermatid head count in peripubertal (28 day-old) or young adult animals (44 day-old). Our results revealed that there was a significant difference in testis to body weight ratio between C57 and TRAIL-/- mice. Also, peripubertal TRAIL-/- mice show a dramatic increase in the basal germ cell apoptotic index (A.I., 21.54%) as compared to the C57BL/6J wild-type strain (5.16%). The A.I. in adult C57 mice had dropped to 1.5%, but remained elevated in adult TRAIL-/- mice (20.2%); indicating a sustained high incidence of germ cell apoptosis. Spermatid head counts in adult TRAIL-/- mice were dramatically reduced compared with C57 (39%), indicating these animals suffer a marked decline in the production of mature spermatozoa. We hypothesize that TRAIL is an important factor for maintaining germ cell homeostasis during germ cell development via a death receptor-dependent mechanism.

**PS 1713 Investigation of Sex-Dependent Toxicity of Cysteinyl Leukotriene Receptor 1 Antagonist Zafirlukast.**

Q. Shi and Z. Weng. *Division of Systems Biology, US FDA, NCTR, Jefferson, AR.*  
Sponsor: X. Yang.

The FDA-approved prescription drug label states zafirlukast, a cysteinyl leukotriene receptor 1 (CysLT1) antagonist, induces adverse hepatic events "predominantly in females." To model this possible sex-dependent toxicity, we examined suspension cultured hepatocytes from male and female rats. Concentrations ranging from 1-200  $\mu$ M were tested at multiple time points (1-4 hr). Three parameters were examined: cytotoxicity (lactate dehydrogenase (LDH) leakage), energy level (cellular adenosine triphosphate (ATP)) and cellular respiration ( $O_2$  consumption). Hepatocytes from female rats were more sensitive than male rats in all three parameters. Changes in ATP and cellular respiration were seen as early as 1 hr while cytotoxicity was not observed until 2 hr. Additional studies are underway and include two pharmacological counterparts to zafirlukast (montelukast and pranlukast). With such studies we hope to identify drugs that exert sex-dependent toxicity and their mechanisms.

**PS 1714 1, 3-Dinitropyrene (1, 3-DNP)- and 1, 8-DNP-Induced DNA Damage and Cell Death: Possible Link to Carcinogenic Effects.**

J. A. Holme<sup>1</sup>, H. E. Nyvold<sup>1</sup>, V. M. Arlt<sup>2</sup>, R. Becher<sup>1</sup>, K. B. Gutzkow<sup>1</sup>, A. Solhaug<sup>3</sup>, L. Ekeren<sup>1</sup>, M. Låg<sup>1</sup>, P. E. Schwarze<sup>1</sup>, M. A. Refsnes<sup>1</sup> and J. Øvreik<sup>1</sup>. <sup>1</sup>Division of Environmental Medicine, Norwegian Institute of Public Health, Oslo, Norway; <sup>2</sup>King's College London, London, United Kingdom; <sup>3</sup>Norwegian Veterinary Institute, Oslo, Norway. Sponsor: M. Lovik.

Nitro-polycyclic aromatic hydrocarbons (nitro-PAHs) are found on particulate matter from diesel and gasoline exhaust. Often they are found to have greater mutagenic and carcinogenic potencies when compared with their parent PAHs. In the present study we have compared the genotoxic and cytotoxic effects of two closely related carcinogenic dinitropyrenes (DNPs); 1,3-DNP and the more potent 1,8-DNP.

In human lung BEAS-2B cells, both compounds induced reactive oxygen species ( $H_2O_2$ ; flow cytometry), oxidative DNA damage (comet assay), and a DNA damage response measured as phosphorylation of p53 (Western blotting) at non-cytotoxic concentrations (3-30  $\mu$ M). In mu-rine hepatoma Hepa1c1c7 cells 1,3-DNP (>3  $\mu$ M) induced cell death (a mixture of apoptosis and necrosis), while 1,8-DNP had no cytotoxic effects. The compounds caused little/less  $H_2O_2$ , and oxidative DNA damage than in BEAS-2B. Interestingly, 1,8-DNP was overall more potent than 1,3-DNP with regard to the induction of single-strand DNA breaks (comet) and the formation of DNA adducts (32P-postlabelling). Furthermore, 1,8-DNP gave a stronger DNA damage response (phosphorylation of H2AX and p53) than 1,3-DNP in Hepa1c1c7 cells. Thus, there was no apparent link between the induction of cell death and early increases in ROS-formation or DNA damage/DNA damage responses in the two cell lines. 1,3-DNP-induced apoptosis in Hepa1c1c7

cells was specifically associated with mitochondrial damage (increased formation of superoxide anion; flow cytometry), but was also dependent on the p53-linked transcriptional apoptotic pathway (inhibitors and siRNA).

We suggest that the stronger carcinogenic potency of 1,8-DNP compared to 1,3-DNP is due to its greater DNA damage properties, which in combination with its lower potency to induce cell death increases the probability of causing mutations.

**PS 1715 Role of NOX Mediated Autophagy in Reducing Cytotoxic Effects of Erlotinib in Head and Neck Cancer Cells.**

A. Sobhakumari<sup>1,2</sup>, E. V. Fletcher<sup>1,2</sup>, A. Raeburn<sup>2</sup>, L. Love-Homan<sup>2</sup> and A. L. Simons<sup>2,1</sup>. <sup>1</sup>Human Toxicology, University of Iowa, Iowa City, IA; <sup>2</sup>Department of Pathology, University of Iowa, Iowa City, IA.

Most head and neck squamous cell carcinomas (HNSCC) overexpress Epidermal Growth Factor Receptor (EGFR) which makes it an attractive candidate for molecular targeted therapies. A combination of surgery, radiation and chemotherapeutic agents like EGFR inhibitors are routinely used in the treatment, however, many HNSCC tumors become resistant to EGFR inhibitors. The cellular self-degradation process autophagy is activated by oxidative stress and has recently been reported to reduce the efficacy of chemotherapy. Previous work in our lab has shown that the EGFR inhibitor Erlotinib induces oxidative stress via NADPH Oxidase 4 (NOX4) in HNSCC cells. The purpose of this study is to determine if Erlotinib induces autophagy in HNSCC cells via NOX4 and if autophagy is a pro-survival or pro-death mechanism. Erlotinib induced cytotoxicity (as determined by clonogenic assay) in FaDu and Cal-27 HNSCC cells compared to control treated cells. Erlotinib induced the expression of the autophagy marker LC3B-II in both cell lines as determined by western blot and immunofluorescence assays. Knockdown of autophagy genes Beclin-1 and Atg5 sensitized both cell lines to the cytotoxic effect of Erlotinib, suggesting that autophagy may be a pro-survival mechanism. Erlotinib increased NOX4 mRNA and protein levels in FaDu and Cal-27 cells. Treatment with DPI (diphenyleneiodonium) and a p38 inhibitor in the presence of Erlotinib suppressed the increase in LC3B-II expression in FaDu and Cal-27 cells. Finally, knockdown of NOX4 using adenoviral siNOX4, partially suppressed the activation of LC3B-II in FaDu and Cal-27 cells. These results suggest that Erlotinib may activate autophagy in HNSCC cells as a pro-survival mechanism, and NOX4 may play a role in mediating this effect. In conclusion, NOX4-induced autophagy may play a role in reducing the efficacy of Erlotinib. [Supported by NIH grant K01-CA134941 and ACS grant IRG-77-004-34].

**PS 1716 The Aryl Hydrocarbon Receptor (AhR) Suppresses Apoptosis in UVB-Irradiated Keratinocytes and May Serve As a New Target for Chemoprevention.**

T. Haarmann-Stemmann<sup>1</sup>, K. Fraenstein<sup>1</sup>, J. Tigges<sup>1</sup>, F. Engel<sup>1</sup>, C. Wiek<sup>2</sup>, H. Hanenberg<sup>2</sup>, E. Fritsche<sup>1</sup> and J. Krutmann<sup>1</sup>. <sup>1</sup>Leibniz Research Institute for Environmental Medicine, Duesseldorf, Germany; <sup>2</sup>Otorhinolaryngology, Heinrich Heine University, Düsseldorf, Germany.

Exposure of keratinocytes to ultraviolet (UV) radiation results in the initiation of apoptosis, a protective mechanism that eliminates cells harbouring irreparable DNA damage. Hence, a modulation of this process may significantly influence the initiation and progression of UV-induced skin cancer. We have found that the aryl hydrocarbon receptor (AHR), a ligand-activated and UVB-sensitive transcription factor, serves an anti-apoptotic function in UVB-irradiated human keratinocytes. Chemical and shRNA-mediated disturbance of AHR signaling significantly enhanced UVB-induced apoptosis. This effect was due to a loss of expression of E2F1 and its downstream target checkpoint kinase-1 (CHK1), two factors critical for cell-cycle control and DNA damage response. Ectopic overexpression of E2F1 in AHR-knockdown keratinocytes restored CHK1 expression and diminished the observed sensitization to UVB-induced apoptosis. Accordingly, experimental CHK1 recovery alone was also sufficient to attenuate UVB-induced apoptosis in AHR-knockdown keratinocytes, indicating that the loss of proper checkpoint control drives damaged keratinocytes into programmed cell death. Our results demonstrate for the first time an interplay between AHR, E2F1 and CHK1 and identify this signaling axis as a novel anti-apoptotic pathway in keratinocytes, which may represent a putative target for chemoprevention of non-melanoma skin cancer.

**PS 1717 Role of Secretory Phospholipase A<sub>2</sub> in the Toxicity of Bile Acids to Prostate Cancer Cells.**

S. L. Wilding and B. S. Cummings. *University of Georgia, Athens, GA.*

Bile acids mediate the digestion and absorption of fats and fat-soluble vitamins; however, pathological increases are associated with cholestasis and cell death. Recent studies show that high concentrations of bile acids can induce apoptosis in

several cells, including cancer cells, by mechanisms that are not fully understood. The goal of this study was to determine the toxicity of three different bile acids (chenodeoxycholic acid, deoxycholic acid, and lithocholic acid) in prostate cancer cell lines (PC-3, LNCaP, and DU-145). Treatment of cells with bile acids induced time- and concentration-dependent decreases in MTT staining, a marker of cytotoxicity, with IC50 values of approximately 100-200  $\mu$ M after 72 hr. In general, lithocholic acid was more potent than chenodeoxycholic acid, followed by deoxycholic acid. Further, LNCaP cells tended to be more susceptible to bile acid-induced toxicity, than either DU-145 or PC-3 cells. Based on reports that bile acids increase the expression of inflammatory enzymes called secretory phospholipase A<sub>2</sub> (sPLA<sub>2</sub>), we tested the hypothesis that these enzymes regulate the mechanisms of bile acid-induced cell death. Analysis of sPLA<sub>2</sub> expression using quantitative PCR showed that several sPLA<sub>2</sub> isoforms were expressed in PC-3, LNCaP and DU-145 cells, including Group IB, IIA, V and X sPLA<sub>2</sub>. Nevertheless, treatment of cells with the sPLA<sub>2</sub> inhibitor LY311727, prior to exposure to bile acids, did not alter MTT staining compared to cells exposed to bile acids alone. Similar results were seen with the calcium-independent PLA<sub>2</sub> (iPLA<sub>2</sub>) inhibitor bromenol lactone. Collectively, these data show the novel finding that bile acids can induce toxicity to prostate cancer cells and suggest the neither sPLA<sub>2</sub> nor iPLA<sub>2</sub> activity mediate the mechanisms of cytotoxicity.

**PS 1718 Etoposide-Induced Mitochondria-Dependent Apoptosis through C-Jun N-Terminal Kinases, Extracellular Signal-Regulated Kinases, and Glycogen Synthesis Kinase-3 $\alpha$ / $\beta$  Pathway in Pancreatic  $\beta$ -Cells.**

K. Lee<sup>1</sup>, S. Hsieh<sup>1</sup>, C. Su<sup>2</sup>, D. Hung<sup>3</sup>, K. Chen<sup>4</sup>, T. Tseng<sup>5</sup>, T. Lu<sup>6</sup>, S. Liu<sup>7</sup>, Y. Chen<sup>6</sup> and C. Huang<sup>8</sup>. <sup>1</sup>Department of Emergency, Buddhist Tzu Chi General Hospital, Taichung, Taiwan; <sup>2</sup>Department of Otorhinolaryngology, Head and Neck Surgery, Changhua Christian Hospital, Changhua, Taiwan; <sup>3</sup>Toxicology Center, China Medical University Hospital, Taichung, Taiwan; <sup>4</sup>Department of Urology, China Medical University Hospital, Taichung, Taiwan; <sup>5</sup>Department of Anatomy, China Medical University, Taichung, Taiwan; <sup>6</sup>Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan; <sup>7</sup>Institute of Toxicology, National Taiwan University, Taipei, Taiwan; <sup>8</sup>School of Chinese Medicine, China Medical University, Taichung, Taiwan.

Etoposide, a semisynthetic derivative of podophyllotoxin, is an important chemotherapeutic agent and widely used to treat human cancers. Etoposide also can produce the severe side effects and cause cell damages and the physiological dysfunctions. However, the toxicological effects of etoposide-induced pancreatic  $\beta$ -cell death remain unclear. Here, we investigate the cytotoxic effect and its possible mechanisms of etoposide on pancreatic  $\beta$ -cells. Treatment of pancreatic  $\beta$ -cell-derived RIN-m5F cells with etoposide (1-100 M) for 24 h significantly reduced cell viability and underwent apoptosis, accompanied with mitochondrial dysfunctions. Moreover, etoposide triggered the protein phosphorylation of glycogen synthesis kinase (GSK-3 $\alpha$ / $\beta$ ) at 8 h treatment and maintained to 24 h, which could be reversed by lithium chloride (LiCl, a specific inhibitor of GSK-3 $\alpha$ / $\beta$ ). In addition, etoposide (20  $\mu$ M) markedly increased the phosphorylation of JNK and ERK1/2, but not p38. Pharmacological inhibitors SP600125 and PD98059 effectively attenuated etoposide-induced caspase-3 activity and JNK and ERK1/2 activation, but LiCl could not reverse the phosphorylation of JNK and ERK1/2 induced by etoposide. In conclusion, these results suggest that etoposide exerts its cytotoxicity on pancreatic  $\beta$ -cells by inducing the mitochondria-dependent apoptosis through JNK/ERK activation-regulated GSK-3 $\alpha$ / $\beta$  signaling pathway.

**PS 1719 Berberine Induces Human Tongue Squamous Carcinoma Cell Apoptosis through PI3K-Regulated ER Stress Pathway.**

C. Su<sup>1</sup>, T. Lu<sup>2</sup>, D. Hung<sup>3</sup>, K. Chen<sup>4</sup>, T. Tseng<sup>5</sup>, C. Huang<sup>6</sup> and Y. Chen<sup>2</sup>. <sup>1</sup>Department of Otorhinolaryngology, Head and Neck Surgery, Changhua Christian Hospital, Changhua, Taiwan; <sup>2</sup>Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan; <sup>3</sup>Division of Toxicology, Trauma and Emergency Center, China Medical University Hospital, Taichung, Taiwan; <sup>4</sup>Department of Urology, China Medical University Hospital and China Medical University, Taichung, Taiwan; <sup>5</sup>Department of Anatomy, China Medical University, Taichung, Taiwan; <sup>6</sup>School of Chinese Medicine, China Medical University, Taichung, Taiwan.

Until now, oral cavity squamous cell carcinoma (OSCC) is the most common head-and-neck cancer, which accounts for approximately 3% of all newly diagnosed cancer cases. Despite of recent advances in surgical, radiotherapy, and chemotherapy treatment protocols, it has been discussed that OSCC could not be eradicated. Berberine is a natural alkaloid. Recently, berberine has been showed to

inhibit metastasis in lung cancer cells, and cytotoxic in glioma, prostate and nasopharyngeal cancer cells. However, the therapeutic effects and the possible mechanisms of berberine in OSCC are still unclear. Results found that berberine significantly decreased cell viability in human tongue squamous carcinoma derived SAS cells line. Besides, berberine increased the ER-stress signals, including Grp94, CHOP, Xbp-1 mRNAs and proteins. Further, the pro-caspase-12 protein level was decreased, and the caspase-12 mRNA level was increased. In mitochondrial pathway, berberine increased Bax, Bak, Bid mRNAs and proteins levels and decreased Bcl-2 mRNAs and proteins levels. Besides, the pro-caspase-9, pro-caspase-7, and pro-caspase-3 proteins level was decreased. We also found that phospho-AKT protein level was decreased after berberine treatment in cells. Besides, LY294002, the inhibitor of phosphoinositide 3-kinases (PI3Ks), promoted ER-stress and mitochondrial related apoptosis signals. Through this study, suggested that berberine may a useful compound in inhibition of OSCC through PI3K-AKT regulated ER-stress and mitochondrial pathways.

**PS 1720 Amiodarone-Induced Autophagy Protects Lung Epithelial Cancer Cells from Death.**

K. Lee<sup>1</sup>, S. Oh<sup>1</sup>, S. Oh<sup>2</sup>, B. Lee<sup>1</sup>, Y. Yang<sup>3</sup>, M. Yang<sup>3</sup> and K. Lee<sup>3</sup>. <sup>1</sup>College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Republic of Korea; <sup>2</sup>Research Center for Resistant Cells, Chosun University, Gwangju, Republic of Korea; <sup>3</sup>Inhalation Toxicology Center, Korea Institute of Toxicology, Jeongseup, Republic of Korea.

Amiodarone-induced toxicities in various off-target organs including cornea, liver, skin, thyroid and lung often limit the use of this drug especially in the case of long-term treatment. Despite low incidence rate, amiodarone-induced pulmonary toxicity is the one of greatest concern and leading cause for discontinuation. In the present study, we investigated the induction of autophagy following amiodarone treatment in vitro and the relevance of autophagy to the pulmonary toxicity. Amiodarone treatment caused morphological change in H460 cells. Increased numbers of cytoplasmic vacuoles as well as round and floating cells were observed. Amiodarone-induced autophagy was demonstrated by increased LC3-II conversion, upregulation of Atg5 and Atg7 and degradation of p62 protein. Autophagic flux as determined by lysosomal inhibitor bafilomycin A1 was also increased by amiodarone. The phosphorylation of AMP-activated protein kinase at Thr172 was increased and that of Akt at Ser473 was decreased by amiodarone which resulted in the reduction of mTOR and p70S6 kinase phosphorylation. To determine the role of autophagy in amiodarone toxicity, amiodarone-induced cell death was evaluated in the presence of 3-methyladenine or by knocking down autophagy related genes, Atg5 or Atg7. Inhibition of autophagy decreased the cell viability and increased apoptosis significantly. In conclusion, amiodarone-induced autophagy functions to rescue stressed cells from death. The findings have important implications in developing further strategy to minimize drug-induced toxicity in human.

**PS 1721 Paraquat Causes Hepatocytes Death via Oxidative Stress-Induced JNK/ERK Activation Regulated Mitochondria-Dependent Apoptosis Pathway.**

D. Hung<sup>1</sup>, T. Tseng<sup>2</sup>, C. Su<sup>3</sup>, K. Lee<sup>4</sup>, K. Chen<sup>5</sup>, S. Hsieh<sup>4</sup>, T. Lu<sup>6</sup>, L. Tsai<sup>6</sup>, S. Liu<sup>7</sup>, Y. Chen<sup>6</sup> and C. Huang<sup>8</sup>. <sup>1</sup>Division of Toxicology, Trauma & Emergency Center, China Medical University Hospital, Taichung, Taiwan; <sup>2</sup>Department of Anatomy, China Medical University, Taichung, Taiwan; <sup>3</sup>Department of Otorhinolaryngology, Head and Neck Surgery, Changhua Christian Hospital, Changhua, Taiwan; <sup>4</sup>Department of Emergency, Buddhist Tzu Chi General Hospital, Taichung, Taiwan; <sup>5</sup>Department of Urology, China Medical University Hospital and China Medical University, Taichung, Taiwan; <sup>6</sup>Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan; <sup>7</sup>Institute of Toxicology, National Taiwan University, Taipei, Taiwan; <sup>8</sup>School of Chinese Medicine, China Medical University, Taichung, Taiwan.

Paraquat (1,1'-dimethyl-4,4'-bipyridium dichloride, PQ), a common herbicide used all over the world, is toxic to human beings and causes severe injuries to multiple organs, including lung and liver. However, the toxicological effects and molecular mechanisms of PQ-induced on hepatocytes are mostly unclear. In this study, we found that PQ significantly reduced the cell viability in rat hepatocytic cell line H4-II-E cells. Treatment of H4-II-E cells with PQ also induced several features of mitochondria-dependent apoptotic signals, including loss of mitochondrial membrane potential (MMP), increase in cytosolic cytochrome c release, activation of PARP and caspase-3/-7, and increased oxidative stress injuries such as reactive oxygen species (ROS) generation and glutathione depletion. These PQ-induced apoptotic-related signals could be effectively reversed by antioxidant NAC. Moreover, PQ increased the phosphorylation of JNK and ERK1/2, but not p38. Pharmacological inhibitors SP600125, PD98059, and NAC significantly attenuated PQ-induced cytotoxicity, caspase-3/-7 activation, MMP loss, and inhibited

the phosphorylation of JNK and ERK1/2. Taken together, these results suggest that PQ exerts its cytotoxicity on hepatocytes by inducing apoptosis via an oxidative stress-induced JNK and ERK1/2 activation regulated mitochondria-dependent signaling pathway

## **PS** 1722 Oxidative DNA Damage and Apoptosis Induction after Enniatin B Exposure in Caco2 Cells.

M. Ruiz, A. Prosperini, A. Juan Garcia and G. Font. *Preventive Medicine, University of Valencia, Burjassot Valencia, Spain.*

Enniatin (EN) B is a cyclohexadepsipeptidic mycotoxin produced by *Fusarium* spp. often found in cereals and cereal-based products. Its cytotoxic potential have been reported but the mechanisms involved in its toxicity remain to be elucidated. Since the oxidative pathway could be implicated in mycotoxin's toxicity, in this study the generation of reactive oxygen species (ROS) and lipid peroxidation (LPO) have been investigated in human colorectal adenocarcinoma (Caco-2) cells. Subsequently the induction of oxidative stress have been assumed to be directly related to DNA damage and apoptosis. Cells were exposed to EN B at sub-cytotoxic concentration of 1.5 and 3  $\mu$ M. A significant increase ( $p \leq 0.05$ ) in ROS production was observed by the fluorescent probe H<sub>2</sub>-DCFDA after 3  $\mu$ M exposure in Caco-2 cells from 10 up to 120 min. LPO was determined by thiobarbituric acid reactive substances (TBARS) after 24 h of exposure. Significant increase of malondialdehyde (MDA) was observed after the highest (3  $\mu$ M) concentration tested of 48% ( $p \leq 0.05$ ), as compared to control. Genotoxicity was evaluated through the alkaline Comet assay after 2 and 24 h of exposure. Median tail moment ( $\mu$ M) was significantly high respect to the control with a dose-dependent relationship ( $p \leq 0.05$ ) after short and longer exposure. The induction of apoptosis and necrosis was assessed by flow cytometry. Annexin V coupled to FITC in combination with PI was used to determine different apoptotic phases after 24 h of exposure to EN B (1.5 and 3  $\mu$ M). Both concentrations induced apoptosis and necrosis in a dose-dependent manner. These findings show that 3  $\mu$ M concentration of EN B caused oxidative damage, by means of ROS generation that could be responsible of LPO, DNA damage and triggers apoptosis in Caco2 cells.

## **PS** 1723 Mevalonate Pathway Plays a Major Role in Adriamycin Resistance.

T. Takahashi, S. Nakashima, T. Masuda, S. Yoneda and A. Naganuma. *Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.*

In a search for novel mechanisms of resistance to adriamycin, an anthracycline anti-tumor antibiotic used in cancer chemotherapy, we have previously screened a ORF library derived from budding yeast for genes related to adriamycin resistance and found that overexpression of the gene for HMG-CoA synthase, an enzyme in mevalonate pathway, confers resistance to adriamycin in budding yeast. We have also found that promotion of mevalonate pathway decreased the toxicity of adriamycin in yeast cells.

In this study, we examined the relationships between enzymes involved in mevalonate pathway and the adriamycin resistance, and found that deletion of the gene for Ram1, a farnesyltransferase, reduced the degree of adriamycin resistance induced by overexpression of HMG-CoA synthase. These results suggest that overexpression of HMG-CoA synthase might decrease the adriamycin toxicity through promotion of farnesylation of proteins. Moreover, overexpression of HMG-CoA synthase or addition of mevalonate to culture medium decreased the toxicity of adriamycin in human breast MCF7 cells, suggesting that mevalonate pathway plays a key role in mechanism of adriamycin resistance not only in yeast cells but also in human cells.

## **PS** 1724 Carbamazepine Suppresses Ischemia/Reperfusion Injury to Mouse Livers by Enhancing Autophagic Flux.

J. Kim, J. Wang and K. E. Behrns. *Surgery, University of Florida, Gainesville, FL.*

**BACKGROUND:** Onset of the mitochondrial permeability transition (MPT) plays a causative role in ischemia/reperfusion (I/R) injury, a pathological event occurring during organ transplantation, cardiac failure and hemorrhagic shock. Current therapeutic strategies for reducing reperfusion injury remain disappointing. As autophagy selectively and timely eliminates abnormal or damaged cellular constituents and organelles such as dysfunctional mitochondria, this lysosome-mediated catabolic process confers cytoprotection against I/R injury and various diseases. We have shown that calpain-dependent depletion of autophagy-related proteins (Atg) causes the MPT and hepatocyte death after I/R. Carbamazepine (CBZ),

an FDA approved anticonvulsant drug, has recently been reported to increase autophagy. The AIM of this study was to investigate the effects of CBZ on hepatic I/R injury.

**METHODS:** Hepatocytes and livers from male C57BL/6 mice were subjected to simulated and *in vivo* I/R, respectively. Cell death, intracellular calcium, calpain activity, changes in Atg, autophagic flux, MPT and mitochondrial membrane potential after I/R were analyzed in the presence and absence of 20  $\mu$ M CBZ.

**RESULTS:** CBZ significantly increased hepatocyte viability after reperfusion, as judged by propidium iodide fluorometry. Confocal microscopy of rhod-2, fluo-4, calcein and tetramethylrhodamine methylester revealed that CBZ prevented reperfusion-induced mitochondrial calcium loading, onset of the MPT and mitochondrial depolarization. Immunoblotting and fluorometric analysis showed that CBZ blocked calpain activation, Atg6 depletion, and loss of autophagic flux after reperfusion. Intravital multiphoton imaging of anesthetized mice demonstrated that CBZ substantially reversed autophagic defects and mitochondrial dysfunction after I/R *in vivo*.

**CONCLUSION:** CBZ protects hepatocytes against I/R injury by preventing a temporal sequence of calcium overloading, calpain activation, Atg6 depletion, defective autophagy, onset of the MPT, and cell death.

## **PS** 1725 A Multiplexed Assay for Differentially Examining Cytostatic and Cytotoxic Effects.

A. L. Niles<sup>2</sup>, M. Zhou<sup>1</sup>, T. L. Riss<sup>2</sup> and D. Lazar<sup>2</sup>. <sup>1</sup>Promega Biosciences, San Luis Obispo, CA; <sup>2</sup>Promega, Madison, WI.

We have developed a multiplexed assay which can conveniently differentiate between cytostatic and cytotoxic effects produced in cell culture under standard compound screening conditions. The assay first employs a pro-fluorescent, cell impermeant, DNA probe which changes fluorescent intensity only with changes in membrane integrity due to cytotoxicity. Second, an ATP detection chemistry is applied to examine the relative number of viable cells after treatment. We examined the utility of this multiplex by dosing a suspension cancer cell line (K562) and attachment-dependent cancer line (HeLa) with serially diluted compounds for a period of 72hrs. We chose the antimetabolite compounds, 6-aminomercaptopurine and methotrexate, because of their anti-neoplastic properties and mechanistic relevance in halting cell growth and division. Here we show that by coupling two convenient biomarkers for viability and cytotoxicity, we can define the differences between anti-proliferative and cytotoxic effects. The distinction between cytostatic and cytotoxic effects on particular target cell populations may ultimately help direct prioritization of oncology drug development efforts or offer insight into rational combinations during chemosensitivity testing.

## **PS** 1726 Amiodarone-Induced Perturbations in Rat Pleural Mesothelial Cells.

S. Chappidi and J. M. Cerreta. *PHS, St. John's University, Queens, NY.* Sponsor: L. Trombetta.

Amiodarone (AM) is an anti-arrhythmic drug whose clinical use is often limited due to its toxic effect on the lungs. AM's pulmonary toxicity is mediated in part through apoptosis of the epithelial cells and their replacement with fibrotic tissue. Our laboratory has previously determined that Caspase 8 and 9 levels are increased in cells exposed to AM. Such increases suggest that both the extrinsic and intrinsic pathways have a role in AM induced apoptosis. The current study was carried out to further examine the pathway of AM induced cell injury and determine cellular changes caused by such injury in rat pleural mesothelial cells (RPMC's). RPMC's were grown to confluence in Ham's F-12 medium containing 15% FBS at 37 °C in a humidified, 5% CO<sub>2</sub> environment. Cultures were treated with increasing concentrations (12.5, 25, 50, or 100  $\mu$ g/ml) of AM for 1, 6, 12, or 24 hours. Cytotoxicity of AM was determined by MTT assay. Cell membrane integrity was observed indirectly by measuring the levels of LDH released into the supernatant after 24hr of treatment with AM. To examine activation of the apoptotic pathway, translocation of BAX protein from cytosol to mitochondria was measured by Western Blot analysis following exposure to the 50  $\mu$ g/ml of AM. Cell extracts of both control and AM treated (50 $\mu$ g/ml) cultures were examined to determine cellular GSH/GSSG levels. AM exposed cultures had a time and concentration dependent cytotoxicity at all points tested. At 24 hrs, cell viability was found to be 96%, 72%, 47% or 13% respectively with increasing concentrations of AM. The LDH levels were found to increase (275%, 550%, 1575%, 2075%) following treatment with increasing concentrations of AM. Cultures exposed to 50 $\mu$ g/ml AM had a 330% increase in levels of BAX present in the mitochondrial fraction. Cells exposed to various concentrations (as above) of AM had a concentration dependent decrease (72%, 85%, 68% or 26%) in the levels of GSH/GSSG ratio when compared to the control. Such results suggest that amiodarone is triggering multiple pathways leading to cell death.

