The cornea is responsible for 2/3 of light refraction in the eye and thus is a critical tissue for clear vision. Alterations in corneal thickness have a direct effect on visual acuity and can be caused by alterations in the function of the corneal endothelium,

aqueous humor composition, drainage or formation rate, or in the glands producing the tear film. There has been an increase in the number of topical ocular therapeutics as this method is deemed one of the simplest clinically. As the formulations are in direct contact with the cornea, it can be an intended or unintended target tissue. In non-clinical topical ocular studies, serial in-vivo measurement of corneal thickness can provide a rapid empirical insight into the health of the cornea during study conduct and whether or not any changes in corneal thickness are reversible. There are several ways to obtain central corneal thickness measurements, two of which are ultrasound pachymetry (UP) that requires contact with the corneal surface and specular microscopy (SM) which is a non-contact procedure. The data presented represent background thickness measurements and precision between the 2 methods. In most cases, animals required sedation in order to reduce eye movements. CCT measurements by UP and SM were: dogs (n=10) 548.5±33 µm and 583.5±27 µm; rabbits (n=12) 378±27 µm and 394±16 µm; NHPs (n=10) 422±21 µm and 440±19 µm. Direct comparison showed a difference of 6% between the 2 methods for dogs, 4% for rabbits and 4% for NHP, with the SM values consistently higher. Precision as determined by 2 separate measurement occasions in dogs was 0.6% for SM and 0.1% for UP. In conclusion, both specular microscopy and ultrasound pachymetry provide reproducible, precise CCT data in dogs, rabbits and non-human primates allowing for repeat measures during the course of a study when corneal changes are of concern. Care should be taken for interpretation if data are acquired using both methods considering the 4-6% lower results using UP.

**PS 1823 In Vivo Evaluation of the Corneal Endothelial Cell Layer Using Specular Microscopy.**

K. Tenneson and M. V zina. *Ocular and Neuroscience, Charles River, Montr al, QC, Canada.*

The corneal endothelium is a monolayer of specialized cells whose primary physiological function is to maintain the health and transparency of the corneal stroma. In preclinical ocular and non-ocular studies, pharmacological and/or toxicological effects of a test compound may produce changes in the structure and function of the corneal endothelium. Additionally, intraocular surgery (including induced disease models) or implanted devices can compromise the endothelium and cause corneal edema. Specular microscopy (SM) enables a rapid, minimally invasive, direct evaluation of the cornea, and can provide supplemental information on corneal endotheliopathies, alone or in combination with direct slit-lamp examination on pre-clinical toxicology studies. SM provides three primary endpoints: number of cells/unit area (density), shape of cells (pleomorphism) and size of cells (polymegathism). When the endothelium is disrupted, there can be an overall shift in the number of cells, proportion of cell shapes (pleomorphism) and sizes (polymegathism). In order to characterize the endothelial layer in species regularly used on ocular toxicology studies, dogs, rabbits and non-human primates (NHP) were subjected to SM. Overall, cell density was similar across species (rabbits: 2769 cells/mm<sup>2</sup>; dogs: 2635 cells/mm<sup>2</sup>; NHPs: 3058 cells/mm<sup>2</sup>). Normal endothelial cells have a hexagonal shape, and account for the majority of cells (rabbits: 75%; dogs: 65%, NHPs: 71%). Average cell sizes were 364 µm<sup>2</sup> for rabbit, 384 µm<sup>2</sup> for dog, and 328 µm<sup>2</sup> for NHP. In conclusion, SM is a sophisticated tool that can complement the standard endpoints performed on specialized ocular preclinical studies and the data presented provides background data in rabbits, dogs and NHPs to facilitate the recognition of compound-related changes.

**PS 1824 Therapeutic Effect of MG132 on Diabetic Cardiomyopathy Is Associated with the Suppression of Proteasome Activities: Roles of Nrf2 and NF- B.**

W. Sun<sup>1</sup>, Y. Fu<sup>2</sup> and L. Cai<sup>1</sup>. <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>Jilin University, Changchun, China.

MG132, a proteasome inhibitor, can up-regulate nuclear factor erythroid 2-related factor 2(Nrf2)-mediated anti-oxidation and down-regulate nuclear factor-(NF)- B-mediated inflammation. The present study was to define whether through above two mechanisms MG132 can provide a therapeutic effect on diabetes-induced cardiomyopathy. To this end, transgenic OVE26 type 1 diabetic mice were used. OVE26 mice develop hyperglycemia at 2 – 3 weeks after birth and exhibit albuminuria and cardiac dysfunction at 3 months of age. Therefore starting at 3 months of age OVE26 diabetic mice were treated intraperitoneally with MG132 at 10 µg/kg body-weight daily for 3 months. At 3 and 6 months of age, cardiac function was measured with M-mode echocardiography. At 6 months, cardiac tissues were subjected to pathological and biochemical examination. OVE26 diabetic mice, but not MG132-treated OVE26 diabetic mice, showed significant cardiac dysfunction, including increased left ventricular systolic diameter and wall thickness and a decreased left ventricular ejection fraction with an increase of heart weight/tibia length ratio. Hearts of OVE26 diabetic mice exhibited structural derangement and remodeling (fibrosis and hypertrophy). In OVE26 diabetic mice,

there was also increased cardiac oxidative damage and inflammation. All of these pathogenic changes were reversed by MG132 treatment, which is associated with a significant suppression of diabetic increase in proteasome activity. In addition, MG132 treatment also significantly up-regulated Nrf2 expression and transcription (shown by increased expression of Nrf2 down-stream antioxidant genes) and down-regulated Ik-B expression and NF- $\kappa$ B nuclear accumulation. These results suggest that MG132 provided a therapeutic effect on diabetic cardiomyopathy in OVE26 diabetic mice possibly via the up-regulation of Nrf2-dependent anti-oxidation and the down-regulation of NF- $\kappa$ B-mediated inflammation.

**PS 1825 MG132 Prevents the Progression of Diabetes-Induced Pathological Damage to Aorta Is Associated with Its Up-Regulation of Nrf2 and Its Down-Stream Antioxidant Proteins.**

X. Miao<sup>1,2</sup>, G. Su<sup>2</sup> and L. Cai<sup>1</sup>. <sup>1</sup>University of Louisville, Louisville, KY; <sup>2</sup>Jilin University, Changchun, China.

Endothelial damage and dysfunction are manifested in diabetic cardiovascular complications. Nuclear factor-erythroid 2-related factor 2 (Nrf2) is one of the most important cellular defense mechanisms against oxidative stress by up-regulation of several antioxidants, phase II detoxifying enzymes, and other proteins that detoxify xenobiotics and neutralize reactive oxygen and/or nitrogen species. Deletion of Nrf2 gene significantly enhances the susceptibility of cardiomyocytes to high-level glucose-induced reactive oxygen species generation and cell death. The present study was to define whether induced Nrf2 by MG132 can provide a therapeutic effect on diabetes-induced aortic pathogenic changes. To this end, transgenic OVE26 type 1 diabetic mice and age-matched control mice were used. OVE26 mice develop hyperglycemia at 2–3 weeks after birth and exhibit renal and cardiac dysfunction at 3 months of age, suggesting the induction of diabetic complications. Therefore starting at 3 months of age, OVE26 diabetic mice were intraperitoneally treated with MG132 at 10  $\mu$ g/kg body weight daily for 3 months. At the end of MG132 treatment, aortas from these mice were morphologically and immunohistochemically examined. Significant increases in the wall thickness and structural derangement of aorta were found in OVE26 diabetic mice, which was accompanied by significant increases in aortic oxidative and/or nitrosative damage (4-HNE as lipid peroxidation and 3-NT as protein nitration), inflammation (TNF- $\alpha$  and PAI-1), and remodeling (CTGF and TGF- $\beta$ 1). These pathological changes were not observed in MG132-treated OVE26 diabetic mice, which was also associated with a significant increase of aortic Nrf2 expression and transcription function. These results suggest the therapeutic effect of MG132 on diabetes-induced aortic pathogenic damages and its association with Nrf2 expression and function.

**PS 1826 Characterization of miR-208a Responses in Isoproterenol-Induced Cardiac Injury in Sod2<sup>-/-</sup> and C57BL/6J Mice.**

L. Liu. Pfizer, San Diego, CA.

The present investigation aimed to characterize miR-208a as a putative biomarker for early cardiac injury in isoproterenol (ISO)-induced acute myocardial damage in mice and to investigate potential strain-dependent effects in response to ISO administration. Plasma from age-matched male C57BL/6J and Sod2<sup>-/-</sup> mice treated with a single intraperitoneal (IP) administration of ISO was collected for measuring cardiac troponin I (cTnI) and miR-208a at 3, 6, and 24 hours post injection. Administration of ISO led to increases in both cTnI and miR-208a at all time points tested. However, the magnitude of increase and the temporal release profiles of these biomarkers were different between the two strains. In C57BL/6J mice, cTnI and miR-208a tracked with each other in both magnitude and time, the highest values were seen at 3 hours. By contrast, in Sod2<sup>-/-</sup> mice, the magnitude of miR-208a was much greater than that of cTnI with the highest values of both biomarkers observed at 6 hours. Similar to C57BL/6J mice, the temporal profile of miR-208a followed that of cTnI in Sod2<sup>-/-</sup> mice. Histopathologic examination of hearts treated with ISO revealed myocardial degeneration at  $\geq$  3 hours in C57BL/6J mice and  $\geq$  6 hours in Sod2<sup>-/-</sup> mice which correlated with the highest concentration of the biomarkers in each strain. The higher systemic exposure of ISO in C57BL/6J mice compared to that in Sod2<sup>-/-</sup> mice may have contributed to the observed earlier response in C57BL/6J mice compared to Sod2<sup>-/-</sup> mice.

**PS 1827 Polybrominated Diphenyl Ethers Exposure and Intrauterine Growth Restriction: A Case-Control Study in Chinese Newborns.**

Y. Zhang<sup>1</sup>, Y. Zhao<sup>1</sup>, H. Ao<sup>1</sup> and X. Meng<sup>2</sup>. <sup>1</sup>Fudan University, Shanghai, China; <sup>2</sup>Tongji University, Shanghai, China. Sponsor: Z. Liu.

**BACKGROUND:** Intrauterine growth restriction (IUGR) is associated with perinatal morbidity and mortality. It has multifactorial etiology. Along with malnutrition and psychosocial, environmental pollutants, including polybrominated diphenyl ethers (PBDEs), have also been considered to be involved in the etiology of this disease.

**OBJECTIVES:** This case-control study was performed to assess maternal-fetal exposure to PBDEs and investigate whether in utero PBDEs exposure is associated with IUGR.

**METHODS:** A total of 29 newborn-mother pairs residing in Wenzhou were enrolled in this study during December 2010 and February 2011. Maternal blood and umbilical cord blood (UCB) samples were collected and analyzed for PBDEs by the method of Gas chromatography-mass spectrometry (GC-MS). Conditional logistic regression and Spearman correlation were used to analyze the association between PBDEs exposure and IUGR.

**RESULTS:** All PBDE congeners in serum were detected except for BDE 138, 183, and 190. BDE 209 was the most abundant congener followed by BDE 207, 208, and 66, with the detection frequencies of 50%, 83%, 74%, and 74%, respectively. The concentrations of BDE 66, BDE 209, BDE 183-209 and 19 PBDEs in UCB are significantly higher in newborns with IUGR than those in controls. BDE 183-209 and 19 PBDEs levels in UCB were inversely associated with birth weight and Quetelet's index ( $p=0.008$ ,  $0.020$  respectively). After controlling for potential confounders, dose-response relationships were observed between IUGR and BDE 183-209 and 19 PBDEs levels in UCB.

**CONCLUSION:** Only one UCB sample from the control group did not detect PBDEs which might indicated that newborns in China were ubiquitously exposed to PBDEs. Significantly higher PBDEs levels were detected in IUGR cases compared with those in controls. In utero PBDEs (especially high-brominated BDE congeners) exposures were associated with IUGR in a dose-dependent manner. Prenatal PBDEs exposure may be a risk factor for IUGR.

**PS 1828 Maternal and Child Polybrominated Diphenyl Ether (PBDE) Levels in US National Children's Study (NCS) Formative Research.**

A. J. Schecter<sup>1</sup>, D. Cherry<sup>2</sup>, L. S. Hyman<sup>3</sup>, D. Cheng<sup>1</sup>, N. Imran<sup>1</sup>, M. Hommel<sup>1</sup>, K. Kannan<sup>4</sup>, L. Wang<sup>4</sup>, S. H. Yun<sup>4</sup>, N. Thiex<sup>5</sup>, B. Spector<sup>5</sup>, J. Moye<sup>6,7,8</sup> and L. S. Birnbaum<sup>9,8,10</sup>. <sup>1</sup>The University of Texas School of Public Health, Dallas, TX; <sup>2</sup>The University of Texas, Tyler, TX; <sup>3</sup>The University of Texas Southwestern Medical Center, Dallas, TX; <sup>4</sup>New York Health Department, Albany, NY; <sup>5</sup>South Dakota State University, Brookings, SD; <sup>6</sup>NCS, Bethesda, MD; <sup>7</sup>NICHD, Bethesda, MD; <sup>8</sup>NIH, Bethesda, MD; <sup>9</sup>NIEHS, Research Triangle Park, NC; <sup>10</sup>NCI, Bethesda, MD.

The NCS is a prospective health study of 100,000 children (birth to 21 years) and their mothers. We report on a nested, formative study involving measurement of lipid soluble persistent PBDE flame retardants. PBDEs have been associated with various health effects. This study involved 20 mother-child pairs; 20 samples each of maternal third trimester blood, maternal blood at birth, cord blood, and breast milk were tested individually for nine PBDE congeners. Total PBDE was the sum of nine PBDE congeners when quantifiable. Some PBDE congeners were detected in maternal blood samples and breast milk samples at all time points. In infant cord blood samples, only BDE 47, BDE 100, BDE 99 and BDE 153 were detected in  $\geq$ 40% of samples. BDE 183 and BDE 209 levels were below detectable levels in all samples. Lipid normalized PBDE levels were higher in maternal birth serum and one month postpartum breast milk than in infant cord blood. Across all congeners, medians for maternal third trimester plasma were highest. Further investigation of PBDE compartmentalization during the prenatal and postpartum periods is warranted to understand fetal and infant exposure. The views expressed in this abstract are those of the authors and do not necessarily reflect the views of the National Institutes of Health or the Department of Health and Human Services. Funded by the Eunice Kennedy Shriver National Institute of Child Health and Human Development, contracts number HHSN 275201100004C and HHSN275200800035C.

**PS 1829 Effect of Body-Weight Loading onto the Articular Cartilage on the Occurrence of Quinolone-Induced Chondrotoxicity in Juvenile Rats.**

K. Goto, M. Imaoka, M. Goto, I. Kikuchi, T. Suzuki, T. Jindo and W. Takasaki. *Medicinal Safety Research Laboratories, DaiichiSankyo Co., Ltd., Tokyo, Japan.*

Quinolone antibacterial agents have been reported to induce chondrotoxicity in juvenile animals, and the mechanism has not yet been clarified. We have reported that gene expression of tumor necrosis factor receptor superfamily, member 12a (Tnfrsf12a, cell death-related gene), prostaglandin-endoperoxide synthase 2 (Ptgs2, inflammatory response-related gene), plasminogen activator, urokinase receptor (Plaur, stress response-related gene), and matrix metalloproteinase 3 (Mmp3, proteolysis-related gene) was involved in the induction of cartilage lesions of the distal femoral articular cartilage in juvenile rats treated orally with ofloxacin (OFLX). In the present study, the effect of body-weight loading onto the articular cartilage on the occurrence of the cartilage lesions was investigated in male juvenile Sprague-Dawley (SD) rats given OFLX orally once at 900 mg/kg. Just after dosing of OFLX, hindlimb unloading was performed for 0 h, 2 h, 4 h, and 8 h by a tail-suspension method. Animals were sacrificed at 8 h post-dose, and then the distal femoral articular cartilage was subjected to a histological examination and an investigation for gene expression of Tnfrsf12a, Ptgs2, Plaur, and Mmp3 by qRT-PCR analysis. As a result, cartilage lesions and up-regulations of these 4 genes that were seen in rats without the tail suspension were not observed in rats with the 8-h tail suspension, and a tendency to decrease in the incidence of the cartilage lesions and the gene expression was noted in a tail-suspension time dependent manner. Our results clearly indicate that body-weight loading onto the cartilage is necessary to induce cartilage lesions and gene expression of Tnfrsf12a, Ptgs2, Plaur, and Mmp3 in juvenile rats treated with OFLX.

**PS 1830 Effects of Maternal Exposure to Phthalates and Bisphenol A on Neonates.**

A. M. Vetrano<sup>1</sup>, F. E. Archer<sup>1</sup>, S. W. Marcella<sup>2</sup>, B. Buckley<sup>3</sup>, D. Wartenberg<sup>1,3</sup>, M. G. Robson<sup>3,4</sup>, L. Wang<sup>5</sup>, D. Q. Rich<sup>5</sup> and B. Weinberger<sup>1</sup>. <sup>1</sup>UMDNJ-Robert Wood Johnson Medicine School, New Brunswick, NJ; <sup>2</sup>UMDNJ-School of Public Health, Piscataway, NJ; <sup>3</sup>Environmental and Occupational Health Sciences Institute - UMDNJ and Rutgers University, Piscataway, NJ; <sup>4</sup>School of Biological and Environmental Sciences - Rutgers University, New Brunswick, NJ; <sup>5</sup>Univ. of Rochester, Rochester, NY.

**RATIONALE:** Phthalate and bisphenol A (BPA) metabolites may have anti-androgenic and pro-inflammatory effects. We hypothesized that maternal exposure to phthalates and BPA in pregnancy is associated with decreased anogenital index in infants and shortened gestation.

**METHODS:** Urinary concentrations of phthalate and BPA metabolites were measured from 72 pregnant women enrolled in a high-risk obstetric clinic, at the last clinic visit prior to delivery, using high-performance liquid chromatography-tandem mass spectrometry. Anogenital index (AGI) was calculated by normalizing anogenital distance to weight. Gestational age was determined by either sonographic dating or date of implantation. Using linear regression models, we estimated the change in gestational age and anogenital index associated with each interquartile range (IQR) increase in phthalate and BPA metabolite concentration.

**RESULTS:** IQR increases in urinary mono(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP) and total BPA concentrations were associated with 4.2 and 1.1 day decreases in gestation, respectively. When stratifying by gender, these alterations were found only in male infants. Levels of monoethyl phthalate (MEP) were associated with lower AGI in males, but this difference (0.2 mm) is not likely to be clinically significant.

**CONCLUSIONS:** MEHHP and total BPA were associated with small reductions in gestation, and MEP with a small reduction in AGI, with effects only in males. Increased sensitivity of males to the effects of phthalates and BPA may be related to the roles of androgen precursors in both genital differentiation and in the initiation of labor.

**PS 1831 Intravenous Dose Range-Finding Toxicity of Allopregnanolone (ALLO) in Neonatal Dogs.**

K. L. Steinmetz<sup>1</sup>, L. Rausch<sup>1</sup>, M. Patrick<sup>1</sup>, J. M. Brune<sup>1</sup>, S. H. Mellon<sup>2</sup> and P. S. Terse<sup>3</sup>. <sup>1</sup>SRI Intl, Menlo Park, CA; <sup>2</sup>Department OB GYN, University of California San Francisco, San Francisco, CA; <sup>3</sup>NCATS, NIH, Bethesda, MD.

Treatment with allopregnanolone (ALLO), a GABA-ergic neurosteroid, may be useful treating Niemann-Pick Type-C (NP-C) disease. NP-C is a rare autosomal recessive neurodegenerative disease caused by genetic mutations, resulting in lysosomal accumulation of unesterified cholesterol and glycolipids. Treatment of neonatal NIH NPC1 mice with a single sc dose of ALLO resulted in increased life span, onset delay of neurological symptoms, survival of cerebellar Purkinje and granule cell neurons, and reduced cholesterol and ganglioside accumulation. Previous toxicity studies with ALLO suggested that the presence of isoflurane anesthesia may have contributed to a relatively low MTD of <3 mpk bolus intravenous (IV) injections to unconscious neonatal Beagle dogs. The current study determined the tolerability of ALLO administered IV with extended infusion or bolus injections in conscious pups. Indwelling IV catheters were placed under isoflurane anesthesia. Animals were allowed to recover from anesthesia for ALLO/vehicle treatment. Pups (1-2 per dose, age: postnatal day (PND) 17-PND59) received vehicle 20% hydroxypropyl  $\beta$ -cyclodextrin (HPBCD) up to 10 hr with no notable clinical signs. After 3 days washout between dose administration, pups received up to 20 mpk (7.5, 15, and 20 mpk) ALLO by IV infusion, which extended up to 4-8 hr. Dose-dependent sedation was observed at all IV infusion dose levels. After determining that ALLO was well tolerated by extended infusion, bolus IV doses were escalated up to 50 mpk in 1-2 pups (age range PND27-59) per dose level. Hematology and clinical chemistry values were within normal ranges. In summary, ALLO can be administered as IV bolus or extended infusion (>8hr) to conscious neonatal dogs. Pups tolerated ALLO in 20%HPBCD vehicle up to the highest doses tested; 20 mpk (PND17) by infusion and 50 mpk (PND59) by bolus. Conscious neonatal pups appear to tolerate higher doses of ALLO as compared with ALLO administered under isoflurane anesthesia suggesting additive and/or synergistic sedative effects.

**PS 1832 Oxidative and Genetic Damage in School Children from a Heavily Polluted City.**

I. Alvarado-Cruz<sup>1</sup>, M. Sánchez-Guerra<sup>1,2</sup>, L. Hernández-Cadena<sup>3</sup>, L. Espinosa-Juárez<sup>1</sup>, N. Pelallo-Martínez<sup>1</sup>, L. Rafael-Vázquez<sup>1</sup>, R. Angulo-Olaiz<sup>1</sup>, M. J. Solís-Heredia<sup>1</sup>, A. De Vizcaya-Ruiz<sup>1</sup>, V. Mugica<sup>4</sup> and B. Quintanilla-Vega<sup>1</sup>. <sup>1</sup>Toxicology Department, CINVESTAV-IPN, Mexico City, Mexico; <sup>2</sup>Public Health School, Harvard University, Boston, MA; <sup>3</sup>INSP, Cuernavaca, Morelos, Mexico; <sup>4</sup>UAM-Azcapotzalco, Mexico City, Mexico.

Ecatepec County is one of the most industrialized, populated and polluted counties in Mexico. Particulate matter (PM<sub>10</sub> and PM<sub>2.5</sub>) concentrations in this area are frequently above the air quality Mexican standards. Other contaminants, such as lead (Pb) are present. PM and Pb are associated with adverse effects, including oxidative and genetic damage. A cross-sectional study was conducted in 185 schoolchildren (7-10 years of both genders) from two regions of Ecatepec; an industrialized area with heavy traffic (Zone 1; n=94) and a zone with moderate vehicular traffic (Zone 2; n= 91). PM was obtained by air sampling, blood lead (PbB) levels were determined by atomic absorption spectroscopy, plasma malondialdehyde (MDA) as oxidative stress indicator by colorimetry and the DNA damage in mononuclear cells by the comet assay; parents answered a structure questionnaire. PM<sub>10</sub> and PM<sub>2.5</sub> levels, as well as the organic and elemental carbon content (CO and CE, respectively) were higher in Zone 1. Children from this zone showed significantly higher PbB (62% showed >5  $\mu$ g/dL) and MDA levels, but similar DNA damage compared to Zone 2 children. We observed positive associations between PM<sub>10</sub> and PM<sub>2.5</sub> and OTM values ( $p<0.05$ ); while a positive association between CO in PM<sub>10</sub> and PM<sub>2.5</sub> and OTM ( $p<0.05$ ) was also found. MDA levels were associated with PM<sub>10</sub>, PM<sub>2.5</sub> and PbB levels, as well as with CO and CE content in both particles ( $p<0.05$ ). Results suggest that children from Ecatepec are exposed to high PM concentrations and that CO and CE content in PM as well as Pb are involved in the genetic and oxidative damages observed in children living in this highly polluted area. Supported by CONACyT-Mexico (Grant #106034).

**PS 1833 Developmental Immunotoxicity Testing for Hazard Identification.**

E. C. Tonk<sup>1,2</sup>, A. Verhoef<sup>1</sup>, E. R. Gremmer<sup>1</sup>, H. van Loveren<sup>1,2</sup> and A. H. Piersma<sup>1,3</sup>. <sup>1</sup>RIVM, Bilthoven, Netherlands; <sup>2</sup>Health Protection, RIVM, Bilthoven, Netherlands; <sup>3</sup>Toxicogenomics, University, Maastricht, Netherlands.

The inclusion of parameters to assess developmental immunotoxicity (DIT) is an important and critical step forward in regulatory toxicity testing of chemicals. We have performed multiple juvenile and generation studies in rats using various study

designs and test compounds (methylmercury, di-octyltin dichloride (DOTC), di(2-ethylhexyl) phthalate, alcohol, nonylphenol) and the results demonstrate the relatively high sensitivity of immune parameters compared to developmental parameters. Specifically, functional immune parameters appeared affected at relatively low doses. An expanded T cell dependent antibody response (TDAR) parameter set and evaluation of LPS-stimulated NO and TNF- $\alpha$  production by adherent splenocytes were identified as sensitive functional immune parameters. For example, in a juvenile exposure study DOTC affected KLH-induced lymphocyte proliferation at BMD 0.29 mg/kg whereas body weight was affected at 57.7 mg/kg. In a generation study design, alcohol affected splenocyte proliferation at BMD 0.49 % whereas developmental delay was noted at 1.2 %. These results support the OECD TG 443 extended one-generation reproductive toxicity study (EOGRS) guideline, including its cohort for DIT assessment. It provides substantial insight in the immunotoxic potential of chemical. Our research thus identified complementary immune parameters as potentially useful additions to the EOGRS guideline which can be easily added to the study protocol. Furthermore, our research demonstrated the relative sensitivity of the juvenile immune system (postnatal day 10-50) and the significance of the juvenile window in DIT testing. The comparisons of various scenarios have provided important lessons about parameter assessment and exposure protocols, which will feed into the definition of a preferred approach to regulatory developmental immunotoxicity testing for chemicals.

### PS 1834 Feasibility of Continuous Intravenous Infusion in Postweaning Juvenile Rats.

L. Allais, J. Briffaux, C. Gerhardy, P. Vignand, S. David and P. Fant. *Ricerca Biosciences SAS, St. Germain sur l'Arbresle, France.*

Juvenile animals are increasingly requested in nonclinical safety studies to contribute to the commercialization of pediatric therapeutics. The main objectives when conducting Pivotal Toxicology studies in juvenile animals are to ensure a complete evaluation of potential adverse effects of the drug at the relevant target pediatric age and additionally to detect any potential delayed toxicity during animal development, regardless of the treatment period duration. The rat is still the most commonly used species in Juvenile Toxicology studies, hence enabling extensive background data starting from birth.

Various administration routes have been investigated in the juvenile rat and are mostly technically feasible from the early days after birth. However, increasing challenging requirements in terms of dosing procedures implies that juvenile study designs need to be adapted taking into account animal welfare recommendations.

We investigated the suitability of a continuous intravenous infusion method for use in a juvenile toxicity study in pups surgically implanted on Post-Natal Day (PND) 21. A polyurethane catheter was implanted into the posterior vena cava via the femoral vein and then tunneled subcutaneously to exit at the nape of the neck. The pups were continuously infused (24 h/day) with sterile physiological saline for 4 weeks and all possible technical challenges with respect to the growth of the animal were investigated. We assessed standard toxicology endpoints (including clinical observations, growth, food intake and clinical pathology) and compared the results with background data from non infused animals at a similar age.

The results of the present evaluation demonstrated that continuous intravenous infusion using adapted equipment is feasible in young pups and did not interfere with the animal growth from PND 21 to the age of 7 weeks.

### PS 1835 Lung Function in Children Chronically Exposed to Arsenic in Drinking Water.

R. Recio-Vega<sup>1</sup>, E. Olivas-Calderon<sup>1</sup>, T. Gonzalez-Cortes<sup>1</sup>, C. Gonzalez-De Alba<sup>1</sup>, G. Ocampo-Gomez<sup>1</sup>, J. A. Gandolfi<sup>2</sup> and R. Lantz<sup>3,4</sup>. <sup>1</sup>Environmental Health, University of Coahuila, Torreon, Mexico; <sup>2</sup>Pharmacology and Toxicology, College of Pharmacy, University of Arizona, Tucson, AZ; <sup>3</sup>Cell Biology and Anatomy, University of Arizona, Tucson, AZ; <sup>4</sup>Southwest Environmental Health Science Center, University of Arizona, Tucson, AZ.

#### Introduction

Arsenic level in drinking water at the Comarca Lagunera in Mexico surpassed (50-120  $\mu\text{g/l}$ ) the permitted levels by the Mexican Official Norms (25 $\mu\text{g/l}$ ) due to the intense over-exploitation of the aquifers.

Arsenic exposure through drinking water has been associated with different cancers. Additionally negative effects over human lung function have been described.

Experimental animal studies have reported pathological changes in pulmonary development as well as bronchial hyperresponsiveness and disturbances in pulmonary tissue repair proteins. Clinical human studies have shown diminishment in spirometric values and higher bronchiectasis and chronic obstructive pulmonary disease frequencies. These findings have been reported in adults but not in children.

#### Objective

To evaluate the relationship between lung function and arsenic levels in children chronically exposed to arsenic.

#### Results

At present, 390 children have been included. The mean age is 9.0 years and 98% have lived in the community all their life. 77.6 % of the children were conceived in their current communities. From the studied population, 6.3% reported chronic cough for more than 2 years and 2.9% for 7-12 years. In addition, 12.1% have been treated for bronchiolitis. The mean urinary arsenic level was 155.4 ppb (range of 14.6-893.8). In all subjects spirometric values of FVC, FEV1 and FEV1/FVC ratio were lower with respect to reference values.

#### Conclusion

A high incidence of lung diseases and a reduction in the lung function were recorded in children chronically exposed to arsenic in drinking water.

### PS 1836 Blood and Urine Cadmium Concentrations and Micronucleus Frequency in Buccal Epithelium from Children in Three Populations in Yucatan, Mexico.

N. Pérez-Herrera<sup>1</sup>, J. Perera-Rios<sup>1</sup>, A. Rodriguez-Uc<sup>1</sup>, J. Gordillo-Mena<sup>1</sup>, J. Uicab-Ventura<sup>1</sup>, J. Alvarado-Mejía<sup>1</sup>, L. González-Navarrete<sup>1</sup>, L. Fargher<sup>2</sup>, R. Moo-Puc<sup>3</sup>, L. Yañez-Estrada<sup>4</sup> and F. Arcega-Cabrera<sup>5</sup>. <sup>1</sup>Faculty of Medicine, Autonomous University of Yucatán, Mérida, Mexico; <sup>2</sup>Human Ecology Department, CINVESTAV, Mérida, Mexico; <sup>3</sup>Research Unit, Mexican Institute of Social Security, Mérida, Mexico; <sup>4</sup>Faculty of Medicine, Autonomous University of San Luis Potosí, San Luis Potosí, Mexico; <sup>5</sup>Faculty of Chemistry, National Autonomous University of Mexico, Mérida, Mexico. Sponsor: B. Quintanilla-Vega.

Buccal epithelium represents the first boundary against inhalation or ingestion of toxicants. Micronucleus (MN) tests of buccal epithelium have been effectively used in epidemiological studies in adult populations exposed to genotoxins; yet, its use in juvenile populations has been limited. A transversal study was conducted in children from the cities: Merida, Progreso and Ticul, in the Yucatan Peninsula to evaluate the MN frequency in exfoliated buccal epithelium and cadmium concentrations in blood and urine from children exposed to different scenarios. Ten children (6 and 8 years of both genders) were selected from each city (n=30). MN frequency was analyzed by microscopy after a Shift staining and Cd concentrations by atomic absorption spectroscopy. MN frequency was similar in the three populations (p=0.7451), Merida 0.33 (0-1.33/1000 cells), Progreso 0.33 (0-1/1000 cells), and Ticul 0.66 (0-2.33/1000 cells). Cadmium levels in urine were higher (p=0.043) in children from Merida (State Capital) compared to the other cities (1.30 vs 1.09 and 0.73  $\mu\text{g/l}$ ). However, urine Cd concentrations did not correlate with MN frequencies (p=0.505). Blood Cd levels were similar in the three populations (p=0.6021), and a significant and positive correlation between MN frequency and blood Cd levels was observed (rs =0.4583, p=0.0484). Our preliminary results emphasize the importance of conducting biomonitoring of metals and early detection of genotoxic effects in children. Supported by CONACYT-México, Grant # FOSEC-Salud 139738.

### PS 1837 Orellanine, a Bipyridyl Mycotoxin, Induces Apoptosis in a Cell Culture Model of Parkinson's Disease.

P. Anantharam<sup>1</sup>, B. Taiwo<sup>1</sup>, J. Luo<sup>2</sup>, V. Anantharam<sup>2</sup>, A. Kanthasamy<sup>2</sup>, A. G. Kanthasamy<sup>2</sup>, E. Whitley<sup>3</sup> and W. K. Rumbleha<sup>1</sup>. <sup>1</sup>VDPAM, Iowa State University, Ames, IA; <sup>2</sup>Biomedical Sciences, Iowa State University, Ames, IA; <sup>3</sup>Pathology, Iowa State University, Ames, IA.

Parkinson's disease (PD) affects over one million people in the U.S. alone and more than 6 million people worldwide. Potential risk factors for PD include aging, genetic alterations, and environmental neurotoxicant exposures. Although incompletely understood, the etiology and pathological mechanism of PD is characterized by a profound degeneration of dopaminergic neurons in the substantia nigra pars compacta. The majority of PD patients do not know the specific trigger of their disease although exposures to environmental factors are believed to contribute to or influence the development and progression of the disease. We have identified a novel environmental bipyridyl mycotoxin similar to Paraquat (PQ) and MPTP. Like PQ and MPTP, orellanine (OR) is a bipyridyl molecule and we hypothesized that OR will induce apoptosis in N27 cells. Here, we investigated the neurotoxic effects of OR (3,3',4,4'-tetrahydroxy-2,2'-bipyridine-1,1'-dioxide) on mesencephalic dopaminergic neuronal cell line (N27 cells), an in vitro model of PD. Using an MTT assay, OR induced a dose-dependent decrease in the viability of N27 cells with an EC50 of 44.9  $\pm$  15.3  $\mu\text{M}$  (six times lower than that of PQ or MPP+), suggesting that OR is more potent than PQ or MPP+ on N27 cells. To explore the

mechanisms of cell death, we investigated the effect of OR on mitochondrial-dependent apoptotic pathway in N27 cells. The results showed that OR (100  $\mu$ M) induces mitochondrial cytochrome C release followed by sequential activation of caspase-9 and caspase-3, and subsequently DNA fragmentation in a dose- and time-dependent fashion, with peak activation occurring 12 h after OR exposure. Co-treatment with caspase-3 specific inhibitor, Z-DEVD-FMK (50 mM) significantly attenuated OR-induced caspase-3 and DNA fragmentation. Together, this study demonstrates that OR induces cytotoxicity in mesencephalic N27 dopamine-producing cells via the caspase-3-dependent apoptotic pathway.

**PS 1838 Trichostatin A (TSA), a Histone Deacetylase Inhibitor, Mediates Dopaminergic Cell Death via an NF- $\kappa$ B Dependent Mechanism.**

V. Lawana, N. Singh, G. Huh, P. Chandramani-Shivalingappa, H. Jin, V. Anantharam, A. G. Kanthasamy and A. Kanthasamy. *Biomedical Science, Iowa State University, Ames, IA.*

Trichostatin A (TSA) is a potent, reversible inhibitor of histone deacetylase (HDACi) that functions through hyperacetylation of core histones. A previous study from our lab has linked histone hyperacetylation to dopaminergic neurodegeneration. TSA has been shown to induce profound dopaminergic neuronal cell death, but the cellular mechanisms underlying HDACi-mediated apoptotic cell death remains unclear. Herein, we show that TSA treatment induced dose dependent apoptotic cell death in the dopaminergic neuronal cell culture model (N27 cells). In order to better define the apoptotic cell death, we investigated the role of caspases including caspase-2, caspase-8, caspase-9, and caspase-3. The caspases (2, 8, 9, and 3) activation coincided with ROS generation and proteasomal dysfunction and was found to occur early and prior to cell death. Additionally, TSA induced apoptotic cell death was preceded by PKC delta activation, upregulation of p44/42 MAP kinase, nuclear translocation of p-65 and hyperacetylation of histone (H3). Conversely, downregulation of I $\kappa$ B $\alpha$  and survivin levels was also observed as revealed by Western blot and immunohistochemical analyses. Notably, pharmacological inhibition of NF- $\kappa$ B and caspases via SN-50 and ZVAD, respectively, conferred resistance against TSA induced apoptotic cell death in dopaminergic neuronal cells. These results suggest that NF- $\kappa$ B mediated and caspase dependent cell death signaling events may be critically linked to TSA induced dopaminergic neuronal degeneration. Further investigation of the mechanistic link between oxidative stress and proteasomal dysfunction in TSA-induced dopaminergic neuronal cell death may enhance our understanding on the influence of histone modifications on the nigrostriatal dopaminergic degeneration (supported by NIH grants ES10586 and NS65167).

**PS 1839 Chemically-Induced Aging of PC12 Cells to Study *In Vitro* Neurodegeneration.**

M. de Groot and R. H. Westerink. *Neurotoxicology Research Group, Institute for Risk Assessment Sciences, Faculty of Veterinary Medicine, University of Utrecht, Utrecht, Netherlands.*

Neurodegenerative diseases, e.g. Parkinson's disease, are multifactorial and the mechanisms underlying these disorders are often unknown. *In vitro* models can increase insight into the cellular and molecular mechanisms by reducing multifactorial diseases to a more controllable set of parameters. A well-known cell model in *in vitro* neurotoxicology is the pheochromocytoma (PC12) cell line. PC12 cells have been used for decades to study the effects of environmental stressors on important processes of neuronal development, function and degeneration, including differentiation and neuritogenesis, the synthesis, storage and release of neurotransmitters and the regulation and function of different ion channels. However, the use of PC12 cells to investigate neurodegeneration *in vitro* is debated as this tumor-derived cell line is rather resistant against environmental insults.

In this study we therefore induced different degrees of aging in PC12 cells by altering their oxidative status to investigate if this would increase the susceptibility to environmental stressors, such as pesticides. The characteristics of these 'aged' PC12 subtypes and their sensitivity to an environmental stressor were investigated using different (functional) assays, i.e. measurements of cell viability, measurements of oxidative stress using the ROS-sensitive dye H<sub>2</sub>-DCFDA, and single cell measurements of [Ca<sup>2+</sup>]<sub>i</sub> using the Ca<sup>2+</sup>-sensitive dye Fura-2.

Our data demonstrate that the different aged PC12 models show a clearly different Ca<sup>2+</sup>-homeostasis as compared to naïve PC12 cells. This altered homeostasis is accompanied by a change in ROS production over time and by an increased sensitivity to an environmental stressor as compared to naïve PC12 cells. As such, these aged PC12 models with increased vulnerability can be used to gain mechanistic insight in *in vitro* neurodegeneration studies.

**PS 1840 Differential Alternate Splicing of L-Type Calcium Channel in Brain Regions: Implication in Parkinson's Disease.**

A. Verma and V. Ravindranath. *Centre for Neuroscience, Indian Institute of Science, Bangalore, India.* Sponsor: B. Moorthy.

Parkinson's disease (PD) is a movement disorder characterized by resting tremors, bradykinesia and rigidity caused by death of dopaminergic neurons in substantia nigra pars compacta (SNpc) of the brain. An intriguing question in the pathogenesis of PD is the selective degeneration of SNpc neurons and their terminals in striatum, while the adjacent dopaminergic neurons in ventral tegmental area (VTA) are affected only in later stages of the disease. Among the several hypotheses that have been put forth to address cell death, mitochondrial dysfunction, oxidative stress and accumulation of misfolded proteins in the cytosol (Lewy body) have been studied extensively. More recently it has been shown that SNpc neurons exhibit L-type calcium channel, Cav1.3, mediated autonomous pace-making, which could potentially result in increased cytosolic calcium resulting in neurotoxicity. While the VTA neurons also exhibit pace-making, it is driven by sodium conductances thereby ensuring that cytosolic calcium levels are not elevated. Thus, Cav1.3 channels could play a role in the selective susceptibility of SNpc neurons in PD. A short splice variant of Cav1.3, Cav1.3-42A has been shown to promote calcium influx into the cell in contrast to the long variant Cav1.3. Thus the presence of greater amounts of Cav1.3-42A relative to Cav1.3 could lead to increased intracellular calcium. We measured the relative levels of Cav1.3 and the short splice variant Cav1.3-42A in brain regions and found that the expression of Cav1.3-42A was 4-fold higher in the ventral midbrain compared to striatum or cortex. Concomitantly, levels of Cav1.3 were significantly less in ventral midbrain. These results indicate that the presence of Cav1.3-42A in significantly higher concentration in ventral midbrain, could contribute not only to amplified pace-making but also result in increased cytosolic calcium levels in neurons thus contributing to the degeneration of these neurons.

**PS 1841 Development of a Cellular Model to Assess Catecholamine Transport and Toxicity.**

K. Stout, A. I. Bernstein and G. W. Miller. *Environmental Health, Emory University, Atlanta, GA.*

Environmental exposure to neurotoxins can lead to catecholaminergic degeneration and subsequent Parkinson's disease (PD) development. Historically, dopamine neurons have been the primary focus of neurotoxicological research in PD though the importance of noradrenergic degeneration is becoming increasingly evident. Our laboratory recently developed a cellular model to assess dopaminergic transport and toxicity. Here we demonstrate the development of a novel noradrenergic cellular model for assessing catecholamine transport and toxicity. Many neurotoxic compounds act as inhibitors of the vesicular monoamine transporter 2 (VMAT2) within monoaminergic neurons. The primary role of VMAT2 is to sequester monoamines into vesicles, protecting them from cytosolic metabolism, and readying them for release upon stimulation. Inhibition of vesicular packaging results in increased metabolism of neurotransmitter. NE metabolites inhibit mitochondrial complex I, thereby reducing ATP synthesis and likely inducing toxicity. To investigate noradrenergic transport and toxicity we are utilizing a monoamine-like fluorescent substrate (Molecular Devices) to investigate VMAT2 function in HEK cells stably transfected with the human norepinephrine transporter (NET) and mCherry-tagged human VMAT2. These cells model physiological NE uptake within NE neurons. NET localizes to the cell membrane and VMAT2 forms intracellular vesicle-like structures. The fluorescent substrate we are utilizing mimics the action of NE in these cells. It is transported into the cell via desipramine-sensitive NET uptake (IC<sub>50</sub> = 113.9 nM). Within the cell, the dye is sequestered into vesicles by VMAT2, evidenced by co-localization of fluorescence between the substrate and mCherry. Tetrabenazine, a VMAT2 inhibitor, inhibits co-localization in a dose-dependent manner (IC<sub>50</sub> = 382.8 nM). Both co-localization and inhibition are detectable by microscopy and analyzed with IDEV (Cellomics). This cellular model allows investigation of both normal and altered transporter function in response to toxicants in a noradrenergic cellular model.

**PS 1842 Alpha-Synuclein Protein Aggregates Activate Microglia and Contribute to Neurotoxicity in the Nigral Dopaminergic System through a Fyn Kinase Dependent Mechanism.**

N. Panicker<sup>1</sup>, K. Kanthasamy<sup>2</sup>, D. Harischandra<sup>1</sup>, H. Saminathan<sup>1</sup>, R. Gordon<sup>1</sup>, V. Anantharam<sup>1</sup>, A. G. Kanthasamy<sup>1</sup> and A. Kanthasamy<sup>1</sup>. <sup>1</sup>Biomedical Sciences, Iowa State University, Ames, IA; <sup>2</sup>Biochemistry & Cell Biology, Rice University, Houston, TX.

Abnormal protein aggregation and chronic neuroinflammation are recognized as key pathophysiological hallmarks of many neurodegenerative diseases including Parkinson's disease (PD). Aggregates of the presynaptic protein  $\alpha$  synuclein are the

major component of Lewy bodies, the histological marker of PD. Aggregated  $\alpha$  synuclein is known to stimulate resident brain microglia, leading to their chronic activation and subsequent production of neurotoxic factors and proinflammatory cytokines. Identification of the molecular signaling events perpetuating  $\alpha$ -synuclein mediated microglial activation could unravel glial neuronal crosstalk mechanisms that lead to persistent gliosis and neurodegeneration in PD. In the present study, we examined the role that Fyn, a major non-receptor tyrosine kinase, plays in aggregated  $\alpha$  synuclein induced microglial activation. Immunocytochemical and Western blot analyses revealed that Fyn was expressed in primary murine microglia as well as in BV2 microglial cells. Stimulation of the cells with  $\alpha$  synuclein aggregates rapidly activated Fyn within 30 minutes of exposure. The time course activation of Fyn also paralleled PKC $\delta$  Y311 phosphorylation. Interestingly, the  $\alpha$ -synuclein induced PKC $\delta$  Y311 phosphorylation was suppressed in primary microglia isolated from Fyn knockout (Fyn  $-/-$ ) mice, implicating Fyn as the kinase that carries out this event. The  $\alpha$ -synuclein induced activation of p44/42 (Erk1/2) and p38 map kinases was diminished in both Fyn, as well as PKC $\delta$  knockout microglia. Notably, the Fyn knockout primary microglia showed attenuated release of cytokines TNF $\alpha$ , IL-10 and IL-12 in response to  $\alpha$  synuclein aggregate stimulation when compared to wild type microglia. Collectively, our results demonstrate a non receptor tyrosine kinase mediated pro-inflammatory signaling pathway that may mediate neuroinflammation in PD (supported by NIH grants ES19276 and NS65167).

### PS 1843 Loss of NF- $\kappa$ B p50 Enhances LPS-Induced Systemic Inflammation and Early Microglial Activation.

T. Taetzsch, S. Levesque, C. McGraw, M. Surace and M. L. Block. *Anatomy & Neurobiology, VCU, Richmond, VA.*

Inflammation associated with chronically activated microglia has been implicated in the progressive degeneration of nigral dopaminergic (DA) neurons in Parkinson's disease (PD), but the mechanisms are not well understood. NF- $\kappa$ B p50 is an important regulator of the pro-inflammatory response with both inhibitory and initiating roles in the production of cytokines. Importantly, reduced NF- $\kappa$ B p50 expression has been observed in the substantia nigra (SN) of patients suffering dementia with lewy bodies, supporting a potential role for NF- $\kappa$ B p50 in PD-like neurodegeneration. To examine the consequences of loss of NF- $\kappa$ B p50 function in microglial activation in vivo, NF- $\kappa$ B p50 $^{+/+}$  and NF- $\kappa$ B p50 $^{-/-}$  mice were injected with 5mg/kg LPS IP and sacrificed after 3 hours. Expression of the pro-inflammatory genes TNF $\alpha$  and IL-1 $\beta$  were significantly higher while iNOS expression was lower and COX2 expression was unchanged in the midbrain of LPS treated NF- $\kappa$ B p50 $^{-/-}$  mice, as compared to NF- $\kappa$ B p50 $^{+/+}$  mice. Analysis of microglia morphology in the SN using unbiased stereology revealed significantly higher numbers of microglia with activated morphology in LPS treated NF- $\kappa$ B p50 $^{-/-}$  mice versus NF- $\kappa$ B p50 $^{+/+}$  mice. In addition, LPS-treated NF- $\kappa$ B p50 $^{-/-}$  mice had significantly elevated serum levels of TNF $\alpha$  when compared to LPS-treated NF- $\kappa$ B p50 $^{+/+}$  mice. In vitro kinetics studies demonstrated that TNF $\alpha$  and iNOS expression is significantly increased at 6 and 12h, but not 3h post-LPS treatment in NF- $\kappa$ B p50 $^{-/-}$  mixed glia cultures, suggesting a possible role of NF- $\kappa$ B p50 in resolution of the glial pro-inflammatory response. These studies underscore that loss of NF- $\kappa$ B p50 function amplifies systemic inflammation, increases neuroinflammation, enhances microglial activation, and may impede glial resolution of the pro-inflammatory response.

### PS 1844 Fungal Volatile Organic Compound(s): Potential Environmental Agent(s) for the Pathogenesis of Parkinson's Disease?

A. A. Inamdar<sup>1</sup>, M. M. Hossain<sup>2</sup>, J. Richardson<sup>2</sup> and J. Bennett<sup>1</sup>. <sup>1</sup>*Plant Bio and Pathology, Rutgers, The State University of New Jersey, New Brunswick, New Jersey;* <sup>2</sup>*EOHSI, Rutgers, The State University of New Jersey, Piscataway, NJ.*

Parkinson's disease (PD) is the most common movement disorder and possesses multifactorial etiology. Recently, environmental contaminants including mold exposure are implicated in PD-like movement disorders in epidemiological studies. Although the exact fungal component responsible to such movement disorder is under speculation, fungal volatile organic compounds (VOCs), a class of fungal secondary metabolites has been reported to be associated with the adverse health effects in the human population. There are few in vitro and human studies demonstrating the biological activity of these fungal VOCs; however, the plausible studies elucidating the mechanism of action of these VOCs are lacking. Our lab has pioneered invertebrate *Drosophila* model to study the neurotoxic effects of common fungal VOCs (Inamdar et al., 2010). We have reported that exposure to chemical standards of 1-octen-3-ol and other fungal VOCs cause loss of dopaminergic neurons and movement deficits in *Drosophila* suggesting that these tested fungal

VOCs has potential to induce Parkinson's disease like symptoms. To determine the mechanism of toxicity of fungal VOCs, we focused on 1-octen-3-ol. Employing the available genetic and molecular tools in our *Drosophila* model, we demonstrate the modulatory effect of 1-octen-3-ol on dopamine regulatory pathway. We show that 1-octen-3-ol inhibits the vesicular monoamine transporter, VMAT thereby causing the induction of oxidation of dopamine and loss of dopaminergic neurons. Furthermore, we show that 1-octen-3-ol alters regulation of JNK and Akt signaling pathways in flies. In conclusion, our data present strong cues in support of Parkinson-mimetic activity of 1-octen-3-ol and provide insights into neurological problems especially movement disorders associated with damp indoor environments.

### PS 1845 Mutations in *pink-1* and *pdr-1* Result in Reduced Dopaminergic Neurodegeneration after Chemical Insult in *Caenorhabditis elegans*.

C. P. Gonzalez, R. K. Bodhicharla and J. N. Meyer. *Nicholas School of the Environment, Duke University, Durham, NC.*

Mitochondrial dysfunction has been linked to neurodegenerative diseases including Parkinson's disease. Neurons are cells with a high energy demand, and as a result are hypothesized to be particularly vulnerable to disturbances to mitochondrial homeostasis. We investigated how knocking out two genes involved in mitochondrial dynamics, *pink-1* and *pdr-1*, affected dopaminergic neuron viability after chemical insult in *Caenorhabditis elegans*. *pink-1* and *pdr-1* are the nematode homologs of the human genes PINK1 and PARK2 which when mutated cause familial Parkinson's disease. We induced neurodegeneration with 6-hydroxydopamine (6-OHDA) and assessed damage 48 hours post-exposure using the BY250 (*dat-1::GFP*) strain in which the four cephalic dopaminergic neurons are visualized with GFP. We used the BY250 strain as wild-type for *pink-1* and *pdr-1*. The strain BY250 was generously provided by Michael Aschner (Vanderbilt University) and the strains *pink-1*; *dat-1::GFP* and *pdr-1*; *dat-1::GFP* were kindly provided by Guy Caldwell (University of Alabama). Each neuron was scored from 0 to 2.5, with zero representing an intact dendrite and 2.5 representing the highest level of neurodegeneration observed, utilizing fluorescent microscopy. Our preliminary results indicate that after exposure to 15 mM 6-OHDA, the wild-type worm had a higher level of neurodegeneration than the *pink-1* knockout ( $p < 0.0001$ ) and the *pdr-1* knockout ( $p = 0.0052$ ). These counterintuitive results might be explained by the fact that loss of *pink-1* promotes mitochondrial fusion, which in turn could protect from 6-OHDA damage through mitochondrial functional complementation. Because 6-OHDA generates reactive oxygen species within the cell, it may cause lipid peroxidation and mitochondrial DNA damage, possibilities that we are currently testing. Future studies will explore the effect of these mutations on mitochondrial homeostasis and neurodegeneration after exposure to 6-OHDA and other toxicants associated with Parkinson's disease including rotenone and paraquat.

### PS 1846 Identification of Novel Genes and Epigenetic Mechanisms in *C. elegans* Models of Idiopathic Parkinson's Disease and Manganism.

R. M. Nass<sup>1</sup>, S. Ghosh<sup>2</sup>, K. Shah<sup>2</sup>, J. Trinidad<sup>3</sup> and N. VanDuyn<sup>1</sup>. <sup>1</sup>*Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN;* <sup>2</sup>*Chemistry, Purdue University, West Lafayette, IN;* <sup>3</sup>*Chemistry, Indiana University, Bloomington, IN.*

Background: Idiopathic Parkinson's disease (PD) and manganism are oxidative stress-related disorders that result in abnormal dopamine (DA) signaling and cell death. Both neurological disorders involve basal ganglia and mitochondrial dysfunction, and suggest overlapping epidemiology, yet the origin of the pathogenesis and the molecular determinants common to both disorders are ill-defined. Recently we have shown that the PD-associated transcription factor SKN-1/Nrf2 is expressed in *C. elegans* DA neurons and inhibits PD-associated DA neurodegeneration. Aims/Objectives: In this study we asked what are the common genes, molecular pathways, and mechanism involved in DA neuron vulnerability to PD-associated toxicants. Methods: We utilized reverse genetics, biochemical assays, immunofluorescence, transgenic *C. elegans*, RT-PCR, Western analysis, behavioral and neuronal morphology analysis to characterize expression, localization and the role that SKN-1, IDN-1, and post-translational modifications play in 6-OHDA-, rotenone-, and manganese (Mn)-induced neuronal death. Results: In this study we demonstrate that IDN-1 mutants render DA neuron up to 15-fold more resistant to the neurotoxins relative to WT. We show that IDN-1 is expressed in DA neurons, and IDN-1 overexpression results in a 2-fold increase DA neuron vulnerability. We also show that DA neuron vulnerability is affected by transcriptional and

post-translational modifications of involving these and other proteins identified using RNAi affects DA neuron vulnerability. Conclusions: This study identifies novel genes and molecular pathways involved in DA neuron vulnerability in PD and manganism, and provides the first *in vivo* evidence that a common epigenetic mechanism likely plays a significant role in both disorders. Support: NIEHS ES014459 and ES003299 to RN, and EPA STAR Graduate Fellowship to NVD.

**PS 1847 Decreased Mitochondrial Biogenesis and Suppression of Mitochondrial Gene Expression Induced by Environmental Toxicants in *Caenorhabditis elegans* Model of Parkinsonism.**

S. Zhou, Z. Wang and J. E. Klaunig. *Indiana University, Bloomington, IN.*

Mitochondrial alterations have been documented in the brains of subjects with Parkinson's disease (PD), a disorder characterized by the selective loss of dopamine (DA) neurons. Recent studies demonstrating that PD-associated proteins are either in the mitochondria or translocated into mitochondria in response to stress. Pesticides and heavy metals have been suggested to be risk factors for PD. While, environmental agents can modulate mitochondrial function, the mechanism of this alteration has not been defined in the context of the development and progression of PD. The complexity of the mammalian neurological system has made it difficult to dissect the molecular components involved in the pathogenesis of PD. In the present study we used *C. elegans* as the model of neuron degeneration and investigated the effect of Mn<sup>2+</sup> and rotenone on mitochondrial biogenesis and gene regulation. Exposure to rotenone (2 or 4  $\mu$ M) resulted in significant loss of dopamine (DA) neuron in *C. elegans*. We then determined if the rotenone-induced neuron degeneration is accompanied by a change in mitochondria biogenesis. Analysis of mitochondrial genomic replication showed a dramatic decrease in mitochondrial DNA (mtDNA) copies in rotenone-treated *C. elegans* compared to control. This decreased mitochondrial biogenesis occurred prior to the development of loss of DA neurons, and was persistent. The inhibition of mtDNA replication was also found in *C. elegans* exposed to neuron toxicant Mn<sup>2+</sup> at the concentration 50 or 100 mM. We further examined the mitochondrial gene expression and found significant lower level of mitochondrial complex IV subunits COI and COII in *C. elegans* exposed to rotenone. These results demonstrated that environmental chemicals cause persistent suppression of mitochondrial biogenesis and mitochondrial gene expression, and suggest a critical role of modifying mitochondrial biogenesis in toxicants-induced neuron degeneration in *C. elegans* model.

**PS 1848 A Genome-Wide RNAi-Based Screen for Enhancers and Suppressors of Manganese Toxicity in *Caenorhabditis elegans*.**

P. Chen<sup>1,2</sup>, T. T. Nguyen<sup>2,3</sup> and M. Aschner<sup>1,2,3</sup>. <sup>1</sup>*Pediatric Toxicology, Vanderbilt University, Nashville, TN;* <sup>2</sup>*Neuroscience, Vanderbilt University, Nashville, TN;* <sup>3</sup>*Pharmacology, Vanderbilt University, Nashville, TN.*

Environmental or occupational exposure to manganese (Mn) causes a neuropathy resembling idiopathic Parkinson's disease (PD). Exposure to excessive Mn levels has been linked to mitochondrial dysfunction, oxidative stress, protein aggregation and disruption of iron homeostasis. However, the mechanisms behind these impairments remain unknown, partially due to limited knowledge about genetic factors associated with Mn toxicity. The complexity of the vertebrate brain and the difficulties associated with vertebrate models of PD has hindered the understanding of molecular mechanisms associated with this disorder. The nematode, *Caenorhabditis elegans* (*C. elegans*) and mammals share a highly conserved genetic code, and offers an innovative and powerful platform to evaluate the genetic factors associated with Mn-induced toxicity. Taking advantage of the RNA interference (RNAi) technique and the available RNAi library, we are able to evaluate the impact of ~ 87% of *C. elegans* genes on Mn toxicity, individually. By feeding the worms with a specific strain of RNAi bacteria, we have successfully knocked down (quantified by qRT-PCR) three selected genes (*smf-2*, *smf-3* and *dpy-7*) in *C. elegans*. In vertebrate, the divalent metal transporter 1 (DMT1) has been shown to regulate Mn transport; its nematode homologs (*smf-1*, 2 and 3) have also been proved to be involved in Mn induced toxicity. We hypothesized that knocking down *smf-1*, 2 or 3 would affect worms' survival after exposure to Mn. Consistent with our hypothesis, knocking down of SMF-1 significantly increases the survival rate of *C. elegans* by 2 fold ( $P < 0.01$ ) and SMF-3 by 1.5 fold ( $P < 0.05$ ) after Mn treatment at the larval (L4) stage; *smf-2* knockdown did not cause to a significant change in Mn-induced survival rate. Taken together, our studies establish that a genome-wide RNAi based screen could be carried out using the survival assay to identify genetic enhancers and suppressors of Mn induced toxicity in *C. elegans*.

**PS 1849 Loss of *Pdr-1/Parkin* Alters Manganese Homeostasis in *C. elegans*.**

S. Chakraborty<sup>1,2</sup> and M. Aschner<sup>2,3</sup>. <sup>1</sup>*Neuroscience Graduate Program, Vanderbilt University, Nashville, TN;* <sup>2</sup>*Center for Molecular Toxicology, Vanderbilt University, Nashville, TN;* <sup>3</sup>*Pediatrics, Vanderbilt University, Nashville, TN.*

Environmental overexposure to the essential trace element manganese (Mn) can result in an irreversible, toxic condition known as manganism. This disorder shares similar neuropathology with Parkinson's disease (PD), exhibiting overt dopaminergic (DAergic) cell loss associated with the presentation of motor and cognitive deficits. However, the mechanisms behind the pathophysiology of both disorders remain unclear. Many PD genes have been identified to explain a subset of cases, including the *parkin/PARK2* gene that encodes for an E3 ubiquitin ligase. Using *Caenorhabditis elegans* (*C. elegans*) as a model that contains the necessary DAergic machinery, we hypothesize that a loss-of-function mutation in *pdr-1*, the worm homolog of *parkin*, would increase vulnerability to Mn toxicity compared to wildtype (WT) worms by altering proper Mn homeostasis. Synchronous L1 worms from WT N2 and *pdr-1(gk448)* mutant strains were acutely exposed to MnCl<sub>2</sub> for 30 minutes, followed by lethality scoring of approximately 40-50 worms 24 hours post-treatment. Here, we show that a loss of *pdr-1* increases Mn-induced lethality compared to WT worms ( $p = 0.0005$ ), as seen with a leftward shift in the dose-response curve. Moreover, *pdr-1* mutants show higher, dose-dependent Mn accumulation compared to WT worms ( $p < 0.001$ ), suggesting overall impaired Mn homeostasis in *pdr-1* mutants. Interestingly, *pdr-1* mutants show altered mRNA expression levels of key *C. elegans* Mn importers, including up-regulation of *smf-1* and *smf-3*, and down-regulation of *smf-2*. However, *pdr-1* mutants do not show any difference in mRNA levels of *ferroportin* (*fpn-1.1* in worms) at baseline, indicating a lack of regulation at the export level. Finally, upon exposure, *pdr-1* mutants show altered total glutathione (GSH) levels compared to WT animals ( $p < 0.05$ ). Such changes indicate a role of *pdr-1* in modulating Mn import through altered transporter expression, implicating a novel role of the PD-associated gene in metal homeostasis and increased oxidative stress.

**PS 1850 Manganese Accumulations in Gill Mitochondria of *Crassostrea virginica*.**

A. Nuhar, B. Boissette, M. A. Carroll and E. J. Catapane. *Biology, Medgar Evers College, Brooklyn, NY.*

Manganese is a neurotoxin causing Manganism in people chronically exposed to elevated levels in their environment. Manganese targets dopamine neurons in basal ganglia. Oxidative stress has been implicated as a factor of manganese toxicity and dopamine dysfunction. Mitochondria play a role as cause and target of oxidative stress damage. The mechanisms of damage is attributed to manganese's capacity to produce toxic levels of free radicals and induce mitochondrial dysfunction. Others report manganese accumulates in mitochondria and represent the primary pool of manganese in cells. Controversy exists to the extent of manganese accumulation in mitochondria. Others report manganese accumulates within nuclei and cytoplasm, but not mitochondria. Our lab is using the oyster, *Crassostrea virginica*, as a test animal to study manganese neurotoxicity. We found manganese disrupts the dopamine system as well as mitochondrial respiration. To study if manganese accumulates within mitochondrial of gill cells of *C. virginica* we used differential centrifugation and atomic absorption spectrometry. Gills were homogenized and centrifuged to isolate nuclear, mitochondrial and post-mitochondrial fractions. Each fraction was analyzed for manganese. To determine if isolated mitochondria accumulate manganese we prepared treated mitochondrial suspensions with up to 300 mM manganese. Results show a dose dependent accumulation of manganese in mitochondria of up to 5000%. Two day treatments of animals with 500 and 1000  $\mu$ M Mn increased manganese ( $\mu$ g/gdw) in gill from a baseline of 5.8 to 41.6 and 133.8, respectively, and centrifugation revealed Manganese accumulations were primarily in nuclear and mitochondrial fractions. The study shows mitochondria accumulate manganese. In vivo treatments reveal accumulations with both the nuclear and mitochondrial fractions.

**PS 1851 Manganese Treatments Decreases Immunofluorescence Emissions of Postsynaptic Dopamine D2 Receptors.**

Y. Chekayev, R. Opoku, M. A. Carroll and E. J. Catapane. *Biology, Medgar Evers College, Brooklyn, NY.*

Manganese a neurotoxin causing Manganism, a Parkinsons-like disease, disrupts dopamine neurotransmission. Gill lateral cell cilia of *Crassostrea virginica* are controlled by serotonergic-dopaminergic innervations. Dopamine causes cilio-inhibition, serotonin cilio-excitation. Our lab showed post-synaptic dopamine receptors in gill cells are D2 type and manganese blocks cilio-inhibitory effects of dopamine

by blocking dopamine post-synaptic receptors. Questions exist in the literature if manganese decreases the number of D2 receptors in brain. To test that we used antibody-antigen histoimmunofluorescence techniques to visualize dopamine D2 receptors in gill and ganglia of *C. virginica*. We used a primary antibody against D2 receptors followed by FITC linked secondary antibody. Animals were treated with 500  $\mu$ M of manganese for 5 days. Gill, cerebral and visceral ganglia were excised and exposed to primary and secondary antibodies. Paraffin embedded sections were viewed with a phase contrast Zeiss epilume fluorescence microscope with a ProgRes C3 Peltier cooled camera. Antibody treated sections showed bright FITC fluorescence in lateral ciliated cells and other areas of gill and ganglia. Sections lacking primary antibody treatment did not display similar fluorescence. We analyzed fluorescence intensity of 120 control and 80 gill lateral cells from animals treated with manganese using ImageJ software. Intensity of manganese treated cells was 70% less than controls. The study identifies dopamine D2 receptors in gill cells and cerebral and visceral ganglia, and shows a negative correlation between fluorescence intensity of dopamine D2 receptors in manganese treated animals and controls. The question if the decrease in intensity is due to decrease in actual number of receptors or if manganese alters protein conformation of D2 receptor and D2-ligand binding sites needs to be further explored.

**PS 1852 Chelating Agents Reverse Neurotoxic Effects of Manganese on Dopaminergic Innervation of Gill of the Bivalve Mollusc *Crassostrea virginica*.**

C. Ojo, K. Rogers, T. Adams, E. J. Catapane and M. A. Carroll. *Biology, Medgar Evers College, Brooklyn, NY.*

Lateral cilia of gill of *Crassostrea virginica* are controlled by a serotonergic-dopaminergic innervation. Dopamine is an inhibitory transmitter at gill causing cilio-inhibition. Manganese is a neurotoxin causing Manganism in people exposed to high levels in the atmosphere. Clinical interventions for Manganism have not been successful. Recently, p-aminosalicylic acid (PAS) was reported to provide effective treatment of severe Manganism in humans. PAS is an anti-inflammatory drug which has been used to treat tuberculosis. It also has chelating properties. Previously, we showed treatments of *C. virginica* with Mn disrupts dopaminergic innervation of gill. Pre- or co-treatments with PAS or calcium disodium EDTA prevented the neurotoxic effects of manganese. We hypothesized chelating agents would be effective in reversing neurotoxic effects of manganese when applied to gills after manganese. We used gills of *C. virginica* to measure lateral cilia beating rates of preparations treated first with manganese followed by treatments with either PAS, calcium disodium EDTA or DMSA (meso-2,3-dimercaptosuccinic acid). Beating of cilia were measured by stroboscopic microscopy. Dose responses of PAS, calcium disodium EDTA and DMSA ( $10^{-11}$  -  $10^{-4}$  M) against beating were conducted after 100  $\mu$ M of manganese was added to gill. All 3 drugs reversed the neurotoxic effects of manganese in a dose-dependent manner. DMSA was the most potent. The study demonstrates these chelators are effective in reversing acute neurotoxicity of manganese. This information should be of interest to those designing therapeutic drug treatments for Manganism.

**PS 1853 Effects of Antioxidants and Anti-Inflammatory Agents on Neurotoxic Effects of Manganese on Dopaminergic Innervation of Gill of the Bivalve Mollusc *Crassostrea virginica*.**

K. LaFleur, M. Rotibi, E. J. Catapane and M. A. Carroll. *Biology, Medgar Evers College, Brooklyn, NY.*

Lateral cilia of the gill of *Crassostrea virginica* are controlled by a serotonergic-dopaminergic innervation. Dopamine acts as an excitatory neurotransmitter within the ganglia, but an inhibitory neurotransmitter at gill, causing cilio-inhibition. The mechanism of action of manganese toxicity is not fully understood, but may be due to oxidative damage. We found several chelators, including p-aminosalicylic acid (PAS) prevented neurotoxic effects of manganese in *C. virginica*. The therapeutic actions of PAS are thought to be due to chelation, but PAS is also anti-inflammatory. We sought to determine if anti-inflammatory agents and/or antioxidants are effective in preventing neurotoxic actions of manganese in gill of *C. virginica*. Indomethacin, an anti-inflammatory agent with antioxidant abilities, and ascorbic acid, an antioxidant with possible anti-inflammatory abilities were tested. We examined acute and short term (3 - 5 days) treatment of indomethacin and ascorbic acid on manganese toxicity on dopaminergic innervation. Beating rates of lateral cilia in gill epithelial cells were measured by stroboscopic microscopy. Acute or short-term treatments of indomethacin or ascorbic acid (25 - 100  $\mu$ M) and had no effect on the cilio-inhibitory effects of dopamine (10-6 - 10-3 M). When acute or short-term manganese treated animals (25 - 100  $\mu$ M) were pretreated with indomethacin or ascorbic acid (25 - 100  $\mu$ M), both drugs effectively prevented the

neurotoxic effects of manganese, with ascorbic acid being more effective than indomethacin. The study demonstrates antioxidants and anti-inflammatory agents can block the neurotoxic actions of manganese and may be possible therapeutic agents in the treatment of Manganism.

**PS 1854 Neurotoxic Effects of Manganese on GABAergic Innervation in the Bivalve Mollusc *Crassostrea virginica*.**

J. Ogunnoiki, K. Jackson, E. J. Catapane and M. A. Carroll. *Biology, Medgar Evers College, Brooklyn, NY.*

High levels of airborne manganese cause Manganism, a neurotoxic, Parkinsons-like disease in humans by interfering with dopaminergic neurotransmission in brain. Recent studies are showing GABAergic neurons also are damaged by manganese. *C. virginica* contains a dopaminergic and serotonergic innervation of its gill. It is a simple system to study manganese toxicity. Previously we showed manganese disrupts dopaminergic innervation. We also showed the cerebral ganglia of *C. virginica* contains GABA and within the cerebral ganglia GABA inhibits serotonergic innervation of gill lateral cell cilia. Here we studied if ganglia and peripheral tissues contain GABA receptors, and if manganese has effects on GABA neurons within cerebral ganglia of *C. virginica*. We used primary antibodies (GABAA Ra1-6 ) and secondary antibodies (IgG-FITC) to detect GABA receptors with paraformaldehyde fixed, paraffin embedded tissues using a Zeiss epilume fluorescence microscope and ProgRes C3 Peltier cooled camera. We found fluorescence due to GABA receptors in cerebral ganglia, visceral ganglia, palps and digestive tract. We also examined effects of manganese treatments on GABAergic inhibition of serotonin neurons in cerebral ganglia. Beating of lateral cilia in gill cells were measured by stroboscopic microscopy. Applying serotonin to cerebral ganglia caused a dose-dependent increase in cilia beating. Applying GABA prior to serotonin prevented the increase. Acute applications of manganese (50 and 500  $\mu$ M) prior to GABA prevented GABA from inhibiting serotonin. The study is showing GABA receptors are present in ganglia and peripheral tissues in *C. virginica*, and acute manganese treatments damage GABA neurons. *C. virginica* preparations are good, simple test preparation to study the GABAergic system and the mechanism underlying the neurotoxic effects of manganese.

**PS 1855 Optimization of Fluorescence Assay of Cellular Manganese Status for High-Throughput Screening.**

K. K. Kumar<sup>1,3</sup>, A. Aboud<sup>1</sup>, D. K. Patel<sup>1</sup>, M. Aschner<sup>2</sup> and A. B. Bowman<sup>1,2</sup>. <sup>1</sup>Department of Neurology, Vanderbilt University, Nashville, TN; <sup>2</sup>Department of Pediatrics, Vanderbilt University, Nashville, TN; <sup>3</sup>Medical Scientist Training Program, Vanderbilt University, Nashville, TN.

The advent of high throughput screening (HTS) technology permits identification of compounds that influence various cellular phenotypes. However, screening for small molecule chemical modifiers of neurotoxicants has been limited by the scalability of existing phenotyping assays. Furthermore, the adaptation of existing cellular assays to HTS format requires substantial modification of experimental parameters and analysis methodology to meet the necessary statistical requirements. Here we describe the successful optimization of the Cellular Fura-2 Manganese Extraction Assay (CFMEA) for HTS. By optimizing cellular density, manganese (Mn) exposure conditions, and extraction parameters, the sensitivity and dynamic range of the fura-2 Mn response was enhanced to permit detection of positive and negative modulators of cellular manganese status. Finally, we quantify and report strategies to control sources of intra- and inter-plate variability by batch level and plate-geometric level analysis. Our goal is to enable HTS with the CFMEA to identify novel modulators of Mn transport. Support: NIH ES016931 and ES010563.

**PS 1856 Manganese Exposure Alters Mitochondrial Biogenesis in Dopaminergic Neuronal Cells.**

M. Ay, A. Kanthasamy, H. Jin, D. Kim, V. Anantharam and A. G. Kanthasamy. *Iowa State University, Ames, IA.*

Excessive manganese (Mn) exposure causes a movement disorder commonly referred to as manganism in humans. Mn mainly accumulates within mitochondria and adversely affects mitochondrial structure and function both in vivo and in vitro. Over the past decades, mitochondrial dependent biochemical processes such

as oxidative stress, Ca<sup>2+</sup> dysregulation and apoptotic signaling have been identified as possible mechanisms of Mn neurotoxicity. However, mitochondrial dynamics and the molecular mechanisms that govern the mitochondrial biogenesis during Mn neurotoxicity are yet to be determined. Since the transcriptional co-activator peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1alpha) is the master regulator of mitochondrial biogenesis, herein, we examined the effect of Mn on PGC-1alpha dependent mitochondrial biogenesis in dopaminergic neuronal cells. The MN9D dopaminergic neuronal cell model was exposed to 100-500  $\mu$ M of manganese, and the mRNA expression levels of several mitochondrial biogenesis markers, including PGC-1alpha, mitochondrial transcription factor A (TFAM), and cytochrome B (CytB), were measured using qRT-PCR analysis. Interestingly, the results revealed a dose-dependent induction of PGC-1alpha, TFAM, and CytB mRNA levels following 24 h of manganese exposure, whereas short-time manganese exposure (3-6 h) did not result in any significant induction of PGC-1alpha mRNA. Since PKD1 serves as a key compensatory anti-apoptotic kinase, we measured PKD1 phosphorylation, and the kinase phosphorylation was significantly decreased at 24 h with 500  $\mu$ M Mn exposure. A decreased level of Bcl-2 (a pro-survival protein) was also observed at 24 h. Importantly, overexpression of PGC-1 alpha protein significantly protected the cells against Mn-induced neurotoxicity. Taken together, our data indicate that Mn exposure induces mitochondrial biogenesis through PGC-1 alpha transcription to counter metal induced neurotoxic stress (NIH grants ES19267, ES10586, and NS074443).

### PS 1857 Manganese Exposure Induces Release of $\alpha$ -Synuclein and Promotes Exosome Mediated Cell to Cell Transmission of Synuclein Aggregates in Neurotoxicity Models.

D. Harischandra, H. Jin, A. Kanthasamy, V. Anantharam and A. G. Kanthasamy. Biomedical Science, Iowa State University, Ames, IA.

Chronic manganese exposure is a well-known occupational and environmental hazard considered to be a potential risk factor for environmentally linked Parkinsonism.  $\alpha$ -Synuclein ( $\alpha$ -syn) is a major presynaptic protein in CNS, and aggregation of  $\alpha$ -syn has been implicated in the pathophysiology of Parkinson's disease. Previously, we showed that  $\alpha$ -syn protects dopaminergic neuronal cells against metal neurotoxicity during early exposure. In the present study, we further characterized the effect of long-term manganese exposure on  $\alpha$ -syn metabolism. A 300  $\mu$ M manganese exposure to human  $\alpha$ -syn stably expressing N27 dopaminergic cells for 24-48 hr induced a time-dependent increase in  $\alpha$ -syn immunoreactive aggregates in the cells. Further analysis of the protein aggregation by inclusion body specific fluorescence probes revealed formation of aggregates in a time-dependent manner. We were also able to detect enhanced accumulation of protein oligomers in manganese treated dopaminergic cells. Studies conducted with MN9D cells stably expressing human  $\alpha$ -syn showed that the  $\alpha$ -syn is secreted out of the cells into extracellular media following manganese exposure, in a time-dependent manner. Further characterization of extracellular media by ultracentrifugation followed by electron microscopic analyses revealed that manganese treatment induces exosome vesicle formation in  $\alpha$ -syn cells. Interestingly, we also observed manganese increased the expression of prion in  $\alpha$ -syn expressing cells as compared to vector control cells. Furthermore, manganese treatment increases GRP 78 and caspase 12 levels, suggesting that manganese induces ER stress in  $\alpha$ -syn expressing cells. Collectively, these results demonstrate that prolonged manganese exposure promotes  $\alpha$ -syn protein aggregation and secretion into extracellular milieu by forming exosomal vesicles, which may contribute to propagation of protein aggregation by a prion-like mechanism in dopaminergic neuronal cells. (NIH grants ES19267, ES10586, and NS65167)

### PS 1858 Trp73 Gene in Dopaminergic Neurons Is Highly Susceptible to Manganese Neurotoxicity.

D. Kim, H. Jin, V. Anantharam, R. Gordon, A. Kanthasamy and A. G. Kanthasamy. Biomedical Science Department, Iowa State University, Ames, IA.

Chronic exposure to elevated levels of manganese has been linked to a Parkinson's disease like movement disorder, resulting from dysfunction of the extrapyramidal motor system within the basal ganglia. However, the exact cellular and molecular mechanisms of manganese-induced neurotoxicity remain elusive. Since oxidative stress and apoptosis are considered to be prime mechanisms of manganese neurotoxicity, we sought to identify genes that are susceptible to manganese-induced neurotoxic insult using the Qiagen mouse apoptosis RT<sup>2</sup> Profiler<sup>TM</sup> PCR array system. C57 black mice were treated with 10 mg/kg manganese via oral gavage for 30 days. The nigral tissue was collected and RT-PCR based gene expression was performed for 84 genes associated with apoptotic signaling. Interestingly, we found significant

down-regulation of a tumor repressor gene, namely Trp73, in manganese treated nigral tissue, as compared to control. To further determine the molecular mechanism of manganese-induced Trp73 down-regulation, we treated N27 dopaminergic cells with 300  $\mu$ M manganese and examined the gene expression. Consistent with our animal study, we found reduced expression of Trp73 at mRNA levels in N27 dopaminergic cells. We further determined the Trp73 protein levels during manganese treatment. Trp73 protein level was also reduced in manganese treated N27 cells as well as in manganese treated nigral lysate. Furthermore, manganese treatment in primary striatal culture down-regulated Trp73 protein level in a dose dependent manner. After confirming Trp73 down-regulation during manganese toxicity in three different models, we have begun additional mechanistic studies in cell culture models of manganese neurotoxicity. Taken together, our results demonstrate Trp73 is a gene susceptible to manganese neurotoxicity, and further characterization of the role of Trp73 in cell survival/cell death will improve our understanding of the molecular underpinnings of manganese neurotoxicity (supported by NIH grants ES10586 and ES19267).

### PS 1859 Mechanism of Manganese-Induced Inhibition of Glutamate Transporter GLAST Function.

A. North<sup>1</sup>, A. Webb<sup>1</sup>, D. Son<sup>1</sup>, M. Aschner<sup>2</sup> and E. Lee<sup>1</sup>. <sup>1</sup>Physiology, Meharry Medical College, Nashville, TN; <sup>2</sup>Pediatrics, Vanderbilt University Medical Center, Nashville, TN.

Manganese (Mn) is an essential trace element required for normal growth, development and homeostasis; however, chronic overexposure to elevated levels of Mn induces a Parkinson's disease-like symptoms referred to as manganism. It has been reported that manganism is associated with excitotoxicity, resulting from the dysfunction of the astrocytic glutamate transporters (GLAST and GLT-1), which take up ~80% of synaptic glutamate. However, the mechanism by which Mn disrupts glutamate transporter function has yet to be elucidated. Our previous studies have shown that Mn suppressed transcriptional activity of astrocytic GLAST by decreasing its mRNA and protein levels. Accordingly, herein, we seek to understand the molecular mechanism of Mn-induced GLAST suppression at transcriptional levels, testing whether Mn induces a modulatory effect on astrocytic GLAST promoter activity. The experiments were conducted by assessing EAAT1 (human form of GLAST) luciferase activity in astrocytes transiently transfected with EAAT1 vectors. We hypothesized that Ying-Yang 1 (YY1) and NF- $\kappa$ B pathways play a critical role in repressing the GLAST gene expression, and that Mn modulates the activities of these transcriptional factors. The results revealed that Mn activates the YY1 promoter (p<0.05), and overexpression of YY1 decreases EAAT1 promoter activity. We have also found that CBP (CREB binding protein) acts as a co-regulator of YY1 on the EAAT1 promoter. NF- $\kappa$ B also regulates EAAT1 promoter activity. Overexpression of NF- $\kappa$ B p65 increases the EAAT1 promoter activity (10 folds, p<0.001), whereas mutation on NF- $\kappa$ B binding sites at -533 or -163 of EAAT1 promoter represses EAAT1 promoter activity (p<0.001) and reduces p65 effects on EAAT1 promoter activity (3 folds, p<0.001). Mn activates NF- $\kappa$ B reporter activity and produces TNF- $\alpha$  which decreases EAAT1 activity via NF- $\kappa$ B activation. Taken together, our results indicate that the YY1 and NF- $\kappa$ B pathways play critical roles in Mn-induced repression of EAAT1 promoter activity.

### PS 1860 Analysis of Brain Mn Distribution Influenced by Disease Stage in Mouse Models of Huntington's Disease.

T. V. Bichell<sup>1,2</sup>, M. Wegrzynowicz<sup>1,2</sup>, M. S. Cardone<sup>1</sup>, M. Uhouse<sup>1</sup>, M. Aschner<sup>1,2,3</sup> and A. B. Bowman<sup>1,2,3</sup>. <sup>1</sup>Department of Neurology, Vanderbilt University, Nashville, TN; <sup>2</sup>Center for Molecular Toxicology, Vanderbilt University, Nashville, TN; <sup>3</sup>Department of Pediatrics, Vanderbilt University, Nashville, TN.

Huntington's disease (HD) is a genetic neurodegenerative disorder primarily affecting the striatum. There is considerable variability in age of onset in HD strongly influenced by environmental factors. We have previously reported a disease-toxicant interaction between HD and manganese (Mn) exposure, wherein the pathogenic HD mutation is associated with a striatal specific defect in net Mn uptake. For example, there is decreased Mn accumulation in the striatum of FVB-YAC128 mice at 13 weeks of age after 7 day subcutaneous Mn exposure with 3 total injections at 50mg Mn chloride tetrahydrate/kg. To determine if increased exposure duration influenced this phenotype we measured striatal Mn after a 9 day exposure with a total of 5 injections. At this age (13 weeks), prior to the onset of neurodegenerative phenotypes, the higher exposure strengthened the difference in striatal Mn accumulation between wildtype and mutant mice. To determine if this Mn phenotype was progressive over the course of disease, we examined striatal Mn levels at 12 months of age. Unexpectedly, no difference in striatal Mn accumulation between wildtype

and HD mice was observed using the 7 day paradigm. This alteration in Mn accumulation may be related to disease processes, or to changes due to normal aging, or it may be that the Mn transport defect diminishes with disease progression. To examine this in more detail we will measure and image regional brain Mn accumulation using Inductively Coupled Plasma Mass Spectroscopy (ICPMS), laser ablation ICPMS and other novel methods in HD mouse models. In addition, we will examine primary cultured glia and neurons for cell-type differences in the HD-Mn phenotype. Our ultimate goal is to determine whether disease progression influences brain Mn deposition in HD, and if so, what role glia and neurons play in this process. Supported: NIH ES016931, T32 ES007028

**PS 1861 Verification of Manganese-Related Choroid Plexus Differentially Expressed Proteins *In Vitro*.**

G. J. Li, Y. Dong, J. Liu, Y. Liu, H. Jing, C. Zhao and L. Ma. *Institute for Toxicology, Beijing Centers for Disease Control and Prevention, Beijing Research Center for Preventive Medicine, Beijing, China.*

The regulation of brain manganese (Mn) depends largely on the blood-brain barrier and blood-cerebrospinal fluid barrier (BCB). The latter is constituted by choroid plexus (CP) epithelial cells, which is specialized for cerebrospinal fluid (CSF) production, has been considered as a primary target in Mn-induced neurotoxicity. In our previous study, a total of 32 Mn-related differentially expressed proteins were identified by 2D-PAGE combined with Nano-LC-MS/MS in an *in vivo* Mn-toxicity rat model, of which 27 were up-regulated, 5 were down-regulated. This study aims to further verify the 7 selected proteins (PHB1, VDAC,  $\beta$ -actin, HSP70, STIP1, TTR, Vimentin) at transcriptional and translational level respectively in immortalized choroid epithelial Z310 cells *in vitro* under manganese chloride (MnCl<sub>2</sub>) exposure. The expressed level of 7 proteins and their mRNA were detected by Western Blot and Real Time RT-PCR, following MnCl<sub>2</sub> (0, 50, 100, 200  $\mu$ mol/l) exposure for 24h or 12h in Z310 cells. The results demonstrated that PHB1,  $\beta$ -actin and STI1 were up-regulated and TTR was down-regulated at both transcriptional and translational levels as compared to controls, which are in accordant with results in *in vivo* study. Whereas VDAC, HSP70 and Vimentin were down-regulated at both transcriptional and translational levels as compared to controls, which are opposite to the results in *in vivo* study. Taking together, this study validated that Mn toxic effects on PHB1,  $\beta$ -actin, STIP1 and TTR in CP are accurate and reliable, which provide the valuable clue for elucidating the molecular mechanism of Mn toxicity on choroid plexus epithelial cells (partly supported by NSFC Grant in China #81273108, Capital Development Project 2011-1013-03, and Beijing Health Bureau Project-2011. Corresponding author: Guojun J. Li, guojunli88@yahoo.com).

**PS 1862 Expression and Aggregation of a-Synuclein in the Blood-CSF Barrier: New Evidence for the Effects of Toxic Intracellular Manganese and Copper Levels.**

C. A. Bates<sup>1</sup>, X. Fu<sup>1</sup>, D. Ysselstein<sup>2</sup>, J. Rochet<sup>2</sup>, H. Gu<sup>3</sup>, Y. Du<sup>3</sup> and W. Zheng<sup>1</sup>. <sup>1</sup>Health Sciences, Purdue University, West Lafayette, IN; <sup>2</sup>Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN; <sup>3</sup>Neurology, Indiana University School of Medicine, Indianapolis, IN.

The blood-cerebrospinal fluid barrier (BCB) is responsible for maintaining the homeostasis of a variety of molecules in the brain and cerebrospinal fluid (CSF) including alpha-synuclein (a-Syn). a-Syn plays an integral role in the pathobiology of Parkinson's disease. Little is known about the role of the BCB in the transport and regulation of a-Syn in the brain and CSF. Previous findings in this lab provided evidence that a-Syn was endogenously expressed in our immortalized Z310 choroid epithelial cell model, and 100  $\mu$ M MnCl<sub>2</sub> exposure for 24 and 48 hours induced a-Syn aggregation in these cells. The current studies test the hypothesis that the increased a-Syn aggregation in Z310 cells may result from Mn interacting with a-Syn expression and/or its aggregation. qPCR was used to quantify a-Syn expression in Z310 cells after 100  $\mu$ M MnCl<sub>2</sub> incubation for 24 hr. Our data revealed that Mn treatment did not affect a-Syn mRNA expression in Z310 cells. Using the Thioflavin T fibril aggregation assay, 70  $\mu$ M recombinant a-Syn was incubated with 2 mM MnCl<sub>2</sub> and CuCl<sub>2</sub> for 7 days *in vitro*. a-Syn aggregation increased significantly (530% and 634%, respectively) as compared to controls (n=3, p<0.05). Finally, we found that 24 hr incubation with 50 and 100  $\mu$ M CuCl<sub>2</sub> induced a-Syn aggregation in Z310 cells. These findings support the hypothesis that cellular aggregation of a-Syn in the BCB is facilitated by exposure to heavy metals. More specifically, Mn exposure induces this effect by two pathways: 1) direct interaction with cellular a-Syn within the cell and/or 2) increasing intracellular Cu levels, shown by our data in literature, leading to Cu-accelerated a-Syn aggregation. (Support by NIH/NIEHS ES08146-S2 Minority Supplemental Award)

**PS 1863 Reduced Copper (Cu) Efflux across the Blood-CSF Barrier (BCB) following Manganese Exposure: Effect on Cu Transporters ATP7A and ATP7B.**

X. Fu, Y. Zhang, W. Jiang and W. Zheng. *School of Health Sciences, Purdue University, West Lafayette, IN.*

Increased Cu levels in blood, saliva and brain are found in Mn-exposed animals and humans. However, the underlying mechanism is unknown. ATP7A and ATP7B are Cu-ATPases that function to maintain intracellular Cu homeostasis by exporting excess Cu from the cytosol to extracellular space. This study was designed to test the hypothesis that Mn exposure disrupted the Cu transport across the BCB by interrupting the intracellular trafficking of ATP7A and ATP7B. Rats received ip injections of 6 mg Mn/kg as MnCl<sub>2</sub> or saline, 5 d/wk for 4 wks. Increased Cu and Mn levels in serum and CSF were observed following Mn exposure. An *in situ* ventriculo-cisternal perfusion by infusing [64Cu] and [14C]-sucrose into brain ventricle was conducted to determine Cu clearance by the BCB. Mn exposure significantly increased [64Cu] radioactivity by 2.6 fold in the CSF outflow, as compared to controls, suggesting a reduced Cu removal by the choroid plexus. Confocal images exhibited both Cu-ATPases distributed in perinuclear region in normal plexus tissues and Z310 cells. Incubation of plexus tissues with Mn or Cu caused translocation of ATP7A from the cytosol toward the apical membrane facing the CSF, whereas ATP7B relocated toward the basal membrane facing the blood. Exposing Z310 cells to 100  $\mu$ M MnCl<sub>2</sub> for 24 hr led to a significant decrease in ATP7A and ATP7B fluorescent intensities, which was consistent with their significant mRNA and protein expression reductions in tissue and Z310 cells. The two-chamber Transwell transport studies showed a reduced Cu efflux from the CSF to the blood following Mn exposure or when ATP7A or ATP7B expression were knocked down by siRNA. Collectively, these data suggest that Mn exposure reduces Cu efflux by the BCB which appears to be due to the reduction of ATP7A and ATP7B. A decreased clearance of Cu by Mn exposure may result in the buildup of Cu in the brain. Opposite translocation of ATP7A vs. ATP7B is interesting, yet how this may help interpret a decreased Cu efflux via the BCB remains uncertain. (Supported by NIH/RO1-ES008146)

**PS 1864 Bone Manganese (Mn) Concentrations in Sprague-Dawley Rats following Subchronic Manganese Exposure.**

L. Hong, S. O. Neal, L. Nie and W. Zheng. *Purdue University, West Lafayette, IN.*

Occupational exposure to Mn causes a Parkinson-type disorder called Manganism, a neurodegenerative disease currently without reliable biomarkers for body burden estimation and for pre-symptomatic toxicity assessment. Data in literature suggest that Mn deposited in bone accounts for 43% of total body Mn. The objective of this study was to determine if bone Mn levels were parallel to Mn concentrations in brain regions known to be the targets of Mn toxicity. Groups of rats (6-7 each) received daily dose of 50 mg Mn/kg as MnCl<sub>2</sub> PO for 0, 2, 4, 6, 8 or 10 weeks before tissue dissection. The metal concentrations of Mn, zinc (Zn), iron (Fe), and copper (Cu) in bone tissues, body fluids, brain tissues, as well as other organs were analyzed by atomic absorption spectrophotometry. Following Mn exposure, bone tissues including femur, tibia, humerus and skull bones showed a dose-time-dependent increase in Mn concentrations, with 1.0-1.6  $\mu$ g/g of bone mass at week 10, which were about 2.3-3.6 fold higher than those in controls (-0.4  $\mu$ g/g) at day 0 (p<0.01). A statistically significant relationship exists between bone Mn concentrations and Mn levels in brain tissues such as striatum (r=0.755, p<0.001), hippocampus (r=0.782, p<0.001) and choroid plexus (0.652, p<0.001), and in brain fluid such as cerebrospinal fluid (r=0.720, p<0.001). Interestingly, *in vivo* exposure to Mn also led to significantly increased Fe (152-372%) and Zn (194-230%) concentrations in bone tissues except the skull bones, with no statistically significant effect on bone Cu (58-95%). These results suggest that bone is a significant storage site for body Mn; the good correlation between bone Mn and brain Mn alludes to bone Mn being an internal source of Mn long-term exposure. Further experimentation for noninvasive quantitation of Mn in bone is well warranted for Mn neurotoxicological research. (Supported in part by R21 OH010044, and RO1 ES008146)

**PS 1865 Effects of Chronic Manganese Exposure on Cognitive Functioning in Nonhuman Primates.**

J. Schneider<sup>1</sup>, C. Williams<sup>1</sup>, M. Ault<sup>1</sup> and T. R. Guilarte<sup>2</sup>. <sup>1</sup>Thomas Jefferson University, Philadelphia, PA; <sup>2</sup>Columbia University, New York, NY.

Exposure to elevated levels of manganese (Mn) can result in neurological dysfunction in humans including effects on cognitive functioning, particularly those that depend on the integrity of frontal cortex. Our group is performing longitudinal

studies assessing cognitive and motor function consequent to Mn exposure along with measures of in vivo brain chemistry in non-human primates to better define the neurological consequences and molecular mechanisms of chronic Mn exposure. Adult cynomolgus monkeys were trained to perform cognitive tasks including tests of attention (5 choice serial reaction time (5-CRT)), executive functioning (spatial and non-spatial working memory (self-ordered spatial search (SOSS) and delayed matching-to-sample (DMTS)), and visuospatial learning (paired associate learning (PAL)). After these (and other) tasks were learned to criterion (using the monkey CANTAB test system) and performance was stable, animals received Mn (1.66 - 2.5 mg Mn/kg per injection, 2x/wk) or vehicle (2x/wk) with an intended total exposure period of 1.5 yrs. Through 8 mos. of exposure, the PAL task, a sensitive index of mild cognitive impairment (MCI) in humans, showed consistent deficits beginning in the second mo. of Mn exposure. Deficits in SOSS and DMTS performance became obvious at 4 and 6 mos. of Mn exposure and attentional impairments, suggested by increased reaction times in the 5-CRT task, were observed consistently at approx. mo. 5. Over the same period of time, performance of the control group either did not change significantly or in some instances, improved. These data show that using a sensitive cognitive assessment battery based on monkey versions of human neuropsychological tests, deficits in several cognitive domains are associated with Mn exposure and in particular, Mn disrupts performance of the PAL task, highly sensitive to detecting early Alzheimer's disease and MCI, and in particular, disrupts frontal-related functions. Supported by NIH RO1 ES010975.

**PS 1866 Neurochemical Alterations in the Nonhuman Primate Brain during Chronic Exposure to Manganese: A 1H MRS Study.**

Alterations in brain chemistry upon chronic manganese (Mn) exposure can be studied non-invasively using 1H Magnetic Resonance Spectroscopy (MRS). In this longitudinal Mn exposure study, 1H MRS was used for the detection of brain metabolite changes that are associated with chronic Mn exposure in non-human primates. A total of 7 adult male cynomolgus monkeys underwent MRS on a 3 T Philips Achieva MRI scanner before Mn exposure and after 8 months of Mn exposure (n=3, 1.66-2.5 mg Mn/kg per injection, 2x/wk). Short echo-time PRESS single voxel MRS data was obtained from frontal cortex (FC), parietal cortex (PC), thalamus, and putamen, and gamma-aminobutyric acid (GABA)-edited MRS data was obtained from FC and striatum using MEGA-PRESS. The quantification of metabolites including N-Acetyl-aspartate (NAA), Glutamate (Glu), Glutamine (Gln), mI (myo-Inositol), total creatine (tCr), choline (tCho) and GABA was done using LCModel. A significant decrease in NAA/tCr (p=0.035) and mI/tCr (p=0.013) and a significant increase in Glu+Gln (p=0.03) from baseline was measured in the PC. The thalamus showed a significant increase in tCr (p=0.041) and a significant decrease in mI/H<sub>2</sub>O (p=0.022). No significant changes were measured in any metabolites in the FC and in GABA levels in any region. The significant differences in major metabolites are quite robust despite the small number of animals and changes in NAA/tCr in the PC are in agreement with our previously published results (Guilarte et al., Toxicol Sci 94: 351-358, 2006). (Supported by NIH ES010975)

**PS 1867 What Is the Mechanistic Evidence for Trichloroethylene As a Cause of Parkinson's Disease?**

D. G. Dodge<sup>1</sup> and B. D. Beck<sup>2</sup>. <sup>1</sup>*Gradient, Bend, OR;* <sup>2</sup>*Gradient, Cambridge, MA.*

Parkinson's Disease (PD) is a type of movement disorder characterized pathologically, in part, by the progressive and selective loss of dopaminergic neuron cell bodies within the substantia nigra pars compacta (SNpc) and associated deficiency of the neurotransmitter dopamine in the striatum. Mitochondrial dysfunction (i.e., Complex I inhibition), oxidative stress, and abnormal protein aggregation (with intracellular  $\alpha$ -synuclein accumulation) have been strongly implicated in PD pathology. A number of recent papers have suggested a causal role for trichloroethylene (TCE) in PD, either directly or via its role in the endogenous formation of 1-trichloromethyl-1,2,3,4-tetrahydro- $\beta$ -carboline (i.e., the TaClo hypothesis). We assess, from a toxicological perspective, the evidence for TCE as a cause or substantial

contributor to PD in humans. With regard to the TaClo hypothesis, in vitro studies in a number of different cell systems have provided evidence that TaClo causes changes in mitochondria and dopaminergic neurons but is not preferentially selective towards dopaminergic cells. In vivo studies in rats have shown that high doses of TaClo injected directly into the brain cause only modest decreases in dopamine neurons; intraperitoneal (i.p.) administration of TaClo was not selective towards dopaminergic neurons; and i.p. and oral exposure of TaClo caused locomotor changes that were not consistent in direction or with dose. Furthermore, there is no experimental or credible human evidence that TaClo is formed in vivo after exposure to TCE. In animal studies conducted to evaluate TCE directly as a potential cause of PD, relatively high i.p. or oral doses have resulted in findings that are both consistent and inconsistent with mechanistic and motor effects thought to be important in PD. Compared to other well-developed models of PD, the TCE model is poorly characterized. Overall, we conclude that TCE as a causal factor in PD has not been demonstrated and remains speculative.

**PS 1868 Neuroprotective Efficacy and Pharmacokinetics of Novel Para-Phenyl Substituted Diindolylmethanes in a Model of Parkinson's Disease.**

B. Trout<sup>1</sup>, J. A. Miller<sup>1</sup>, R. Hansen<sup>1</sup>, S. H. Safe<sup>2</sup>, D. Gustafson<sup>1</sup> and R. B. Tjalkens<sup>1</sup>. <sup>1</sup>*Center of Environmental Medicine, Environmental Radiological and Health Science, Colorado State University, Fort Collins, CO;* <sup>2</sup>*Center for Environmental and Genetic Medicine, Institute of Biosciences and Technology, Texas A&M Health Science Center, Houston, TX.*

There are no approved therapeutics that block the chronic inflammatory component of neurodegenerative diseases such as Parkinson's. This is partly because of poor distribution to the central nervous system for compounds with demonstrated efficacy in vitro. This study examined selected para-phenyl substituted diindolylmethane (C-DIM) compounds, which we previously demonstrated to be effective at decreasing glial-derived inflammatory gene expression in vitro. We postulated that the pharmacokinetic properties of C-DIM compounds would positively correlate with neuroprotective efficacy in a progressive model of Parkinson's disease (PD) in vivo. Pharmacokinetics and metabolism of 1,1-bis(3'-indolyl)-1-(p-methoxyphenyl)methane (C-DIM5), 1,1-bis(3'-indolyl)-1-(p-hydroxyphenyl)methane (C-DIM8), and 1,1-bis(3'-indolyl)-1-(p-chlorophenyl)methane (C-DIM12) were determined in plasma and brain of C57Bl/6 mice. Intravenous (1 mg/kg) and oral (10 mg/kg) doses were given to determine the optimal route of administration and putative metabolites were measured in plasma, liver, and urine. Oral dosage of C-DIM compounds displayed greater AUC, C<sub>max</sub>, and T<sub>max</sub> levels than intravenous administration. C-DIM12 exhibited distinguished pharmacokinetics of the selected C-DIMs, with an oral bioavailability of 42% in comparison of C-DIM8 (6%). Following pharmacokinetic studies, efficacy of C-DIM5, C-DIM8, and C-DIM12 (50 mg/kg, oral gavage) was established using a progressive, neuroinflammatory PD model employing MPTP and probenecid (MPTPp) over a period of 14 days. By first creating a lesion in the region of the brain affected in PD (substantia nigra) and then treating with anti-inflammatory C-DIMs, we determined that C-DIM5 and C-DIM12 demonstrated the greatest efficacy in attenuating the progressive loss of dopamine neurons.

**PS 1869 Neurotoxicity Study of Lipopolysaccharide (LPS) Induced Mouse Model of Parkinson's Disease.**

Z. Nan<sup>1</sup>, W. Wang<sup>2</sup> and W. Low<sup>1</sup>. <sup>1</sup>*Neurosurgery, University of Minnesota, Minneapolis, MN;* <sup>2</sup>*Global Regulatory, HB Fuller, St. Paul, MN.*

Parkinson's disease (PD) is a debilitating neurodegenerative disease characterized by gradual and progressive loss of dopaminergic (DA) neurons in substantia nigra pars compacta (SNc). 95% of PD may be attributed to multi-variant etiology; among them, inflammation is getting more attention. Current understanding is that inflammation in the central nervous system can produce large amount of pro-inflammatory factors such as tumor necrosis factor  $\alpha$ , interleukin-1 $\beta$ , interleukin-6, proteinases, and glial activation; the subsequent interaction among these factors and host cells leads to progressive death of dopaminergic neurons in SNc, resulting in PD. Lipopolysaccharide (LPS) is an endotoxin derived from gram-negative bacteria and is widely used as an inflammation inducer. In this preliminary study, we wanted to know what dose level of LPS can effectively induce PD in C57Bl/6 mice by direct brain injection at the SNc site. Six groups of mice were injected with low dose LPS (200 microgram/Kg), high dose LPS (400microgram/Kg) and normal saline as control, respectively, into one side of the SNc site or the target it projects to (striatum of the same side). The surviving DA neurons in the SNc site were shown and counted by immunohistochemistry method using rabbit anti-tyrosine

hydroxylase and visualized by diaminobenzidine staining at 1st and 3rd week after injection. We compared the number of surviving DA neurons at SNc with DA neurons at SNc on the contralateral side. We found significant loss of DA neurons at SNc in both injection sites of SNc and striatum in the high dose groups at 1st and 3rd week. No significant loss of DA neurons was observed in the low dose and the control groups. We concluded that LPS at the dose level of 400microgram/kg can effectively and rapidly induce PD in C57Bl/6 mice through direct brain injection, and the pathological change resembles the neurodegenerative characteristics found in PD. The dose response relationship and the pro-inflammatory characteristics associated with the DA neuron loss may need further investigation.

## PS 1870 Neuroinflammation and Microglial Dysfunction.

M. Entezari<sup>1</sup> and M. Javdan<sup>2</sup>. <sup>1</sup>Natural Sciences, LaGuardia Community College, Long Island City, NY; <sup>2</sup>Biological Sciences and Geology, Queensborough Community College, Bayside, NY.

Neuro-inflammation and accumulation of A $\beta$ -containing amyloid plaques are critical components in the pathogenesis of Alzheimer's disease (AD). Microglia are the brain tissue macrophages that play critical roles in the inflammatory aspects of AD by releasing proinflammatory cytokines. Activated microglia are also able to migrate to the sites of A $\beta$  deposition and eliminate A $\beta$  by phagocytosis. Thus, the impairment of microglia migration and A $\beta$  phagocytosis appear to be closely involved in the progression of AD. The underlying molecular mechanisms responsible for disease progression are still unclear. Previously we have shown that elevated levels of high-mobility group box 1 (HMGB1), a ubiquitous DNA binding protein that promotes inflammatory tissue injury impairs the peritoneal macrophages' functions. Therefore, we hypothesized that HMGB1 contributes to microglial dysfunction in neuro-inflammation. In this study we demonstrate that HMGB1 levels were significantly elevated in the extracellular space of cultured BV2 macroglia cells 24 hours after exposure to 1  $\mu$ g/ml Lipopolysaccharide (LPS) compare to untreated control cells. Exposure to 1  $\mu$ g/ml LPS also resulted in significant suppression of microglia's ability to migrate and to phagocytose. Simultaneous treatment of BV2 cells with LPS and anti-HMGB1 antibody significantly improved the migration and phagocytic ability of these cells. Moreover, treating BV2 cells with recombinant HMGB1 not only induced impairment in migration and phagocytosis but also accompanied by the expression of Toll-like receptor 4 (TLR4) on these cells. These results suggest that activation of the LPS-induced HMGB1/TLR4 signaling pathway contributes to the microglia dysfunction. Thus, inhibiting of HMGB1 may provide a therapeutic target for enhancing of microglia's ability to migrate and phagocytose in AD.

## PS 1871 Translocator Protein 18 KDa (TSPO) in Sandhoff Disease: An Update on a Preclinical Biomarker of Neurodegeneration.

M. Loth<sup>1</sup>, J. Choi<sup>1</sup>, J. L. McGlothlan<sup>1</sup>, H. Wang<sup>2</sup>, M. Pomper<sup>2</sup> and T. R. Guilarte<sup>1</sup>. <sup>1</sup>EHS, Columbia University, NYC, NY; <sup>2</sup>Radiology, Johns Hopkins University, Baltimore, MD.

Translocator protein 18 kDa (TSPO) is extensively used as a biomarker of active brain disease and neuroinflammation (Chen & Guilarte, Pharm Ther 118: 1-17, 2008). Sandhoff disease, which is clinically similar to Tay-Sachs's disease, is a neurodegenerative condition in which a deficiency in the enzyme lysosomal  $\beta$ -hexosaminidase leads to accumulation of gangliosides and glycolipids in the brain, resulting in progressive and widespread neurodegeneration. We previously reported the longitudinal expression of TSPO in a mouse model of Sandhoff disease at the later stages of the disease (2 and 3 months). Now we report TSPO expression at early disease time points (1 and 1.5 months) in order to assess the temporal expression of TSPO and its relationship to behavioral and neuropathological endpoints. Using TSPO quantitative autoradiography with the TSPO specific ligands [125I]iodo-DPA-713 and [3H]-DPA-713, we show that TSPO levels are increased as early as 1 month in relevant brain regions concurrent with behavioral expression of disease. We also demonstrate that the temporal increase in TSPO levels is associated with ongoing neurodegenerative changes and activation of microglia and astrocytes using silver staining (marker of active degeneration) and immunohistochemistry of Mac-1 (microglia) and GFAP (astrocytes). Triple labeled immunofluorescent confocal imaging confirmed that TSPO colocalized with microglial markers as well as with the gp91phox subunit of NADPH oxidase at an age when brain tissue is undergoing neurodegeneration. These results further strengthen the evidence that TSPO can be used as an early and sensitive preclinical biomarker of brain injury and inflammation [Supported by NIEHS grant ES007062 to TRG].

## PS 1872 Characterization of Mice with Overexpression of the Vesicular Monoamine Transporter 2 (VMAT2; Slc18a2).

K. Lohr<sup>1</sup>, A. I. Bernstein<sup>1</sup>, T. Guillot<sup>1</sup>, K. Stout<sup>1</sup>, E. Heath<sup>1</sup>, M. Wang<sup>1</sup>, Y. Li<sup>1</sup>, A. Salahpour<sup>2</sup> and G. W. Miller<sup>1</sup>. <sup>1</sup>Environmental Health, Emory University, Atlanta, GA; <sup>2</sup>University of Toronto, Toronto, ON, Canada.

The vesicular monoamine transporter 2 (VMAT2) is responsible for packaging monoamines for rapid release at neuronal synapses. VMAT2 is also responsible for sequestering toxicants away from their sites of action in the cell. Despite previous evidence suggesting that decreased levels of VMAT2 can contribute to cellular dysfunction, it was not known if an increase in VMAT2 protein would result in increased function in vivo. We generated C57BL6 BAC transgenic mice with increased VMAT2 expression to determine the effects of increased vesicular monoamine filling on associated neurochemical and behavioral outcomes. Our VMAT2-HI mice show robust VMAT2 overexpression, proper localization of VMAT2, increased whole brain synaptic vesicle [3H]-dopamine uptake, and a measurable behavioral phenotype. These data show the effects of elevated VMAT2 levels on neurochemistry and behavior, suggesting that increased vesicular dopamine storage mediated by increased VMAT2 levels can alter the neurochemical and behavioral output of the monoaminergic system. Finally, as VMAT2 acts as a neuroprotective mechanism in monoaminergic neurons, these VMAT2-HI mice serve as a valuable tool to investigate resistance to toxicant exposure.

## PS 1873 Background Survival of Transgenic Mouse Models of Alzheimer's Disease in Our Laboratories.

J. Douville and C. Copeman. Charles River, Montréal, QC, Canada. Sponsor: M. Vézina.

Transgenic mouse models of Alzheimer's disease are of great value for evaluating efficacy and/or toxicology of drug therapies. These models typically present hallmarks of the disease between 12 and 20 months of age; however, age-related attrition represents a challenging issue that may impair the statistical significance of the data generated. We present survival data of three different transgenic Alzheimer mouse models when housed under our optimized laboratory conditions. The homozygous strain of PDAPP mouse (STOCK-TgN(APP)<V717F> (line number 6042M)) showed mortality rates of 13 (males) and 21% (females), between the ages of 7 to 12 months and of 70 (males) and 60% (females), between the ages of 12 to 21 months. Heterozygous PDAPP mice (STOCK-TgN(APP)<V717F> (line number 6042T)) showed greater survival with only 6.4 and 16.8% mortality for males and females, respectively at 14 to 20 months of age and 16% and 42% mortality for males and females, respectively, between 20 to 26 months of age. Young Tg2576 mice (B6; SJL-Tg (APPswe) 2576Kha) presented a survival rate comparable to wild type mice with 100 and 90% survivors between the ages of 9 and 14 weeks. When survival is calculated for older Tg2576 mice, 79 and 75 % of males and females, respectively, survive over the age of 13 to 22 months. As the survival rates vary between the different strains and the age-related attrition is relatively high, consideration for increased population should be given accordingly in study designs using these transgenic mouse models.

## PS 1874 Oxidative Damage and Age-Related Alterations in Kainic Acid-Induced Excitotoxicity.

R. C. Gupta<sup>1</sup>, S. Zaja-Milatovic<sup>2</sup> and D. Milatovic<sup>3</sup>. <sup>1</sup>Toxicology, Murray State University, Hopkinsville, KY; <sup>2</sup>University of Virginia, Charlottesville, VA; <sup>3</sup>Vanderbilt University Medical Center, Nashville, TN.

Recent research findings in brain have highlighted increased excitatory stimulation as a contributor to aging as well as neuronal damage that accompanies multiple neurodegenerative diseases. Findings from patients and animal models have widely supported the hypothesis that neuronal oxidative/nitrosative damage is a major effector contributing to neurodegeneration. Therefore, the present study investigated antioxidative and neuroprotective effects of the antioxidant vitamin E ( $\alpha$ -tocopherol) and the NMDA receptor antagonist memantine in age-related excitotoxicity induced by kainic acid (KA). Mice exposed to KA (1 nmol/5  $\mu$ l, icv) showed significant increases in cerebral oxidative biomarker F2-isoprostanes (F2-IsoPs, 158%) and nitrosative biomarker citrulline (249%) formation when determined at 30 min after exposure. At the same time, pyramidal neurons in the hippocampus of young and old mice showed significant reductions in dendritic length (60%) and spine density (40%) compared to controls (100%). Pretreatment with vitamin E (100 mg/kg, ip/day for 3 days) and memantine (5 mg/kg, ip, but not 1 mg/kg) attenuated the KA-induced increases in cerebral F2-IsoPs and citrulline and decrease in

spine density of hippocampal pyramidal neurons in young mice. However, vitamin E (100 mg/kg, ip/day for 3 days) and memantine (5 mg/kg, ip) were not effective in suppressing KA-induced oxidative stress and a decrease in the dendritic length of hippocampal pyramidal neurons in aged mice. These data strongly suggest that different mechanisms are involved in cerebral neuroprotection of aged mice compared to young mice. Elucidation of these mechanistic changes has important clinical implications for therapeutic strategies in both normal aging and neurodegenerative disease.

## PS 1875 Rapid Immunoassay Development and Evaluation of ICAM-1 and E-Selectin As Potential Biomarkers of Vascular Injury in Rats.

M. J. Cameron<sup>1</sup>, H. W. Smith<sup>2</sup>, J. L. Weaver<sup>4</sup>, N. King<sup>5</sup>, N. Vansell<sup>3</sup> and B. E. Enerson<sup>3</sup>. <sup>1</sup>Immunology, MPI Research, Mattawan, MI; <sup>2</sup>Investigative Toxicology, Eli Lilly and Company, Indianapolis, IN; <sup>3</sup>Drug Safety Research and Development, Pfizer Inc, Groton, CT; <sup>4</sup>DDSR/OTR/OPS/CDER, FDA, Silver Spring, MD; <sup>5</sup>Predictive Safety Testing Consortium, Critical Path Institute, Tucson, AZ.

To qualify biomarkers of vascular injury in support of the Predictive Safety Testing Consortium's (PSTC) Vascular Injury Working Group (VIWG) we developed biomarker immunoassays on the Gyros platform for rat ICAM-1 and E-Selectin using a fit-for-purpose approach. ICAM-1 (Intercellular Adhesion Molecule 1), also known as CD54, is a cell surface glycoprotein typically expressed on endothelial cells. E-Selectin, also known as CD62 and endothelial leukocyte adhesion molecule 1, is typically expressed on activated endothelial cells. The assays were developed using commercially sourced reagents. Rats (n=5/group) were treated with either 60 mg/kg of CI-1044 (oral gavage) or 100 mg/kg of fenoldopam (subcutaneous). Both drugs are known to cause vascular injury. Samples were taken at 4, 8, 16, 24, 48, 72 hours and recovery for CI-1044 and at 0.5, 2, 6, 24, 72 hours and recovery for fenoldopam and serum was evaluated for levels of ICAM-1 and E-Selectin. Histopathologic examination indicated vascular lesions were present from the CI-1044 rats starting at 16 hours post dose consisting of perivascular inflammation of the mesenteric arteries and progressing to fibrinoid necrosis at later time points. The mesenteric vascular lesions in fenoldopam-treated rats consisted of arterial necrosis/apoptosis observed at 24 hours post dose, followed by perivascular inflammation and fibrinoid necrosis at later time points. There was no significant change noted in the circulating levels of ICAM-1 in CI-1044 or fenoldopam treatment groups. There was a significant decrease in serum E-Selectin levels in both CI-1044 and fenoldopam treated groups after 48 hours. E-Selectin has the potential to become a valuable biomarker in the evaluation of vascular injury for preclinical drug safety studies.

## PS 1876 Synthesis and Characterization of PEG-Ylated Meso-Porphyrins for Targeting the Epidermal Growth Factor Receptor in CRC.

R. J. Ledet<sup>1</sup>, K. R. Fontenot<sup>2</sup> and G. H. Vicente<sup>2</sup>. <sup>1</sup>Chemistry and Biology, Southern University and A&M College, Baton Rouge, LA; <sup>2</sup>Chemistry, Louisiana State University and A&M College, Baton Rouge, LA. Sponsor: W. Gray.

This project introduces a novel macrocycle conjugated to polyethylene glycol linker, which we hypothesize will serve as the template for a selective molecule with high fluorescence yields that greatly increases earlier detection of CRC by utilizing the EGFR as a biomarker. Our targeted remedy is a porphyrin that is conjugated to a peptide with an affinity for the Epidermal Growth Factor Receptor (EGFR). Porphyrins are characteristically aromatically stable, contain trademark absorption bands in the visible and near-IR range, and have fluorescence quantum yields much above the current fluorophores. This makes the macrocycle optimal for confocal laser endomicroscopy (CLE) agent production. Consequently, we use a polyethylene glycol linker in order to increase water solubility, retain low toxicity, and to achieve high fluorescence quantum yields, as well as high conjugation yields. In this research, we were able to produce both precursors to the porphyrin-peptide conjugate, MesoPOR-(mono)-3PEG and MesoPOR-(di)-3PEG. These molecules were synthesized successfully with the use of peptide conjugation mechanisms. Molecular weights were confirmed using Matrix Assisted Laser Desorption Ionization Mass Spectrometry (MALDI-MS). Characterization was performed using <sup>1</sup>H Nuclear Magnetic Resonance (<sup>1</sup>H-NMR) and Ultraviolet-Visible Spectroscopy (UV-Vis) of the intended molecules. The synthesized molecules, MesoPOR-(mono) 3PEG and MesoPOR-(di) 3PEG, will be useful in peptide conjugation that targets EGFR. These peptide ligands will increase selectivity and detect CRC via CLE.

## PS 1877 Multiplex Analysis of Urinary Protein Biomarkers for the Detection of Vancomycin Induced Sub-Acute Nephrotoxicity.

W. Zheng<sup>1</sup>, T. C. Fuchs<sup>2</sup>, I. Yoon<sup>1</sup>, D. Droll<sup>1</sup>, X. Qiang<sup>1</sup> and P. Hewitt<sup>2</sup>. <sup>1</sup>R&D, EMD Millipore, St. Charles, MO; <sup>2</sup>Non-Clinical Safety R&D, Merck Serono, Darmstadt, Germany.

In pharmaceutical and chemical industries the kidney is routinely assessed during preclinical safety evaluations. The importance of the kidney as a central detoxification organ leads to a high exposure of renal tissue to drugs, reactive metabolites or environmental compounds. Traditional markers for assessing renal toxicity, such as blood urea nitrogen (BUN) and serum creatinine (SCR), are insensitive. Although both are direct measurements of renal function, increases in serum concentrations of these biomarkers occur only after substantial renal injury. For improved detection of acute nephrotoxicity a panel of novel urinary kidney biomarkers has been approved by the FDA, EMA and PMDA. However, limited data regarding the performance of these acute markers after sub-acute or sub-chronic treatment are publicly available. To increase the applicability of these markers, it is important to evaluate the ability to detect these markers after 28 days or even longer. In this study, Wistar rats were treated with three doses of Vancomycin to induce renal damage and studied for 28 days. Urine was collected under cooled conditions on an 18-hour cycle on days 4, 8, 15 and 29. Luminex® xMAP® based MILLI-PLEX® Rat Kidney Toxicity Magnetic Bead Assays were used to measure 14 candidate protein biomarkers simultaneously from the urine samples. Vancomycin treatment resulted in a dose-dependent increase in urinary biomarkers, specific for the observed areas within the nephron, determined histopathologically. Several biomarkers were found promising in this study, which includes NGAL, Cystatin C, KIM-1, Osteopontin, Clusterin and Albumin. The simultaneous measurement of these proteins with multiplex technology offered a robust and convenient method to study these biomarkers. Taken together, our data demonstrate the high accuracy and predictivity of some of these new markers to detect sub-acute treatment with one well described nephrotoxin, Vancomycin.

## PS 1878 Association of the Cumulative Body Burden of Estrogen-3, 4-Quinone with Body Mass Index and Breast Cancer Risk Using Albumin Adducts As Biomarkers.