**PS 1727 Characterization of Cigarette Smoke and Menthol on Human Alveolar Adenocarcinomic (A549) Cells.**

E. R. Esposito, B. Greene, M. L. Coronel and H. Tran. *Pharmaceutical Sciences, Sullivan University College of Pharmacy, Louisville, KY.*

**Purpose:** Menthol provides local anesthesia to nerve endings, allowing smokers to take deeper, longer inhalations, thus giving longer exposure to carcinogenic elements found in cigarette smoke. There are few cellular studies addressing evidence concerning the risk of developing lung cancer between mentholated and non-mentholated cigarettes. We would like to determine if an association exists between mentholated cigarettes and incidence of lung cancer in the smoker population. Using an in vitro model, we aimed to characterize the effects of cigarette smoke, with or without menthol, in human alveolar adenocarcinomic (A549) cells and determine if the rate of cell proliferation and cell death is altered.

**Methods:** Dose response studies were conducted to determine appropriate concentrations of cigarette smoke condensate (CSC) and menthol for cell viability assays. Cells were treated for 24 hours with either: CSC, menthol, or CSC + menthol compared to vehicle controls. Several techniques were applied to measure cell death and apoptosis. Cell viability was measured using Trypan blue, while intracellular caspase activation was determined using a fluorescein-conjugated antibody designed for flow cytometric applications. Early and late indicators of apoptosis were assessed using Annexin-V and propidium iodide detection assay.

**Results:** Data suggest that menthol alone decreased cell viability and increased Annexin positive cells while co-treatment with CSC + menthol did not affect cell viability. Pan-caspase activation was not significantly altered for CSC, menthol, or CSC + menthol treated cells. Interestingly, cells treated with CSC only appeared to emit a source of auto fluorescence. Future studies are required to address the issue. Data are the average of three independent experiments  $\pm$  standard error of the mean (S.E.M.) Statistical significance is determined  $p < 0.05$ .

**PS 1728 Induction of Late-Apoptosis on Chinese Hamster Ovary Cells by Sandalwood (*Santalum album*) Essential Oil.**

C. M. Ortiz-Sanchez, L. Morales-Torres and J. L. Matta. *Physiology, Pharmacology and Toxicology, Ponce School of Medicine and Health Sciences, Ponce, Puerto Rico.*

Essential oils (EOs) are volatile aromatic compounds that can be extracted from any part of a given medicinal or aromatic plant. EOs have a wide range of applications in the pharmaceutical, food, and cosmetic industries. Recently, there has been an increased interest regarding the pharmacological properties of EOs. Among the large diversity of commercially available EOs, sandalwood essential oil (SEO) is used in food industry as a flavoring ingredient with a daily consumption of 0.0074 mg/kg. It is also used in perfumery and other cosmetic products. SEO has antiviral and antimicrobial properties. However, its pharmacological activity on mammalian cells is largely unknown. The aim of this study was to determine the effect of SEO on Chinese hamster ovary cell (CHO-K1) proliferation and viability. These cells were exposed to concentrations of SEO ranging from 1 – 600  $\mu$ g/mL for 24, 48, 72, and 96 hours. Cell viability was measured by Trypan blue exclusion using the Cellometer Auto T4, while cell proliferation was determined by the tetrazolium salt (MTT) assay. Apoptosis detection was performed by flow cytometry using Annexin-V-PE (a marker for early apoptosis) and 7-AAD (a marker for late apoptotic/necrotic cells). Among all exposure times studied, the same tendency was seen at 24, 48, 72, and 96 hours; SEO decreased cell proliferation in a dose-dependent manner to around 80%. The inhibitory concentration (IC50) was approximately 31  $\mu$ g/mL. Apoptotic effects were studied in concentrations above and below the IC50 using three doses: 25, 30 and 35  $\mu$ g/mL. An increase of 3% and 15% in late apoptotic cells was detected with increasing SEO concentration at 30 and 35  $\mu$ g/mL, respectively ( $p < 0.05$ ). In conclusion, SEO has the potential to decrease cell proliferation by inducing late apoptosis in CHO-K1 cells. However, further analyses are needed to elucidate the pathways involved in this process. Research supported by the NIGMS-NIH Award # R25GM082406.

**PS 1729 Investigating the Role of HO-1/BVR Expression on Apoptosis Regulation.**

C. George and M. J. Jenny. *Department of Biological Sciences, University of Alabama, Tuscaloosa, AL.*

Cadmium (Cd)-resistant cells, when exposed to a variety of chemicals capable of inducing oxidative stress, exhibit significantly lower occurrences of apoptosis compared to non-resistant cells, suggesting that Cd-resistance is in part an adaptation to oxidative stress. Previous studies have attributed this adaptation to increased expression of metallothionein genes and genes involved in the glutathione synthesis/recycling pathway. However, recent studies over the last several years have demonstrated

novel anti-oxidant and anti-apoptotic properties with members of the heme oxygenase-1 (HO-1)/biliverdin reductase (BVR) pathway. To investigate the role of HO-1/BVR in resistance to Cd-toxicity we established a Cd-adapted human hepatocellular liver (HepG2) Ter-On cell line by continuously culturing the cells in 5 $\mu$ M Cd for 16 weeks, with routine media change and cell passage every 3-4 days. After 16 weeks, control and Cd-adapted cells were dosed with additional 0.1, 0.5, 1, 10 and 20 $\mu$ M Cd concentrations and real-time PCR was used to compare gene expression of HO-1, BVRa, BVRb and glutathione reductase (GSR). Interestingly, basal expression of GSR was significantly down-regulated while HO-1, BVRa and BVRb was up-regulated in the Cd-adapted cell line. In addition, there was greater induction of BVRa and BVRb expression in the Cd-adapted cells after additional Cd treatment as compared to control cells. Custom PCR arrays (QIAGEN Inc) were used to analyze expression of genes related to stress and toxicity when control and Cd-adapted cells were dosed with 10 $\mu$ M Cd. The Cd-adapted cells displayed significant alterations in other genes related to oxidative stress, DNA repair and cell division/apoptosis signaling pathways, including many pathways linked to BVRa/ERK regulation, such as tumor necrosis factor (TNF), TNF receptor, lymphotoxin alpha, early growth response 1, insulin-like growth factor 1, interferon alpha and interferon beta 1. Future studies will investigate the direct role of HO-1 and BVR in regulating the potential anti-apoptotic properties of these Cd-adapted cells. [Supported by R00ES017044]

**PS 1730 Role of BCL-2 Proteins in Heat Shock-Induced Apoptosis.**

I. M. Mahajan<sup>1,2</sup>, M. Chen<sup>1,2</sup>, I. Muro<sup>2</sup>, C. W. Wright<sup>2</sup> and S. B. Bratton<sup>1,2</sup>.

<sup>1</sup>Molecular Carcinogenesis, UT Austin/MD Anderson Cancer Center, Smithville, TX;

<sup>2</sup>Pharmacology and Toxicology, University of Texas at Austin, Austin, TX.

Apoptosis is a programmed form of cell death executed by caspases (cysteine proteases) that cleave substrates exclusively after aspartic acid residues. In response to stress, cells often activate the intrinsic apoptotic pathway, wherein mitochondrial outer membrane permeabilization (MOMP) initiates the release of proapoptogenic proteins, such as cytochrome c and Smac, into the cytosol. In particular, cytochrome c promotes formation of a caspase-activating complex known as the Apaf-1-caspase-9 apoptosome. Heat shock (HS) is an ancient stress that activates both prosurvival (thermotolerance) and prodeath cellular responses, and we have previously shown that HS induces apoptosis through pathways that involve MOMP and downstream effector caspase-3 activation, but do not require activation of the apoptosome. HS-induced MOMP is strictly controlled by BCL-2 family members, which include both pro-apoptotic (e.g. Bax, Bim, Bid, etc.) and anti-apoptotic (e.g. Bcl-2, Mcl-1, etc.) proteins. Other studies suggest that HS initiates MOMP following cleavage of Bid by caspase-2. However, we observe that mouse embryonic fibroblasts (MEFs), lacking either caspase-2 or Bid, remain sensitive to HS. In contrast, we find that bim<sup>-/-</sup> MEFs are highly resistant to HS-induced apoptosis and exhibit significantly decreased levels of MOMP. Thus, our findings indicate that Bim is essential for HS-induced death, while caspase-2 and Bid function as part of an amplification loop. Interestingly, Bim is known to induce MOMP through direct activation of Bax and/or Bak, but we find that bax<sup>-/-</sup>/bak<sup>-/-</sup> MEFs are only partially resistant to HS-induced cell death, implying the existence of a Bim-dependent, Bax/Bak-independent pathway. We speculate that another proapoptotic Bcl-2 family member, namely Bok, may functionally substitute for Bax and Bak, or alternatively that Bim may directly permeabilize lysosomal membranes, resulting in the release of proapoptotic cathepsins. (These studies were supported by grants, CA129521 and GM096101, from the NIH.)

**PS 1731 SDF-1 $\beta$  Protects High Fat-Induced Cardiac Cell Apoptosis through Its Receptor CXCR7-Mediated AMPK Activation.**

Y. Zhao<sup>1,2</sup>, L. Cai<sup>2,1</sup> and W. Li<sup>1</sup>. <sup>1</sup>Cancer Center, First Bethune Hospital of Jilin University, Changchun, China; <sup>2</sup>KCHRI, University of Louisville, Louisville, KY.

Hyperlipemia often occurs in the patients with obesity and type 2 diabetes, and is also primary trigger for cardiac remodeling and dysfunction. Stromal cell-derived factor-1 $\beta$  (SDF-1 $\beta$ ) was cardiac protective, but whether it also protects the cardiac cells from high fat-induced apoptosis remains unknown. By using H9c2 cardiac muscle cell line, we observed the effect of SDF-1 $\beta$  on saturated free fatty acid-induced its apoptotic response. Exposure of H9c2 cells to palmitate at 62.5 nM for 15 h caused a significant apoptotic effect, shown by up-regulation of cleaved-caspase3. Pretreatment with SDF-1 $\beta$  significantly prohibited palmitate-induced apoptosis along with significant increases in AMPK-mediated IL-6 production. AMPK activator (AICAR) significantly prevents palmitate-induced cardiac apoptosis while AMPK inhibitor (compound C) prohibited SDF-1 $\beta$ 's protective effect. Direct addition of recombinant human IL-6 to cell cultures prevented palmitate-induced

apoptosis whereas IL-6 siRNA abolished the protective effect of SDF-1 $\beta$ . CXCR7 siRNA, but not CXCR4 antagonist abolished SDF-1 $\beta$ 's protective effect and above related signal transduction. These in vitro results suggest that SDF-1 $\beta$  prevents palmitate-induced cardiac apoptosis via its receptor CXCR7 and further activating AMPK-mediated IL-6 excretion. In vivo studies, by using type 2 diabetes models, we confirmed that high fat diet induced cardiac apoptosis, and that SDF-1 $\beta$  prevented high fat diet-induced cardiac apoptosis along with its activation of AMPK. This important finding opens a new road for the research of SDF-1 $\beta$ 's cardiac protection that is irrelevant with its well-known function of stem cell mobilization.

### PS 1732 Paraoxon Induces Cell Death by the Activation of Caspases in Cultured Human Pulmonary Cells.

D. J. Angelini<sup>1,2</sup>, R. A. Moyer<sup>3</sup>, A. Hajjaj<sup>1,4</sup>, S. Cole<sup>1,2,3</sup>, K. L. Willis<sup>1,2,3</sup>, J. Oyler<sup>5</sup>, R. M. Dorsey<sup>1</sup> and H. Salem<sup>1,6</sup>. <sup>1</sup>Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD; <sup>2</sup>National Research Council, Washington DC; <sup>3</sup>Defense Threat Reduction Agency, Fort Belvoir, VA; <sup>4</sup>Science Applications International Corporation, Abingdon, MD; <sup>5</sup>US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD; <sup>6</sup>Department of Homeland Security, Chemical Security Assessment Center, Aberdeen Proving Ground, MD.

**INTRODUCTION:** Organophosphate chemicals are known to induce pulmonary toxicity in both humans and experimental animals. To elucidate the mechanism of organophosphate-induced cytotoxicity, we examined the effects of parathion and paraoxon on primary cultured normal human bronchial epithelial cells (NHBEs) as well as small airway cells (SAECs).

**METHODS:** We evaluated the viability/cytotoxicity of primary NHBEs and SAECs following exposures to the organophosphate chemicals parathion and paraoxon. Since caspases have a major role in the regulation of apoptosis and cell death, we evaluated paraoxon-induced cell death in the presence of the caspase inhibitor Z-VAD.

**RESULTS:** Parathion failed to induce losses in cellular viability at concentrations known to cause toxicity in vivo following a 24 hour treatment (IC50 >9mM) in either NHBEs or SAECs. Its toxic metabolite, paraoxon, produced a dose-dependent decrease in cell viability following a 24 hour treatment period for both pulmonary cell types (IC50 ~0.5mM). Treatment with paraoxon also induced caspase activation in these cells. Pharmacological inhibition of caspases with Z-VAD during paraoxon treatment protected against paraoxon-induced cell death.

**CONCLUSIONS:** These combined data suggest that paraoxon induces cell death in NHBEs and SAECs, at least in part, through the activation of caspases.

### PS 1733 BDE-154 Decrease Cell Proliferation, Viability and Mitochondrial Membrane Potential Leading to HepG2 Cell Death.

A. O. Souza<sup>1</sup>, L. C. Pereira<sup>2</sup>, M. Tasso<sup>1</sup>, D. P. Oliveira<sup>2</sup> and D. J. Dorta<sup>1</sup>. <sup>1</sup>Química, FFLRP-USP, Ribeirão Preto, Brazil; <sup>2</sup>Análises Clínicas, Bromatológicas e Toxicológicas, FCFRP-USP, Ribeirão Preto, Brazil.

**INTRODUCTION:** Polybrominated diphenyl ethers (PBDEs) are a class of flame retardants composed by 209 different congeners with evidences of several toxic potential on the organisms. Toxic damages of lower and higher brominated congeners have been widely reported but more information about other congeners to clarify of risk of PBDEs class on the health is still necessary. **OBJECTIVE:** The aim of this work was to investigate the effects of the BDE-154 on HepG2, because it had showed growth levels of bioaccumulation on the biotic compartments.

**METHODOLOGY:** We performed a cell proliferation test using SRB colorimetric assay in order to evaluate its inhibitory effects on cell proliferation and then we did a cell viability test by MTT assay, that was performed to investigate relationships between the inhibitory potential of cell growth with the induction of cell death. Subsequently, the effect on the mitochondrial membrane potential (MPP) using TMRM dye was performed to evaluate a possible effect on the cell mitochondria and finally the exposure of phosphatidylserine on the outer membrane using Annexin V and propidium iodeto (PI) staining was evaluated. In all tests, the cells were exposure at concentrations ranging from 0.1 to 25 $\mu$ M for 24 and 48 hours.

**RESULTS:** Our results shown that BDE-154 are capable of inhibiting cell proliferation at doses starting at 10 $\mu$ M ( $p < 0.05$ ) after 48 hours of exposure, although the results of MTT assay had shown a significant decrease in cell viability on lower doses in both times of incubation. Changes on cell proliferation and viability were followed by decrease of MPP and an increase of phosphatidylserine exposure at the cell membrane. **CONCLUSIONS:** According to our results, BDE-154 presents a significant potential to interfere with the mitochondrial homeostasis of HepG2 cells which can lead to apoptosis in the concentration of 25  $\mu$ M.

### PS 1734 Computational Dosimetry Driven Hazard Ranking of 25 Metal Oxide Nanomaterials Using Low- and High-Throughput In Vitro Toxicity Data.

D. Telesca<sup>2</sup>, J. G. Teeguarden<sup>1</sup>, T. Xia<sup>3</sup>, H. Zhang<sup>3</sup>, A. Nel<sup>3</sup>, J. G. Pounds<sup>1</sup> and B. D. Thrall<sup>1</sup>. <sup>1</sup>Biological Sciences, Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Biostatistics, University of California Los Angeles, Los Angeles, CA; <sup>3</sup>Nanomedicine, California Nanosystems Institute, University of California Los Angeles, Los Angeles, CA.

Seeking to integrate broad sets of mechanistic and more traditional dose-response data across in vitro and in vivo systems, and between species, the nanotoxicology field faces the challenge of translating these data into knowledge that will impact public health policy for this emerging class of materials. Using a rich data set on in vitro toxicity of 25 metal oxides as an example, we present framework for nanomaterial risk assessment and hazard ranking based on a paradigm for nanomaterial dosimetry in vitro and in vivo that is consistent with current practice for chemical risk assessment. Integrating cytotoxicity and high-throughput data on 25 metal oxide nanoparticles with cellular dosimetry data derived from in vitro and in vivo models of nanoparticle dosimetry, we demonstrate the impact of cellular dosimetry on hazard ranking schemes. Specifically, the dosimetry hazard ranking approach showed that on a cellular dose and tissue-dose basis, the relative toxicity of the metal oxides is fundamentally different than those bases solely on exposure measures ( $\mu$ g/ml). For example, Co<sub>3</sub>O<sub>4</sub> was ranked #10 based on in vitro studies, but scaled based on tissue doses in exposed humans, Co<sub>3</sub>O<sub>4</sub> was the most hazardous material. Human exposure equivalents calculated using ISDD and MPPD models for each nanomaterial ranged from 0.1 to 10,000 mg/m<sup>3</sup>, indicting some but not all might pose a hazard for exposed humans. Making dosimetry corrections for iron oxide particles, we also show good correspondence between in vitro and in vivo inflammatory responses. The framework, along with high-throughput in vitro data, can clearly be used to rank nanomaterial hazards for broad classes of particles, though it remains an untested hypothesis that such approaches accurately reflect risk in exposed humans.

### PS 1735 Ranking and Profiling Nanomaterial (NM) Bioactivity by ToxCast High-Throughput Screening (HTS).

A. Wang<sup>1</sup>, E. Berg<sup>2</sup>, M. A. Polokoff<sup>2</sup>, J. Yang<sup>2</sup>, A. El-Badawy<sup>3</sup>, D. Reif<sup>1</sup>, N. Kleinstreuer<sup>1</sup>, S. Marinakos<sup>4</sup>, A. Badireddy<sup>4</sup>, S. H. Gavett<sup>1</sup>, D. Rotroff<sup>1</sup>, S. Gangwal<sup>5</sup>, J. Rabinowitz<sup>1</sup>, C. W. Matson<sup>6</sup>, T. Tolavmat<sup>3</sup>, M. Wiesner<sup>4</sup> and K. Houck<sup>1</sup>. <sup>1</sup>ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>BioSeek, LLC, San Francisco, CA; <sup>3</sup>ORD, US EPA, Cincinnati, OH; <sup>4</sup>CEINT, Duke University, Durham, NC; <sup>5</sup>Xanofi, Raleigh, NC; <sup>6</sup>Environmental Sciences, Baylor University, Waco, TX.

HTS allows for rapid examination of large numbers of chemicals for biological effects and the results can be used to prioritize them for further assessment and provide mechanistic insight. To prioritize NMs for further testing, we screened NMs (Au, Ag, CeO<sub>2</sub>, CNT, CuO, TiO<sub>2</sub>, SiO<sub>2</sub>, or ZnO core) and their ion and micro counterparts for cytotoxicity, transcription factor activation, and cellular protein expression. We ranked samples by promiscuity (the number of assays affected) and potency. Two ranking methods produced very similar results and high promiscuity was coupled with high potency. Ag, Cu, and Zn samples were ranked highest priority for further testing. Sample replicates, screened in different test runs, had the same rankings, indicating consistency in data among test runs. To research potential mechanisms of bioactivity, we tested ion contribution to Cu NM bioactivity and compared CNT to asbestos in 8 BioMAP® human primary cell systems for tissue and inflammatory responses. 3 Cu stocks (micro-CuO, nano-CuO, fungicide A containing nano-Cu(OH)<sub>2</sub>) were split and one half was repeatedly washed until the wash liquid had the same electrical conductivity as pure H<sub>2</sub>O, indicating very few released ions. This wash decreased, but did not eliminate, bioactivity, suggesting released ions contribute to bioactivity. The bioactivity profiles of micro-CuO, nano-CuO, and washed nano-CuO were more similar to each other than to other Cu samples, including washed micro-CuO, implying micro- and nano-CuO were affected by the wash differently. The 3 asbestos had similar profiles but only minimal overlap with CNTs. One CNT had a similar profile with Cu, suggesting Cu was present in this sample. Thus HTS can be used to prioritize NMs and provide info on potential mechanism of bioactivity including chemical composition of the samples.

**PS 1736 Coating Nanoporous Alumina: Cellular Responses to Surface Layers of Zinc and Titanium Oxides.**

P. E. Petrochenko<sup>2,1</sup>, G. Kumar<sup>1</sup>, W. Fu<sup>3</sup>, S. A. Skoog<sup>2,1</sup>, Q. Zhang<sup>1</sup>, J. Zheng<sup>1</sup>, C. Liang<sup>3</sup>, P. L. Goering<sup>1</sup> and R. J. Narayan<sup>2</sup>. <sup>1</sup>CDRH, US FDA, Silver Spring, MD; <sup>2</sup>Joint Department of Biomed Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Chemical Sciences Division, Oak Ridge National Lab, Oak Ridge, TN.

Nanoporous anodic aluminum oxide (AAO) membranes have applications in skin wound repair; the surface topography of these materials has been shown to modulate wound healing. Previous work by our group has shown that coating titanium dioxide (TiO<sub>2</sub>) onto nanoporous AAO does not affect cell viability and that zinc oxide (ZnO)-coated AAO membranes exhibit antimicrobial activity against several bacterial strains associated with skin infection. In this study, the nanoporous structure of 20, 100, or 200 nm pore diameter AAO membrane substrates was maintained by depositing nm-thick layers of TiO<sub>2</sub> or ZnO using an atomic layer deposition (ALD) process involving alternative adsorption/hydrolysis of Ti isopropoxide or diethyl Zn, respectively. X-ray spectroscopy (EDX) confirmed the presence of ZnO or TiO<sub>2</sub> on AAO membranes. Cell viability and inflammatory responses were evaluated on ZnO- and TiO<sub>2</sub>-coated AAO membranes. RAW 264.7 macrophages cultured on ZnO-coated AAO exhibited a significant decrease in metabolic activity (MTT reduction) after 24 or 48 h exposure; however, no changes were observed in lactate dehydrogenase (LDH) release or reactive oxygen species (ROS) production. L929 fibroblasts grown on TiO<sub>2</sub>-coated AAO had higher viability (MTT assay) than controls (uncoated AAO) after 48 hrs; no change in viability was observed using the Neutral Red assay. No significant increase in fibroblast cell proliferation (DNA assay) was observed. No TNF- $\alpha$  production or decrease in viability was seen in RAW 264.7 macrophages grown on TiO<sub>2</sub>-coated membranes. The total adsorbed protein per unit area on uncoated and TiO<sub>2</sub>-coated AAO was up to 12-times greater than that on tissue culture polystyrene. The results show that nm-thick ALD coatings maintain the nanoporous structure of AAO membranes. Further, antimicrobial ZnO coatings decrease cell viability and TiO<sub>2</sub> coatings appear to be more biocompatible *in vitro*.

**PS 1737 Potential Phototoxicity of Aged Al(OH)<sub>3</sub>-Coated TiO<sub>2</sub> Nanoparticles in Retinal Pigment Epithelial Cells.**

J. N. Ortenzio<sup>1</sup>, L. L. Degen<sup>2</sup>, R. Zucker<sup>2</sup>, J. Virkutyte<sup>3</sup>, S. R. Al-Abed<sup>4</sup>, H. Ma<sup>5</sup>, S. Diamond<sup>6</sup>, K. Dreher<sup>2</sup> and W. K. Boyes<sup>2</sup>. <sup>1</sup>Contractor, Research Triangle Park, NC; <sup>2</sup>US EPA, Research Triangle Park, NC; <sup>3</sup>Contractor, Cincinnati, OH; <sup>4</sup>US EPA, Cincinnati, OH; <sup>5</sup>Contractor, Duluth, MN; <sup>6</sup>US EPA, Duluth, MN.

Titanium dioxide (TiO<sub>2</sub>) nanoparticles (NPs) exposed to UVA radiation generate reactive oxygen species (ROS). As a component of sunscreen formulations, TiO<sub>2</sub> NPs may be coated with Al(OH)<sub>3</sub> to prevent ROS from causing oxidative damage to tissues. Simulated swimming pool water (SSPW) degrades the Al(OH)<sub>3</sub> coating which could reduce the coating's protective function. We examined the potential phototoxicity of 25 nm, Al(OH)<sub>3</sub>-TiO<sub>2</sub> NPs that had been aged in SSPW for 0 min, 45 min, 1 day, 3 days, 10 days, or 14 days. In two non-cellular assays, measuring methylene blue degradation or thiobarbituric acid reactive species, aged Al(OH)<sub>3</sub>-TiO<sub>2</sub> showed substantially less photocatalytic activity than the positive control: uncoated Aeroxide P25, 31 nm. In a cellular assay, a human-derived retinal pigment epithelium cell line (ARPE-19) was used as a site of photoreactivity. Cells were split into 24-well culture plates, incubated for 24h, then treated with 0, 3, 10, 30, or 100  $\mu$ g/ml of each aged NP or 30  $\mu$ g/ml of positive control. After treatment, the cells were either exposed to 1.5h UVA radiation or no light. 24h later, cell viability was assessed by live/dead assays (calcein-AM/propidium iodide). Flow cytometry and dark field microscopy verified that the TiO<sub>2</sub> NPs entered the cells. Flow cytometry showed dose-related increased side-scatter signal consistent with uptake of NPs, and dark field microscopy showed TiO<sub>2</sub> accumulation along the nuclear envelope and near the endoplasmic reticulum of ARPE-19 cells. No difference in cytotoxicity was observed after UVA irradiance among the SSPW-aged groups. The positive control yielded 100% cytotoxicity under UVA irradiation. The lack of phototoxicity observed with SSPW-aged Al(OH)<sub>3</sub>-TiO<sub>2</sub> suggests that degradation of the particle coating did not increase the risk of phototoxic reactions under the conditions tested.

This abstract does not reflect EPA policy.

**PS 1738 Silica and Gold Nanoparticle Exposure Decreases Phagocytosis in Mouse Raw 264.7 Cells.**

S. Bancos and K. M. Tyner. US FDA, Silver Spring, MD.

Silica (SiO<sub>2</sub>) and gold (Au) nanoparticles (NPs) have been proposed for various therapeutic and diagnostic applications. It has been previously shown *in vivo* that administration of NPs leads to particle accumulation in macrophages of the reticu-

loendothelial system independent of NP core composition, size, or mode of administration. There is, however, little to no information on whether NP accumulation affects macrophage function. Using a panel of *in vitro* assays, we assessed the proliferation, activation, cytokine production and phagocytosis ability of RAW 264.7 cells in response to non-toxic concentrations of SiO<sub>2</sub> NPs (~10 nm) and Au NPs (~10 nm) during a 6h-48h time course. There was a 50-60% reduction in cell number in SiO<sub>2</sub> NP-treated cells that was associated with an increase in the percentage of cells arrested in G0/G1 phase and a decrease in the percentage of cells in the S phase; there were no significant changes in the expression of CD40, CD80 and CD86 markers. Au NP-treated cells showed a 14- 40% decrease in cell number; neither the cell cycle status of Au NP-treated cells nor the expression of surface markers could be assessed due to Au NP interference with the flow cytometry assay. Among the cytokines analyzed, TNF- $\alpha$  levels increased only in cells treated with 0.01 g/L SiO<sub>2</sub> NP, whereas IL-6 and IL-10 levels did not change in SiO<sub>2</sub> NP- or Au NP-treated cells. The ability of SiO<sub>2</sub> NP- and Au NP- treated cells to phagocytose FITC-E. coli bioparticles was evaluated by flow cytometry and confocal microscopy. The results show that phagocytosis was reduced by ~50% in both SiO<sub>2</sub> NP- and Au NP- treated macrophages. Overall, the results indicate that 10 nm SiO<sub>2</sub> NP and Au NP exposure can impact macrophage phagocytosis *in vitro*, but does not appear to impact cytokine production or the expression of activation markers. A decrease in phagocytosis may lead to decreased immunity and diminished response to bacterial infections.

**PS 1739 Comprehensive Assessment of Property-Dependent Bioimpact of Engineered Nanomaterials Using Novel 'Bench-Top' Human Tissue Screening Platforms.**

R. Iyer<sup>1</sup>, J. Gao<sup>2</sup>, A. Nagy<sup>2</sup>, S. Iyer<sup>2</sup>, J. Hollingsworth<sup>3</sup>, J. Drocco<sup>4</sup>, J. Song<sup>2</sup>, T. Sanchez<sup>2</sup> and H. Wang<sup>5</sup>. <sup>1</sup>Defense Systems and Analysis, Los Alamos National Lab, Los Alamos, NM; <sup>2</sup>Biosciences Division, LANL, Los Alamos, NM; <sup>3</sup>MPA-CINT: Center for Integrated Nanotechnologies, LANL, Los Alamos, NM; <sup>4</sup>Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM; <sup>5</sup>Chemistry Division, LANL, Los Alamos, NM.