P. Lin<sup>1</sup>, D. Chen<sup>2</sup>, C. Lin<sup>1,2</sup>, W. Hsieh<sup>3</sup>, W. Yu<sup>3</sup>, C. Lin<sup>1</sup>, M. Go<sup>1</sup> and C. Juan<sup>1</sup>. <sup>1</sup>Environmental Engineering, National Chung Hsing University, Taichung, Taiwan; <sup>2</sup>Comprehensive Breast Cancer Center, Changhua Christian Hospital, Changhua, Taiwan; <sup>3</sup>Department of Laboratory Medicine, Da-Chien General Hospital, Miaoli, Taiwan.

Both 17 $\beta$ -estradiol-2,3-quinone (E2-2,3-Q) and 17 $\beta$ -estradiol-3,4-quinone (E2-3,4-Q) are reactive metabolites of estrogen. Elevation of E2-3,4-Q to E2-2,3-Q ratio is thought to be an important indicator of estrogen-induced carcinogenesis. Our current study compared the cumulative body burden of these estrogen quinones in serum samples taken from Taiwanese women with breast cancer (n=152) vs healthy controls (n=140) by using albumin (Alb) adducts as biomarkers. Results clearly demonstrated the presence of cysteinyl adducts of E2-2,3-Q-4-S-Alb and E2-3,4-Q-2-S-Alb in all study population at levels ranging from 61.7-1330 and 66.6-1590 pmol/g, respectively. Correlation coefficient between E2-2,3-Q-4-S-Alb and E2-3,4-Q-2-S-Alb was 0.610 for controls and 0.767 for breast cancer patients (p<0.001). We also noticed that in subjects under age 50 with body mass index (BMI) less than 27, background levels of E2-3,4-Q-2-S-Alb was inversely proportional to BMI with about 25% increase in E2-3,4-Q-2-S-Alb per 5 kg/m<sup>2</sup> decrease in BMI (p<0.001). In addition, we confirmed that mean levels of E2-3,4-Q-2-S-Alb in breast cancer patients were ~5 fold greater than in those of controls (p<0.001). Overall, this evidence suggests that disparity in estrogen disposition and the subsequent elevation of cumulative body burden of E2-3,4-Q may play a role in the development of breast cancer. (This work was supported by the National Science Council, Taiwan, through Grants NSC99-2314-B-005-001-MY3)

## PS 1879 Biomarker-Based Evaluation of Diesel Exhaust Emissions from 2007-Compliant Engines in Rats and Mice Exposed for Defined Time Periods.

L. M. Hallberg<sup>1</sup>, J. L. Parks<sup>1</sup>, C. M. Norton<sup>2</sup>, C. Hernandez<sup>1</sup>, J. B. Ward<sup>1</sup>, B. T. Ameredes<sup>1</sup> and J. K. Wickliffe<sup>2</sup>. <sup>1</sup>University of Texas Medical Branch, Galveston, TX; <sup>2</sup>Tulane University Health Sciences Center, New Orleans, LA.

In 2001 the USEPA adopted new air quality standards for diesel fuels and emissions; the health impact was not established. Diesel exhaust (DE) is associated with adverse health effects, including cardiovascular, lung cancer, and neurological

deficits. Proposed mechanisms include damage to DNA and lipids through exposure to reactive oxygen, toxic DE particulates, and inflammation. Our objective is to determine if engineering changes in 2007 diesel engines significantly reduces DNA and lipid damage.

To determine the extent of oxidative and genotoxic damage caused by inhaled DE, biomarkers of lipid peroxidation (LP) and DNA damage were employed being assessed by the Comet assay (DNA damage), serum levels of 8-OHdG, and LP.

In rats (1 month exposure), no significant differences (NSD) were noted by Comet assay (exposure level vs air control  $p < 0.53$  Low(L), 0.92 Mid(M), 0.77 High(H) nor were there gender effects in either tail moment (TM) or tail length (TL) ( $p < 0.59$  L, 0.90 M, 0.42 H, 0.16 gender effects). After 3 months exposure, NSD were noted in TM or TL in rats. NSD in mice (1 month,  $p < 0.56$  L, 0.20 M, 0.61 H, 0.79 gender effects) in TM or TL ( $p < 0.60$  L, 0.21 M, 0.63 H, 0.73 gender effects). After 3 months, NSD in TM or TL ( $p < 0.15$ ,  $p < 0.16$ ) nor gender were observed.

In serum (8-OHdG ELISA) NSD were observed in rats ( $p < 0.86$ ) or mice ( $p < 0.46$ ) among 1 and 3 month groups. In rodent hippocampus (L P-T-Bars assay), significant differences were observed in rats between L and M groups ( $p < 0.02$ ) but NSD among other groups. NSD were observed among mice ( $p < 0.92$ ) treatment groups. In mouse, 1 month was significantly higher than 3 months ( $p < 0.01$ ).

In conclusion, NSD was evident comparing air controls to 3 treatment groups. Based on the endpoints evaluated, we conclude that 2007-compliant engines did not produce any significant, persistent, oxidatively-induced DNA damage (lung) or exposure-dependent lipid peroxidation in (hippocampus) from these exposures.

## PS 1880 Investigation of Early Biomarkers of Doxorubicin (DOX)-Induced Cardiac Tissue Injury in B6C3F1 Mice.

V. Desai<sup>1</sup>, E. Herman<sup>2</sup>, C. Moland<sup>1</sup>, S. Lewis<sup>3</sup>, K. Davis<sup>4</sup>, N. George<sup>5</sup>, S. Kerr<sup>6</sup> and J. C. Fuscoe<sup>1</sup>. <sup>1</sup>Division of Systems Biology, NCTR, US FDA, Jefferson, AR; <sup>2</sup>Division of Applied Pharmacology Research, CDER, US FDA, Silver Spring, MD; <sup>3</sup>Division of Scientific Coordination, NCTR, US FDA, Jefferson, AR; <sup>4</sup>Toxicologic Pathology Associates, NCTR, US FDA, Jefferson, AR; <sup>5</sup>Division of Bioinformatics and Biostatistics, NCTR, US FDA, Jefferson, AR; <sup>6</sup>Arkansas Heart Hospital, Little Rock, AR.

Cardiac troponins (cTn) are widely used as biomarkers for assessing cardiac injury in preclinical and clinic testing. Here we report a study that was designed to identify early biomarkers of cardiac injury in male B6C3F1 mice. Mice were treated weekly for 2, 3, 4, 6, and 8 weeks with (a) 3 mg/kg DOX given intravenous (i.v.) via tail vein, resulting in cumulative doses of 6, 9, 12, 18, and 24 mg/kg, respectively, (b) an equivalent volume of saline (SAL) given i.v. via tail vein, (c-d) 60 mg/kg dexrazoxane (DXZ), a cardioprotective drug, given intraperitoneal (i.p.) 30 min before i.v. injection of DOX or SAL, and (e) SAL given i.p. 30 min before i.v. injection of SAL. At necropsy, which was performed a week after the last dose, blood samples were collected for measurements of cTnT and hematological parameters. Also, hearts were collected for evaluations by light and electron microscopy, genomics, proteomics, and metabolomics. Preliminary results showed a release of cTnT in plasma in 8% of mice at 6 mg/kg, 17% of mice at 9 and 12 mg/kg, and 92% of mice at 18 and 24 mg/kg cumulative DOX doses, indicating a dose-related increase in cardiac injury. Plasma cTnT levels were also elevated in 16%, 58%, and 55% of mice treated with DXZ+DOX for 3, 6, and 8 weeks, respectively. Microscopic examination of hearts revealed the presence of cardiac lesions only in mice exposed to 24 mg/kg cumulative DOX dose, suggesting that DXZ provided cardioprotection against irreversible damage. The presence of histological damage in the heart of only mice exposed to the highest cumulative DOX dose yet some elevation in cTnT at lower cumulative DOX doses suggests that our ongoing evaluation of molecular changes may reveal more sensitive biomarkers of cardiac injury.

## PS 1881 Investigation on Plasma Bile Acids As Biomarkers of Cholestasis Induced by Bsep Inhibition in Preclinical Animals.

M. Miyake<sup>1</sup>, T. Shimizu<sup>1</sup>, M. Kobayashi<sup>1</sup>, M. Yamazaki<sup>2</sup>, H. Satou<sup>1</sup>, T. Honda<sup>1</sup>, T. Tomari<sup>1</sup> and N. Masutomi<sup>1</sup>. <sup>1</sup>Safety Research Laboratories, Research Division, Mitsubishi Tanabe Pharma Corporation, Chiba, Japan; <sup>2</sup>Advanced Medical Research Laboratories, Research Division, Mitsubishi Tanabe Pharma Corporation, Saitama, Japan. Sponsor: J. Sugimoto.

[Purpose] The bile salt export pump (BSEP) is a bile acid efflux transporter, the inhibition of which has been proposed to play a role in drug-induced cholestasis. However, there are no known biomarkers (BMs) to detect BSEP inhibition. We previously performed metabolomics analyses on rat plasma treated with cyclosporin A, a well-known BSEP inhibitor, and found that plasma bile acids (PBA) could be BMs for BSEP inhibition. To further evaluate the usefulness of PBA, we characterized the specificity and time-course changes of PBA in rats and dogs. [Methods and

Results] PBA were measured by LC/MS in rats dosed rifampicin (a BSEP inhibitor), methapyriline (a hepatocellular toxicant), 2,3,5,6-tetramethyl-1,4-phenylenediamine (a muscular toxicant) and dexamethasone (a hepatic glyconeogenesis inducer). Increase of cholic acid and taurocholic acid, accompanied by decrease of glycocholic acid and chenodeoxycholic acid were specific to rifampicin treatment, confirming the reproducibility of the previous analyses. Next, single dosing studies were conducted in rats and dogs to investigate the time-course changes of PBA. In rats, PBA were increased maximally at 6-9 hrs after cyclosporin A dosing and tended to return to the normal level at 24 hrs after dosing, which corresponded to the toxicokinetics of cyclosporin A. On the other hand, PBA were detected only after feeding in untreated dogs, and rifampicin intensified the rise in PBA concentration induced by meal. [Conclusion] The results show that PBA can be specific BMs of BSEP inhibition in preclinical animals. Since PBA showed time-course changes associated with plasma drug concentrations and were also affected by meal in dogs, plasma sampling time point would be critical to evaluate changes in PBA induced by BSEP inhibition.

## PS 1882 Kidney Injury Biomarkers Lipocalin-2, Clusterin and Albumin, but Not Kidney Injury Molecule 1, Are More Sensitive Than Traditional Markers of Gentamicin-Induced Kidney Injury in Beagles.

M. Wagoner<sup>1</sup>, L. Cheatham<sup>1</sup>, D. Eisinger<sup>2</sup>, E. Sace<sup>3</sup>, K. M. Lynch<sup>4</sup>, J. McDuffie<sup>5</sup>, M. Sonce<sup>5</sup>, K. Marshall<sup>2</sup>, M. Damour<sup>2</sup>, L. Stephen<sup>1</sup>, Y. P. Dragan<sup>1</sup>, J. Fikes<sup>1</sup> and L. B. Kinter<sup>1</sup>. <sup>1</sup>Safety Assessment, AstraZeneca Pharmaceuticals, Waltham, MA; <sup>2</sup>Myriad RBM, Saranac Lake, NY; <sup>3</sup>Pfizer, San Diego, CA; <sup>4</sup>GlaxoSmithKline, King of Prussia, PA; <sup>5</sup>Janssen Pharmaceuticals, La Jolla, CA.

A panel of 8 novel urinary protein biomarkers were recently qualified by the FDA for the detection of acute kidney injury (AKI), significantly improving the sensitivity and specificity with which renal injury may be detected in rat. However, the translation of these biomarkers to dogs, one of the most common species used in preclinical drug development, remains unknown yet must be established prior to broad implementation in toxicity screens. Here, we monitored AKI biomarkers kidney injury molecule 1 (Kim-1), lipocalin-2 (NGAL), clusterin and albumin in urine from male beagles infused once daily for 10 days with the nephrotoxic antibiotic gentamicin. Histological examination of the kidneys following treatment revealed severe epithelial degeneration, necrosis and regeneration alongside tubular dilation in gentamicin-treated dogs only. In gentamicin-treated dogs, significantly elevated urinary protein levels of albumin, clusterin and NGAL were measurable as early as 3 days after start of treatment with peak levels >100-fold above background. Both the speed and magnitude of response detected with these new biomarkers were superior to traditional AKI biomarkers, blood urea nitrogen (BUN) and serum creatinine (sCr), which did not increase until day 8. Urinary Kim-1 levels peaked around 2-fold, an order of magnitude lower than published levels from a similar 10-day rat study. Further analysis of samples for Kim-1 mRNA and protein will tell whether the canine Kim-1 response is markedly different from that observed in rats. These data indicate that three of four novel biomarkers qualified in rat (NGAL, clusterin and albumin) translate to canine and represent a substantial improvement over traditional AKI biomarkers in preclinical drug development.

## PS 1883 Bio-Monitoring of Multimycotoxin Exposure in Human Urine Samples from Cameroon Using a Multibiomarker Approach.

W. A. Abia<sup>1,2</sup>, B. Warth<sup>2</sup>, M. Sulyok<sup>2</sup>, R. Krska<sup>2</sup>, A. T. Chana<sup>1</sup>, P. B. Njobeh<sup>3</sup>, P. C. Turner<sup>4</sup>, C. Kouanfack<sup>5</sup>, M. M. Dutton<sup>3</sup> and P. F. Moundipa<sup>1</sup>. <sup>1</sup>Biochemistry, University of Yaounde I, Yaounde, Cameroon; <sup>2</sup>Department for Agrobiotechnology (IFA-Tulln), University of Natural Resources and Life Sciences, Vienna, Austria; <sup>3</sup>Food, Environment and Health Research Group (FEHRG), University of Johannesburg, Doornfontein, South Africa; <sup>4</sup>MIAEH, School of Public Health, University of Maryland, College Park, MD; <sup>5</sup>Day Hospital, Central Hospital, Yaounde, Cameroon.

Mycotoxins are secondary metabolites of fungi that contaminate food, but bio-monitoring of human exposure has mostly been limited to a few individually measured mycotoxin biomarkers, mainly aflatoxin. The aim of this study was to determine frequency of exposure and level of multi-mycotoxin in urine samples obtained from Cameroonian adults, mostly from HIV infected individuals. 175 urine samples (145/175; 83% from HIV positive individuals) as well as food frequency questionnaire responses were collected from consenting Cameroonians, and analyzed for 8 parent mycotoxins and 7 key metabolites using liquid chromatography separation and tandem mass spectrometry detection. In total, 11 mycotoxin biomarkers [e.g. aflatoxin M1 (AFM1), fumonisin B1 (FB1), ochratoxin A and total deoxynivalenol] and bio-measures [FB2, nivalenol and total zearalenone] were recovered,

individually or in combinations, in 110/175 (63%) samples; from HIV positive (64%) and HIV negative (57%), with additional 4 analytes present only in HIV positive samples. AFM1 (10%; mean 0.5, range <LOQ-1.4µg/L) and FB1 (3%; mean 0.6, range 0.5-15µg/L) were detected in the HIV subpopulation whilst low levels (<LOQ) were found in one sample each from HIV negative group. One HIV positive individuals' urine contained 6 metabolites. Levels of these metabolites were generally similar to those reported elsewhere in Africa. For the first time in Africa and elsewhere, this study has reported on 11 mycotoxin biomarkers/bio-measures quantified in human urine. Mycotoxin exposures in HIV individuals may require particular attention. The findings may constitute a major step towards mycotoxin exposure assessment and national mycotoxin regulations in Cameroon.

#### **PS 1884 Development of a New Oxidative Stress Biomarker Dityrosine ELISA.**

K. Sakai<sup>1</sup>, M. Takeuchi<sup>1</sup>, T. Ochi<sup>1</sup>, R. Rathnam<sup>2</sup> and Y. Kato<sup>3</sup>. <sup>1</sup>Japan Institute for the Control of Aging, Fukuroi, Japan; <sup>2</sup>Genox Corporation, Baltimore, MD; <sup>3</sup>School of Human Science and Environment, University of Hyogo, Himeji, Japan. Sponsor: K. Rao.

Accumulating evidence indicates that oxidative stress plays an important role in various diseases such as cancer, diabetes and hypertension. Recently it is also reported that oxidative stress is involved in toxicity of chemical substances such as arsenic, asbestos, diesel exhaust micro particles and antineoplastic drugs, and monitoring of oxidative stress inside human body may be informative for toxicological study. Oxidative stress may cause oxidative damages to biomolecules such as nucleic acids, lipids, proteins and enzymes, and oxidized products of such biomolecules have been used for the assessment of oxidative stress in the living bodies. Although protein is one of the most important biomolecules, only limited number of reports about the oxidized proteins has been published. Tyrosine is one of the major targets of protein oxidation, and dityrosine is known to be formed by oxidative stress. In this presentation, development of a new dityrosine ELISA is reported. A competitive dityrosine ELISA is established using anti-dityrosine monoclonal antibody (clone 1C3) which was developed by Kato et.al. 50 µL of diluted samples or standards are poured into micro plate wells which is pre-coated by dityrosine antigen, and incubated at 4 degree C overnight. After washing by PBS-tween buffer, 100 µL of HRP-conjugated anti mouse antibody is poured, and incubated for 1 hour at room temperature. TMB is used for color development. Assay range of dityrosine ELISA is 0.05 to 12 µmol/L, and shows good linearity and reproducibility. Dityrosine concentration in human urine ranges between 0.12 and 3.95 µmol/L (mean 1.44 µmol/L), and urinary dityrosine concentration measured by ELISA significantly correlated with that measured by LC-MS/MS. In conclusion, dityrosine ELISA may be useful for the assessment of oxidative stress in the living bodies.

#### **PS 1885 Method Development of Serum Canine Inhibin B Enzyme-Linked Immunosorbent Assay (ELISA).**

R. Kuk<sup>1</sup>, D. Kumar<sup>2</sup> and S. B. Laffan<sup>1</sup>. <sup>1</sup>Reproductive Toxicology, Safety Assessment, GlaxoSmithKline, King of Prussia, PA; <sup>2</sup>Assay Development, Bristol-Myers Squibb, Syracuse, NY.

Inhibin B (INH-B) is a heterodimeric glycoprotein consisting of an alpha and a beta-B subunit linked by disulphide bridges. INH-B is produced by the testes as well as the ovaries, and is responsible for the selective negative feedback control of follicle stimulating hormone. In males, INH-B is synthesized by the sertoli cells in the testis, and can be used as a marker of sertoli cell function and spermatogenesis in adult males. Hence, it is being considered a biomarker for detecting testicular damage. INH-B has been quantified in humans, rats and non-human primates, but not in canines due to lack of availability of reagents. Here, we report the methods development of the canine INH-B ELISA from Cusabio Biotech Co. (Wuhan, China). Assay standard curve is ranged from 4 to 1000 pg/mL with serum requirement of 50 µL. Assay optimization included modification of the procedure to include sample mixing followed by prolonged primary antibody-antigen incubation time to ensure saturation. Two custom quality controls were prepared at levels that are on the sensitive part of the standard curve. Qualification criteria included assessment of the standard curve, quantification range, reproducibility (precision) and dilutional linearity (% recovery). Standard curve was made more robust by adding more points on the sensitive part of the curve. Lower limit of quantification was qualified to be statistically above the variance of the blank value. Reproducibility was good (%CV≤30%) among assays. Linearity was acceptable for kit standards diluted with castrated dog serum or commercially available serum matrix, also, for intact serum diluted with its respective castrated serum (R<sup>2</sup>>0.9). This assay can detect >8 fold INH-B difference between intact and castrated canine

serum samples. Other parameters like frozen storage, freeze/thaw and lot-to-lot stability are pending. We conclude that this canine INH-B assay can consistently quantify INH-B levels in canine serum under the modified procedures.

#### **PS 1886 Mitigation of Fumonisin Biomarkers by Green Tea Polyphenols.**

K. Xue<sup>1</sup>, L. Tang<sup>1</sup>, Q. Cai<sup>2</sup>, L. Xu<sup>1</sup>, J. Su<sup>3</sup> and J. Wang<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Texas Tech University, Lubbock, TX; <sup>3</sup>Guangxi Cancer Institute, Nanning, China.

Fumonisin B1 (FB1) is a carcinogen and a strong tumor promoter in animal models. Green tea polyphenols (GTP) are highly effective in inhibition of a variety of carcinogen-induced tumorigenic effects in many model systems. In this study we assessed mitigative effects of GTP on FB1-biomarkers in blood and urine samples collected from a randomized, double blinded, and placebo controlled intervention trial, which recruited a total of 124 people aged 20-55 who exposed FB1 via their corn-based diet. These participants were consented, randomly divided into 3 groups, and daily treated with either low-dose (GTP 500 mg, n=42), high-dose (1,000 mg, n=41) or placebo (n=41) for 3 months. Urinary levels of free FB1 at baseline were comparable (medium at 560.73, 574.56, and 559.09 pg/mg creatinine) for all three groups (p=0.162). Levels at urine samples collected at 1-month of the intervention was significantly decreased in the high-dose group (medium: 364.94 pg/mg creatinine; p<0.01) as compared with level in the placebo group (medium: 575.25 pg/mg creatinine). The inhibition rate is 18.95% in low-dose group and 33.62% in high-dose group. Levels of free FB1 at samples collected at 3-month of the intervention showed significant decrease in both low-dose (medium: 319.45pg/mg creatinine; p<0.01) and the high-dose (medium: 215.83pg/mg creatinine; p<0.01) groups as compared with the levels of the placebo group as well as the baseline levels. The inhibition rate is 40.18% in low-dose GTP group and 52.6% in high-dose GTP group. Levels of sphinganine (Sa), sphingosine (So), and their ratio in urine and serum samples were also evaluated in this study. These results demonstrate that supplement of GTP effectively mitigates urinary excretion of free FB1 via to be specified pathways in humans.

#### **PS 1887 Variation of Urinary Creatinine.**

H. Na and M. Yang. Sookmyung Women's University, Seoul, Republic of Korea.

Urinary creatinine has been commonly used for adjusting dilution status of urine species in biological monitoring. However, it can vary according to sex, age, race, BMI, meat intake, etc. The purposes of our study are to investigate the intra- and inter-individual variations of urinary creatinine in a sex, age and race matched subjects, and to study the impact of meat intake on the variations of urinary creatinine. We designed a diet-controlled study among the subjects who were Korean healthy females (N=9, age= 20±4 yrs, BMI 19.7±2.4 kg/m<sup>2</sup>) and measured urinary creatinine at 5 intervals during 24 hours with and without meat consumption. As results, diverse intra- and inter-variations of creatinine levels were shown in the subjects: When subjects did not take meat, the largest and smallest intra-variations in urinary creatinine ranges were detected in the subject C and G, i.e. 0.34-2.97 (Δ2.63)g/L and 0.93-1.63 (Δ0.7) g/L, respectively. In addition, creatinine levels at 5-intervals were significantly different between the highest and lowest average levels-subjects, i.e. 2.13±0.73 g/L of the subject I and 0.86±0.52 g/L of the subject A (p<0.05), respectively. With intake of meat (charcoal-grilled Korean beef tenderloin), the trend of intra-variation of urinary creatinine in each subject was not different (p=1.00 by Fisher exact test). It suggests that meat intake had little influence on intra- and inter-variation of urinary creatinine. In conclusion, our data re-emphasize that urinary creatinine must be measured in each spot urine even among the subjects who have similar age, sex, race and BMI due to its intra- and inter-variation. In the near future, the causes of intra- and inter-individual variations of urinary creatinine should be further studied.

#### **PS 1888 Cardiolipin As a Biomarker of Mitochondrial Dysfunction Associated with Parkinson's Disease.**

Y. Tyurina<sup>1,2</sup>, D. Winnica<sup>1,2</sup>, V. Kapralova<sup>1,2</sup>, V. Tyurin<sup>1,2</sup> and V. Kagan<sup>1,2</sup>. <sup>1</sup>Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Center for Free Radical and Antioxidant Health, Pittsburgh, PA.

A commonly used pesticide, rotenone, is a mitochondrial respiratory complex I inhibitor capable of selective oxidation of mitochondrial phospholipid, cardiolipin (CL). Given that rotenone exposure is associated with the development of

Parkinson disease (PD), we hypothesized that CL peroxidized molecular species accompanying mitochondrial dysfunction may represent a new biomarker of PD. In this study, we used circulating lymphocytes isolated from human blood and found that rotenone (50-250 $\mu$ M, 12-18h) caused apoptosis (phosphatidylserine externalization, caspase 3/7 activation), reactive oxygen species production (superoxide, H<sub>2</sub>O<sub>2</sub>), mitochondrial dysfunction (inactivation of complex I, decrease of mitochondria membrane potential, depletion of ATP) and activation of peroxidase activity of mitochondria. Using an oxidative lipidomics approach, we found that treatment of lymphocytes with rotenone resulted in accumulation of monolysio-CL and oxygenated free fatty acids. In addition we were able to detect oxygenated molecular species of tetra-linoleyl CL, a major CL molecular species in lymphocytes. Notably, molecular species of oxygenated CL formed in human lymphocytes were similar to those formed in cyt c driven reaction in the presence of H<sub>2</sub>O<sub>2</sub> – in line with the known participation of cytochrome as a catalyst of CL peroxidation during apoptosis. Using the combination of lipidomics and oxidative epitope-targeted enzymatic digestion of oxidized tetralinoleoyl-CL we found that its oxygenated LA species were represented by hydroxy- and hydroperoxy-derivatives. Thus, we conclude that CL and its oxygenation products and metabolites may represent a new biomarker of rotenone-induced mitochondrial dysfunction associated with PD. Supported by NIOSH OH008282; NIH ES020693, U19 AI068021, HL70755.

**PS 1889 Evaluation of Insulin-Like Growth Factor Acid-Labile Subunit As a Novel Biomarker of Effect to the Mycotoxin Deoxynivalenol.**

B. Flannery<sup>1,2</sup>, C. J. Amuzie<sup>2</sup> and J. Pestka<sup>1,2,3</sup>, <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.

Deoxynivalenol (DON) is a trichothecene mycotoxin produced from *Fusarium* species frequently found in grain products due to its recurrent contamination and resistance to food processing treatments. In growing experimental animals, chronic low-level DON exposure has resulted in anorexia, weight suppression and growth hormone axis perturbations. As a result, children are thought to be especially sensitive to DON. Though a biomarker of exposure exists to measure DON exposure in humans, no biomarker of effect is currently available to predict the adverse negative weight effects of DON, thereby hindering complete risk assessment of this mycotoxin. Two studies were conducted to assess the potential of plasma insulin-like growth factor acid-labile subunit (IGFALS) to be used as an effect biomarker for DON. In the first study, a 9 wk dietary DON exposure was employed in mice to test the hypothesis that depression in plasma IGFALS occurs at toxicologically relevant doses prior to significant weight suppression. Results showed that the 1) NOAEL for depressed plasma IGFALS and weight was 2.5 ppm DON and 2) decreased plasma IGFALS was detectable before significant weight suppression was evident. In the second study, the specificity of reduced plasma IGFALS to DON, rather than DON-induced anorexia, was assessed using a dietary restriction study. Mice were fed ad-lib control diet, restricted control diet or identical amounts of restricted 15 ppm DON diet. Mice fed restricted DON diet exhibited significantly less plasma IGFALS than the restricted control indicating the specificity of plasma IGFALS reductions to DON. Thus, plasma IGFALS might be one suitable biomarker for predicting DON's adverse growth effects in animals and humans.

**PS 1890 Validation of a Meso Scale Discovery Immunoassay for KIM-1 Renal Biomarker in Cynomolgus Monkey (*Macaca fascicularis*) Urine.**

D. Fix and W. J. Reagan. *Drug Safety, Pfizer, Groton, CT.* Sponsor: J. Aubrecht.

The purpose of this study was to validate an immunoassay for detection of Kidney Injury Molecule 1 (KIM-1) in the urine of cynomolgus monkeys (NHP). Monkeys were treated with escalating doses of a compound that induced tubular degeneration/regeneration as determined by histopathology. Urine was collected pre-dose, 16 days post dose and 21 days post dose and urine with low, medium and high values of KIM-1 were used to validate the Meso Scale Discovery (MSD) Human KIM-1/TIM-1 (single-plex) immunoassay kit as this kit cross reacts with NHP KIM-1. Additional urine from older colony monkeys as well as normal younger NHPs were also used to establish a preliminary observed range (<0.01ng/mL). We determined intra-assay (7.7% CV) and inter-assay precision (24.5% CV), limit of blank (0.000331ng/mL), limits of quantitation (0.01ng/mL to 10ng/mL), dilutional linearity (not linear when diluted), recovery (84.8% - 122.8%), preliminary quality control range evaluation (0.438ng/mL/ CV 18.7%; 0.615ng/mL/ CV 16.8%), freeze/thaw (F/T) stability out to 4 F/T cycles (95.5% - 112.5%), and sample storage stability out to 10 weeks. There was also a good biologic correlation with time and dose-dependent increases in KIM-1 for the toxicity

study samples. All parameters measured showed acceptable immunoassay assay performance except dilutional linearity. Based on this assay performance and the other results obtained, the validated method is robust and can be performed under good laboratory practice conditions to support nonclinical studies to assess for renal toxicity.

**PS 1891 Evaluation of a Three-Dimensional Oral Cell Model for the Assessment of Tobacco Products.**

W. Fields, K. Fowler and B. R. Bombick. *R. J. Reynolds Tobacco, Company, Winston-Salem, NC.* Sponsor: S. Theophilus.

Oral disease is frequently associated with viral and environmental exposures as well as oral hygiene. The goals of this study were to evaluate the impact of smokeless tobacco extracts (STE) and cigarette total particulate matter (TPM) on cell survival, oxidative stress, inflammatory response and tissue integrity using three-dimensional cultures of human buccal (EpiOral™) cells.

EpiOral™ cells were treated with extracts of 1S2 (reference dry snuff), 2S3 (reference moist snuff) and a smokeless tobacco blend prepared in complete artificial saliva (CAS) as well as with TPM from Kentucky Reference 3R4F cigarette (DMSO-based) for time points through 24 hours. Toxicity was assessed with the lactate dehydrogenase (LDH) assay. Glutathione (GSH) measurement and histological analyses were used to assess oxidative stress and changes in tissue integrity, respectively. Gene expression analyses were also conducted via QRT/PCR and multiplex cytokine testing.

Dose- and time-dependent release of LDH was observed for all test articles. The optimal exposure time appears to be 12 hours where 3R4F TPM elicited up to a 3-fold increase in LDH release; the 1S2 and 2S3 extracts yielded a 2-fold increase while no increase was observed for the smokeless tobacco blend. Tissue integrity was slightly disrupted by TPM exposure, while no impact was observed for the STEs.

Oxidative stress as measured by GSH analysis was not apparent for any of the test articles; however, altered inflammatory response was observed by changes in IL-1 $\alpha$  and G-CSF cytokine release and modulations in at least one of the following genes, IL-1 $\alpha$ , TNF $\alpha$  or COX-2. The test articles also induced increases in cellular stress and xenobiotic metabolism as determined by changes in HO-1, HSP-70, CYP1A1 and CYP1B1.

Collectively, the data suggest that the EpiOral™ three-dimensional human cell culture model may be useful in evaluating tobacco extracts.

**PS 1892 Assessment of Cardiac Biomarkers in Cynomolgus Macaques.**

T. Parman, N. Chini, D. Vuong, M. Patrick, B. Schneider, K. Tinajero, L. Tang, D. Fairchild, K. Lopez and J. C. Mirsalis. *SRI International, Menlo Park, CA.*

A number of new cardiac biomarkers have recently been developed for use in rodents; however, there are no validated cardiac biomarkers suitable for use in nonhuman primate (NHP) studies. We previously reported results of cardiac markers in African green monkeys (AGM) and Rhesus macaques (RM). In the current study we have extended these evaluations to Cynomolgus macaques (CM), the most widely used NHP species for toxicity studies. Two CM/sex were given a single subcutaneous (sc) injection of isoproterenol (IPT; 4 mg/kg); 1 CM/sex received sc saline. Cardiac effects of IPT were observed within 1 hr postdose and included hypotension, ventricular premature complexes, ventricular bigeminy, atrial premature complexes, with or without aberrant conduction and ST segment elevation. Blood samples were collected prestudy and at 1, 4, 24, 48 and 72 hr postdose, and evaluated with MSD MIP-1 muscle injury kits (rat: cTnI, cTnT, FABP3, Myl3, sTnI; human: TNI). IPT produced significant increases in the level of most cardiac biomarkers: cTnT, FABP3, Myl3, sTnI and human cTnI were increased over predose levels by 4.2-, 2.5-, 25-, 28- and 23-fold, respectively, with peak times ranging from 4 to 48 hours. Similar results were seen in females, though rat cTnI was not increased in males, but a 4.9-fold increase was seen in females. At 72 hr postdose, there were still elevations in Myl3 and sTnI. IPT plasma levels at 1 hr postdose were higher in males (708 ng/ml) than in females (324 ng/ml) and fell to 324 and 102 ng/ml at 4 hr in males and females, respectively. Heart histopathology 3 days postdose revealed minimal to moderate cardiac myofiber degeneration, myofiber karyomegaly and leukocyte infiltration in all treated animals. These results indicate that the MSD rat and human muscle injury panel provides excellent sensitivity for assessing cardiac effects in CMs, and these data are consistent with the utility of these kits previously reported in RM and AGM. Work supported by NIAID Contract N01-AI-70043.

**PS 1893 A Comparative Study on Renal Toxicity of Industrial Chelates Using Novel Urinary Protein Biomarkers As Early Predictors of Nephrotoxicity.**

R. Krishnaraj<sup>1</sup>, E. C. Bisinger<sup>1</sup>, N. Edgerton<sup>2</sup>, D. E. Dodd<sup>2</sup> and J. Mapes<sup>3</sup>.  
<sup>1</sup>AlzoNobel Services, Inc., Chicago, IL; <sup>2</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>Myriad RBM, Inc., Austin, TX.

Toxicogenomic approaches have identified protein biomarkers of renal cell injury/repair as early predictors of renal toxicity prior to changes in renal histopathology. We used these novel biomarkers to determine if rats orally dosed with industrial chelates exhibited altered urinary biomarker levels that preceded histopathologic changes in kidney. The nephrotoxicant/renal carcinogen, nitrilotriacetic acid (NTA), is known to cause rat proximal tubule cell injury/repair (3–7 weeks) followed by renal tumors (2 years) after oral dosing. A new, readily biodegradable chelate, L-glutamic acid diacetic acid (GLDA), previously which showed no significant microscopic renal changes (90-day, oral), and EDTA, known non-carcinogen (oral bioassay) were also included in our study. Male Wistar rats were gavaged daily (oral, 28 days, 1000 mg/kg/day; n=10/group) with Na<sup>+</sup> salts of these chelates. As expected, mean urinary levels of Na<sup>+</sup> & Zn<sup>2+</sup> were elevated in all chelate-treated groups. Two rats in NTA group were euthanized as moribund on Day 13. The surviving NTA group showed decreases in mean body weights, food and water consumption, and urine Mg<sup>2+</sup>, and increases in the mean levels of urine Ca<sup>2+</sup>, total protein, lactate dehydrogenase, kidney injury molecule-1 (Kim-1), Clusterin (CLU) and increased proximal tubule cell proliferation (BrdU). No such changes were seen with GLDA. Kim-1 and CLU are inducible kidney proteins and are approved by FDA as predictive, early and noninvasive urinary biomarkers of kidney cell injury/repair. At necropsy, bilateral kidney enlargement (mean relative kidney weights) was noted with NTA, but not GLDA. In conclusion, our study showed that NTA, but not GLDA or EDTA, caused significant early renal cell toxicity when evaluated with urinary protein biomarkers as early predictors of nephrotoxicity.

**PS 1894 Identifying Biomarkers of Kidney and Liver Toxicity by Integrating Toxicogenomics Datasets with Biological Networks.**

P. Hewitt<sup>1</sup>, T. C. Fuchs<sup>1</sup>, R. B. Russell<sup>2</sup>, D. Mitic<sup>2</sup> and G. Apic<sup>2</sup>. <sup>1</sup>Merck KGaA, Darmstadt, Germany; <sup>2</sup>Cambridge Cell Networks Ltd., Cambridge, United Kingdom.

The aim of this study was to identify candidate biomarkers of kidney toxicity by interrogating transcriptome profiles from hundreds of publicly available toxicogenomics datasets and to test the findings with additional *in vivo* studies. We manually annotated 34,837 toxicogenomics observations from over 345 articles. Additionally, raw transcriptomics datasets from the EU PredTox and Japanese TG-GATEs projects were assessed. We ranked biomarkers by a combination of scores: 1) presence of the datasets where biomarkers were sought (e.g. nephrotoxicity); 2) absence in control datasets (e.g. other toxicities); 3) network centrality within the dataset (by exploiting, curated dataset of interactions between protein, gene and chemicals, which considers the nature of the interaction and its confidence; 4) previously observed presence of the protein coded by the gene in urine or blood samples. Application of these approaches to the three datasets identifies 43 significant candidates (of 1273 genes identified at least once in a kidney array) including NGAL, HAVCR1 (Kim-1) and clusterin and several new candidates. These findings correspond to tests performed on model nephrotoxic compounds (cisplatin (0.3 and 0.6 mg/kg), vancomycin (50 and 300 mg/kg) and puromycin (10 and 30 mg/kg)) using whole genome expression profile experiments [Illumina RefSeq] both *in vivo* (Rat; 3, 7, 14 and 28 days) and *in vitro* (rat NRK cells; 24 and 72h), and a battery of biomarker detection assays in urine. Four of the six best kidney toxicity biomarker candidates identified by these experiments were among the 43 candidates above. Overall, the results demonstrate that our *in silico* approach can greatly enrich candidates for those likely to be true biomarkers when given large datasets of dysregulated genes.

This project was funded by the German Federal Ministry of Education and Research (BMBF) under the BioRhine-Neckar Spitzencluster (BioRN-BMC-TP08).

**PS 1895 Evaluation of Novel Biomarkers of Nephrotoxicity in Monkeys Treated with Gentamicin.**

J. Gautier<sup>1</sup>, X. Zhou<sup>2</sup>, Y. Yang<sup>3</sup>, T. Gury<sup>1</sup>, Z. Qu<sup>2</sup>, J. Léonard<sup>1</sup>, J. Wang<sup>2</sup>, P. Detilleux<sup>1</sup> and B. Li<sup>2</sup>. <sup>1</sup>Preclinical Safety, Sanofi, Vitry-sur-Seine, France; <sup>2</sup>National Center for Safety Evaluation of Drugs, Beijing, China; <sup>3</sup>Preclinical Safety, Sanofi, Shanghai, China.

Most studies to evaluate renal safety biomarkers have been performed in rats. This preliminary study was conducted in cynomolgus monkeys to define the optimal conditions to evaluate the potential usefulness of novel biomarkers of nephrotoxicity in this species. Groups of 3 males were given daily intramuscular injections of 10, 25, 50 mg/kg/day gentamicin, a known nephrotoxic agent, for 10 days and 75 mg/kg/day for 9 days and were sacrificed on Day 10 or 11. Blood samples and 16-hour urine samples were collected on Days -7, -3, 2, 4, 7 and at the end of the dosing period. In parallel to conventional parameters, the novel urinary renal biomarkers evaluated (after normalization to urinary creatinine) included  $\alpha$ 1-microglobulin, microalbumin, clusterin and calbindin. Kidney microscopic findings consisted in dose dependent increase in tubular cell degeneration/necrosis from minimal to mild at 10 mg/kg/day, moderate at 25 mg/kg/day, to severe at 50 and 75 mg/kg/day gentamicin. Serum creatinine was slightly increased at 10 mg/kg/day on Day 11 (less than 25% increase as compared to pre-test values in each individual animals), moderately increased (2-fold) at 25 mg/kg/day on Day 11, and markedly increased (more than 2-fold) at 50 and 75 mg/kg/day from Day 7. Parallel increases were observed with BUN. Urinary  $\alpha$ 1-microglobulin was increased by 4.5-fold and microalbumin, clusterin, calbindin were increased by more than 20-fold as compared to pre-test values in each individual animals at 10 mg/kg/day on Day 11. Marked increases in these urinary biomarkers were also observed at higher doses of gentamicin from Day 7. These first results indicate that the urinary biomarkers  $\alpha$ 1-microglobulin, microalbumin, clusterin and calbindin may be useful sensitive biomarkers of nephrotoxicity in monkeys and potentially in humans.

**PS 1896 Restricted Diet Prevents Negative Effects of OVX on Soft Tissue Composition.**

R. Samadfam and S. Y. Smith. Bone Research, Charles River, Montréal, QC, Canada. Sponsor: M. Vézina.

Ovariectomy (OVX) in rats is associated with weight gain and loss of bone mass. The increased body weight is in part attributed to increases in growth, consistent with OVX-induced hyperphagia. The objective of this study was to determine the effects of OVX on body composition in aged rats (over 6 months of age) with or without food restriction. PMI Nutrition International diet was used for all animals with animals assigned to the restricted diet groups receiving 21 g/day. Body composition was evaluated at baseline and at 4, 8, 12 and 19/20 weeks post surgery using DXA (Dual Energy X-ray Absorptiometry) and/or pQCT (Peripheral Quantitative Computed Tomography). DXA evaluation showed increases in whole body area and BMC for OVX rats on both restricted and unrestricted diet compared to their corresponding sham controls, with greater increases for animals fed *ad libitum*. Overall, BMD for OVX groups were comparable to baseline values whereas increases up to 2 and 6% were noted for sham controls respectively on the restricted and fed *ad libitum*. Significant increases were noted over the study period in muscle mass for rats on restricted diet, with trends for increases in fat mass. For *ad libitum* fed rats, although an increase in muscle mass was noted 4 weeks following surgery compared to sham controls, muscle mass gradually declined over the remaining study period with lower values 20 weeks post surgery. Fat mass increased for this group. When muscle mass and fat mass values were adjusted for body weight, no significant differences were noted between OVX and sham controls for animals on the restricted diet, indicating that the increased body weight is the result of proportional increases in muscle and fat mass, likely related to the effect of OVX on skeletal growth. For animals fed *ad libitum*, significant decreases in lean mass with significant increases in fat mass were noted when adjusted for body weight, compared to sham controls, indicating negative effects on soft tissue composition. Data from the restricted diet group suggest that calorie restriction prevents OVX-induced muscle loss and fat gain.

**PS 1897 3, 3', 4, 4', 5-Pentachlorobiphenyl (PCB 126) Decreased the Ratios of Epoxide Metabolites to Their Corresponding Diols in Male Rodents.**

X. Wu<sup>1</sup>, J. Yang<sup>2</sup>, C. Morisseau<sup>2</sup>, L. W. Robertson<sup>1</sup>, B. D. Hammock<sup>2</sup> and H. Lehmler<sup>1</sup>. <sup>1</sup>Department of Occupational and Environmental Health, University of Iowa, Iowa City, IA; <sup>2</sup>Department of Entomology, University of California Davis, Davis, CA.

Oxylipins are oxygenated metabolites of certain fatty acid species. Changes in the homeostasis of these regulatory lipid mediators are of interest as markers of exposure to certain toxicants, including the aryl hydrocarbon receptor agonist 3,3',4,4',5-pentachlorobiphenyl (PCB 126). Here we test the hypothesis that chronic exposure to PCB 126 alters the levels of regulatory lipid mediators (oxylipins) in rats. Male Sprague-Dawley rats (5 weeks old) were treated biweekly with injections of PCB 126 in corn oil over a period of 3 months, representing cumulative PCB doses of 0, 0.06, 0.3, and 1.2 µg/kg body weight. PCB 126 treatment caused a dose-dependent reduction in growth and relative thymus weight, while relative liver weight was increased with PCB dose. PCB 126 levels in the liver increased in a dose-dependent manner, while PCB 126 levels in plasma were below the detection limit. The ratios of epoxide/diol metabolites displayed a dose-dependent decrease in plasma for oxylipins derived from arachidonic acid (ARA), eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA) and linoleic acid (LA), as determined by metabolomics profiling of oxylipins with liquid chromatography-tandem mass spectrometry. Similarly, the epoxide/diol ratios for ARA and DHA derived oxylipins decreased in a dose-dependent manner in the liver. The effects of PCB treatment on epoxide/diol ratios were associated with significantly increased activities of soluble epoxide hydrolase (sEH) in cytosol and peroxisomes in the liver at the highest PCB 126 dose. Since increased sEH activity and decreased epoxide/diol metabolites ratios have been linked to cardiovascular disease and inflammation, our results suggest that changes in oxylipin plasma levels may be useful biomarkers of human exposure to PCB 126 and other dioxin-like compounds [supported by NIH grants ES04699 and ES013661].

**PS 1898 Identification of Neural Biomarkers of Altered Sexual Differentiation following Gestational Exposure.**

G. W. Louis<sup>1,2</sup>, D. R. Hallinger<sup>1</sup> and T. E. Stoker<sup>1</sup>. <sup>1</sup>Endocrine Toxicology Branch, Toxicity Assessment Division, US EPA, Research Triangle Park, NC; <sup>2</sup>ORISE Program, Department of Energy, Oak Ridge, TN.

Sexual differentiation of the brain occurs during late gestation through the early postnatal period. The development of the phenotypical male brain is dependent on the aromatization of circulating testosterone to estradiol. Exposure to endocrine disrupting chemicals (EDCs) during early-life alters sexual maturation of the rat hypothalamic-pituitary-gonadal axis and subsequently, the timing of puberty and adult reproductive behavior. We set out to identify predictive neuronal biomarkers for use in evaluating the effect of EDCs on sexual differentiation in the male and female. We examined changes in gene expression in the rat hypothalamus [(specifically, in the anteroventral periventricular nucleus (AVPV) and arcuate nucleus (ARC)] after in utero exposure to the aromatase inhibitor, letrozole. Pregnant dams were gavaged with vehicle or letrozole (0.1mg/kg) on gestational days 20 and 21. The AVPV and ARC were microdissected from male and female offspring on several pre-, peri-, and post-pubertal postnatal days (PND) and were evaluated for changes in expression of a number of neuropeptides that have sex specific patterns during development. These genes include those that encode for kisspeptin (Kp) and tachykinin-2 (Tac2). We identified an increase with age in the expression of Kp in the AVPV of the genetic female, but not the genetic male. Kp expression in the AVPV of the letrozole-exposed genetic male was increased to the same level observed in the genetic female on PND 14, 25 and 49. However, Kp expression in the male ARC was not altered by letrozole. ARC Tac2 expression in the male was also not changed by letrozole. This work will provide optimal time points for these measures, but additional studies are needed to determine whether these, and other CNS biomarkers, are predictive of altered puberty and/or sexual behavior due to early-life EDC exposure. *This abstract does not necessarily reflect EPA policy.*

**PS 1899 Biomarkers of Exposure and Effect in Long-Term Smokers and Moist Snuff Consumers.**

B. A. Jones<sup>1</sup>, G. L. Prasad<sup>1</sup>, P. Chen<sup>1</sup> and D. W. Graff<sup>2</sup>. <sup>1</sup>R & D, RJ Reynolds Tobacco Co., Winston-Salem, NC; <sup>2</sup>Celerion, Lincoln, NE. Sponsor: G. Krautner.

To assess the effects of chronic exposure to combustible and non-combustible tobacco product use, a single site, cross-sectional clinical study was conducted. Three cohorts of healthy males (40/cohort, 35-60 years) were enrolled: long-term smokers

and moist snuff consumers (MSC), and non-tobacco consumers (NTC). Select biomarkers of exposure (BioExp) and potential biomarkers of effect (BioEff) indicating oxidative stress, inflammation and metabolomic changes, among others, were investigated. Blood biomarkers were measured in subjects abstaining overnight from both food and tobacco, and urinary biomarkers were measured in ambulatory collections of 24h urine samples. Nicotine (and its metabolites) and total tobacco specific nitrosamines (TSNAs) were higher in MSC followed by smokers and NTC. Tobacco combustion-related BioExp (polycyclic aromatic hydrocarbons, aromatic amines and mercapturic acid metabolites) were significantly higher in smokers, with no difference observed between MSC and NTC cohorts. Compared to NTC and MSC, smokers exhibited significantly elevated levels of biomarkers associated with oxidative stress, inflammation, and platelet activation. Smokers also exhibited significantly higher levels of apolipoprotein B100 and oxidized low-density lipoprotein relative to NTC and MSC. Thus, alterations in BioEff suggesting inflammation, oxidative stress and altered lipid metabolism were detected in smokers compared to the non-smoking cohorts. In summary, our findings are in agreement with existing epidemiological data which show the reduced harm from smokeless tobacco consumption compared to smoking, with no-tobacco-use being the least risky. The BioExp and BioEff evaluated in this study are likely to be useful in future assessments of the health effects of new tobacco products.

**PS 1900 Mechanistic Biomarkers Provide Early Detection of Acetaminophen-Induced Acute Liver Injury at First Presentation.**

D. Antoine<sup>1</sup>, C. Goldring<sup>1</sup>, P. Starkey-Lewis<sup>1</sup>, J. Dear<sup>2</sup>, J. Moggs<sup>3</sup>, V. Platt<sup>1</sup> and B. Park<sup>1</sup>. <sup>1</sup>MRC Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom; <sup>2</sup>NPIS Edinburgh, University of Edinburgh, Edinburgh, United Kingdom; <sup>3</sup>Preclinical Safety, Novartis Institutes for Biomedical Research (NIBR), Basel, Switzerland. Sponsor: D. Mendrick.

We investigated the potential of a panel of novel biomarkers - which demonstrate either enhanced liver expression or are linked to the mechanisms of toxicity - to identify patients with paracetamol (acetaminophen)-induced acute liver injury at first presentation to hospital when current liver injury markers are normal. In plasma samples from patients (n=129), at first presentation to hospital following paracetamol overdose, we measured microRNA-122 (miR-122; high liver specificity), High Mobility Group Box-1 (HMGB1; marker of necrosis), full length and caspase-cleaved Keratin-18 (K18; markers of necrosis and apoptosis, respectively) and glutamate dehydrogenase (GLDH; marker of mitochondrial dysfunction). In all patients, the biomarkers at first presentation significantly correlated with peak ALT/INR (International Normalized Ratio). In patients with normal ALT/INR at presentation, miR-122, HMGB1 and necrosis K18 identified the development of liver injury (n=15) or not (n=84) with a high degree of accuracy, and significantly outperformed ALT activity, INR and plasma paracetamol concentration for the prediction of subsequently liver injury (n=11) compared with no injury (n=52) in those patients presenting within 8 hours of overdose. Elevations in plasma miR-122, HMGB1, and necrosis keratin-18 identify subsequent development of acute liver injury in patients on admission to hospital, soon after paracetamol overdose, and in patients with ALTs in the normal range. The clinical development of such a biomarker panel could improve the speed of clinical decision making, both in the treatment of acute liver injury and in the design/execution of new treatment strategies that aim to refine the management of this common poisoning.

**PS 1901 Lead Concentrations Correlation between Fingernails and Whole Blood.**

K. P. Olympio<sup>1</sup>, C. A. Cardoso<sup>2</sup>, M. C. Rodrigues<sup>2</sup>, I. Ramires<sup>2</sup>, M. S. Luz<sup>3</sup>, L. G. Albuquerque<sup>3</sup>, F. Barbosa<sup>4</sup>, M. A. Cardoso<sup>1</sup>, P. V. Oliveira<sup>3</sup>, W. R. Günther<sup>1</sup> and M. A. Buzalaf<sup>2</sup>. <sup>1</sup>Faculdade de Saúde Pública - USP, São Paulo, Brazil; <sup>2</sup>Faculdade de Odontologia de Bauru - USP, Bauru, Brazil; <sup>3</sup>Instituto de Química - USP, São Paulo, Brazil; <sup>4</sup>Faculdade de Ciências Farmacêuticas - USP, Ribeirão Preto, Brazil.

Whole blood has been the biological fluid of choice to assess lead exposure. Other biomarkers need to be studied deeply, and the analysis of trace metals concentrations in nails is a non-invasive and simple collection procedure. The aim of this study was to investigate possible correlations between blood lead levels (BLL) and washed and non-washed fingernails lead levels (FLL) in 55 adults living in a lead contaminated area. Venous blood and fingernails (thumbs and forefingers) samples were collected. The nails of the left hand were washed with acetone and HCl 0.1 mol/L and the nails from right hand were not submitted to any pre-analytical procedure. Samples were analyzed by GF AAS and pairwise correlations were used to correlate lead concentrations between: BLL and FLL; nails from fingers from the

same hand and between washed and non-washed fingernails. It was found a non-significant correlation between BLL and washed forefinger nails lead ( $r=0.219$ ,  $p=0.112$ ) and between BLL and thumb nails lead ( $r=0.182$ ,  $p=0.191$ ). Comparing fingernails from the same hand (thumb and forefinger), lead concentrations of non-washed nails varied largely, even when transversal fragments from the same nail were analyzed. Lead concentrations in non-washed forefingers nails were not found to be correlated with non-washed thumb nails ( $r=0.169$ ,  $p=0.219$ ). On the other hand, for washed nails, thumb and forefinger nails were found to be correlated ( $r=0.39$ ,  $p=0.003$ ). In conclusion, the results showed that non-washed nails are not a reliable biomarker for lead exposure. However, although washing up the nails may diminish the lead external contamination, the correlation between fingers is still weak to consider fingernail as a biomarker to lead exposure. In addition, even the washed nails were not found to be significantly correlated to BLL.

## PS 1902 Detecting and Quantifying Endogenous and Exogenous Formaldehyde Adducted Hemoglobin Utilizing Selected Reaction Monitoring.

G. L. Andrews Kingon<sup>1</sup>, B. C. Moeller<sup>1</sup> and J. A. Swenberg<sup>1,2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Widely recognized as a highly toxic compound, formaldehyde (FA) is considered to be a known animal and human carcinogen. It is ubiquitously present through normal cellular metabolism as well as from environmental pollutants. This compound is highly reactive towards macromolecules, forming diverse protein adducts and DNA damage that can be employed as biomarkers of chemical exposures. In particular, hemoglobin and red blood cells (RBCs) exposed to FA have been shown in laboratory studies to form an imidazolidone-type structure on the N-terminal peptides of hemoglobin alpha and beta chains. This data and the long lifetime of hemoglobin in RBCs (63 days in rats and 120 days in humans) afford investigation of the formation of endogenous and exogenous FA-hemoglobin adducts and the accumulation and loss of adducts. Monitoring this biomarker may reveal if inhaled FA enters the systemic circulation and reaches distant sites. In order to differentiate the origin of FA (endogenous versus exogenous), 10 ppm [<sup>13</sup>CD<sub>3</sub>]-FA rat inhalation exposures of 6 hours/day for 1 or 5 days were performed and globin was isolated from the washed RBCs. Stable isotope labeled peptides for the alpha and beta chains of hemoglobin were synthesized and purified then reacted with FA to achieve the imidazolidone modification. These internal standards were then spiked into the globin samples prior to trypsinization and off-line fractionation. Utilizing protein cleavage isotope dilution mass spectrometry and selected reaction monitoring, methods were developed for quantification of the N-terminal valine FA hemoglobin adduct peptides. In vitro reactions of RBCs and FA are ongoing to determine penetration of the chemical into the RBCs and biomarker stability following exposure. Additional globin samples from exposed and control rats and nonhuman primates have been collected and analyses are in progress.

## PS 1903 Assessment of the Relative Performance of Ten Urinary Biomarkers for Renal Safety across Twenty-Two Rat Toxicology Studies.

Z. Erdos, K. Vlasakova, H. Jin, K. McNulty, L. Phadtare, V. Chapeau, N. Mokrzycki, S. P. Troth, N. Muniappa, E. Wang, D. Holder, W. J. Bailey, F. D. Sistare, W. E. Glaab and Y. Gu. Safety Assessment and Laboratory Animal Resources, Merck Research Laboratories, West Point, PA.

Novel kidney injury markers have been recently identified which may outperform or add value to the conventional kidney injury biomarkers blood urea nitrogen (BUN) and serum creatinine. To assess the relative performance of the growing list of these novel biomarkers, a comprehensive evaluation was conducted for 10 urinary biomarkers in 22 rat studies including both kidney toxicants and compounds with toxicities observed only in other organs. Furthermore, these kidney toxicity studies included proximal tubule toxicants as well as glomerular toxicants. The ten urinary biomarkers evaluated included Kim-1, Clusterin, Osteopontin, Osteoactivin, Albumin, Lipocalin-2, GST-alpha,  $\beta$ 2-Microglobulin, Cystatin C, and Retinol Binding Protein 4 using novel immuno-based assays developed on the MesoScale platform. Receiver operator characteristic (ROC) curves were employed as the main criteria to compare the performance of this panel of biomarkers in individual study animals against the microscopic histomorphologic changes observed. Of the kidney toxicity studies analyzed, Kim-1, Clusterin, and Albumin showed the highest overall sensitivity for detecting tubular injury, while Albumin exceeded all other markers in detecting glomerular injury. The data presented here represents a comprehensive parallel analysis of the performance of leading renal biomarker candidates, and further demonstrates that this multiplexed approach enhances the ability to monitor drug-induced renal injuries as well as provide insight to linkages between individual biomarkers and specific histopathologic processes.

## PS 1904 Drug-Induced Kidney Injury Urinary Biomarker Response in Rats after Treatment with Nonnephrotoxicants.

L. Besenhofer, M. Wagoner, L. Cheatham, F. McGrath, P. Bentley, J. Fikes and L. B. Kinter. Safety Assessment US, AstraZeneca, Waltham, MA.

Drug induced kidney injury (DIKI) biomarkers are important tools with which to monitor and diagnose acute and chronic kidney injury. Qualification of the biomarkers for use in nonclinical studies requires an understanding of the DIKI biomarker profile after treatment with nephrotoxicants and non-nephrotoxicants to fully understand the potential for false positives in future studies. Renally-acting pharmacotherapies were used in this study to investigate the renal biomarker profile of non-nephrotoxicant drugs. Diuretic drugs were chosen to target specific nephron segments including furosemide (Loop of Henle), hydrochlorothiazide (distal tubule), spironolactone (collecting duct), and erythritol (pan-nephron). Male and female Han-Wistar rats ( $n=10$ ) were treated orally for 14 days and biomarker excretion was measured on days 1, 8, 15 and 22 (recovery groups,  $n=5$ ). Data were normalized to urine creatinine and then to control levels. There were no significant differences between controls and treated rats in excretion of any of the eight biomarkers assessed including: alpha-glutathione-s-transferase ( $\alpha$ GST), mu-GST, renal papillary antigen-1 (RPA-1), clusterin, albumin, lipocalin-2, osteopontin and kidney injury molecule-1 (KIM-1). Osteopontin excretion in female rats and clusterin excretion in male rats were the most variable with up to 19.1 and 9.9 fold differences from controls, respectively, despite mean values being roughly equivalent to vehicle controls. The results from this study indicate that diuretic treatment affecting different portions of the nephron does not result in increased biomarker signal. As such, the likelihood of obtaining false positive results due to physiological differences in animals in nonclinical safety screening studies is minimal.

## PS 1905 Urinary Biomarker Response to Hepsera-Induced Kidney Toxicity in Rats.

Y. Yang, S. Morgan, C. Thompson, D. Desmond, D. Zhao, R. Yeager and E. Blomme. Abbott Laboratories, Abbott Park, IL.

Hepsera (adefovir dipivoxil) is an acyclic nucleoside phosphonate analog approved for treatment of hepatitis B infection. It is associated with renal tubular toxicity in rats and monkey, and has dose-limiting nephrotoxicity in the clinic. The purpose of this study was to evaluate urinary biomarker response for Hepsera-induced kidney toxicity in rats. Male Sprague-Dawley rats were first administered Hepsera at 20, 40 and 60 mg/kg/day orally for 14 days. Minimal to mild tubular degeneration was observed at 20 mg/kg/day with increased severity at 40 and 60 mg/kg/day. There were no changes in BUN or serum creatinine. In contrast, urinary biomarkers (KIM1, albumin, NAGL, and osteopontin) were dose-dependently elevated. To further investigate the time-course of the biomarker changes, male and female rats were treated with 20 mg/kg/day Hepsera for 1, 2, 4 weeks with 4 weeks of recovery. Tubular degeneration was observed with males more affected than females. This was first observed on Day 8 (minimal) and increased in incidence and severity with longer duration of dosing. Renal histopathology was still present at the end of recovery in males. There were no changes in BUN, while serum creatinine was slightly increased in males on Days 16 and 29. In males, urinary KIM1, beta2-microglobulin (B2M), albumin, and NGAL were increased (2.5-37 fold) on Days 16 and 29. NGAL and B2M levels were still elevated after 29 days of recovery in contrast to KIM1 and albumin levels. Similar changes were observed in females on Day 29, but not on Days 8, 16 or recovery Day 29. These results indicate that urinary biomarkers can be more sensitive for Hepsera-induced kidney toxicity than BUN and serum creatinine.