The core focus of our effort was to develop human three-dimensional (3-D) *in vitro* tissue models to serve as a realistic representation of human exposures and for assessing NM toxicity to decisively rank what physico-chemical parameters can drive toxicity. Core NM parameters including composition, size, shape, redox activity, functionalization and charge were all tested by investigating a multitude of NMs. Kinetics of bioresponses such as necrosis, apoptosis, oxidative stress, cytokine secretion and changes in gene and protein expression were all evaluated in response to nanomaterial exposure. We also developed novel computational analytics to differentiate bioresponses as a factor of NM property. Network-inference-based methods, such as context-likelihood of relatedness (CLR), as well as clustering-based methods, such as principal component analysis (PCA) were used to identify a set of known regulons as well as other co-regulated transcripts potentially unique to nanotoxicity. Further investigation revealed that NM composition, followed closely by charge, were parameters which significantly influenced NM-driven toxicity. Moreover, we found significant differences between the molecular mechanisms of NMs toxicity in monolayer cell culture models versus our complex, more physiologically relevant tissue models. As such, we conclude that further development of human 3-D tissue models is warranted in order to gain accurate information regarding the risk and consequences of NM exposure.

**PS 1740 Genotoxicity of TiO<sub>2</sub> Anatase Nanoparticles in B6C3F1 Male Mice *Pig-A* and Flow Cytometric Micronucleus Assays.**

J. Yan<sup>1</sup>, R. Sadiq<sup>2,1</sup>, J. A. Bhalli<sup>1</sup>, R. S. Woodruff<sup>3</sup>, M. G. Pearce<sup>1</sup>, Y. Li<sup>1</sup>, T. Mustafa<sup>4</sup>, F. Watanabe<sup>4</sup>, L. M. Pack<sup>5</sup>, A. S. Biris<sup>4</sup>, Q. M. Khan<sup>2</sup> and T. Chen<sup>1</sup>. <sup>1</sup>Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>National Institute for Biotechnology and Genetic Engineering, Faisalabad, Pakistan; <sup>3</sup>Division of Microbiology, Arkansas Regional Laboratory, US FDA, Jefferson, AR; <sup>4</sup>Nanotechnology Center, University of Arkansas at Little Rock, Little Rock, AR; <sup>5</sup>Nanotechnology Core Facility, National Center for Toxicological Research, US FDA, Jefferson, AR.

*In vivo* micronucleus and *Pig-a* (phosphatidylinositol glycan, class A gene) mutation assays were conducted to evaluate the genotoxicity of 10 nm titanium dioxide anatase nanoparticles (TiO<sub>2</sub>-NPs) in mice. Groups of five 6- to 7-week-old male B6C3F1 mice were treated intravenously for three consecutive days with 0.5, 5.0, and 50 mg/kg TiO<sub>2</sub>-NPs for the two assays; mouse blood was sampled one day before the treatment and on Day 4, and Weeks 1, 2, 4, and 6 after the beginning of the treatment; *Pig-a* mutant frequencies were determined at Day -1 and Weeks 1, 2, 4 and 6, while percent micronucleated-reticulocyte (%MN-RET) frequencies were measured on Day 4 only. Additional animals were treated intravenously with three

daily doses of 50 mg/kg TiO<sub>2</sub>-NPs for the measurement of titanium levels in bone marrow after 4, 24, and 48 hrs of the last treatment. The measurement indicated that the accumulation of the nanoparticles reached the peak in the tissue 4 hrs after the administration and the levels were maintained for a few days. No increase in either *Pig-a* mutant frequency or the frequency of %MN-RETs was detected, although the %RETs was reduced in the treated animals on Day 4 in a dose-dependent manner indicating cytotoxicity of TiO<sub>2</sub>-NPs in the bone marrow. These results suggest that although TiO<sub>2</sub>-NPs can reach the mouse bone marrow and are capable of inducing cytotoxicity, the nanoparticles are not genotoxic when assessed with *in vivo* micronucleus and *Pig-a* gene mutation tests.

#### PS 1741 Comparative Assessment of Nanomaterial Definitions and Considerations for Implementation.

R. David<sup>4</sup>, D. R. Boverhof<sup>1</sup>, J. H. Butala<sup>2</sup>, S. Clancy<sup>3</sup>, M. Lafronconi<sup>5</sup> and J. West<sup>6</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Ferro Corp, Cleveland, OH; <sup>3</sup>Evonik Degussa, Parsippany, NJ; <sup>4</sup>BASF Corp, Florham Park, NJ; <sup>5</sup>Procter & Gamble, Cincinnati, OH; <sup>6</sup>American Chemistry Council, Washington DC.

The use of nanomaterials is bringing promising new advances to science and technology. In concert have come calls for increased regulatory oversight to ensure their appropriate identification and control. If nanomaterial-specific regulations are implemented, it will be critical that they are accompanied by definitions that are clear, consistent and practical to apply. Numerous definitions for nanomaterials have been proposed by various government, industry, and standards organizations; however, these definitions differ in their core elements and scope. A comprehensive comparative assessment was conducted on existing nanomaterial definitions with the goal of identifying elements essential for a sound regulatory definition. Common elements across definitions included size and dimensions; however, size limits were inconsistent and several important elements were not captured consistently including: consideration of agglomerates and aggregates, distributional thresholds, novel properties and solubility. Other important differences included number size distributions versus weight distributions and natural versus intentionally-manufactured materials. Accordingly, this analysis was extended to identify the critical elements to clearly define the materials subject to a nanomaterial regulation. The analysis also evaluated the extent of characterization required to determine whether a material falls within current nanomaterial definitions and found that some are not aligned with currently available analytical capabilities. Overall, this analysis highlights the similarities and differences in currently proposed nanomaterial definitions as well as the technical constraints that will need to be addressed for the successful implementation of a regulatory nanomaterial definition.

#### PS 1742 Cytotoxicity and Genotoxicity Studies in A549 Cells Cultured with Metal Oxide Nanoparticles.

A. Miyajima-Tabata<sup>1</sup>, K. Sakai<sup>1</sup>, T. Kawakami<sup>2</sup>, R. Kato<sup>1</sup>, A. Matsuo<sup>1</sup> and K. Isama<sup>2</sup>. <sup>1</sup>Division of Medical Devices, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Division of Environmental Chemistry, National Institute of Health Sciences, Tokyo, Japan. Sponsor: A. Hirose.

Nanomaterials are now widely used in various fields of science, technology and medicine. However, there are many unclear safety issues because they are new materials. An *in vitro* cellular toxicological study using well-characterized nanoparticles is conducted for the evaluation of the biological effects of nanoparticles. In this study, we compared the sensitivity of human lung-derived epithelioid-like cell line A549 cells and Chinese hamster lung fibroblast (CHL) cells to nanoparticles. This study also evaluated the cytotoxicity and the genotoxicity of ten kinds of metal oxide nanoparticles (MNs; primary diameter: <50 nm) in A549 cells.

A549 and CHL cells were treated with ZnO or polystyrene as typical nanoparticles and the cytotoxicity and the genotoxicity were examined. A549 cells were treated with MNs and the cytotoxicity and the genotoxicity of MNs were evaluated. The cytotoxicity was evaluated with colony formation and MTT assays, and the genotoxicity test was evaluated with an *in vitro* micronucleus test. The physicochemical properties, such as the hydrodynamic diameter of secondary MNs, the zeta potential etc., were determined in both suspension and 10%FBS-MEM.

No remarkable difference was observed between A549 and CHL cells in the cytotoxicity and the genotoxicity when treated with ZnO or polystyrene. The hydrodynamic diameter of MNs observed in suspension and 10%FBS-MEM were 41.0 to 256.8 nm and 152.9 to 1388.6 nm, respectively. Although the zeta potentials of MNs measured in suspension were positive (+41.6 to +62.1 mV), except SiO<sub>2</sub> and ZnO (-54.4 and -7.5 mV), all of the zeta potentials of MNs measured in 10%FBS-MEM were negative (-22.7 to -10.7 mV). Cytotoxicity was observed following treatment with CuO, NiO, ZnO, ITO, and Y<sub>2</sub>O<sub>3</sub> in the colony formation assay and with CuO, NiO, and ZnO in the MTT assay. The results of the genotoxicity study will be discussed.

#### PS 1743 In Vitro Toxicity Evaluation of Chemical Biological Defense (CBD) Nanomaterials.

C. J. Cao, A. O'Neill, L. C. Crouse and M. S. Johnson. *Toxicology Portfolio, US Army Institute of Public Health, Aberdeen Proving Ground, MD.*

Nanomaterials are gaining in commercial and military applications which yield new capabilities applicable to CBD. US Army Public Health Command (US-APHC) and Office of the Surgeon General (OTSG) have made efforts in chemical, biological, radiological and nuclear incident response for protecting the work force, civilian and military, from the unintended consequences of nanotechnology processes and materials exposures. The study used the Microtox® Toxicity Test System and Neutral Red Uptake (NRU) assay to fast evaluate four CBD nanomaterials for their aquatic toxicity in marine organisms, *Vibrio fischeri*, and basal cytotoxicity in human liver cells in support of the ongoing USAPHC/OTSG efforts. Four nanomaterials: RNP-212 and FAST-ACT®, proprietary formulation of nanocrystalline metal oxides used for neutralizing a wide range of toxic chemicals and chemical warfare agents; PhotoScrub™, a fiberglass cloth coated with TiO<sub>2</sub> that uses UV light induced catalytic ionization of TiO<sub>2</sub> to destroy chemical/biological warfare agents; Nano SBC, a nanosized sodium bicarbonate being investigated as a replacement fire extinguishing agent in hand held fire extinguishers of Army Aviation Weapons Systems, were selected for these tests. Microtox toxicity (EC50 15min; mg/L) shows FAST-ACT (13.78) > RNP-212 (362) > Nano SBC (1394) > PhotoScrub (>2500). Using US Fish and Wildlife Service aquatic toxicity criteria, FAST-ACT and RNP-212 are considered "slightly toxic" and "practically nontoxic", respectively; both Nano SBC and PhotoScrub are considered "relatively harmless". The Microtox study fills the data gap for aquatic toxicity information for the new nanomaterials. Neither FAST-ACT, RNP-212, PhotoScrub at 1250 µg/mL, nor Nano SBC at 2500 µg/mL were found toxic to human cells with NRU assay. The human basal cytotoxicity data and predicted LD50 are comparable with the results from animal studies. Both *in vitro* and *in vivo* studies assessed these four nanomaterials as low hazard.

#### PS 1744 Inhibition of Adipogenic Differentiation of Human Mesenchymal Stem Cells by TiO2 Nanoparticles.

Y. Zhang<sup>1</sup>, L. Guo<sup>2</sup>, L. Yu<sup>2</sup>, Y. Gao<sup>2</sup>, Y. Jones<sup>1</sup>, A. Keasling<sup>1</sup>, B. Green<sup>2</sup>, D. Hansen<sup>2</sup>, A. Inselman<sup>2</sup>, L. Shi<sup>2</sup>, P. C. Howard<sup>1</sup> and B. Ning<sup>2</sup>. <sup>1</sup>NCTR/ORANanotechnology Core Facility, Office of Scientific Coordination, NCTR/FDA, Jefferson, AR; <sup>2</sup>Division of Systems Biology, NCTR/FDA, Jefferson, AR.

Nanotechnology has resulted in the creation of many new materials and devices with a vast range of applications. TiO<sub>2</sub> has historically been used as a pigment with many applications, and nanoscale TiO<sub>2</sub> is additionally appearing in human consumer products, raising safety issues of human health and environmental concerns. Stem cells are proposed to be attractive tools for toxicity testing because of their sensitivity to external stimuli during differentiation. The physical and chemical properties of TiO<sub>2</sub> nanoparticles were characterized using transmission electron microscopy (TEM), nanoparticle tracking analysis, dynamic light scattering, Brunauer-Emmett-Teller, Raman and X-ray fluorescence spectroscopy. We examined the impact of TiO<sub>2</sub>, and other nanomaterials, on cytotoxicity and differentiation of human mesenchymal stem cells (hMSC). TiO<sub>2</sub> nanoparticles induced cytotoxicity in a concentration-dependent manner in hMSCs. Additionally, the differentiation of hMSCs to adipocytes, determined using imaging and Oil Red O staining, was inhibited in a concentration-dependent manner. Moreover, uptake of the TiO<sub>2</sub> nanoparticles by hMSCs was confirmed using TEM, suggesting a possible endocytosis pathway. The mRNA expression for the adipogenic markers adiponectin, aP2, and LPL were significantly reduced to 61%, 53%, and 61% of control levels following exposure to TiO<sub>2</sub> nanoparticles. Furthermore, incubation of the TiO<sub>2</sub> with the mesenchymal stem cell lysate resulted in the identification of 208 proteins associated with the nanoparticles using proteomic and mass spectrometry analyses. These results indicate (i) the interaction and impact of nanoparticles with stem cells is selective (other nanoparticles did not induce this effect), (ii) TiO<sub>2</sub> nanoparticles inhibited differentiation of mesenchymal stem cells, and (iii) further work is needed to elucidate the mechanism of action of TiO<sub>2</sub> in this cell population.

**PS 1745 Comparison of Toxicity of Bare- and Phospholipid-Coated Iron Oxide Nanoparticles in Different Cell Lines.**

E. Park<sup>1</sup>, D. Choi<sup>1</sup>, H. Umh<sup>2</sup>, J. Kim<sup>1</sup>, D. Kim<sup>1</sup>, S. Kim<sup>1</sup> and Y. Kim<sup>2</sup>.  
<sup>1</sup>Department of Molecular Science and Technology, Ajou University, Suwon, Republic of Korea; <sup>2</sup>Department of Chemical Engineering, Kwangju University, Seoul, Republic of Korea. Sponsor: E. Park.

We pursue a better quality of life as well as a rich life through the development of science and technology. However, the scientific principles and its application threaten our health sometimes. In this study, we compared the toxicity of phospholipid coated-iron oxide nanoparticles (PLC-FeNPs) and bare-FeNPs in different cell lines. PLC-FeNPs showed higher negative charge than that of bare-FeNPs in the vehicle, but not in the cell culture media containing fetal bovine serum. In addition, the trend of uptake in each cell lines was very similar between both types of FeNPs, despite differences in their diameters. However, cell cycle changes varied according to the cell line and the type of FeNPs. We performed further study using two macrophage cell lines. At 1 h after exposure, MH-S cells exposed to both types of FeNPs showed a strong correlation between gene expression changes despite the uptake process was different, but RAW264.7 cells exposed to both types of FeNPs showed a weak correlation between gene expression changes despite the uptake process was similar. At 24 h after exposure, two macrophage cells exposed to PLC-FeNPs and RAW264.7 cells exposed to bare-FeNPs induced the increase in the number of autophagosome-like vacuoles. While, the cytosolic component of MH-S cells exposed to bare FeNPs completely disappeared, although the membrane remained intact. The predominant gene in MH-S and RAW264.7 cells was also different. Furthermore, when treated with both types of FeNPs, RAW264.7 cells secreted TNF $\alpha$  only, whereas MH-S cells secreted IL-1 $\beta$  and IL-6 along with TNF $\alpha$ . Based on these results, choice of cell line is very important to improve the reliability of in vitro toxicity data. Further, we think that the increase of autophagosome-like vacuoles may be an important cause of cell death which is caused by nanoparticles.

**PS 1746 Mechanisms of Silica Nanoparticle-Induced Interleukin-8: Requirement of p38/TACE/TGF- $\alpha$ /EGFR-Cascade and NF- $\kappa$ B Signalling in Lung Epithelial Cells.**

M. A. Refsnes, T. Skuland, J. Øvrevik, P. E. Schwarze and M. Låg. Department of Air Pollution and Noise, Norwegian Institute of Public Health, Oslo, Norway. Sponsor: M. Løvik.

Nanoparticles (NPs) of non-crystalline (amorphous) silica particles (SiNPs) are used in a large range of products. Inhalation of NPs represents a potential health hazard and may induce inflammation in lung tissues. We have previously shown that SiNPs induced marked cytokine responses independently of particle uptake in human bronchial epithelial cells (BEAS-2B). In the present study the mechanisms involved in SiNP-induced IL-8 responses were further examined. SiNP-exposure induced an early increase in phosphorylation of p65 (NF- $\kappa$ B) as well as the three main MAP-kinases ERK1/2, p38 and JNK, concurrent with an early up-regulation of IL-8 mRNA. SiNP also induced a time-dependent increase in phosphorylation of the epidermal growth factor receptor (EGFR) and release of the EGFR-ligand transforming growth factor (TGF)- $\alpha$ . SiNP-induced IL-8 responses were attenuated by the p38-inhibitor SB202190, the NF $\kappa$ B-inhibitor PDTC-p65 and siRNA against p65, as well as the EGFR-inhibitor AG1478, a TGF- $\alpha$ -neutralizing antibody and TAPI-1 (inhibitor of the metalloprotease TACE which cleaves pro-TGF- $\alpha$  to TGF- $\alpha$ ). However, inhibitors of ERK and JNK did not exert any effect on SiNP-induced IL-8. Moreover, SiNP-induced EGFR-phosphorylation was inhibited by AG1478 and TAPI-1, and SB202190 reduced the SiNP-induced TGF- $\alpha$  response. The SiNP-induced phosphorylations of p38 and p65 were not affected by TAPI-1 or AG1478. Thus, SiNP appeared to induce EGFR-phosphorylation through a p38- and TACE-dependent cleavage/release of TGF- $\alpha$ . Interestingly, EGF and TGF- $\alpha$  induced little effect on IL-8 release compared to SiNP, suggesting that EGFR-signalling alone is an insufficient stimuli for IL-8 induction. In conclusion, SiNP-induced IL-8 responses seemed to require activation of p38/TACE/TGF- $\alpha$ /EGFR-cascade, presumably acting in concert with the classical NF- $\kappa$ B pathway in BEAS-2B cells.

**PS 1747 Role of Tungstate Nanoparticles in the Production of ROS and Induction of Cellular Damage.**

K. M. Dunnick<sup>1,2</sup>, M. A. Badding<sup>1</sup>, N. R. Fix<sup>1</sup>, J. M. Patete<sup>3</sup>, S. S. Wong<sup>3,4</sup>, V. Castranova<sup>1</sup> and S. S. Leonard<sup>1,2</sup>. <sup>1</sup>HELD, National Institute for Occupational Safety and Health, Morgantown, WV; <sup>2</sup>Pharmaceutical and Pharmacological Sciences, West Virginia University, Morgantown, WV; <sup>3</sup>State University of New York at Stony Brook, Stony Brook, NY; <sup>4</sup>Brookhaven National Laboratory, Upton, NY.

Alkaline-earth metal tungstate AWO<sub>4</sub> (A= Ca, Ba, Sr) nanoparticles are currently being used in a variety of applications including use as components of medical equipment, optical fibers, gas sensors, and scintillator detectors. Due to tungstate nanoparticle versatility, their manufacturing is expected to increase within the next 10 years. Our ongoing study is designed to examine the effects of tungstate nanoparticle exposure in order to develop safe workplace practices to limit exposure. Electron Spin Resonance (ESR) was used to measure hydroxyl radical ( $\cdot$ OH) production of tungstate nanoparticles following incubation with either hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) or RAW 264.7 cells. Additionally, enhanced dark field microscopy was used to assess nanoparticle association and engulfment by RAW cells over multiple time points up to 3 hours. Assays measuring H<sub>2</sub>O<sub>2</sub> production, oxygen consumption, DNA damage and lipid peroxidation were used to assess possible cellular injury following RAW cell incubation with tungstate nanoparticles. Data showed that tungstate nanoparticles are capable of producing  $\cdot$ OH in the presence of H<sub>2</sub>O<sub>2</sub> and RAW cells. Further, tungstate nanowires produced significantly greater  $\cdot$ OH compared to nanospheres as shown through ESR measurements. Initial dark field microscopy data showed an increase in association between tungstate nanoparticles and cells and a decrease in non-specific binding after 3 hours of exposure. Cellular damage results in conjunction with ESR data will promote an understanding of tungstate nanoparticle toxicity. It is important to understand the damaging effects and free radical production produced by tungstate nanoparticle exposure in order to ensure that accurate toxicity models are developed and to promote proper training in nanoparticle inhalation prevention.

**PS 1748 Comparative *In Vitro* Toxicity Study of Bismuth and Bismuth-Derivatives Nanoparticles.**

A. De Vizcaya-Ruiz<sup>1</sup>, M. Esquivel-Gaón<sup>1,6</sup>, O. C. Barbier<sup>1</sup>, M. Uribe-Ramirez<sup>1</sup>, J. Narváez-Morales<sup>1</sup>, J. Muñoz-Saldaña<sup>2</sup>, S. Velumani<sup>3</sup>, Y. Matsumoto<sup>3</sup>, D. Diaz<sup>4</sup>, E. Berea<sup>5</sup>, K. A. Dawson<sup>6</sup> and S. Anguissola<sup>6</sup>. <sup>1</sup>Toxicology, Cinvestav, Mexico City, Mexico; <sup>2</sup>Unidad Queretaro, Cinvestav, Queretaro, Mexico; <sup>3</sup>Electrical Engineering Department, Cinvestav, Mexico City, Mexico; <sup>4</sup>Facultad de Química, UNAM, Mexico City, Mexico; <sup>5</sup>Farmaquímica, Mexico City, Mexico; <sup>6</sup>CBNI, University College Dublin, Dublin, Ireland.

Bismuth and bismuth-derived nanoparticles (Bi-NP) were developed for safer consumer applications as bioprobes, photocatalysts, piezoelectrics and contrast agents. A comparative in vitro study was performed to test the biointeraction and toxicity of Bi-NP - bismuth trioxide (Bi<sub>2</sub>O<sub>3</sub>), bismuth vanadate (BiVO<sub>4</sub>), bismuth antimony (Bi-Sb), bismuth-sodium-barium-titanate (BNT-BT), and zero-valent colloidal Bi (ZV-Bi). Dispersion and stability in biological fluids and in vitro toxic effects in target cells (liver-HepG2, kidney-LLCPK1, lung-A549 and brain-SHSY5Y) were evaluated using a nanometer fractionized suspension (<200 nm) achieved through sonication, centrifugation, and addition of bovine serum albumin (BSA) to reduce agglomeration. Scanning electron microscopy (SEM) confirmed morphological analysis and dispersion of Bi-NP. Cytotoxicity was observed at high concentrations (100  $\mu$ g/ml) at 24 to 72 h, using well established LDH and MTT assays and High Content Analysis. Lung and brain cells were more susceptible, the main form of cell death was necrosis without involving reactive oxygen species (ROS) generation. Cell cycle analysis showed arrest at G0-G1 phase with BNT-BT and Bi-Sb. With BiVO<sub>4</sub> treatment an increase in S-phase and significant DNA damage assessed with the comet assay, were observed. No relevant acute cytotoxicity was observed in the exposed cell systems from the initial screening of Bi-NP. The severity of biological outcomes of Bi-NP in descending order were BiVO<sub>4</sub>>Bi<sub>2</sub>O<sub>3</sub>>Bi-Sb>BNT-BT>ZV-Bi. Further work is underway to elucidate the mechanisms and nuclear effects, and to connect the biological effects with the physicochemical properties of the Bi-NP. Funding from the European Community Seven Framework Programme and CONACYT (Grant agreements #263878 and 12514).

**PS 1749 Long-Term Inhalation Study with Nanomaterials: Characterization of As-Produced Properties and Persistence Simulation Assays.**

W. Wohlleben<sup>3,1</sup>, L. Ma-Hock<sup>1</sup>, J. Keller<sup>1</sup>, K. Wiench<sup>2</sup> and R. Landsiedel<sup>1</sup>.  
<sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany;  
<sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Polymer Physics, BASF SE, Ludwigshafen am Rhein, Germany.

The most urgent knowledge gap in nanosafety research concerns the long-term fate and effects of nanomaterials that may have been released into the air or the environment. BASF and the German Ministry for the Environment (BMU) have initiated a chronic inhalation study as part of the EU project NanoREG. Here we report whether the materials chosen can be regarded as representatives of poorly soluble biopersistent (PSB) particles.

The original batch of CeO<sub>2</sub> distributed as NM212 from the OECD sponsorship program and an identical reproduction of the BaSO<sub>4</sub> distributed as NM220 were characterized by 20 physical-chemical endpoints according to the nanospecific REACH guidance R7.1, benchmarked against TiO<sub>2</sub> (NM105) and the non-persistent SiO<sub>2</sub> (Aerosil 150). The as-tested solubility was simulated by incubation for 28d in buffer (PBS) or phagolysosomal fluid (PSF), or 1d in stomach (0.1N HCl). Analysis included released ions by atom spectroscopy, agglomeration by analytical ultracentrifugation and laser diffraction, morphology by electron microscopy (TEM, SEM) and selected area electron diffraction (SAD).

The re-characterization of CeO<sub>2</sub> NM212 and BaSO<sub>4</sub> NM220 confirms their conformity with earlier work on the OECD batches by PROSPECT and NanoCare projects. The solubility of CeO<sub>2</sub> NM212 is as low as TiO<sub>2</sub> NM105. The positive control SiO<sub>2</sub> dissolves as expected. The solubility of BaSO<sub>4</sub> NM212 in all media, including PSF, is vanishing against the positive control, and noticeable only in 0.1N HCl. All materials, incl. TiO<sub>2</sub>, undergo morphological changes by Ostwald ripening and recrystallization in PSF and HCl, but retain their crystallinity.

Dissolution is 0 to 0.1% per month; extrapolated on the chronic inhalation study, CeO<sub>2</sub> NM212 and BaSO<sub>4</sub> NM220 remain 99% persistent.

**PS 1750 Intracellular Generation of Reactive Oxygen Species As a Central Parameter for the Interaction of Manganese Oxide Nanoparticles with Lung Epithelial Cells.**

U. Sydikl<sup>1</sup>, C. Bieschke<sup>1</sup>, D. Ströckmann<sup>1</sup>, M. Gotic<sup>2</sup>, S. Music<sup>2</sup> and K. Unfried<sup>1</sup>. <sup>1</sup>IUF, Dueseldorf, Germany; <sup>2</sup>Institute Ruder Boskovic, Zagreb, Croatia. Sponsor: T. Haarmann-Stemmann.

Nanoparticles consisting of manganese oxide have been suggested for several innovative technological approaches, including the use in nanomedicine and diagnostics. Therefore, the interaction of such nanoparticles with human target cells is of particular interest for the success of nanomedical approaches but also with regard to unintended side effects. To address this problem, we tested different kinds of manganese nanoparticles (MnNP) in an in vitro system which we earlier evaluated for proliferative, apoptotic, and pro-inflammatory endpoints induced by poorly soluble nanoparticles.

MnNP were synthesized and the biological and toxic effects of the generated particles were studied in comparison to carbon nanoparticles (CNP) in dose response experiments with rat and human lung epithelial cell lines. After physico-chemical characterization, a set of three MnNP consisting of Mn<sub>3</sub>O<sub>4</sub> or MnO<sub>2</sub> with significant differences in size and shape were selected. According to the different oxidation stages of manganese, the particles showed significant differences in Fenton reactivity in the cell free system. These data, however, did not reflect the capacity of the particles to induce intracellular oxidative stress. However, quantitative differences in intracellular reactive oxygen species (ROS) correlated with the capacity to trigger membrane-dependent signaling processes. Furthermore, the metabolic activity (WST-Assay) was negatively correlated with intracellular ROS, indicating a link between mitochondrial activity and ROS generation. None of the particles had effects on the membrane integrity of the cells. The data clearly demonstrate that the intracellular generation of ROS by MnNP, probably determined by particle size and shape, has more relevance for nanoparticle cell interaction than the oxidative capacity of the particles themselves.

**PS 1751 The Effects of Ceria Nanoparticles on Primary Human Monocyte-Derived Macrophages and Bronchial Macrophages.**

J. D. Marshburn<sup>1</sup>, A. B. Rice<sup>1</sup>, M. D. George<sup>1</sup>, S. M. Anderson<sup>1</sup>, N. J. Walker<sup>2</sup>, S. Garantzotis<sup>1</sup> and S. Hussain<sup>1</sup>. <sup>1</sup>Clinical Research Program, NIEHS/National Institute of Health, Durham, NC; <sup>2</sup>National Toxicology Program, NIEHS, Durham, NC.

Cerium dioxide (CeO<sub>2</sub>) nanoparticles (NPs) are used in various industrial and consumer product applications and are of significant environmental health interest. The health effects of CeO<sub>2</sub> NPs on primary human cells are poorly understood. We have previously shown that CeO<sub>2</sub> NPs are toxic to primary human peripheral blood monocytes at relatively low doses, which led to apoptosis and autophagy. Now we aimed at deciphering the cytotoxic effects of CeO<sub>2</sub> NPs in mature macrophages (human peripheral blood monocyte-derived macrophages) and bronchial macrophages. CD14<sup>+</sup> cells were isolated from peripheral blood samples of healthy volunteers and matured ex-vivo over a 7 day period to obtain macrophages. Bronchial macrophages were isolated from sputum inductions of healthy volunteers. Cells were exposed to 0, 1, 5, 10, or 20 µg/mL CeO<sub>2</sub> NPs for over a period of 24 or 48 hours. Transmission electron microscopy analysis revealed that both, blood and bronchial macrophages were internalizing CeO<sub>2</sub> NPs and were found either in vesicles or free cytoplasm. No significant change was observed in the viability of both types of cells after exposure to CeO<sub>2</sub> NPs. Moreover, we did not observe any increase in caspase 3/7 activity after exposure to CeO<sub>2</sub> NPs. We found that this increased resistance to NPs as compared to monocytes was due to decreased apoptosis and autophagy induction in mature cells. In conclusion we demonstrate that mature antigen presenting cells are resistant to the cytotoxic effects of environmentally relevant CeO<sub>2</sub> NP exposures.