## PS 1906 Novel Noninvasive Biomarker of Irradiation-Induced Gastro-Intestinal Injury.

A. Banerjee<sup>1</sup>, N. Sieracki<sup>2</sup>, A. Zakharov<sup>1</sup>, M. Bonini<sup>2</sup> and A. Lyubimov<sup>1</sup>. <sup>1</sup>Toxicology Research Laboratory, UIC, Chicago, IL; <sup>2</sup>Pharmacology, UIC, Chicago, IL.

A non-invasive early marker of radiation induced gastro-intestinal (GI) injury continues to be in high demand. Hence, our aim was to establish a novel fecal biomarker of GI damage in mouse models which can be further extrapolated for use in non-human primates as well as in humans. A Reactive Nitrogen Species (RNS)-detector compound NMAA-1 was established as a novel GI irritation/oxidative stress biomarker in an irradiated mouse model. NMAA-1 is a small molecule, which upon reaction with peroxynitrite (ONOO<sup>-</sup>) produces cleaved NMAA-1. The ability of NMAA-1 to detect ONOO<sup>-</sup> selectively and in a concentration-dependent manner in aqueous solution and in living cells is known. We exploited this selectivity in the quantification of NMAA-1 and cleaved NMAA-1 in feces of mice with irradiation-induced GI damage. C57Bl/6 mice were irradiated at a high lethal dose of

13Gy or at a LD<sub>70/30</sub> of 8.1Gy in two independent experiments using a Cs<sup>137</sup> source. NMAA-1 was administered at 40-60 µM per animal via oral gavage without any signs of toxicity. Fecal samples were collected from the irradiated and non-irradiated control mice at different time points (pre-dose, 4, 6 and 8 hr post dose) prior to irradiation and also on days 1, 5 and 7 post irradiation from all animals. NMAA-1 and cleaved NMAA-1 levels were measured in the feces using LC-MS/MS method. Up to a three-fold increase in the level of the marker was noted in the fecal samples collected between days 5 to 7 in mice irradiated at 13Gy as compared to the control levels with C<sub>max</sub> at about 6 hrs post dose. In case of 8.1Gy irradiation, two-fold or more increase in NMAA-1 and % cleaved NMAA-1 levels was seen in the feces until day 7. It was also observed that post irradiation the appearance of the fecal marker was moved to later time points probably due to decreased GI motility. NMAA-1 has proven to be very distinctive in its role as an indicative marker of GI damage due to radiation-induced toxicity. This promises to be an extremely important diagnostic tool for such condition and further optimization is ongoing.

**PS 1907 Exploring Challenges in Reconstructing Doses or Estimating Blood Concentrations from Urinary Biomarker Data Using a Pharmacokinetic Model for Perchlorate.**

C. Tan, M. B. Phillips and J. Sobus. *US EPA ORD NERL, Research Triangle Park, NC.*

Many human biomarkers of current-use environmental chemicals are measured in urine. While urinary biomarkers are easier to collect than others (e.g., blood markers), reconstructing doses from urinary biomarkers is challenging. In many cases there exists a complicated relationship between dose and biomarker, for example, when a common biomarker for several chemicals exists and the concentration/relative proportion of the exposures from the environment are unknown. Even when there is a simple dose-biomarker relationship, many factors can impact the interpretability of urinary biomarker data, including urine volume, time between voids, and time between dose(s) and sample collection. In this study, a physiologically based pharmacokinetic (PBPK) model of perchlorate was used to examine how these various factors impact our ability to reconstruct doses from urinary biomarkers. The selection of perchlorate was based on its simple dose-biomarker relationship: 100% oral bioavailability and 100% excretion of the parent compound in urine. First, synthetic exposure profiles (varying daily intake doses, time of exposure, etc.) were generated and used as inputs to the PBPK model for simulating three biomarker sampling protocols: random spot voids, first voids, and 24 h cumulative voids. Correlations between simulated urinary concentrations and intake doses were calculated at both the individual- and population-level to determine which sampling protocol provides a more accurate and precise intake estimate. The strongest correlations were observed between the 24 h cumulative concentrations and average daily intake. Additional considerations for the impacts of changing urine volume, time between voids, and time between exposure and sample collection showed that random spot urine samples were highly sensitive to all three factors whereas 24 h cumulative samples were less sensitive.

[This abstract has been cleared by the EPA but solely expresses the view of the authors]

**PS 1908 Fecal and Blood Biomarkers for Gastrointestinal Injury and Subsequent Recovery.**

A. Lyubimov<sup>1</sup>, Y. Chen<sup>2</sup>, J. Anwer<sup>2</sup>, A. Zakharov<sup>1</sup> and A. Banerjee<sup>1</sup>. <sup>1</sup>*Toxicology Research Laboratory, UIC, Chicago, IL;* <sup>2</sup>*Center for Biomedical Testing, Chicago, IL.*

The search for reliable, non-invasive biomarkers of gastro-intestinal (GI) injury/recovery is ongoing but so far no biomarkers as reliable as histopathology have been identified in animal models. Our aim was to establish such biomarkers in non-human primates (NHPs). Previously we established ELISA and MSD methods for lactoferrin and calprotectin measurements in NHPs feces. These methods are currently being improved by multiplexing on one MSD platform. Two new markers including intestinal and liver fatty acid binding protein (I-FABP) and L-FABP were established as markers of intestinal epithelial integrity. These are released rapidly from GI enterocytes into the blood after cellular damage. I-FABP was assayed on a MSD standard plate with a specific antibody (LLOD=5.95 pg/mL), whereas L-FABP was analyzed using ELISA (LLOD=102 pg/mL). Our MSD method for I-FABP has about 10 times lower LLOQ (9.7 pg/mL) as compared to its ELISA method (94 pg/mL). Normal ranges in NHPs plasma were established and found to be above the LLOD for both methods. These biomarkers proved to be helpful for assessment of drug therapeutic effect and potentially survival prognosis after irradiation GI damage. Additionally an LC-MS/MS method was established to estimate the systemic citrulline levels as a marker of GI injury. Citrulline is an amino acid released in circulation predominantly by the intestine enterocytes and is considered a

marker of intestinal integrity. The LC-MS/MS method works in the dynamic range of 125-125000 ng/mL (-0.7-700 µM) of citrulline concentration in plasma. The L-FABP and I-FABP changes correlated well with the citrulline levels as well as histopathology findings based on the analysis of the samples obtained from a NHP irradiation study. Further optimization of the MSD, ELISA and LC-MS/MS methods are being undertaken to provide more sensitive assays from smaller sample volume (including dried blood spot measurements) for these fecal and/or circulating biomarkers of gastro-intestinal inflammation, injury, and recovery.

**PS 1909 Clearance Rates of Organophosphate Metabolites in an Occupationally-Exposed Cohort of Farmworkers.**

Our studies in the Yakima valley of Washington state follow a cohort of 99 farmworkers (orchard workers) and 95 non-farmworkers to investigate potential exposures to organophosphate pesticides (OPs) by assaying urine samples for the 6 di-alkyl non-specific metabolites of OPs. Urine samples were collected April-June 2005 on three dates spaced two days apart when OP pesticides were being applied and workers were in the orchards. The most commonly used OP in this time period was azinphos-methyl and one of its metabolites, DMTP, had the highest concentration in urine compared to other metabolites of OPs for both farmworkers and non-farmworkers. We used a Bayesian Markov chain Monte Carlo method to estimate the joint distribution of the metabolites and clearance rates in a mixed effects model. The farmworker levels of DMTP were 19 times non-farmworkers. The clearance half-life of DMTP had a geometric mean (95% confidence interval) of 3.6 (2.5,6.0) days across all of the farmworkers (fixed effects), whereas non-farmworkers showed no clearance. The half-lives for individual farmworkers (random effects) varied between 1.5 days and no clearance. The shorter half-lives occurred in farmworkers who had higher first day concentrations of DMTP and farmworkers with no clearance with those who had lower first day concentrations. These results are consistent with a continuing variable level of occupational exposure of the farmworkers but some of the farmworkers having a higher exposure before our collection of urine. The pattern in the non-farmworkers is consistent with exposures to metabolites of OPs through diet and other routes of non-occupational exposure. Similar results were also found for DMP. (Supported by grants P01 ES009601, P30 ES007033 from NIEHS and RD-834514, RD-831709, RD-832733 from US EPA. Contents are authors' responsibility.)

**PS 1910 Assessment of MMP-3 and MMP-9 As Preclinical Biomarkers of Drug-Induced Vascular Injury.**

R. J. Gonzalez, B. Bednar, S. Lin, B. Connolly, S. Patel, G. Mesfin, T. Johnson, H. Miyazaki, W. E. Glaab and F. D. Sistare. *Merck & Co., West Point, PA.*

Drug-induced vascular injury (DIVI) continues to be a major obstacle in drug development. Attempts to correlate this observation in preclinical toxicity studies with hemodynamic changes are not always successful. Additionally, no accessible and specific biomarkers of DIVI exist, making risk assessment and monitoring in humans a challenge during drug development and regulatory approval. It has been previously reported that circulating levels of matrix metalloproteinases (MMPs), specifically MMP-3 and MMP-9, were able to distinguish between patients with active antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and remission. In order to determine whether MMPs are involved in the arterial pathology associated with DIVI observed in animal toxicology studies, a fluorescent imaging probe, MMPSenseTM, was used to measure activity of MMPs along with a fluorescent blood pooling agent, AngioSenseTM, ex-vivo in the mesenteric arteries of rats following administration of fenoldopam. Increased fluorescence in the mesenteric arteries from both imaging probes correlated well with vascular injury, as determined histologically, and was in agreement with increases in both MMP-3 and -9 expression in the affected arteries using immunohistochemical staining. To assess whether changes to circulating levels of MMP-3 and -9 respond to incidence and severity of DIVI, we compared their levels in plasma from several models of DIVI in rat, dog and monkey. Circulating levels of MMP-3 appear to correlate well with DIVI and the response is conserved across our pre-clinical species. In summary, MMPs appear to have a role in the arterial pathology associated with DIVI seen in animal toxicology studies, which is reflected in circulating levels of MMP-3 in pre-clinical species, and provide a potential accessible biomarker to monitor for DIVI in animals and in the clinic.

**PS 1911 Molecular, Cellular, and Histological Changes in Mice Living on Sand Contaminated with Coal Dust under Laboratory Conditions.**

K. Caballero-Gallardo, L. Carranza-Lopez and J. Olivero-Verbel. *Environmental and Computational Chemistry Group Pharmaceutical Sciences, University of Cartagena, Cartagena, Colombia.*

Coal mining is one of the most important economical activities in Colombia. However, few data have been gathered concerning the impact of these activities on human and ecosystem health. During coal mining and transport, different types of dust material are formed. The aim of this work was to evaluate the toxic effects associated with the exposure to total suspended particle matter fraction of coal dust (<38 µm), from a sample collected in the Loma mine, Cesar, Colombia. Washed and sterilized sand was contaminated with coal dust to obtain concentrations ranging from zero (control) to 4%. Six different mice per group were allowed to live in boxes with this bed for eight weeks with ad libitum water and food. At the end of the experiment, animals were euthanized and blood and tissues collected. Mice in contact with coal dust did not evidence significant weight or hepatosomatic changes compared to control. However, animals in the 4% coal dust group grew faster. Real Time PCR analysis revealed an increase in Cyp1A1 mRNA for animals living on sand with concentrations greater than 2% coal dust. Unexpectedly, for mice on polluted sand, SOD and MT1 hepatic mRNA were downregulated, and no changes were observed on Myc expression. The results of comet assay in peripheral blood cells, and the micronucleus test in blood smears revealed significant potential genotoxic damage at the greatest tested coal dust level. Histopathological analysis showed a dose-response relationship for the presence of hepatic necrosis, steatosis, vacuolization and nuclei enlargements in exposed animals. These results suggest that soil contaminated with coal dust induces several molecular, cellular and histopathological changes in mice. Accordingly, it is necessary to revise the current legislation on mining practices in Colombia in order to prevent health problems derived from these particles. Vice-Rectoría for Research. UniCartagena. 2011-2012. Colciencias-UniCartagena, Colombia. Grant 110749326186 (2009).

**PS 1912 Advancing Adoption of Novel Safety Biomarkers into Drug Development through Voluntary Submission of Data at US FDA, EMA, and PMDA.**

E. G. Walker, M. Brumfield and E. H. Dennis. *Critical Path Institute, Tucson, AZ.*

Regulatory science, the science of developing new tools, standards, and approaches to assess the safety, efficacy, quality, and performance of regulated medical products, has advanced over time due to a number of factors. However, many safety biomarkers used in nonclinical and clinical safety assessment in drug development have not changed in decades. Recently established channels for FDA, EMA, and PMDA to receive and evaluate scientific data supporting novel tools for use in drug development are now better defined in guidances, e.g. FDA's Draft Guidance for Industry "Drug Development Tool Qualification" and EMA's "Evaluation of novel methodologies for use in drug development." The outcome of a qualification submission to one of these regulatory agencies is a formal opinion regarding the utility of a novel drug development tool (DDT) for a particular and well-circumscribed application in the drug development process, defined within a "context of use." While recognizing that other mechanisms exist within the research community for driving scientific consensus on novel biomarkers, this study focuses on the formal regulatory qualification process. This study compares the procedure, volume and types of submissions, and proposes a framework for assessing success at FDA, EMA, and PMDA. Safety biomarkers comprise over half of the sixteen unique biomarkers qualified thus far, and are highlighted. Qualification of new safety biomarkers by regulatory agencies and subsequent adoption by drug developers is anticipated to speed therapeutic development for patients in need, build scientific consensus as to the usefulness and readiness of novel tools for understanding disease and therapeutic development, and decrease uncertainty between the regulators and sponsors regarding their appropriate application.

**PS 1913 Growth Hormone and IGF-1 Measurements in Beagle Dogs by ELISA: Assay Implementation and Variations in Baseline Levels.**

C. Gauthier, J. Leiva, G. Gonzalez and A. Nelson. *Immunology, ITR International, Baie d'Urfe, QC, Canada.* Sponsor: W. Ruddick.

Scope :

Measurements of GH and IGF-1 in Beagle dogs are complicated by several technical and biological issues. In this poster, we present data from ELISA methods that were specially adapted and qualified at our facility for the quantification of GH & IGF-1 in canine serum. During assay implementation and routine use, several observations have been made with these hormone baseline levels and some biological & technical parameters.

**Experimental Procedures & Results :**

Beagle dog serum was obtained from males and females, originating from two different breeders; Marshall and Covance. Samples were tested from dogs housed at three different preclinical testing facilities; ITR Laboratories Canada Inc. ("ITR") and two other undisclosed facilities ("Lab B" & "Lab C"). A commercial GH ELISA kit designed for rat/mouse GH and another commercial human IGF-1 kit were adapted for use with dog serum samples. Typical basal GH levels in Beagle dogs vary from < 6.25 to 40 ng/mL. No significant differences were observed in the GH basal level between different genders, breeding source or test facility. However, GH levels generally increased with higher body weight and age. GH varied between individuals of the same study. Typical basal IGF-1 levels in Beagle dogs varied greatly, from < 42 to 150 ng/mL (ex. from Marshall-bred dogs housed at ITR), while the normal range increase to 150-500 ng/mL with Covance-bred dogs housed at "Lab C". Age and body weight only had minor impact on the IGF-1 basal levels, while a gender difference was only seen within the Covance-bred dogs housed at "Lab C".

**Conclusions :**

The GH/IGF-1 data gathered internally from several preclinical studies with Beagle dogs of various origins have shown that basal IGF-1 levels can vary significantly depending on the dog breeding source and housing facility, in addition to age and body weight. It was also found that due to the natural cyclic activity of GH, multiple pre-dose samplings are useful, with the last pre-dose sample being ideally taken as close as possible to dosing with the test item.

**PS 1914 Evaluation of Iodide Deficiency in the Lactating Rat and Pup Using a Biologically-Based Dose Response (BBDR) Model.**

J. W. Fisher<sup>1</sup>, S. Li<sup>2</sup>, K. Crofton<sup>3</sup>, R. Zoeller<sup>4</sup>, E. D. McLanahan<sup>3</sup>, A. Lumen<sup>1</sup> and M. E. Gilbert<sup>3</sup>. <sup>1</sup>FDA/NCTR, Jefferson, AR; <sup>2</sup>Georgia Health Sciences University, Augusta, GA; <sup>3</sup>EPA/ORD, Research Triangle Park, NC; <sup>4</sup>University of Massachusetts, Amherst, MA.

A biologically-based dose response (BBDR) model for the hypothalamic-pituitary thyroid (HPT) axis in the lactating rat and nursing pup was developed to describe the perturbations caused by iodide deficiency on the HPT axis. Model calibrations, carried out by adjusting key model parameters, were used as a technique to evaluate HPT axis adaptations to dietary iodide intake in euthyroid (4.1 -39 µg iodide/d) and iodide deficient (0.31 and 1.2 µg iodide /d) conditions. Iodide deficient conditions in both the dam and pup were described with increased blood flow to the thyroid gland, TSH-mediated increase in thyroidal uptake of iodide and binding of iodide in the thyroid gland (organification), and in general, reduced thyroid hormone production and metabolism. Alterations in thyroxine (T4) homeostasis were more apparent than for triiodothyronine (T3). Model predicted average daily area-under-the-serum- concentration-curve (AUC, nM\*day) values for T4 at steady-state in the dam and pup decreased by 14-15% for the 1.2 µg iodide /d iodide deficient diet and 42 to 52% for the 0.31 µg iodide /d iodide deficient diet. In rat pups that were iodide deficient during gestation and lactation, these decreases in serum T4 levels were associated with synaptic response suppression in the hippocampal region of the brain, while other measures of neurotoxicity were unaltered.

**PS 1915 An Animal Model of Marginal Iodine Deficiency during Development: The Thyroid Axis and Neurodevelopmental Outcome.**

M. E. Gilbert<sup>1</sup>, J. M. Hedge<sup>1</sup>, L. Valentin-Blasini<sup>2</sup>, B. C. Blount<sup>2</sup>, K. Kannan<sup>3</sup>, J. Tietge<sup>4</sup>, R. Zoeller<sup>5</sup>, K. Crofton<sup>1</sup>, J. Jarrett<sup>2</sup> and J. W. Fisher<sup>6</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>CDC, Atlanta, GA; <sup>3</sup>SUNY, Albany, NY; <sup>4</sup>US EPA, Duluth, MN; <sup>5</sup>University of Massachusetts, Amherst, MA; <sup>6</sup>FDA, Jefferson, AR.

Thyroid hormones (TH) are essential for brain development and iodine is required for TH synthesis. Environmental chemicals that perturb the thyroid axis result in modest reductions in TH, yet there is a paucity of data on the neurological impairments associated with low level TH disruption. This study examined the dose-response characteristics of marginal iodine deficiency (ID) on parameters of thyroid function and neurodevelopment. ID diets were prepared by adding varying concentrations of iodine to a casein-based diet producing 5 nominal iodine levels ranging from ample (1000 µg iodine/kg chow) to deficient (25 µg iodine/kg chow).

Female Long Evans rats were maintained on these diets beginning 7 wk prior to breeding until the end of lactation. Dams were sacrificed on gestational days 16 and 20, or when pups were weaned on postnatal day (PN) 21. Fetal tissue was harvested with sacrifice of the dams, pups were sacrificed on PN14 and PN21. Blood, thyroid gland, and brain were analyzed for iodine, TH, TH precursors and metabolites. Serum and thyroid gland iodine and TH were reduced in the two most deficient diets. T4 was reduced in the fetal brain but was not altered in the neonate. Cognitive function, assessed by acoustic startle, water maze learning and fear conditioning, was unchanged in adult offspring, but excitatory synaptic transmission was impaired in the dentate gyrus by the two most deficient diets. A 15% reduction in cortical T4 in the fetal brain was sufficient to induce permanent reductions in synaptic function in the adult. These findings have implications for regulation of TH-disrupting chemicals, and suggest that standard behavioral assays do not readily detect neurotoxicity induced by modest developmental TH disruption. (Does not reflect EPA or CDC policy).

## PS 1916 Association of Paraoxonase-1 Activity and Gene Polymorphisms with Type 2 Diabetes Mellitus.

P. Eden<sup>1,2</sup>, E. Olsen<sup>3</sup>, J. Watt<sup>3</sup> and J. E. Chambers<sup>2</sup>. <sup>1</sup>711th Human Performance Wing, Wright-Patterson AFB, OH; <sup>2</sup>Mississippi State University, Starkville, MS; <sup>3</sup>81st Medical Group, Keesler AFB, MS.

Paraoxonase-1 (PON-1) is an HDL-associated lactonase that hydrolyses organophosphates such as paraoxon and diazoxon, the active metabolites of the insecticides parathion and diazinon, as well as affords protection against LDL oxidation. There is evidence that Type 2 diabetes mellitus (T2DM) patients display lower PON-1 activity. This study examined plasma from 150 T2DM and 150 non-diabetic subjects to evaluate PON-1 activity and relevant genetic variations associated with changes in PON-1 activity. PON-1 activity was measured spectrophotometrically using the substrates paraoxon, diazoxon, and phenyl acetate. Two significant genetic polymorphisms (PON-1192 and PON-155) were also determined using real-time polymerase chain reaction melting curve analysis. The PON-1192 genotype displayed an average melting curve peak at  $61.1^{\circ}\text{C} \pm 1.1$  (SD) for the (R) homozygous allele while the (Q) homozygous allele showed a peak of  $66.3^{\circ}\text{C} \pm 0.6$ . The PON-155 genotype had an average melting curve peak at  $61.9^{\circ}\text{C} \pm 0.9$  for the (L) homozygous allele and  $66.3^{\circ}\text{C} \pm 0.9$  for the (M) homozygous allele. A prevalence of the PON-1192RR polymorphism was found between T2DM subjects and non-diabetics (odds ratio = 2.3; 95% confidence interval = 1.25- 4.21,  $p = 0.01$ ). The substrate diazoxon demonstrated lower plasma PON-1 activity in T2DM subjects ( $7469 \pm 140$  U/L) compared to non-diabetics ( $8287 \pm 151$  U/L),  $p = 0.02$ . In addition, African-Americans in this study demonstrated a higher association with the PON-1192RR genotype (51.5%) than did Caucasians (9.1%) ( $p < 0.001$ , odds ratio = 10.66). The genetic and plasma PON-1 activity results suggest that the PON-1192RR polymorphism is less protective against development of T2DM and that decreased PON-1 activity is associated with increased development of T2DM.

## PS 1917 Effect of Dioxin on the Nursing Behavior of Dams and the Growth of Pups: A Study for the Mechanism Focusing on Damage to Maternal Prolactin and Fetus/Infant Growth Hormone.

M. Fujii<sup>1</sup>, T. Takeda<sup>1</sup>, J. Taura<sup>1</sup>, Y. Hattoni<sup>1</sup>, Y. Ishii<sup>1</sup>, H. Uchi<sup>2</sup>, K. Tsukimori<sup>3</sup>, M. Furue<sup>2</sup> and H. Yamada<sup>1</sup>. <sup>1</sup>Graduate School of Pharmaceutical Sciences, Kyushu University, Fukuoka, Japan; <sup>2</sup>Kyushu University Hospital, Fukuoka, Japan; <sup>3</sup>Fukuoka Children's Hospital, Fukuoka, Japan. Sponsor: Y. Kumagai.

Maternal exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) causes a number of developmental disorders including growth retardation in the pups. Although our previous studies have demonstrated that TCDD imprints defects in gender-specific phenotypes through a reduction in gonadotropin production in perinatal pups (1,2), the mechanism for growth retardation by TCDD remains unknown. In this study, we investigated a hypothesis that maternal exposure to TCDD damages to maternal prolactin, a regulator of milk secretion and maternal care to the pups, and growth hormone (GH) in the pups to disturb the growth of offsprings. As has been reported so far, oral administration of TCDD (1  $\mu\text{g/kg}$ ) to pregnant Wistar rats at gestational day 15 attenuated the body weight and height of infants and their short-term memory examined 5 weeks after birth. In addition, we observed that TCDD reduced the number of pups after birth, whereas the same was not seen at fetal stages. In relation to this finding, TCDD reduced not only maternal expression of prolactin in a nursing period-specific manner, but also the frequency of licking, one of the maternal nursing behaviors. Furthermore, maternal exposure to

TCDD attenuated the serum concentration of GH in perinatal pups. Such attenuation may be an outcome due to the reduced expression of a receptor for GH-releasing hormone (GHRH), a regulator of GH biosynthesis, because a lowered expression of GHRH receptor cause by TCDD also appeared during the same period. Taken together, it is suggested that maternal exposure to TCDD produces its developmental toxicity on pups by a combination of a reduction in the expression of maternal prolactin and pup GH.

## PS 1918 Effects of Perfluorooctane Sulfonate (PFOS) on the Hypothalamic-Pituitary-Testicular Axis Activity in Adult Male Rat.

M. A. Lafuente and N. Pereiro. Laboratory of Toxicology, University of Vigo, Orense, Spain.

Perfluorooctane sulfonate (PFOS) is considered such as an endocrine disruptor. This study was designed to evaluate the possible alterations induced by PFOS on the hypothalamic-pituitary-testicular axis activity. For this purpose, male Sprague-Dawley rats were orally treated for 28 days with PFOS, at the doses of 0.5, 1.0, 3.0 and 6.0 mg/kg/day. Control rats received 0.5% Tween-20 vehicle. Twenty four hours after the last dose of PFOS, rats were killed by decapitation and the hypothalamus was removed in order to determine in this brain region both neuropeptide Y (NPY) and gonadotropin-releasing hormone (GnRH) concentration by specific enzyme-linked immunoabsorbent (ELISA) assays. Serum luteinizing hormone (LH), follicle stimulating hormone (FSH) and testosterone levels were measured by specific commercial kits. In addition, the relative gene expression of NPY and GnRH in hypothalamus, of GnRH receptor in pituitary and of LH receptor and FSH receptor in testis was determined by quantitative real time PCR. Serum LH and testosterone levels and relative gene expression of GnRH and of FSH receptor were decreased in rats treated with PFOS. Serum FSH concentration and relative gene expression of LH receptor in testis were increased in these same animals. Hypothalamic concentration of NPY and GnRH was decreased with the doses of 1.0 and 3.0 mg/Kg/day, but GnRH levels were increased with the dose of 6.0mg/Kg/day. Relative gene expression of NPY was diminished with the dose of 0.5mg/Kg/day, but it was increased with the dose of 6.0mg/Kg/day. Finally, relative gene expression of GnRH receptor was not modified in pituitary by PFOS. The obtained results suggest that PFOS exposure can modify the hypothalamic-pituitary-testicular axis activity at several levels, and these alterations seem to be dependent of the administered dose. This work was supported by a grant from the Ministry of Education and Science, Spain (AGL2009-09061).

## PS 1919 Conditional Knockout of the Aryl Hydrocarbon Receptor in the Liver Alters Mouse Phenotype As Well As Glucose and Lipid Homeostasis.

D. Carter and C. Elferink. Pharmacology and Toxicology, UTMB, Galveston, TX.

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor historically known for its role in the adaptive metabolism of xenobiotics. However, generation of the AhR knockout mouse (AhR-KO) has provided evidence of physiological roles for the AhR. To study the physiological role of AhR in the liver, AhR conditional knockout (AhR-CKO) mice were utilized by crossing AhR  $\text{fx}/\text{fx}$  (control) mice with mice that express Cre recombinase under the control of the albumin promoter, resulting in loss of AhR expression specifically in the liver parenchyma. Our experiments indicate a novel sex dependent phenotype wherein, AhR-CKO females exhibited reduction in body weight, loss of adipose tissue and increased basal glucose levels ( $218 \pm 19.73$  mg/dl). Therefore, our goal is to characterize the AhR-CKO mouse phenotype and identify potential AhR-dependent mechanisms responsible for lipodystrophy and abnormal glucose homeostasis. AhR-CKO and control mice were subjected to glucose and insulin tolerance tests. Our data suggests decreased glucose tolerance and increased insulin sensitivity in AhR-CKO females compared to their controls. Plasma analyses also suggest alterations in leptin (control  $3.227 \pm 0.27$  vs CKO  $1.028 \pm 0.129$ ), FFA (control  $0.3630 \pm 0.026$  vs CKO  $0.594 \pm 0.02$ ) and insulin levels (control  $0.495 \pm 0.008$  vs CKO  $0.253 \pm 0.004$ ). Immuno-Histochemical staining for insulin revealed reduced insulin content and smaller pancreatic islets in AhR-CKO mice. We also conducted histopathological analysis using Oil red O staining, which revealed decreased lipid content in AhR-CKO mice livers compared to controls. Our experiments strongly suggest that AhR activity in the liver communicates with extra-hepatic tissues and alters their function. AhR-CKO mice may offer an elegant model to study the link between endogenous AhR activity in the liver and clinically relevant metabolic disorders such as diabetes, lipodystrophy and obesity.

**PS 1920 Endocrine Modulatory Effects of Cadmium and Activation of MAPK Signaling.**

I. Ali<sup>1</sup>, P. Damdimopoulou<sup>2</sup>, S. I. Mäkelä<sup>3</sup>, M. Berglund<sup>1</sup>, U. Stenius<sup>1</sup>, A. Adamsson<sup>4</sup>, A. Åkesson<sup>1</sup>, H. Håkansson<sup>1</sup> and K. Halldin<sup>1</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden; <sup>2</sup>Department of Biosciences and Nutrition, Karolinska Institute, Huddinge, Sweden; <sup>3</sup>Department of Cell Biology and Anatomy and Turku Center for Disease Modeling, Institute of Biomedicine, University of Turku, Turku, Finland; <sup>4</sup>Department of Physiology, Institute of Biomedicine, University of Turku, Turku, Finland.

Research on endocrine modulatory effects of Cadmium (Cd) started over a decade ago, when this metalloestrogen was found to interact with the estrogen signaling pathway. Since then, several independent in vitro as well as in vivo reports have emerged on this topic. Our objective has been to characterize the details of molecular mechanisms of action for the endocrine modulatory effects of Cd. We applied a combined in vivo and in vitro approach by using transgenic ERE-luc reporter mice model as well as hepG2, MCF-7 and ECC-1 cell lines. After 3-days s.c. exposure to CdCl<sub>2</sub>, we did not detect reporter gene activation in the dose ranges 5-500 µg/kg bw and 0.5-500 µg/kg bw in female and male mice respectively. Nevertheless, we observed significant thickening of the uterine epithelium in the absence of uterine weight increase in females, and detected activation of Raf, Erk1/2 MAPK in the liver of both genders in low dose groups. Further, in our in vitro settings, low doses of CdCl<sub>2</sub> (1nM-100nM) also activated Raf, Erk1/2 MAPK and this effect disappeared with the inhibition of GPR30 and EGFR receptors. Our data shows that the molecular markers that are modulated by Cd differ depending on the exposure level; i.e. low doses relevant to human exposure via diet stimulate cytoplasmic kinases, while higher doses induce cellular stress responses. We conclude that CdCl<sub>2</sub> affects cellular signaling pathways that can produce physiological effects reminiscent of bona fide estrogen stimulation. However, CdCl<sub>2</sub> does not activate canonical estrogen signaling.

**PS 1921 Bisphenol A (BPA) Levels Were Associated with Increased Estrogen.**

M. Lind<sup>1</sup>, T. Naessen<sup>2</sup>, J. Bergquist<sup>3</sup>, M. M. Kushnir<sup>3,4</sup> and L. Lind<sup>5</sup>. <sup>1</sup>Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden; <sup>2</sup>Department of Women's and Children's Health, Section for Obstetrics and Gynecology, Uppsala University, Uppsala, Sweden; <sup>3</sup>Analytical Chemistry/Department of Physical and Analytical Chemistry, Uppsala University, Uppsala, Sweden; <sup>4</sup>ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT; <sup>5</sup>Department of Medical Sciences, Acute and Internal Medicine, Uppsala University, Uppsala, Sweden.

**BACKGROUND:** The plastic associated compound bisphenol A (BPA) is a known estrogen-receptor agonist. Since background exposure to BPA could be detected in most individuals, we explored the relationships between BPA levels in serum and levels of endogenous sex hormones and their precursors in a population-based sample.

**METHODS:** 1,016 subjects all aged 70 years were investigated in the Prospective Investigation of the Vasculature in Uppsala Seniors (PIVUS) study. BPA was measured in serum at ALS Canada using an API 4000 liquid chromatograph/ tandem mass spectrometer, and sex hormones were measured at ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, by high-specificity liquid chromatography-tandem mass spectrometry.

**RESULTS:** In men, BPA levels were related to estrone (E1,  $p < 0.00001$ ) and estradiol (E2,  $p = 0.02$ ) levels. BPA levels were also related to levels of the precursors pregnenolone and 17-OH-pregnenolone ( $p < 0.05$ ) and estimated aromatase activity ( $p < 0.05$ ), indicating an increased formation of estrogens from androgen precursors. In women, only weaker relationship compared with E1 was found ( $p < 0.05$ ).

**IN CONCLUSION:** increased levels of BPA were associated with increased estrogen levels in elderly males, indicating endocrine disrupting activity in the elderly.

**PS 1922 A Comparison of RIA and LC-MS/MS Methods to Quantify Steroids in Rat Serum and Urine following Exposure to an Endocrine Disrupting Chemical.**

B. W. Riffle<sup>1,2</sup>, S. C. Laws<sup>1</sup> and W. M. Henderson<sup>3</sup>. <sup>1</sup>ETB, TAD, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>ORISE, US Department of Energy, Oak Ridge, TN; <sup>3</sup>ERD, NERL, ORD, US EPA, Athens, GA.

Commercially available radioimmunoassays (RIA) are frequently used in toxicological studies to evaluate effects of endocrine disrupting chemicals (EDCs) on steroidogenesis in rats. Currently there are limited data comparing steroid concentrations in rats as measured by RIAs to those obtained using liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). This study evaluates the

concordance of serum and urine steroid concentrations as quantified by both RIA and LC-MS/MS following exposure to a known EDC, atrazine (ATR). Adult male rats were dosed with ATR (200 mg/kg/d) or methylcellulose (solvent control) by oral gavage for 5 days. Animals were decapitated 2 hours after the final dose. Serum was collected and separated into 2 aliquots for analysis. Serum was assayed by RIA for androstenedione (A), corticosterone (CORT), estradiol (E2), estrone (E1), progesterone (P4), and testosterone (T). Serum was extracted via solid phase extraction prior to LC-MS/MS analysis with positive electrospray ionization in multiple-reaction monitoring mode for A, CORT, P4, and T. E1 and E2 serum concentrations were quantified similarly by LC-MS/MS, following derivatization with dansyl chloride. To compare CORT values from urine, pregnant adult rats were dosed with either ATR (100 mg/kg/d) or methylcellulose by oral gavage for 5 days (i.e., gestational days 14-18). Urine samples were collected daily for 2 consecutive 6 hour intervals following dosing and assayed for CORT by RIA and LC-MS/MS as described above. Data analyses demonstrated a high degree of correlation between the two detection methods ( $R^2 = 0.88 - 0.92$ ). No statistically significant differences were observed between RIA and LC-MS/MS means for any of the steroids assayed. These findings indicate that steroids may be reliably measured in rat biological media using RIAs or LC-MS/MS in toxicological studies. This abstract does not reflect U.S. EPA policy.

**PS 1923 Exposure of Pregnant Fischer 344 Rats to Low Levels of Dietary Zearanol Induces Precocious Puberty and Decreased Mammary Tumor Latency in F1 and F2 Progeny.**

C. Lewis<sup>1</sup>, J. T. Barrett<sup>1</sup>, M. A. Gallo<sup>1,2</sup> and H. Zarbl<sup>1,2</sup>. <sup>1</sup>Environmental and Occupational Medicine, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ; <sup>2</sup>Environmental and Occupational Health Sciences Institute, Robert Wood Johnson Medical School, Piscataway, NJ.

Zearanol (Zer) is a synthetic derivative of zearalenone (Zea), a potent myco-estrogen produced by several species Fusarium that contaminate grain. Zer has estrogenic activity comparable to that of DES and is ~1000 times more estrogenic than Bisphenol A. After its growth promoting effects on livestock were noted in the early 1970's, Zer replaced diethylstilbestrol (DES) in implants to enhance meat production and quality. Accidental and occupational exposures were associated with precocious puberty and gynecomastia. Banned in Europe and Asia, Zer is introduced into livestock in the Americas, can be detected in the finished product, and is stable at cooking temperatures. Our recent studies in prepubescent girls indicate that human exposure is primarily via the consumption of beef and corn, and urinary levels of unconjugated Zer were associated with differences in the onset of puberty, height and weight (Bandera et al., Science of the Total Environment 409(24):5221-5227, 2011). Our studies in rats indicated that exposure to non-toxic doses of Zer in utero (between prenatal day 7 to term) via the mother's diet (0.1µg/day in safflower oil), results in precocious puberty in females F1 progeny, defined by a three day decrease in age at vaginal opening. F1 male progeny showed feminization as assessed by a decreased ano-genital distance. F1 female treated with a single carcinogenic dose of N-Nitroso-N-methylurea (NMU) showed a decrease in latency and an increase in the incidence of mammary tumors. Similar effects on puberty and carcinogenesis were also observed in the F2 progeny, but only if both the dam and the sire were exposed to Zer in utero. Together these studies suggest that in utero exposure to the Zer may produce transgenerational effects on sexual maturation and carcinogenesis.

Supported by grants from The NJCCR and the NIEHS (ES005022).

**PS 1924 P-p-DDE Levels Are Associated with Reduced Testosterone Levels in Elderly Males.**

L. Lind<sup>1</sup>, T. Naessen<sup>2</sup>, J. Bergquist<sup>3</sup>, M. M. Kushnir<sup>3</sup> and M. Lind<sup>2</sup>. <sup>1</sup>Department of Medicine, Uppsala, Sweden; <sup>2</sup>Uppsala University, Uppsala, Sweden; <sup>3</sup>ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT.

**Background:** The DDT metabolite p-p-DDE is a known androgen-receptor agonist. Since background exposure to p-p-DDE still could be detected in most individuals, we explored the relationships between p-p-DDE levels in serum and levels of endogenous sex hormones and their precursors in a population-based sample.

**Methods:** 1,016 subjects all aged 70 years were investigated in the Prospective Investigation of the Vasculature in Uppsala Seniors (PIVUS) study. p-p-DDE was measured in plasma by a high-resolution chromatography coupled to high resolution mass spectrometry (HRGC/HRMS), and sex hormones by high-specificity liquid chromatography-tandem mass spectrometry.

**Results:** In men, p-p-DDE levels were related to both reduced testosterone ( $p = 0.006$ ) and SHBG levels ( $p = 0.008$ ). Furthermore, also reduced levels of the precursors pregnenolone and 17-OH-pregnenolone were related to high p-p-DDE levels ( $p < 0.05$ ), indicating a general reduction in endogenous sex hormone synthesis in subjects with high p-p-DDE levels. Similar tendencies, but less pronounced, were seen in women.

In conclusion, increased levels of p-p-DDE levels were associated with both reduced testosterone and SHBG levels in elderly males, indicating endocrine disrupting activity by DDT in the elderly.

## **PS** 1925 *In Utero* Bisphenol A (BPA) Exposure, the Developing Immune System and Memory.

J. N. Franklin, Q. Hu and J. DeWitt. *Pharmacology and Toxicology, East Carolina University, Greenville, NC.*

Exposure to exogenous agents during susceptible stages of neurodevelopment may be associated with the onset of neurological disorders. The emerging contaminant bisphenol A (BPA) is a widely used ingredient in the production of plastics and resins utilized in food and beverage packaging. Our hypothesis is that developmental exposure to BPA induces neural and behavioral alterations and that these alterations will be associated with developmental immunotoxicity. C57BL/6 female mice were given 0, 25, 50, or 100 mg/kg of BPA in a corn oil vehicle by gavage, beginning at pairing with males and ending at weaning of pups. Littermates were assessed on a Barnes maze at postnatal day 21 (PND21), PND42, and PND60. Splenic lymphocytes, including B cells, natural killer cells (NK cells) and T cells (CD3, CD4, CD8, and CD25 subclasses), were immunofluorescently labeled to determine the immunophenotype of offspring from each treatment group. The Barnes maze is a reliable indicator of hippocampal-dependent learning and memory that has been used to link immune dysfunction with altered neurodevelopment. On the Barnes maze, the time to initially reach the escape hole did not significantly differ among treatment groups. A significant interaction between sex and dose was detected in offspring immunophenotype, indicating that immune cell subpopulations responded differently between sexes by dose. Liver weights increased in adult offspring by dose, though this trend was not statistically significant. Our data indicate that developmental exposure to BPA does not alter aspects of learning and memory as evaluated by the Barnes maze, but may induce differences in immunophenotype between sexes that may confound behavioral responses. Additional work is ongoing to evaluate changes to hippocampal neurons induced by developmental BPA exposure.

## **PS** 1926 Low-Dose Evaluation of the Antiandrogen Flutamide in a 28-Day Toxicity Study in the Rat.

A. Sarabay<sup>1</sup>, H. Tinwell<sup>1</sup>, O. Blanck<sup>1</sup>, F. Schorsch<sup>1</sup>, M. Pallardy<sup>2</sup>, R. Bars<sup>1</sup> and D. Rouquié<sup>1</sup>. <sup>1</sup>Bayer CropScience, Sophia Antipolis, France; <sup>2</sup>Faculty of Pharmacy, University Paris-Sud, INSERM UMR 996, Châtenay-Malabry, France.

The dose-response characterization of endocrine mediated toxicity is an on-going debate which is controversial when exploring the nature of the dose-response curve and the effect at the low end of the curve. Therefore, to contribute to this debate we have assessed the effects of a wide range of dose levels of the antiandrogen flutamide (FM) on male rats using omic and traditional tools. Flutamide was administered to Wistar rats at the doses of 0, 0.001, 0.01, 0.1, 1 and 10 mg/kg/day for 28 days. The highest dose level corresponds to a therapeutic dose in humans and it is also known to induce changes in male reproductive tissues in rodents. At necropsy, blood samples were collected for testosterone measurements. Male reproductive tissues were weighed. The testes were collected for histopathological assessment in addition to the evaluation of gene expression changes. Results showed that testicular lesions (Leydig cell hyperplasia) were detected from 1 mg/kg/day whereas the testosterone levels were only increased at 10 mg/kg/day. A preliminary molecular investigation of targeted genes by qPCR shows changes at 1 and 10 mg/kg/day. Based on the available results, only monotonic responses were observed based on gravimetry, microscopic examination, hormonal analyses and gene expression using qPCR analyses. Full genome gene expression evaluation using DNA microarrays is on-going to evaluate the shape of the global gene expression dose response curves.

## **PS** 1927 Investigation of Vinclozolin at Environmentally-Relevant Concentrations.

S. Gröters<sup>1</sup>, S. Schneider<sup>1</sup>, K. C. Fussell<sup>1</sup>, V. Strauss<sup>1</sup>, M. Frericks<sup>2</sup>, S. Melching-Kolmuss<sup>2</sup>, B. Siddeek<sup>3</sup>, M. Benahmed<sup>3</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>U895, équipe 5, Bâtiment Universitaire Archimède, Centre Méditerranéen de Médecine Moléculaire (C3M), Inserm, Nice, France.

Endocrine disruption has become an important topic of public concern. Despite an increasing amount of attention, little is understood about if environmentally relevant doses of endocrine disrupting chemicals (EDCs) affect homeostasis.

Furthermore, there are often knowledge gaps in the studies used to assess EDCs. To address these concerns, we performed a pre-/post-natal reproductive toxicity study of vinclozolin as part of a larger BASF and CEFIC funded project to measure the developmental toxicity of low single- and mixture-doses of anti-androgens. The tested doses were selected to mimic a low-effect level, the no observed adverse effect level (NOAEL) for endocrine effects, and the acceptable daily intake (ADI). At the LOAEL dose, female offspring developed normally, while the male offspring showed effects known for anti-androgens. No effects at all were noted at the lowest two doses, the NOAEL and the ADI. At the top dose, an increase was noted in nipples and/or areolas in male animals on PND 12. This effect was transient, as all had regressed by PND 21. In both of these dose groups, male offspring which were reared to young adulthood displayed additional anti-androgen effects including, delayed sexual maturation and reduced male sex organ sizes and weights. However, no significant decrease in anogenital distance on PND 1 was noted in the animals of this dose group. Similarly, assessment of sexual steroid hormones and their precursors revealed no effects at any of the dose levels. Taken together, the weight of evidence of the clinical and pathological findings suggests a lack of a non-monotonic dose-response curve.

## **PS** 1928 Investigation of Flutamide at Environmentally-Relevant Concentrations.

S. Melching-Kolmuss<sup>2</sup>, S. Schneider<sup>1</sup>, K. C. Fussell<sup>1</sup>, S. Gröters<sup>1</sup>, V. Strauss<sup>1</sup>, B. Siddeek<sup>3</sup>, M. Benahmed<sup>3</sup>, M. Frericks<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>U895, équipe 5, Bâtiment Universitaire Archimède, Centre Méditerranéen de Médecine Moléculaire (C3M), Inserm, Nice, France.

Endocrine disruption has become an important topic of public concern. Despite an increasing amount of attention, little is understood about if environmentally relevant doses of endocrine disrupting chemicals (EDCs) affect homeostasis. Furthermore, there are often knowledge gaps in the studies used to assess EDCs. To address these concerns, we performed a pre-/post-natal reproductive toxicity study of flutamide as part of a larger BASF and CEFIC funded project to measure the developmental toxicity of low single- and mixture-doses of anti-androgens. The tested doses were selected to mimic a low-effect level, the no observed adverse effect level (NOAEL) for endocrine effects, and the acceptable daily intake (ADI). While female offspring developed normally, the male offspring showed effects known for anti-androgens. No effects were noted at the lowest dose, the ADI. Significant decreases in anogenital distance on PND 1 were noted in animals exposed to the top dose. An increase in nipples and/or areolas in male animals on PND 12 was noted at the top two doses. This effect was partially transient, as all had regressed by PND 21, except at the flutamide top dose. In both of these dose groups, male offspring which were reared to young adulthood displayed additional anti-androgen effects including, delayed sexual maturation and reduced male sex organ sizes and weights; however, offspring from the top dose group also had an increased incidence of developmental sexual defects including hypospadias, short penis, and cryptorchidism. Assessment of sexual steroid hormones and their precursors revealed no effects at any dose level. Taken together, the weight of evidence of the clinical and pathological findings suggests a lack of a non-monotonic dose-response curve.

## **PS** 1929 The Effects of 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) on Hypothalamus-Pituitary-Gonadal (HPG) Axis in Female Rat Primary Cultures.

K. Solak, F. Wijnolts, B. J. Blaauboer, M. van den Berg and M. B. van Duursen. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) belongs to a group of structurally persistent, highly lipophilic compounds, that exerts a variety of adverse effects on the development and physiology of the reproductive system. TCDD and other dioxin-like PCBs act as endocrine disruptive compounds (EDCs) on the hypothalamus-pituitary-gonad (HPG) reproductive axis, mainly through the activation of aryl hydrocarbon receptor (AHR) signaling. Females are believed to display higher sensitivity to TCDD mainly due to the sex differences in adipose tissue percentage and thus higher accumulation of TCDD in female tissues, including ovaries. The present study was designed to explore the mechanisms of endocrine disrupting properties of TCDD on female adult rat hypothalamus-pituitary-gonadal axis (HPG axis) in vitro by employing primary hypothalamus, pituitary and ovaria cultures. In all HPG axis compartments, TCDD elevated its sensitive markers CYP1a1 and AhR after 24 hours. No changes in gonadotropin-releasing hormone (GnRH) and gonadotropins mRNA and protein levels were observed after 10nM TCDD treatment. TCDD exerted its anti-estrogenic effects by alteration of the crucial enzymes in ovarian steroidogenesis. Significant down-regulation of CYP17 and

CYP19 mRNA levels were observed with a slight decrease of estradiol levels after 24 hours. Furthermore, the FSH receptor was significantly down-regulated by TCDD, indicating that TCDD may disturb the HPG axis via this receptor by modulation of ovarian response to gonadotropins. This process may which further lead to ovarian desensitization. To investigate the AhR involvement in these enzyme and receptor mRNA observed changes, siRNA against AhR was applied. The results suggest a key role of the AhR in CYP19 gene regulation in the regulation of female reproductive tract.

### PS 1930 BPA and TBBPA Target ATP Binding Cassette Transporters in the Blood-Testis Barrier and Impair Leydig Cell Steroidogenesis.

M. J. Roelofs<sup>1</sup>, A. C. Dankers<sup>2</sup>, A. H. Piersma<sup>1,3</sup>, F. G. Russel<sup>2</sup>, R. Masereeuw<sup>2</sup> and M. B. van Duursen<sup>1</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands; <sup>2</sup>Department of Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre (RUNMC), Nijmegen, Netherlands; <sup>3</sup>Center for Health Protection, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands.

Disturbances of androgen production in Leydig cells and/or androgen function in Sertoli cells in the (fetal) testis have been shown to cause a wide variety of male reproductive abnormalities in experimental animals. Drug transporters in the blood-testis barrier (BTB) prevent entry and accumulation of xenobiotics in the testis, but are also involved in local transport of steroid hormones. Among these are the ATP-binding cassette (ABC) transporters, P-glycoprotein (P-gp/ABCB1), breast cancer resistance protein (BCRP/ABCG2), multidrug resistance protein 1 (MRP1/ABCC1) and 4 (MRP4/ABCC4). We studied the interaction of Bisphenol A (BPA) and Tetrabromobisphenol A (TBBPA) with human P-gp, BCRP, MRP1 and MRP4-mediated transport using membrane vesicles of human embryonic kidney (HEK293) cells overexpressing these transporters. Also, the effects of these compounds on testosterone production and expression of steroidogenic genes (Star, Cyp11A1, 3 $\beta$ -HSD, 17 $\beta$ -HSD, Ins13, Cyp17A, Cyp19, LH receptor, Srd5a1) in mouse Leydig MA-10 cells were determined. BPA and TBBPA concentration-dependently induced testosterone secretion by MA-10 cells and expression of testis-specific mRNAs of 17 $\beta$ -HSD and Srd5a1 (5 $\alpha$ -reductase 1) were upregulated. BPA and TBBPA differentially inhibited P-gp, BCRP, MRP1 and/or MRP4 activity. Blocking P-gp using PSC833, increased testosterone secretion upon BPA and TBBPA exposure. The MRP inhibitor MK571 completely blocked testosterone secretion elicited by BPA and TBBPA. Our data suggest that EDCs might disrupt local androgen production and androgen transport from the Leydig into Sertoli cells thus affecting normal germ cell development.

### PS 1931 Effects of GPER Activation on (Xeno) Estrogen-Induced Cellular Responses.

L. C. Smith<sup>1</sup>, K. Ralston-Hooper<sup>2</sup>, P. Ferguson<sup>2</sup> and T. Sabo-Attwood<sup>1</sup>. <sup>1</sup>Department of Physiological Sciences, Environmental & Global Health and Center for Environmental and Human Toxicology, University of Florida, University of Florida, Gainesville, FL; <sup>2</sup>Department of Civil and Environmental Engineering and Nicholas School of the Environment, Duke University, Durham, NC.

Estrogen can exert cellular effects through both nuclear (ESR1 and ESR2) and membrane-bound receptors (GPER). It is unclear if these receptors act independently or engage in crosstalk to influence hormonal responses. To investigate each receptor's role in proliferation, activation of reporter genes and protein phosphorylation in breast cancer cells (MCF-7), we employed ESR1 (PPT), ESR2 (DPN) and GPER (G1) selective agonists. As anticipated, 17 $\beta$ -estradiol (E2), PPT and DPN, enhanced cell proliferation, whereas G1 had no impact. However, E2, PPT- and DPN-induced proliferation was repressed when cells were co-exposed with G1. Similar results were observed for activation of an estrogen response element (ERE)-driven luciferase reporter gene where G1 elicited a dose-dependent decrease in E2-, PPT- and DPN induced activity. As membrane receptors typically initiate a series of phosphorylation events, we performed global cytosolic phosphoproteome analysis by HPLC-MS/MS on cells exposed to E2 or G1. Of the 238 phosphorylated proteins identified only 10 sites were shared between E2 and G1 whereas 31 and 13 events were specific for each ligand, respectively. Using pathway analysis we developed a putative network of proteins that are influenced by GPER activation and have identified 'central nodes' (i.e. NDRG2) which highlights a possible role for these proteins as targets of GPER activity. As xenoestrogens, such as bisphenol-A and genistein, bind to ESRs and GPER we are currently investigating the impact these compounds have on nuclear and membrane estrogen receptor signaling networks. Overall, our proteomic and mechanistic approaches will lead to the identification and sorting of GPER networks and the potential interplay with ESRs that will illuminate the role of these receptors in cellular responses to E2 and xenoestrogens.

### PS 1932 Antiproliferative, Antiandrogenic, and Cytotoxic Effects of Novel Synthetic Derivatives of Caffeic Acid in LNCaP Human Androgen-Dependent Prostate Cancer Cells.

T. Sanderson<sup>1</sup>, H. Clabault<sup>1</sup>, C. Patton<sup>1</sup>, L. M. LeBlanc<sup>2</sup>, M. Hébert<sup>2</sup> and M. Touaibia<sup>2</sup>. <sup>1</sup>INRS-Institut Armand-Frappier, Laval, QC, Canada; <sup>2</sup>Département de Chimie et Biochimie, Université de Moncton, Moncton, NB, Canada.

Caffeic acid and its naturally occurring derivative caffeic acid phenethyl ester (CAPE) have antiproliferative and cytotoxic properties in a variety of cancer cell lines, but little is known about their effects on prostate cancer cells. We evaluated the effects of caffeic acid, CAPE and 18 novel synthetic derivatives on cell proliferation, subcellular localisation and expression of androgen receptor (AR) and secretion of prostate-specific antigen (PSA) in LNCaP human hormone-dependent prostate cancer cells. LNCaP cells cultured in steroid-free medium were exposed to 0.1 nM dihydrotestosterone (DHT) in combination with various concentrations of caffeic acid derivatives (0.3-100  $\mu$ M) for 24-72 h during which cell proliferation was followed using an xCELLigence cell monitoring system (Roche). Cytoplasmic and nuclear levels of AR were determined by immunoblotting and PSA secretion using a commercial ELISA. Cytotoxicity was measured by assessing mitochondrial function using a WST-1 assay. Seven synthetic derivatives of CAPE were strong, concentration-dependent inhibitors of androgen-stimulated LNCaP cell proliferation with up to 3-fold greater potencies (IC<sub>50</sub>=8-24  $\mu$ M) than CAPE (IC<sub>50</sub>=28.9 $\pm$ 4.5  $\mu$ M); caffeic acid had no effect. Concomitant with inhibition of cell proliferation, DHT-stimulated PSA secretion was reduced by CAPE and the 7 derivatives. The most potent derivative MT-30 (IC<sub>50</sub>=7.9  $\pm$  2.4  $\mu$ M) inhibited DHT-stimulated cell proliferation and PSA secretion significantly at 0.3  $\mu$ M. Exposure to 10 nM DHT increased cytoplasmic and nuclear AR levels and co-treatment with increasing concentrations of MT-30 and CAPE, interestingly, further increased these levels. In conclusion, a number of synthetic derivatives of caffeic acid are potent inhibitors of androgen-dependent prostate cancer cell growth, acting via an antiandrogenic mechanism that involves increased nuclear accumulation of (possibly inactive) AR.

### PS 1933 Cadmium Content in Human Pancreatic Insulin Producing Beta Cells.

M. El Muayed<sup>1</sup>, K. W. MacRenaris<sup>2</sup> and W. L. Lowe<sup>1</sup>. <sup>1</sup>Division of Endocrinology, Northwestern University Medical School, Chicago, IL; <sup>2</sup>The Chemistry of Life Processes Institute, Northwestern University, Chicago, IL. Sponsor: J. Bolton.

Evidence suggests that chronic low level cadmium exposure impairs the function of insulin producing beta cells and may be associated with type 2 diabetes mellitus. We previously reported that insulin producing beta cells accumulate Cd avidly and gradually in a dose and time dependent manner over prolonged time periods, leading to impaired beta cell function at environmental Cd exposure concentrations. This is likely due to the high beta cell Zn turnover and the significant overlap between Zn and Cd transport and buffering mechanisms. In the present study we compared the content of cadmium (Cd) and Mercury (Hg) between native human islets with that of liver samples (10 human subjects living in the USA). The content of Cd and Hg in these tissues lysates was measured by ICP-MS. All studies were approved by our institutional review board. The cadmium (Cd) content in islets from 10 human non-diabetic subjects ranged from 7.4 to 71.92 nM/g protein (average 28.80  $\pm$  6.73 nM/g protein). The concentration of mercury (Hg) was significantly lower ranging from undetectable (detection threshold 4 nM/g protein) to 5.05 nM/g protein. In comparison, human liver lysates contained significantly less Cd (9.04  $\pm$  1.99 nM/g protein). No Hg was detected in any of the liver samples (detection threshold 4 nM/g protein). We conclude that human islets accumulate measurable, and likely relevant quantities of Cd that are higher than those of Hg under normal environmental exposure conditions. In comparison, the Cd concentration in Liver samples was significantly lower, likely due to the significantly lower Zn turnover rate in liver cells compared to that in beta cells.

### PS 1934 Formulation Development and Analysis Methods for Bisphenol AF in 5K96 Verified Casein Feed.

K. Aillon<sup>1</sup>, V. Ault<sup>1</sup>, A. Sullivan<sup>1</sup>, R. Mathias<sup>1</sup>, J. Algaier<sup>1</sup>, R. Harris<sup>1</sup>, B. Collins<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>MRIGlobal, Kansas City, MO; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

Bisphenol AF (BPAF), a perfluorinated BPA homologue, is a cross linking agent in fluoroelastomers used in food and pharmaceutical processing equipment. Due to inadequate toxicity data, occupational and potential consumer exposure, and structural similarity to bisphenol A, BPAF was selected for evaluation by the National Toxicology Program (NTP). MRIGlobal supported the NTP by formulating BPAF

into a phytoestrogen-free rodent diet, LabDiet 5K96 Verified Casein diet, developing the associated formulation analysis methods, and evaluating homogeneity and storage stability in the formulated diet.

The analysis method involved the extraction of BPAF from feed using acetonitrile/acetic acid (99/1 v/v). The method covered a formulation range of ~200 to ~10,000 µg/g with dilution into the curve up to 15,000 µg/g. The method was linear, accurate, and precise with BPAF recoveries ≥ 99%.

Homogeneity evaluation of 937.5 and 15,000 µg/g formulations showed recoveries ≥ 99% with RSD values ≤ 0.9%. Long-term BPAF stability for the 937.5 µg/g formulation showed the formulation was stable for 42 days (recovery ≥ 94.5%) when stored under refrigerated or freezer conditions.

When the 937.5-µg/g formulation was stored under simulated dosing conditions, in the presence of rat urine and feces, the ACN/acetic acid extraction resulted in an 68% BPAF recovery after 7 days, indicating possible BPAF instability or extensive binding to feed under these conditions. To investigate this, several solvents with different polarity and pH were tested. ACN/acetic acid 99/1 extraction resulted in 79% BPAF recovery after 8 days storage in the presence of rat urine and feces. Adding an additional acid-digestion and extraction step, in which the formulation was digested with 8.3N HCl at ~ 75°C and extracted with ethyl ether:petroleum ether (1:1), BPAF recovery increased to 90% in Day 7 samples. This suggests that BPAF is stable but exhibits non-covalent binding to feed components.