**PS 1752 Structural Basis for the Toxic Potential of Cellulose Nanocrystals.**

F. L. Sinche<sup>1</sup>, J. Simonsen<sup>3</sup> and S. Harper<sup>1,2</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR; <sup>2</sup>Chemical, Biological and Environmental Engineering, Oregon State University, Corvallis, OR; <sup>3</sup>Wood Science & Engineering College of Forestry, Oregon State University, Corvallis, OR.

Cellulose nanocrystals (CNCs) are a renewable nanomaterial that holds promise for an array of nano-related applications such as drug delivery and reinforcing nanocomposites. Although the core material of CNC is widely believed to be biocompatible, some of its intrinsic features such as geometrical ratio (L/d) and its high strength and stiffness are reminiscent of other fiber-like nanomaterials such as carbon nanotubes and metal oxides crystals, which have been reported to induce toxicity. Despite these similarities, we still lack knowledge of how those features of CNC may affect biological responses in vivo. Following acid hydrolysis of cellulose fibers to obtain CNC, we further used surface modifications and a wide range of concentrations to study the influence of fibrous and spherical shapes of CNC on the biological responses using zebrafish embryos as a model organism. We account for the surface modifications of CNC and differentiate between the responses elicited by embryos exposed to nanofibrillated cellulose (NFC) synthesized via TEMPO (T) and mechanical homogenization (H). We found chemical modifications of CNC yielded homogenous dispersion and the conversion of surface functional groups for charge modifications was high. Using morbidity and mortality measures in embryonic zebrafish exposed to the CNC formulations, our findings suggest relatively low toxicity from both CNC and surface-modified CNCs compared to hundreds of other nanomaterials that have been tested in our model system (nbi.oregonstate.edu). However, NFC-T and NFC-H influenced the toxicity in a concentration-dependent manner. Our results give insight into the biological responses from in vivo exposures using cellulosic nanomaterials with fiber-like and modified-charge features.

**PS 1753 Identification of Metal and Silicate Particles Including Nanoparticles in Electronic Cigarette Fluid and Aerosol.**

M. T. Williams<sup>1</sup>, A. Villarreal<sup>1</sup>, K. Bozhilov<sup>2</sup>, S. Lin<sup>1</sup> and P. Talbot<sup>1</sup>. <sup>1</sup>Cell Biology and Neuroscience, University of California, Riverside, Riverside, CA; <sup>2</sup>Central Facility for Advanced Microscopy, University of California Riverside, Riverside, CA.

Electronic cigarettes (EC) deliver aerosol by heating fluid containing nicotine, flavorings, and a humectant. EC cartomizers combine the fluid chamber and heating element in a single unit. Because EC do not burn tobacco, they may be safer than conventional cigarettes. Their use is rapidly increasing worldwide with little prior testing of their aerosol. We hypothesized that EC aerosol contains metals derived from the various components. Cartomizer contents and aerosols were analyzed

using microscopy, cytotoxicity testing, x-ray microanalysis, particle counting, and inductively coupled plasma optical emission spectrometry. A nickel-chromium filament was coupled to a thicker silver coated copper wire. The silver coating was sometimes missing. Four tin solder joints attached the wires to each other and coupled the copper/silver wire to the air tube and mouthpiece. All cartomizers had evidence of use before packaging (burn spots on the fibers and electrophoretic movement of fluid in the fibers). Fibers in two cartomizers had green deposits that contained copper. Centrifugation of the fibers produced large pellets containing tin. Tin particles and tin whiskers were identified in cartridge fluid and outer fibers. Cartomizer fluid with tin particles was cytotoxic in assays using human pulmonary fibroblasts. The aerosol contained particles >1µm comprised of tin, silver, iron, nickel, aluminum, and silicate and nanoparticles (< 100 nm) of tin, chromium, and nickel. Of 22 elements identified, 12 were present in concentrations higher than the minimum risk level. Many of the elements identified in EC aerosol are known to cause respiratory distress and disease. The presence of metal and silicate particles in cartomizer aerosol, often above minimal risk levels, demonstrates the need for improved quality control in EC design and manufacture and studies on how EC aerosol impacts the health of users and bystanders.

#### PS 1754 Does Nanostructured Synthetic Amorphous Silica Disintegrate after Oral Uptake?

M. Maier<sup>1</sup>, F. Babick<sup>2</sup>, R. R. Retamal Marin<sup>2</sup> and M. Stintz<sup>2</sup>. <sup>1</sup>Evonik Industries AG, Hanau, Germany; <sup>2</sup>Technical University Dresden, Dresden, Germany. Sponsor: D. Warheit.

The interest in manufactured nanomaterials with potential new properties has led to increasing concern about their potential systemic uptake and fate as well as the associated risk to humans. Materials applied in processed food are of special interest. Synthetic amorphous silica (SAS) is a nanostructured material formed by flame hydrolysis or precipitation that has been used for decades. In commercial products, basic structural elements are submicron aggregates (fused nanosized primary particles) that themselves form micrometer (or even larger) agglomerates. SAS is employed in a variety of products, e.g. as free-flow agent in soup powders. As to risk evaluation, it is important to understand whether structural changes may occur during the further processing or after oral uptake.

In a first step, we addressed possible effects of heating in water (modeled processing of soup powder) and acid environment (pH of gastric juice) on the structure and size distribution of SAS. Methods for the reproducible dispersion of SAS and the reliable determination of the volume weighted particle size distribution of SAS suspensions were developed and validated. Two food grade SAS types were studied: precipitated SAS and pyrogenic (fumed) SAS. SAS was first heated in water (100 °C) and then poured into HCl to reach pH=1.3 (paddle apparatus). During both steps time dependent changes in the volume weighted size distribution were monitored using laser diffraction (LD).

LD with validation, e.g. by comparison to microsieving analysis, proved as a reliable technique to characterize the dispersity of SAS suspensions and to evaluate the volume fraction of fine particles. Heating of SAS in water is only a weak dispersion leading to size distributions well above 1 µm. In acid environment (2 hours, pH=1.3) no significant changes in dispersity of SAS – neither agglomeration nor erosion of agglomerates or aggregates – was observed. In separate animal studies (rats, oral, repeated dose), no isolated nanosized primary particles of SAS were detected in the blood or organs.

#### PS 1755 In Situ Characterization of Nanoparticles: Surface Properties Affecting Agglomeration and Particle's Corona.

A. Haase<sup>1</sup>, M. D. Driessen<sup>1</sup>, C. Schulze<sup>2</sup>, M. Wiemann<sup>3</sup>, H. Galla<sup>4</sup>, M. Lehr<sup>2,5</sup>, A. Luch<sup>1</sup> and W. Wohlleben<sup>6</sup>. <sup>1</sup>Federal Institute for Risk Assessment (BfR), Berlin, Germany; <sup>2</sup>Saarland University, Saarbrücken, Germany; <sup>3</sup>IBE, Münster, Germany; <sup>4</sup>University of Münster, Münster, Germany; <sup>5</sup>Helmholtz Institute for Pharmaceutical Research, Saarbrücken, Germany; <sup>6</sup>BASF SE, Ludwigshafen, Germany. Sponsor: M. Pallardy.

In situ characterization of 'as-tested' nanoparticles is essential to understand their toxic effects and to develop Nano-QSARs. The national project nanoGEM correlates as-produced with as-tested and as-released properties, and further to uptake and effects in-vitro and in-vivo.

Here we report on lipid and protein interactions of 16 nanoparticles in a) serum containing cell culture medium, b) pure phospholipids vs. CuroSurf vs. native lung surfactant.

The surface of suspended nanoparticles with sizes of 10nm (ZrO<sub>2</sub>), 15nm (SiO<sub>2</sub>) and 50nm or 200nm (Ag) was furnished either with acidic, amino-functional, PEG, acrylic and electro-steric functionalities. Characterization followed the

nanospecific REACH guidance R7.1, benchmarked against OECD reference materials TiO<sub>2</sub>, ZnO, BaSO<sub>4</sub>, AlOOH. We assessed in situ agglomeration by light scattering, nanoparticle tracking and analytical ultracentrifugation; protein corona by 1D/2D gel electrophoresis with mass spectrometry; lipid interaction by secondary ion mass spectrometry (SIMS), phosphate assays and film balances.

In protein containing media, only nanoparticles with electro-steric functionalities remained dispersed, partially due to negative charge; all nanoparticles attracted a corona with BSA as main component that often decreased during 1h to 24h. Astonishingly, phospholipids had a low affinity to nanoparticles. Only few functionalities attracted lipids and then agglomerated afterwards. The presence of proteins in CuroSurf or native surfactant may induce lipid binding in some cases but not vice versa.

The surface coating controls the dispersability and the corona of proteins and lipids by kinetic properties. However, nanoparticles behave completely different in lung lining fluid compared to serum containing cell culture media. This has implications for the validity of toxicity testing.

#### PS 1756 Possible Adjuvant Role of Manufactured Nanoparticles in Chemical-Induced Sensitization.

B. Baré<sup>1</sup>, N. Lambrechts<sup>1</sup>, P. Hoer<sup>2</sup> and I. Nelissen<sup>1</sup>. <sup>1</sup>Environmental Risk and Health Unit, Flemish Institute for Technological Research (VITO NV), Mol, Belgium; <sup>2</sup>Lung Toxicology Unit, Catholic University Leuven (KULeuven), Leuven, Belgium.

The adjuvant activity of air pollution particles on allergic airway sensitization is well known, but a similar role of manufactured nanoparticles in allergic sensitization following chemical exposure has not been clarified. Such mixed exposure situations may be relevant to daily life activities.

The goal of our study is to assess the possible adjuvant effect of manufactured nanoparticles (NPs) on a chemical-induced sensitization response in vitro.

Human cord blood-derived CD34+ progenitor cells that are differentiated into immature myeloid dendritic cells (CD34-DC) are used as in vitro antigen-presenting cell model. These are exposed to sensitizing model chemicals, such as nickel sulphate, and spherical Au-NPs (5, 50 and 250 nm) for 6 and 24 hours, either as separate inducers or as a mixture. Concentration-response series of the chemicals are used. Cytotoxic effects of the chemicals and NPs are assessed using flow cytometric analysis of propidium iodide incorporation. Triggering of antigen-presenting properties of the exposed CD34-DC is assessed by expression analysis of the VI-TOSSENS® genes CCR2 and CREM (Lambrechts et al., Toxicol. Lett. 2011) on mRNA samples of lysed cells after 6 hours of exposure using RT-qPCR. Additionally, maturation of CD34-DC is assessed by quantifying cell surface expression of HLA-DR and the co-stimulatory molecules CD80, CD86, and CD83 after 24 hours using flow cytometry.

The results that are obtained in this study, clarify whether gold nanoparticles operate as adjuvants for allergenic responses and as such enhance our insight in the risks that nanoparticle exposure may pose to our health.

#### PS 1757 Zinc Oxide Particles Induced Migration of Monocytes and Increased Macrophage Cholesterol Uptake.

Y. Suzuki<sup>1</sup>, S. Tada-Oikawa<sup>1</sup>, G. Ichihara<sup>2</sup> and S. Ichihara<sup>1</sup>. <sup>1</sup>Graduate School of Regional Innovation Studies, Mie University, Tsu, Japan; <sup>2</sup>Department of Occupational & Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: Metal oxide nanoparticles have been widely used in industry, cosmetics, as well as biomedicine. However, the correlation between exposure to metal oxide nanoparticles and the increased incidence of cardiovascular disease remains elusive. The present study investigated the migration of monocytes and macrophage cholesterol uptake that are essential for atherosclerotic progression induced by nano-sized metal oxide particles.

Methods and results: Human umbilical vein endothelial cells (HUVECs) were cultured and exposed to nano-sized TiO<sub>2</sub> and ZnO. Exposure to ZnO for 6 hours reduced the cellular viability in a dose-dependent manner and increased the production of reactive oxygen species (ROS) whereas there were no changes by the exposure to TiO<sub>2</sub>. Exposure to ZnO for 21 hours increased the level of monocyte chemoattractant protein-1 (MCP-1) in HUVECs, and cell migration of human monocytic leukemia (THP-1) was observed after incubation with HUVEC supernatants. We also investigated the effect of nano-sized metal oxide particles on cholesterol uptake in THP-1 macrophages after stimulation with acetylated-LDL. The exposure to ZnO up-regulated the expression of membrane scavenger receptors of modified LDL particles and increased cholesterol uptake.

Conclusion: The exposure to ZnO reduced the cellular viability in a dose-dependent manner and increased the production of ROS in HUVECs. The exposure to ZnO also induced THP-1 cell migration and increased macrophage cholesterol uptake. The study indicates that nano-sized ZnO particles accelerate foam cell formation in THP-1 macrophages.

## PS 1758 Comparison of Cellular Uptake of Titanate Nanomaterials by Human Monocytes.

S. Boonrungsiman, W. Suchaoin and R. Maniratanachote. *National Nanotechnology Center, National Science and Technology Development Agency, Pathum Thani, Thailand.*

Titanate nanomaterials (TiNMs) have been applied in various industrial products, including cosmetics, dye sensitized solar cells, and photocatalytic materials. There is also increasing concern on human health risk due to exposure to these nanomaterials during production and application of the products. Therefore, safety assessment of TiNMs is required. Several studies have been focused on toxicity and biological interactions of titanate nanoparticles (TiNPs), but less is known for titanate nanofibers (TiNFs). The aim of this study was to investigate the uptake patterns and toxicity of two TiNFs with different dimensions (about 50 and 70 nm in diameter and 500 and 1500 nm in length, respectively) compared with a spherical TiNP (about 170 nm in diameter) in human monocytes, THP-1 cells. The uptake of TiNMs into the cells was observed over the time for up to 24 hours using side scatter cytometry (SSC), which reflect internal cellular complexity, and electron microscopy. The results showed that all of TiNMs were immediately absorbed on plasma membrane when they exposed to the cells as observed by SEM and SSC. Engulfment of both TiNFs and TiNPs by THP-1 cells occurred within 10 minutes exposure. Interestingly, SSC profile may suggest the different uptake patterns between TiNFs and TiNPs. In addition, the results from SSC and SEM suggested that TiNFs were taken up by the cells which took longer time than that of TiNPs because of their length. TiNFs with concentrations up to 100 µg/ml did not reduce cell viability, while TiNPs significantly reduced cell viability at concentration of 100 µg/ml. None of TiNMs (with concentrations up to 100 µg/ml) significantly trigger intracellular ROS generation. This information on cellular uptake and response might be useful for risk assessment of nanomaterials.

## PS 1759 Air-Liquid Interface Exposure of Lung Cells to Metal Nanoparticles Generated by a Spark Discharge System.

J. Kim, J. Park, T. M. Peters and P. S. Thorne. *Occupational and Environmental Health, The University of Iowa, Iowa City, IA.*

Metal-based nanoparticles (NPs) are generated from a variety of processes including welding, cutting and brazing. Airborne NPs are of particular concern over human exposure, as they can readily move in ambient air and enter the body through inhalation. The objective of this study was to investigate toxic effects on human alveolar type-II cells (A549) after air-delivery of various metal NPs. We used a spark discharge system (SDS) capable of generating and depositing airborne NPs directly onto cells at an air-liquid interface (ALI). The generated NPs (from various source materials including Cu, Zn electrodes and welding rods) were characterized by using a scanning mobility particle sizer, inductively coupled plasma-mass spectrometer and electron microscopes (SEM, TEM). To better model *in vivo* repeated-low dose protocols we sequentially exposed lung cells to NPs *in vitro* (4 h exposure-2 h rest in an incubator-4 h exposure) and cell viability was determined by Alamar Blue assay at 4 h post-exposure. The SDS produced stable NP aerosols for 4 h (Cu,  $8 \times 10^6$ ; Zn,  $6 \times 10^6$ ; welding rods,  $7 \times 10^6$  particles/cm<sup>3</sup>). Particle size distribution indicated the geometric mean diameter of the generated particles to be average 15 (Cu), 25 (Zn) and 16 nm (welding rods) with a geometric standard deviation of 1.5, 1.7 and 1.4, respectively. SEM and TEM results confirmed the deposition of nano-sized particles on cell-free transwells. The cellular concentration of Cu NPs was 5.9 µg Cu/transwell (4.7 cm<sup>2</sup>) and a substantial amount of Cu was released to the basolateral medium (0.3 µg) during air-delivery of Cu NPs in 4 h. Viability for cells exposed to Cu NPs was significantly reduced to 79% ( $p < 0.05$ ) at 4 h post-exposure compared to cells maintained in an incubator. Our results demonstrated that the SDS can be useful for generating metal NPs and simulating welding fumes for their toxicity assessment. In addition, integrated ALI exposures of human lung cells with SDS can provide screening data to aid prediction of toxicity of metal NPs.

## PS 1760 Engineered Nanoparticles Enhanced CD8<sup>+</sup> T Cell Cytokine Production.

B. L. Kaplan<sup>1,4</sup>, W. Chen<sup>2,4</sup>, Q. Zhang<sup>3</sup>, G. L. Baker<sup>3</sup> and N. E. Kaminski<sup>1,4</sup>.  
<sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI;  
<sup>2</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI;  
<sup>3</sup>Chemistry, Michigan State University, East Lansing, MI; <sup>4</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Engineered nanoparticles are being used in various commercial products; however, a significant concern is the potential of these particles to cause adverse effects on human health, as evidenced by exacerbation of allergic airway disease. The objective of this interdisciplinary research is to investigate the putative adjuvant properties of

engineered nanoparticles on biological responses at the animal, cell, and membrane levels. Silica nanoparticles (SNPs) were modified with alkyne-terminated surfaces and appended with polyethylene glycol azides via "click" chemistry. At the cell level, *in vitro* mouse models were utilized to examine the effect of modified SNPs on dendritic cell (DC)-induced T cell effector function. Ovalbumin (OVA)-derived peptides OVA<sub>257-264</sub> or OVA<sub>323-339</sub> were presented by endogenous antigen presenting cells in splenocytes or a mouse DC line, DC2.4. IFNγ and IL-2 production by CD8<sup>+</sup> or CD4<sup>+</sup> T cells in response to OVA peptides was measured by flow cytometry. At modest peptide stimulation levels, modified SNPs (up to 10 µg/ml) enhanced the proportion of CD8<sup>+</sup>, but not CD4<sup>+</sup>, T cells that produced cytokines. Various functional groups (-COOH, -NH<sub>2</sub>, -OH) on modified SNPs enhanced cytokine production to different levels, with -COOH SNPs being the most effective. Furthermore, 50 nm -COOH SNPs exhibited greater enhancement effect on CD8<sup>+</sup> T cell response than the other sizes. Importantly, modified SNPs did not aggregate in *in vitro* culture media, demonstrating their effect at the true nanoscale. Collectively, our results demonstrated the potential adjuvant effect of modified SNPs on CD8<sup>+</sup> T cell function and will also complement other studies being conducted by the team at the membrane and the intact animal level. (Supported by NIH Grant RC2 ES018756)

## PS 1761 Biological Impacts of Ferroelectric Nanoparticles: Comparison between Lead and Bismuth.

M. Esquivel-Gaón<sup>1,3</sup>, M. Uribe-Ramirez<sup>1</sup>, E. Herrera-Jimenez<sup>2</sup>, J. Muñoz-Saldaña<sup>2</sup>, L. M. Del Razo<sup>1</sup>, M. Monopoli<sup>3</sup>, K. A. Dawson<sup>3</sup>, S. Anguissola<sup>3</sup> and A. De Vizcaya-Ruiz<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav, Mexico City, Mexico; <sup>2</sup>Unidad Queretaro, Cinvestav, Queretaro, Mexico; <sup>3</sup>CBNi, University College Dublin, Dublin, Ireland.

The risk posed by lead during manufacturing of ferroelectric ceramics has led to efforts to develop lead-free options, bismuth sodium titanate with barium titanate (BNT-BT) nanoparticles (NP) have become a strong candidate to replace lead zirconate titanate (PZT)-based ceramics. In order to evaluate the biological effects generated by PZT and BNT-BT NP we investigated their interaction with biomolecules adsorbed on the NP surface, which defines the interface with cellular membranes, the uptake and potential toxicity in human cell lines. The NP were dispersed, stabilized with bovine serum albumin (BSA) and characterized in complete cell culture medium showing an average size of 188 nm (BNT-BT) and 168 nm (PZT), as measured by differential centrifugal sedimentation. The analysis of the proteins adsorbed with high affinity to the NP surface (hard corona) after the incubation with FBS showed prevalently BSA and complex protein profiles dependent on the concentration of FBS. Uptake studies in cell cultures rely on fluorescently labeled NPs; we generated BNT-BT and PZT NP showing fluorescent properties by labeling BSA used to stabilize the dispersions. The NP were tracked through the endolysosomal pathway using a time lapse live cell imaging approach. For cytotoxicity assessment, cell membrane damage and mitochondrial activity were measured in Hep G2, LLC-PK1, A549 and SH-SY5Y cells after exposure to increasing concentrations of BNT-BT and PZT NP for 24 or 48 h. The integrity of the cell membrane was not significantly affected; however the mitochondrial activity decreased after 48 h with 100 µg/ml for both NP being more evident for the PZT NP in neuroblastoma cells. Our results suggest that BNT-BT showed lower levels of toxicity compared to PZT thus it could be a good replacement for PZT-based ceramics. Funding from the European Community Seven Framework Program and CONACYT (Grant agreements #263878 and 12514) and Epitope Map Program.

## PS 1762 Role of Lung Surfactant Lipid and Protein Corona in Airborne Positively Charged Nanoparticle Exposure.

Y. Xie, A. Tolic, W. Chrisler, C. Mihai, C. Szymanski, D. Hu and G. Orr. *Pacific Northwest National Laboratory, Richland, WA.*

Airborne nanoparticles (NPs) that reach the alveolar region are likely to be presented to alveolar epithelial cells coated with a corona of lung surfactant lipids and proteins. However, the effect of the corona on airborne NP toxicity is still unclear, mainly because most studies were conducted in cells exposed to NPs in growth media, limiting the corona to molecules found in the media. Furthermore, accumulating observations support a role for positive surface charge in NP toxicity, but the impact of the corona, which shifts the NP surface charge to more negative values, is unclear. To understand the role of coronas in airborne NP exposure, we exposed alveolar epithelial cells at the air-liquid interface (ALI) to aerosolized NPs that were pre-incubated with a natural surfactant lipid and protein (Infasurf®) or BSA solution. Bare polystyrene (PS) NPs, showing no toxicity, were compared with aminated or carboxylated PS NPs, showing high or low level of toxicity, respectively. Cellular response was compared between NPs at the same cellular dose, measured as µg/cm<sup>2</sup> using a quartz crystal microbalance. We found that the lowest dose required to induce toxicity by aminated NPs with no corona was 3 folds lower than the dose required to induce toxicity by aminated NPs with a surfactant co-

rona, and 1.8 folds lower than the dose required by aminated NPs with a BSA corona. In contrast, BSA corona eliminated toxicity of carboxylated NPs at all measured doses. With no corona, the level of aminated NPs at the cell surface or inside the cytoplasm was significantly higher than the level of carboxylated NPs. To evaluate the possibility that the observed protective effect of surfactant or BSA coronas from aminated or carboxylated NP toxicity, respectively, is due in part to a decrease in NP-cell interaction and internalization, we currently quantify any changes in these processes that might be induced by the coronas. This work was funded by NIEHS grant 1RC2ES018786-01 to GO.

### PS 1763 Metastatic Capacity Induced by Cells Exposed to Titanium Dioxide Nanoparticles.

A. Déciga-Alcaraz<sup>1</sup>, V. Freyre-Fonseca<sup>1,2</sup>, E. I. Medina-Reyes<sup>1</sup>, N. L. Delgado Buenrostro<sup>1</sup> and Y. I. Chirino<sup>1</sup>. <sup>1</sup>Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México, México City, México; <sup>2</sup>Departamento de Graduados e Investigación en Alimentos, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, México City, México.

**Background.** Titanium dioxide nanoparticles (TiO<sub>2</sub> NPs) have been classified as a possibly carcinogenic to humans (Group 2B) by the International Agency for Research in Cancer. In this regard, its potential carcinogenic effects have been under research. However, less has been investigated about the effects of cells exposed to TiO<sub>2</sub> NPs when they reach bloodstream, especially if TiO<sub>2</sub> NPs exposed cells could proceed from a tumor.

**Aim.** We hypothesized that tumor cells exposed to TiO<sub>2</sub> NPs could promote a metastatic events. To test this hypothesis, lung adenocarcinoma cells were exposed to TiO<sub>2</sub> NPs (1, 5 and 10 µg/cm<sup>2</sup>) for 7 days and 30,000 cells of each concentration were injected into bloodstream of chicken chorioallantoic membrane (CAM) of free pathogens fertilized eggs previously incubated during 11 days at 37°C and 80% humidity. Analysis of morphological changes was performed at 16th day.

**Results.** TiO<sub>2</sub> NPs were characterized by transmission electronic microscopy (TEM) suspended in F12K medium with 10% Serum Fetal Bovine (SFB) and zeta potential was -20.98±0.75, and TiO<sub>2</sub> NPs agglomerate size was 212.3 ±4.417nm, 630.2±20.94 nm and 588.3±43.11 nm for 1, 5 and 10 µg TiO<sub>2</sub>/mL respectively. Images showed that there is an increase in distance between blood vessels and a decrease in number of nodes in CAM treated with cells exposed to 10 µg/cm<sup>2</sup> of TiO<sub>2</sub>. In addition, there were observed cell clusters on the CAM treated with cells exposed to 1 and 5µg/cm<sup>2</sup> of TiO<sub>2</sub> NPs.

**Conclusion.** TiO<sub>2</sub> NPs exposure (10 µg/cm<sup>2</sup>) to lung adenocarcinoma cells induced an increase in blood vessel distance and a decrease the number of nodes, which seems to be a downregulation effect in angiogenesis. However, pre-exposed lung adenocarcinoma cells to 1 and 5 µg/cm<sup>2</sup> of TiO<sub>2</sub> NPs provided a capacity to form clusters, which could represent a higher metastatic effect.

### PS 1764 Phenotypic Polarization and Attenuation of Toll Receptor Signaling Functions in Macrophages Exposed to Engineered Nanoparticles.

V. K. Kodali<sup>1</sup>, M. H. Littke<sup>1</sup>, S. C. Tilton<sup>2</sup>, J. G. Teeguarden<sup>1</sup>, L. Shi<sup>1</sup>, C. W. Frevert<sup>3</sup>, W. Wang<sup>4</sup>, J. G. Pounds<sup>1</sup> and B. D. Thrall<sup>1</sup>. <sup>1</sup>Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Computational Sciences Division, Pacific Northwest National Laboratory, Richland, WA; <sup>3</sup>Department of Comparative Medicine, University of Washington, Seattle, WA; <sup>4</sup>Bioscience Division, Oak Ridge National Laboratory, Oak Ridge, TN.

Although macrophages play a critical role in scavenging engineered nanoparticles (ENPs) from tissue, relatively little is known about how their normal innate immune function is impacted. We investigated how pretreatment of macrophages with 33 nm superparamagnetic iron oxide (SPIO) or 50 nm amorphous silica modulated the transcriptional response of macrophages to the toll 4 receptor (TLR4) ligand LPS. Affymetrix microarray analysis showed over 5000 mRNAs were differentially regulated (>1.5 fold, p<0.05) in response to LPS (10 ng/ml, 6 hrs). SPIO pretreatment (25 µg/ml) alone altered expression of a smaller set of genes (1029 total), but modulated expression of nearly 500 LPS regulated genes in a greater than additive manner. In contrast to SPIO, relatively few LPS regulated genes were modulated by silica pretreatment. Pathway analysis showed that pretreatment with SPIO suppressed LPS activation of several key cellular functions like chemotaxis, interferon and Jak-Stat inflammation signaling while enhancing cell adhesion and oxidative/nitrate stress responses. Pretreatment of macrophages with SPIO also caused a dose dependent decrease in phagocytosis of *S. pneumoniae* and *S. typhimurium*, whereas silica pretreatment had no effect. Flow cytometry studies using fluorescent LPS or antibodies against TLR4 revealed that SPIO exposure caused dose-dependent down regulation of cell surface TLR4 level while silica had no effect. Our results demonstrate that macrophages exposed to some ENPs are polarized toward an anti-inflammatory phenotype which attenuates pro-inflammatory signaling by TLR4, and suppresses their phagocytic activity against pathogens.

### PS 1765 Intracellular Trafficking and Accumulation Dynamics of Zinc Ions in Alveolar Epithelial Cells Exposed to Airborne ZnO Nanoparticles at the Air-Liquid Interface.

C. Mihai, W. Chrisler, Y. Xie, C. Szymanski, A. Tolic, D. Hu, B. Tarasevich and G. Orr. Pacific Northwest National Laboratory, Richland, WA.

Airborne nanoparticles (NPs) that enter the respiratory tract are likely to reach the alveolar region. Accumulating observations support a role for zinc oxide (ZnO) NP dissolution in toxicity, but the majority of the studies were done in cells exposed to NPs in growth media, where large doses of dissolved ions are shed into the exposure solution. To better represent the exposure in the respiratory tract and focus on the dissolution of airborne NPs in the cellular environment, we exposed alveolar epithelial cells to aerosolized NPs at the air-liquid interface (ALI). Using a fluorescent indicator for zinc ions (Zn<sup>2+</sup>) and organelle-specific fluorescent proteins, we quantified Zn<sup>2+</sup> in single cells and organelles over time and correlated these values with toxicity. We found that intracellular Zn<sup>2+</sup> in cells exposed at the ALI peaked 3 h post exposure and decayed to normal levels by 24 h, which was in contrast to exposures in submersed cultures where intracellular Zn<sup>2+</sup> continued to increase over time. For the lowest toxic dose at 24 h, the peak at the ALI was ~3 folds lower than the 24 h value in submersed cells, and ~8 folds lower than the 24 h value in submersed cells exposed to Zn<sup>2+</sup> only. At the ALI, 45% of intracellular Zn<sup>2+</sup> was found in endosomes at 1 h post exposure, decreasing to 24% by 3 h. In contrast, 20% of intracellular Zn<sup>2+</sup> was found in lysosomes at 1 h, increasing to 42% by 3 h. Interestingly, exposure of submersed cells to Zn<sup>2+</sup> only, led to a minimal accumulation of ions in either the endosomes or lysosomes, with the majority of ions found in larger vesicles. Our observations indicate that airborne ZnO NPs induce toxicity at the ALI at intracellular Zn<sup>2+</sup> levels that are significantly lower than those detected when toxicity is induced in submersed cultures, and the localized dissolution and trafficking of Zn<sup>2+</sup> in endosomes following with their accumulation in lysosomes play critical roles in airborne NP toxicity. This work was funded by NIEHS grant 1RC2ES018786-01 to GO.

### PS 1766 Aggregation Dynamics and Structure Measurements of Nanomaterials in Biologically Relevant Conditions.

N. B. Saleh<sup>1</sup>, S. M. Hussain<sup>2</sup> and A. Afroz<sup>1</sup>. <sup>1</sup>Civil and Environmental Engineering, University of South Carolina, Columbia, SC; <sup>2</sup>Wright-Patterson AFB, US Air Force, Dayton, OH.

Nanomaterial dosimetry for in vitro studies continued to be debated in nanotoxicology literature, particularly due to the propensity of aggregation of highly diffusive nano-scale materials. In classical nanotoxicology literature, average particle size and surface charge are the typical measured parameters either initially or at the end of exposure time period; with no information on the dynamic behavior throughout the process. Moreover, aggregate structural information is mostly ignored. This study focuses on monitoring dynamic aggregation behavior of metallic and carbonaceous nanoparticles under biological (i.e., in exposure media with added penicillin streptomycin, at 37 °C) exposure conditions. The aggregation dynamics is monitored by employing state-of-the-art ALV goniometer system. Suspension-phase fractal dimension was measured with angle-dependent static light scattering for an angular range of 12°-120°. Aggregation dynamics results indicate that electrostatic interaction serves as the key interfacial force to providing stability to nanomaterials. In addition, continuous measurements of aggregate size in physiological condition show network formation. Furthermore, time dependent fractal dimension results indicate that aggregate structure remains unchanged over time; however, were significantly altered by the background solution chemistry. The key implications of the study include: consideration of intermediate time-endpoint (instead of 24 hr); aggregation dynamics and network formation can minimize size-effects on nanotoxicology; aggregation dynamics with aggregate structure information can better determine nanomaterial dosimetry.

### PS 1767 Targeting Alternatively Activated Rat Macrophages Using Mannose Functionalized Nanocarriers.

P. Chen<sup>1</sup>, X. Zhang<sup>1</sup>, A. Venosa<sup>2</sup>, Z. Szekely<sup>1</sup>, D. L. Laskin<sup>2</sup> and P. J. Sinko<sup>1</sup>. <sup>1</sup>Pharmaceutical Science, Rutgers University, Piscataway, NJ; <sup>2</sup>Department of Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.

In response to inflammatory signals generated at sites of injury, macrophages are activated into two main phenotypes: classically activated M1 cells and alternatively activated M2 cells. Whereas M1 macrophages release cytotoxic/proinflammatory

mediators that contribute to tissue injury, M2 macrophage-derived mediators suppress inflammation and initiate wound repair. Mannose receptor (MR) is known to be expressed at high levels on M2 macrophages. In these studies, a mannose functionalized nanocarrier (NC) was designed and developed with the goal of selectively targeting M2 macrophages. Mannose functionalized NC (FITC-Gaba-Ser(Man)-PEG12-Ser(Man)-Gaba-Gaba-Cys) were prepared using solid phase synthesis and their identity confirmed by MALDI-TOF/MS and HPLC analysis. Rat peritoneal macrophages (PMs) were incubated for 24-48 h with IFN- $\gamma$  (20ng/ml) or IL-4/IL-13 (10ng/ml), to induce M1 or M2 activation, respectively. mRNA levels of the M1 marker, inducible nitric oxide synthase (iNOS) and the M2 marker, arginase (Arg)-1 were quantified by RT-PCR, and protein levels by western blotting. Treatments of PMs with IFN- $\gamma$  resulted in increased expression of mRNA and protein for iNOS, whereas IL-4/IL-13 upregulated Arg-1 expression. After incubating for 60 min, NC binding to macrophages was quantified by confocal microscopy. Confocal microscopy showed that uptake of mannosylated NC into M2 PMs was 2.4 fold greater than control PMs, and 11.8 fold greater than M1 PMs. M2-macrophage phenotype-specific uptake was completely abolished by mannan, suggesting MR-mediated targeting. NCs were co-localized with rhodamine-dextran, a general fluid phase endocytosis marker, indicating that the NCs were internalized by PMs. The present studies demonstrate that mannosylated NCs are specific for macrophages expressing mannose receptor. These NC may be useful for delivery of drugs to sites of injury and infection. Support: NIH AI51214, AR055073, CA132624, ES004738, ES005022, and GM034310

**PS 1768 Synthesis, Characterization and Toxicological *In Vitro* Activity of Nanomaterials Containing Active Ingredients of *Matricaria chamomilla* L.**

A. Vera<sup>1</sup>, L. A. Flores<sup>1</sup>, F. M. Mercado<sup>1</sup>, R. Vazquez<sup>1</sup>, J. A. Soriano<sup>1</sup>, R. L. Ortega<sup>1</sup>, A. Jain<sup>2</sup>, P. Sengar<sup>2</sup>, G. A. Hirata<sup>3</sup>, R. E. Cachau<sup>4</sup>, R. Hernandez<sup>5</sup>, U. Pal<sup>6</sup>, Z. N. Juarez<sup>1</sup>, M. C. Miranda<sup>1</sup> and **T. D. Palacios-Hernandez<sup>1</sup>**. <sup>1</sup>Ciencias Biológicas, UPAP, Puebla, Mexico; <sup>2</sup>School of Biosciences and Technology, VIT, Vellore, India; <sup>3</sup>Centro de Nanociencias y Nanotecnología, UNAM, Ensenada, Mexico; <sup>4</sup>Frederick National Laboratory for Cancer Research, Frederick, MD; <sup>5</sup>Ciencias Químico-Biológicas, UDLAP, Puebla, Mexico; <sup>6</sup>Instituto de Física, BUAP, Puebla, Mexico.

In this contribution, the synthesis, characterization and biological activity of polymeric nanocapsules (PNC) and iron oxide nanoparticles (NPs) containing active ingredients of *Matricaria chamomilla* L., is being evaluated. *M. chamomilla* L. specimens were collected and dried, to obtain the chloroform, hexane and water extracts. Iron oxide NPs were prepared by a co-precipitation method using FeCl<sub>3</sub>, Na<sub>2</sub>SO<sub>3</sub> and NH<sub>4</sub>OH. PNC were prepared by emulsion method using aqueous solutions of sodium alginate containing the active principle, calcium chloride and dioctyl sodium sulfosuccinate. Characterization of all the materials was done by dynamic light scattering (DLS), transmission electron microscopy (TEM), phase contrast microscopy, RAMAN spectroscopy, X-ray diffraction (XRD) and Fourier Transformed Infrared spectroscopy (FTIR). Plant extracts are being purified by column chromatography and were characterized by proton (1H) and carbon (13C) Nuclear Magnetic Resonance (NMR). TEM analysis confirmed the presence of nanoparticles in a size range of 6-10 nm, XRD and RAMAN showed the magnetite phase at SPION and FTIR showed the characteristic vibrations for OH in magnetite NPs and organic groups at PNC. A high particle size distribution (93-200 nm) was obtained in polymeric nanocapsules by DLS and confocal microscopy, due the presence of aggregates. NMR showed in the hexane extract the presence of flavonoids, sugars and phenols. At this moment we are still working on the purification of *M. chamomilla* L. extracts and the evaluation of biological activity upon bacterial cultures, to determine ecotoxicity of all the materials synthesized.

**PS 1769 Comparative *In Vitro* Cell Uptake of Bismuth and Bismuth-Derivatives Nanoparticles in Lung Cells.**

L. M. Del Razo<sup>1</sup>, B. Quintanilla-Vega<sup>1</sup>, O. C. Barbier<sup>1</sup>, M. Esquivel-Gaón<sup>1,2</sup>, M. Uribe-Ramírez<sup>1</sup>, A. Barrera-Hernández<sup>1</sup>, L. C. Sanchez-Peña<sup>1</sup>, K. A. Dawson<sup>2</sup>, S. Anguissola<sup>2</sup> and **A. De Vizcaya-Ruiz<sup>1</sup>**. <sup>1</sup>Toxicology, Cinvestav-Instituto Politécnico Nacional, Mexico, City; <sup>2</sup>CBNI, University College Dublin, Dublin, Ireland.

Bismuth (Bi) has exceptionally low magnetic susceptibility and very low thermal conductivity which favors their use as a thermoelectric material. Therefore, low-dimensional Bi compounds are good candidates as nanomaterials. In this study, the physicochemical properties of Bi-derived nanoparticles (Bi-NP) – Bi trioxide (Bi<sub>2</sub>O<sub>3</sub>), Bi vanadate (BiVO<sub>4</sub>), and zero valent Bi in colloidal form (ZV-Bi) – and uptake in A549 lung cells were evaluated. The properties include the dispersion and

stability, elemental composition and uptake in lung cell cultures. Testing for biocompatible dispersants for biological and toxicological evaluations was performed using sonication and centrifugation steps, combined with stabilization of the NP surface with bovine serum albumin (BSA; 10mg/ml) to reduce agglomeration. Its dispersion properties and elemental composition were confirmed using dynamic light scattering and energy dispersive X-ray spectroscopy. Average size of Bi<sub>2</sub>O<sub>3</sub>, BiVO<sub>4</sub>, and ZV-Bi was 9.2 nm (0.34 pdl), 49.9 nm (1 pdl) and 3.3 ± 1nm, respectively. Elemental content was in 67.6%-Bi, 32.4%-O in Bi<sub>2</sub>O<sub>3</sub>, 55.5%-Bi, 25.9%-V and 18.6%-O in BiVO<sub>4</sub> and 49.9%-Bi, 33.7%-O and 16.4%-Na in ZV-Bi. From a parallel cytotoxicity study of the exposure to Bi<sub>2</sub>O<sub>3</sub>, BiVO<sub>4</sub>, and ZV-Bi the 50 µg/ml non-cytotoxic level was chosen to assess the cellular uptake of Bi at 6, 24 or 48 h in lung cells by atomic fluorescence spectrophotometry by hydride generation. A differential uptake of Bi was observed, BiVO<sub>4</sub> was internalized in cells in 86.6% while Bi<sub>2</sub>O<sub>3</sub> and ZV-Bi in 27.8 and 26.1%, respectively. Our results suggest that Bi-NP cellular internalization is dependent of the physicochemical properties, where a more conductive NP such as BiVO<sub>4</sub> was more effectively internalized; therefore, NP transport and uptake is a relevant process that needs to be thoroughly investigated. Funding from the European Community Seven Framework Programme and CONACYT (Grant agreements #263878 & 12514).

**PS 1770 Oxidative Stress, Cell Viability and Types of Cell Death Induced by Transition Metal Oxide Nanoparticles Depend on Surface Charge, Available Surface Binding Site, and Ion Dissolution.**

Y. Huang<sup>1</sup>, C. C. Chusuei<sup>2</sup>, C. Wu<sup>1</sup>, S. Mallavarapu<sup>2</sup>, J. G. Winiarz<sup>3</sup> and R. S. Aronstam<sup>1</sup>. <sup>1</sup>Biological Sciences, Missouri University of Science and Technology, Rolla, MO; <sup>2</sup>Chemistry, Middle Tennessee State University, Murfreesboro, TN; <sup>3</sup>Chemistry, Missouri University of Science and Technology, Rolla, MO.

We investigated physicochemical properties of nano-sized oxides of Fourth Period transition metals that contribute to cytotoxicity. The cytotoxicity (i.e., cell killing) of nanoparticles (NPs) TiO<sub>2</sub>, Cr<sub>2</sub>O<sub>3</sub>, Mn<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, NiO, CuO, and ZnO increases as atomic number increases. This trend is not cell type specific, as it is observed in nontransformed human lung (BEAS-2B) and adenocarcinomic human alveolar basal (A549) epithelial cell lines. We assessed physicochemical properties of NPs to discover the determinants of cytotoxicity: 1) the point-of-zero charge (PZC) (i.e., isoelectric point) describes the surface charge of NPs in cytosolic and lysosomal compartments; 2) the relative number of available binding sites on the NP surface was used to estimate the probability of biomolecular interactions on the particle surface; 3) band-gap energy predicts electron abstraction from NPs which might lead to oxidative stress and subsequent cell death; and 4) ion dissolution. Our results indicate that that cytotoxicity is a function of particle surface charge, relative number of available surface binding site, and metal dissolution from NPs. These NPs are capable of inducing oxidative stress that is consistent with the trend of cell killing; however, H<sub>2</sub>DCFDA is not a suitable dye to accurately assess oxidative stress due to quenching effect. Ratio of apoptosis and necrosis also follows the trend of cell killing. Our findings provide a basis for both risk assessment and the design of safer nanomaterials.

**PS 1771 Cytotoxic and Antitumor Effect of Vitamin E Analogues Functionalized to Magnetite Nanoparticles.**

A. Angulo Molina<sup>1,2,3</sup>, J. Reyes Leyva<sup>3</sup>, J. Hernández<sup>1</sup>, **T. D. Palacios-Hernández<sup>2,4</sup>**, M. A. Méndez Rojas<sup>2</sup>, M. Cerro López<sup>2</sup>, J. Flores<sup>3</sup>, F. Ruiz<sup>5</sup>, O. Contreras<sup>5</sup> and G. A. Hirata<sup>5</sup>. <sup>1</sup>Centro de Investigación en Alimentación y Desarrollo, CIAD, AC, Hermosillo, Mexico; <sup>2</sup>Universidad de las Américas Puebla, UDLAP, Puebla, Mexico; <sup>3</sup>Centro de Investigaciones Biomédicas de Oriente CIBIOR, IMSS, Metepec, Puebla, Mexico; <sup>4</sup>Universidad Popular Autónoma del Estado de Puebla, UPAP, Puebla, Mexico; <sup>5</sup>Centro de Nanociencias y Nanotecnología, CNYN, Ensenada, Mexico.

**BACKGROUND:** Magnetite nanoparticles (Nps) can be used as nanocarriers to enhance and improve the efficiency of delivery of vitamin E analogues. Herein we report the cytotoxic and antitumor effect of magnetite Nps functionalized with alpha tocopheryl succinate (α-TOS), the most effective analogue of vitamin E in inducing death in cancer cells. One problem with α-TOS is its vulnerability to esterases, making impossible its oral use or in cancer cells with high levels of esterases. **OBJECTIVE:** To investigate the cytotoxicity and antitumor effect of magnetite Nps functionalized with α-TOS (Nps-α-TOS).

**METHODS:** Magnetite Nps-α-TOS were functionalized mixing Nps, silane agents and α-TOS under vigorous stirring (40oC) for 4 h. The Nps-α-TOS were characterized by FTIR, EDS, TEM, SEM and DLS. Then a human cervix cancer cell line (SiHa) high in esterases was treated with the various concentrations by 72 h. Its effects on cytotoxicity and antitumor effect were evaluated using confocal microscopy and MTT assay.

**RESULTS:** Electronic microscopy studies revealed an average Nps size of 130 nm ( $\sigma = \pm 32.7$  nm) and irregular spherical in shape. IR, EDS and DLS results support the formation of Nps detecting mineral and organics constituents respectively with high stability. The in vitro tests shows by first time the Nps- $\alpha$ -TOS can be internalized and are more cytotoxic and effective that  $\alpha$ -TOS alone and inhibits the growth of resistant cervix cancer cell.

**CONCLUSION:** In this study we found that magnetite Nps can work as nanocarriers of  $\alpha$ -TOS. This composite protect the anticancer activity of  $\alpha$ -TOS and enhances the anti-tumor effect in resistant cancer cells.

**PS 1772 Cellular Internalization and Trafficking of Individual Nanoparticles Investigated with Nanometer Resolution Using Super Resolution Fluorescence Microscopy.**

G. Orr, D. Hu, A. Tolic, Y. Xie, C. Mihai, C. Szymanski, M. Markillie, L. Cosimbescu and B. Tarasevich. *Pacific Northwest National Laboratory, Richland, WA.*

The cellular internalization mechanism of engineered nanoparticles (NPs) and their intracellular trafficking govern the cellular interactions of the particles, which ultimately determine their impact on the cell. These cellular mechanisms largely depend on the size of the NPs or the aggregates that are often formed. To identify mechanisms specific to individual NPs or small nano-scale aggregates, we used stochastic optical reconstruction microscopy (STORM) to resolve the intracellular location of individual NPs within organelles and in respect to subcellular structures with 10-20 nanometer resolution. Using FastLime, a photo-switching derivative of green fluorescent protein, we created fluorescent chimeras for clathrin, caveolin and actin, and expressed the proteins in alveolar epithelial cells. The transfected cells were exposed to amorphous silica NPs, tagged with a photo-switching dye, and imaged at 2 h and 16 h post exposure. We found NPs within clathrin- and caveolin-coated vesicles in both time-points, suggesting a preferential binding of the NPs to molecules found in clathrin-coated pits and caveolae at the cell surface. A significant number of NPs were found aligned along actin filaments at 16 h post exposure. The distance between the NPs and the filaments was calculated for more than 1100 NPs, and the distribution of the distances in the range of 0 to 100 nm was significantly different from the distribution expected to occur if the NPs were randomly placed in the cytoplasm. Together, our observations suggest a mechanism for the internalization and trafficking of amorphous silica NPs in alveolar epithelial cells that occurs through interactions with molecules found in caveolae and clathrin-coated pits, followed by internalization via vesicles that eventually are shuttled along actin filaments within the cytoplasm. This work was funded by NIEHS grant 1RC2ES018786-01 to GO.

**PS 1773 Signaling Pathways and microRNA Changes in Nano-TiO<sub>2</sub> Treated Human Lung Epithelial (BEAS-2B) Cells.**

S. Thai, C. P. Jones, K. Wallace, H. Ren, R. Y. Prasad, W. O. Ward, M. J. Kohan and C. F. Blackman. *US EPA, Research Triangle Park, NC.* Sponsor: C. Corton.

The effect of titanium dioxide nanoparticles (nano-TiO<sub>2</sub>, Degussa p25, 86% anatase and 14% rutile) treatment of human lung epithelial cells (BEAS-2B) was examined by analyzing changes in messenger [mRNA] and microRNA [miRNA]. BEAS-2B cells were treated with 0, 3, 10, 30 or 100 ug/ml nano-TiO<sub>2</sub> for 1 day (for mRNA analysis) or 3 days (for miRNA analysis). Differentially expressed mRNA and miRNA were analyzed using Affymetrix microarrays (human U133 Plus 2.0) and Affymetrix miRNA microarrays, respectively. Although, the tested doses were not cytotoxic, there were alterations in both mRNA and miRNA expression. The expression of mRNA/miRNA changes were examined in MetaCore (GeneGo) and IPA (Ingenuity Pathway Analysis) to delineate associated signaling pathways. Signaling pathways altered by nano-TiO<sub>2</sub> treatments included: cell cycle regulation, apoptosis, calcium signaling, translation, NRF2-mediated oxidative response, IGF1 signaling, RAS signaling, PI3K/AKT signaling, cytoskeleton remodeling, cell adhesion, BMP signaling, and inflammatory response. Many of the genes in these signaling pathways are known to be regulated by the miRNAs that were altered by the nano-TiO<sub>2</sub> treatment. The miRNA 17-92 cluster and let-7 miRNA family that are reportedly involved in lung cancer formation were altered by nano-TiO<sub>2</sub> treatment. The miR-17-92 cluster, an oncogenic microRNA cluster, is induced while the tumor suppressor microRNA, let-7 family, is suppressed. The observed changes in miRNA expression introduces an additional mechanistic dimension that supports the significance of the observed mRNA expression changes, and demonstrated that the nano-TiO<sub>2</sub> treatment can cause diverse but coordinated pathway alterations associated with changes in in vivo response to tumorigenes. [This abstract does not necessarily reflect the policies of the U.S. EPA.]

**PS 1774 In Vitro Co-Culture System to Examine the Effects of Inhaled Nanoparticles.**

K. B. Donohue<sup>1</sup>, A. M. Mayo<sup>2</sup>, D. R. Johnson<sup>1</sup>, R. Nellums<sup>3</sup>, S. F. Son<sup>3</sup> and J. A. Stevens<sup>1</sup>. <sup>1</sup>Environmental Laboratory, US Army Engineer Research & Development Center, Vicksburg, MS; <sup>2</sup>Badger Technical Services, Vicksburg, MS; <sup>3</sup>Purdue University, West Lafayette, IN.

Engineered nanoparticles (NPs) possess numerous potential benefits to society in fields as diverse as electronics, textiles, medicine, energy and construction. The respiratory system represents a unique target for the potential toxicity of NPs. Due to their dimensions, inhaled NPs can reasonably be expected to penetrate to the deepest part of the lungs, the alveolar sacs. Completed inhalation studies in laboratory rats have demonstrated that some NPs induce oxidative stress, inflammation and fibrosis. In this study, we examine the effects of nanothermite and parent nano-materials (bismuth oxide [Bi<sub>2</sub>O<sub>3</sub>] and copper oxide [CuO] spheres and rods) on an alveolar co-culture model consisting of human type II pneumocytes and alveolar macrophages. Co-cultures were set up with a ratio of 3:1 of type II pneumocytes to each alveolar macrophage 24 h prior to treatment. Media was then removed and co-cultures were treated with 0.001 100 mg/l NPs for 24 h. Cell viability was only affected by CuO at 100 mg/l; CuO spheres and rods had similar effects. These studies demonstrate that only high concentrations of raw Bi<sub>2</sub>O<sub>3</sub> and CuO NPs affect respiratory co-cultures and that CuO NP size does not affect respiratory co-cultures. Additional phagocytosis studies and cytokine analysis studies (intracellular and secreted concentrations) are being conducted to evaluate inflammatory effects of these NPs in the respiratory co-culture immune cells.

**PS 1775 Metabolomic Studies of the Nanotoxicity of TiO<sub>2</sub> and CeO<sub>2</sub>.**

K. T. Kitchin<sup>1</sup>, B. Robinette<sup>1</sup>, B. Castellon<sup>1</sup> and R. Michalek<sup>2</sup>. <sup>1</sup>US EPA, Durham, NC; <sup>2</sup>Metabolon, Durham, NC.

Nanomaterial exposures to humans and wildlife pose unknown degrees of risk to major organ systems including the liver. TiO<sub>2</sub> and CeO<sub>2</sub> nanomaterial exposures (3 or 30 ug/ml for 3 days) were performed in cultures of human liver HepG2 cells. TiO<sub>2</sub> and CeO<sub>2</sub> nanomaterial exposures altered the concentrations of biochemicals associated with arginine metabolism, lipids and fatty acids, TCA cycle and glutathione. Some metabolites that were significantly altered in 4 or more of the 8 TiO<sub>2</sub> or CeO<sub>2</sub> nanomaterial treatments were cysteine, GSH, asymmetric dimethylarginine and gamma-glutamyl amino acids. Asymmetric dimethylarginine (a competitive inhibitor of nitric oxide synthase) was significantly increased by many nanomaterial exposures, particularly by CeO<sub>2</sub> exposures. One CeO<sub>2</sub> nanomaterial with smaller primary particle size caused increases in many lipids, including long chain fatty acids, lysolipids, membrane sphingolipids, monacylglycerols and diacylglycerols; six other nanomaterial exposures did not. With respect to the TCA cycle, nanomaterial exposures sometimes decreased the concentrations of glutamate, glutamine, malate, fumarate and succinate. In 5 nanomaterial treatment groups, hepatocyte glutathione depletion reached 13 to 34% of control levels. Overall, our nanotoxicology studies have shown (a) many biochemical effects in HepG2 cells and (b) major differences in the biochemical and biological responses between different TiO<sub>2</sub> and CeO<sub>2</sub> nanomaterials and (c) oxidative stress (major GSH depletion) was caused by exposure to both TiO<sub>2</sub> and CeO<sub>2</sub> of different primary particle sizes. Disclaimer: [This is an abstract or a proposed presentation and does not necessarily reflect EPA policy. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.]

**PS 1776 Neurotoxicity of Au-NPs in an In Vitro Blood Brain Barrier (BBB) Model.**

M. Sharma<sup>1,2</sup>, C. E. Sulentic<sup>2</sup>, J. J. Schlager<sup>1</sup> and S. M. Hussain<sup>1,2</sup>. <sup>1</sup>711 HPW/RHDJ, AFRL, Wright-Patterson AFB, Dayton, OH; <sup>2</sup>Department of PharmTox, WSU, Dayton, OH.

Gold nanoparticles (Au-NPs) have demonstrated great potential in the development of a variety of tools with applications ranging from biomedical to military fields. Biodistribution studies indicate differential uptake of NPs depending on their functionalization, treatment conditions, and location in the body. Unlike other organ systems, brain vasculature is comprised of endothelial cells that form an anatomical and physiological barrier that protects neurons from metabolic fluctuations and toxins. The cost and extent of expertise required for in vivo studies, pose limitations, and therefore, better in vitro models are pursued to study toxicophysiological aspects of the BBB. The main aim of this study is to modify a previously described static in vitro BBB model by adding a constant flow of media containing NPs and then studying the NP trafficking across the endothelial cells. Murine brain endothelial cells (bEnd3) and astrocytes (C8D1A) were cultured on the luminal

and abluminal sides, respectively, of a transwell membrane. Permeability studies using Fluorescein isothiocyanate-tagged dextran and polyethylene glycol (PEG) confirmed a tight layer of bEnd3 cells with transendothelial resistance of  $122 \pm 3 \Omega\text{cm}^2$ . This culture set up was treated with citrate and PEG-coated Au-NPs (50  $\mu\text{g/ml}$ ) for 24 hr to quantify non-specific leakage of substrates across the cell barrier and to evaluate the association of NPs with astrocytes, with and without flow of media. Inductively coupled plasma mass spectrometry results show fewer NPs on the abluminal side confirming a tight cell barrier and transmission electron microscopy imaging suggest endosomal localization of NPs in bEnd3 cells. Unlike the static set up, brightfield imaging suggested less aggregation of NPs with flow and citrate-coated NPs associate more with astrocytes in comparison to PEGylated NPs. These data demonstrate that surface properties influence passage of NPs across bEnd3 cells. This multicell model could be applied as a rapid screening technique to analyze uptake and toxicity of NMs across the BBB.

## PS 1777 Effect of Surface Modification of Metal Oxide Nanoparticles upon Cell Viability and Genotoxicity of Epithelial Breast Cells.

T. D. Palacios-Hernandez<sup>1</sup>, E. Gonzalez<sup>2</sup>, M. A. Mendez<sup>3</sup>, G. A. Hirata<sup>4</sup>, D. Momot<sup>5</sup>, E. E. Hernandez<sup>5</sup>, A. Marogi<sup>5</sup>, M. Poirier<sup>5</sup>, O. Olivero<sup>5</sup> and R. E. Cachau<sup>6</sup>. <sup>1</sup>Biological Sciences, UPAEP, Puebla, Mexico; <sup>2</sup>Chemistry Center, ICUAR, Puebla, Mexico; <sup>3</sup>Chemical and Biological Sciences, UDLAP, Puebla, Mexico; <sup>4</sup>Nanosciences and Nanotechnology Center, UNAM, Ensenada, Mexico; <sup>5</sup>National Cancer Institute, NIH, Bethesda, MD; <sup>6</sup>Frederick National Laboratory of Cancer Research, Frederick, MD.

In this work, the biological activity of different metal oxide nanoparticles (Fe<sub>3</sub>O<sub>4</sub>, Co<sub>3</sub>O<sub>4</sub>, CuO) upon epithelial breast cells MCF-10A have been evaluated. The first step is the fabrication and characterization of the metal-oxide nanoparticles (MONPs) followed by the functionalization with folic acid, L-arginine and L-cysteine which is confirmed by Fourier Transform Infrared Spectroscopy (FTIR) and Low Voltage Electron Microscopy (LVEM) measurements. In order to determine real time cell viability, semi-confluent cells were exposed to either 0, or 0.2 mg/mL of particles with and without functionalization.  $2 \times 10^3$  cells/well were grown in a gold wired 16-well plate for 15 hours, with readings of impedance collected every 15 minutes to monitor cell proliferation. To determine cell-nanoparticle interactions, cells were grown during 24 hours, exposed to 0.2 mg/mL of particles and allowed to grow for additional 48 hours. After that, cells were fixed and stained with DAPI to evaluate apoptosis necrosis and characterization of normal nuclear morphology. Additionally a dose-response growth curve using Fe<sub>3</sub>O<sub>4</sub> nanoparticles, presumably, the less toxic exposure, free and functionalized with folic acid (Fe-AF) was carried out. Results indicate that the most toxic treatment was Fe<sub>3</sub>O<sub>4</sub> and the less toxic was Fe<sub>3</sub>O<sub>4</sub> functionalized with folic acid, although all the MONPs evaluated didn't cause a strong toxic response due the values of cell index obtained by impedance evaluation. However, the presence of particles interacting with the cell and nucleus showed the possibility of genotoxic effects, and for that reason, in an attempt to explore this condition, the micronucleus assay employing Cytochalasin B (Cytome assay) is being conducted as a follow up.

## PS 1778 Synthesis, Characterization and Evaluation of Biological In Vitro Activity of Eu<sup>3+</sup> Doped Hydroxyapatite.