### PS 1935 Silencing of Testisin through CpG Methylation from Exposure to Phthalates in Ntera-2 Cells.

J. Gomes, J. Kapongo, B. Nguyen and D. Krewski. *University of Ottawa, Ottawa, ON, Canada.*

Di (2-ethylhexyl) phthalate (DEHP) is one of the most highly produced and frequently studied phthalates. Its metabolite, monoester mono (2-ethylhexyl) phthalate (MEHP) is reported to be a testicular toxicant. Following toxicity pathway analyses we identified Testisin, GSTP1 and MGMT genes to study their expression in testicular germ cells (Ntera-2). Testisin present in normal tissue but absent in neoplastic tissue and regulates proteolytic reactions in testicular germ cells; GSTP1 inactivates carcinogens and is a member of glutathione-S-transferase; and Methylguanine DNA methyltransferase (MGMT) provides defense against neoplasm. Testicular cells under laboratory conditions were exposed to MEHP in a dose- and time-dependent manner at concentrations of 1µM, 10µM, and 100µM at 24, 48, 72 and 96hr time points. The control was made by exposure of MEHP to 5'aza (demethylating agent) for hypermethylation. After exposure, those genes were analyzed by Quantitative Real Time PCR (qRT-PCR). The results revealed an overall down regulation for each gene as the concentration and/or time increased. The expression of Testisin, GSTP1 and MGMT was downregulated but not significantly in the last two cases. Following exposure to 5-aza treatment and coexposure, there was a significant up-regulation and restoration of the expression of the Testisin gene. This suggests that MEHP may down-regulate Testisin gene expression by DNA methylation. These findings provide evidence that MEHP can alter the expression of Testisin, GSTP1 and MGMT, genes. Testisin which is associated with testicular germ cell tumors and its downregulation and subsequent restoration may be caused by DNA methylation following exposure to MEHP. The expression of GSTP1 which is a xenobiotic metabolizing enzyme gene and the DNA repair enzyme gene suggests that the toxicant is fairly active in these cells exposed to MEHP. The investigation of DNA methylation at the CpG islands of the promoter region of Testisin is described.

### PS 1936 An Examination of the Effects of Methyltriclosan on Early-Embryonic Development in the South African Clawed Frog (*Xenopus laevis*).

M. Cromie<sup>1</sup>, M. Wages<sup>2</sup>, B. Perafan<sup>1</sup>, E. Smith<sup>2</sup> and J. Carr<sup>1</sup>. <sup>1</sup>*Biological Sciences, Texas Tech University, Lubbock, TX;* <sup>2</sup>*The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.* Sponsor: [W. Gao](#).

Triclosan (5-chloro-2-(2,4-dichlorophenoxy)phenol) is a commonly used bactericide present in many personal care products such as detergents, liquid hand soaps, deodorants, cosmetics, lotions, mouthwash, and toothpaste, and it can be integrated with fabrics, plastics, carpets, and toys. Methyltriclosan is a derivative that is formed from triclosan via biological methylation at an unknown interval during waste water treatment. Methyltriclosan is more abundant in the environment, more lipophilic than triclosan, and has a greater potential to accumulate in fatty tissues. The global decline of amphibian populations has raised awareness surrounding the possible effects of poor water quality on the health of habitats. Since metamorphosis and reproductive development in amphibians is highly regulated by thyroid hormone (TH), and the structure of triclosan is similar to that of TH, there is the possibility that triclosan and methyltriclosan may act on TH receptors to alter

metamorphosis and reproductive development. Standard 96-hour Frog Embryo Teratogenic Assay-Xenopus protocols were followed using South African Clawed Frog (*Xenopus laevis*) embryos. After measuring the larvae the data revealed that early embryonic exposure to environmentally relevant concentrations of methyltriclosan resulted in statistically significant alterations in total body length, snout-to-vent length and crown width. Furthermore, molecular studies were performed to identify the effects of methyltriclosan exposure on the TH-responsive gene, TH/bZIP. The results of the quantitative real-time polymerase chain reaction did not support the induction of TH/bZIP gene expression after exposure to environmentally relevant concentrations of methyltriclosan. However, the expression of other TH-responsive genes may be altered upon exposure. Collectively, these data are the first to report on the responsiveness of vertebrate embryos to methyltriclosan exposure.

### PS 1937 No Evidence of Endocrine Disruption by Glyphosate in Male and Female Pubertal Assays.

J. Bailey<sup>1,2</sup>, J. Hauswirth<sup>2</sup> and D. Stump<sup>3</sup>. <sup>1</sup>*Dow AgroSciences, LLC, Indianapolis, IN;* <sup>2</sup>*Joint Glyphosate Task Force, Raleigh, NC;* <sup>3</sup>*WIL Research Laboratories, LLC, Ashland, OH.*

The Food Quality Protection Act and Safe Drinking Water Act amendments (1996) required the USEPA to develop the Endocrine Disruptor Screening Program (EDSP), which currently consists of 11 Tier 1 screening assays to evaluate the potential for a chemical to interact with the endocrine system. Glyphosate was included in the first list of 67 compounds subject to the EDSP, which were selected for screening based on their potential for exposure rather than suspected interference with the endocrine system.

The potential for glyphosate (G) to induce endocrine disruption has now been evaluated in the male and female Pubertal assays, the two most apical mammalian EDSP Tier 1 assays.

The female pubertal assay evaluates potential effects on pubertal development and thyroid function in the juvenile female. Four groups of fifteen juvenile female rats were dosed with the following: 0, 100, 300 and 1000 mg/kg/d G once daily via oral gavage from postnatal day (PND) 22 to 42. There was no evidence of any direct test substance-related estrogenic or anti-estrogenic effects, nor was there any evidence of direct test substance-related effects on pubertal development or thyroid function in the juvenile female rat following oral administration of glyphosate at any dosage level tested.

The male pubertal assay evaluates potential effects on pubertal development and thyroid function in the juvenile males. Four groups of fifteen juvenile male rats were dosed with the following: 0, 100, 300 and 1000 mg/kg/d G once daily via oral gavage from PND 23 to 53. There was no evidence of any direct test substance-related androgenic or anti-androgenic effects, nor was there any evidence of direct test substance-related effects on pubertal development or thyroid function in the juvenile male rat at any dosage level tested.

Based on these results, glyphosate does not exhibit endocrine disruption in the male and female pubertal assays.

### PS 1938 Exposure to G-1, a Selective Agonist for G Protein-Coupled Estrogen Receptor 1 (GPER), Results in Elevated Levels of Vitellogenin in Adult Fathead Minnows (*Pimephales promelas*).

S. Jayasinghe<sup>1</sup>, K. Kroll<sup>1</sup>, N. Denslow<sup>1</sup> and T. Sabo-Attwood<sup>2</sup>. <sup>1</sup>*Department of Physiological Sciences, Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL;* <sup>2</sup>*Department of Environmental and Global Health, Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL.*

Several research groups have shown that G protein-coupled estrogen receptor-1 (GPER) mediates 17β-estradiol (E2) activation through non-genomic membrane initiated pathways. Estrogens play critical roles in a variety of biological processes, including reproduction and development in vertebrates. In fish, hepatic synthesis of vitellogenin (VTG), a precursor egg yolk protein that is vital to successful reproduction, is controlled by E2 via nuclear estrogen receptors (ESR). However, the involvement of GPER in vitellogenesis has not been investigated. As the GPER is not a well characterized in fish the aims of our study are to: (1) assess the tissue-specific expression of GPER in adult fathead minnows (FHM) and (2) determine the effect of GPER activation on VTG synthesis in FHM males and females using a selective GPER agonist (G-1) and antagonist (G-15). Using qRT-PCR we show that GPER mRNA is detectable in numerous organs, and is most highly expressed in the brain followed by gall bladder, trunk kidney, intestine, liver, heart, ovary and muscles. Aqueous exposure to G-1 (5, 30 and 100 ng/L) for 48 hours resulted in a dose dependent increase of hepatic VTG expression compared to vehicle control in both

males and females. In efforts to block GPER-mediated induction of VTG expression, we co-exposed male fish to G-1 and the GPER antagonist G-15. Preliminary results were surprising as the combination of G-1/G-15 enhanced VTG expression compared to each agent singly. Overall, these data suggest that control of VTG synthesis likely involves both nuclear and membrane receptors that are sensitive to E2 activation. We are currently investigating the impact of xenoestrogens on GPER activation in control of VTG synthesis.

**PS 1939 Study on the Subchronic Oral Toxicity of the Circuit Board Powder in Rats.**

N. Wu. Institute of Hygiene, Zhejiang Academy of Medical Sciences, Hangzhou, Zhejiang, China.

**Objective** To investigate the subchronic oral toxicity of the circuit board powder in SD rats. **Methods** Male and female SD rats were randomly divided into four groups named A, B, C and D, A and D group had 16 rats, B and C group had 14 rats, A and D group retained 4 rats for a 45d recovery experiment after the 90d subchronic experiment. A group was given normal diet as control, B, C and D groups were given mixed feed which was made from adding the circuit board powder 10, 20, 50g per kg to the normal diet. All of the groups were ate and drank freely under natural light. After 90 days' feeding, each group calculated the major organ coefficient, measured the blood biochemical parameters, and determined the content of serum triiodothyronine (T3), thyroxine (T4) and testosterone (T) after 45d, 90d and 45d recover. **Results** Compared with the control group, each dose group of the circuit board powder have no significant difference in body weight. There were significant differences between the high-dose group and control group of female rats in some blood biochemical parameters. The organ coefficient of liver in the medium- and high-dose groups of female rats was also significant increase. The content of serum T3, T4 and T in each dose group were significantly higher than that of the control group after 45d and 90d, each index had the most obviously increase in the low-dose group. There was no significant difference between the high-dose group and control group in serum T3, T4 and T after 45d recovery. **Conclusion** subchronic oral exposure to the circuit board powder can cause liver damage in rats, and elevated the content of serum T3, T4 and T.

**PS 1940 Activation of the Hypothalamic-Pituitary-Adrenal (HPA) Axis following Extended Exposure to Atrazine (ATR).**

S. C. Laws<sup>1</sup>, R. Cooper<sup>1</sup> and B. W. Riffle<sup>1,2</sup>. <sup>1</sup>ETB, TAD, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>ORISE, US Department of Energy, Oak Ridge, TN.

While it is known that adrenal steroids impact reproduction and a variety of other physiological and behavioral functions, disruption of the HPA-axis is not typically considered in toxicological studies. Here we characterize changes in basal corticosterone (CORT) and progesterone (P4) over a 21- day exposure to the chlorotriazine herbicide, ATR. Adult Wistar male rats were dosed by oral gavage with 0, 5, 25, 75, or 200 mg/kg/d given either as a single dose or multiple daily doses (7, 14, or 21 doses) at 0900 hrs (nadir of circadian CORT rhythm) and were decapitated 30 minutes after the last dose (n=10/group). Necropsy body weight was significantly lower than controls (p < 0.05) only in the 200 mg/kg group dosed for 21 days. Adrenal weights were unaffected by ATR at any time point. Serum CORT was elevated in response to a single dose of ATR (LOEL=5mg/kg). Serum CORT was also increased following 7 (LOEL=75mg/kg), 14 (LOEL=25mg/kg), and 21 (LOEL=75mg/kg) daily doses. A similar profile was observed for serum P4 following a single dose (LOEL=25 mg/kg), or 7 (LOEL=75 mg/kg), 14 (LOEL=75 mg/kg), and 21 (LOEL=200 mg/kg) doses of ATR. Urinary CORT (ratio of CORT/urinary creatinine), measured over a 6 hr period after dosing, was significantly increased in the ATR groups (e.g., LOEL for one dose =75 mg/kg, LOEL for 21 doses =75 mg/kg). These data demonstrate a HPA response after daily doses of ATR (e.g., 75 and 200 mg/kg) for up to 21 days. Further work is needed to evaluate the effects of ATR on the circadian CORT rhythm and to discern any impact on reproductive function. This abstract does not reflect U.S. EPA policy.

**PS 1941 2-Isopropylthioxantone (ITX) Induces Endocrine Disrupting Effects and Increases Liver Weight during Puberty in Male Wistar Rats.**

P. Hendriksen, E. Kramer, M. Groot, J. C. Rijk, R. L. Hoogenboom and A. A. Peijnenburg. Toxicology, RIKILT Institute of Food Safety, WUR, Wageningen, Netherlands. Sponsor: S. Rangarajan.

2-isopropylthioxantone (ITX) is a photo-initiator used in the printing process of many materials. ITX has been detected as contaminant in food such as milk and fruit beverages. Previous in vitro studies revealed ITX acting agonistic on the aryl

hydrocarbon receptor (AhR) and antagonistic on both the androgen receptor and estrogen receptor. In addition, ITX increases aromatase activity in vitro. To validate these findings in vivo, male rats were treated daily with 50, 150 or 500 mg/kg/day ITX during their puberty period from PND 23 to 53. For comparison, rats were treated with 50 ng/kg/day TCDD (AhR agonist), 30 mg/kg/day Casodex (AR antagonist) or 50 mg/kg/day flutamide (both AhR agonist and AR antagonist). ITX, from the lowest dose onwards, exerted a decrease in weight of the ventral prostate, and the highest dose of ITX decreased the weight of the seminal vesicles and coagulating gland, and reduced the number of spermatozoa in the cauda. The same effects, but more severe, were induced by flutamide and Casodex. Epididymal weight, caput sperm counts and preputial separation were negatively affected by Casodex and flutamide and not by ITX. ITX reduced testosterone and increased estrogen levels confirming the in vitro finding on increased aromatase activity. 500 mg/kg/day ITX-500 reduced the body weight, while it increased liver weight with 20% and relative liver weight with 38%. Whole genome mRNA expression profiling of the liver revealed a striking similarity of genes affected by ITX and flutamide. Furthermore, many TCDD-affected genes, including many known AhR target genes, were regulated by ITX as well. Taken together, these results convincingly demonstrates ITX to be an endocrine disruptor that exerts AhR agonistic and AR antagonistic activities both in vitro and in vivo.

**PS 1942 In Vivo Human Pharmacokinetics of Dibenzo[DEF, P]Chrysene (DBC) following Microdosing—Bridging the Gap between High-Dose Animal Data and Environmentally-Relevant Human Exposures.**

E. P. Madaan<sup>1,4</sup>, R. Corley<sup>3</sup>, K. W. Turteltaub<sup>2</sup>, T. Ognibene<sup>2</sup>, M. Malfatti<sup>2</sup>, M. Garrard<sup>1,4</sup>, K. Sudakin<sup>1,4</sup>, T. Mcquistan<sup>1,4</sup> and D. E. Williams<sup>1,4</sup>. <sup>1</sup>Oregon State University, Corvallis, OR; <sup>2</sup>Lawrence Livermore National Lab, Livermore, CA; <sup>3</sup>Pacific Northwest National Lab, Richland, WA; <sup>4</sup>Linus Pauling Institute, Corvallis, OR.

Polycyclic Aromatic Hydrocarbons (PAHs) comprise environmental mixtures of toxicants resulting from the combustion of carbonaceous material, of which some high molecular weight constituents are carcinogens in animal models. There is little data currently available on the pharmacokinetics or pharmacodynamics of any PAHs, especially the higher molecular weight, carcinogenic PAHs, in humans. Utilizing the sensitivity of accelerator mass spectroscopy (AMS), <sup>14</sup>C- labeled PAHs can be studied at environmentally relevant concentrations, below the average daily exposure and at levels regulatory agencies have determined from animal studies to be safe daily exposures over a lifetime. The 30 ng DBC dose utilized in this study has an EPA estimated B(a)Peq of 300-900 ng, falling within the U.S. daily dietary estimate of an average B(a)P exposure of 40-2800 ng/person . Over 90% of exposure to carcinogenic PAHs is through the diet. <sup>14</sup>C-DBC was detected in blood and urine post ingestion of a 5 nCi (30ng) <sup>14</sup>C- DBC dose given by capsule to healthy male and healthy, infertile female volunteers (n=9). Blood was collected at 15 time points over 72 hours with 11 collections during the first 8 hours post-dosing. Urine was collected in 5 pools over 72 hours with 3 pools in the first 24 hours. Plasma concentrations of <sup>14</sup>C reached maximal concentrations of 11 to 68 fg DBC eq./ml within 1.5-4 hr after consumption with an alpha phase half-life for <sup>14</sup>C clearance that averaged 3.5 ± 2.3 hr across all volunteers. A more prolonged beta-elimination phase was also observed. These results are the first available human pharmacokinetic data from a high molecular weight, probable human (IARC class 2A) carcinogenic, PAH. This unique dataset can be used to enhance the confidence of human health risk assessments to PAH exposures.

**PS 1943 Evaluation of Tumor Pathology Concordance between Epidemiological and Rodent Studies.**

J. Wan<sup>1</sup>, J. W. Card<sup>1</sup>, H. Fikree<sup>1</sup>, L. Haighton<sup>1</sup>, V. Lee-Brotherton<sup>1</sup> and B. Sangster<sup>2</sup>. <sup>1</sup>Intertek Cantox, Mississauga, ON, Canada; <sup>2</sup>ASAT Foundation, Leidschendam, Netherlands.

To assist with evaluating human cancer risk from chemical exposures, an investigation was conducted to assess concordance at the tissue level between tumors reported in epidemiological investigations and rodent bioassays for a selected group of chemicals. This investigation focused on chemicals that were considered to be probable human carcinogens (Group 2A) by IARC or "Reasonably Anticipated" carcinogens by the US NTP, and for which there was evidence of tumor concordance at the organ level. The 7 chemicals identified for this evaluation, and the organ-level tumor concordances for each, were as follows: 1-amino-2,4-dibromanthraquinone (lung), tetrachloroethylene (liver, kidney), trichloroethylene (liver, kidney), inorganic lead compounds (lung, kidney, brain), 2,4,6-trichlorophenol (lymphoma), polychlorinated biphenyls (liver, gastrointestinal), and benzyl chloride (lung). Based on pathology, concordance between rodent and human tumors for at least 1 tumor type was identified for 4 of the 7 compounds (tetrachloroethylene, trichloroethylene, inorganic lead compounds, and polychlorinated biphenyls);

however, the strength of the concordance was considered weak in all cases. For the same 4 compounds, there were a large number of tumors which lacked concordance between animal and epidemiological studies. Of the remaining compounds, insufficient data were available for an evaluation of tumor pathology (1-amino-2,4-dibromoanthraquinone and 2,4,6-trichlorophenol) or there was an absence of concordance at the tissue level (benzyl chloride). In conclusion, this investigation of concordance between animal and human tumors reported to be caused by specific compounds shows that, even when chemically-induced tumors are identified to be occurring in the same organ in both rodents and humans, there is no strong evidence of concordance of these tumors at the level of the affected tissue.

## PS 1944 Benchmark Dose Models for Benzene Genotoxicity Using the Diversity Outbred Mouse.

K. L. Witt<sup>1</sup>, G. E. Kissling<sup>1</sup>, D. L. Morgan<sup>1</sup>, K. R. Shockley<sup>1</sup>, D. M. Gatti<sup>2</sup>, G. A. Churchill<sup>2</sup> and J. E. French<sup>1</sup>. <sup>1</sup>DNTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>Center for Genome Dynamics, The Jackson Laboratory, Bar Harbor, ME.

The genetic basis for inter-individual variation in response to toxicant exposure is poorly understood. The Diversity Outbred (DO) mouse is a new model that can be used to explore population based response variation. DO mice were derived from a set of eight inbred founders and are maintained by random breeding as an heterozygous population containing over 38 million SNPs and 5 million indels (CNV). The genetic diversity and a fine recombination haplotype structure allow high mapping resolution. In experiments reported here, J:DO male mice were exposed to benzene (0, 1, 10, 100 ppm; 75 mice/group) by inhalation, 6 hr/day, 5 days/wk for 28 days in two independent cohorts (300 mice each). Samples of pre- and post-exposure peripheral blood (PB) or post-exposure for bone marrow (BM) were evaluated for frequency of micronucleated reticulocytes (MN-RET) using flow cytometry. MN-RET showed significant increasing trends in response to benzene exposure ( $p < 0.0001$ ) in both cohorts and were significantly higher than controls in both the 10 ppm ( $p = 0.013$ ) and the 100 ppm ( $p < 0.0001$ ) groups. Genotoxicity was highly variable within the 100 ppm groups. Linkage analysis identified quantitative trait loci (QTL) on chromosome 10 (Chr10) between megabase 26 and 35 (LOD=14.6). We identified benzene resistant and susceptible Chr10 QTL genotypes from the lowest and highest quartiles of the BM MN-RET response in the 100 ppm group. Animals in the 0, 1, and 10 ppm groups having these genotypes were placed into the resistant or susceptible groups for modeling. The benchmark concentration (BMC) and its 95% lower confidence limit (BMCL) were estimated from the best-fit model for the most resistant (BMCL = 5.9 ppm) and most susceptible (BMCL = 0.01 ppm) animals, a 590-fold difference between subpopulations. These data suggest that an uncertainty factor of 100 for interspecies and intraspecies variation may not be sufficient for calculation of a human benzene reference concentration based on benzene genotoxicity.

## PS 1945 Is There a Subset of Susceptible Individuals in Controlled Air Pollution Studies?

M. Seeley and J. E. Goodman. *Gradient, Cambridge, MA.*

To establish primary National Ambient Air Quality Standards for criteria air pollutants such as nitrogen dioxide (NO<sub>2</sub>), ozone (O<sub>3</sub>) and sulfur dioxide, US EPA evaluates results from epidemiology, controlled human exposure, and animal studies. For the controlled human exposure studies, which focus on individuals with asthma, there is concern that there may be a subset of susceptible individuals who respond to lower concentrations than the average individual with asthma, but whose response is obscured by evaluating group-level data. To address this, we identified controlled human exposure studies with more than one exposure concentration that provided individual-level data for airway hyper-responsiveness. We identified three studies involving exposure to NO<sub>2</sub> (including data for 38 subjects), and one study each for ozone (O<sub>3</sub>) and sulfuric acid (each including data for 10 subjects). For each study, we compared individual data across exposures to determine whether there were individuals who were consistently more or less responsive, defined by having a response that differed by more than two standard deviations from the group mean response. To determine whether evaluating group-level responses might obscure responses for potentially susceptible individuals, we compared the concentration-response function (CRF) for all subjects to the CRF for a subset that excluded less responsive subjects and the CRF for only more responsive subjects. Among the five studies, we identified only one subject, in one study, who was considerably more responsive at both exposure levels in the study. The shapes of the CRFs, however, were similar for the group as a whole and the more responsive subject. We also identified one subject, in one study, who was less responsive at all exposure levels in the study. Exclusion of data for this subject did not qualitatively change the shape of the CRF. Our analysis of these five studies indicates that evaluating group-level responses to air pollutants does not obscure CRFs for potentially susceptible individuals.

## PS 1946 Concordance of Transcriptional and Apical Benchmark Dose Levels for Conazole-Induced Liver Effects in Mice.

V. S. Bhat<sup>1</sup>, S. Hester<sup>2</sup>, S. Nesnow<sup>2</sup> and D. A. Eastmond<sup>1</sup>. <sup>1</sup>Environmental Toxicology, University of California Riverside, Riverside, CA; <sup>2</sup>NHEERL, US EPA, Research Triangle Park, NC.

The ability to anchor chemical class-based gene expression changes to phenotypic lesions and to describe these changes as a function of dose and time can inform mode of action and improve quantitative risk assessment. Previous research identified a 330-gene cluster commonly responsive to three hepatotumorigenic conazoles (cypro-, epoxi- and propiconazole) at 30 days. Extended to two more conazoles (triadimefon and myclobutanil), the present assessment encompasses four tumorigenic and one non-tumorigenic conazole. Transcriptional benchmark dose levels (BMDL<sub>T</sub>) were estimated for a subset (~50 genes) of the gene cluster that had a ≥5-fold change in signal intensity at the tumorigenic dose and demonstrated dose-responsive behavior. The modeled genes primarily encompassed pathways involved in Phase I/II or lipid metabolism, oxidative stress, MAP kinase signaling, and/or apoptosis (such as Cyp2b10, Lcn13, Abcc4, Akr1b7, Gadd45b). The median BMDL<sub>T</sub> estimates from the gene subset were concordant (within a factor of 0.8 to 1.2) with the apical benchmark dose (BMDL<sub>A</sub>) for increased liver weight at 30 days for the four tumorigenic conazoles. The 30-day median BMDL<sub>T</sub> estimates were within one-half order of magnitude (generally more sensitive) of the chronic BMDL<sub>A</sub> for liver tumors. Discordant 30-day BMDL<sub>T</sub> and BMDL<sub>A</sub> values were obtained for the non-tumorigenic conazole (myclobutanil). Potency differences seen in the dose-responsive transcription of some of these biomarker genes, particularly those involved in Phase II metabolism and bile acid transport (such as Gstm3, Gstm3, Abcc4, Akr1b7), mirrored each conazole's tumorigenic potency. The 30-day BMDL<sub>T</sub> and BMDL<sub>A</sub> estimates corresponded to tumorigenic potency on a mg/kg-day basis with cyproconazole > epoxiconazole > propiconazole > triadimefon > myclobutanil (non-tumorigenic). These initial results support the utility of measuring short-term gene expression changes to inform quantitative risk assessments from long-term exposures. This abstract does not reflect EPA policy.

## PS 1947 Assessment Factors for Susceptible Populations—Analysis of Airway Response during Short-Term Exposure to Volatile Chemicals.

M. Johansson, G. Johanson and M. Öberg. *Institute of Environmental Medicine, Stockholm, Sweden.*

Health-based guidance values for short-term exposure to airborne hazardous chemicals are developed to support the protection of the general population, including susceptible sub-groups such as asthmatics, in the case of sudden release of chemicals. The Acute Exposure Guideline Level (AEL) program is one of the most well-known set of short-term values. Our analysis of AEL documents reveals that only 8% include data on asthmatics. A comparison of documents in nine additional sets of short-term values shows that data on asthmatics are frequently disregarded. The aim of the present study was to investigate the experimental support of a general difference in airway response between healthy and asthmatic individuals during short-term exposure. We performed a review of experimental data from 108 studies including both asthmatic and healthy subjects exposed to airborne chemicals during identical experimental conditions. In total, experimental data for 19 chemicals and 9 mixtures were identified. Thresholds for airway response and the difference between asthmatic and healthy subjects were calculated in each study. The difference between subgroups was compared to the general assessment factors applied for susceptible populations in the derivation of guidance values. In addition, dose-response relationships of four high volume chemicals were calculated for healthy and asthmatic individuals, separately, to identify threshold concentrations for effects on lung function. Our results show that asthmatic individuals generally are more susceptible than healthy individuals. An inter-individual assessment factor of three may not be sufficiently protective for all chemicals.

## PS 1948 Thermal Constraints and Chemical Exposure in the Workplace: Prioritization of Occupations for Better Prevention.

A. Adam-Poupart<sup>1</sup>, G. Truchon<sup>2</sup>, M. Lévesque<sup>1</sup>, M. Busque<sup>2</sup>, P. Duguay<sup>2</sup>, R. Bourbonnais<sup>3</sup> and J. Zayed<sup>1,2</sup>. <sup>1</sup>Environmental and Occupational Health, Université de Montréal, Montréal, QC, Canada; <sup>2</sup>Institut de recherche Robert-Sauvé en santé et sécurité du travail (IRSST), Montréal, QC, Canada; <sup>3</sup>ROH Consultant, Laval, QC, Canada.

Chemicals and heat exposure are common hazards found in the workplace and their coexposure may lead to increased health risk due to potential interactions: some chemicals can affect the thermoregulatory mechanisms and reduce the

worker's capacity to adapt to heat, while heat exposure can modify physiological parameters and increase the absorption of some chemicals. Therefore, the aim of this research was to identify the occupations at risk of concomitant exposure to heat and chemicals in Quebec (Canada). To achieve this goal, a list of occupations from all industry sectors of Quebec was built from national employment data, and occupations at risk of heat stress were determined with a risk rating matrix based on the probability of occurrence and the severity of health effect. For occupations judged as having significant and critical heat stress risk, the presence of chemicals that may be found at work was documented (solvents, dust, pesticides, polycyclic aromatic hydrocarbons, toxic gases, heavy metals, asbestos/silica and reagents/other chemicals) and a list of occupations with high potential of simultaneous exposure to heat and chemicals was produced and submitted to a panel of experts for prioritization. From an initial set of 1010 occupations, 257 were judged as having significant and critical heat stress risk and 136 of these were included in the list of occupations with high potentially simultaneous exposure. Experts identified 22 priority occupations grouped in metal manufacturing, non-metallic mineral product, construction and public administration sectors. This innovative approach, based on a matrix analysis and judgment of experts, served as a useful tool to identify sectors/occupations where health risk assessments, preventive interventions and regulatory practices should be conducted or developed.

#### PS 1949 Acute and Chronic Noncancer Inhalation Toxicity Factors for Acrylonitrile.

J. Lee, R. L. Grant and S. Shirley. *Toxicology, TCEQ, Austin, TX.*

Acrylonitrile (AN) is used extensively in the production of plastics, synthetic rubber, nitrile elastomers, resins, and acrylic fibers. The USEPA indicates that Texas contributes 11% of the nations reported ambient AN emissions annually. Inhalation of AN vapors can cause respiratory irritation, and at higher levels, neurological symptoms including dizziness, weakness, headache, and impaired judgment. To ensure that the general public in Texas is protected against potential inhalation effects from AN exposure, the Texas Commission on Environmental Quality (TCEQ) has developed acute and chronic reference values (ReVs). An acute ReV (1-hr exposure duration) of 1100 µg/m<sup>3</sup> was derived based on no signs or symptoms observed in human volunteers exposed to AN for up to 8 hours. A chronic ReV of 2.2 µg/m<sup>3</sup> was derived based on benchmark dose modeling for increased nasal lesions observed in female rats. The chronic ReV is comparable to the California EPA reference exposure level of 5 µg/m<sup>3</sup>. Effects Screening Levels (ESLs) were calculated from ReVs by applying a target hazard quotient of 0.3, to account for possible cumulative exposure. ESLs are used to evaluate modeled ground level concentrations due to emissions from facilities during air permit reviews. The corresponding acute and chronic ESLs were 330 and 0.7 µg/m<sup>3</sup>, respectively. Reproductive/developmental animal and epidemiological data were not used to derive ReVs since AN is not expected to be a developmental or reproductive toxicant in the absence of significant maternal toxicity. Furthermore, the overall carcinogenic weight-of-evidence shows that while AN is capable of causing tumors in rats and mice at high doses, AN does not appear to contribute to the development of cancerous tumors in humans. Thus, no inhalation unit risk factor was derived. The derived chronic ESL, however, is within the range of the concentrations at 1 x 10<sup>-5</sup> cancer risk estimated by USEPA and thus, is expected to be protective against potential cancer risk.

#### PS 1950 Hexavalent Chromium Carcinogenicity: Use of a Nonlinear-Threshold Assessment to Develop a Cancer-Based Chronic Inhalation Reference Value.

N. Erraguntla<sup>1</sup>, J. T. Haney<sup>1</sup>, R. L. Sielken<sup>2</sup> and C. Valdez-Flores<sup>2</sup>. <sup>1</sup>*Toxicology Division, Texas Commission on Environmental Quality, Austin, TX;* <sup>2</sup>*Sielken & Associates Consulting, Bryan, TX.*

It is important to conduct up-to-date chemical assessments for known human lung carcinogens such as hexavalent chromium (CrVI). An updated carcinogenic assessment has been conducted for CrVI, which has been the subject of recent scientific debate. In addition to default linear low-dose extrapolation methods used to calculate an inhalation unit risk factor (URF), the study authors believe epidemiological data supported by data relevant to the mode of action (MOA) are sufficient to justify considering the results of a nonlinear-threshold carcinogenic assessment for comparison to URF-based de minimis excess risk (e.g., 1 in 100,000) air concentrations. The intent of the current study is not to perform an exhaustive weight of evidence evaluation of all data potentially relevant to the MOA (or MOAs), but rather to present available summary MOA information and statistical evidence interpreted as supporting a potential practical threshold for CrVI-induced carcinogenicity and the results of the consequential nonlinear-threshold inhalation carcinogenic assessment. Relevant epidemiological studies available in the scientific

literature were reviewed and additional statistical dose-response analyses conducted to identify potential carcinogenic thresholds and points of departure (PODs). Occupational-to-environmental dosimetric adjustment of the "sub-threshold" cumulative exposure POD selected (0.195 mg CrVI/m<sup>3</sup>-yr) resulted in a POD<sub>HEC</sub> of 0.0071 mg CrVI/m<sup>3</sup>. Uncertainty factors (total UF of 30) were then applied to derive a cancer-based chronic inhalation reference value (ReV) of 0.24 µg CrVI/m<sup>3</sup>. The margin of exposure is ≈16,000-475,000 based on the ratio of the "sub-threshold" cumulative exposure POD to cumulative exposures estimated based on annual average CrVI ambient air concentrations measured at various sites in Texas (5.9E-06 to 1.7E-04 µg CrVI/m<sup>3</sup>), which are ≈1,400-41,000 times lower than the calculated cancer-based chronic ReV.

#### PS 1951 Hypothesis-Based Weight-of-Evidence Evaluation of the Human Carcinogenicity of Toluene Diisocyanate.

R. L. Prueitt<sup>1</sup>, J. E. Goodman<sup>2</sup> and L. R. Rhomberg<sup>2</sup>. <sup>1</sup>*Gradient, Seattle, WA;* <sup>2</sup>*Gradient, Cambridge, MA.*

Humans are exposed to toluene diisocyanate (TDI) primarily through inhalation in workplaces where it is produced or used. It is classified as a possible human carcinogen, based primarily on increased tumor incidences in rodents treated with TDI by oral gavage. We used the hypothesis-based weight-of-evidence (HBWoE) method to conduct a novel evaluation of all the evidence regarding the hypothesis that TDI is a human carcinogen. We weighed the available data from epidemiology, animal toxicity, and mechanistic studies in terms of quality and relevance to humans, allowing each data set to inform one another. We then evaluated all of the data together to determine whether TDI carcinogenicity is plausible in humans. Our analysis determined that the epidemiology data are not sufficiently robust to support TDI as a human carcinogen; the few positive associations are more likely attributable to alternative explanations than causation. The experimental animal studies indicate that inhalation exposure to TDI does not induce tumors in rats or mice. Tumors observed after oral gavage exposure are most likely due to the conversion of a small amount of the administered TDI to toluene diamine (TDA), which also causes tumors in rats and mice when administered through this physiological exposure route. Further, TDA is formed in *in vitro* TDI genotoxicity assays. While TDI is genotoxic in these assays, it is not genotoxic in rodents or humans *in vivo* after inhalation exposure (during which TDA is not formed). Our HBWoE analysis indicates that the conversion of TDI to TDA is necessary for carcinogenesis to occur, but it does not occur in mammalian species under physiological exposure conditions. Thus, our analysis demonstrates that a causal association between TDI exposure and carcinogenic effects is not plausible in humans. This analysis not only provides insight about TDI carcinogenicity, but it addresses the larger issue of combining human, animal, and mechanistic data for risk assessment.

#### PS 1952 Evaluation of Toxic Effects of 3-MCPD and Associated Esters in Rats.

S. Onami<sup>1</sup>, Y. Cho<sup>1</sup>, T. Toyoda<sup>1</sup>, Y. Ishii<sup>1</sup>, T. Umemura<sup>1</sup>, M. Yoshida<sup>1</sup>, K. Horibata<sup>2</sup>, M. Honma<sup>2</sup>, T. Nohmi<sup>3</sup>, A. Nishikawa<sup>3</sup> and K. Ogawa<sup>1</sup>. <sup>1</sup>*Pathology, NIHS, Tokyo, Japan;* <sup>2</sup>*Genetics and Mutagenesis, NIHS, Tokyo, Japan;* <sup>3</sup>*Biological Safety Research Center, NIHS, Tokyo, Japan.*

3-Monochloropropane-1,2-diol (3-MCPD) is regarded as a rodent renal and Leydig cell carcinogen. Furthermore, 3-MCPD esters may be generated in various foods and food ingredients as a result of food processing. Since there are limited reports about toxicity of these compounds, we conducted the following two studies. 1) *In vivo* genotoxicity study (Pig-A and *gpt* gene mutation assays in the kidneys and testes, micronucleus assay) with male F344 *gpt* delta transgenic rats carrying reporter genes for mutations, treated by gavage with a carcinogenic dose of 3-MCPD (3.6×10<sup>-4</sup> mol/kg body weight) or its esters, i.e., 3-MCPD palmitate diester (PD), 3-MCPD palmitate monoester (PM) and 3-MCPD oleate diester (OD) at the molar equivalents for 4 weeks. 2) 13-Week subchronic toxicity study of these compounds with F344 rats at three doses where the highest was the same as that in the genotoxicity study. In the first study, no clear *in vivo* genotoxicity of 3-MCPD or its esters was observed in the three assays. In the 13-week study, the absolute and relative kidney weights were significantly increased in rats treated with 3-MCPD at a carcinogenic dose and the esters at high and medium doses. Relative liver weights were significantly increased in the 3-MCPD-treated rats and the high dose ester-treated rats, except for female rats treated with PM. By 4 weeks, 1 male and 5 females of 3MCPD group died from the renal tubular necrosis. On histopathological analysis, a significantly increased incidence of renal mineralization in all high dose ester-treated females and of apoptotic epithelial cells in the epididymis of 3-MCPD and high dose ester-treated male were observed as compared to vehicle control. The results suggest 3-MCPD fatty acid esters may be non-genotoxic but have potential toxicity for kidneys and epididymis of rats. NOAELs of PD, PM and OD were suggested to be 14, 8 and 15 mg/kg/day, respectively.

**PS 1953 A Simulation Study Investigating the Risk of Obtaining BMDs Which Are Higher Than the "True" BMD.**

J. Ringblom, G. Johanson and M. Öberg. *Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden.*

A central aspect of quantitative health risk assessment of chemicals is the derivation of the point of departure (POD). Historically, calculating NOAELs has been the most common way to obtain the POD. However, Benchmark Dose (BMD) analysis has been recommended as a more robust alternative, as it uses data from all dose groups in the study to derive the POD. An important step in the BMD approach is the identification of the BMDL, i.e. the lower limit of the confidence interval for the BMD. The aim of this study was to investigate how often the estimated BMDL corresponds to an effect greater than the critical effect, thereby underestimating the risk in the derivation of guidance values.

In this simulation study we assume a known sigmoidal dose-effect curve (and hence a known BMD) and examine how often the BMDL is higher than the "true" BMD. Effects were generated by Monte Carlo simulations using 5 different dose placement scenarios. All scenarios used 4 dose groups (control, low, medium and high dose) and logarithmic dose spacing. Each scenario was simulated using 5, 10, 20 or 50 animals per group, assuming dose-effect curves typically seen in continuous data from experimental studies. The BMD and the BMDL values were calculated using a set of 5 nested exponential models implemented in available BMD-software (BMDs and PROAST).

The results suggest that the risk of obtaining a BMDL which is higher than the true BMD can be considerably larger than normally expected. In one scenario the BMDL was higher than the true BMD in 74% of the simulations. This occurs because the second model in the nested set of models lacks the ability to level off at higher doses.

It is therefore suggested that the second model in the nested set ( $y = a \cdot e^{bx}$ ) should be used with caution. It is also important to visually inspect the dose effect curve and the individual data points.

**PS 1954 Characterizing the Impacts of Uncertainty and Scientific Judgment in Exposure Limit Development.**

A. Maier<sup>1</sup>, R. Sussman<sup>2</sup>, B. Naumann<sup>3</sup> and R. Roy<sup>4</sup>. <sup>1</sup>*Toxicology Excellence for Risk Assessment, Cincinnati, OH;* <sup>2</sup>*SafeBridge Consultants, Inc., New York, NY;* <sup>3</sup>*Merck and Co., Whitehouse Station, NJ;* <sup>4</sup>*Corporate Toxicology, 3M, St. Paul, MN.*

There is a misperception by some that exposure limits are precise estimates. In the eyes of risk managers, one discrete value is often considered to be "correct" and all others considered "incorrect." Exposure limits should be evaluated based on whether the value is derived in a manner "consistent with current principles" or "not consistent." An analysis of current risk assessment methods was conducted to identify the bases for variability in exposure limits for individual chemicals. The role of scientific judgments, risk policy perspectives, and evolving science methods were evaluated in the context of exposure limit setting methods. A systematic methods analysis shows that important drivers to be considered in evaluating acceptability of an exposure limit include: thoroughness of the review of available data, interpretation of results according to current scientific principles under the regulatory framework being used, and consideration of sufficient sources of variability and uncertainty. Sources of variability that may be encountered in risk assessments performed by different industrial hygienists or toxicology professionals using identical data sets include: selection of the point of departure, uncertainty factors used for data extrapolation, and use of adjustments for toxicokinetics, among others. These and related considerations form the basis of a "quality evaluation" process proposed for assessing the robustness of an exposure limit. Transparency in methods to assure robustness is a core principle embedded in risk assessment methods harmonization. Application of a systematic quality evaluation process provides for more informed use of exposure limits for risk management. A clear understanding of the basis for disparate values can provide useful information regarding the current level of uncertainty in the science and the level of confidence appropriate in using different exposure limits to characterize risk.

**PS 1955 Chemical-Induced Methemoglobin Formation and Exploration on Its Biological Threshold.**

Z. Yan<sup>1</sup> and Q. Zhao<sup>2</sup>. <sup>1</sup>*ORISE, Cincinnati, OH;* <sup>2</sup>*NCEA, US EPA, Cincinnati, OH.*

Methemoglobin (metHb) is hemoglobin with the iron oxidized from Fe<sup>2+</sup> to the Fe<sup>3+</sup> state. An accumulation of metHb in the blood (methemoglobinemia) is often observed in response to exposure to many chemical agents, such as aniline and aniline derivatives like dapsone, and is often used as the basis for the derivation of non-cancer risk values. Therefore, an understanding of the relative sensitivity of com-

mon laboratory animals compared to humans to these metHb-forming agents is important. In this research, we compared the relative sensitivities to dapsone, a metHb-forming agent in rats, mice, and humans based on the data from in vitro and in vivo studies. In vivo data indicate that humans are more sensitive to dapsone than rats, followed by mice. However, in vitro results are inconsistent in terms of metHb formation. The inconsistency can be explained by differences in liver metabolism among species. In vitro comparisons between the parent compound (dapsone) and its metabolite (hydroxylamine) also suggest that the metabolite is more potent than the parent compound to induce metHb. Due to a higher sensitivity in vivo, the rat might be a more suitable animal model than the mouse for predicting metHb-forming effects in humans. In addition to the relative sensitivities, we further examined the background levels of metHb to explore the potential for identifying the biologically significant threshold of metHb formation after exposure to metHb-forming agents. F344 rats were used as an example. We identified a 100% increase above the control mean as a benchmark response (BMR) based on the collected metHb background levels. A comparison of the identified BMR and one standard deviation from the control mean, as commonly used in benchmark dose modeling, suggests that the new BMR generates lower or comparable benchmark dose lower confidence limits (BMDLs). Therefore, a 100% increase above the control mean could be another way to establish a BMR for methemoglobinemia in F344 rats. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.

**PS 1956 Analysis of Possible Changes to the Levels of Concern for Polycyclic Aromatic Hydrocarbons in Seafood.**

R. E. Weil, L. D. Stuchal, A. S. Kane and S. M. Roberts. *University of Florida, Gainesville, FL.*

Anthropogenic contamination of coastal regions with oils from drilling operations, spills and tanker leaks has impacted coastal communities and seafood safety for decades, and will likely continue based on our oil-based economy. Federal and state agencies suspend commercial and recreational harvests in oil-affected regions based on testing for petrogenic toxicants, including polycyclic aromatic hydrocarbons (PAHs). Criteria for re-opening affected fisheries are dependent on human health risk-based levels of concern (LOCs) developed by the US Food and Drug Administration (FDA) for specific petroleum-related contaminants in seafood, including seven carcinogenic PAHs. As with the Deepwater Horizon oil spill and other oil spill events, FDA cancer-based risk assessment for seafood consumption applies the US Environmental Protection Agency (EPA) cancer slope factor for benzo[a]pyrene (BaP), and relative potency factors (RPFs) for the remaining six PAHs relative to BaP. Use of LOCs in risk assessment is based on numerous assumptions. Here we examine how LOCs for PAHs change with modifications based on: (1) variable seafood consumption rates using data reflective of high-end seafood consumers in affected regions, (2) an expanded list of carcinogenic PAHs and changes in relative potency factors as described in the EPA draft document "Development of a Relative Potency Factor Approach for Polycyclic Aromatic Hydrocarbon Mixtures," (3) the proposed change in the EPA cancer slope factor for BaP (the index carcinogenic PAH), and (4) exposure assumptions relevant to children, including incorporation of an age-dependent adjustment factor for PAH carcinogenicity. Analyses provide an indication of both direction and magnitude of changes in LOCs associated with each possible modification. This study suggests that LOCs for PAHs in seafood from the Gulf of Mexico may be more numerous and markedly lower than the suite currently applied relative to the Deepwater Horizon oil spill.

**PS 1957 The Use of Genetically Modified Mice in Cancer Risk Assessment: Challenges and Limitations.**

S. V. Vulimiri<sup>1</sup>, D. A. Eastmond<sup>2</sup>, J. E. French<sup>3</sup> and B. Sonawane<sup>1</sup>. <sup>1</sup>*National Center for Environmental Assessment, US EPA, Washington DC;* <sup>2</sup>*Cell Biology & Neuroscience, University of California Riverside, Riverside, CA;* <sup>3</sup>*NIHES, Research Triangle Park, NC.*

The use of genetically modified (GM) mice to assess carcinogenicity is playing an increasingly important role in the safety evaluation of chemicals. While progress has been made in developing and evaluating models such as the *Tsp53+/-*, the *Tg.AC* and the *nash2* models, the suitability of these models as replacements for the conventional rodent cancer bioassay and for assessing human health risks remains uncertain. The objective of this research was to evaluate the prospective use of GM mice and the recently developed accelerated cancer bioassays in evaluating the potential health risks associated with exposure to carcinogenic agents. We compared the published results from the GM bioassays with those obtained using the National Toxicology Program's conventional chronic mouse bioassay for their potential use in risk assessment. To date, the GM models have shown moderate success in distinguishing carcinogens from non-carcinogens. Analysis of information

from different studies indicates that the GM models are less efficient in detecting carcinogenic agents but more consistent in identifying non-carcinogenic agents. We identified several issues of concern related to the assay design of GM models (e.g., sample size, study duration, genetic stability, and reproducibility) as well as pathway-dependent effects, and different carcinogenic mechanisms operable in GM and non-GM animals. The use of the GM models for dose-response assessment is particularly problematic as these models are, at times, much more or less sensitive than the conventional cancer bioassays. Thus, the existing GM mouse models may be useful for hazard identification, but will be of limited use for dose-response assessment. Hence, caution should be exercised when using GM mouse models to assess the carcinogenic risks of chemicals.

**PS 1958 Integrating Local Communities in the Health Risk Assessment Process following the Deepwater Horizon Oil Spill—A Focus on Vietnamese-Americans.**

M. J. Wilson<sup>1</sup>, S. Frickel<sup>4</sup>, D. Nguyen<sup>5</sup>, J. Howard<sup>1</sup>, B. R. Simon<sup>3</sup> and J. Wickliffe<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Environmental and Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Vietnamese-American populations in southeast Louisiana consist largely of commercial and subsistence fisherfolk and represent one of the highest seafood consuming groups in the Gulf South. We collected targeted survey data from a Vietnamese-American fishing community in Orleans Parish Louisiana, to determine shrimp consumption rates, body weights, ages, and genders in order to conduct deterministic and probabilistic health risk assessments tailored to this unique population. Cancer risk estimates and levels of concern (LOCs) for several polycyclic aromatic hydrocarbons were determined using GC/MS in SIM mode on a sample of white shrimp collected from the Gulf with shrimpers from this community. Our approach also developed health risk assessments using LOCs, oral slope factors, and risk levels used by the Food and Drug Administration and the Natural Resources Defense Council. Our results demonstrate the need to include key populations in the risk assessment process and measure risk model parameters in such populations rather than rely solely on generic exposure assumptions.

**PS 1959 Challenges in Safety Assessment of Botanicals in Cosmetics: A Possible Risk Assessment Strategy.**

B. Mukerji, P. Hepburn, E. Antignac, T. Ashikaga, D. Chavez, K. Khoo, P. Sinhaseni and A. Khaiat. *Safety and Toxicology, Asean Cosmetic Association, Singapore, Singapore.*

There is a growing trend of using botanical raw materials in personal care products, such as those used in traditional medicine or those from the many exotic plants which may be part of local folklore or food use. These materials present a challenge to both the Product Developer and Regulator alike, in assuring the development of safe cosmetic products, from the complex composition of the materials through to the lack of documented data on history of use and safety.

This paper presents a strategy for the safety assessment of these botanicals used in cosmetics, based on various risk assessment concepts. A critical first step in the risk assessment is the characterisation of the botanical raw material, with key measurements being identified. A complete understanding of "what is known?" about the material should then be developed from both literature sources as well as traditional knowledge. It may then be possible to determine whether a history of safe use (HOSU) can be established and if the material can be considered safe at that stage for particular cosmetic applications. If not then further risk assessment approaches (ie comparative approach, threshold of toxicological concern (TTC)) are proposed. Finally, in order to complete the risk assessment there may be a need to fill gaps in the hazard profile and/or potential consumer exposure scenarios, by conducting some further testing.

**PS 1960 Simulation of Acute Reference Dose (ARfD) Setting for Pesticides in Japan.**

M. Yoshida<sup>1</sup>, D. Suzuki<sup>1</sup>, K. Matsumoto<sup>2</sup>, K. Inoue<sup>1</sup>, M. Takahashi<sup>1</sup>, T. Morita<sup>3</sup>, M. Shirota<sup>4</sup> and A. Ono<sup>5</sup>. <sup>1</sup>Department of Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Research Center for Human and Environmental Sciences, Shinshu University, Nagano, Japan; <sup>3</sup>Division of Safety Information on Drug, Food and Chemicals, National Institute of Health Sciences, Tokyo, Japan; <sup>4</sup>Laboratory of Comparative Toxicology, School of Veterinary Medicine, Azabu University, Kanagawa, Japan; <sup>5</sup>Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan.

We conducted simulations of Acute Reference Dose (ARfD) setting, based on review documents of 208 pesticides published by Food Safety Commission (FSC) in Japan. These pesticides were evaluated in FSC during last 8 years. We applied the conceptual framework of Solecki, et al.(2005) to create and implement a conceptual framework adapted to current assessment needs in Japan. Through this process, we were able to set the ARfDs for over 90% of those 208 pesticides. The studies that provided the rationale for ARfD setting were primarily reproductive and developmental toxicity studies, acute neurotoxicity studies, and pharmacology studies. It was not necessary to establish ARfDs for approximately 30% of the pesticides simulated in the present study. Some of the simulated ARfDs might be conservative, and some endpoints for ARfD setting might not be proper, because the published data obtained in the present study were written for acceptable daily intake (ADI) setting. We were unable to set an ARfD for 14 pesticides because of insufficient data on acute toxicities. This could be improved by more complete record-keeping (for example, the type of changes observed immediately after administration, and the duration of the observation period). Furthermore, we categorized the 208 pesticides by mechanism of action or chemical structure. In comparison of absolute ARfDs or relative ARfDs to ADI among the categories, considerable number of pesticides with similar mechanisms of action or similar chemical structure also showed similar ARfDs.

**PS 1961 Tumour and In-Life Data from CD-1 Mouse Dietary and Oral Gavage Tumorigenicity Studies, Completed over the Period of 1995 to 2011.**

W. N. Hooks<sup>1</sup> and I. Taylor<sup>2</sup>. <sup>1</sup>Safety Assessment, Huntingdon Life Sciences, Huntingdon, United Kingdom; <sup>2</sup>Pathology, Huntingdon Life Sciences, Huntingdon, United Kingdom. Sponsor: D. Mitchell.

A previous review (1) of Crl:CD-1 ® (ICR) BR mouse tumorigenicity studies indicated terminal (Week 104) mortality values of 53±10.2% for males and 57±7.7% for females, with no major differences between the dietary and oral gavage routes of administration. Expanding on this, the aim of this review was to establish if the in-life data and tumour profile had changed over time and if there were any differences between the routes of administration. Data was analysed from over 60 mouse studies terminated at or about 2 years and completed over the period of 1995 to 2011. Analysis of bodyweight gain and food consumption over the first year revealed lower values for oral gavage studies (both sexes) when compared with dietary studies. The analyses over time (Period 1, 1995-2001 against Period 2, 2002-2011), performed for oral gavage studies only, did not show any remarkable differences. The most prevalent tumours were hepatocellular adenoma/carcinoma and adrenal adenoma (males), bronchioalveolar adenoma/carcinoma, Harderian gland adenoma and haemopoietic tumours (males and females), and uterine polyps (females). Generally, excluding the latter, these tumours were also the major pathological factors contributory to death (FCTD). Other major FCTD included urinary tract lesions (males) and ovarian haemorrhagic cysts (females). The most prominent difference between dietary and oral gavage studies was a lower incidence of hepatocellular tumours (males) in the latter. Analyses over time (for oral gavage studies only), indicated a lower incidence of hepatocellular tumours (males) and Harderian gland adenoma (both sexes) in Period 2. In conclusion, although there were some differences in the mortality patterns, in-life parameters, tumour profile and FCTD between the alternative oral routes and between the time periods, the CD-1 mouse has a well-defined tumour profile and continues to be suitable strain for use in tumorigenicity bioassays.

**PS 1962 Factors Influencing the Outcome of Developmental Neurotoxicity Studies of Bisphenol A—Implications for Regulatory Testing and Risk Assessment.**

A. Beronius<sup>1</sup>, N. Johansson<sup>1</sup>, C. Rudén<sup>2</sup> and A. Hanberg<sup>1</sup>. <sup>1</sup>*Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden;* <sup>2</sup>*Department of Applied Environmental Science, Stockholm University, Stockholm, Sweden.* Sponsor: G. Johansson.

Developmental neurotoxicity (DNT) of bisphenol A (BPA) has been investigated in a large number of studies. However, there are discrepancies in the results reported between these studies. This investigation aims to identify and analyze factors that have contributed to these differences and to assess whether there are sex-differences in the sensitivity of certain endpoints or tests used in DNT-studies.

Forty-four DNT studies of BPA were identified in the open literature. Details about study design and results from each study, as well as the criteria for DNT testing according to the standardized OECD test guideline (TG) 426, were collected in a data base. This enabled systematic and detailed comparisons between studies as well as to the TG criteria. Multivariate analyses of the compiled data were applied in order to investigate how different factors of the study design contribute to differences in outcomes between studies.

The results from this investigation indicate that the choice of behavioral endpoints and the behavioral test methods used seem to have the largest impact on study outcome. In general, the most sensitive endpoints were the ones not required according to the standard OECD TG 426. Interestingly, non-standard endpoints seem to be especially important to detect effects in females.

One main conclusion from this investigation is that non-standardized studies seem to provide information that could be pivotal for the risk assessment of BPA, especially in the identification of effects in females. There is a need to develop tools that improve the usability of non-standardized studies in risk assessment of chemicals, particularly with regard to endocrine disrupting compounds, and that can facilitate the evaluation of data obtained from such studies.

**PS 1963 Development of Human Health Benchmarks for Pesticides.**

S. Ramasamy<sup>1</sup>, E. Doyle<sup>1</sup>, B. Behl<sup>1</sup>, B. May<sup>2</sup>, M. Goodis<sup>2</sup> and S. Knizner<sup>3</sup>. <sup>1</sup>*Office of Water, US EPA, Washington DC;* <sup>2</sup>*Office of Pesticide Programs, US EPA, Arlington, VA;* <sup>3</sup>*Office of Environmental Information, US EPA, Washington DC.*

On March 22, 2010, EPA Administrator, Lisa P. Jackson announced a new drinking water strategy that outlines four principles to expand public health protection. One of these principles is to use the authority of multiple laws to more effectively protect drinking water, by sharing data collected under different statutes. Under this principle, the Office of Water (OW) and the Office of Pesticide Programs (OPP) collaborated to develop the human health benchmarks for approximately 350 pesticides (HHBPs) that are currently registered to be used on food crops. These HHBPs are levels of certain pesticides in water at or below which adverse health effects are not anticipated from one-day or lifetime exposures. EPA derived the HHBPs using toxicity studies conducted on laboratory animals submitted to EPA under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA) the Federal Food Drug and Cosmetics Act (FFDCA) as amended by the Food Quality Protection Act (FQPA), with the typical methods used for developing drinking water health advisories under the Safe Drinking Water Act (SDWA). Specifically, EPA used the acute or chronic reference doses established for human dietary assessment for the most sensitive population and applied standard exposure assumptions used in calculating drinking water health advisories based on gender, age, body-weight, and water consumption of target populations. For the acute benchmark, the entire exposure is assumed to occur from drinking water (100 percent). For the chronic benchmark, EPA applied a default relative drinking water source contribution (20 percent), assuming additional exposure may arise from other sources. The HHBPs are not enforceable. EPA is providing the benchmarks for informational purposes for use by states, water systems and the public to help understand monitoring data for pesticides that have no drinking water standards or health advisories. The HHBPs can be found on EPA's website at: <http://www.epa.gov/pesticides/hhbp>

**PS 1964 Differences between US EPA Iris Inhalation Reference Concentrations (RfCs) and European Chemicals Agency (ECHA) Long-Term Inhalation Derived No Effect Levels (DNELs) for the General Population.**

M. Jackson<sup>1</sup>, R. Lemus-Olalde<sup>2</sup>, C. Inhof<sup>2</sup>, Z. Yin<sup>2</sup>, B. Locey<sup>1</sup>, B. H. Magee<sup>3</sup> and K. T. Connor<sup>3</sup>. <sup>1</sup>*ARCADIS, Brighton, MI;* <sup>2</sup>*ARCADIS, Cincinnati, OH;* <sup>3</sup>*ARCADIS, Chelmsford, MA.*

ECHA previously released manufacturer/importer REACH (Registration, Evaluation, Authorization and Restriction of Chemicals) chemical registration files, making available the Derived No Effect Levels (DNELs) for hundreds of substances. The DNEL is defined as "the level of exposure above which humans should not be exposed" and needs to reflect the likely route(s), duration and frequency of exposure. Typically, DNELs are developed by Industry using ECHA's guidance; the registrant has the final decision on the selection of the key studies, endpoints of concern, and the assessment factors to account for sources of uncertainty, instead of a regulatory agency such as the U.S. EPA for the IRIS program. Considering this major difference, we have conducted a comparison analysis between REACH's long-term inhalation DNEL for non-carcinogenic effects for the general population and IRIS' chronic RfC, which is defined as "an estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime." Overall, despite being defined similarly, many of the current U.S. EPA IRIS inhalation RfCs for which long-term inhalation DNELs were available are lower by a factor of at least 10. The differences between these RfCs and DNELs may be a result of differences in the processes by which they are derived, including differences in the availability of toxicity data, as unpublished data or ECHA-required data may be used in the REACH assessments [ECHA requires the registrant to conduct toxicity testing (when data for a required endpoint are not available)], the entity (industry versus regulatory agency) responsible for generating the reference values, the methodologies and selection of default values used in the derivation, and the process by which the final values are accepted.

**PS 1965 Assessment Factors in Human Health Risk Assessment and Their Associated Level of Safety.**

S. Escher<sup>2</sup>, S. Hoffmann-Doerr<sup>1</sup>, M. Batke<sup>2</sup> and I. Mangelsdorf<sup>2</sup>. <sup>1</sup>*BASF Personal Care and Nutrition GmbH, Duesseldorf, Germany;* <sup>2</sup>*Fraunhofer Institute for Toxicology and Experimental Medicine - ITEM, Hannover, Germany.* Sponsor: K. Wiench.

Human health risk assessment requires solid information on adverse effects after long-term exposure. Because of ethical considerations, human data or long-term studies with animals are in general scarce. Consequently, reliable assessment factors (AF) are needed in risk assessment to overcome differences between short-term animal studies and the human situation.