J. Delgado-Jimenez<sup>1</sup>, T. D. Palacios-Hernandez<sup>2</sup>, A. Angulo Molina<sup>1</sup>, J. L. Varela<sup>3</sup>, R. Agustin<sup>3</sup> and E. Rubio-Rosas<sup>3</sup>. <sup>1</sup>Ciencias Químico-Biológicas, UDLAP, Puebla, Mexico; <sup>2</sup>Ciencias Biológicas, UPAEP, Puebla, Mexico; <sup>3</sup>Centro de Vinculación Universitaria y Transferencia de Tecnología, BUAP, Puebla, Mexico.

In this work, the synthesis, characterization and biological in vitro activity of Eu<sup>3+</sup>-doped hydroxyapatite (Eu-HAp) is being evaluated. Hydroxyapatite synthesis is being carried out by microwave-hydrothermal techniques, modifying parameters such as temperature, power, pH and calcium precursors. In a typical process, the synthesis was carried out by the mixture of CaCl<sub>2</sub> or Ca(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O and Eu(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O. After that, a solution of (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> was added. The full mixture was alkalized and transferred into a Milestone START D Microwave Digestor System. Power and temperature measurements were adjusted regarding the literature, and after that the product was purified and dried. The products obtained, as powders, were grinded and characterized by X-Ray Diffraction (XRD), Scanning and Transmission Electron Microscopy (SEM, TEM), Atomic Force Microscopy (AFM) and Fourier-Transformed Infrared Spectroscopy (FTIR). As preliminary results, infrared spectroscopy showed the signals corresponding to O-H stretching at approximately 3500 cm<sup>-1</sup>. Regarding PO<sub>4</sub> vibrations, we found approximately at 400, 550, a small signal at 600, 1000 and 1100 cm<sup>-1</sup> the characteristic vibration of this group. Regarding XRD, we have obtained nanocrystals at a size range of 37-50 nm, and the crystalline phase corresponding to hydroxyapatite

was confirmed in the samples obtained by the most alkaline pH ranges (above 10), while at pH 9 we obtained a mixture between hydroxyapatite and monetite phases. To evaluate the biological in vitro activity of our materials, MTT assay is being performed upon mouse fibroblasts that are treated with representative samples of Eu-HAp nanoparticles previously synthesized by our group.

## PS 1779 Interactive Toxicity of Usnic Acid and Lipopolysaccharide in Human Liver HepG2 Cells.

S. C. Sahu, M. W. O'Donnell and R. L. Sprando. *Toxicology, US FDA, Laurel, MD.*

Usnic acid (UA), a natural botanical product, is a constituent of some dietary supplements used for weight loss. It has been associated with clinical hepatotoxicity leading to liver failure in humans. The present study was undertaken to evaluate the interactive toxicity, if any, of UA with lipopolysaccharides (LPS), a potential contaminant of food, at low nontoxic concentrations. The human hepatoblastoma HepG2 cells were treated with the vehicle control and test agents, separately and in combination (UA+LPS) at concentrations of UA 1.0  $\mu\text{M}$  and LPS 1.0 ng/ml, for 24 h at 37.0 °C in 5% CO<sub>2</sub>. Following the treatment period, the cells were evaluated by the traditional biochemical endpoints of toxicity in combination with the toxicogenomic endpoints that included cytotoxicity, oxidative stress, mitochondrial injury and changes in pathway-focused gene expression profiles. Compared to the controls, low nontoxic concentrations of UA and LPS separately showed no effect on the cells as determined by the biochemical endpoints. However, the simultaneous mixed exposure of the cells to their mixture resulted in increased cytotoxicity, oxidative stress and mitochondrial injury. The pathway-focused gene expression analysis resulted in the altered expression of several genes out of 84 genes examined. Most altered gene expressions induced by the mixture of UA and LPS were different from those induced by the individual constituents. The genes affected by the mixture were not modulated by either UA or LPS. The results of this study suggest that the interactions of low nontoxic concentrations of UA and LPS produce toxicity in HepG2 cells.

## PS 1780 Dihydroartemisinin Inhibits PMA-Induced Cyclooxygenase-2 Expression through Downregulating AKT and MAPK Signaling Pathways in Murine Macrophages.

E. Han<sup>1</sup>, H. Kim<sup>1</sup>, J. Choi<sup>1</sup>, Y. Hwang<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Korea International University, Jinju, Republic of Korea.

Dihydroartemisinin (DHA), a semi-synthetic derivative of artemisinin isolated from the traditional Chinese herb *Artemisia annua* L., has recently been shown to possess antitumor activity in various cancer cells. However, the effect of anti-inflammatory potentials of DHA in murine macrophage RAW 264.7 cells has not been studied. The present study investigated the effect of COX-2 and molecular mechanisms by DHA in phorbol 12-myristate 13-acetate (PMA)-stimulated RAW 264.7 cells. DHA dose-dependently decreased PMA-induced COX-2 expression and PGE<sub>2</sub> production, as well as COX-2 promoter-driven luciferase activity. Additionally, DHA decreased luciferase activity of COX-2 regulation-related transcription factors including NF- $\kappa$ B, AP-1, C/EBP and CREB. DHA also remarkably reduced PMA-induced p65, C/EBP $\beta$ , c-jun and CREB nuclear translocation. Furthermore, DHA evidently inhibited PMA-induced phosphorylation of AKT and the MAP Kinases, such as ERK, JNK and p38. These data indicated that DHA effectively attenuates COX-2 production via down-regulation of AKT and MAPK pathway, revealing partial molecular basis for the anti-inflammatory properties of DHA. These findings demonstrate that DHA effectively attenuates COX-2 production, and provide further insight into the signal transduction pathways involved in the anti-inflammatory effects of DHA.

## PS 1781 Protective Role of Silymarin against Oxidative Stress Induced in Human Neuroblastoma Cell Line SH-SY5Y.

A. Anadon, M. A. Martinez, E. Ramos, V. Castellano, I. Ares, M. Martinez, M. R. Martinez-Larrañaga and A. Romero. *Toxicology & Pharmacology, Complutense University, Madrid, Spain.*

Silymarin (SM) is a mixture of bioactive flavonolignans isolated from *Silybum marianum* (L.) Gaertn., employed usually in the treatment of alcoholic liver disease and as anti-hepatotoxic agent in humans. The essential activity of SM is an antioxidant

effect of its flavonolignans. Because of the importance of oxidative stress and mitochondrial dysfunction in causing neuronal death, prompted us to investigate the effects of SM against an in vitro model of reactive oxygen species (ROS) production in the human neuroblastoma cell line SH-SY5Y. We selected two cytotoxic stimuli, for one hand, hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) (500  $\mu$ M), and on the other hand the combination of 30  $\mu$ M rotenone plus 10  $\mu$ M oligomycin-A (R/O) that inhibit mitochondrial respiration complexes I and V, respectively. Cell viability, measured as MTT reduction, was decreased to 70% in cells treated with H<sub>2</sub>O<sub>2</sub> and to 60% in cells exposed to R/O. Cell incubation with increasing concentrations of SM (1-1000  $\mu$ M) for 24 hr, followed by a 24-hr period with H<sub>2</sub>O<sub>2</sub> (extracellular ROS) or R/O (intracellular ROS). Maximum protection was achieved with 300  $\mu$ M SM (30% protection). Our results showed that R/O and H<sub>2</sub>O<sub>2</sub>-induced cytotoxicity in SH-SY5Y cells was suppressed by treatment with SM. Because, it is recently reported that SM crosses the blood-brain barrier and enters the CNS and it is non-toxic even at higher doses, this flavonoid may be useful in diseases known to be aggravated by reactive oxygen species and in the development of novel treatments for neurodegenerative disorders. This work was supported by projects Ref. BSCHGR58/08(UCM), Ref. No. S2009/AGR-1469(CAM) and Consolider-Ingenio 2010 No.CSD2007-063(MEC), Spain.

**PS 1782 Thymoquinone, a Bioactive Component of *Nigella sativa*, Modulates Redox Status and Insulin Secretion from Pancreatic Beta Cells.**

J. P. Gray<sup>1,3</sup>, R. Follmer<sup>1</sup>, R. Rebar<sup>1</sup>, N. Seeram<sup>2</sup> and E. Heart<sup>3</sup>. <sup>1</sup>Science, US Coast Guard Academy, New London, CT; <sup>2</sup>Bioactive Botanical Research Laboratory, University of Rhode Island, Kingston, RI; <sup>3</sup>Cellular Dynamics, Marine Biological Laboratory, Woods Hole, MA.

*Nigella Sativa* is a traditional medicine that has been used in the Mediterranean to treat a variety of disorders, including type 2 diabetes. A primary component of *Nigella sativa* extract is thymoquinone which, like *Nigella sativa* extract, attenuates diabetes symptoms. The molecular targets and interactions of thymoquinone with metabolic pathways relevant to glucose-stimulated insulin secretion (GSIS) from pancreatic  $\beta$ -cells have not yet been identified. Our laboratory previously demonstrated that low (nM- $\mu$ M) doses of various quinones such as menadione stimulate insulin secretion from  $\beta$ -cells, and this action was coupled to the generation of low levels of H<sub>2</sub>O<sub>2</sub>, a putative mediator of GSIS. Here we compared the mechanism of action of thymoquinone to that of menadione in  $\beta$ -cells. Like menadione, thymoquinone induced a dose-dependent increase in the production of H<sub>2</sub>O<sub>2</sub>. Unlike menadione, the redox cycling of thymoquinone was not dependent on the glucose concentration. Both NADPH and NADH supported the redox cycling of thymoquinone in cytosolic and mitochondrial fractions. This was consistent with the ability of thymoquinone to decrease NADH/NAD<sup>+</sup> and NADPH/NADP<sup>+</sup> ratios, thus reducing intracellular redox poise. Thymoquinone-dependent redox cycling activities were inhibited by diphenylene iodonium, an inhibitor of flavin-containing oxidoreductases. Dicoumarol and MAC220, NQO1 inhibitors previously shown to inhibit menadione-dependent redox cycling, failed to inhibit thymoquinone-dependent redox cycling. Unlike menadione, thymoquinone was found to potentiate GSIS in a dose-dependent manner at stimulatory glucose (concentrations which potently stimulate insulin secretion). These data suggest that while the mechanisms of thymoquinone redox cycling are different than those of menadione, thymoquinone retains the ability to regulate both redox status and insulin secretion from  $\beta$ -cells.

**PS 1783 Antioxidant and DPPH-Scavenging Activities of Compounds and Ethanolic Extract of the Leaf and Twigs of *Caesalpinia bonduc* L. Roxb.**

O. O. Olubanke<sup>1</sup>, O. E. Ogunlana<sup>2</sup>, A. T. Lawa<sup>1</sup>, J. O. Olagunju<sup>3</sup>, A. A. Akindahunsi<sup>4</sup> and N. H. Tan<sup>5</sup>. <sup>1</sup>Biological Sciences, Covenant University, Ota, Nigeria; <sup>2</sup>Biological Sciences, Crawford University, Igbesa, Nigeria; <sup>3</sup>Medical Biochemistry, College of Medicine, Lagos State University, Ikeja, Nigeria; <sup>4</sup>Biochemistry, Federal University of Technology, Akure, Nigeria; <sup>5</sup>State Key Laboratory of Phytochemistry and Plant Resources, Kunming Institute of Botany, Kunming, China.

Antioxidant effects of ethanolic extract of *Caesalpinia bonduc* and its isolated bioactive compounds were evaluated *in vitro*. The compounds included two new cassane diterpenes, 1 $\alpha$ ,7 $\alpha$ -diacetoxyl-5 $\alpha$ ,6 $\beta$ -dihydroxyl-cass-14(15)-epoxy-16,12-olide (1) and 12 $\alpha$ -ethoxyl-1 $\alpha$ ,14 $\beta$ -diacetoxyl-2 $\alpha$ ,5 $\alpha$ -dihydroxyl-cass-13(15)-en-16,12-olide (2); and others, bonducellin (3), 7,4'-dihydroxy-3,11-dehydrohomoisoflavanone

(4), daucosterol (5), luteolin (6), quercetin-3-methyl ether (7) and kaempferol-3-O- $\alpha$ -L-rhamnopyranosyl-(1 $\rightarrow$ 2)- $\beta$ -D-xylopyranoside (8). The antioxidant properties of the extract and compounds were assessed by the measurement of the total phenolic content, ascorbic acid content, total antioxidant capacity and 1-1-diphenyl-2-picryl hydrazyl (DPPH) and hydrogen peroxide radicals scavenging activities. Compounds 3, 6, 7 and ethanolic extract had DPPH scavenging activities with IC<sub>50</sub> values of 186, 75, 17 and 102  $\mu$ g/ml respectively when compared to vitamin C with 15  $\mu$ g/ml. On the other hand, no significant results were obtained for hydrogen peroxide radical. In addition, compound 7 has the highest phenolic content of 0.81 $\pm$ 0.01 mg/ml of gallic acid equivalent while compound 8 showed the highest total antioxidant capacity with 254.31 $\pm$ 3.54 and 199.82 $\pm$ 2.78  $\mu$ g/ml gallic and ascorbic acid equivalent respectively. Compound 4 and ethanolic extract showed a high ascorbic acid content of 2.26 $\pm$ 0.01 and 6.78 $\pm$ 0.03 mg/ml respectively. The results obtained showed the antioxidant activity of the ethanolic extract of *C. bonduc* and deduced that this activity was mediated by its isolated bioactive compounds.

**PS 1784 Selective Elimination of Malignant Melanomas through Autophagic and Mitochondria-Based Mechanisms by the Antitumor Agent Osw-1.**

K. Riaz Ahmed, C. Garcia-Prieto, L. Feng and P. Huang. *Molecular Pathology, University of Texas MD Anderson Cancer Center, Houston, TX.* Sponsor: M. Smith.

Drug resistance and lack of therapeutic selectivity are two of the biggest challenges to successful melanoma therapy. Constitutive activation of Extracellular Signal Regulated Kinase 1/2 (ERK1/2) and subsequent chemoresistance has been reported in malignant melanomas. ERK1/2 has also been implicated in activation of mitochondrial gene expression and regulation of autophagy thus making it an important therapeutic target.

The natural product, OSW-1, isolated from the bulbs of ivory coast lily, has been shown to be highly cytotoxic in numerous cancer cell lines with yet undefined mechanisms of action. Herein, we report our results on the anticancer activity and selectivity of OSW-1 in malignant melanoma cells and its potential mechanisms of action.

Our preliminary results demonstrated that OSW-1 was highly effective in killing tumor cells that are resistant to most of the currently available anticancer drugs, with IC50 values in sub-nM concentrations. Importantly, OSW-1 preferentially killed melanoma cells and exerted much lower toxicity to normal melanocytes in culture. Biochemical analysis revealed that OSW-1 treatment caused damage of the mitochondrial membrane integrity, leading to a decrease in transmembrane potential and subsequently initiating cell death, apparently through autophagy. Further study demonstrated that OSW-1 inhibited ERK1/2 expression in melanoma cells and caused a significant disturbance of cellular calcium homeostasis, leading to aberrant calcium-mediated processes including mitochondrial impairment. Based on these results, we postulate that OSW-1 inhibits ERK1/2 mediated signaling and triggers mitochondrial damage in cells leading to a significant disturbance of cellular calcium and cell death through autophagy. This study is of great significance since ERK1/2 signaling is important to melanoma cell survival and inhibition of ERK1/2 expression and induction of autophagic cell death by OSW-1 will be critical to combat therapeutic resistance and enhance drug selectivity.

**PS 1785 3-Caffeoyl, 4-Dihydrocaffeoylquinic Acid from *Salicornia herbacea* Attenuates High Glucose-Induced Hepatic Lipogenesis in Human HepG2 Cells.**

H. Chun<sup>2</sup>, Y. Hwang<sup>3,1</sup>, J. Choi<sup>1</sup>, H. Kim<sup>1</sup>, Y. Chung<sup>3</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Korea Research Institute of Bioscience and Biotechnology, Jeongseup, Republic of Korea; <sup>3</sup>International University of Korea, Jinju, Republic of Korea.

3-Caffeoyl, 4-dihydrocaffeoylquinic acid (CDCQ) from *Salicornia herbacea* has a variety of pharmacological properties, including antioxidant and anti-inflammatory and hepatoprotective properties. The aims of our study were to provide new data on the molecular mechanisms underlying the role of CDCQ in prevention of high glucose-induced lipid accumulation in human HepG2 cells. We found that CDCQ suppressed high glucose-induced lipid accumulation in HepG2 cells. CDCQ strongly inhibited the high glucose-induced FAS expression by modulating SREBP-1c activation. Moreover, the use of a specific inhibitor or liver kinase B1 (LKB1)-siRNA transfected HepG2 cells showed that CDCQ activated AMP-activated protein kinase (AMPK) via silent information regulator T1 (SIRT1) or LKB1 in HepG2 cells. These results indicate that CDCQ prevents lipid accumulation by

blocking the expression of SREBP-1c and FAS through LKB1/SIRT1 and AMPK activation in HepG2 cells, suggesting that CDCQ is a novel AMPK activator with a potential role in the prevention obesity.

**PS 1786 Effects of Saponins from the Roots of *Platycodon grandiflorum* on TGF- $\beta$ 1-Induced Epithelial-Mesenchymal Transition in A549 Cells.**

C. Ho<sup>1</sup>, H. Kim<sup>1</sup>, Y. Hwang<sup>2</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Epithelial to mesenchymal transition (EMT) is a key event in the progression of cancer. EMT is characterized by the loss of epithelial and the gain of mesenchymal features. Previous studies have revealed that treatment with CKS, saponins from the roots of *Platycodon grandiflorum*, significantly reduces metastasis and tumorigenesis, but the underlying mode of action has not been elucidated. In this study, we investigated the inhibitory effect of CKS on transforming growth factor (TGF)- $\beta$ 1-induced alterations characteristic of EMT in human lung carcinoma cells. We found that CKS-treated cells displayed inhibited TGF- $\beta$ 1-mediated E-cadherin down-regulation and Vimentin up-regulation and also retained epithelial morphology. Furthermore, TGF- $\beta$ 1-increased Snail expression was reduced by CKS. Pretreatment of cells with CKS blocked TGF- $\beta$ 1-induced Smad2/3 phosphorylation and Smad7 down-regulation. CKS inhibited TGF- $\beta$ 1-mediated phosphorylation of Akt, ERK1/2, and glycogen synthase kinase-3 $\beta$  (GSK-3 $\beta$ ). Furthermore, TGF- $\beta$ 1-increased Snail expression was reduced by pharmacology inhibitors of Akt, ERK1/2, and GSK-3 $\beta$ . These results indicate that pretreatment with CKS inhibits the TGF- $\beta$ 1-induced EMT process and prevents TGF- $\beta$ 1-induced transdifferentiation via activation of Akt and ERK1/2 and inactivation of GSK-3 $\beta$  in A549 cells.

**PS 1787 Platycodin D Regulates Hepatic Lipogenesis via an AMP-Activated Protein Kinase Dependent Signaling Pathway in Human HepG2 Cells.**

H. Lee<sup>2</sup>, Y. Hwang<sup>3,1</sup>, J. Choi<sup>1</sup>, H. Kim<sup>1</sup>, Y. Chung<sup>3</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Korea Research Institute of Bioscience and Biotechnology, Daejeon, Republic of Korea; <sup>3</sup>International University of Korea, Jinju, Republic of Korea.

Platycodin D, the saponins from the roots of *Platycodon grandiflorum* (CKS), has a variety of pharmacological properties, including anti-hyperlipidemic, antioxidant and hepatoprotective properties. This study was conducted to suggest the role of AMP-activated protein kinase (AMPK) pathway in the anti-obesity effect of platycodin D. We characterized the underlying mechanism platycodin D's effects in HepG2 cells by Western blot and RT-PCR analysis. Platycodin D increased the phosphorylation of AMPK and acetyl-CoA carboxylase (ACC) in HepG2 cells. Use of a specific inhibitor showed that platycodin D activated AMPK via SIRT1/calmodulin-dependent kinase kinase (CaMKK) in HepG2 cells. Taken together, these data suggest that platycodin D exert improving effects on high glucose-induced lipogenesis by reducing of SREBP-1c and FAS expression via AMPK activation.

**PS 1788 Rutaecarpine Suppresses LPS-Induced Inflammation in Mouse Macrophages: A Possible Pathway through the Induction of Heme Oxygenase-1 Expression.**

S. Jin<sup>1</sup>, Y. Hwang<sup>2</sup>, H. Kim<sup>2</sup>, J. Choi<sup>1</sup>, H. Kim<sup>1</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Rutaecarpine, a quinazolinocarboline alkaloidal compound, is a natural product isolated from *Evodia rutaecarpa* and has various biological and pharmacological effects, including anti-inflammatory and anti-oxidative properties. In the present study, we investigated the effect of rutaecarpine against lipopolysaccharide (LPS)-induced inflammation in RAW264.7 macrophages. Treatment with rutaecarpine suppressed inducible nitric oxide synthase expression and nitric oxide (NO) production by downregulating NF- $\kappa$ B activity in lipopolysaccharide (LPS)-stimulated RAW264.7 macrophages. Rutaecarpine acts by inducing the expression of heme

oxygenase-1 (HO-1) in a dose- and time-dependent manner. The signaling pathway involved in rutaecarpine-mediated HO-1 induction included Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (CaMKII) and extracellular signal regulated kinase 1/2 (ERK1/2). Furthermore, the CaMKII-ERK1/2 cascade targets the transcription factor, NF-E2-related factor-2 (Nrf2). Taken together, our results demonstrate that rutaecarpine-induced expression of HO-1 is mediated by the Ca<sup>2+</sup>-CaMKII-Nrf2-HO-1 pathway and inhibits LPS-induced inflammation in RAW264.7 macrophages.

**PS 1789 Cultivated Ginseng Inhibits Tarc Expression by Suppressing the Activation of NF- $\kappa$ B and STAT1 in Human Keratinocyte Cells.**

B. Park<sup>1</sup>, J. Choi<sup>1</sup>, J. Choi<sup>2</sup>, Y. Chung<sup>2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Atopic dermatitis (AD) is associated with the paradigm of an allergic T helper (Th) 2-mediated disease, characterized by abnormal IgE production, peripheral eosinophilia, mast cell activation, as well as Th2 and Th1 cytokine up-regulation in chronic skin lesions. This study examined the inhibitory effects of cultivated ginseng (CG) (*Panax ginseng* C.A. Meyer) on atopic dermatitis in HaCaT cells. CG, an herb used in Korean herbal medicine, has been widely used in China and Japan to treat fatigue and to enhance resistance to many diseases. CG suppressed TNF- $\alpha$ /IFN- $\gamma$ -induced TARC, CTACK, and MDC mRNA expression in HaCaT cells. Additionally, CG inhibited TNF- $\alpha$ /IFN- $\gamma$ -induced activation of NF- $\kappa$ B and STAT1. These results indicate that CG inhibits chemokine expression in keratinocytes by suppressing of NF- $\kappa$ B and STAT1 activation.

**PS 1790 Mollugin Inhibits Proliferation and Induces Apoptosis by Inhibiting HER2 Expression in HER2-Overexpressing Breast and Ovarian Cancer Cells.**

M. Do, T. Tran, M. Na and H. Jeong. Pharmacy, Chungnam National University, Daejeon, Republic of Korea.

Overexpression of the HER2 gene causes many cancer types and has been reported to enhance cell proliferation, tumor growth, angiogenesis, and metastasis. This study investigated the molecular mechanisms by which mollugin exerts anti-tumor effect in HER2-overexpressing breast and ovarian cancer cells. Mollugin exhibited potent inhibitory effects on cancer cell proliferation, especially in HER2-overexpressing SK-BR-3 human breast cancer cells and SK-OV-3 human ovarian cancer cells in a dose- and time-dependent manner. Additionally, caspase-3 activity and PARP cleavage were significantly upregulated in HER2-overexpressing SK-BR-3 and SK-OV-3 cells treated with mollugin. Mollugin treatment caused a dose-dependent inhibition of HER2 gene expression at the transcriptional level, potentially in part through suppression of NF- $\kappa$ B activation. Moreover, mollugin inhibits cyclin D1 expression by downregulating HER2 activation and consequently reducing PI3K/Akt signaling. These results suggest that mollugin is a novel modulator of the HER2 pathway in HER2-overexpressing cancer cells with a potential role in the treatment and prevention of human breast and ovarian cancer with HER2 overexpression.

**PS 1791 Multiple Signaling Pathways Involved in Suppression of MDR1 by Mollugin from *Rubica cordifolia*.**

T. Tran, H. Kim, M. Do, S. Jin, E. Shim, H. Han, M. Na and H. Jeong. Pharmacy, Chungnam National University, Daejeon, Republic of Korea.

Multidrug resistance (MDR) is known to be a serious problem in cancer treatment and has been identified as a negative prognostic factor in malignancies. This study investigated mollugin, purified from roots of *Rubica cordifolia* L., down-regulated MDR1 expression in MCF-7/adriamycin (MCF-7/adr) cells, human breast multidrug-resistant cancer cell. Mollugin treatment significantly inhibited MDR1 expression by blocking MDR1 gene transcription. Mollugin treatment also significantly increased intracellular accumulation of the fluorescently-tagged P-gp substrate, rhodamine-123. The suppression of MDR1 promoter activity and protein expression was mediated through mollugin-induced activation of AMP-activated protein kinase (AMPK) and inhibited NF- $\kappa$ B as well as CREB activation.

These results suggest that mollugin treatment enhanced suppression of P-gp expression by inhibiting the NF- $\kappa$ B signaling pathway and attenuating CRE transcriptional activity through AMPK activation.

**PS 1792 Liver Kinase B1 Is Required for Phillyrin-Induced AMPK Activation in Human HepG2 Hepatocytes.**

H. Han, M. Do, H. Kim, T. Khanal, T. Tran, M. Na and H. Jeong. *Pharmacy, Chungnam National University, Daejeon, Republic of Korea.*

Phillyrin, an active constituent found in certain functional foods, has anti-obesity activity in vivo. This study investigated the ability of phillyrin to induce AMP-activated protein kinase (AMPK) in human HepG2 hepatocytes. Phillyrin strongly activated the phosphorylation of AMPK $\alpha$  at Thr172 in HepG2 cells under normal glucose condition. Additionally, the phosphorylation of AMPK $\alpha$  at Thr172 and ACC at Ser79 was significantly suppressed in cells treated with high glucose, phillyrin dose-dependently recovered the phosphorylation of AMPK $\alpha$  at Thr172 and the downstream target acetyl-CoA carboxylase (ACC) phosphorylation at Ser79 in HepG2 cells pretreated by phillyrin. Moreover, phillyrin significantly stimulated the phosphorylation of liver kinase B1 (LKB1) at Ser428 in a time-dependent manner, with a time course matching that of AMPK $\alpha$  phosphorylation at Thr172. In addition, the defeat of phillyrin-stimulated AMPK $\alpha$  activation in HeLa cells deficient in LKB1 or in siRNA LKB1-transfected HepG2 cells, suggesting that LKB1 is required for phillyrin-induced AMPK activation. These results indicate that anti-obesity effects are mediated, at least in part, by the activation of LKB1/AMPK.

**PS 1793 Prevention of Free Fatty Acid-Induced Hepatic Steatosis by S-Allyl Cysteine through AMPK Pathways.**

H. Jeong<sup>1</sup>, Y. Hwang<sup>2</sup>, H. Kim<sup>1</sup>, J. Choi<sup>1</sup> and Y. Chung<sup>2</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>Korea International University, Jinju, Republic of Korea.

S-allylcysteine (SAC) is the most abundant organosulfur compound in aged garlic extract (AGE), which has been used to standardize commercial aged extracts. SAC has been reported to have antioxidant, anti-cancer, anti-hepatotoxic and neurotrophic properties. In this study, we provide evidence that SAC prevented free fatty acid (FFA)-induced lipid accumulation and lipotoxicity in hepatocytes. SAC significantly reduced FFA-induced generation of reactive oxygen species, caspase activation, and subsequent cell death. Also, SAC mitigated total cellular lipid and TG accumulation in steatotic HepG2 cells. SAC significantly increased the phosphorylation of AMP-activated protein kinase (AMPK) and acetyl-CoA carboxylase (ACC) in HepG2 cells. Additionally, SAC down-regulated the levels of sterol regulatory element binding protein-1 (SREBP-1) and its target genes, including ACC and fatty acid synthase (FAS). Use of a specific inhibitor showed that SAC activated AMPK via calcium/calmodulin-dependent kinase kinase (CaMKK) and SIRT1. Our results demonstrate that SAC activates AMPK through CaMKK and inhibits SREBP-1-mediated hepatic lipogenesis. The results indicate that SAC inhibit lipogenesis in cultured human hepatocytes, and further suggest that SAC impair triglyceride synthesis in part due to decreased de novo fatty acid synthesis resulting from inhibition on AMPK-dependent FAS and SREBP-1c.

**PS 1794 Cyto-/Genotoxic Effect of Extract from *Bufo bufo* gargarizans Cantor in Human T Cell Leukemia Cells.**

S. Lee, Y. Lee, Y. Choi and H. Chung. *School of Public Health, Seoul National University, Seoul, Republic of Korea.* Sponsor: J. Chung.

Cinobufacini (Huachansu), an extract from the skins of *Bufo bufo* gargarizans Cantor and has been widely used as an oriental medicine for cancer therapy. Although numerous experimental studies on cinobufacini have been investigated its anti-cancer properties, there is no information whether cinobufacini has anti-cancer effects on human leukemia. The genotoxicity of cinobufacini has not been determined. The aim of the present study was to examine the cyto-/genotoxic effect of cinobufacini in human T cell leukemia (Jurkat T-cells) and human normal lymphocytes.

Jurkat T-cells and normal lymphocytes were treated for 24 or 48 hours with various concentrations of cinobufacini. Cytotoxicity was evaluated by Trypan blue exclusion assays. Apoptotic cell death was detected by propidium iodide (PI) staining, and intracellular reactive oxygen species (ROS) was determined by fluorescent dye 5-(and 6)-141 carboxy-2, 7-dichlorodihydrofluorescein diacetate (DCF-DA;

Molecular Probes) using flow cytometry analysis. The genotoxicity of cinobufacini in Jurkat-T cells was measured by comet assay and cytokinesis-block micronucleus assay.

Cinobufacini significantly inhibited cell viability in Jurkat-T cells but not in normal lymphocytes in dose- and time- dependent manner. Jurkat T-cells treated with cinobufacini induced significantly higher levels of sub-diploid cells compared with control. The DNA content in the sub-G1 region increased from 3.35 % to 22.2 % and from 6.13 % to 42.25 %, when Jurkat-T cells treated with cinobufacini for 24 or 48 hours, respectively. Cinobufacini treatment resulted in significantly higher levels of intracellular ROS. Cinobufacini also induced significant DNA damage determined by comet assay and cytokinesis-block micronucleus assay. In conclusion, these findings suggest that an extract from *Bufo bufo* gargarizans Cantor may be effective for treatment of leukemia.

**PS 1795 Potentially Toxic Minerals Used in South African Traditional Medicine.**

R. Street and M. P. Cele. *University of KwaZulu-Natal, Durban, South Africa.* Sponsor: A. Ndfor.

The World Health Organization recognizes the incorporation of plant, animal and/or mineral based products in traditional medicines. Millions of South Africans rely on traditional medicines for their primary health care needs. Heavy metal toxicity related to the use of traditional medicine has been reported worldwide. Although minerals are widely available at South African traditional medicine markets, there is insufficient pragmatic information regarding them. Thus the aim of this study was to identify the commonly used crude metal and crystalline salts in the South African traditional medicine trade. Premarket surveys indicated commonly available minerals. These minerals were then purchased from a rural traditional medicine market. Information regarding the colloquial name, mode of administration as well as the price and weight were recorded. Scanning electron microscopy-energy dispersive X-ray was used to determine the composition of the unknown medicinally used powdered products. The elemental spectra was viewed using a Leo 1450 SEM. Mineral salts identified included ammonium chloride, calcium sulphate and sulphur powder. If not handled correctly, such salts can cause numerous infirmities including eye irritation and dermal toxicity. Among the available metal salts were potassium dichromate, a Class 1 carcinogen, which is routinely taken both orally and as an enema, and potassium permanganate. Also very concerning was the finding of liquid mercury documented as being ingested for female reproductive complaints. This study is the first to classify and document the commonly available minerals used in South African traditional medicine. Identifying such products has revealed actual and present hazards in the South African traditional medicine trade. Training programmes are underway to alert traditional healers to the risks involved in handling and consuming such potentially harmful substances as well as to provide healthcare workers with algorithms for metal poisonings.

**PS 1796 Safety Assessment of Botanical Extracts in Cosmetics.**

J. Song and Y. Yang. *L'Oreal R&I, Shanghai, China.*

It's a worldwide trend that customers prefer to use personal care products (PCP) containing natural and organic ingredients from botanicals. However natural does not equal safe. In fact, various preparations and complex compositions of plants have great potential to cause adverse effects such as irritation, sensitization and systemic toxicity. The current dilemma is that there is no official guideline to evaluate botanicals in PCP and the chemical assessment cannot be easily adapted to the safety assessment of botanic substances. In line with the guideline issued by Scientific Committee on Consumer Safety in EU, we proposed a strategy to guide the safety evaluation of botanical extracts. The first and foremost is a good characterization of the botanicals which include species, geographic origin, growing and harvesting conditions, manufacturing process, profile of macro and micronutrients, analytical markers, chromatographic fingerprint, known toxins, etc. Other commonly checked points are UV absorptive capability, 26 major allergens, residual solvents, and additives. For botanical ingredients from food or herbal medicines with a safe history of use, the assessment should be carefully made by taking into consideration of all factors such as parts of plants used, genetic modifications, safety files for registration, and exposed population etc. The focus is to assure that botanicals intended to be used as a cosmetic ingredient is similar to its traditional counterpart used as food and / or herbal drugs in terms of composition, specifications, quality, and safety. After identifying the potential hazard, the exposure analysis will cover all relevant toxicological endpoints. Special attention should be paid to the type I allergy and local tolerance i.e., skin/mucous irritation, phototoxicity/photoallergy, and

Type IV sensitization. In risk assessment, besides in vitro, in vivo and clinical tests, the threshold of toxicological concern (TTC) is a popular and robust tool to support safety of the concerned or unknown partition in composition.

**PS 1797 Effects of Crocetin and Safranal, Constituents of Saffron, in 22Rv1 Prostate Cancer Cells.**

F. F. Albaqami and K. L. Willett. *Department of Pharmacology and ETRP, University of Mississippi, University, MS.*

Saffron extracts have induced apoptosis, cell cycle arrest, inhibited cellular proliferation, and tumor progression in various cancer cell lines. We are interested in studying the potential chemopreventative effects of saffron especially as it relates to prostate cancer. Recognized active constituents of saffron are crocetin and safranal. Cytotoxicity of safranal was investigated using the androgen responsive 22Rv1 prostate cancer cell line. The cytotoxicity IC50 of safranal at 24 hr was 141  $\mu$ M using the tetrazolium dye assay (XTT). The assay was incompatible with crocetin. Using the Caspase-Glo® 3/7 assay system, it appears that apoptotic mechanisms were involved in safranal's cytotoxicity because after 6 hr of exposure, the EC50 of apoptosis was similar to the cytotoxicity IC50. Safranal's antioxidant activity as measured by a 2',7'-dichlorodihydrofluorescein diacetate assay indicated decreased reactive oxygen species formation. Ongoing studies are investigating the potential of saffron to also inhibit prostate cell invasion and migration in vitro. (Supported by Saudi Arabian Ministry of Higher Education and Salman bin Abdulaziz University)

**PS 1798 Kahweol Induces Apoptosis Through Inhibition of STAT3 Phosphorylation in Human Lung Adenocarcinoma A549 Cells.**

H. Kim<sup>1</sup>, J. Choi<sup>1</sup>, K. Tilak<sup>1</sup>, Y. Hwang<sup>1,2</sup> and H. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Chungnam National University, Daejeon, Republic of Korea; <sup>2</sup>International University of Korea, Jinju, Republic of Korea.

Epidemiological studies have shown that unfiltered coffee consumption is associated with a low incidence of cancer. Kahweol, the coffee-specific diterpene, has been reported to have anti-carcinogenic properties. Animal data support such a chemopreventive effect of coffee. However, the precise underlying protective mechanisms are poorly understood. In this study, the apoptotic effect of kahweol in human lung adenocarcinoma A549 cells was investigated. In cell viability assays and cell proliferation assays, kahweol exhibited anti-proliferative and pro-apoptotic effects on A549 cells in a time- and dose-dependent manner. Kahweol considerably inhibited the expression of Bcl-2 but increased that of Bax; it also stimulated the cleavage of caspase-3 and poly ADP-ribose polymerase. In addition, kahweol-induced apoptosis was confirmed by TUNEL assays. Furthermore, kahweol inhibited dose-dependent phosphorylation of signal transducer and activator of transcription 3 (STAT3). An overexpression in STAT3 led to resistance to kahweol-induced apoptosis, suggesting that STAT3 was a critical target of kahweol. These findings suggest that kahweol inhibited A549 cell growth and induced apoptosis via down-regulation of STAT3 signaling pathway. These data may contribute to the explanation of the reported antitumoral effects of kahweol, including the recent epidemiological meta-analysis showing that drinking coffee could decrease the risk of certain cancers.

**PS 1799 In Vitro Antioxidant Activities of Fractions of Clerodendrum violaceum Leaf Extract.**

E. A. Balogun, A. Zailani and J. O. Adebayo. *Biochemistry, University of Ilorin, Ilorin, Nigeria.*

Many diseases are mediated by reactive oxygen species. Clerodendrum violaceum is a medicinal plant used indigenously in Nigeria for the treatment of some of such diseases. In this study, the antioxidant activities of the hexane, ethyl acetate and methanolic fractions of Clerodendrum violaceum leaf extract were evaluated in vitro using 2,2-diphenyl-1-picryl-hydrazyl-hydrate (DPPH), superoxide anion and hydrogen peroxide scavenging assays. The antioxidant components of the extract fractions were also determined. The results showed that the methanolic fraction had the highest concentrations of vitamin C, vitamin E, selenium, phenols and flavonoids. Moreover, the methanolic fraction of the extract had the highest free

radical scavenging activities against DPPH, superoxide anion and hydrogen peroxide with EC50 values of 0.08, 0.45 and 0.60 mg/ml respectively. It also had the highest reducing power against ferric ion. The results of the study suggest that the methanolic fraction of Clerodendrum violaceum leaf extract may be a potent source of antioxidant compounds which may be useful for the prevention and treatment of reactive oxygen species-mediated diseases.

**PS 1800 Comparative Pharmacodynamic Effects of Rituximab-EU (MabThera®) and Rituximab-Pfizer in Cynomolgus Monkeys.**

A. M. Ryan<sup>1</sup>, S. Sokolowski<sup>1</sup>, M. Collinge<sup>1</sup>, A. Shen<sup>1</sup>, J. Arrington<sup>2</sup>, T. Cummings<sup>1</sup>, S. Ploch<sup>2</sup>, S. Stephenson<sup>2</sup>, N. Tripathi<sup>2</sup>, S. Hurst<sup>1</sup>, G. Finch<sup>1</sup> and M. Leach<sup>1</sup>. <sup>1</sup>Pfizer WRD, Groton, CT; <sup>2</sup>Covance, Madison, WI.

Background: Rituximab-Pfizer is in Phase 1/2 in RA patients as a potential biosimilar. Analytical and functional characterization has demonstrated in vitro similarity to the licensed rituximab products. Methods: The pharmacodynamic effects of rituximab-Pfizer and rituximab-EU were compared in sexually-mature cynomolgus monkeys in single-dose PK and repeat-dose toxicity studies; both had a 13-week postdose observation period to assess B cell repletion. Peripheral blood lymphocytes were evaluated by flow cytometry, and spleen and axillary and mesenteric lymph nodes (repeat-dose only) were examined microscopically by CD20+ immunohistochemistry. Results: B cell effects were similar in magnitude and time course between rituximab-Pfizer and rituximab-EU. Marked to complete depletion of peripheral blood B cells occurred on Day 4 (the first time point evaluated) in both studies. In the single-dose study, repletion of B cells began on Day 15 (2 mg/kg) and Day 29 (10 and 20 mg/kg) and continued through Day 92, with a subset of animals in each group near or above the pre-dose values at the end of the 13-week observation period. In the repeat-dose study, peripheral B cell depletion persisted through Day 30 of the dosing phase and was associated with lower splenic weights, decreased lymphoid follicle cellularity and decreased CD20+ cells in lymphoid tissues. After repeat-dosing, partial repletion of peripheral blood B cells was noted in recovery animals by Day 92 of the recovery phase. Complete histopathologic recovery occurred in 3 recovery animals (2 rituximab-Pfizer and 1 rituximab-EU). Lymphoid cellularity and CD20+ cells were increased in the remaining 9 recovery animals (relative to the dosing phase results), indicating partial recovery. Conclusion: The magnitude and time course of B cell depletion and repletion were similar between rituximab-Pfizer and rituximab-EU and were consistent with the expected pharmacology of anti-CD20 monoclonal antibodies and the reported innovator data.

**PS 1801 Brain Microhemorrhage Assessment of an Antiamyloid Beta Peptide (A $\beta$ ) Monoclonal Antibody (mAb) Using a Transgenic Mouse Model of Alzheimer's Disease (AD).**

L. A. Buckley<sup>1</sup>, D. Hall<sup>1</sup>, J. Douville<sup>2</sup>, W. H. Jordan<sup>3</sup>, D. Koger<sup>1</sup>, W. H. Anderson<sup>1</sup>, D. G. Waters<sup>1</sup> and R. B. DeMattos<sup>1</sup>. <sup>1</sup>Eli Lilly & Co., Indianapolis, IN; <sup>2</sup>Charles River Laboratories, Montréal, QC, Canada; <sup>3</sup>Vet Path Services, Inc., Mason, OH.

Solanezumab (SLZ), a humanized mAb against A $\beta$  peptide, is being developed for the treatment of AD. SLZ recognizes a mid domain epitope of the A $\beta$  peptide with high affinity and selectivity to soluble monomer. The potential to cause cerebral amyloid angiopathy (CAA)-associated microhemorrhage (MH) was studied in an aged transgenic mouse (APPV717F) model of AD using a murine surrogate of SLZ, m266.2. Critical study design factors included the use of: 1) age-optimized mice (>21 months) known to have established cerebral amyloid prior to treatment and thus potentially susceptible to CAA-MH; 2) sufficient numbers ( $\geq 25$ ) of mice/group; 3) a dose projected to achieve a near-maximal pharmacologic response; 4) a positive control mAb against an N-terminal epitope of A $\beta$  peptide (3D6); 5) meticulous attention to brain collection and processing; 6) expanded brain sectioning and specialized microscopy; and 7) examinations by primary and peer-review pathologists experienced in neuropathologic assessments. Groups of mice received either vehicle control, 50 mg/kg m266.2, or 50 mg/kg 3D6 by weekly ip injection for 4 months (curtailed from the original 6-month duration due to age-related mortality). Plasma exposure to m266.2 and 3D6 was demonstrated at the end of the study. Multiple histologic brain sections stained with Perl's Prussian Blue/DAB-enhanced Perls from each animal were evaluated to score siderophages resulting from hemorrhage, and multiple H&E stained slides were examined with both brightfield and epifluorescent illumination for the presence of other changes in the brain. While the positive control 3D6 elicited the expected robust microhemorrhage response associated with vascular degeneration, the brains of mice given

m266.2 were not different from those of vehicle control mice. In conclusion, m266.2 did not induce CAA-MH or microscopic evidence of any inflammatory or degenerative changes in the brain.

**PS 1802 Safety Assessment of REGN1001 a Monoclonal Antibody Against Angiopoietin-Like 4 (AngPTL4) in Cynomolgus Monkey Toxicology Studies Under Normal and High-Fat Diet Feeding Regimens.**

J. Trejors<sup>1</sup>, R. Soltys<sup>1</sup>, T. Daly<sup>1</sup>, T. O'Neill<sup>2</sup>, K. Mozzachio<sup>2</sup> and A. Arulanandam<sup>1</sup>. <sup>1</sup>Drug Safety, Regeneron Pharmaceuticals, Tarrytown, NY; <sup>2</sup>General Toxicology, WIL Research, Ashland, OH.

REGN1001 is an antibody directed against Angiopoietin-like 4 (AngPTL4) and blocks its ability to inhibit lipoprotein lipase (LPL), an enzyme that hydrolyzes triglycerides (TG) and hence leads to a reduction in plasma TG levels. Evidence for the role of AngPTL4 as a regulator of TG metabolism has been obtained in AngPTL4 gene knockout studies in which profound decreases in TG levels were observed. Several studies have also indicated that AngPTL4 ablation in rodents either via AngPTL4 gene KO or Ab inhibition during high-fat diet (HFD feeding) regimens can lead to the prominent appearance of foamy macrophages and severe inflammatory changes in mesenteric lymph nodes (MLN). To better predict the safety profile of REGN1001 in hyperlipidemic patients (prone to ingest a high fat diet), a toxicology program evaluating REGN1001 intravenous dosing under normal diet and high-fat diet conditions was undertaken in 2 separate 13-week cynomolgus monkey toxicology studies. The first study utilized a normal (high-fiber) feeding regimen; the second study used a HFD regimen that closely resembles a western diet. Consistent with the data described in rodents, only the HFD regimen resulted in foamy macrophages in the MLN in monkeys. After a 15-week treatment free recovery period, during which half the animals were withdrawn from HFD, the incidence/severity of foamy macrophages in MLN was decreased relative to those maintained on the HFD regimen. These studies for the first time demonstrate in primates that AngPTL4 inhibition under HFD fed conditions can result in the presence of foamy macrophages in the MLN. In addition, these toxicology studies demonstrate the importance of incorporating human disease factors in to animal models for safety testing. Given these data, the likelihood of a similar, clinically-relevant toxicity occurring in hyperlipidemic humans receiving REGN1001 or other ANGPTL4 inhibitors cannot be discounted.

**PS 1803 13-Week Toxicity Study of an Anti-Interleukin-6 Antibody (MEDI5117) by Every Other Week Intravenous or Subcutaneous Injection to Cynomolgus Monkeys.**

T. S. Manetz<sup>1</sup>, P. C. Ryan<sup>1</sup>, R. Faggioni<sup>2</sup>, Z. Yao<sup>2</sup>, R. Lee<sup>2</sup>, A. Schneider<sup>2</sup>, I. Vainstein<sup>2</sup>, C. Nhan<sup>2</sup>, K. Mojica<sup>2</sup>, C. Chavez<sup>2</sup>, K. McKeever<sup>1</sup> and R. Dixit<sup>1</sup>. <sup>1</sup>Translational Sciences, MedImmune, LLC, Gaithersburg, MD; <sup>2</sup>Translational Sciences, MedImmune, LLC, Hayward, CA.

MEDI5117 is a human immunoglobulin G1 (IgG1)-YTE (triple mutation) monoclonal antibody that binds to interleukin 6 (IL-6) with sub-pM affinity and neutralizes it by preventing binding to the interleukin 6 receptor (IL-6R). The Fc domain of MEDI5117 contains the YTE mutation that increases MEDI5117 Fc-binding to the neonatal Fc receptor (FcRn) at pH 6.0 and thus increases the antibody half-life. To support the first in human clinical study, the nonclinical safety of MEDI5117 was assessed in a GLP repeat IV or SC administration study in cynomolgus monkeys when given by IV bolus injection (15 or 100 mg/kg) or SC injection (15 or 50 mg/kg) every other week for 13 consecutive weeks (7 total dose administrations). Administration of MEDI5117 by SC injection did not result in adverse findings. Administration of MEDI5117 by IV bolus injection resulted in the unscheduled euthanasia of one 15 mg/kg animal that had apparent and treatable anaphylactic reactions to the two previous MEDI5117 dose administrations. There were no similar findings for the other 15 mg/kg IV animals or for animals administered the higher 100 mg/kg IV dose level, and the data demonstrated decreased observed pharmacodynamic and toxicokinetic profiles from this animal as compared to other 15 mg/kg IV animals, as well as the presence of anti-drug antibodies. Since this was most likely related to the formation of anti-drug antibody that has been recognized by regulatory agencies as not predictive of immunogenicity in humans and there was a lack of any other findings which is consistent with the toxicology profiles reported for other anti-IL-6 antibodies (Martin et al., 2004 and Femta Pharmaceuticals IND Submission Press Release), this adverse event was not factored into the NOEL determination. Therefore, the NOEL from the GLP study was 100 mg/kg for animals dosed IV and 50 mg/kg for animals dosed SC, the highest doses tested.

**PS 1804 Mavrilimumab (CAM-3001): A Novel Anti-GM-CSF Receptor Alpha Monoclonal Antibody for the Treatment of Rheumatoid Arthritis.**

P. C. Ryan<sup>1</sup>, M. Sleeman<sup>2</sup>, M. Rebelatto<sup>1</sup>, B. Wang<sup>3</sup>, H. Lu<sup>3</sup>, X. Chen<sup>3</sup>, C. Wu<sup>3</sup>, L. Roskos<sup>3</sup>, D. Close<sup>2</sup>, H. Towers<sup>2</sup>, K. McKeever<sup>1</sup> and R. Dixit<sup>1</sup>.

<sup>1</sup>Biologics Safety Assessment, MedImmune, Gaithersburg, MD; <sup>2</sup>Research and Development, MedImmune, Cambridge, United Kingdom; <sup>3</sup>Clinical Pharmacology and DMPK, MedImmune, Hayward, CA.

Rheumatoid arthritis is a progressive and disabling autoimmune disease characterized by inflammation of the joints, with subsequent long term structural damage, chronic pain, and limited daily activity. Despite the availability of a variety of effective therapies, a significant portion of patients fail to achieve optimal outcomes including clinical remission and ongoing low disease activity. MedImmune is currently pursuing development of mavrilimumab (CAM-3001), a human monoclonal antibody (mAb) targeting GM-CSF receptor alpha, as a novel treatment for RA. GM-CSF plays a central role in the pathogenesis of rheumatoid arthritis (RA) through the activation, differentiation, and survival of macrophages and neutrophils. The nonclinical safety of mavrilimumab was evaluated in several studies in cynomolgus monkeys as the pharmacologically relevant species. Overall, the nonclinical safety results supported the continued clinical development of mavrilimumab. In clinical studies in RA patients, mavrilimumab has demonstrated good clinical activity with adequate safety to support further clinical development. A Phase 2b study of mavrilimumab in subjects with RA is in progress.

**PS 1805 Preclinical Safety and Pharmacodynamics of an Anti-GM-CSF Monoclonal Antibody in Cynomolgus Macaques.**

D. Blanset, E. Musvasva, A. Avakian, S. van Tongeren, J. Phillips, C. Grimaldi and S. Cannan. Boehringer-Ingelheim, Ridgefield, CT.

Administration of anti-GM-CSF monoclonal antibodies (mAb) have been proposed as potential therapeutics for inflammatory diseases. In addition to its role in immunity and inflammation, GM-CSF is required for proper maintenance of surfactant catabolism by pulmonary alveolar macrophages (PAM). In humans, loss of GM-CSF signalling results in deregulated surfactant turnover and can manifest as pulmonary alveolar proteinosis (PAP). Therefore, specialized assessments were included in a toxicology study to assess the potential for an anti-GM-CSF mAb to affect surfactant catabolism. The mAb was given intravenously at 0.25 or 50 mg/kg once weekly for 4 weeks or subcutaneously at 0.25, 5 or 50 mg/kg for 13 weeks. In addition to standard toxicity endpoints, bronchoalveolar lavage fluid (BALF) was assessed for cell differentials, intracellular lipids and surfactant protein-D (SP-D) levels. Serum SP-D levels were also evaluated. The mAb was well tolerated with no clinical signs of toxicity. There were no adverse effects on clinical or anatomic pathology. Non-adverse effects in the lung included a dose related increase in the percentage of enlarged PAM, increased numbers of lipid containing PAM and increased BALF SP-D levels. These minor changes may be related to changes in surfactant catabolism but were not accompanied by clinical or histopathological findings indicative of PAP. Serum SP-D values were comparable across groups, consistent with absence of PAP as determined by histopathology. In ex vivo assays, GM-CSF induced CD11b, pStat5 and proliferation of TF-1 cells were inhibited in a dose related manner consistent with the expected pharmacology. Exposure at 0.25 mg/kg was significantly decreased by the formation of anti-drug antibodies which correlated with decreased activity in the ex vivo assays. In conclusion, anti-GM-CSF mAb was well tolerated by cynomolgus monkeys and produced expected pharmacological effects that were reversible upon treatment cessation.

**PS 1806 Nonclinical Safety Evaluation of Anti-PD-L1 (MDPL3280A) in Mice and Cynomolgus Monkeys.**

R. Prell, R. Fuji, R. Deng, R. Pai, N. Ma and J. McBride. Genentech, S. San Francisco, CA.

Programmed cell death 1 (PD-1) is a receptor expressed on T cells following activation and binding to its ligand, PD-L1, down-regulates the quality and magnitude of T-cell responses. Many neoplastic cells express PD-L1 and evade destruction by the immune system. MPDL3280A, an effectorless (FcγR-binding deficient) human IgG1 mAb that blocks PD-1/PD-L1 interactions, is in development as a potential therapy for solid tumors. The nonclinical safety program included an in vitro cytokine release assay with human PBMCs, a tissue cross reactivity study, an exploratory 15-day repeat-dose study in C57BL/6 and CD-1 mice, and an 8 week repeat dose toxicity study in monkeys. MPDL3280A did not induce cytokine release from human PBMCs. MPDL3280A-specific staining was detected in the lymph node of monkey tissues and the placenta, lymph node, tonsil, and thymus of

human tissues. In vivo, no adverse drug related changes in immunologic endpoints were observed in either species. Drug-related findings were consistent with the expected pharmacology following PD-1/PD-L1 pathway inhibition. In mice, this included reversible increases in splenic weights in both strains, attributed to an enhanced immune response to a heterologous mAb. Minimal sciatic neuropathy with inflammation was observed in C57BL/6 mice only, a strain expressing the MHC H-2b haplotype that in PD-1-deficient mice, develops spontaneous autoimmune peripheral neuropathy. In monkeys, arteritis/periarthritis in parenchymal and/or tubular organs was observed, which is a recognized spontaneous inflammatory condition in this species, and may reflect an MPDL3280A-related enhancement of a pre-existing condition. A high incidence of anti-therapeutic antibodies (50/56 (89%)), which had no consistent impact on exposure, and minimal SC injection sites reactions were also attributed to MPDL3280A-enhanced immune responses. These findings are consistent with PD-1/PD-L1 inhibition and identify heightened immune responses and the potential to increase autoimmune liabilities in predisposed individuals as possible safety risks in patients.

## PS 1807 Investigation of the Potential Role of Immunogenicity in Abatacept-Related Lymphocytic Inflammation in Adult and Juvenile Rats.

J. Li<sup>1</sup>, J. Mysore<sup>1</sup>, D. A. DeVona<sup>1</sup>, M. Abbott<sup>2</sup>, M. P. Bernard<sup>1</sup>, S. Eble<sup>1</sup>, W. J. Freebern<sup>1</sup> and H. G. Haggerty<sup>1</sup>. <sup>1</sup>Drug Safety Evaluation, Bristol-Myers Squibb, New Brunswick, NJ; <sup>2</sup>Drug Safety Evaluation, Bristol-Myers Squibb, Syracuse, NY.

Abatacept is a fusion protein of a human IgG1 Fc and the extracellular domain of human CTLA-4 that inhibits T-cell activation. Species specific lymphocytic inflammation of the thyroid and pancreatic islets was observed in adult and juvenile rats treated with abatacept subcutaneously (SC) every 3 days for 3 months at pharmacologic doses of 65 and 20 mg/kg/day respectively. Studies in adult and juvenile rats were performed to assess a potential relationship of immunogenicity to lymphocytic inflammation observed in juvenile and adult rats. Abatacept was administered SC at 0 (control) or 0.03 mg/kg (a subpharmacologic dose) to adult rats (20/sex/group) on Days 1 and 29, or to juvenile rats (20/sex/group) on Days 1 (postnatal day 28), 15, 29, and 43. Anti-drug antibodies (ADA) were measured pretest, on Days 29, 43, 57, and 85. Additional criteria for evaluation included survival, toxicokinetics, clinical observations, body weights, food consumption, T cell-dependent antibody response (TDAR), peripheral blood T-regulatory cell phenotyping, selected organ weights, gross and microscopic pathology analyses. Scheduled necropsies were conducted 3 months following study initiation. Abatacept was clinically well tolerated in both adult and juvenile rats with no abatacept-related toxicologic effects. There were no effects on TDAR or the percentage of CD4+CD25+Foxp3+ lymphocytes (a T-regulatory cell population) in abatacept-treated rats consistent with a lack of pharmacologic activity. Robust and persistent ADA responses were detected in all abatacept-treated rats, with no evidence of lymphocytic inflammation of the thyroid or pancreatic islets. Thus, the lymphocytic inflammation previously observed in abatacept-treated adult and juvenile rats at pharmacologic doses was most plausibly due to pharmacologic immunosuppression and not a consequence of immunogenicity.

## PS 1808 Assessment of Biocomparability of NU100 and Betaferon in Cynomolgus Monkeys.

A. M. Brooks<sup>1</sup>, V. Tammara<sup>2</sup>, D. Hobson<sup>3</sup>, E. Shaw<sup>2</sup>, D. Zeng<sup>2</sup>, F. G. Burleson<sup>4</sup> and H. Hu<sup>1</sup>. <sup>1</sup>Toxicology, Covance Laboratories Inc., Madison, WI; <sup>2</sup>Nuron Biotech Inc., Exton, PA; <sup>3</sup>LoneStar PharmTox LLC, Boerne, TX; <sup>4</sup>Burleson Research Technologies, Morrisville, NC.

Betaferon is a marketed recombinant human interferon beta-1b (IFN beta-1b) for treatment of relapsing-remitting multiple sclerosis (RRMS). NU100 is an improved recombinant human IFN beta-1b produced using proprietary manufacturing technology. NU100 is aggregate-free and HSA-free in its formulation. In a GLP monkey study for NU100 safety assessment, male and female cynomolgus monkeys were assigned to 2 groups (4 animals/sex/group), and received once every other day NU100 or Betaferon at a dose level of 0.06 mg/kg/dose for 15 days. Animals were monitored for safety; blood samples were collected to determine serum levels of IFN beta-1b, neopterin (a biomarker for IFN-beta-1b pharmacodynamic profile), and anti drug antibodies (ADA). No NU-100- or Betaferon-related adverse safety signs occurred within these 15 days. IFN-beta-1b levels peaked approximately 3 hours postdose; Cmax and AUCall for NU100 and Betaferon were 23.7 (CV 49.1%) and 14.3 (CV 48.0%) ng/mL and 225 (CV 51.6%) and 157 (CV 40.6%) h\*ng/mL at steady state, respectively, and were not statistically significantly different. Neopterin levels peaked 24 hours postdose on Day 1; Emax and EAUCall for NU100 and Betaferon were 5.4 (CV

41.4%) and 6.29 (CV 31.7%) nMol/L and 65.9 (CV 45.2%) and 75.7 (CV 39.5%) h\*nMol/L, respectively; whereas Neopterin concentrations reached steady state on Day 15; Emax and EAUCall for NU100 and Betaferon were 1.71 (CV 78.1%) and 1.03 (CV 107.2%) nMol/L and 21 (CV 77.3%) and 35.6 (CV 7.9%) h\*nMol/L, respectively, and were not statistically significantly different. This reduced response on Day 15 to treatment was likely due to the production of anti-drug antibody (ADA), with 3 of 8 animals in the Betaferon group and 1 of 8 animals in the NU100 group positive for ADA. In conclusion, NU100 and Betaferon had comparable safety, toxicokinetic, and pharmacodynamic profiles in cynomolgus monkeys.