In human health risk assessment, traditional AF are established, e.g. a factor of 100 (10 x 10) for interspecies/intraspecies extrapolation. Some of these AF were substantiated by either deterministic or probabilistic approaches, whereas other factors lack a scientific rationale. Furthermore, the level of safety achieved with the application of more than one AF has remained an open question so far. Our analyses aimed therefore at the derivation of AF and their corresponding level of safety when applied solely or in combination in human health risk assessment.

The toxicological database RepDose(TM) (containing appr. 2500 repeated dose studies on appr. 700 chemicals) served as the basis for the derivation of AF. Pairs of NOEL ratios - e.g. obtained from two studies with the same chemical and species, but different application durations if time AF were analyzed - were plotted in a distribution curve. Distribution curves for interspecies and time extrapolation were evaluated. All distribution functions were best described by lognormal curves. Furthermore, the combinations of these distributions were analyzed in probabilistic approaches by means of Monte Carlo simulations. On the basis of the resulting distribution curves, overall AF were determined, for which the corresponding percentile indicates the associated level of safety. Our results demonstrate that the probabilistic approach is well suited to derive AF, provided that the database is comprehensive and contains studies of good quality.

**PS 1966 Associations between Carcinogenic and Immune Suppression Activities of PAHs: Insights into Improving Cancer Risk Assessment for PAH Mixtures.**

K. Zaccaria and P. McClure. *SRC, Inc., Syracuse, NY.*

Multiple studies have noted that many carcinogenic polycyclic aromatic hydrocarbons (PAHs) also demonstrate immunosuppressive effects. Here, we have tested the strength of this association by deriving both cancer and immunotoxic relative potency factors (RPFs) for multiple PAHs, using the well-studied carcinogenic and immunotoxic compound benzo(a)pyrene (BaP) as the index PAH. Our quantitative analysis demonstrated a correlation between the immunosuppressive and carcinogenic potential of PAHs. As evasion of immune destruction has been identified as an "emerging hallmark of cancer" (Hanahan and Weinberg, 2011 Cell 144: 646-674), we propose that this association between carcinogenic and immune suppression activities of PAHs offers an opportunity to improve cancer risk assessment for PAH mixtures. While current assessments of cancer risks from PAH-containing fractions of environmental mixtures rely on a component-based RPF approach, we hypothesize that a more scientifically defensible whole mixtures approach would be advanced not only by a battery of inexpensive, short-term tests of different modes of carcinogenic action (e.g., genotoxic and non-genotoxic), but also a battery of tests for immunosuppressive activity. The addition of immunotoxicity tests may improve the ability to discern the similarity of an untested environmental mixture with reference mixtures that have cancer slope factors. Therefore, we performed a comprehensive review of the immunotoxic effects of BaP, and developed an integrated knowledge map illustrating immunosuppressive effects of BaP and, when known, tissue-specific mechanistic information. Our analysis revealed that research to date has not yet identified a transcriptional signature(s) for immune suppression to aid in the development of a specific battery of short-term in vitro test for immunotoxicity. Thus, future directed research to develop and validate a battery of tests for immunotoxicity is warranted and could find widespread use in assessing cancer risk from environmental PAH-containing mixtures.

**PS 1967 Potential Involvement of Oxidative Stress and Iron Disturbance in the Development of Oral Cavity Tumors in Rats Exposed to Hexavalent Chromium.**

M. Suh<sup>1</sup>, C. T. Thompson<sup>1</sup>, G. Hixon<sup>1</sup>, M. A. Harris<sup>1</sup>, C. R. Kirman<sup>2</sup>, S. M. Hays<sup>2</sup>, L. C. Haws<sup>1</sup> and D. M. Proctor<sup>1</sup>. <sup>1</sup>*ToxStrategies, Katy, TX*; <sup>2</sup>*Summit Toxicology, Allenspark, CO.*

In the NTP 2-year Cr(VI) drinking water study, the incidence of oral cavity tumors was significantly increased in male and female rats of the highest dose group (516 mg/L sodium dichromate dihydrate [SDD]). We investigated the potential involvement of iron (Fe) disturbance and oxidative stress in rat oral cavity tumor formation because Cr(VI) has been shown to compete with Fe uptake and causes microcytic anemia at high doses. Also, Fe deficiency can cause oxidative stress. We measured the GSH/GSSG ratios in rat oral mucosa and plasma following 90-days of treatment, and observed a significantly decreased ratio in oral mucosa at exposures  $\geq 60$  mg SDD/L, and in plasma at  $\geq 170$  mg SDD/L. We also found that Fe levels were significantly decreased in rat liver at  $\geq 60$  mg SDD/L, in bone marrow at  $\geq 170$  mg SDD/L, and in the duodenum at 520 mg SDD/L. A statistical mediation analysis using the NTP data on rat oral cavity tumor incidence and that for chronic liver inflammation, bone marrow hyperplasia, and salivary gland atrophy—all of which may be caused by Fe disturbance—was conducted to assess the association between Fe disturbance and oral cavity tumors in treated rats. The link from Cr(VI) exposure to these three endpoints combined was significant, as well as the link from these endpoints combined to oral tumors,  $t(498)=3.985$ ,  $p<1\times 10^{-4}$ . When each endpoint was analyzed separately, only the link from Cr(VI) exposure to salivary gland atrophy, and that from salivary gland atrophy to tumors were significant,  $t(498)=4.282$ ,  $p<1\times 10^{-4}$ . Taken together, these findings suggest that Fe metabolic disruption, oxidative stress and salivary gland atrophy may contribute to tumor formation in Cr(VI)-exposed rats. Further, these cancers may be species-specific as rats are generally more susceptible to oral cancers than mice, oral tumors were not observed in the NTP Cr(VI) treated mice, and no increase in oral cavity tumors have been reported in Cr(VI)-exposed workers.

**PS 1968 Estimating the Relative Bioavailability of Polycyclic Aromatic Hydrocarbons (PAHs) from Soil at Environmentally-Relevant Concentrations.**

J. W. Munson<sup>1</sup>, Y. W. Lowney<sup>2,1</sup>, M. V. Ruby<sup>3</sup> and S. M. Roberts<sup>1</sup>. <sup>1</sup>*CEHT, University of Florida, Gainesville, FL*; <sup>2</sup>*Exponent, Boulder, CO*; <sup>3</sup>*Integral Consulting, Louisville, CO.*

Polycyclic aromatic hydrocarbons (PAHs) are common soil contaminants at a variety of sites, including industrial facilities, military bases, and former skeet ranges. The risk from exposure to PAHs in soil is driven primarily from incidental ingestion of carcinogenic PAHs, and as with many other soil contaminants, is dependent in part upon their oral bioavailability. Most previous studies attempting to understand PAH bioavailability from soil have used PAH concentrations well above the range of greatest environmental interest. We report here a method by which the relative oral bioavailability (RBA) of 3H-benzo[a]pyrene (BaP) in vivo in constructed, weathered soils and PAH source materials can be measured at BaP concentrations in the ppb range. A suite of these materials is being used to examine the BaP-soil interactions that may control in vivo RBA, as well as for the development of in vitro PAH RBA estimation methods. Soil was spiked with 3H-BaP in varying concentrations and allowed to weather for up to two months. No loss of BaP or 3H label was observed as a result of weathering. Rats were administered a single dose of soil or PAH source material by gavage, and blood samples were taken via jugular cannula for up to six days after the dose. For comparison, in order to estimate RBA, other rats were given a comparable gavage dose of 3H-BaP added to food. The area under the curve (AUC) for total radioactivity in blood was used to indicate absorbed BaP dose for each animal, and the ratio AUCs for soil versus food doses was used to estimate RBA for the soil or PAH source material. AUCs could be measured without difficulty for soil/food BaP concentrations as low as 200 ppb, facilitating study of critical factors controlling bioavailability at environmentally relevant concentrations. Supported in part by a grant from the Strategic Environmental Research and Development Program (SERDP).

**PS 1969 Mode-of-Action Evaluation for Lung Tumors in Mice Exposed to Ethylene Oxide via Inhalation.**

Moore<sup>2</sup>. <sup>1</sup>*Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH*; <sup>2</sup>*Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR*; <sup>3</sup>*Dow Europe GmbH, Horgen, Switzerland*; <sup>4</sup>*Toxicology & Environmental Research and Consulting, Dow Chemical Company, Midland, MI.*

Ethylene oxide (EO) is a direct acting mutagen and a rodent carcinogen, but it is uncertain whether EO is carcinogenic through a mutagenic mode of action (MOA). To address the MOA for mouse lung tumors, an integrated study was conducted evaluating a variety of biomarkers related to oxidative stress, DNA reactivity/ breakage, mutations in a reporter (cII) and endogenous (K-ras) gene, and cell proliferation as putative key events, in the target tissue. The dose response and temporality for these key events was assessed in male B6C3F1 mice exposed to 0, 10, 50, 100, or 200 ppm EO (4 weeks) or 0, 100, or 200 ppm EO (8 or 12 weeks) by inhalation (6 hours/day, 5 consecutive days/week). Results indicate that: (1) EO does not appear to cause the lung tumors primarily via its DNA reactivity, since a sustained increase in cII MF was not seen at 100 ppm (which produced substantial increases in lung tumors in the mouse NTP study), and the increase at 200 ppm was only weak. (2) Oxidative stress is likely to play a multifaceted role in the tumorigenic process, in light of the absence of an effect on 8-OHdG adducts, and the observed mutation spectra of K-ras codon 12 and cII. The role of EO-induced DNA adducts in the etiology of the observed mutations needs further elucidation. (3) The available data on cell proliferation and K-ras mutations support a MOA that includes effects on intracellular signaling pathways and selection of preexisting K-ras mutant cells, as well as an interplay between oxidative stress and RAS activation. These results suggest a complex multi-faceted MOA, potentially involving EO action at multiple steps along the pathway to tumor development.

**PS 1970 Challenges in Estimating Safe Levels of Nanomaterials for Humans from Animal Toxicology Experiments.**

A. Bacom<sup>1</sup>, M. Odin<sup>1</sup>, P. McClure<sup>1</sup>, K. Salinas<sup>1</sup>, P. Wood<sup>2</sup>, D. Bottimore<sup>2</sup> and T. Thomas<sup>3</sup>. <sup>1</sup>*SRC, Inc., East Syracuse, NY*; <sup>2</sup>*Versar, Inc., Springfield, VA*; <sup>3</sup>*US Consumer Product Safety Commission, Bethesda, MD.* Sponsor: *G. Diamond.*

The use of nanosized particles in commercial products is increasing, leading to greater exposure of people to these materials. Exposure is most likely to occur through inhalation and dermal routes, but oral exposure may also occur. We evaluated published toxicity data for 3 different nanomaterials: nanosilver (nAg), nanotitanium dioxide (nTiO<sub>2</sub>), and carbon nanotubes (CNT), as a preliminary step for

deriving safe exposure levels for these materials. Each of these materials comes in a multitude of forms, varying in size, shape, structure, purity, and surface coating, which affect chemical properties, such as solubility, reactivity, and propensity for agglomeration. All 3 nanomaterials have multiple repeated exposure inhalation studies available, suitable for use in dose-response assessment, but only nAg has repeated dose oral studies, and none of the materials has a suitable dermal study. The lung was the critical target in the inhalation studies of all 3 materials, with pulmonary inflammation being the most sensitive endpoint. For nAg, the liver was also identified as a target by both inhalation and oral exposure (bile duct hyperplasia). Using these data, it is possible to derive safe exposure levels for long-term exposure to the specific forms of nAg, nTiO<sub>2</sub>, and CNT tested in these studies. It is, however, unclear to what extent these levels may apply to other forms of nAg, nTiO<sub>2</sub>, and CNT. Mechanistic data for all 3 nanomaterials show that the specific physical and chemical characteristics of the particles can influence toxicity in defined ways. However, the relationships are complex, and as yet, only partially understood, making the task of estimating safe levels of a particular nanomaterial challenging. Toxicity assessments for nanomaterials must take these additional uncertainties into account. (The views expressed in this abstract are those of the authors only and do not necessarily reflect the views or policies of the U.S. CPSC).

## PS 1971 Quality Assurance and Quality Control for an xCelligence High-Throughput Risk Assessment Assay.

M. Stampfl<sup>1</sup>, F. Ackah<sup>2</sup>, V. Charoensuk<sup>3</sup>, T. Pan<sup>4</sup>, C. Jin<sup>1</sup>, Y. A. Abassi<sup>1</sup>, X. Xu<sup>1</sup>, X. Wang<sup>1</sup>, B. Huang<sup>4</sup>, D. Kinniburgh<sup>3</sup>, W. Zhang<sup>2</sup> and S. Gabos<sup>2</sup>.  
<sup>1</sup>Acea Biosciences, Inc, San Diego, CA; <sup>2</sup>Alberta Health and Wellness, Edmonton, AB, Canada; <sup>3</sup>Alberta Centre for Toxicology, University of Calgary, Calgary, AB, Canada; <sup>4</sup>University of Alberta, Edmonton, AB, Canada.

Taking advantage of impedance based non-invasive, real time cell analysis (RTCA) technology, and human cell lines with different organ origins, a High Throughput Risk Assessment (HTRA) assay is under development to meet 21st century toxicity testing requirement for hazard identification, chemical mode of action understanding, and eventually human health risk assessment. The HTRA assay is run on an fully automated system, composed of 4 xCELLigence RTCA HT stations running 384 well EPlates, liquid handler, and compound/cell culture hotels. Impedance signal derived from adherent cells in the EPlate 384 are continuously monitored for 100 hours to reflect cell growth and responses to testing chemicals. To assess and validate the usefulness of this new in vitro screening system for identifying general toxicity of environmental hazards, 14 chemicals with known in vivo LD50 values were tested with 11 different concentrations in duplicate or quadruplicate, and repeated in 2 separate experiments. The quality assurance program includes the generation of SOPs for experiments and data analysis. Specifically, experimental plate layout to reduce false responses is discussed. The quality control system includes variability and reproducibility analysis. Coefficient of variation, signal to noise ratio and Z factor were calculated to evaluate variability. The analysis excluded one cell line from the cell panel. Intra-plate reproducibility of impedance signals was within acceptable range. Intra-plate reproducibility based on LC50 values from different cell lines, was acceptable. Inter-laboratory validation is in progress. In summary, results from HTRA assay system showed good screening quality and reproducibility. Together with its higher throughput, rich real-time information, HTRA assay system could effectively provide biologically relevant cytotoxicity information for human health risk assessment.

## PS 1972 Advancing Human Health Risk Assessment: Charting a Course through Committee Recommendations.

M. Dourson<sup>1</sup>, R. Becker<sup>2</sup>, L. T. Haber<sup>1</sup>, L. H. Pottenger<sup>3</sup>, T. Bredfeldt<sup>4</sup> and P. Fenner-Crisp<sup>5</sup>. <sup>1</sup>Toxicology Excellence for Risk Assessment, Cincinnati, OH; <sup>2</sup>American Chemistry Council, Washington DC; <sup>3</sup>The Dow Chemical Company, Midland, MI; <sup>4</sup>Texas Commission on Environmental Quality, Austin, TX; <sup>5</sup>Independent Consultant, North Garden, VA.

Over the last dozen years, many national and international expert groups have weighed in on specific improvements to risk assessment. Many of their stated recommendations are mutually supportive, but others appear conflicting, at least in an initial assessment. This effort synthesizes these opinions, identifies areas of consensus and sources of differences, and recommends a biological-centric, practical course forward for risk assessment, which includes: (1) Incorporating a clear problem formulation process at the outset of the assessment to ensure the level of complexity in design of the risk assessment is appropriate for informing the relevant risk management decision; (2) Use of mode of action (MOA) information and an understanding of the relevant biology as the key, central organizing principle for dose-response assessment; (3) Integrating MOA information into dose-response assessments using existing guidelines for noncancer and cancer assessments, and applying this knowledge with toxicokinetics to enable interpretation of human biomonitoring data in a risk context; (4) Using the tiered, iterative approach developed by the

World Health Organization International Programme on Chemical Safety as a scientifically robust, fit-for-purpose approach for risk assessment of combined exposures (chemical mixtures). While scientifically-based defaults will remain important and useful when data on MOA or other data to refine an assessment are absent or insufficient, assessments should always strive to achieve the ultimate goal—to use 21st century knowledge of biological processes, dose-response, and chemical interactions at the molecular, cellular, organ and organism levels to minimize the need for extrapolation and reliance on default approaches.

## PS 1973 Assessment on Health Risk and Risk Factors Related to Lead Exposure by Ingestion of Aquatic Animals from the Overflow Marsh.

S. Chaiklang<sup>1</sup> and S. Kiatsayomphu<sup>2</sup>. <sup>1</sup>Environmental Health Science, Faculty of Public Health, Khon Kaen University, Muang, Thailand; <sup>2</sup>Central Laboratory, Faculty of Public Health, Khon Kaen University, Muang, Thailand.

The previous study identified that aquatic animals in Loeng Puay marsh were lead polluted. The lead concentrations in River snails were exceeded the food standard. This survey research aimed to determine health risk on ingestion of lead-contaminated aquatic animals from Loeng Puay marsh and the adverse health effects. The interviews of 75 residents at Loeng Puay on the consumptions of the aquatic animals and adverse health effects related to lead toxicity were conducted. The lead concentrations in aquatic animals (n=100) i.e. Nile tilapia, Common silver barb, River snail and Golden apple snail were analyzed by using Atomic Absorption Spectrophotometry. Health risk assessment was performed according to the US EPA guideline (2004). The correlated factors with the adverse health effects were identified by the univariate analysis.

The highest lead concentration in all kind of aquatic animals was found in River snail and was used as represent concentration for health risk assessment on the acute effect. By considering the total intake rate of all aquatic animal consumption in the day, the maximum dose of lead exposure was 26.46 g/kg/day which was higher than the provisional tolerable weekly intake (PTWI=25 g/kg). The adverse health effects related to lead toxicity were reported from 46.67% of residents. Most of symptoms were disorders of joints and skeleton, numbness, and acroanesthesia, respectively. The univariate analysis identified that the fishermen had the higher risk on lead exposure (justified by adverse health effect) when compared to other occupations (OR=7.07, 95% CI: 2.20-23.81, p<0.001). The findings indicated the health risk from high dose ingestion of lead-contaminated aquatic animals. However, the potential health risk depends on amount of food ingestion and personal factors. There should be continuously environmental monitoring of the lead accumulation in this overflow marsh for the safety of food chain and the health surveillance program.

## PS 1974 Integrating Hazard Characterization Approaches for Evaluating the Potential of Consumer Products to Cause Asthma.

J. Patterson, A. Maier, M. J. Vincent and B. K. Gadagbui. TERA, Cincinnati, OH.

Concerns have been raised regarding the potential for consumer products, including cleaning products to cause or exacerbate asthma or asthma-like responses. Although many forms of asthma are inflammation-based, some low-molecular-weight chemicals have been shown to trigger immunoglobulin E (IgE) independent occupational asthma. Single exposures to high concentrations of chemical irritants are also known to elicit an asthma-like response: reactive airways dysfunction syndrome (RADS). RADS can occur within hours of the initial exposure and may continue, as non-specific bronchial hyper-responsiveness, for extended durations. Exposure to irritants may be a trigger for respiratory symptoms in individuals with pre-existing asthma. Current methods cannot adequately assess the potential for consumer product ingredients to trigger asthma or asthma-like responses; epidemiological studies can only measure possible effects associated with a multitude of chemicals and products, and no single animal model can reliably replicate the complexity of an asthma-like response in humans. In order to characterize asthma and respiratory related hazards associated with consumer products, a decision system is needed that incorporates existing guidance, frameworks, and models. To develop such a tool, we compiled and evaluated in vivo, in vitro, and in silico methods that may provide data, or insight, to predict potential asthma or asthma-like responses (e.g., respiratory sensitization) and noted strengths and weaknesses associated with each method. We collaborated with asthma research experts to refine our findings and approach. Despite the wealth of information on asthma, current guidelines, bioassays, and computer models cannot definitively identify whether a particular ingredient, or chemical, causes or exacerbates asthma or asthma-like responses. However, possible predictors of allergy-induced asthma, such as respiratory sensitization, are useful to assess the likelihood that a particular chemical, ingredient, or product may be associated with asthma induction.

**PS 1975 Assessment of the Impacts of Changes in Regulatory Toxicology of Polycyclic Aromatic Hydrocarbons on Site Assessments.**

J. H. Salatas<sup>1</sup>, M. R. Garry<sup>1</sup> and Y. W. Lowney<sup>2</sup>. <sup>1</sup>Exponent, Bellevue, WA; <sup>2</sup>Exponent, Boulder, CO.

Polycyclic aromatic hydrocarbons (PAHs) are common soil contaminants at many industrial facilities, military bases, and other sites. For PAH mixtures, the U.S. Environmental Protection Agency (EPA) and other regulatory agencies use relative potency factors (RPFs) to assess the potential toxicity of individual PAHs. EPA currently provides RPF values for cancer risks for seven individual PAHs, but is considering RPFs for 25 individual PAHs, spanning values of potency relative to benzo[a]pyrene (BaP) from 0.009 to 60. As part of a larger study aimed at tying together research on soil PAH chemistry with *in vivo* measures of bioavailability across diverse soil types and contaminant sources for the purpose of improving remedial decisions for soil PAHs at U.S. Department of Defense (DOD) sites, we investigated the potential impacts of proposed changes in regulatory toxicology of PAHs on regulatory decision-making. Specifically, we investigated the degree to which changes in PAH RPFs could alter conclusions about health-based screening at DOD sites. Using EPA's Records of Decision database for Superfund sites, we identified 11 DOD sites with 22 exposure units in which PAHs were identified as chemicals of concern in surface or subsurface soil. Site data were evaluated for exceedances of health-based soil screening levels using current and proposed RPFs. Results indicate that the percentage of sites exceeding a screening level would increase; up to twice as many sites for some individual PAHs (e.g., chrysene). In addition, the magnitude of exceedance would increase for all sites. The results suggest that both the number of sites and the areal extent of individual sites requiring remediation could increase with the proposed changes in RPFs. Additional issues include lack of background data for PAHs newly added to the risk assessment paradigm and methods for assessing undetected PAHs. This work was supported in part by a grant from the Strategic Environmental Research and Development Program.

**PS 1976 Rapid Risk-Based Response to a Crude Oil Spill.**

K. Philipps and D. B. Davies. *Intrinsic Environmental Sciences Inc., Calgary, AB, Canada.*

Issues surrounding pipeline safety and the potential health and environmental impacts that can result from pipeline accidents and malfunctions have led to considerable debate lately across North America. A number of recent high-profile oil spills in areas that are populated highlight the need for risk assessment to be completed rapidly to inform risk-based decision making. An example of such an assessment was completed in response to a break at an underwater pipeline crossing in which a sweet crude oil was released in a watercourse, upstream of several residences, active livestock farming operations, recreational properties and a municipal drinking water intake. Within 24-hours, a clean-up and contaminant sampling strategy was developed and implemented, and continued over several weeks. Preliminary evaluation and interpretation of the contaminant data was completed to aid in community consultation, to identify the need for further monitoring, and to provide risk-based decision making strategies to local authorities managing drinking water and recreational use access. The conclusions of an initial risk assessment completed two weeks after the spill served to provide reassurance to regulators and the general public regarding the safety of drinking water for residents and livestock, resulting in the re-opening of some drinking water intakes in the impacted area. The assessment considered the nature and levels of the contaminants that were determined to be present in the water column and sediments, the results of toxicity studies for the various contaminants, and the opportunity for exposure of people and animals to the contaminants. Following the analysis of additional sampling results, a more comprehensive risk assessment was completed. The final results of the assessment revealed that the clean-up efforts had successfully mitigated risk to human health and the local ecosystem.

**PS 1977 Validation Oral Slope Factors for Benzo(a)pyrene Using Whole Mixture Results.**

K. T. Connor and B. H. Magee. *Risk Assessment, ARCADIS, Chelmsford, MA.*

EPA's draft Integrated Risk Information System Assessment of Benzo(a)pyrene (BaP) is due to be released for public review in 2013. The document will present an Oral Slope Factor (OSF) that will replace the current value of 7.3 (mg/kg-day)<sup>-1</sup>. The OSF will be coupled with new Relative Potency Factors (RPFs) when EPA finalizes the PAH Mixtures guidance document. A literature search identified the available studies that meet EPA's study quality criteria and OSFs were derived using EPA's benchmark dose model software (BDMs) in accordance with standard EPA

policy and guidance. The OSFs and the proposed RPFs have been validated against the results of rodent mixture studies to determine if the BaP OSF in conjunction with EPA's proposed RPFs properly estimate PAH mixture effects. Benchmark dose modeling Culp et al. (1998) data results in two BaP OSFs with reasonable model fits: forestomach – 1.23 (mg/kg-day)<sup>-1</sup> and esophagus – 0.19 (mg/kg-day)<sup>-1</sup>. Culp et al. (1998) also tested two coal tar samples in the same study. BaP-Toxic Equivalents were calculated for the coal tar mixtures using the EPA proposed RPFs. A nominal concentration of 100 ppm was assumed for unusual PAHs for which concentrations were unknown. When compared to the whole mixture OSFs for two separate coal tar mixtures, the current BaP OSF overestimates carcinogenic risk by 20 to 31-fold. The BaP OSF based on forestomach tumors in Culp et al. (1998) overestimates risk by 3 to 5-fold, whereas the BaP OSF based on esophagus tumors in the same study gives no overestimation. If the unusual PAHs with new RPFs are present in coal tar at concentrations significantly higher than the assumed 100 ppm, then the BaP OSF based on esophagus tumors will overestimate the coal tar tumorigenic risks observed in the whole mixture studies. This validation exercise demonstrates that the EPA proposed RPFs have to be implemented side-by-side with an OSF for BaP that is less than 1 (mg/kg-day)<sup>-1</sup> to ensure that risks from real world PAH mixtures are not overestimated by the RPF risk assessment approach.

**PS 1978 Cytotoxicity Test for Hazardous Substances by Using the RTCATM High-Throughput Assay.**

Y. Li<sup>1</sup>, D. Y. Huang<sup>1</sup>, W. Zhang<sup>2</sup>, S. Gabos<sup>3</sup> and D. Kinniburgh<sup>1</sup>. <sup>1</sup>Alberta Centre for Toxicology, University of Calgary, Calgary, AB, Canada; <sup>2</sup>Health Protection Branch, Family and Population Health, Alberta Health, Edmonton, AB, Canada; <sup>3</sup>Canadian Institute of Public Health Inspectors - Alberta Branch, Edmonton, AB, Canada.

Most current toxicity tests require the use of laboratory animals and involve exposure by various routes and monitoring whether animals die or exhibit any clinical signs of toxicity. Increasing societal concerns about animal use have led to the development of alternative *in vivo* test methods that can significantly reduce and refine the use of mammals for this purpose. The emerging *in vitro* cell based assays endeavor to provide information about the mode or mechanism of action that causes cytotoxicity and use such information to develop cell-based *in vitro* tests that can adequately model and predict *in vivo* toxicity. A non-invasive biophysical approach for the detection of cellular changes, the RTCATM instrument was developed for screening hazardous substances. In the present study, 6 chemicals (sodium arsenate, cadmium chloride, colchicine, verapamil, propranolol and mercury chloride) were applied to human renal adenocarcinoma cell line (ACHN) at 11 serial diluting working concentrations, respectively. The net cellular responses (the Cell Index) were recorded for 72 hours after adding chemicals. The real-time and unique time-concentration-dependent response curves (TCRC) were obtained. The experimental design composed two stages: initial screening test (range finder test) and definitive test (more defined test concentrations). The better TCRC patterns were observed in the latter. The patterns were associated with some toxicity pathways or mode of action for these chemicals. The lethal concentrations could be calculated, which could be used to predict the starting lethal doses *in vivo* test. Based on these preliminary findings, other 8 substances in other 6 cell lines will be tested in the future. This work will facilitate cellomic based test development and achieve the replacement of animals in acute oral toxicity testing.

**PS 1979 Advancements in Arsenic Research Suggest a Dose-Dependent Transition Concentration for Cancer Endpoints.**

R. Gentry<sup>1</sup>, H. J. Clewell<sup>2</sup>, P. Balbuena<sup>2</sup>, A. Efremenko<sup>2</sup>, M. B. Black<sup>2</sup> and J. W. Yager<sup>3</sup>. <sup>1</sup>ENVIRON International Corporation, West Monroe, LA; <sup>2</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>University of New Mexico, Albuquerque, NM.

Recent *in vitro* studies have been conducted in both animal and human primary bladder cells to investigate the potential mode of action for bladder cancer following exposure to arsenic compounds. Results from 24 hour *in vitro* gene expression studies with human uroepithelial cells treated in culture with mixtures of inorganic arsenic and its pentavalent or trivalent metabolites provide evidence of a common suite of gene changes consistently identified for a number of key signaling pathways: oxidative stress, protein folding, growth regulation, metallothionein regulation, DNA damage sensing, thioredoxin regulation, and immune response. Lowest observed effect levels (LOELs) ranged from 0.6 – 6.0  $\mu$ M total arsenic and no observed effect levels (NOELs) ranged from 0.18 – 1.8  $\mu$ M total arsenic. Benchmark dose modeling of the responses indicated lower confidence limits (BMDLs) ranging from 0.09 – 0.58  $\mu$ M total arsenic for the eight genes most commonly significantly expressed across individual samples for the trivalent arsenical mixture, and from 0.35– 1.7  $\mu$ M for total arsenic in the pentavalent arsenical mixture. These studies

provide the first evidence of no effect levels for arsenical-induced cell signaling perturbations in normal human cells exposed to biologically plausible concentrations of arsenic. Results from longer term exposures, again in primary human cells, provide consistent results that also suggest a dose-dependent transition for arsenic. Results of these *in vitro* studies, in combination with evidence from epidemiological studies, provide the basis for a shift in the approach for conducting a cancer risk assessment for arsenic. It also provides support for a concentration demonstrating a dose-dependent transition in responses from those representing adaptive change to those that may be key events in the development of cancer endpoints.

## PS 1980 Refining the Application of a Database Uncertainty Factor in Human Health Risk Assessment.

C. Fleming<sup>1</sup>, Z. Yan<sup>1</sup>, J. Lambert<sup>2</sup> and Q. Zhao<sup>2</sup>. <sup>1</sup>ORISE, Cincinnati, OH; <sup>2</sup>US EPA, Cincinnati, OH.

In human health risk assessment (HHRA), lack of information on a chemical is typically accounted for by the use of uncertainty factors (UFs). Typically, UFs are applied to account for five major areas of uncertainty: interspecies variation, intraspecies variation, extrapolation from subchronic to chronic exposure duration, extrapolation from a LOAEL to a NOAEL, and an incomplete database. To reduce uncertainty inherent in HHRA, methods are needed to replace or better assign values to these UFs. In this preliminary analysis, we analyzed all chemicals from the USEPA's Toxicity Reference Database (ToxRefDB) with complete databases (i.e., general toxicity studies in two species, developmental toxicity studies in two species, and a multigeneration reproductive study) to assess whether a database UF (UFD) of 3 or 10 is sufficient to account for missing data. A subtractive approach was employed in which the points of departure (PODs) based on reported LOAELs and NOAELs in the ToxRefDB were compared for the complete database and following removal of selected studies. Removal of developmental toxicity studies from the database increased the POD by >3-fold in 12/186 (6.5%) chemicals and by >10-fold in only 1 chemical. Removal of multigeneration reproductive toxicity studies from the database increased the POD by >3-fold in 18/186 (9.7%) chemicals and by >10-fold in 4/186 (2.2%) chemicals. Removal of general toxicity studies from the database increased the POD by >3-fold in 59/186 (31.7%) chemicals and by >10-fold in 27/186 (14.5%) chemicals. This analysis will need to be supplemented with studies from a broader spectrum of chemical types (ToxRefDB is composed almost entirely of pesticides). When completed, this analysis could provide a method to systematically and empirically select the UFD in cases where chemical-specific information to inform selection of the UFD is lacking. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.

## PS 1981 Short-Term Exposure to Perfluoroalkyl Acids Causes Increase of Hepatic Lipid and Triglyceride in Conjunction with Liver Hypertrophy.

K. P. Das<sup>1</sup>, C. R. Wood<sup>1</sup>, M. B. Rosen<sup>2</sup>, C. Lau<sup>1</sup> and B. D. Abbott<sup>1</sup>. <sup>1</sup>Toxicity Assessment Division, ORD, NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>Integrated Systems Toxicology Division, ORD, NHEERL, US EPA, Research Triangle Park, NC.

Persistent presence of perfluoroalkyl acids (PFAAs) in the environment is due to extensive use of industrial and consumer products. These chemicals activate peroxisome proliferator-activated receptor- $\alpha$  (PPAR $\alpha$ ) in liver and alter lipid metabolism. The current study was designed to evaluate liver toxicity of perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorohexane sulfonate (PFHxS), and perfluorophosphonic acid (PFPA), with emphasis on hepatocellular hypertrophy and steatosis. SV129 wild-type (WT) and PPAR $\alpha$ -null (Null) adult male mice were dosed for 7 days with vehicle, PFOA, PFNA, PFHxS (10 mg/kg), and PFPA (20 mg/kg); and WY14643 (50 mg/kg) was a positive control. Mice were killed 24 h after the last treatment. Liver samples were collected for biochemical analysis of triglyceride (TG) and DNA content. Frozen 6  $\mu$ m sections of liver were stained with Oil Red O for lipid and used for morphometric analysis. Liver weights were elevated in both WT and Null mice in all of the treatment groups, except in Null mice of the PFPA and WY groups. Morphometric analysis revealed an increase in cell size in WT and Null livers exposed to PFOA, PFNA, PFHxS or PFPA, except for the PFPA and WY groups in Null mice. This pattern of change is consistent with the reduced DNA content per mg liver. In the Oil Red O stained sections, WT liver showed increased lipid accumulation in all treatment groups; whereas in Null livers, this was seen only after PFNA and PFHxS treatment. Similarly, elevated TG level was found in PFAA-exposed WT but not in WY-exposed mice, and increased TG was seen in Null mice only after PFNA treatment. Null livers had more lipid and TG than WT livers, both in control and treated mice. These results indicate that PFAAs induce liver hypertrophy and steatosis in WT; and the involvement of PPAR $\alpha$  is suggested by observations in Null mice. (This abstract does not necessarily reflect US EPA policy.)

## PS 1982 Structure-Activity Relationships for Perfluoroalkane-Induced Interference with Rat Liver Mitochondrial Respiration.

K. B. Wallace<sup>1</sup>, G. E. Kissling<sup>2</sup>, R. Melnick<sup>3,4</sup> and C. R. Blystone<sup>3</sup>. <sup>1</sup>Biochemistry & Molecular Biology, University of Minnesota Medical School, Duluth, MN; <sup>2</sup>Biostatistics Branch, NIEHS, Research Triangle Park, NC; <sup>3</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>4</sup>Ron Melnick Consulting, LLC, Chapel Hill, NC.

Perfluorinated alkanes (PFAAs) represent a broad class of commercial products detected primarily for the coatings industry. Unfortunately, residues have been detected in a variety of species world-wide prompting aggressive toxicity testing. Although some effects of PFAA exposures are linked to activation of the PPAR $\alpha$  nuclear receptor, interference with mitochondrial bioenergetics has been implicated as an alternate and possibly important mechanism of cytotoxicity. The current investigation was designed to explore structure-activity relationships for the various modalities by which PFAAs interfere with mitochondrial respiration. Freshly isolated rat liver mitochondrial were incubated with one of 16 different PFAAs. The effects of each PFAA on mitochondrial respiration was measured at five different concentrations and dose-response curves generated. All PFAAs tested inhibited mitochondrial respiratory control, mostly by stimulating state 4 and inhibiting state 3 respiration with the EC20 ranging from 1  $\mu$ M to 413  $\mu$ M. The perfluoroalkyl sulfonamides were most potent with an EC20 between 1 and 11  $\mu$ M. The results are consistent with evidence that the perfluorinated carboxylic acids stimulate the mitochondrial permeability transition whereas the sulfonamides act as protonophoric uncouplers of oxidative phosphorylation. In all cases, there was a pronounced increase in potency with increasing carbon number, with a prominent inflection in potency between the six and eight carbon congeners. The results provide a foundation for classifying PFAAs according to specific modes of mitochondrial toxicity and establishing structure-activity evidence-based initial estimates of safety for PFAA congeners for which minimal *in vivo* toxicity testing currently exists. (This work was funded by NIEHS NTP contract 273200620005C).

## PS 1983 Determination of Polychlorinated Biphenyls (PCBs) and Hydroxylated Metabolites (OH-PCBs) in Human Blood Serum from Two Populations in East Chicago, IN and Columbus Junction, IA.

W. Koh<sup>1</sup>, R. Marek<sup>2</sup>, J. DeWall<sup>3</sup>, P. S. Thorne<sup>1,3</sup> and K. C. Hornbuckle<sup>1,2</sup>. <sup>1</sup>Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa City, IA; <sup>2</sup>Department of Civil and Environmental Engineering, The University of Iowa, Iowa City, IA; <sup>3</sup>Department of Occupational and Environmental Health, The University of Iowa, Iowa City, IA. Sponsor: L. Robertson.

PCBs are persistent and bioaccumulating toxic pollutants which pose health risk to humans and organisms. Although commercial production of these compounds was reduced and then banned in the 1970s, they are still present in our environment and found in human blood serum. In this study, we determined PCBs and their metabolites in human blood serum in these two populations. Human blood serum samples were collected as part of the Airborne Exposure to Semi-Volatile Organic Pollutants (AESOP) study from East Chicago, an industrialized area with known high PCBs exposure in the past, and Columbus Junction, a rural area with no recognized historical PCB contamination. Our methods, which emphasize rigorous quality assurance and control (QA/QC), enabled us to evaluate all 209 PCB congeners and a sub-set of OH-PCBs congeners. After a series of extraction and cleanup procedures, samples were analyzed using gas chromatography with tandem mass spectrometry (GC-MS/MS) for PCBs and gas chromatography with electron capture detection (ECD) for OH-PCBs. Our results show that the sum of PCB congeners ranged from non-detect to 658 ng/g l.w. (median = 33.5 ng/g l.w.) and the sum of the four major OH-PCB congeners ranged from non-detect to 1.2 ng/g f.w. (median = 0.07 ng/g f.w.). We conclude that PCBs and OH-PCBs are detected in human blood serum from populations living in East Chicago, IN and Columbus Junctions, IA.

## PS 1984 Associations among Polychlorinated Biphenyls (PCBs) and Chlorinated Pesticides and Serum Lipids in Residents of Anniston, Alabama.

M. Pavuk<sup>1</sup>, Z. Aminov<sup>2</sup>, R. Haase<sup>2</sup>, D. O. Carpenter<sup>3,2</sup> and W. E. Turner<sup>4</sup>. <sup>1</sup>ATSDR/CDC, Atlanta, GA; <sup>2</sup>School of Public Health, University at Albany, Rensselaer, NY; <sup>3</sup>Institute for Health and the Environment, University at Albany, Rensselaer, NY; <sup>4</sup>NCEH/CDC, Atlanta, GA. Sponsor: N. Karch.

Associations among total cholesterol, triglycerides, and high density lipoprotein cholesterol (HDL) and serum polychlorinated biphenyls (PCBs) and chlorinated pesticides concentrations were examined in a sample of residents of Anniston, Alabama, participants of the Anniston Community Health Survey (ACHS).

For this analysis, nine PCBs with different number of chlorines (in brackets) and toxicological characteristics were selected: PCBs 74 (4), PCB 99 (5), PCB 118 (5), 153 (6), 170 (7), 187 (7), 196-203 (8), 206 (9), and 209 (10) were included. Four chlorinated pesticides were also included in the analyses:  $\beta$ -HCH, Oxychlorane, trans-Nonachlor, and p,p'-DDE.

Study includes 765 subjects with PCBs and lipid measurements. We wanted to minimize the effect of altered lipid levels due to presence or progression of disease(s) in studying the associations. Persons on lipid lowering medications, with dyslipidemia, diabetes, and coronary heart disease were excluded from the statistical analyses. Multiple linear regression models adjusted for age, race, gender, and BMI were used to analyze the data. Other major CHD risk factors such as smoking, exercise, and family history of heart disease were also examined.

Only higher chlorinated PCBs 206 and 209 were related to total cholesterol. Seven out of 9 PCBs were related to triglycerides; PCBs 99, 118 were not associated with triglycerides. Oxychlorane and p,p'-DDE were related to both total cholesterol and triglycerides; trans-Nonachlor was associated with triglycerides only. No association with PCBs or pesticides was found for HDL.

Interpretations of these results are limited. In particular, potential sequence of events relating lipid levels and PCB exposure is complex and uncertain and can only be elucidated with longitudinal study design.

## PS 1985 Persistent Organic Pollutants and Transthyretin-Bound Thyroxine in Plasma of Inuit Women of Childbearing Age.

Y. Audet-Delage<sup>1</sup>, R. Dallaire<sup>1</sup>, N. Ouellet<sup>1,2</sup>, <ls>Dewailly<sup>1</sup> and P. Ayotte<sup>1,2</sup>. <sup>1</sup>Axe en Santé des Populations et Environnementale, Centre de Recherche du CHUQ, Québec, QC, Canada; <sup>2</sup>Laboratoire de Toxicologie, Institut National de Santé Publique du Québec, Québec, QC, Canada.

The Inuit population of Nunavik (Northern Quebec, Canada) is highly exposed to persistent organic pollutants (POPs) through their traditional diet which comprises fatty tissues from marine mammals. Some POPs – i.e. hydroxylated metabolites of polychlorinated biphenyls (HO-PCBs), pentachlorophenol (PCP) and perfluorooctane sulfonate (PFOS) – are known to compete with thyroxine (T4) for binding sites on transthyretin (TTR), a T4 transport protein located in plasma and cerebrospinal fluid. Displacement of T4 from TTR could result in decreased T4 delivery to the developing fetus and in turn delayed growth and impaired neurodevelopment in infants. We set out to test the hypothesis that POPs or their metabolites decrease circulating concentrations of T4 bound to TTR (T4-TTR) in Inuit women of reproductive age. We measured T4-TTR concentrations in archived plasma samples obtained from 120 Inuit women (18-39 year old) by combining native polyacrylamide gel electrophoresis and liquid chromatography-tandem mass spectrometry (LC-MS/MS) techniques. Total T4 concentration was measured by LC-MS/MS, while those of TTR and thyroxine binding globulin (TBG) were determined by gel densitometry and an ELISA assay, respectively. POPs levels had been previously determined in those samples. The mean T4-TTR concentration was 8.4 nmol/L (SD = 2.4) with values ranging from 2.9 to 14.4 nmol/L, representing on average 6% of total T4 circulating concentration. Plasma levels of HO-PCBs, PCP or PFOS were not correlated to T4-TTR concentrations. Linear regression analysis revealed that TTR, TBG and total T4 concentrations were significant predictors ( $p < 0.001$ ) of T4-TTR levels (adjusted R-square = 0.26,  $p < 0.001$ ), but not POPs levels. Our results suggest that actual circulating levels of POPs in Inuit women of childbearing age are not high enough to affect TTR-mediated thyroid hormone transport.

## PS 1986 Effect of TCDD on Peripheral Hormones Regulating Feed Intake and Energy Balance in Rats.

R. Pohjanvirta<sup>1</sup>, S. Lensu<sup>2</sup> and J. Lindén<sup>1</sup>. <sup>1</sup>Department of Food Hygiene and Environmental Health, University of Helsinki, Helsinki, Finland; <sup>2</sup>Department of Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland. Sponsor: M. Viluksela.

A lethal dose of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) brings about a drastic body weight loss dubbed the wasting syndrome in rats. The decline of body weight primarily results from severe hypophagia but at present next to nothing is known about the factors underlying the reduced feed intake. The most important peripheral hunger signal in the body is ghrelin, mainly secreted into blood by stomach cells, whereas the principal satiety hormone is leptin produced by the white adipose tissue. Practically no data exist on the impact of TCDD on these hormones. In the present study, we exposed TCDD-sensitive Long-Evans (*Turku/AB*; L-E) and TCDD-resistant Han/Wistar (*Kuopio*; H/W) rats to 100 µg/kg TCDD ig. and euthanized the rats at days 1, 4 or 10. The dose selected is lethal to all L-E rats but sublethal to H/W rats. A feed-restricted control (FRC) group of L-E rats was included in the study to help distinguish between primary and secondary effects. In addition to leptin and ghrelin, also glucagon was determined in serum samples with

the Bio-Plex Suspension Array System. By 10 days, body weight dropped by about 30% in TCDD-treated and FRC L-E rats but only by some 5% in TCDD-treated H/W rats. Concurrently, serum leptin decreased to non-detectable levels in FRC. It diminished also in TCDD-treated L-E and H/W rats but less prominently. Serum ghrelin was elevated by TCDD in L-E rats at all time-points, and in H/W rats on day 10; in FRC, the increase was lesser on day 4 and comparable on day 10. Glucagon took an upward course in TCDD-treated L-E rats alone reaching a nine-fold increase vs. control on day 10. These data reveal that the major peripheral signals of energy balance remain intact and change appropriately in lethally TCDD-treated L-E rats. However, they do not lead to the normal behavioural response (i.e. feeding) to rectify the tilted energy status.

## PS 1987 Effects of Developmental PCB Exposure on Energy Metabolism in Adult and Aged Mice.

A. Brown, A. Ashworth, K. Smith and C. P. Curran. *Biological Sciences, Northern Kentucky University, Highland Heights, KY.*

Polychlorinated biphenyls (PCBs) are known to cause learning, memory, and behavioral deficits in the developing human brain. Our previous work showed that allelic differences at the *Ahr* and *Cyp1a2* loci alter susceptibility to developmental PCB neurotoxicity. While exploring behavioral differences in aged animals, we discovered a significant divergence in weights dependent on sex, genotype and treatment. The experiments described here were designed to see if gestational and lactational PCB exposure could alter energy metabolism in adult and aged mice. We compared blood glucose, triglycerides and cholesterol in PCB-treated and corn oil-treated control mice with the following genotypes: *AhrbCyp1a2*(+/+), *AhrbCyp1a2*(-/-) and *AhrdCyp1a2*(-/-). The knockout lines were both backcrossed onto a C57BL/6J background which was our wild type control. Pregnant dams were exposed to an environmentally relevant PCB mixture during gestation and lactation. One male and one female per litter were tested at 6 months and 13 months of age. There was a significant effect of genotype and a significant gene x treatment x sex interaction for fasting blood glucose levels. For glucose tolerance testing, mice were fasted overnight, then injected with 2 mg/kg glucose and blood collected over two hours. There was a significant main effect of sex and genotype in glucose tolerance at 6 months. We observed a significant main effect of genotype and sex for plasma cholesterol and a significant genotype x sex interaction for triglycerides. At 13 months, there was a significant genotype x treatment interaction for triglycerides, but only a main effect of sex for cholesterol with male mice having significantly higher levels. We replicated our prior weight trends with PCB-treated male *AhrbCyp1a2*(-/-) mice weighing significantly less than their corn oil-treated controls. These mice also had significantly lower triglyceride levels compared with the corn oil-treated controls. Our results indicate that the metabolic effects of developmental PCB exposure are persistent, but vary depending on both sex and genotype.

## PS 1988 Parent PBDEs and the Hydroxylated Congeners Alter Normal Thyroid Activity.

E. D. Bruce and C. Y. Usenko. *Biology, Baylor University, Waco, TX.*

Polybrominated diphenyl ethers (PBDEs) are brominated flame retardants that have been used for over 30 years. In recent years, the different technical mixtures have been banned or phased out, however there are still significant environmental concentrations. Due to the similarity in chemical structure between PBDEs and thyroid hormones, it has been postulated that PBDEs act through an endocrine disruption pathway by mimicking thyroid hormone. In this study, embryonic zebrafish are used to investigate the interaction of PBDEs on thyroid hormone homeostasis. Thyroid hormone levels were increased following exposure to BDEs 47, 99, and 100. Furthermore, co-exposure with propylthiouracil, a thyroid hormone inhibitor, exacerbated the effects of BDE 47 exposure on spontaneous movement. Additionally, alterations in gene transcription of thyroid-related genes to several different PBDE congeners (BDE 28, BDE 47, BDE 99, and BDE 100) were compared. There was limited alteration in gene expression for most of the genes examined. Deiodinase 1 and the sodium-iodide symporter (SLC5r) were upregulated following exposure to all congeners. Additionally, a hydroxylated PBDE was also investigated for disruption of thyroid-related gene expression. Thyroid transcription factor (NKX2.1) was downregulated by exposure to BDEs 28, 99, and 100; however it was significantly increased following exposure to 6-OH-BDE 47. Exposure to 6-OH-BDE 47 induced the greatest amount of induction, even at concentrations 4-fold below the parent PBDE exposure concentrations. Hydroxylated PBDEs have an even greater similarity to thyroid hormone structure and may be primarily responsible for the adverse effects of PBDE exposure. These results demonstrate that PBDEs do affect thyroid homeostasis; however hydroxylated PBDEs may pose the greatest risk of exposure.

**PS 1989 Search for the Basis of PCB126-Triggered Disruption of Hepatic Metal Homeostasis in Rodents.**

W. D. Klaren<sup>1,2</sup>, I. K. Lai<sup>1,2</sup> and L. W. Robertson<sup>1,2</sup>. <sup>1</sup>Interdisciplinary Graduate Program in Human Toxicology, University of Iowa, Iowa City, IA; <sup>2</sup>Occupational and Environmental Health, College of Public Health, University of Iowa, Iowa City, IA.

PCBs, industrial chemicals and persistent environmental pollutants, are found in many rural and urban settings. Previous studies have shown that the treatment of rats with PCB126 causes a significant disruption of hepatic metal homeostasis that could potentially alter antioxidant defenses. The current study is focused on this metal disruption, in particular on Cu, Zn and Se. Two copper-containing proteins were investigated, tyrosinase (TYR) and cytochrome c oxidase (COX), along with metal chaperones ceruloplasmin (CP), selenoprotein p (SeP) and metallothionein (MT). These proteins cover a wide range of functions from intra- and extracellular metal trafficking (MT, SeP and CP), pigment production (TYR) and electron transport (COX). An animal study was conducted where 56 rats were fed one of three AIN diets containing levels of copper (2, 6 & 10 ppm). After three weeks, animals were given a single IP injection of PCB126 (1 µmol/kg or 5 µmol/kg in corn oil) and euthanized two weeks later. The expression levels of these proteins were investigated by qRT-PCR, ELISA, and western blot. Metals analysis showed a decrease of Zn and Se, but an increase of Cu in the liver. Serum CP concentration and hepatic mRNA levels were increased with dietary copper and PCB treatment (although the latter not significantly). TYR was expressed in the liver both transcriptionally and translationally a new finding. COX was decreased with PCB126 exposure and had no statistical association with dietary copper. SeP was unchanged either by PCB126 or dietary copper, not reflecting the decrease of hepatic Se. MT was highly increased by PCB126 at the 1 µmol/kg dose. The increase of metallothionein seen along with the higher binding affinity of Cu potentially explains the changes seen with Zn. Although metallothionein may contribute to the disruption of hepatic metal homeostasis, it fails to fully explain the Se and Cu changes. (P42 ES 013661)

**PS 1991 Adduction of Cytochrome C by Quinoid Metabolites of Polychlorinated Biphenyls (PCBs).**

M. Li<sup>1</sup>, L. Teesch<sup>3</sup>, D. Murry<sup>1,4</sup>, L. W. Robertson<sup>1,2</sup> and G. Ludewig<sup>1,2</sup>. <sup>1</sup>Interdisciplinary Graduate Program in Human Toxicology, University of Iowa, Iowa City, IA; <sup>2</sup>Department of Occupational and Environmental Health, University of Iowa, Iowa City, IA; <sup>3</sup>High Resolution Mass Spectrometry Facility, University of Iowa, Iowa City, IA; <sup>4</sup>College of Pharmacy, University of Iowa, Iowa City, IA.

PCBs, a group of 209 individual congeners, were widely used as industrial chemicals and are ubiquitous and persistent human and environmental contaminants. Even though PCBs are carcinogens in rodents, they are still in use in closed applications. Lower chlorinated biphenyls can be metabolized to dihydroxy metabolites and further oxidized to quinoid metabolites both *in vitro* and *in vivo*. Quinoid metabolites may form adducts at nucleophilic sites of proteins like cytochrome c, an essential component in the mitochondrial electron transport chain. We hypothesized that the PCB-quinones covalently bind to cytochrome c thereby causing defects in mitochondrial function. LC-MS was used to detect adducts of cytochrome c with selected PCB-quinones *in vitro*. SDS PAGE gel electrophoresis followed by NBT staining was employed to separate the adducted proteins. Trypsin digestion and LC-tandem MS were applied to identify the amino acid binding sites on cytochrome c. SYBYL-X was employed to simulate the conformation change of cytochrome c after binding with PCB3-*para*-Q. We found that more than one molecule of PCB-quinone can bind to one molecule of cytochrome c. In addition, cross-linking of cytochrome c was observed on the SDS PAGE gel. Different conditions, such as pH, incubation time and concentrations of PCB quinones, influence the formation of cross links. Lysine (K27, K39, K54/56, K73/74) and glutamic acid (E61, E62) were identified as binding sites by LC-tandem MS. Software simulation showed conformation changes of adducted cytochrome c. These preliminary data provide evidence that covalent binding of PCB quinone metabolites to cytochrome c, may be included among the toxic effects of PCBs. (Supported by NIEHS Superfund Program P42 ES013661.)

**PS 1990 Aroclor 1254-Induced Modulation of Osteoblast Differentiation Is Predominantly AhR-Dependent.**

M. Herlin<sup>1</sup>, M. Korkalainen<sup>2</sup>, J. Ringblom<sup>1</sup>, M. Öberg<sup>1</sup>, M. Viluksela<sup>2</sup> and H. Håkansson<sup>1</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>National Institute of Health and Welfare, Kuopio, Finland.

Exposure to food-derived mixtures of persistent organic pollutants modulates developing bone tissue properties. To further clarify details in the mode-of-action involved in the *in vivo* findings, this study used a comparative approach to elucidate qualitative and quantitative details in the modulations of osteoblast differentiation *in vitro*. MC3T3-E1 cells were exposed to Aroclor 1254 (A1254) or 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), the model compound for high affinity ligands of the aryl hydrocarbon receptor (AhR). Following A1254 exposure, the expression of the matrix maturation and mineralization marker genes ALP and OCN, were decreased, while no effects were seen on the proliferation marker gene RUNX2. These results suggest that the late phases of osteoblast differentiation were affected, which is in accordance with observations following TCDD exposure. However, higher doses of A1254, as compared to TCDD, were required to achieve significant effects and the maximal effects were lower. The AhR-dependent genes, CYP1A1 and AhRR, were induced by A1254 and TCDD at doses comparable to those where the differentiation markers were affected. Taken together, these results show that A1254, which is a technical mixture of dioxin-like and NDL-PCB congeners predominantly, exhibits dioxin-like modulations on osteoblast differentiation, suggesting that, in accordance with the *in vivo* findings, the A1254 induced effects are mainly AhR-dependent. We further evaluated the relative potency (REP) of A1254 as compared to TCDD. The REP values for OCN, CYP1A1 and AhRR expression were a magnitude higher as compared to the estimated toxic equivalent dose based on the chemical composition of A1254, while the REP value for ALP expression was at the same level as the estimated equivalent chemical dose. Therefore, on a quantitative basis the higher than expected REP values in this study might indicate a contribution also of NDL-PCB congeners to the observed *in vitro* responses.

**PS 1992 Alterations in Xenobiotic Metabolizing Enzyme and Immune Relevant Genes following Administration of Brominated and Chlorinated Dioxins and Furans in Female B6C3F1 Mice.**

R. Frawley<sup>1</sup>, M. Smith<sup>2</sup>, K. White Jr<sup>2</sup>, N. J. Walker<sup>1</sup>, L. S. Birnbaum<sup>1,3</sup>, T. Maynor<sup>4</sup>, M. DeVito<sup>1</sup> and D. R. Germolec<sup>1</sup>. <sup>1</sup>DNTP NIEHS, Research Triangle Park, NC; <sup>2</sup>VCU, Richmond, VA; <sup>3</sup>NCI, Research Triangle Park, NC; <sup>4</sup>ILS, Inc, Research Triangle Park, NC.

Increased use of brominated flame-retardants and incineration of bromine-containing materials has lead to an increase in the presence of polybrominated dibenzo-p-dioxins and dibenzofurans (PBDD/Fs) in the environment. Measurable amounts of PBDD/Fs have been detected in sediment, seafood, and human serum. Previous studies indicated that an acute single exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), 2,3,7,8-tetrabromodibenzofuran (TBDF), 2,3,7,8-tetrachlorodibenzofuran (TCDF), 1,2,3,7,8-pentabromodibenzofuran (1PeBDF), 1,2,3,7,8-pentachlorodibenzofuran (1PeCDF), 2,3,4,7,8-pentabromodibenzofuran (4PeBDF), 2,3,4,7,8-pentachlorodibenzofuran (4PeCDF), and 2,3-dibromo-7,8-dichlorodibenzo-p-dioxin (DBDCDD) suppressed antigen-specific antibody forming cell (AFC) responses in B6C3F1/N mice, and that the brominated compounds were more potent than their chlorinated analogs. In addition, we evaluated expression of xenobiotic metabolizing enzyme (XME) and immune-relevant genes in the livers from these mice. Gene expression was measured using qRT-PCR. TCDD, TBDF, TCDF, 1PeBDF, 1PeCDF, 4PeBDF, 4PeCDF, and DBDCDD up-regulated the phase I XME genes Cyp1a1 and Cyp1a2. Based on estimated ED50, the rank order of potency for Cyp1a1 was TCDD>TBDF>4PeBDF>1PeBDF>TCDF>4PeCDF>1PeCDF, and for Cyp1a2 was TCDD>TBDF>1PeBDF>4PeCDF>4PeBDF>TCDF>1PeCDF. TCDD, 4PeBDF, TBDF, TCDF, and DBDCDD altered expression of phase II XME, phase III XME, and the thyroid transport protein transthyretin (Ttr) genes. 4PeCDF and 1PeBDF altered a phase II XME and Ttr genes. Additionally, 4PeBDF, TBDF, TCDF, and DBDCDD downregulated several genes that have been associated with antibody production and/or inflammation. Collectively these changes in gene expression are consistent with previously reported suppression of the AFC response and induction of aryl hydrocarbon-mediated and thyroid hormone responses. This abstract does not necessarily reflect the policies or views of NIH.

**PS 1993 PBDE-100 Induces Mitochondrial and HepG2 Impairment.**

L. C. Pereira<sup>1</sup>, A. O. Souza<sup>2</sup>, M. J. Tasso<sup>2</sup> and D. J. Dorta<sup>2</sup>. <sup>1</sup>FCFRP, Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Ribeirão Preto, Brazil; <sup>2</sup>FFCLRP, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Ribeirão Preto, Brazil.

**INTRODUCTION:** Polybrominated diphenyl ethers (PBDEs) have been used in diverse products and are ubiquitous contaminants in sediments, in biota and are also found in human tissues, raising concerns about its toxicity. Many studies have reported liver toxicity and induction of apoptosis by mitochondrial dysfunction. **OBJECTIVE:** The aim of this work was to investigate the mechanisms of toxicity using HepG2 cells and isolated rat liver mitochondria. **METHODS:** Briefly, the effects of BDE-100 (0,1-50  $\mu\text{mol/L}$ ) was assessed on the mitochondrial respiration; Mitochondrial Membrane Potential ( $\Delta\psi$ ); mitochondrial swelling; interaction with membrane using 1-anilino-8-naphthalene sulfonate (ANS) and 1,6-diphenyl-1,3,5-hexatriene (DPH);  $\text{Ca}^{2+}$  release and mitochondrial ATP levels with the luciferin-luciferase system using isolated rat liver mitochondria. Furthermore, cytotoxic effect was investigated by testing cell viability with (4,5 dimethylthiazol-2-yl) - 2,5 diphenyltetrazolium bromide dye (MTT) assay and cell proliferation with Sulphorhodamine B. **RESULTS:** In higher concentrations BDE-100 was able to induce mitochondrial alterations, and interact with the mitochondrial membrane, inhibiting the phospholipidation; leading to dissipation of the  $\Delta\psi$ , deregulation of calcium homeostasis and mitochondrial swelling add a reduction in mitochondrial ATP content. In addition, it was observed inhibition the proliferation and reduce viability of the cells showing its cytotoxic action. **CONCLUSIONS:** These results suggest the formation of pores in the mitochondrial membrane and alteration in mitochondrial structure and function, leading to cell death due to cytotoxic effects in HepG2, perhaps through mitochondrial pathway. **Word Keys:** Mitochondria; HepG2; BDE-100 Supported by: FAPESP

**PS 1994 Genomic Plasticity and Polychlorinated Biphenyls: Telomerase Reactivation and AhR Desensitization in Human Keratinocytes after Long-Term Exposure to PCB126.**

S. Pk, L. W. Robertson and G. Ludewig. *Human Toxicology, The University of Iowa, Iowa City, IA.*

Polychlorinated biphenyls (PCBs) are environmental pollutants and dioxin-like PCB126 (3,3',4,4',5-pentachlorobiphenyl) is classified by IARC as a human carcinogen. Chromosome ends have 'telomeres' which shorten with age in somatic cells. Lengthening of telomeres and high telomerase activity, the telomere maintaining enzyme, are key steps in carcinogenesis. To examine if PCB126 carcinogenicity is mediated through this mechanism, we exposed immortalized human skin keratinocytes (HaCaT) for 90 days to 5  $\mu\text{M}$  PCB126. Every sixth day cells were re-seeded and telomerase activity, telomere length, cMyc, hTERT and hTR (telomerase components), TRF1 and TRF2 (reduce telomerase access to telomeres) mRNA, CYP1A1 mRNA and activity, superoxide and  $\text{H}_2\text{O}_2$  levels were determined. PCB126 caused an increase in CYP1A1 mRNA and activity, TRF1/2 mRNA, and superoxide and  $\text{H}_2\text{O}_2$  and a reduction of telomerase activity (50%), hTERT and hTR mRNA (10%), telomere length (40%), and cell growth from Days 6 to 48. From Day 54 on, an increase in cell growth, cMyc, hTERT, and hTR mRNA levels (to 130%), reactivation of telomerase activity (to 100%), elongation of telomere length (to 90%), and a decrease in TRF1 and TRF2 mRNA were observed. In addition, from Day 78 PCB126 no longer activated the AhR response (CYP enzymes) and no mutation were found on the AhR ligand binding region. Microarray results confirmed an increase in expression of cell growth genes on Day 54 and desensitization of AhR-response on Day 78. This study shows for the first time a telomerase reactivation, telomere lengthening, and increased cell growth after telomeres were significantly shortened by PCB-exposure in human cells. Possible mechanisms include de novo cMyc amplification (telomerase) and/or selection of a small subpopulation of cells. Either way, this work adds a new toxicity pathway for PCBs and a possible mechanism of carcinogenesis for this and related contaminants to be considered in their safety evaluation and risk assessment.

**PS 1995 Exposure to PCB 126 Triggers Antioxidant Defense through Cross-Talk of Caveolae and Nrf2 Signaling.**

M. C. Petriello, B. Hennig and S. Han. *Toxicology, University of Kentucky, Lexington, KY.*

Environmental toxicants such as polychlorinated biphenyls have been implicated in the promotion of multiple inflammatory diseases including cardiovascular disease, but information regarding mechanisms of toxicity and cross-talk between relevant signaling pathways is lacking. We have reported that coplanar PCBs promote endothelial cell activation through the lipid microdomain caveolae, and the loss of

caveolin-1 (Cav-1) ameliorates these detrimental effects. We have also shown that PCB 126 can activate the antioxidant transcription factor Nrf2 resulting in upregulation of antioxidant genes and downregulation of inflammatory markers. Normally, Nrf2 is sequestered in the cytoplasm and degraded through inhibitory action of Keap1, but upon activation via toxicants such as PCBs, can enter the nucleus and activate the transcription of a battery of protective genes. Our previous data suggests downregulation of Cav-1 and upregulation of Nrf2 protects against PCB-induced cellular dysfunction, but here we show for the first time an intimate example of cross-talk between these two cellular signaling pathways. To examine the cross-talk between Cav-1 and Nrf2 pathways in PCB-induced inflammation we silenced cav-1 in vascular cells. Importantly, Cav-1-silenced cells treated with PCB126 resulted in increased levels of Nrf2-ARE binding determined by EMSA. Also, in cells treated with PCB 126, silencing of Cav-1 resulted in decreased protein levels of both inhibitory Keap1 and Fyn kinase, which both have been shown previously to be implicated in Nrf2 deactivation. We also show that Keap1 levels were significantly decreased in livers from Cav-1 KO mice when compared to control C57BL/6 mice. Finally, Cav-1 silencing allowed for a more effective antioxidant response, as observed by higher levels of the antioxidant genes glutathione S-transferase (GST) and NADPH dehydrogenase quinone 1 (NQO1) in cells exposed to PCB 126. Ultimately, these data introduce novel cross-talk between Cav-1 and Nrf2 and implicates the ablation of Cav-1 as a protective mechanism of PCB-induced cellular dysfunction and inflammation.

**PS 1996 Fibroblast Growth Factor 21 (FGF21) Is a Target Gene of the Aryl Hydrocarbon Receptor (AhR).**

X. Cheng<sup>1,2</sup> and C. D. Klaassen<sup>2</sup>. <sup>1</sup>Pharmaceutical Sciences, St. John's University, Queens, NY; <sup>2</sup>Internal Medicine, KU Medical Center, Kansas City, KS.

Dioxins, such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), are environmental pollutants. The toxic effects of TCDD are well documented mainly through activating the aryl hydrocarbon receptor (AhR). However, the underlying mechanisms for TCDD's adverse effects, such as the wasting syndrome, are not well understood. Fibroblast growth factor (Fgf) 21 plays critical roles in metabolic adaptation to fasting by increasing lipid oxidation and ketogenesis in the liver. The present study was performed to determine whether activation of the aryl hydrocarbon receptor (AhR) induces Fgf21 expression. In mouse liver, TCDD increased Fgf21 mRNA in both a dose- and time-dependent manner. Moreover, TCDD increased Fgf21 mRNA levels in livers of wild-type mice, but not of AhR-null mice. Chromatin immunoprecipitation assays indicate that TCDD increased AhR protein binding to the Fgf21 promoter (-105/+1 base pair). Diethylhexylphthalate (DEHP) decreased Fgf21 mRNA expression and DEHP pretreatment attenuated TCDD-induced Fgf21 expression, which may explain a previous report that DEHP pretreatment decreases TCDD-induced toxicities. In mouse liver, TCDD increased the mRNA of fatty acid uptake protein CD36 but decreased mRNA of de novo fatty acid biosynthesis enzyme fatty acid synthase (FAS). In addition to these findings in liver, TCDD induced Fgf21 mRNA in mouse white adipose tissue. In conclusion, TCDD induces Fgf21 expression via activation of the AhR-signaling pathway. Pharmacological manipulation of Fgf21 expression by AhR activators may provide an effective strategy for treating obesity, diabetes, and the metabolic syndrome. (Supported by NIH grants DK-081461, ES-09649, ES-019487, and RR-021940.)

**PS 1997 Human Transcription Factor Activation by Polychlorinated Biphenyls and Organochlorine Pesticides.**

B. Wahlang<sup>1</sup>, L. Al-Eryani<sup>1</sup>, K. Falkner<sup>1</sup>, H. Bellis-Jones<sup>1</sup>, H. Clair<sup>1</sup>, R. Prough<sup>3</sup> and M. Cave<sup>1,2</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY; <sup>3</sup>Biochemistry, University of Louisville, Louisville, KY.

**Introduction:** Polychlorinated Biphenyls (PCBs) are persistent environmental toxins, present in 100% of the US adult population and theoretically predicted to act as ligands for transcription factors involved in xenobiotic/endobiotic detoxification, obesity and steatosis. These human receptors include pregnane xenobiotic receptor (PXR), arylhydrocarbon receptor (AhR) and possibly the liver-X-receptor- $\alpha$  (LXR). This study evaluates a PCB mixture, Aroclor 1260, and selected individual PCB congeners, as potential ligands for these receptors. Additionally, we also look at PXR activation by selected organochlorine pesticides. **Methods:** MTT assay was performed to determine acutely toxic concentrations for Aroclor 1260. HepG2 cells were transfected with plasmids expressing human LXR or human PXR; and receptor-responsive plasmids including tk-LXR-RE-luciferase, pGL3-PXR-RE-luciferase or pGL3-AhR-RE-luciferase. Transfected cells were treated with ligands for LXR (T0901317:100nM), PXR (Rifampicin:10 $\mu\text{M}$ ) and AhR

(Benanthracene:50µM); varying concentrations of Aroclor 1260 or individual congeners and organochlorine pesticides. Results: The toxicity threshold of Aroclor 1260 in HepG2 cells was 26.0±3.7µg/mL. Aroclor 1260 did not activate the LXR/LXR-RE system and had no effect on LXR-dependent induction by T0901317. Aroclor 1260 induced the PXR reporter system in a simple monotonic fashion with significant inductions being observed at concentrations of 10µg/mL or greater. Amongst congeners tested, 126 and 196 activated PXR. Aroclor 1260 did not activate AhR but as expected, individual congeners 126 and 118 were potent inducers of AhR. Organochlorine pesticides including dieldrin and chlordane activated PXR. Conclusion: Aroclor 1260 is a direct agonist of human PXR but not LXR. This mixture did not significantly activate AhR. PCB 126 activated both PXR and AhR and 196 activated PXR only.

**PS 1998 Validation of QuEChERS-Based Extraction for the Determination of Organochlorine Pesticides in Liver and Serum Using GC-MS/MS.**

M. Bokhart<sup>1</sup>, A. Lehner<sup>2</sup>, M. Johnson<sup>2</sup> and J. P. Buchweitz<sup>2,3</sup>. <sup>1</sup>Chemistry, Michigan State University, East Lansing, MI; <sup>2</sup>Diagnostic Center for Population and Animal Health, Michigan State University, East Lansing, MI; <sup>3</sup>Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

Organochlorine (OC) pesticides are chemically stable, have low volatility, and low rates of degradation which lead to their persistence in the environment and classification as persistent organic pollutants (POP). OC pesticides bioaccumulate and biomagnify to greater extents in animals at higher trophic levels due to their high lipid solubility. These compounds generally affect the nervous system of the target organism. The mechanism of action involves the disruption of chemical ion movement in neurons but the major pathologic changes are observed in the liver and reproductive systems. Michigan State University Diagnostic Center for Population & Animal Health (MSU DCPAH) has developed and validated a quantitative QuEChERS approach for 24 organochlorine analytes in liver and blood serum. Identification and quantitation of the extracted compounds is by capillary gas chromatography interfaced to a tandem quadrupole mass spectrometer (GC-MS/MS). The QuEChERS approach utilizes an acetonitrile extraction, partitioning facilitated by the addition of salts and a dispersive solid phase extraction cleanup. Depending on compound and matrix, the limits of detection (LOD) vary from 0.002-2.4 ppb and limits of quantification (LOQ) vary from 0.01-7.4 ppb. Compared to other multiresidue methods for trace pesticide detection, the QuEChERS extraction method has many advantages including less sample size required, faster throughput time of samples, and less solvent used per sample leading to a reduction in overall cost, a lower carbon footprint and improved lab safety.

**PS 1999 Development of Weighted Distributions of Relative Potency Estimates for Dioxin-Like Compounds.**

L. C. Haws<sup>1</sup>, G. Hixon<sup>1</sup>, M. DeVito<sup>2</sup>, N. J. Walker<sup>2</sup>, L. Kuriakose<sup>3</sup>, L. S. Birnbaum<sup>4</sup>, M. Harris<sup>3</sup> and D. Wolkoff<sup>1</sup>. <sup>1</sup>ToxStrategies, Austin, TX; <sup>2</sup>NIEHS, Research Triangle Park, NC; <sup>3</sup>ToxStrategies, Houston, TX; <sup>4</sup>NCI, Research Triangle Park, NC.

Potential human health risks associated with exposure to dioxin-like compounds (DLCs) are evaluated using toxic equivalency factors (TEFs). TEFs are single point estimates even though they are based on relative estimates of potency (REPs) that often span several orders of magnitude. One potential improvement to the TEF methodology would be to use the full distributions of REP values for each congener. WHO recognized the value of such an approach during their most recent review of the TEF methodology but expressed concern that all REP values are not of equivalent quality or relevance. As such, we previously established a consensus-based framework that weights REPs based on REP quality and relevance and to develop a numerical approach for quantitatively weighting each REP using machine learning. Since that time, we have applied the quantitative weighting framework to the REP database to develop a numerical weight for each REP value, which in turn has been used to develop a weighted distribution of REPs for each congener, and have also developed 95% confidence intervals (CIs) around the percentile associated with the TEF values using the R statistical programming environment. The weighted distributions were generally tighter than were the unweighted distributions. Additionally, when examining where the current WHO TEFs fell on the weighted distributions for each congener, we found a lack of consistency across congeners, with values percentiles ranging from the 1st-99th percentiles. The CIs for many of the congeners were also quite broad. For example, the TEF for 12378 PeCDF fell on the 47th percentile of the weighted distribution, but the CI ranged from the 29th to the 68th percentile. These calculations improve characterization

of the variability and uncertainty inherent in the health risk estimates for this class of compounds, demonstrating that reliance on the point estimate TEFs could significantly under- or over-estimate risk. (This abstract does not reflect the policies or views of NIEHS or NCI).

**PS 2000 Uptake and Systemic Relative Effect Potencies of 4-PECDF, PCB-126, PCB-118 and PCB-156 in Female Mice after Acute Exposure.**

K. I. van Ede<sup>1</sup>, P. Andersson<sup>2</sup>, K. P. Gaisch<sup>1</sup>, M. van den Berg<sup>1</sup> and M. B. van Duursen<sup>1</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands; <sup>2</sup>Faculty of Science and Technology, Umeå University, Umeå, Sweden.

Risk assessment of mixtures of chlorinated dioxins (PCDDs), furans (PCDFs) and biphenyls (PCBs) is performed using Toxic Equivalency Factors (TEFs) that are derived from multiple relative effect potencies (REPs) linking administered dose levels to toxic/biologic effects. Increasing evidence suggests that using administered dose levels instead of systemic levels (e.g. liver or plasma concentrations), may lead to misinterpretation of risk. In this study, REPs of 4-PeCDF, PCB-126, PCB-118 and PCB-156 were determined in female mice three days after a single oral dose. REPs were calculated relatively to TCDD, based on cytochrome P450 1A1 (EROD) activity in liver and gene expression of CYP1A1, 1A2 and 1B1 in liver and peripheral blood lymphocytes (PBL) using administered dose, liver levels and plasma levels. Using the administered dose, REPs for the various endpoints ranged between 0.01 – 0.2 for 4-PeCDF (WHO-TEF 0.3), 0.005 – 0.04 for PCB-126 (WHO-TEF 0.1), 0.000005 – 0.00003 for PCB-118 (WHO-TEF 0.00003) and 0.00001 – 0.00003 for PCB-156 (WHO-TEF 0.00003). Recalculating the REPs using plasma levels increased REPs 4- to 9-fold for 4-PeCDF and 2-fold for PCB-126. In contrast, plasma-based REPs for PCB-118 and PCB-156 were slightly lower than the REPs based on administered dose. Recalculating the REPs using liver levels resulted in a decrease in REPs for 4-PeCDF and PCB-126 and an increase for PCB-118 and PCB-156. In general, deviation in REPs using either administered or systemic levels were seen for all tested congeners. However, most administered and systemic REPs were within or below one order magnitude uncertainty of WHO-TEFs. Only liver REPs for PCB-118 and PCB-156 based on liver concentration were higher. Even though, tissue specific REPs might give a more accurate value of the potency of a single compound. Additional rat and human in vitro data will be used to further confirm and/or explore these findings.

**PS 2001 Phenylethyl Isothiocyanate and Dithiocarbamate Restore Proangiogenic Properties of Cyp1b1-Deficient Vascular Cells through Decreased NF-κB Activity and Oxidative Stress.**

T. L. Palenski<sup>1</sup>, C. M. Sorenson<sup>2</sup> and N. Sheibani<sup>1</sup>. <sup>1</sup>Ophthalmology & Visual Sciences, University Wisconsin-Madison, Madison, WI; <sup>2</sup>Pediatrics, University Wisconsin-Madison, Madison, WI.

**Purpose:** Cytochrome P450 1B1 (Cyp1B1) is expressed in the vasculature and loss of its expression/activity is associated with increased oxidative stress, increased thrombospondin-2, and NF-κB activation. This is concomitant with attenuation of angiogenesis in vivo and in vitro. Both phenylethyl isothiocyanate (PEITC), found in cruciferous vegetables, and pyrrolidine dithiocarbamate (PDTC) inhibit NF-κB activity. The objective of this study was to determine if inhibition of NF-κB by PEITC or PDTC restores the reductive and proangiogenic properties of Cyp1B1-deficient vascular cells.

**Methods:** Primary cultures of retinal endothelial (EC) and pericytes (PC) were prepared from Cyp1B1+/+ and Cyp1B1-/- mice. Cyp1B1-/- retinal vascular cells were incubated with either 1 µM PEITC or 10 nM PDTC for 24 h, unless indicated otherwise. NF-κB expression and activity were determined by Western blot analysis and luciferase reporter activity. Immunofluorescence staining was performed to visualize p65 localization. Oxidative stress was measured using dihydroethidium staining. The ability of Cyp1B1+/+ and Cyp1B1-/- vascular cells to undergo capillary morphogenesis in Matrigel was also determined after 8 h incubation with PDTC or PEITC. Rates of cell migration were compared using a transwell assay. **Results:** PEITC and PDTC both inhibited NF-κB p65 expression and activity. NF-κB inhibition decreased p65 staining and nuclear localization in Cyp1B1-/- retinal vascular cells. Inhibition of NF-κB restored capillary morphogenesis and migration of retinal vascular cells. Oxidative stress in Cyp1B1-/- retinal vascular cells was relieved with incubation with PEITC and PDTC.

**Conclusion:** Cyp1B1 expression/activity is essential for maintaining the normal proliferative, migratory, and reductive state of the vascular cells, and its alteration has significant impact on vascular development and angiogenesis.

**PS 2002 Cyp1b1-Deficiency Alters Structure and Function of Trabecular Meshwork via Increased Oxidative Stress.**

Y. Zhao<sup>1</sup>, S. Wang<sup>1</sup>, C. M. Sorenson<sup>2</sup>, D. M. Peters<sup>1,3</sup>, L. Teixeira<sup>5</sup>, R. R. Dubielzig<sup>5</sup> and N. Sheibani<sup>1,4</sup>. <sup>1</sup>Departments of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, WI; <sup>2</sup>Pediatrics, UW-Madison, Madison, WI; <sup>3</sup>Pathology, UW-Madison, Madison, WI; <sup>4</sup>Pharmacology, UW-Madison, Madison, WI; <sup>5</sup>Comparative Ocular Pathology Laboratory of Wisconsin, UW-Madison, Madison, WI.

Cytochrome P450 1b1 (Cyp1b1) is a member of the cytochrome P450 super family of proteins with mono-oxygenase activity. Although mutations in Cyp1b1 gene have been reported in patients with congenital glaucoma, the role Cyp1b1 plays in the development and function of trabecular meshwork (TM) remains unknown. Here we determined the impact of Cyp1b1 deficiency on the development and function of TM tissue in C57Bl/6 mice. The intraocular pressures (IOPs) of Cyp1b1<sup>+/+</sup> and Cyp1b1<sup>-/-</sup> mice were measured non-invasively with a commercially available tonometer. The integrity of TM tissues of 1-week to 8-month-old Cyp1b1<sup>+/+</sup> and Cyp1b1<sup>-/-</sup> mice were assessed by electron microscopy (EM). Oxidative stress in the TM tissues was evaluated by immunostaining for 4-hydroxyl-2-noneal (HNE). N-Acetylcysteine (NAC; 1.5 mg/g body weight, once every three days for three weeks, IP) was administered in 3-day-old Cyp1b1<sup>-/-</sup> mice and the morphology of TM was assessed by EM. Our results showed a modest but significant increase in diurnal IOP of Cyp1b1<sup>-/-</sup> mice at 6-12 weeks of age. The 2-week-old Cyp1b1<sup>-/-</sup> mice presented ultra structural irregular collagen distribution in the TM tissue, which became more severe as mice aged. Increased HNE staining was observed in TM tissue of Cyp1b1<sup>-/-</sup> mice in vivo. Administration of NAC prevented the postnatal formation of lesions in Cyp1b1<sup>-/-</sup> TM. These results were consistent with our previous in vitro findings that TM cells prepared from Cyp1b1<sup>-/-</sup> mice exhibit increased oxidative stress and cellular defects, which are reversed when incubated with NAC. Thus, the metabolic activity of Cyp1b1 contributes to oxidative homeostasis and integrity of ultra-structure and function of TM.

**PS 2003 Macrophage Toxicity in Response to Particles Collected from Indium-Tin Oxide Production.**

M. A. Badding<sup>1</sup>, N. R. Fix<sup>1</sup>, K. M. Dunnick<sup>1</sup>, K. J. Cummings<sup>2</sup>, V. Castranova<sup>1</sup> and S. S. Leonard<sup>1</sup>. <sup>1</sup>Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Morgantown, WV; <sup>2</sup>Division of Respiratory Disease Studies, National Institute for Occupational Safety and Health, Morgantown, WV.

Occupational exposure to indium compounds has recently been associated with lung disease among workers in the indium-tin oxide (ITO) industry. Previous studies have suggested that autoantibodies and reactive oxygen species (ROS) may play a role in the development of pulmonary lesions following indium compound exposures. However, the molecular mechanisms behind indium compounds' toxicity remain largely unknown. Thus, we aim to uncover how compounds encountered in the ITO production process affect cultured macrophages and ultimately, contribute to the pathogenesis of indium lung disease. The indium compounds used in this study were collected from different process stages at an ITO production facility. Darkfield microscopy has revealed that various indium compounds interact with the cells as early as 5 minutes post-exposure, suggesting that cellular reactions to the ITO compounds may be occurring very rapidly. Indeed, using electron spin resonance (ESR) to measure ROS generation, we found that various collected indium compounds produce free radicals in the presence and absence of RAW 264.7 mouse macrophages within 5 minutes. We also hypothesize that indium compound particle uptake by macrophages leads to subsequent cellular damage, which could be contributing to lung pathology. Therefore, various imaging techniques are being used to observe particle association with and uptake by macrophages over a time course. Current studies are underway to evaluate the effects of the collected indium compounds on intracellular ROS production, lipid peroxidation, DNA damage, and cell proliferation over the same time course. These findings will provide a foundation for the molecular basis behind an emerging occupational health issue and assist in the prevention indium lung disease.

**PS 2004 Role of Cytochrome P450 (CYP)1A Enzymes in Sex-Specific Differences in Hyperoxic Lung Injury.**

K. Lingappan, W. Jiang, L. Wang, X. Couroucli and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Preterm male infants have a higher incidence of chronic lung disease (CLD) compared to females and hyperoxia contributes to its pathogenesis. Cytochrome P450(CYP)1A enzymes attenuate hyperoxic lung injury. The mechanisms responsible for sex differences in hyperoxic lung injury and the role of CYP1A enzymes remain largely unknown. We tested the hypothesis that mice will display sex-specific

differences in hyperoxic lung injury and that this phenomenon will be altered in mice lacking the genes for CYP1A1 or 1A2. Male (M) and Female (F) (8-10 wk) wild type (WT) (C57BL/6J), Cyp1a1-null, and Cyp1a2-null mice were exposed to hyperoxia (FiO<sub>2</sub>>0.95). Lung injury was estimated by lung-weight/body-weight (LW/BW) ratios, histopathology and immunohistochemistry for quantitation of neutrophil infiltration. Levels of 8-iso PGF<sub>2</sub>α (lung) were determined by LC-MS/MS and apoptosis was assessed by TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick end-labeling) staining. Measurement of cytokine protein expression levels in lung homogenates was done using suspension bead array. CYP1A1 and A2 expression was quantified in the lungs and liver at the enzyme, protein and mRNA level. Upon exposure to hyperoxia, WT males showed a greater increase in LW/BW ratios, displayed greater perivascular and alveolar injury, neutrophil infiltrates and TUNEL+ cells than females. The suspension bead array assay revealed increases in mouse lung tissue homogenate levels of IL-6 (F>M) and VEGF (M>F). WT females showed higher hepatic and pulmonary CYP1A level and activity compared to males. Strikingly, the sex-based differences were lost in mice lacking Cyp1a1 or 1a2. The increased susceptibility of WT males to hyperoxic lung injury suggests modulation by sex-specific factors like reactive oxygen species, inflammatory cytokines, and factors that regulate apoptosis. Further studies to elucidate the mechanistic role of CYP1A in the sex specific modulation of hyperoxic injury could lead to the development of strategies to prevent or treat CLD in the premature infant.

**PS 2005 Towards Elucidating the Pathophysiological Role of Reactive γ-Ketoaldehydes Formed through the Isoprostane Pathway of Lipid Peroxidation.**

T. T. Nguyen<sup>1,2</sup>, P. Chen<sup>2,3</sup>, M. Aschner<sup>1,2,3</sup> and L. Roberts<sup>1,4</sup>. <sup>1</sup>Pharmacology, Vanderbilt University Medical Center, Nashville, TN; <sup>2</sup>Pediatrics, Vanderbilt University Medical Center, Nashville, TN; <sup>3</sup>Neuroscience, Vanderbilt University Medical Center, Nashville, TN; <sup>4</sup>Medicine, Vanderbilt University Medical Center, Nashville, TN.

Numerous environmental toxins cause oxidative damage to lipids, proteins, and DNA. Lipid peroxidation leads to the formation of reactive aldehydes amongst which the γ-ketoaldehydes formed via the isoprostane pathway of lipid peroxidation, termed isoketals (IsoKs), are the most reactive and injurious. Selective scavengers of IsoKs have been developed which have shown remarkable protection against oxidative damage in animal models of oxidative stress. However, the precise molecular processes preserved due to scavenging IsoKs have not been defined. This can, however, be elucidated studying the highly tractable organism, *Caenorhabditis elegans* (*C. elegans*). Accordingly, to identify the pathophysiological roles of IsoKs in oxidative injury, *C. elegans* are exposed to oxidative insult in the absence and presence of salicylamine. A fluorescent *C. elegans* strain containing a GFP transcriptional reporter for the SKN-1 target gene *gst-4* (*P<sub>gst-4</sub>::GFP*) was utilized for detection of altered gene expression in order to determine processes protected by reactive γ-ketoaldehyde scavengers. Late-stage L4 worms were dosed with a submaximal dose of a SKN-1 activating xenobiotic, juglone, for one hour and plated for recovery for one hour. Current studies show a nearly 4-fold increase in fluorescent intensity after a submaximal (LD<sub>20</sub>) dose of juglone (p-value = 0.02). These results demonstrate that a brief exposure to the xenobiotic juglone is sufficient in activating SKN-1 in *C. elegans*, and can be used in oxidative and xenobiotic stress studies. (Supported by T32ES007028-38 [T.T.N.]).

**PS 2006 High-Content Imaging Assay to Detect Drug-Induced Reactive Oxygen Species Generation.**

Y. Will, R. Swiss and S. Nadanaciva. *Pfizer Inc, Groton, CT.*

The disruption of cellular redox circuits can lead to an increase in reactive oxygen species (ROS) within cells, causing oxidative stress and eventually cell damage. Mitochondria are the main producers of ROS in the form of superoxide anion. Two of the electron transport chain complexes, Complex I and Complex III, are thought to be responsible for most of the ROS generated in mitochondria. Several drugs associated with oxidative stress have been shown to contribute to toxicity in the liver, heart, kidney and central nervous system. Thus, it is important to be able to screen new chemical entities that may cause an increase in ROS production in order to reduce compound attrition at the early drug discovery stage. Hence, we developed a 384-well format high content imaging assay that measures superoxide production. The effect of 60 compounds including thiazolidinediones, antipsychotics, antidepressants and anticancer agents was measured in this assay in transformed human liver epithelial cells (THLE) using the fluorescent dyes, Dihydroethidium (for superoxide levels) and Hoechst (for cell number). In a separate 384-well format high content imaging assay, we tested the effect of the compounds on the mitochondrial membrane potential (MMP) of the cells using the

fluorescence dye, TMRM. Quantitative image analysis showed that the compounds could be grouped into four categories: (a) those that caused superoxide formation and a loss in MMP at similar concentration ranges (for example, astemizole, sorafenib), (b) those that caused superoxide production but had no effect on MMP (dasatinib), (c) those that caused a loss in MMP but had no effect on superoxide formation (tamoxifen, sertraline), and (d) those that had no effect either on superoxide formation or on the MMP over 24 hours (pioglitazone, risperidone). Both high content imaging assays were robust and rapid and can be implemented within a screening paradigm to identify compounds that modulate oxidative stress and mitochondrial membrane potential.

## PS 2007 The Antioxidant Lipoic Acid Exacerbates Paraquat-Induced Cytotoxicity.

Z. Suntutres<sup>1,2</sup>, R. Pycko<sup>2</sup> and J. Coccimiglio<sup>2</sup>. <sup>1</sup>Northern Ontario School of Medicine, Thunder Bay, ON, Canada; <sup>2</sup>Biology, Lakehead University, Thunder Bay, ON, Canada.

In several countries the use of herbicides has become important in the preservation of sustainable agriculture. A widely used herbicide for broadleaf weed control is paraquat (PQ) known to be toxic to humans and animals. The treatment against PQ poisoning remains supportive with no antidotes or specific treatments available. Recognizing that PQ induces its toxicity primarily via oxidative stress-mediated mechanisms, modulating the levels of cellular antioxidants seems to serve as a potential treatment strategy. We studied the in vitro effects of the thiol-containing antioxidant lipoic acid (LA) in a human lung adenocarcinoma epithelial cell line. Incubation of control A549 cells with PQ resulted in time- and concentration-dependent increases in intracellular PQ levels with concomitant decreases in cell viability and mitochondrial membrane permeability (MMP) and increases in intracellular calcium concentrations [Ca<sup>2+</sup>]<sub>i</sub>. Challenge of cells with LA alone did not cause any changes in any of the biochemical parameters measured with the exception of the MMP being significantly decreased. Co-treatment of A549 cells with LA and PQ potentiated the PQ-induced cytotoxicity as evidenced by the further exacerbation of PQ-induced decreases in MMP and increases in DNA fragmentation and [Ca<sup>2+</sup>]<sub>i</sub>. Chromatographic analysis (GC/MS/MS) showed that LA was primarily associated with cell membranes. These data suggest that LA does not offer any protective effects against PQ-induced toxicity. The mechanism(s) for its ability to modulate cell survival/death by modulating the cellular redox-regulated signal transduction in PQ-challenged cells is under investigation. This research project was supported by Natural Sciences and Engineering Research Council of Canada (NSERC).

## PS 2008 Lipid Droplets with Oxygenated Fatty Acids and Triglycerides in Dendritic Cells: Possible Role in Antigen Presentation in Cancer.

V. Tyurin<sup>1,2</sup>, W. Cao<sup>3</sup>, J. Loomen<sup>3</sup>, V. Kagan<sup>1,2</sup> and D. Gabrilovich<sup>3</sup>. <sup>1</sup>Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Department of Immunology, H. Lee Moffitt Cancer Center, Tampa, FL.

Immuno-surveillance plays a critical role in control of tumor progression whereby dendritic cells (DC) are the most potent antigen presenting cells responsible for the development of immune responses. Our previous work has identified lipid droplets as potent regulators of DC's immune functions. Notably, DCs isolated from tumor-bearing mice or treated with tumor explant supernatants (TES) accumulated lipid droplets containing considerable amounts of PUFA (C18:2, C18:3, C20:4 and C22:6). Among those, the amounts of C18:2 were significantly higher compared to other PUFA species. Since accumulation of lipid droplets in DCs in cancer was mediated via Msr1 receptor, which is primarily responsible for the uptake of oxidatively modified lipids, we performed analysis of oxidized lipids in DCs using LC-ESI-MS. To investigate possible role of oxidized fatty acid in antigen presentation we used a model system where DCs from naïve mice were grown in the presence of C18:2. Treatment of DCs with C18:2 in combination with a hydrophobic free radical generator, an azo-initiator AMVN, - but not with C18:2 alone - resulted in accumulation of oxygenated lipid droplets and caused significant decrease in antigen presentation. Oxygenated FFA containing one, two and three oxygens as well as oxygenated triacylglycerols, TAGs, including truncated TAGs with m/z 766 [M+NH<sub>4</sub>]<sup>+</sup>, containing acyl corresponding to 9-oxo-nonanoic acid, were observed in DC grown in the presence of TES and DC treated with C18:2 and AMVN. Given that lipid droplets can directly co-localize with cellular compartments involved in antigen processing and formation of pMHC complexes, it is likely that accumulation of oxygenated FFAs and TAGs in DC may be responsible for the loss of their immune-regulatory functions in cancer. Supported by grant with CA165065, NIOSH OH008282, NIH U19 AI068021, HL70755.

## PS 2009 Mitochondrial Cardiolipin As a Substrate for Cytochrome C-Catalyzed Production of Oxygenated Lipid Mediators.

V. Kagan<sup>1</sup>, V. Tyurin<sup>1</sup>, S. Poloyac<sup>2</sup>, M. Epperly<sup>3</sup>, J. Greenberger<sup>3</sup>, H. Bayir<sup>4</sup> and Y. Tyurina<sup>1</sup>. <sup>1</sup>Department of EOH, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Pharmaceutical Science, University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Radiation Oncology, University of Pittsburgh, Pittsburgh, PA; <sup>4</sup>Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA.

Lipid mediators - central to the normal homeostasis and responses to stress and disease - are generated through oxygenation of polyunsaturated fatty acids (PUFA), such as linoleic acid (LA), arachidonic acid (AA) and docosahexaenoic acid. Their regulatory effects are believed to depend on a fine balance between PUFA esterification/reacylation of phospholipids and on their hydrolysis by phospholipases A (PLA). We suggested that mitochondrial cardiolipins (CLs) can be a source of bioactive lipid mediators generated with the catalytic participation of cytochrome c (cyt c). In this study we employed models of rat traumatic brain injury (TBI) and mouse total body irradiation (TIR). Using oxidative lipidomics approach and MS/MS analysis, we found that TBI resulted in oxidation of polyunsaturated molecular species of CL and accumulation of its hydrolysis products such as oxygenated LA, AA and monolysio-CL. Similar, a significant increase of oxidized CLs in small intestine of TIR mice (9.5 Gy) was accompanied by accumulation of CL hydrolysis products. To generate oxygenated CL in vitro we utilized brain CL, with its highly diversified polyunsaturated molecular species, and cyt c. We found that incubation of brain CL with cyt c in the presence of H<sub>2</sub>O<sub>2</sub> yields a rich assortment of oxygenated CL species, hydrolysis of which by PLA1 and A2 generated multiple oxygenated fatty acids similar to those that were formed in vivo in brain after TBI and small intestine after TIR. An oxidation-specific lipoprotein lipase A2, was able to utilize peroxidized tetralinoleoy-CL to yield different oxygenated species of linoleic acid and lyso-CLs. Thus, mitochondrial CL/cyt c represents a novel mechanisms involved in lipid mediators-generating pathways. Supported by NIH ES020693, ES021068, U19 AI068021, HL70755; NIOSH OH008282, NS076511, NS061817.

## PS 2010 Development of a Mitochondria-Targeted Nano-Complex of Imidazole-Substituted Oleic Acid As a Radiomitigator.

A. Star<sup>1,3</sup>, A. Kapralov<sup>2,3</sup>, A. Amoscatto<sup>2,3</sup>, V. Tyurin<sup>2,3</sup>, W. Seo<sup>1,3</sup>, M. Epperly<sup>4,3</sup>, J. Greenberger<sup>4,3</sup>, Y. Tyurina<sup>2,3</sup> and V. Kagan<sup>2,3</sup>. <sup>1</sup>Department of Chemistry, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Center for Medical Countermeasures against Radiation, University of Pittsburgh, Pittsburgh, PA; <sup>4</sup>Radiation Oncology, University of Pittsburgh, Pittsburgh, PA.

Increasing likelihood of intended or accidental exposure to ionizing radiation dictates the necessity to develop effective medical countermeasures of radiation injury as has been recognized as a high priority both in the US and worldwide. No effective medical radiation countermeasures of acute and delayed radiation injuries are currently known. Based on newly discovered mechanisms of radiation damage - oxidation of cardiolipin by cytochrome c in mitochondria as a required stage in radiation-induced apoptosis - we designed and synthesized mitochondria-targeted triphenylphosphonium-conjugated imidazole-substituted oleic (TPP-IOA) which prevented/mitigated cell death induced by irradiation and protected C57BL6 mice against total body irradiation. To improve therapeutic efficiency of TPP-IOA we chose to employ branched polyethylene glycol (PEG) functionalized single walled carbon nanotubes (SWCNT) and use it as a carrier to deliver mitochondria-targeted TPP-IOA to tissues. We found that loading of PEG-SWCNT with TPP-IOA caused a marked extension of the life-span of TPP-IOA in circulation. Moreover we showed that TPP-IOA-nano-complex was more effective as radiomitigator than free TPP-IOA. While the dose of TPP-IOA in TPP-IOA-nano-complexes was two times lower compared with free TPP-IOA the mitigating effect of TPP-IOA-nano-complexes was higher than that of TPP-IOA alone. Importantly, we were able to detect TPP-IOA nano-complexes in radiosensitive tissue such as small intestine. These data warrant further studies aimed at the development of radioprotectors/radiomitigators with broad spectrum of applications in biomedicine and biodefense. Supported by NIOSH OH008282; NIH U19 AI068021, HL70755, ES019304.

## PS 2011 XBP1, SYVN1 and Nrf2: At the Crossroads of ER Stress and Oxidative Stress.

T. Wu and D. D. Zhang. College of Pharmacy, University of Arizona, Tucson, AZ.

Transcription Factor Nrf2 has long time been revealed as the master regulator of intracellular redox homeostasis. As an adaptive response to oxidative stress, Nrf2 activates transcription of a battery of genes encoding antioxidant protein, detoxification

enzymes and xenobiotic transporters by binding to the cis-antioxidant response elements in the promoter region of these genes. Previous works by our lab and others demonstrated that Nrf2 is subject to poly-ubiquitin-mediated proteasomal degradation in a Keap1-dependent manner. Here we report that active form of XBP1, XBP1s suppresses Nrf2 and its downstream signal under ER stress condition, through activation transcription of synovial apoptosis inhibitor 1 (SYVN1). SYVN1, also known as Hrd1, is an ER-associated degradation (ERAD) ubiquitin ligase. We have determined that SYVN1 directly interacts with the Neh4 and Neh5 domain within Nrf2. Overexpression of SYVN1 attenuates Nrf2 signaling, whereas knockdown of SYVN1 enhances expression of Nrf2 and its downstream genes. Furthermore, SYVN1 accelerates the clearance of Nrf2 protein through promoting ubiquitination of Nrf2. These findings demonstrate that XBP1 and SYVN1 are involved in regulating the Nrf2 pathway in a new Keap1-independent mechanism. Moreover, our data revealed a possible crosstalk between ER stress pathway and oxidative responses via UPR and Nrf2 signaling pathway in order to protect cells against environmental stress.

**PS 2012 Sulforaphane Stimulates Basal but Inhibits Glucose-Stimulated Insulin Secretion in Beta-Cells: Role of Reactive Oxygen Species and Induction of Endogenous Antioxidants.**

J. Fu<sup>1</sup>, Q. Zhang<sup>1</sup>, C. G. Woods<sup>1</sup>, H. Zheng<sup>1</sup>, B. Yang<sup>1,2</sup>, M. E. Andersen<sup>1</sup> and J. Pi<sup>1</sup>. <sup>1</sup>Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Durham, NC; <sup>2</sup>College of Basic Medical Science, China Medical University, Shenyang, China.

Excessive oxidative damage by reactive oxygen species (ROS) is a major contributor to pancreatic  $\beta$ -cells dysfunction. Interestingly, ROS are also involved as a second messenger in glucose-stimulated insulin secretion (GSIS) in  $\beta$ -cells. This paradox obscures the regulatory role of antioxidants in insulin secretion. In the present study, we used an integrated mathematical modeling and in vitro approach to understand the effects of antioxidant sulforaphane (SFN) on insulin secretion. Experiments with INS-1(832/13) cells and isolated mouse islets showed that 30-min SFN treatment stimulated basal insulin secretion in a concentration-dependent manner at low glucose conditions (3 mM). This acute stimulatory effect resulted from an initial SFN-elicited increase of ROS, and when suppressed with cell-permeable ROS scavenger N-acetylcysteine or glutathione ethyl ester, SFN-stimulated insulin secretion was diminished. Due to the negative feedback and incoherent feedforward loops comprising the redox homeostatic control circuit, cells can adapt to prolonged SFN treatment and settle to a steady state exhibiting strong induction of antioxidants but only marginally increased ROS levels. This adapted state slightly increased basal insulin secretion in INS-1(832/13) cells. More importantly, the model predicted that the elevated antioxidant capacity at the adapted state attenuates glucose-stimulated ROS signal and GSIS. This effect was validated in INS-1(832/13) cells exposed to low, non-cytotoxic concentrations of SFN. Despite suppressing GSIS, prolonged exposure to SFN protected INS-1(832/13) cells from cytotoxicity induced by exogenous H<sub>2</sub>O<sub>2</sub>. Taken together, our studies demonstrated that SFN has divergent effects on basal and glucose-stimulated insulin secretion in  $\beta$ -cells. Although the adaptive induction of endogenous antioxidants by SFN enhances  $\beta$ -cell survival, it suppresses GSIS.

**PS 2013 Generation of Reactive Oxygen Species by Process Materials from Indium-Tin Oxide Production.**

N. R. Fix<sup>1</sup>, K. M. Dunnick<sup>1</sup>, M. A. Badding<sup>1</sup>, A. B. Stefaniak<sup>2</sup>, K. J. Cummings<sup>2</sup>, V. Castranova<sup>1</sup> and S. S. Leonard<sup>1</sup>. <sup>1</sup>Health Effects Laboratory Division, National Institute of Occupational Safety and Health (NIOSH)/CDC, Morgantown, WV; <sup>2</sup>Division of Respiratory Disease Studies, National Institute of Occupational Safety and Health (NIOSH)/CDC, Morgantown, WV.

The transition metal indium has been used for decades for various applications including electronics, fusible alloys, and solar cells. Indium compounds usage has increased dramatically based on the rise in demand of touch screens and flat panel displays (LCD's). With this growth of industry, there is potential for increase of indium lung disease among workers who produce, use, or reclaim indium-tin oxide (ITO). Inhalation exposure of indium samples can occur during various times of manufacturing. Materials from different process stages were collected from an ITO production facility. While the pathogenesis of indium lung disease is unknown, previous work has suggested a role for reactive oxygen species (ROS). Chemical characteristics of the process materials will aid in determination of reactivity differences between compounds. Electron spin resonance (ESR), a common tool used for measuring ROS, was used in both acellular and cellular exposures. Acellular samples were evaluated by combining 10 mg/mL process material, phosphate buffered saline (PBS), 10mM hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), and 100mM DMPO (spin trap). RAW 264.7 mouse monocyte macrophages, DMPO, and the same concentration

of composite were used in the cellular samples conducted in ESR. Scavengers and chelators were used to define radical mechanisms. Results indicated that ventilation dust (VD), tin-oxide (SnOX), and unsintered ITO (UITO) cause a greater increase in ROS production than the other process material. H<sub>2</sub>O<sub>2</sub> and O<sub>2</sub> consumption measurements were used to determine the source of the ROS. ESR studies combined with investigation of ROS production will help to determine the mechanisms behind indium lung disease. Data from this study will be used to determine possible hazards in occupational exposure of indium process material while increasing the understanding of indium lung disease.

**PS 2014 Lower Expression of Nrf2 Promotes Proliferation, Migration and Invasion of Prostate Cancer Cells.**

R. Khatri and A. K. Jaiswal. *Pharmacology and Experimental Therapeutics, University of Maryland Baltimore, Baltimore, MD.*

The nuclear factor Nrf2 is known to play a critical role in cellular protection against oxidative stress and cellular transformation. However, unabated nuclear accumulation of Nrf2 is also known to reduce apoptosis, promote cancer cell survival and drug resistance. Mutations in INrf2 and Nrf2 leading to nuclear accumulation of Nrf2 in many cancers including prostate and breast cancer are known. These also raise interesting questions regarding the role of Nrf2 in cancer metastasis and/or metastasis progression that remains elusive. In this study we have investigated the hypothesis that loss of Nrf2 is associated with metastasis/metastasis progression. We used less metastatic LNCaP and highly metastatic LNCaP derived C4-B2 prostate cancer cell lines to test our hypothesis. The analysis revealed that highly metastatic C4-B2 cells expressed higher INrf2 and lower Nrf2 levels as compared to less metastatic LNCaP cells. We used control, INrf2 and Nrf2 shRNA to generate C4-B2 and LNCaP derived cells with altered levels of INrf2 and Nrf2 to determine the role of Nrf2 in metastasis and metastasis progression in Soft agar colony formation and X-CELLigence proliferation, migration and invasion assays. C4-B2-INrf2shRNA cells expressing inhibited levels of INrf2 and higher levels of Nrf2 showed fewer colonies in soft agar and proliferated faster but did not migrate as compared to C4-B2-Control shRNA cells. Similarly, LNCaP-Nrf2shRNA cells expressing inhibited levels of Nrf2 in less metastatic LNCaP cells demonstrated significantly higher number of colonies in soft agar, proliferated faster and showed greater migration and invasion as compared to LNCaP-Control shRNA cells. These results together suggest that lower Nrf2 levels are associated with higher proliferation, migration and invasion or metastatic progression. Currently, we are investigating the mechanism of the role of Nrf2 in metastasis progression and plan in vivo experiments to test our hypothesis of the association of lower Nrf2 with metastasis progression in mice.

**PS 2015 Mechanisms of Oxidative Stress Promoted by 1, 4-Diamino-2-Butanone in Trypanosoma cruzi and Mammalian Cells.**

E. J. Bechara<sup>1,2</sup>, C. O. Soares<sup>2</sup>, W. Colli<sup>2</sup> and M. M. Alves<sup>2</sup>. <sup>1</sup>Ciências Exatas e da Terra, Universidade Federal de São Paulo, Diadema, Brazil; <sup>2</sup>Bioquímica, Universidade de São Paulo, São Paulo, Brazil.

The putrescine analogue 1,4-diamino-2-butanone (DAB) is highly toxic to pathogenic microorganisms, including various fungi and Trypanosoma cruzi. Similar to other  $\alpha$ -aminocarbonyl metabolites such as aminoacetone and 5-aminolevulinic acid, DAB exhibits pro-oxidant properties. DAB reportedly undergoes metal-catalyzed oxidation in aerobic medium yielding H<sub>2</sub>O<sub>2</sub>, NH<sub>4</sub><sup>+</sup> ion, and 4-amino-2-oxobutanal, a highly toxic  $\alpha$ -oxoaldehyde. Administered to mammalian cell cultures, DAB decreases the cell viability which was shown to be associated with changes in redox balance. Thus, treatment of RKO cells derived from human colon carcinoma or cultured LL-MK2 Rhesus epithelial cells with millimolar DAB caused significant decline in cell viability, which was inhibited by pre-addition of catalase, aminoguanidine (an  $\alpha$ -oxoaldehyde trap), N-acetyl cysteine or reduced glutathione. Now we explore the mechanisms by which DAB exhibits pro-oxidant effects on trypanostigotes and on intracellular T. cruzi amastigotes. DAB (0.05-5.0 mM) exposure in trypanostigotes, the infective stage of T. cruzi, leads to a decline in parasite viability (IC<sub>50</sub> c.a. 0.2 mM DAB; 4 h incubation), changes in morphology, thiol redox imbalance, and increased TcSOD activity. Medium supplementation with catalase (2.5  $\mu$ M) protects trypanostigotes against DAB toxicity, while host cell invasion by trypanostigotes is hampered by DAB. Additionally, intracellular amastigotes are susceptible to DAB toxicity. Furthermore, pre-treatment with 100-500  $\mu$ M buthionine sulfoximine (BSO) of LLC-MK2 potentiates DAB cytotoxicity, whereas 5 mM N-acetyl-cysteine (NAC) protects cells from oxidative stress. Together, these data support the hypothesis that redox imbalance, not only the long reported DAB-promoted inhibition of polyamine metabolism, contributes to its cytotoxicity in both T. cruzi and mammalian host cells.

**PS 2016 Receptor-Mediated Reactive Oxygen Species Contribute to Impaired Coronary Vasodilation following Acute Ozone Exposure in Rat.**

M. Paffett<sup>1</sup>, S. Robertson<sup>1</sup>, S. Lucas<sup>1</sup>, T. Anderson<sup>2</sup>, M. Nysus<sup>2</sup>, J. Norenberg<sup>2</sup> and M. J. Campen<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM; <sup>2</sup>Radiopharmaceutical Sciences, University of New Mexico, Albuquerque, NM.

Ozone (O<sub>3</sub>) exposure in both humans and rodents leads to elevations in alveolar and peripheral inflammation, believed to promote endothelial dysfunction. Although pulmonary inflammation is a well-defined response to inhaled O<sub>3</sub>, little is known regarding acute effects of O<sub>3</sub> exposure on the mechanisms responsible for impaired coronary vasodilation. We hypothesized that a single, whole-body O<sub>3</sub> exposure will induce pulmonary inflammation and the transference of pulmonary inflammatory elements will contribute to reactive oxygen species (ROS)-induced endothelial dysfunction. We tested this hypothesis by assessing pulmonary immune infiltrates from bronchial alveolar fluid lavage (BALF), circulating WBCs and coronary artery endothelial function 24 hrs following O<sub>3</sub> exposure (4h at 1ppm) or filtered air (FA). BALF total protein, cell number, macrophage/neutrophil counts and circulating WBC differentials were assessed. Furthermore, experiments assessing the effects of O<sub>3</sub> on the endothelial-dependent vasodilator, acetylcholine (ACh), in coronary arteries pre-constricted (~50%) with a thromboxane mimetic (U46619) in the presence or absence of luminal administration of the superoxide dismutase mimetic (PEG-SOD). Parallel experiments were performed where rodents were injected (i.p.) with inhibitory antibodies directed against lectin-like oxidized low density lipoprotein receptor-1 (LOX-1). Our results demonstrate significant increases in BALF total protein and cell number were evident in O<sub>3</sub> exposed rats, specifically neutrophils, compared to FA controls. Systemic increases in circulating neutrophils were also evident following O<sub>3</sub> exposure. Moreover, ACh-mediated vasodilation was restored in vessels loaded with PEG-SOD and partially restored in rodents pretreated with the LOX-1 inhibitor. Our data suggest that that O<sub>3</sub>-induced pulmonary inflammation contributes to increased ROS-mediated endothelial dysfunction downstream of LOX-1.

**PS 2017 In Vitro Modification of Plasminogen by Methylglyoxal Disrupts Normal Zymogen Activation.**

O. R. Kinsky, M. J. Kimzey, T. J. Monks and S. S. Lau. Southwest Environmental Health Sciences Center, Department of Pharm/Tox, College of Pharmacy, University of Arizona, Tucson, AZ.

Reactive dicarbonyls such as methylglyoxal (MG) are present in blood and react with arginines (R) of target proteins, leading to diabetic micro- and macrovascular complications. Normal MG plasma concentrations are estimated to reach 4.5 μM, with these values tripling as diabetic complications progress. Dicarbonyls irreversibly modify R residues, resulting in a net loss of positive charge via hydroimidazolone formation. Previous shotgun LC/LC-MS/MS proteomics analysis of human serum reacted with MG (18 hrs at 37°C) indicated that plasminogen (PLG) was readily modified at multiple sites. Subsequent studies in our laboratory determined that modification at R561 of PLG resulted in drastic energy-of-interaction changes between PLG and tissue plasminogen activator (tPA). The model revealed that a MG-adduct formed at R561 decreased the interaction energy by up to 410.4 kcal/mol, 164-fold higher than the minimum energy change necessary for an altered interaction. Modified R561 in PLG is of particular biological interest because of its role in the thrombolytic cascade, R561 being the site of cleavage from PLG to plasmin. In an effort to determine functional consequences of this adduction, MG-modified PLG and its activation by both exogenous and endogenous activators was studied. The activation of MG-modified PLG by streptokinase (STK) was altered in both a time (0-60 min) and concentration (1-500 μM MG) dependent manner. Unmodified PLG (90-100 kDa) was cleaved by STK, with the concurrent formation of angiostatin (ANG; 38 kDa) and plasmin light chain (PLC; 25 kDa). In contrast, such effects were diminished in MG-modified PLG, with reduced accumulation of ANG and PLC, and reduction in the disappearance of PLG. Similar studies are underway with tPA and urokinase. The findings indicate that MG-modification of PLG may disrupt the thrombolytic cascade thereby contributing to vascular complications associated with diabetes. (R24DK083948, ABRG, ES016652, T32ES007091, P30ES006694).

**PS 2018 Oxidative Stress-Dependent Destruction of Cdc25C As a Novel Chemotherapeutic Strategy for the Targeted Induction of Cell Cycle Arrest.**

S. Qiao<sup>1,2</sup> and G. T. Wondrak<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, University of Arizona, Tucson, AZ; <sup>2</sup>Arizona Cancer Center, University of Arizona, Tucson, AZ. Sponsor: W. Klimecki.

Cellular oxidative stress is an established causative factor in carcinogenesis. Recent research suggests that elevated oxidative stress in cancer cells represents a phenotypic vulnerability that can be targeted by redox intervention. Multiple myeloma is a redox sensitive hematological malignancy characterized by dysregulation of cell cycle progression and checkpoint control. Guided by a phenotypic drug screen for novel leads that display antiproliferative activity through induction of oxidative stress, we have identified the FDA-approved antimicrobial thiostrepton (T) as multiple myeloma-directed experimental chemotherapeutic. In RPMI-8226 multiple myeloma cells, major hallmarks of hyperproliferation including hyperphosphorylation of retinoblastoma (pRb; Ser 780, Ser807/811) and overexpression of c-myc and cyclin D1 were fully suppressed at both mRNA and protein levels at submicromolar concentrations of T. Moreover, T-induced G2/M cell cycle arrest was characterized by inhibitory phosphorylation of cyclin-dependent kinase 1 (CDK1; Tyr15), dephosphorylation of histone H3 (Ser10), and cyclin B1 accumulation as revealed by immunodetection. Flow cytometric analysis indicated rapid induction of cytotoxic oxidative stress followed by destruction of the redox-sensitive oncogenic phosphatase cdc25C (cell division cycle 25C), known to abrogate the G2/M checkpoint by activation of dephosphorylation of cyclin B-CDK1 (Tyr15). Strikingly, hydrogen peroxide treatment mimicked T-induced destruction of cdc25C. Vice versa, antioxidant pretreatment (N-acetyl-L-cysteine) prevented cdc25C depletion, inhibitory phosphorylation of CDK1, and enrichment of the G2/M fraction, further substantiating the causative role of ROS in T-induced cell cycle arrest. Taken together, these data suggest feasibility of T-based prooxidant intervention targeting the oncogenic redox-sensitive G2/M regulator cdc25C and its downstream effectors for experimental chemotherapy of multiple myeloma.

**PS 2019 Selective Detoxification of Hypothiocyanite by Mammalian Thioredoxin Reductase, the Missing Link in Lung Innate Immunity and Antioxidant Defense.**

J. D. Chandler<sup>1,2</sup>, R. J. Hondal<sup>3</sup> and B. J. Day<sup>1,2</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Colorado Denver, Denver, CO; <sup>2</sup>Medicine, National Jewish Health, Denver, CO; <sup>3</sup>Biochemistry, University of Vermont, Burlington, VT.

Haloperoxidases metabolize thiocyanate (SCN) in the presence of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) producing the thiol-selective oxidant hypothiocyanite (OSCN). OSCN has been implicated in innate immunity through its ability to inhibit the growth of multiple pathogens. Paradoxically, SCN has been shown to protect cells from promiscuous oxidizing species such as hypochlorite (OCl) by a direct reaction forming OSCN, suggesting its selective detoxification by mammalian cells. Mammalian thioredoxin reductase (TR) is distinguished from lower order TRs by its C-terminal selenocysteine (Sec) redox couple and broader substrate specificity. Recombinant rat TR1, recombinant mouse TR2 and purified rat TR metabolized OSCN with high affinity but do not metabolize OCl. Mutant forms of mouse TR2 lacking Sec had significantly higher Km for OSCN. Recombinant E. coli TR did not metabolize OSCN or OCl. Lysates from human lung epithelial cells (16HBE) readily metabolized OSCN but lysates from E. coli and P. aeruginosa were inactive. Auranofin, a TR inhibitor, decreased OSCN metabolism in 16HBE lysates. 16HBE cells and P. aeruginosa were exposed to an oxidase-peroxidase coupled system that generated a 100 μM steady state exposure of OSCN or OCl for 2 hours. OCl was highly toxic to both 16HBE and P. aeruginosa, but OSCN was only toxic to P. aeruginosa. Inhibition of mammalian TR with auranofin increased OSCN toxicity in 16HBE cells. These findings implicate mammalian TR as the major detoxification pathway for OSCN and suggest a novel mechanism of innate immunity and antioxidant defense in mammals wherein OSCN formation simultaneously results in pathogen inhibition while preventing damage to host tissue. This study was funded by NIH Grant HL084469 and a Cystic Fibrosis Foundation Research Grant.

**PS 2020 GRP78 Contributes to the Selective Cytoprotection Afforded by All-Trans-Retinoic Acid against Renal Injury.**

J. Sapiro, A. C. Gallegos, I. Y. Rojas, A. B. Romans, R. D. Canatsey, T. J. Monks and S. S. Lau. SWEHSC, Pharm/Toxicol, University of Arizona, Tucson, AZ.

Chemical-induced nephrotoxicity is a major cause of acute kidney injury. Pretreatment of LLC-PK<sub>1</sub> cells with all-trans-retinoic acid (ATRA) affords cytoprotection against chemical nephrotoxins. ATRA pretreatment (25 μM, 24 hrs)

protected against p-aminophenol (PAP, 150  $\mu$ M, 3 hr), iodoacetamide (25  $\mu$ M, 2 hr), and  $H_2O_2$  (250  $\mu$ M, 3 hr)-induced cytotoxicity as assessed by the MTS assay. Moreover, ATRA suppressed tumor necrosis factor- $\alpha$  (TNF- $\alpha$ , 30 ng/mL, 2 hr)-induced caspase-3 cleavage by 4-fold, indicative of a reduction in apoptosis. In contrast, pretreatment of cells with ATRA had no effect on cisplatin (25  $\mu$ M, 24 hr)-induced caspase-3 cleavage. The data reveal that ATRA selectively protects against toxicants that induce necrotic and death receptor-mediated (extrinsic) apoptotic cell death but not against mitochondrial-mediated (intrinsic) apoptotic cell death. Although the molecular mechanism(s) underlying the cytoprotective effects of ATRA remain unclear, the endoplasmic reticulum (ER) molecular chaperone Grp78 is a pivotal contributor to the cytoprotective/adaptive response to cell stress. Therefore, we subsequently used Grp78 non-inducible cells to explore the relationship between the ER stress response and ATRA signaling. LLC-PK<sub>1</sub> cells, in which the induction of grp78 expression was disrupted via stable expression of an antisense grp78 RNA (pKASgrp78), were more sensitive to the cytotoxic effects of PAP relative to control cells transfected with an empty vector (PKNEO). Furthermore, although ATRA itself induced Grp78 in naive LLC-PK<sub>1</sub> and PKNEO cells, it was unable to do so in the pKASgrp78 cells. Thus, Grp78 may contribute to ATRA-mediated cytoprotection and ATRA may provide an effective therapeutic intervention for chemical-induced renal injury or other pathological conditions. (ES006694, ES016578).