## PS 1809 Preclinical Development and Safety Assessment of the First Inhaled Nanobody ALX-0171.

S. Jacobs<sup>1</sup>, E. Depla<sup>1</sup>, S. Rossenu<sup>2</sup>, S. Priem<sup>1</sup>, E. Vanheule<sup>1</sup>, A. Schoolmeester<sup>1</sup>, K. Allosery<sup>1</sup>, S. De Boever<sup>1</sup>, L. Detalle<sup>1</sup>, V. H. Chen<sup>3</sup> and J. Baumeister<sup>1</sup>. <sup>1</sup>Ablynx NV, Zwijnaarde, Belgium; <sup>2</sup>MSD BV, Oss, Netherlands; <sup>3</sup>Boehringer Ingelheim, Ridgefield, CT.

Nanobodies are therapeutic proteins based on the smallest functional fragments of naturally occurring heavy chain only antibodies. The trivalent Nanobody ALX-0171 targets the respiratory syncytial virus (RSV) with high specificity and potency. It has the potential to be effective in prevention and treatment of RSV infection, a cause of severe upper and lower airway inflammation in susceptible populations. The medical need is high in young children, with 0.3million patients younger than 5 years hospitalised every year. ALX-0171 is formulated as a nebulizer solution for pulmonary inhalation as clinical route of administration. Using a vibrating mesh nebulizer, a droplet size  $\leq 3.4 \mu\text{m}$  (MMAD) was achieved, while the drug's stability was maintained. The preclinical package consisted of 2-week repeated dose toxicity studies via iv administration or inhalation in adult rats, a respiratory safety pharmacology study in rats via single inhaled dose and a cardiovascular safety pharmacology study in dogs (iv, single ascending dose). No drug- or immunogenicity-related safety findings were observed. A standard BCOP assay demonstrated the non-corrosive nature of the compound. In addition, a cotton rat disease model was performed to assess safety, tolerability and efficacy of ALX-0171 (intratracheal delivered). A dose-dependent reduction of viral transcripts following viral re-challenge in lung tissue of RSV-infected cotton rats was demonstrated as efficacy marker. A significant improvement of infection-related events (body weight stagnation, organ weight, BALF inflammatory cell counts) was demonstrated without signs of immune-induced events upon ALX-0171 administration. Treatment-induced anti-drug antibodies were measured in BALF and plasma and results indicated a mild immunogenicity response. It can be concluded that ALX-0171 was well-tolerated in safety assessments in preclinical species. ALX-0171 successfully completed a phase I clinical trial.

## PS 1810 The Occurrence of Microscopic Vacuoles in Toxicology Studies with Marketed Pegylated Proteins Is Associated with High Doses, High Clinical Multiples, and Accumulation.

L. S. Kaufman<sup>1</sup>, C. Conover<sup>2</sup> and A. Buchbinder<sup>2</sup>. <sup>1</sup>PDS, Mt Arlington, NJ; <sup>2</sup>Enzon Pharmaceuticals, Piscataway, NJ.

To obtain a more complete understanding of the clinical significance of microscopic vacuoles observed in toxicology studies with marketed pegylated proteins, nonclinical programs were reviewed from FOI data (publicly available BLA reviews) for Omontys, Krystexxa, Cimzia, Mircera, Macugen, Somavert, Pegasys, Neulasta, PegIntron, and Adagen. Cumulative toxicology doses for conjugate, PEG, and protein were calculated for each study and compared with cumulative recommended clinical doses over the same interval. None of the studies included PEG control groups. Microscopic pathology evaluations across programs were part of GLP toxicology studies and were performed on formalin/immersion-fixed tissues. There was no indication of whole-body perfusion techniques. Microscopic vacuoles were noted in toxicology studies with Omontys, Krystexxa, Cimzia, Macugen (IV but not intravitreal), Somavert, and Neulasta but not for Mircera, Macugen (intravitreal), Pegasys, PegIntron or PEG12kD. Across programs, their appearance and reversibility were dose-related and associated with large cumulative PEG/conjugate doses, short inter-dose intervals, longer study durations, drug accumulation, and large clinical multiples. At high cumulative doses (up to 14,000-fold the recommended clinical dose based on mg/m<sup>2</sup> and PEG doses of 2720 mg/m<sup>2</sup>), vacuoles were noted in the macrophage phagocyte system and, in some instances, choroid plexus, uterus, ovary, pituitary, and adrenal cortex. Nearly all of the high doses associated with vacuoles exceeded high-dose guidelines per ICH S6 Addendum. In conclusion, the appearance of microscopic vacuoles in toxicology studies with marketed pegylated proteins appears related to high cumulative doses

and associated drug accumulation, which is not present at recommended clinical doses. This review does not address the potential for vacuole formation in pegylated proteins associated with toxicities in excess of those appropriate for marketed products.

**PS 1811 TAS-116, an Orally Highly Potent HSP90 $\alpha/\beta$  Selective Inhibitor, Leads Minimized Ocular Toxicity in Both Albino and Pigmented Rats.**

H. Hitotsumachi<sup>1</sup>, Y. Kodama<sup>2</sup>, S. Ohkubo<sup>2</sup>, K. Yonekura<sup>2</sup>, K. Besshi<sup>1</sup>, F. Morita<sup>1</sup> and T. Hayashi<sup>1</sup>. <sup>1</sup>*Tokushima Research Center, Taiho Pharmaceutical Co., LTD., Tokushima, Japan;* <sup>2</sup>*Tsukuba Research Center, Taiho Pharmaceutical Co., LTD., Tsukuba, Japan.* Sponsor: *M. Takahashi.*

**BACKGROUND:** Heat Shock Protein 90 (HSP90) is a key chaperon which has a critical role for cancer cell growth and survival. Several HSP90 inhibitors have been developed clinically, however, visual symptoms have limited the ability to maximize drug exposure in patients. TAS-116 is an orally available HSP90 $\alpha/\beta$  selective inhibitor showing high antitumor activity in various human tumor xenograft models. To evaluate the effect of TAS-116 to the optic organ, we confirmed the safety profiles of TAS-116 in both albino and pigmented rat.

**RESULTS:** When TAS-116 administered orally for 14 days, no dose-related change was revealed in ophthalmological examination in albino rat. In histopathology, reference HSP90 inhibitors (AUY922 and 17-DMAG) caused degeneration and/or disarrangement of photoreceptor cells and increase in TUNEL positive apoptotic cells in retinal outer nuclear layer (ONL). On the other hand, TAS-116 demonstrated no histological changes or increase in TUNEL positive cells in ONL in albino rat. When all compound administered intravenously in albino rat, AUY922 and 17-DMAG showed greater exposure in retina compared to plasma, whereas TAS-116 showed less distribution in retina than in plasma. In addition, oral administration of TAS-116 demonstrated less retinal distribution and did not accumulate in retina after 2-week repeated dosing. In contrast, TAS-116 indicated a much higher distribution in subcutaneously implanted tumor over retina in rat model. Furthermore, TAS-116 had no melanin affinity because TAS-116 did not induce the retinal toxicity and also showed less distribution in retina in pigmented rat.

**CONCLUSION:** TAS-116 does not induce ocular toxicity in both albino and pigmented rat. This is probably due to less distribution in retinal tissue of TAS-116. These unique profiles of TAS-116 indicate that TAS-116 has a potential to be a best-in class HSP90 inhibitor with minimized ocular toxicity.

**PS 1812 ETEC Vaccines: An 85-Day Intradermal Repeat Dose Toxicity Study of Three Candidates in Guinea Pigs.**

C. S. Godin<sup>1</sup>, M. Maciel<sup>2</sup> and S. Savarino<sup>2</sup>. <sup>1</sup>*AVANZA Laboratories, Gaithersburg, MD;* <sup>2</sup>*Naval Medical Research Center, Silver Spring, MD.*

A vaccine against enterotoxigenic *E. coli* (ETEC) is being developed to protect travelers and young children that are at risk from this disease. The purpose of this study was to evaluate the potential toxicity and immunogenicity of three vaccine candidates, proteins 1, 2 and adjuvant, when administered either alone or in combination to guinea pigs by the intradermal route on Days 1, 22, 43, and 64 at a dose of 100  $\mu$ g. Animals were dosed with saline, proteins 1, 2, and adjuvant alone, a combination of protein 1 and adjuvant, or a combination of protein 2 and adjuvant. Evaluations included mortality, physical examinations, body weights, body temperatures, dermal Draize scores/induration measurements, gross pathology, organ weights, and histopathology. On Day 3, punch biopsies were collected from the first injection site. Punch biopsies of the remaining vaccination sites, from all vaccination sites of the remaining animals, and from a naïve site distant from the sites of vaccination, were collected at necropsy. Administration of protein 1 alone, protein 2 alone, adjuvant alone, protein 1 with adjuvant, and protein 2 with adjuvant in guinea pigs was well tolerated as all animals survived to termination with no adverse clinical signs. There were no test article-related effects upon the following parameters: mortality, physical examinations, body temperature, and body weights. Dermal erythema and induration were more significant when the vaccines were in combination with adjuvant than when administered alone or when adjuvant was administered alone. However, these observations resolved over time. On Days 3 and 63, but not at other intervals, total protein and/or albumin were increased in some treated groups suggesting immune stimulation correlating with inflammation at the injection site. Increased incidence and severity of cellular infiltrate, edema, and hemorrhage in the dermis and subcutis were noted in biopsy sites collected on Days 3 and 66. Following recovery, all findings had either resolved or would be expected to resolve.

**PS 1813 The Inhibin B Response to a Motilin Receptor Agonist in Male Rats.**

M. K. Ziejewski<sup>1</sup>, J. D. Vidal<sup>2</sup>, D. J. Stanislaus<sup>1</sup>, A. R. Apostoli<sup>1</sup>, P. Chowdhury<sup>3</sup> and S. B. Laffan<sup>1</sup>. <sup>1</sup>*Safety Assessment - Reproductive Toxicology, GlaxoSmithKline, King of Prussia, PA;* <sup>2</sup>*Safety Assessment - Pathology, GlaxoSmithKline, King of Prussia, PA;* <sup>3</sup>*Safety Assessment - Toxicology, GlaxoSmithKline, Ware, United Kingdom.*

**Background:** In a repeat oral dose toxicity study, 16/16 male rats given 100 mg/kg/day GSK1322888 sustained testicular injury after 4 weeks of treatment; the findings were not reversible after 12 weeks off-dose. A subsequent study was conducted to further characterize testicular toxicity and to explore the possible relationship between onset of lesions and, changes in circulating hormone levels. **Methods:** Male Sprague-Dawley rats (11 weeks old at study start) were orally administered 30 or 100 mg/kg/day GSK1322888 for 2 weeks with a 4 week off-dose period. Blood was collected via tail vein twice during the treatment period (Day 4 and 11) and three times during the off-dose period (Day 28, 36 and 42) for measurement of serum testosterone (T), dihydrotestosterone (DHT), and inhibin B (InhB), luteinizing hormone (LH), and follicle stimulating hormone (FSH) concentrations. A histopathologic examination of testes was performed at the end of the treatment and off-dose periods. **Results:** At 100 mg/kg/day, microscopic findings of the testis (degeneration of the germinal epithelium) were evident for 9/10 male rats on Day 14 and 10/10 rats at the end of the 4-week recovery period. There was no testicular toxicity observed at 30 mg/kg/day. During all stages of evaluation, there was no apparent difference among control and treated animals in hormone concentrations. **Conclusion:** There was poor correlation between changes in serum levels of InhB and testis histopathology. Based on these observations, the utility of InhB as a hormonal marker for germ cell toxicity is limited.

**PS 1814 Preclinical Safety Evaluation of JNJ-35815208, a Selective Estrogen-Related Receptor Alpha Modulator.**

J. Zhou, F. Selan, L. Hall, R. Mamidi, M. Duvall and C. Loudon. *Drug Safety Sciences, Janssen Research & Development, LLC, Raritan, NJ.*

Estrogen-related receptor- $\alpha$  (ERR $\alpha$ ) is an orphan nuclear receptor that has emerged as a novel therapeutic target for the treatment of type II diabetes and cancer. Here we describe non-clinical safety evaluation in rats and dogs of a novel and selective ligand, JNJ-35815208, for ERR $\alpha$  as a potential anti-diabetic agent. Following single oral administration in rats, mortality was observed at  $\geq$  1000 mg/kg. Repeated dose for 14 days to rats at 8, 40, and 200 mg/kg/day was well tolerated at doses up to 40 mg/kg. At 200 mg/kg/day, microscopic findings were observed in the testes and epididymides, characterized by mild bilateral degeneration/atrophy of the seminiferous tubules, minimal bilateral degeneration of the germ cells, luminal cellular debris, and oligospermia in the epididymides. In the 4-week rat study at 1, 6, or 40 mg/kg/day, there were no toxicological findings. In dogs, following single-dose administration at 50 and 250 mg/kg, as well as during the 5-day repeat dose at 150 and 250 mg/kg/day, the primary finding was emesis noted at all dose levels. In the four-week dog study at 2, 16 and 75.5/100 mg/kg/day, microscopic findings were noted in the female reproductive organs and the mammary glands at all doses. That resulted in reductions in the size of the ovaries, uterus, and vagina as well as atrophy of the mammary glands. These effects were associated with a persistent anestrus of the reproductive cycle. In male dogs, multifocal atrophy of the glandular epithelium of the prostate gland was observed at the mid- and high doses and small testes accompanied by mild degeneration of the germinal epithelium and vacuolated Sertoli cells at the high dose. Erythroid hypocellularity in the bone marrow was noted in males at 16 mg/kg/day and in both sexes at 75.5/100 mg/kg/day, with corresponding decreases in RBC, hemoglobin, hematocrit and reticulocyte counts at the high dose. Overall, these data suggest ERR $\alpha$  may play a role in both male and female reproductive organs as well as in the bone marrow.

**PS 1815 Humanized Mice: A New Animal Model for Risk Assessment of Biologics.**

K. E. Howard<sup>1</sup>, X. H. Li<sup>1</sup>, C. M. Gonzalez<sup>1</sup> and J. A. Ragheb<sup>2</sup>. <sup>1</sup>*CDER/OTR, US FDA, Silver Spring, MD;* <sup>2</sup>*CDER/OBP, US FDA, Bethesda, MD.* Sponsor: *J. Weaver.*

Testing of biological drug products for safety and efficacy in animal models has been difficult to assess because common models such as rodents, canines and non-human primates do not necessarily share common biological receptors with humans. A new animal model, the humanized mouse, has recently emerged in widespread use for infectious disease pathogenesis and vaccine testing research. Humanized mice are made via ablation of the bone marrow followed by surgical

implantation of human liver and thymic tissue underneath the kidney capsule and CD34+ hematopoietic stem cell transplantation. Approximately 12-16 weeks following surgery, the mice have an engrafted functional human immune system, achieve 20-25% humanization in peripheral blood and are suitable for studies. This approach potentially offers the ability to test for efficacy and safety of drug products in an in vivo model of the human immune system. If proven reliable via testing of commercially available biologics, this animal model could be a powerful tool in drug testing.

In order to begin assessing the ability of this model to predict uniquely human immune responses, we tested two forms of interferon- $\beta$  (IFN- $\beta$ ) currently marketed in the USA using clinically relevant dosing regimens and routes. Humanized mice were initially given IFN- $\beta$ -1a subcutaneously (sc) at doses 0.6  $\mu$ g, 1.5  $\mu$ g or 3.0  $\mu$ g once weekly or IFN- $\beta$ -1b sc at doses of 2.5  $\mu$ g, 12.5  $\mu$ g or 25  $\mu$ g three times weekly for four weeks to determine if acute toxicity would result. A follow-up study using doses of 0.3  $\mu$ g of IFN- $\beta$ -1a or 5  $\mu$ g of IFN- $\beta$ -1b for eight weeks assessed serum drug levels, immunogenicity and immune responses. The results of these studies demonstrated that (1) standard drug doses used in IFN- $\beta$  studies in transgenic IFN $\beta$  mice can be toxic to mice with a human immune system, as humanized mice can respond to the drug in a clinically relevant manner; (2) presence of the appropriate human receptors makes drug level assessment possible in humanized mice; and (3) humanized mice respond immunologically to IFN $\beta$ .

### PS 1816 Evaluation of Antisense Oligonucleotides in Human Pbmcs and Association of Release of IL-6 *In Vitro* to Constitutional Symptoms.

H. S. Younis, T. Machemer, D. A. Norris and S. P. Henry. *Preclinical Development, ISIS Pharmaceuticals, Carlsbad, CA.*

Oligonucleotide based therapeutics produce low-grade non-specific proinflammatory responses that manifest as increased cytokine/chemokine production, splenomegaly and/or lymphohistiocyte cell infiltrates in multiple tissues in animal models of toxicity. In humans, antisense oligonucleotides are well tolerated and may produce constitutional effects such as flu-like symptoms and injection site erythema that are typically self-limiting. The objective of this research was to determine if in vitro cytokine production from human peripheral blood mononuclear cells (PBMC) may be used to determine the potential for antisense oligonucleotides (ASO) to produce constitutional symptoms in humans. Fresh PBMC (n=50 donors) were cultured with a selected list of ASOs (ISIS 104838, ISIS 113715, ISIS 325568 and ISIS 353512; 0-80uM) that have been evaluated in humans and produced a broad range of constitutional symptoms (none to moderate). By 24 hr of treatment, the culture supernatant was harvested for measurement of cytokine (IL-6 and IL-10) release. A sigmoidal Emax model was used to determine the Emax and EC50 for the IL-6 response of each ASO. Dose-dependent increases in IL-6 were consistently greater (0.3uM EC50) for ISIS 353512 (the ASO that produced the most pronounced constitutional symptoms in humans) than for the other evaluated ASOs (1.3-3uMEC50 range). The IL-6 Emax/EC50 ratio was 10-fold greater for 353512 than the least responding ASO ISIS 104838, and provided the best term for differentiating ISIS 353512 from the ASOs generating lesser responses. The release of IL-10 was also greater for ISIS 353512 but was more difficult to quantify given the lack of a dose response and relative low magnitude of change. Collectively, the results suggest that human PBMC may be a viable in vitro model to rank order ASOs for their potential to produce constitutional symptoms in humans and to investigate the mechanisms of ASO mediated proinflammation.

### PS 1817 Mechanistic Basis of the Species-Specific Complement Activation in Cynomolgus Monkeys with Oligonucleotide Treatment.

L. Shen<sup>1</sup>, A. Frazer-Abel<sup>2</sup>, P. C. Giclas<sup>2</sup> and S. P. Henry<sup>1</sup>. <sup>1</sup>Isis Pharmaceuticals, Inc., Carlsbad, CA; <sup>2</sup>National Jewish Health, Denver, CO.

Antisense oligonucleotide (ASO)-mediated alternative pathway of complement (APC) activation is a common class effect in macaque monkeys at high doses. Activation is due to the interaction between ASO and complement Factor H (CFH), the inhibitory protein of the APC. Transient reduction of circulating CFH protein is observed after each dosing in monkeys, and is correlated with peak ASO plasma concentration. While common across multiple ASO sequences in macaque monkeys, there is no evidence of APC activation in rodents, dogs, or humans. The mechanistic basis of the sensitivity for macaque monkeys to ASO-induced APC activation was studied using an in vitro model with serum from various species. Dose-dependent increase in C3a was found in cynomolgus monkey serum after incubation with ISIS 104838, replicating the phenomena seen in vivo. No evidence of complement activation was observed in human serum under the same conditions. Serum collected from the new world monkeys, such as marmoset and squirrel monkeys, also showed no ASO-induced APC activation. There is 88% amino acid sequence homology found between cynomolgus and human CFH proteins, and

CFH gene single nucleotide polymorphisms (SNP) in human have been associated with functional change of the protein. Therefore, the relative inhibitory effect of cynomolgus and human CFH proteins in ASO-induced APC activation was evaluated by supplementing the purified CFH proteins in cynomolgus serum followed by ASO challenge. Dose-dependent inhibition in C3a formation was observed with CFH from both species, however, the IC<sub>50</sub> for the human CFH protein was about 3-fold lower than the monkey protein, suggesting stronger fluid phase inhibition to its substrate. Collectively, the results suggest a species and possible strain-specific complement effect with ASO in cynomolgus monkeys that likely due to the difference in regulatory function of the CFH protein and the result of interaction with ASO.

### PS 1818 Perturbation of Autophagy by Basic Lipophilic Compounds: Correlation of LC3 and P62 Abundance Employing U2OS-GFP Cells.

R. L. Yafawi, S. Lu, B. Jessen and A. John-Baptiste. *Drug Safety, Pfizer Global Research and Development, San Diego, CA.*

Many psychotropic compounds possess weakly basic lipophilic properties, with lysosomal trapping being an important mechanism of their distribution. Weakly basic lipophilic compounds accumulate in acidic intracellular organelles (i.e. lysosomes, endosomes, and phagosomes) via pH partitioning which may result in cytotoxicity. Multiple mechanisms regulate autophagy, with the lysosome being the major component of the autophagic pathway. Recognizing the potential toxicity caused by modulation of autophagy is critical, and understanding possible factors attributing to its dysfunction is necessary. We hypothesized that psychotropic agents with lysosomotropic properties have the potential to disrupt autophagy. We examined the link between lysosomal accumulation and autophagic dysfunction in osteosarcoma cells (U2OS), by examining the effects of eleven weakly basic lipophilic compounds known to accumulate in lysosomes. Their effects on autophagy were determined by using specific autophagy markers (Microtubule Associated Protein 1 Light Chain 3 (LC3), Sequestosome 1 (p62), and p70S6K). LC3 and p62 were employed to measure either the induction of autophagy, or the inhibition/perturbation of autophagolysosomal degradation. To gain greater insight regarding the pathway regulating autophagy, p70S6K (phosphorylation) a downstream marker of the Mammalian Target of Rapamycin (mTOR) activity was examined. All compound treatments resulted in at least a 3-fold increase in LC3 immunofluorescence and p62 abundance relative to controls. Treatment with compounds did not inhibit phosphorylation of p70S6K as observed via immunofluorescent staining. The data presented indicates lysosomotropic compounds may contribute to the perturbation of autophagy. However, mTOR activity did not seem to play a part in altering the autophagic process.

### PS 1819 Effects of Tyrosine Kinase 2 Inhibitors on Megakaryocyte Development.

H. Uppal<sup>1</sup>, D. Danilenko<sup>1</sup>, E. Harstad<sup>1</sup>, J. Tarrant<sup>1</sup>, E. Clarke<sup>2</sup>, P. Dhawan<sup>1</sup>, A. Kauss<sup>1</sup>, B. McCray<sup>1</sup>, D. Misner<sup>1</sup> and J. Singh<sup>1</sup>. <sup>1</sup>Safety Assessment, Genentech Inc., San Ramon, CA; <sup>2</sup>ReachBio LLC, Seattle, WA.

Background: Tyrosine Kinase 2 (Tyk 2) is a member of the Janus Activated Kinase (Jak) family. Tyk 2 is associated with signaling of pro-inflammatory cytokines, IL-12 and IL-23. Therefore, inhibition of Tyk 2 may potentially treat inflammatory diseases such as inflammatory bowel disease (IBD), rheumatoid arthritis, and psoriasis. Tyk 2 is also activated during thrombopoietin signal transduction, a pathway necessary for megakaryocyte development and platelet production. Studies were conducted in vitro and in vivo with potent Tyk 2 inhibitors with varying levels of JAK-family and general kinase selectivity to understand potential effects of these Tyk 2 inhibitors on platelet development.

Methods: Tyk 2 inhibitors were evaluated in vitro in human, mouse and cynomolgus monkey megakaryocyte colony forming cell assays. General cytotoxicity was evaluated by measuring cellular ATP levels. Direct effects of Tyk 2 inhibitors on platelet function (aggregation), energetics (oxygen consumption), and viability (ATP levels) were also evaluated in vitro. The effect of Tyk 2 inhibitors on platelet number was evaluated in short term (5-10 day) mouse studies. Tyk 2 and Jak mRNA expression was evaluated in human megakaryocytes by quantitative PCR to understand target expression.

Results: Tyk 2 inhibitors caused a comparable reduction in the number of colony forming cells and the viability of megakaryocytes from human, mouse and non-human primates. There were no direct effects of Tyk 2 inhibitors on the aggregation capacity, oxygen consumption, or ATP levels of human platelets in plasma. Tyk 2 inhibitors caused platelet reduction in mice. Tyk2 and Jak 1, 2, and 3 were comparably expressed in human megakaryocytes.

Summary: The in vitro and in vivo findings demonstrate that platelet reductions caused by multiple Tyk 2 inhibitors (with varying selectivity against other Jak family kinases) are likely due to effects on megakaryocyte development.

**PS 1820 Application of Canine Kidney Tissue Slices to Detect the Toxicity of Prototypical Nephrotoxic Agents.**

K. Kowalkowski, M. Klapczynski, D. J. Cugier, E. A. Blomme, W. R. Buck and M. J. Liguori. *Cellular and Molecular Exploratory Toxicology, AbbVie, Abbott Park, IL.*

Precision-cut renal tissue slices retain the multicellular, structural, and functional features of their original organ and offer a more relevant approach to interrogate toxicity compared to traditional cell-based in vitro systems. Here, we sought to evaluate the utility of this system to detect toxicity induced by prototypical kidney tubular toxicants, including cadmium chloride (CdCl<sub>2</sub>) and cisplatin. Kidneys from male beagle dogs were cut into 300 µm slices, and cultured at 37°C in an O<sub>2</sub> rich atmosphere for 24 to 48 h. Initial experiments optimized the culture conditions to maintain viability to at least 48 h. The slices were immediately treated after isolation with multiple doses of CdCl<sub>2</sub>, cisplatin, or vehicle. Multiple endpoints of toxicity were evaluated including H&E stained sections, intracellular ATP content, LDH release, total RNA integrity, and a novel endpoint for this type of system, kidney injury molecule-1 (Kim-1) mRNA levels via in situ hybridization. There was a significant elevation of LDH leakage at all doses tested for both compounds. The intracellular level of ATP also declined significantly at 100 µM CdCl<sub>2</sub> and 100 µM cisplatin, indicative of substantial cellular damage. Mild to marked degeneration and necrosis of renal tubules was evident beginning at 24 h upon microscopic examination. Kim-1, which has been previously demonstrated as a promising in vivo kidney injury biomarker and is not normally expressed in normal tissue, was clearly overexpressed in CdCl<sub>2</sub> treated slices, but not vehicle treated slices, especially along the tubular epithelium. In severely necrotic slices, Kim-1 was undetectable, likely due to RNA destabilization as later confirmed using integrity assessments. These data demonstrate that a renal slice in vitro model can be used to detect potent nephrotoxicants and that Kim-1 should be further explored as a novel in vitro biomarker to monitor toxicity in renal slice systems.

**PS 1821 Investigation of Protein Kinase C Inhibitor-Induced Steroid Hormonal Perturbation in Rat.**

H. Schadt, M. Schwald, D. Ledieu, U. Junker Walker, F. Spence, S. Chibout, A. Wolf and F. Pognan. *Preclinical Safety, Novartis Pharma AG, Basel, Switzerland.*

Steroid hormones are crucial endogenous mediators synthesized and secreted into the bloodstream by endocrine glands, such as the adrenal cortex and gonads. They mediate a wide variety of physiological functions. Altered steroid hormone status may affect the progression of various types of cancer. For instance, prepubertal ovariectomy in BFU/Mna rats accelerated the growth of spontaneous thymoma, which could be mitigated by intraperitoneal injection of estrogens. In azaserine-treated rats, the rate of spontaneous pancreatic tumors in males is increased, while orchidectomy reduced the incidence of such neoplasms compared to intact animals.

In a 104-week oral carcinogenicity study in rat with a protein kinase C inhibitor, a treatment related increased incidence of pancreatic acinar adenoma in males and thymoma in females were observed at dosages  $\geq$  100 mg/kg/day. Since changes in steroid hormones are considered to potentially affect the development of pancreatic and thymus neoplasia in rodents, a 2-week oral mechanistic follow-up study was conducted in rats to investigate this hypothesis. For this purpose, a mass spectrometry method previously developed in our lab for the quantification of steroid hormones in plasma, was further applied to analyze 17 steroids in adrenal, testicular and ovarian tissues. Aldosterone was increased in plasma and adrenals in treated males with a concomitant and pronounced decrease of androstenedione and testosterone in plasma, adrenals and testes. In female rats, progesterone, together with corticosterone, showed a trend towards increased concentrations in adrenals and ovaries after treatment, whereas ovarian androstenedione and estrogen levels tended to be reduced. This correlated with a circulating luteinizing hormone decrease in both sexes. In conclusion, the reduction in ovarian estrogen levels might be connected to the thymus neoplasias of the previous study. As androgen levels were found to be decreased, a direct connection to the previously reported pancreatic tumors is unlikely.

**PS 1822 Comparison of In Vivo Central Corneal Thickness (CCT) Measurements in Dogs, Rabbits, and Nonhuman Primates Using a Handheld Ultrasound Pachymeter or Specular Microscope.**

M. Vézina<sup>1</sup>, S. Wise<sup>1</sup>, K. Tenneson<sup>1</sup> and M. Bussi res<sup>2</sup>. <sup>1</sup>Charles River, Montr al, QC, Canada; <sup>2</sup>V&O Services, St. Lazare, QC, Canada.