## PS 2021 Sulfur Dioxide Modulates Oxidative Stress Responses in IL-10-Deficient Mice with Airway Inflammation.

A. L. Reno<sup>1</sup>, L. M. Hallberg<sup>2</sup>, W. C. Spear<sup>1</sup>, J. L. Parks<sup>1</sup>, A. P. Chaparro<sup>3</sup>, E. G. Brooks<sup>3</sup> and B. T. Ameredes<sup>1</sup>. <sup>1</sup>Internal Medicine, University of Texas Medical Branch, Galveston, TX; <sup>2</sup>Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX; <sup>3</sup>Pediatrics, University of Texas Health Science Center, San Antonio, TX.

**RATIONALE:** Inhaled sulfur dioxide (SO<sub>2</sub>) at low concentrations (1-5 ppm) can produce bronchospasm in asthmatics, linked to increased oxidative stress and airway inflammation (AI), potentially due to a deficiency in IL-10 production. We tested this hypothesis in IL-10-sufficient C57Bl6 (C57), and IL-10 knockout (-/-) mice, with experimentally-induced AI.

**METHODS:** AI was induced by sensitization and challenge with ovalbumin (OVA, O/O), with and without inhaled SO<sub>2</sub> (1 ppm for 6 hr/day over 10 days). Bronchoalveolar lavage fluid (BALF) was analyzed for leukocyte counts; a pro-oxidant/anti-oxidant balance (PAB) assay provided an index of oxidative stress, and interleukin-4 (IL-4) levels in lung homogenates were measured by ELISA, as an indicator of AI. Nitrite levels were measured in BALF by Griess assay, as an index of iNOS activity.

**RESULTS:** Respective mean eosinophil counts ( $\times 10^3$ /g mouse) for C57 and IL-10-/- mice ( $P < 0.05$ ) were: O/O-SO<sub>2</sub> (3.1 vs. 1.4; n.s.), and O/O+SO<sub>2</sub> (3.0 vs. 4.3; n.s.), indicating eosinophilia in mice with mild AI alone, and those that inhaled SO<sub>2</sub>, as compared to saline-challenged controls having no eosinophils. SO<sub>2</sub> shifted the PAB toward pro-oxidative in C57 mice with AI, whereas the opposite was found for their IL-10-/- counterparts ( $P < 0.05$ ). IL-4 levels in the O/O+SO<sub>2</sub> C57 mice were significantly increased compared to their IL-10-/- counterparts. BALF nitrite levels ( $\mu$ M/kg body weight) were decreased in the C57 O/O+SO<sub>2</sub> group (61 $\pm$ 5; n.s.) as compared to O/O-SO<sub>2</sub> (86 $\pm$ 15). A similar trend was seen for the IL-10-/- mice (62 $\pm$ 7 vs. 80 $\pm$ 10; n.s.).

**CONCLUSIONS:** The results indicate there is a robust inflammatory response in the lungs of mice exposed to OVA allergen attenuated by SO<sub>2</sub> inhalation, perhaps via an anti-oxidant promotion mechanism.

## PS 2022 Statin-Induced Cytotoxicity in C2C12 Myoblasts Is Accompanied by Mitochondrial Dysfunction and Excessive ROS Production.

T. Schirris<sup>1,3</sup>, J. J. Nabers<sup>1,3</sup>, J. D. Beyrath<sup>2,3</sup>, J. A. Smeitink<sup>2,3</sup> and F. G. Russel<sup>1,3</sup>. <sup>1</sup>Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; <sup>2</sup>Pediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; <sup>3</sup>Centre for Systems Biology and Bioenergetics, Nijmegen, Netherlands.

Statins are widely used cholesterol-lowering drugs that are generally well-tolerated. The most important adverse effects are muscle pain and inflammation of muscle cells. The mechanism is not fully understood, although for some statins a direct effect on mitochondrial function has been found. Here, we systematically studied the effect of a series of sixteen different statin drugs on mitochondrial function and cytotoxicity in a mouse myoblast cell line (C2C12). A high-content method was developed to measure the viability and ROS production of C2C12 cells using a 384-well microscopy assay. Furthermore, mitochondrial function was assessed using

high-resolution oxygen consumption measurements in comparison with maximal ATP production rates. Nine of the sixteen statins studied induced cell death after 24h, including cerivastatin, simvastatin, atorvastatin and rosuvastatin, which are most frequently associated with clinical cases of myopathy. Of these nine statins, rosuvastatin lactone had the highest potency (IC<sub>50</sub> 22 $\pm$ 10  $\mu$ M) and atorvastatin the lowest (IC<sub>50</sub> 182 $\pm$ 36  $\mu$ M). After 8h treatment at IC<sub>50</sub> concentrations, all nine statins showed increased ROS levels; itavastatin lactone gave the largest increase of 4300 $\pm$ 36AU compared to control (585 $\pm$ 99AU,  $P < 0.001$ ). Moreover, these nine statins reduced the ATP production, most potently by cerivastatin lactone (16 $\pm$ 8% of control,  $P < 0.05$ ). These results were further confirmed by a reduced malate-, glutamate-, and succinate-driven oxygen consumption by all nine statins. In conclusion, a series of clinically relevant statins affected mitochondrial function and viability of C2C12 myoblasts with different potencies. Further research is needed to investigate the link between the observed mitochondrial dysfunction and the inflammatory and the apoptotic hallmarks of statin-induced myopathies.

## PS 2023 Screening and Characterization of Aldehydes on the Basis of Protein Carbonylation.

H. Dhot<sup>1,2</sup> and P. J. O'Brien<sup>2</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.

Proteins are easily susceptible to Post Translational Modifications (PMT) where protein carbonylation is the most common type that plays a pivotal role in etiology and/or progression of lethal diseases like neurodegenerative diseases, cancers, aging, diabetes and sepsis. Since, ROS and secondary by products of oxidative stress can induce the protein carbonylation and this type of protein oxidation is regarded as a well-known biomarker of oxidative stress with different susceptibility for different amino acids. In this study, we studied the protein carbonylation caused by different aliphatic (formaldehyde to decanal i.e. aldehydes from carbon 1 to carbon 10) and aromatic (benzaldehyde and its derivatives) aldehydes by applying BSA Protein carbonylation assay. Taking into account the ED 50 values of the aliphatic aldehydes, 2mM and 4mM concentrations of aldehydes were used. Among aliphatic aldehydes, only first two aldehydes (HCHO and CH<sub>3</sub>CHO) showed the highest protein carbonylation in a dose dependent manner. On the other hand, aromatic aldehydes showed the following trend: 4Chlorobenzaldehydes (max at 120 mins) > Cinnamaldehyde (max at 120 mins) > benzaldehyde (max at 120 mins) > p-Tolualdehyde (max at 60 mins) > m-Tolualdehyde (max at 40 mins). GSH was found effective against protein carbonylation. Protein carbonylation increased with increase in dose except in case of cinnamaldehyde and benzaldehyde where high dose decreased the carbonylation. So, our result suggests that aliphatic aldehydes can be characterized as less reactive towards protein carbonylation reaction than aromatic aldehydes. Among aromatic aldehydes, cinnamaldehyde and 4-chlorobenzaldehyde can be regarded as fast reacting aldehydes, m-tol and p-tol as slowly reacting with or without lag phase respectively, ortho substituted aldehydes as causing no protein carbonylation.

## PS 2024 Autophagy Is Protective against CYP2E1-Dependent Arachidonic Acid, Buthionine-Sulfoximine, and Carbon Tetrachloride Cytotoxicity in E47 HepG2 Cells through Preventing Mitochondrial Dysfunction.

D. Wu and A. I. Cederbaum. *Pharmacology & Systems Therapeutics, Mount Sinai School of Medicine, New York, NY.* Sponsor: Y. Lu.

The goal of this study was to evaluate if autophagy promotes or is protective against CYP2E1 toxicity. E47 HepG2 cells express CYP2E1 and control C34 cells which do not express CYP2E1 were treated with arachidonic acid (AA), or buthionine-sulfoximine (BSO), or carbon tetrachloride (CCl<sub>4</sub>), in the presence or absence of 3-methyladenine (3MA) or rapamycin. All three compounds reduced cell viability in E47 cells but not in C34 cells. 3MA further reduced cell viability while rapamycin increased it. These results suggested that autophagy prevented against AA, BSO and CCl<sub>4</sub> cytotoxicity in E47 cells. These compounds induced oxidative stress in E47 cells as TBARS increased and GSH decreased. 3MA enhanced TBARS and decreased GSH while rapamycin prevented these changes. Flow cytometry suggested that these compounds mainly induced necrosis and 3MA enhanced necrosis but not apoptosis; rapamycin prevented the necrosis. These compounds induced mitochondrial membrane swelling, cytochrome c release, reducing mitochondrial ATP production, 3MA enhanced but rapamycin prevented these changes. Mitochondrial ROS production was enhanced by rapamycin but decreased by 3MA. E47 cells were transfected with Atg7 siRNA which enhanced AA cytotoxicity, increased oxidative stress. The decline in viability was restored and oxidative stress was blocked in the presence of rapamycin. The antioxidant N-acetyl-L-cysteine prevented the AA or Atg 7 siRNA-induced oxidant stress and loss of E47 cell viability.

and the potentiation of these effects by 3MA. Treating the E47 cells with AA induced p38 MAPK, 3MA enhanced the activation and rapamycin inhibited it. This study shows that autophagy is protective against AA, BSO and CCl<sub>4</sub> induced CYP2E1 dependent cytotoxicity. This protection may be due at least in part through prevention of mitochondrial dysfunction to maintain cell survival.

## PS 2025 Absence of Upstream Consensus Regulatory Element Sequences for Nrf2 in Human Glutathione S-Transferase Genes.

C. M. Schaupp<sup>1</sup>, T. K. Bammler<sup>2</sup>, R. P. Byer<sup>2</sup>, T. J. Kavanagh<sup>1,2</sup> and D. L. Eaton<sup>1,2</sup>. <sup>1</sup>Environmental and Occupational Health Sciences, University of Washington, Seattle, WA; <sup>2</sup>Center for Ecogenetics & Environmental Health, University of Washington, Seattle, WA.

Nuclear factor erythroid-derived 2-like 2 (NFE2L2, or NRF2) is involved in antioxidant response to cellular stress. In response to oxidative or electrophilic stimuli, NRF2 binds its target genes containing an antioxidant response element (ARE), upregulating expression of detoxifying/antioxidant enzymes. Numerous studies have demonstrated that some rodent liver GSTs are highly inducible via activation of the Keap1/Nrf2/ARE antioxidant response pathway by prototypical Nrf2 activators such as BHA, sulforaphane and oltipraz. Thus, these chemicals may have therapeutic value based on their putative ability to activate NRF2-mediated antioxidant pathways. However, human studies in vitro and in vivo have not generally seen a robust induction of GSTs following administration of Nrf2 activators, suggesting that human liver GSTs are less responsive to ARE-mediated induction. To identify the potential basis for a possible inter-species difference in GST inducibility, we used the web-based oPOSSUM software to identify ARE sequences up to 10,000 base pairs upstream of the transcriptional start sites of antioxidant enzymes putatively regulated by NRF2 in murine and human genomes. Only three out of 19 human GST genes (GSTM2, GSTO2, and GSTZ1) contained an ARE consensus sequence within 10kb of the transcriptional start site, whereas ARE sequences were present in 11 of 17 murine GSTs analyzed. Notably, none of the common, highly expressed human alpha or mu class GSTs contained consensus NRF2 elements, whereas 2 of 4 alpha class, and 5 of 7 mu class, mouse GSTs contained one or more Nrf2 response elements. Our data suggest that inter-species differences in GST inducibility may result from differences in the presence and location of ARE consensus sequences upstream of murine and human GST genes—a conclusion which may have major implications in the clinical setting.

## PS 2026 Pharmacological Inhibition of Thioredoxin Reductase I Attenuates Hyperoxic Lung Injury by Augmenting Glutathione Synthesis.

L. K. Rogers<sup>1,3</sup>, R. D. Britt<sup>1</sup>, T. E. Tipple<sup>1,3</sup> and M. Velten<sup>1,2</sup>. <sup>1</sup>Center for Perinatal Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; <sup>2</sup>Anesthesiology and Intensive Care, Rheinische Friedrich-Wilhelms University, Bonn, Germany; <sup>3</sup>Pediatrics, The Ohio State University, Columbus, OH.

Inflammation and oxygen toxicity increase free radical production and contribute to the development of acute respiratory distress syndrome (ARDS). We have previously shown increased glutathione (GSH) levels in lung epithelial cells in vitro and attenuated adult murine hyperoxic lung injury in vivo following thioredoxin reductase-1 (TrxR1) inhibition with auranofin and aurothioglucose (ATG), respectively. The present studies tested the hypothesis that ATG treatment increases pulmonary GSH levels, decreases lung injury, and improves survival. Adult male mice were given a single IT dose of 0 or 0.375 µg/g E. coli LPS. After 12 h, an injection of 0 or 25 mg/kg ATG or a combination of ATG and 800 mg/kg buthionine sulfoximine (BSO) were administered, i.p. Mice were then exposed to room air (RA) or >95% hyperoxia (O<sub>2</sub>). After 3 d exposure, bronchoalveolar lavage (BAL) and lung tissues were collected. BAL protein concentrations were significantly greater in LPS/O<sub>2</sub>-exposed mice when compared to PBS/RA controls. In LPS/O<sub>2</sub>-exposed mice, ATG treatment significantly decreased BAL protein concentrations, increased lung GCLM expression, GSH levels, and GSH/GSSG ratios, and improved survival compared to PBS-treated LPS/O<sub>2</sub>-exposed mice. BSO treatment dramatically decreased the survival of ATG-treated LPS/O<sub>2</sub>-exposed mice. In summary, ATG enhances GSH levels, decreases lung injury, and improves survival in a GSH-dependent manner in a murine model of ARDS. If enhancement of pulmonary GSH levels can be accomplished via drug-mediated TrxR1 inhibition, which seems to be without detrimental effects, this approach could constitute a novel strategy to improve outcomes in patients with oxidant-mediated lung injury. ## PS 2027 Aniline Up-Regulates Cyclins via Induction of Oxidative Stress in Rat Spleen.

J. Wang, G. Wang, H. Ma and M. Khan. University of Texas Medical Branch, Galveston, TX.

Aniline exposure is associated with toxicity to the spleen leading to splenomegaly, fibrosis and a variety of sarcomas of the spleen. In earlier studies, we have shown that aniline exposure leads to iron overload, oxidative and nitrosative stress and activation of redox-sensitive transcription factors, which could regulate various genes leading to a tumorigenic response in the spleen. However, molecular mechanisms leading to aniline-induced cellular proliferation in the spleen remain largely unknown. This study was undertaken to further assess the role of oxidative and nitrosative stress in the regulation of cell cycle proteins (cyclins) following aniline exposure. Groups of male SD rats were treated with aniline (1 mmol/kg/day by gavage), aniline plus N-acetylcysteine (NAC, an antioxidant, 300 mg/kg/day, i.p.), aniline plus aminoguanidine (AG, an iNOS inhibitor, 200 mg/kg/day, i.p.) or aniline plus zinc protoporphyrin (ZP, a heme oxygenase inhibitor, 50 µmol/kg/day, i.p.) for 7 days (controls received drinking water only), and mRNA expression of cyclins A, B, D3 and E were measured in spleen. Aniline treatment resulted in significant increases in the expression of cyclin A (7.9-fold), cyclin B (7.3-fold), cyclin D3 (3.7-fold) and cyclin E (5.4-fold) as compared to the controls. Interestingly, all of the three inhibitors significantly reduced the aniline-induced overexpression of cyclins. Specifically, NAC reduced the expression of cyclins A, B, D3 and E by 61%, 48%, 38%, and 41%, AG reduced cyclins A, B, D3 and E by 60%, 63.0%, 51%, and 37%, whereas ZP reduced cyclins A, B, D3 and E by 30%, 61%, 62%, and 44%, compared to aniline only treated rats, respectively. Our data suggest that oxidative and nitrosative stress play a role in aniline-induced overexpression of cyclins which could be critical in cell proliferation, and may contribute to aniline-induced tumorigenic response in the spleen. Supported by NIH ES06476.

## PS 2028 Understanding the Role of UCP2 in Fatty Acid Beta-Oxidation and Drug-Induced Liver Injury.

J. E. Montanez<sup>1</sup>, P. B. Smith<sup>2</sup> and A. D. Patterson<sup>1,2</sup>. <sup>1</sup>Veterinary and Biomedical Science, The Pennsylvania State University, University Park, PA; <sup>2</sup>Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.

UCP2, originally described as a mitochondrial uncoupling protein, has been reported to serve many other functions including regulation of glucose and lipid metabolism as well as regulation of ROS in cancerous cells. We recently reported that under hepatotoxic conditions such as that induced by acetaminophen, UCP2 expression was found to protect against liver damage in a PPARα-dependent fashion. Interestingly, polymorphisms in the coding sequence of the UCP2 gene have been found to be associated with obese and/or diabetic individuals further implicating UCP2 in the fatty acid beta-oxidation pathway. However, the precise mechanism by which UCP2 exerts these salubrious effects is unknown. In this study, the metabolic functions of UCP2 and UCP2 (A55V) variant were compared using a gas chromatography coupled with mass spectrometry-based metabolomics approach. COS-7 cells were transfected with myc/flag-tagged UCP2 and UCP2 (A55V). After confirming expression of the constructs via Western blotting (no difference was observed between UCP2 and UCP2 (A55V)), the cells were extracted, metabolites derivatized using methoxamine and MSTFA, and the samples ran on an Agilent 5975C Series GC/MSD. Principal component analysis of the data show distinct separation of the UCP2 transfected cells from the control and UCP2 (A55V) transfected cells. Among others, palmitic acid was found to be dramatically decreased (~2.3 fold) in the UCP2-transfected cells compared to control and UCP2 (A55V) transfected cells. Further, palmitic acid is thought to induce UCP2 expression through PPARα activation. This study illustrates the utility of the metabolomics approach for elucidating and/or clarifying the metabolic function of UCP2.

## PS 2029 Real-Time Monitoring of Xenobiotic-Induced Intracellular Redox Changes Using Ozone As a Model Oxidant.

E. A. Gibbs-Flournoy<sup>1</sup>, S. O. Simmons<sup>2</sup>, P. A. Bromberg<sup>3</sup> and J. M. Samet<sup>4</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>ISTD/NHEERL, US EPA, Research Triangle Park, NC; <sup>3</sup>Center for Environmental Medicine, Asthma, and Lung Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>4</sup>EPHD/NHEERL, US EPA, Chapel Hill, NC.

Oxidative injury is often cited as a key feature in the toxic action of many xenobiotics; however, unambiguous indices of xenobiotic-induced oxidative stress have proven elusive. A new generation of sensors capable of reporting intracellular redox

status has shown much promise. However, their use in toxicological assessments involving strong electrophiles remains to be validated. Exposure to ozone ( $O_3$ ), a highly reactive oxidant gas, induces pulmonary function decrements and inflammatory responses in the airways through oxidative mechanisms. An important unresolved toxicological question concerns the effect of  $O_3$  exposure on intracellular redox status. Using live-cell microscopy, we addressed this issue directly with the novel application of roGFP2, a genetically-encoded fluorescent reporter of the intracellular glutathione redox potential,  $E_{GSH}$ . BEAS-2B human bronchial epithelial cells transduced to stably express cytosolic roGFP2 were exposed to concentrations of  $O_3$  ranging from 0.15 - 1.0 ppm. Cells were imaged in real-time during  $O_3$  exposure in a custom-built stage-top exposure chamber.  $O_3$  exposure induced a dose- and time- dependent increase of the cytosolic  $E_{GSH}$ . Modulation of glutathione system components confirmed that roGFP2 is not directly oxidized but properly equilibrates with the oxidation status of the glutathione pool. Exposure to  $O_3$  induces a substantial increase in  $E_{GSH}$  in BEAS-2B cells that is indicative of an oxidant-dependent impairment of redox homeostasis. Moreover, this study demonstrates the utility of using redox reporters in making reliable assessments of cells undergoing exposure to xenobiotics with potent oxidizing properties. THIS ABSTRACT OF A PROPOSED PRESENTATION DOES NOT NECESSARILY REFLECT EPA POLICY.

**PS 2030 Formation 4-Hydroxynonenal, an Electrophilic Lipid Peroxidation End Product, in Rabbit Corneal Organ Cultures Treated with Nitrogen Mustard.**

A. T. Black<sup>1</sup>, R. Zheng<sup>1</sup>, I. Po<sup>1</sup>, D. E. Heck<sup>2</sup>, D. L. Laskin<sup>1</sup>, D. R. Gerecke<sup>1</sup>, M. K. Gordon<sup>1</sup> and J. D. Laskin<sup>3</sup>. <sup>1</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Environmental Science, New York Medical College, Valhalla, NY; <sup>3</sup>Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Sulfur mustard (SM, bis (2-chloroethyl) sulfide) and nitrogen mustard (NM, mechlorethamine) are cytotoxic vesicants that can cause ocular injury. The cornea is particularly sensitive, developing opacity and ulcerations following SM exposure. In these studies we used an air-liquid interface (air lifted) organ culture model in which vesicants are applied directly to the central cornea to assess mustard-induced oxidative stress. Three and six hr post treatment (100 nmol NM in 10  $\mu$ l PBS), the corneal epithelial layer was found to express proteins containing the lipid peroxidation product 4-hydroxynonenal (4-HNE). This was associated with expression of the antioxidant hemeoxygenase-1 (HO-1). To assess molecular mechanisms underlying this response, we analyzed the effects of 4-HNE on human corneal epithelial cells (HCEC) in culture. 4-HNE (0.03 mM) was found to cause a time-dependent induction of HO-1 mRNA and protein; optimal expression of the enzyme was evident after 10 hr. HO-1 is known to be regulated by both MAP kinases and phosphatidylinositol (PI)-3 kinase (PI3K)/Akt signaling. Treatment of corneal cells with a p38 MAP kinase inhibitor (SB203580, 10  $\mu$ M) blocked upregulation of HO-1 protein by 4-HNE. Inhibitors of the MAP kinases Erk1/2 (PD98059, 10 $\mu$ M) and JNK (SP600125, 20 $\mu$ M), and PI-3K (Wortmannin, 100 nM), partially suppressed HO-1 expression. These data indicate that NM is an effective inducer of oxidative stress in corneal epithelial cells, as measured by the formation of 4-HNE protein adducts. Moreover, induction of HO-1 is regulated by 4-HNE in a process dependent on MAP kinase and PI3K/Akt signaling. Countermeasures that target oxidative stress may be effective countermeasures for SM-induced corneal injury. Supported by NIH grant U54AR055073.

**PS 2031 Isoniazid-Induced Cellular Challenge in HL-60 Cells: An In-Depth Proteomic Perspective.**

M. R. Khan<sup>1</sup>, A. Baghdasarian<sup>1</sup>, R. P. Fahlman<sup>2</sup> and A. Siraki<sup>1</sup>. <sup>1</sup>Pharmacy & Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada; <sup>2</sup>Biochemistry, University of Alberta, Edmonton, AB, Canada.

**INTRODUCTION:** Isoniazid (INH) is the first line therapy to combat tuberculosis. However, its use is associated with potent clinical toxicity, particularly liver damage. However, the rare but important side-effect of INH-induced agranulocytosis is an idiosyncratic drug reaction for which the toxicity mechanism is unclear. Since INH forms various reactive metabolites, we hypothesized that intracellular protein modification by INH could reveal a possible mechanism of INH-induced agranulocytosis. **METHODS:** HL-60 (promyelocytic leukemia) cells were used for these studies. Trypan Blue exclusion was performed for cytotoxicity. Immunoblot assays were conducted by using anti-INH and anti-DMPO antibodies to identify INH-covalently bound proteins and INH-induced protein radicals, respectively. Later, these modifications were confirmed by MALDI-TOF MS. For quantitative proteomics, we performed SILAC (stable isotope labelling by amino acids in cell culture). **RESULTS:** 5 mM INH had no significant cytotoxicity after 48 hrs. Anti-DMPO (protein radicals) showed a prominent protein radical at 50 kDa, however,

multiple INH covalent protein adducts were found by anti-INH immunoblotting. In SILAC experiments, we found changes in 101 proteins (very high confidence limits) of which 38 were upregulated and 63 were downregulated. We observed a significant down regulation of ribosomal proteins, transcriptional factors and splicing factors. But at the same time, factors associated with protein stability were up-regulated. Pro-apoptotic signals were counterbalanced by anti-apoptotic signals, and cell growth factors were upregulated. **CONCLUSION:** Our result showed that INH is acutely non-toxic to HL-60 cells, and is unlikely to possess direct toxicity to neutrophils or bone marrow precursors. INH treatment appeared to induce cellular energy conservation through downregulation of protein synthesis and enhanced protein stability. Further pathways will be elucidated once INH-induced protein radicals and covalent adducts are identified.

**PS 2032 Attenuation of Experimental Retinopathy of Prematurity by Vitamin A in the Newborn Rat.**

X. Courouclis<sup>1</sup>, Y. Liang<sup>1</sup>, G. Zhou<sup>2</sup>, W. Jiang<sup>1</sup> and B. Moorthy<sup>1</sup>. <sup>1</sup>Pediatrics, Baylor College of Medicine, Houston, TX; <sup>2</sup>Institute of Biosciences and Technology, Texas A&M University Health Science Center, Houston, TX.

Supplemental oxygen administration is frequently encountered in the treatment of premature infants suffering from respiratory distress. However, hyperoxia contributes to the development of chronic lung disease [bronchopulmonary disease (BPD)] and retinopathy of prematurity (ROP). In this investigation, we tested the hypothesis that exposure of newborn rats to vitamin A and hyperoxia would attenuate retinopathy and abnormal neovascularization compared to those exposed to hyperoxia alone. Newborn Fisher 344 rats were maintained in room air or exposed to hyperoxia ([gt] than 95% O<sub>2</sub>) for 7 days. Some animals were treated i.p. with vitamin A [2 mg/kg], once daily for the first 5 days of hyperoxic exposures. Animals were sacrificed at selected time points after termination of hyperoxia. Retinal vascular densities of flat mounted retinas were assessed. Protein expression of HIF-1 $\alpha$  was determined by Western blotting. Oxidative DNA damage in retinal tissue was determined by 32P-postlabeling. Immediately after 7 days of exposure to hyperoxia alone, we observed constricted retinal vessels, compared to those given vitamin A + hyperoxia. Seven to thirty days after termination of hyperoxia alone, the animals displayed formation of abnormal retinal vessels and capillaries, compared to the vitamin A + hyperoxia group. At the 7 day time point, the HIF-1 $\alpha$  protein expression in the hyperoxia + vitamin A group was much higher than the hyperoxia alone group. On the other hand, at later time points, the HIF-1 $\alpha$  protein levels were higher in the hyperoxia group. Interestingly, oxidative DNA adducts were significantly decreased in the retinas of animals given vitamin A + hyperoxia. Our study supports the hypothesis that vitamin A protects retina from oxygen-induced abnormal neovascularization, and this is the first report that shows oxidative DNA damage to contribute to experimental ROP.

**PS 2033 Systemic Nerve Growth Factor Modulates the Transcription of Amino Acid Transporters and Glutathione (GSH) Synthesis in Mice Striatum.**

C. Valdovinos-Flores and M. E. Gonssebatt. Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

Nerve growth factor (NGF) is a member of structurally related proteins, named neurotrophins (NTs), that regulate neuronal survival, development, function, and plasticity. Moreover, NGF is an important activator of antioxidant mechanisms. These functions of NGF are mediated by the tropomyosin-related kinase receptor A (TrkA). There is evidence that NTs and their receptors are expressed also in visceral tissues. Physical exercise and stress increase levels of NGF in plasma. Using a murine model we have shown that systemic inhibition of GSH synthesis with L-buthionine-S-R-sulfoximine (BSO) increased brain GSH content and induced the transcription of ngfb in liver. Murine striatum cholinergic neurons express TrkA receptors thus, we investigated if an i.p. injection of BSO or of sodium arsenite (iAs) modulate the transcription of ngfb and trka as well TrkA phosphorylation in mice striatum. Both agents induced the activation of the NGF/TrkA pathway which correlated with an increased transcription of xCT, LAT1, EAAC1 amino acid transporters system genes that provide L-cys / L-cys2 to central nervous system and of GCLm which participates in the de novo synthesis of GSH. The inhibition of TrkA phosphorylation by K252a or anti-NGF neutralizing antibody abrogated the BSO and iAs induced transcription of xCT, LAT1, EAAC1 and GCLm suggesting the participation of this pathway in the *in vivo* antioxidant response at least in striatum. Furthermore, since anti-NGF neutralizing antibodies would not cross the blood-brain barrier, our results suggest that NGF functions as a systemic redox-sensor in both CNS and peripheral tissues and that the NGF/TrkA pathway plays a critical role in the antioxidant response in the striatum in our murine model. Supported by CONACYT 102287

**PS 2034 HMGB1 Mediates Hyperoxia-Induced Impairment of *Pseudomonas aeruginosa* Clearance and Inflammatory Lung Injury in Mice.**

V. S. Patel<sup>1</sup>, R. Sitapara<sup>1</sup>, A. Gore<sup>1</sup>, B. Phan<sup>1</sup>, L. Sharma<sup>1</sup>, V. Sampat<sup>1</sup>, J. Li<sup>2</sup>, H. Yang<sup>2</sup>, S. Chavan<sup>2</sup>, H. Wang<sup>2</sup>, K. Tracey<sup>2</sup> and L. Mantell<sup>1,2,3</sup>.

<sup>1</sup>Pharmaceutical Sciences, Saint John's University, Fresh Meadows, NY; <sup>2</sup>Center for Inflammation and Immunology, The Feinstein Institute for Medical Research, North Shore-LIJ Health Science, Manhasset, NY; <sup>3</sup>Center for Heart and Lung Research, The Feinstein Institute for Medical Research, North Shore-LIJ Health Science, Manhasset, NY.

Mechanical ventilation with supraphysiological concentrations of oxygen (hyperoxia) is routinely used to treat patients with respiratory distress. However, a significant number of patients on ventilators have enhanced susceptibility to infections and develop ventilator-associated pneumonia (VAP). *Pseudomonas aeruginosa* (PA) are one of the most common bacteria found in these patients. Previously, we demonstrated that prolonged exposure to hyperoxia can compromise the ability of alveolar macrophages (AM), an essential part of the innate immunity, to phagocytose PA. The objective of this study was to investigate potential molecular mechanisms underlying hyperoxia-compromised innate immunity against bacterial infection in a mouse model of PA pneumonia. Here, we show that exposure to hyperoxia ( $\geq 99\%$  O<sub>2</sub>) led to a significant elevation in levels of airway HMGB1 and an increased mortality in C57BL/6 mice infected with PA. Treatment of these mice with neutralizing anti-HMGB1 monoclonal antibody (mAb) resulted in a reduction in bacterial counts, injury, and number of neutrophils in the lung and an increase in leukocyte phagocytic activity compared to mice receiving control mAb. This improved phagocyte function was associated with reduced levels of airway HMGB1. The correlation between phagocytic activity and levels of extracellular HMGB1 was also observed in cultured macrophages. These results indicate a pathogenic role for HMGB1 in hyperoxia-induced impairment in host ability to clear bacteria and inflammatory lung injury. Thus, HMGB1 may provide a novel molecular target for improving hyperoxia-compromised innate immunity in patients with VAP.

**PS 2035 Exposure to Perfluorooctanoic Acid (PFOA) Causes Oxidative Stress in the Mouse Pancreas.**

Q. Wu, A. A. Bond, L. M. Kamendulis and B. A. Hocevar. *Environmental Health, Indiana University School of Public Health, Bloomington, IN.*

Perfluorooctanoic acid (PFOA), a perfluoroalkyl compound used in the manufacture of many industrial and commercial products, does not readily decompose in the environment, and is biologically persistent in fish, animals and humans. Human exposure to PFOA occurs through both environmental and occupational exposures. Due to the long half-life of PFOA in humans (3.8 yrs), the potential exists for PFOA exposure to participate in chronic diseases. Chronic PFOA exposure in rodents induces pancreatic acinar cell tumors (PACTs), and human epidemiologic studies also suggest that PFOA exposure may have adverse effects on the pancreas. While multiple animal studies have examined PFOA-mediated liver toxicity, very little is known about the effects of PFOA on pancreatic function. To assess the role of PFOA on the pancreas, we treated C57BL/6 mice with vehicle, or PFOA at doses of 0.5, 2.5 or 5.0 mg/kg BW/day for 28 days. In addition, mice were treated with cerulein, which induces mild pancreatitis and produces an oxidative stress in the pancreas. We found significant accumulation of PFOA in the serum, liver and pancreas of PFOA treated animals, which was associated with induction of oxidative stress, as measured by the lipid peroxidation products malondialdehyde and F2 $\alpha$ -isoprostanes, as well as the oxidatively modified DNA base, 8OHdG. The serum, liver and pancreatic ratio of reduced to oxidized glutathione decreased with increased PFOA dose, again indicating the stimulation of oxidative stress in the liver and pancreas. For both of these responses, the pancreas was more severely affected in comparison to the liver. As a further response to oxidative stress, induction of anti-oxidant genes was also evaluated. While mitochondrial superoxide dismutase mRNA levels were induced to comparable levels in both liver and pancreas, the pancreas failed to upregulate either glutathione peroxidase or catalase genes. These results suggest that the pancreas may be highly susceptible to oxidative damage elicited by exposure to perfluoroalkyl compounds.

**PS 2036 Chronic Over-Expression of Receptor Tyrosine Kinase ErbB2 in the Heart Alters Redox-Sensitive Molecules in the Mitochondria.**

F. Belmonte<sup>1,2</sup>, S. Das<sup>3</sup>, V. Sivakumaran<sup>3</sup>, P. Sysa Shah<sup>2</sup>, C. Steenbergen<sup>3</sup> and K. Gabrielson<sup>2</sup>. <sup>1</sup>Environmental Health Sciences-Molecular and Translational Toxicology, Johns Hopkins University, Baltimore, MD; <sup>2</sup>Molecular and Comparative Pathology, Johns Hopkins University, Baltimore, MD; <sup>3</sup>School of Medicine, Johns Hopkins University, Baltimore, MD.

Previous studies on cardiac-specific over-expression of epidermal growth factor receptor 2 (ErbB2) demonstrated that ErbB2 activates protective signaling pathways (pro-survival) and induces a hypertrophic phenotype that does not progress to heart failure. To explore this interesting phenomenon, we used the ErbB2 transgenic murine model to determine whether the observed phenotypes are due to redox-sensitive molecules in the mitochondria that alter mitochondrial function by regulating reactive oxygen species (ROS) formation. Microarray data that compare the transgenic mice to wild type mice suggest that ErbB2 alters various oxidative stress genes. We found that ErbB2 over-expression in the heart upregulates glutathione reductase (Gsr), glutathione peroxidase 1 (Gpx1), and peroxiredoxin 5 (Prdx5) proteins. We measured ROS production and found that the transgenic mitochondria produce less ROS than the wild type mitochondria. Total glutathione (GSH) levels and glutathione peroxidase activity are higher in the transgenic mice compared to the wild type group. We measured the mitochondrial Ca<sup>2+</sup> retention capacity and found that the transgenic group has less Ca<sup>2+</sup> uptake than the wild type group. The mitochondrial membrane potential ( $\Delta\Psi$ ) was measured with the fluorescent dye tetramethylrhodamine ethyl ester (TMRE) and we found that the transgenic group has a higher baseline  $\Delta\Psi$  than the wild type group. Our data suggest that ErbB2 over-expression alters redox-sensitive genes that regulate ROS production through pro-survival and mitochondrial pathways to ultimately prevent heart failure.

**PS 2037 The Role of NO and the Glutathione Pathway in Menadione-Induced Oxidative Stress.**

P. Venkatakrishnan, B. Masters and L. J. Roman. *Biochemistry, UTHSCSA, San Antonio, TX.*

Skeletal muscle cells undergo frequent oxidative challenges due to rapid changes in energy demand, high metabolic activity, and high levels of heme-proteins. The induction of oxidative stress and resulting protective responses involves many pathways. Among them are the products of oxygen metabolism by flavoproteins, hemo-proteins, Fe-S-center-containing proteins and other oxidation-reduction centers. Nitric oxide synthases (NOSs) reduce redox-cycling compounds such as menadione (MD), forming superoxides, which in the presence of nitric oxide (NO) reacts to form peroxynitrite, both of which cause oxidative injury. Therefore, we examined the mechanistic role of NO for cell survival during MD-induced oxidative stress under NOS inhibition using a NOS inhibitor, L-NAME. Dose viability studies performed with various amounts of MD +/- L-NAME for 24 hrs allowed us to choose 10  $\mu$ M MD for further studies and also showed that NOS inhibition did not significantly affect the cell viability at any concentration. Increased nNOS protein expression and increased 3-nitrotyrosine formation, a biomarker for peroxynitrite formation was observed with MD and MD + L-NAME over the controls alone by both Western blotting and Immunocytochemistry, suggesting that the cells compensate for decreased bioavailable NO by increasing nNOS. We examined the major antioxidant involved in cellular protection mechanism at 24 hours. Glutathione peroxidase1 protein levels was decreased with MD+L-NAME treatment which was reversed in the presence of NO donor deta-NONOate with MD+L-NAME. On the other hand, SOD1 and PRDX6 levels remain unchanged. Interestingly, at 24 hrs, GSH assays and stable isotope labeling of amino acids with cell culture along with LC-MS analysis also reveal that proteins in glutathione homeostasis are modulated by NO under oxidative stress as a mechanism of cell survival. Current studies are aimed to dissect the relationship between NO and glutathione under MD-induced oxidative stress.

**PS 2038 Synthesis and Crystal Structure of N-Acetyl-5-Chloro-3-Nitro-L-Tyrosine Ethyl Ester.**

T. T. Mutahi<sup>1</sup>, B. J. Edagwa<sup>2</sup>, F. R. Fronczek<sup>2</sup> and R. M. Uppu<sup>1</sup>. <sup>1</sup>Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA; <sup>2</sup>Chemistry, Louisiana State University, Baton Rouge, LA.

3-Nitro-L-tyrosine and 3-chloro-L-tyrosine are widely regarded as markers of peroxynitrite (PN) and HOCl formation (respectively) *in vivo*. A question that follows naturally but never addressed in detail is what happens when PN and HOCl that are co-produced at the inflammatory sites react simultaneously with tyrosine

residues in proteins. The significance of these combined oxidations on the issue of biomarker validation could be overwhelming given the report by Whiteman and Halliwell (*Biochem. Biophys. Res. Commun.* 258,168–172,1999) wherein it was shown that the 3-nitro-L-tyrosine was lost to some unknown product(s) following oxidation with HOCl. Another important consequence could be that we need additional biomarkers and their validation. Herein, we report the synthesis and characterization of the oxidation product of HOCl reaction with N-acetyl-3-nitro-L-tyrosine ethyl ester (NANTEE), a model for protein-bound 3-nitro-L-tyrosine. When HOCl was a limiting reagent (HOCl < NANTEE), the major product at pH 7.2 was found to be N-acetyl-5-chloro-3-nitro-L-tyrosine ethyl ester (NACNTEE). Following purification (reversed phase HPLC) and characterization (<sup>1</sup>H-NMR; 400 MHz, CD<sub>3</sub>OD: δ 1.23 (t, J = 7.1 Hz, 3H), 1.92 (s, 3H), 2.92 (dd, J = 14.1, 8.7 Hz, 1H), 3.12 (dd, J = 14.1, 5.8 Hz, 1H), 4.16 (q, J = 7.0 Hz, 2H), 4.63 (dd, J = 8.6, 5.8 Hz, 1H), 7.60 (d, J = 2.1 Hz, 1H), 7.86 (d, J = 2.1 Hz, 1H), 8.43 (s, 1H)), single crystals of NACNTEE obtained in methanol were used for the determination of crystal structure using KappaCCD (charge-coupled device) diffractometer. It was found that the OH group forms an intramolecular O—H...O hydrogen bond to the nitro group and the N—H group forms an intermolecular N—H...O hydrogen bonds to an amide O atom, linking the molecules into chains along [1 0 0]. The crystal studied was a non-merohedral twin, with a 0.907 (4):0.093 (4) domain ratio. [Support from NSF (HRD-1043316) and the US DoED (PO31B040030) is acknowledged. ### PS 2039 Oxidative Stress Mediates Chlorpromazine-Induced Cholestasis in Human HepaRG Cells.

A. Guilloze<sup>1</sup>, S. Antherieu<sup>1</sup>, P. Bachour-El Azzi<sup>1,2</sup>, J. Dumont<sup>1</sup>, Z. Abdel-Razzak<sup>2</sup>, C. Guguén-Guilloze<sup>1</sup>, B. Fromenty<sup>1</sup> and M. Robin<sup>1</sup>. <sup>1</sup>Inserm 991, University of Rennes, Rennes, France; <sup>2</sup>Lebanese University, EDST-PRASE and EDST-AZM Center-LBA3B, Hadath, Lebanon.

Intra-hepatic cholestasis represents a frequent manifestation of drug-induced liver injury in humans. However, the mechanisms involved are diverse and remain poorly understood. Early hepatic effects of chlorpromazine (CPZ), known for years to induce intra-hepatic cholestasis, have been analyzed using differentiated human HepaRG cells. Bile acids (BA) efflux was found to be inhibited as early as after 30min-CPZ treatment as shown by [H<sup>3</sup>]-taurocholic acid (TA) intracellular accumulation. This accumulation seemed to be mediated by reactive oxygen species generated by CPZ since it was mostly prevented by N-acetyl cysteine co-treatment. In addition, CPZ-induced ROS generation was accompanied by a disruption of the pericanalicular distribution of F-actin as well as an alteration of the inner mitochondrial membrane potential. Following 24 hour-treatment, CPZ inhibited the expression of the two main canalicular bile transporters BSEP and MDR3. Moreover, NTCP mRNA and activity as well as CYP8B1 mRNA were inhibited, while MRP4 was overexpressed. These alterations indicate that BA uptake and synthesis were decreased, whereas basolateral transport was enhanced. These alterations likely represent hepatoprotective mechanisms against BA toxicity. These data support the conclusion that among other mechanisms, oxidative stress plays a major role as both a primary causal and an aggravating factor in early CPZ-induced intra-hepatic cholestasis in human hepatocytes (This work was supported by the European Community, Contracts LIINTOP-STREP-037499 and Predict-IV-202222).

### PS 2040 Evaluation of Thiotaurine for Effects against Ethanol-Induced Oxidative Stress in the Presence and Absence of Inhibitors of Ethanol Metabolism in the Rat.

M. C. Parikh, Y. Shen and C. A. Lau-Cam. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.* Sponsor: B. Blase.

The present study was undertaken to verify the in vivo effects of thiotaurine (TTAU), a sulfane compound reported to exhibit antiradical activity in vitro, against ethanol (EtOH)-induced oxidative stress. For this purpose, TTAU was given to male Sprague-Dawley rats (200–250 g) as a single, 2.4 mmol/kg, intraperitoneal (i.p.) dose 30 min before an oral, 4 g/kg, dose of EtOH (40% w/v). The same experiments were carried out with rats treated with the alcohol dehydrogenase inhibitor 4-methylpyrazole (4MP, 75 mg/kg, i.p.) and the aldehyde dehydrogenase inhibitor cyanamide (CYN, 60 mg/kg, i.p.), administered 30 min and 60 min, respectively, before EtOH. Control animals received only physiological saline. All the rats were sacrificed by decapitation at 1 hr after EtOH administration, and their blood and livers were collected for the assay of plasma and hepatic levels of malondialdehyde (MDA) and reduced (GSH) and oxidized (GSSG) glutathione and of corresponding activities of the antioxidant enzymes catalase (CAT), glutathione peroxidase (GPx) and superoxide dismutase (SOD). EtOH elevated the plasma

(+34%) and liver (+32%) GSH, lowered the plasma (–65%) and liver (–63%) GSH/GSSG ratio, and lowered the corresponding activities of CAT (–86% and –77%, respectively), GPx (–91% and –70%, respectively) and SOD (–45% and –54%, respectively). Both CYN and 4MP attenuated the alterations caused by EtOH, with the latter compound appearing more potent than the former. In contrast, the GSH/GSSG ratio seen with ethanol was lowered further by CYN but raised by 4MP. TTAU was not only more protective than 4MP against EtOH-induced alterations in the liver and plasma but in its presence the protective actions of CYN and 4MP became enhanced. The present results indicate that EtOH metabolism to acetaldehyde and beyond influences oxidative stress by EtOH to a greater extent than EtOH itself, and that such an event can be effectively counteracted by TTAU.

### R 2041 Skeptically Examining the Limits of Toxicology Evidence in the Courtroom.

G. B. Corcoran<sup>1</sup>, J. Norman<sup>2</sup>, M. J. Saks<sup>3</sup>, S. Bobst<sup>4</sup> and R. T. Kennedy<sup>5</sup>.

<sup>1</sup>Pharmaceutical Sciences, Wayne State University, Detroit, MI; <sup>2</sup>ExxonMobil Biomedical Sciences, Annandale, NJ; <sup>3</sup>Sandra Day O'Connor College of Law, Arizona State University, Tempe, AZ; <sup>4</sup>Nexeo Solutions, The Woodlands, TX; <sup>5</sup>New Mexico Court of Appeals, Albuquerque, NM.

The opposing orientation of toxicology experts and select evidence can skew the accuracy and value of testimony in court. Lawyers and judges are acquiring increasing skills to evaluate technical and scientific assertions with skepticism. Scholarly scientific approaches are required to establish whether techniques and methods asserted to be scientifically sound are valid and support justice. An introduction briefly covers topics helpful to understanding what happens to experts in litigation. This includes the law's theory of expert evidence, rules of evidence and procedure relating to expert testimony, alternative admissibility rules (Frye v Daubert trilogy), the NRC report and Canadian parallels, a law-science syllogism, the adversary process in theory and practice, ethical principles, clashes of ethics, data (especially quantitative), disclosure of evidence helpful to the other side, and for whom the litigation expert works. The toxicology expert must address relevant science in a fair, representative manner and communicate effectively. The use of Bradford-Hill Criteria (1964) has been promoted to address general causation in toxic torts. While comprehensive, it poses challenges including jargon and communication. Recently, a five question approach was introduced to address specific causation. Explanations and examples of causation will be reviewed. Finally, the 2009 National Academies report recommends that forensic sciences look to academic scientific models for reliable practice and technique validation to support court testimony. Lawyers and courts have become more skeptical of unsupported opinions and increasingly aware of how to combat them. Academic toxicology can offer much to advance the legitimacy of admitted evidence, including in the area of forensics. A discussion will include foibles and solutions.

### IS 2042 Harnessing Electronic Standards and Informatics to Transform the Use of Regulatory Toxicological Data.

L. P. Myers<sup>1</sup>, L. Burns Naas<sup>2</sup>, T. Kropp<sup>1</sup>, A. Nanzer<sup>3</sup> and T. Smyrniotis<sup>4</sup>. <sup>1</sup>Center for Drug Evaluation and Research, US FDA, Silver Spring, MD; <sup>2</sup>Gilead Sciences, Inc., Foster City, CA; <sup>3</sup>F. Hoffmann-La Roche Ltd., Basel, Switzerland; <sup>4</sup>MPI Research, Inc., Mattawan, MI.

One of the major efforts in nonclinical regulatory informatics has centered on the development and testing of the electronic data submission standard, also called SEND (Standard for Exchange of Nonclinical Data). This standard was developed by the Clinical Data Interchange Standards Consortium's (CDISC) SEND Team for nonclinical data collected from animal toxicology studies and allows for the electronic submission of tabulated toxicology data in an electronic format. The initial pilot project began in 2003 and was followed by a second pilot in 2007 focused on CDER-regulated projects. The production of the SEND 3.0 Implementation Guide in 2011 was a major step forward for the electronic submission and exchange of standardized data and enablement of data warehousing efforts that better support scientific review and regulatory science initiatives. However, it is recognized that data standards are simply enablers to support the broader goals of better exploring and exploiting diverse study data and metadata in order to answer important scientific review and regulatory science questions. The range of needs and challenges in the regulatory pharmacology and toxicology field can be daunting but many of the challenges are shared among key stakeholders (e.g., the US FDA, sponsors, and CROs). These challenges, which range from warehousing to analysis to QA/GLP ramifications, are laying the foundation for a compliant exchange of data and opportunities for collaboration through public/private partnerships. This session will discuss the current computational science initiatives at the US FDA and in industry, existing partnerships, challenges and successes, as well as the transformative effect on the CRO model.

## EC 2043 Regulatory Science and Risk Assessment: Lessons for Early-Career Scientists on What to Expect and How to Pursue This Career Path.

B. J. Lew<sup>1</sup>, J. A. Torres<sup>2</sup>, D. L. Bjerke<sup>1</sup>, J. C. Lipscomb<sup>3</sup>, A. Maier<sup>4</sup> and D. Jacobson Kram<sup>5</sup>. <sup>1</sup>PS&RA, Procter & Gamble Company, Cincinnati, OH; <sup>2</sup>Environmental Toxicology, Texas Southern University, Houston, TX; <sup>3</sup>NCEA, US EPA, Cincinnati, OH; <sup>4</sup>Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH; <sup>5</sup>CDER, US FDA, Silver Spring, MD.

During academic training, postdoctoral and graduate students generally are not provided with opportunities for interacting with toxicologists who are involved in risk assessment and regulatory affairs. The educational training mainly focuses on basic sciences or solving mechanistic problems and thus lacks the practical aspects of risk assessment and regulatory preparation. This concern was discussed at the Education Summit in October 2011, which was organized by the Education Committee of the SOT. Dr. John Doull's comment that, "toxicology is what we do, but risk assessment is why we do it," shows the importance for trainees to become aware of both. Unfortunately, when it is time for the trainee to make the decision on what will be the next step in their careers, they are well prepared on what we do, but fall short on why we do it. The objectives of this session are to provide postdoctoral and graduate students with basic understanding of approaches in risk assessment and regulatory affairs in some of the sectors and to educate them about necessary preparative steps in this field. In this 80-minute Education-Career Development Session, trainees will become more familiar with the routine job of toxicologists outside of the academic setting. Further, there will be a panel discussion on steps that can be taken during graduate school and postdoctoral training to improve the preparation for a career in risk assessment and regulatory fields. Thus, the participants are expected to gain a basic knowledge of risk assessment and regulatory preparation in the life of a toxicologist and how to pursue this field.

## PS 2044 Surgical Alternatives for Multiple CSF Sampling in Conscious Cynomolgus Monkeys: A Novel Approach.

J. Sternberg, S. H. Korte and C. B. Rose. Covance Laboratories GmbH, Muenster, Germany. Sponsor: G. Weinbauer.

Intrathecal infusion via the lumbar route represents an accepted while specialized clinical route for drug delivery in humans. Since primates are often required as relevant species for pre-clinical safety assessment, this dose route is well established in cynomolgus monkeys. However, for the majority of these studies, CSF (cerebrospinal fluid) for bioanalysis, clinical chemistry as well as cell counts needs to be collected at multiple time points within few days. Sampling using spinal needle (Pencan Paed®: 25G, 50 or 25 mm, B. Braun Melsungen AG, Melsungen, Germany) on sedated animals (Ketamin and Domitor; Antisedan as antidote) is limited to three occasions within the first 24 hours, hence limiting the ability for a detailed evaluation. In this study, three female cynomolgus monkeys (~3.5 kg) where implanted (L2-L3) using MID-LOVOL port (Solomon Scientific, USA), connected to a 3FR intrathecal PU catheter. To compare our established technique of s.c. port placement under the shoulder blade, the MID-LOVOL port was implanted in the established way (animal A), in the thoraco-lumbar region (animal B) and in the region of the sacrum (animal C). To ensure the patency of the system it was flushed every three days with 0.5 ml artificial CSF beginning on the day of surgery. On day 14, 17, 20 and 23 after surgery a Huber needle was used for CSF collection, while the animals were placed in a restraint chair. There were no adverse clinical signs, body weight changes, clinical pathology or neurological findings directly after surgery in all three animals. Successful CSF collection could only be performed in animal C. The port position of this animal proved to be an advantage for needle insertion/fixation hence CSF collection in the restraint chair. In conclusion, port implantation under the shoulder blade, in the thoraco-lumbar region as well as in the region of the sacrum is possible.

## PS 2045 Hydration with Saline Decreases Toxicity of Calcitriol-Injected Mice in Preclinical Studies.

A. Azari, M. Kanavi, S. Darjatmoko, V. Lee, H. Potter, L. Teixeira and D. Albert. Ophthalmology, University of Wisconsin Madison, Madison, WI.

Purpose: To study the effectiveness of saline injection in reducing the toxicity profile of calcitriol when coadministered in mice.

Design: Meta-analysis of published mice studies with calcitriol.

Methods: A comprehensive PubMed and ISI web of knowledge search was performed to identify all published case control articles of calcitriol injection in mice, and relevant articles were selected. Using mortality as an end point to study the toxic effects of calcitriol, the relative risk of mortality in mice given saline injections was evaluated for different calcitriol dosages, as well as mouse and tumor types.

Results: Coadministration with 0.25 ml of normal saline solution injected intraperitoneally is associated with a lower mortality rate than calcitriol given alone. The calculated relative risk of mortality was 0.1419 (95% CI 0.0093-2.2133, z-statistic 1.393, p-value = 0.1636) when saline is administered with calcitriol compared to calcitriol alone.

Conclusions: Hydration with saline is a common practice in patients receiving calcitriol, which appears to be pertinent in experimental studies of mice receiving calcitriol. It is important to note that results of preclinical studies form the basis for decisions in drug use in patient trials. Decreasing mortality in animal experiments will prove to be a meaningful contribution to the field of research. To avoid some mortality due to toxicity, a common practice for investigators was administering less than the target doses or even skipping doses in order to decrease calcitriol induced mortality in mice. Combination of high mortality in mice and administration of suboptimal dose in certain situations may impede evaluation of the potential therapeutic effects of calcitriol. The same problem is likely to exist with other drugs as well (e.g., chemotherapeutic agents). This preliminary data indicates that supplemental hydration should be kept in mind in evaluating drug toxicology.

## PS 2046 Identification of Behaviorally Active Doses of Morphine and Evaluation of Its Analgesic Effects in the Rhesus Monkey.

T. Wolinsky<sup>1</sup>, C. Cruz<sup>2</sup>, I. Hubert<sup>2</sup>, G. Froget<sup>1,2</sup>, M. Lemaire<sup>1</sup> and D. Virley<sup>1,2</sup>. <sup>1</sup>Porsolt SAS, Le Genest-St-isle, France; <sup>2</sup>Porsolt Inc. USA, San Antonio, TX.

Pain affects millions of people worldwide and is commonly treated with opioid analgesics, despite considerable safety/risk management concerns. The purpose of this study was two-fold: First, to establish a therapeutic index for morphine by determining the behaviorally active range in an operant responding procedure and second, to work within this dose range to evaluate the analgesic effects of morphine in the rhesus monkey (*Macaca mulatta*) in a thermal pain tail withdrawal procedure.

For the operant responding procedure, 2 monkeys were trained to lever-press for food on a fixed-ratio (FR30) schedule. The sessions lasted 120 minutes (8 cycles of 15 minutes) during which the rate of responding was recorded. Acute doses of morphine sulfate (0.3 – 3 mg/kg s.c.) were administered at the beginning of the session. For the tail withdrawal procedure, 4 monkeys were seated in restraint chairs and the lower section of the shaved tail was immersed into water at 40, 50, and 55 °C. Sessions began with a control tail withdrawal latency determination at each temperature followed by an acute dose of morphine sulfate (0.3 – 3 mg/kg s.c.). Temperatures were presented to the animals in a randomized order at 15, 30, 60, 90 and 120 minutes post-dose.

Morphine markedly decreased the rate of operant responding at 1 mg/kg and eliminated lever-pressing at 3 mg/kg. Analgesic effects of morphine in the tail-withdrawal assay were observed at all doses tested: The onset and duration of action were dose-dependent. The minimum effective dose was found to be 0.3 mg/kg, while 3 mg/kg produced the maximal effect in all 4 animals tested.

These results suggest that acute morphine has a narrow therapeutic index in the rhesus monkey. The selected behavioral test procedures could therefore provide appropriate efficacy and safety measures for assessing novel opioid and non-opioid based analgesics with high translational validity and relevance.

## PS 2047 Pharmacodynamic Glycemia Effects from Rapid and Long-Acting Insulins Administered at Mealtime to Alloxan-Induced Diabetic Miniature Yucatan Swine.

L. D. Brown<sup>1,2</sup>, T. J. Madsen<sup>1</sup>, E. C. Blair<sup>1</sup>, B. C. Hanks<sup>1,2</sup>, K. P. Horlen<sup>1</sup>, J. Hiemstra<sup>2</sup>, A. Stricker-Krongrad<sup>1</sup>, J. Liu<sup>1</sup> and G. F. Bouchard<sup>1,2</sup>. <sup>1</sup>Sinclair Research Center, LLC, Columbia, MO; <sup>2</sup>Sinclair BioResources LLC, Auxvasse, MO.

Pharmacodynamic effects from various insulins with known properties in humans were studied in the Yucatan miniature swine for comparative purposes. Yucatan miniature swine (*Sus scrofa*, at least 3 months, 20-60 kg) were made diabetic with intravenous alloxan and regulated on insulin. Animals were considered diabetic if they became hyperglycemic ( $\geq 150$  mg/dL) within 2-5 days following induction. All procedures were on overnight fasted animals (no feed or insulin for 18 hrs). Our diabetic miniswine average baseline bG of  $429 \pm 84.5$  (SD) mg/dL (N=148 measurements) while non-diabetics average  $58.7 \pm 8.2$  (SD) mg/dL (N=238 measurements). For this study, well-known prototypical marketed insulins (Apidra<sup>TM</sup>, Humalog<sup>TM</sup>, Lantus<sup>TM</sup>, 0.25 or 0.45 U/kg s.c.) were administered at mealtime, then blood glucose profiles recorded using handheld glucometer devices (One Touch Ultra<sup>®</sup>, Lifescan) over the next 8 hrs (rapid-acting) or 24 hrs (long-acting). Venous blood samples were collected from vascular access ports for bG readings. Blood glucose profile data in the diabetic Yucatan generally compared well to published human glucodynamic data for glycemia effects following insulin. These data suggest the Yucatan diabetic model has similar pharmacodynamic responses to the presentation of exogenous insulins for onset and peak effects but not duration for the rapid-acting insulins. The long-acting insulin (Lantus<sup>TM</sup>) peaked in swine

where no peak (same action throughout day) is normally reported in humans. These differences could be due to either the duration of the fasting, the relative high doses of insulin or the use of a small number of animals in this study.

#### **PS 2048 Toxicity Mechanisms of Anti-Inflammatory Kinase Inhibitors.**

E. Berg, M. A. Polokoff, A. O'Mahony, J. Melrose and D. Nguyen. *BioSeek LLC, South San Francisco, CA.* Sponsor: K. Houck.

Improving the safety of drug candidates that enter clinical development requires assays that are more predictive of human outcomes. The BioMAP® platform uses human primary cells to model complex aspects of disease and tissue biology and can be applied to better understand biological mechanisms that underlie drug adverse effects. Here we present the analysis of several anti-inflammatory kinase inhibitors, including inhibitors of p38 MAPK, Jak kinase (tofacitinib) and Syk kinase (fostamatinib) tested in a panel of 12 BioMAP® systems covering a broad range of human biology. Specific effects of these compounds in BioMAP® assays modeling aspects of wound healing and vascular biology appear to correlate with certain side effects of these drugs in patients, including skin rash (p38 MAPK), gastrointestinal perforations (Jak), and hypertension (syk). These *in vitro* effects may be useful in screening lead candidates prior to testing in animals or humans.

#### **PS 2049 Evaluation of PBPK Models for Medical Decision Making upon Acute Chemical Exposure: Dichloromethane (DCM) As an Example.**

R. Z. Boerleider<sup>1,2</sup>, C. C. Hunault<sup>1</sup>, J. C. van Eijkeren<sup>3</sup>, I. de Vries<sup>1</sup>, J. G. Bessems<sup>3</sup> and J. Meulenbelt<sup>1,2</sup>. <sup>1</sup>National Poisons Information Center, University Medical Center Utrecht, Utrecht, Netherlands; <sup>2</sup>IRAS, Utrecht University, Utrecht, Netherlands; <sup>3</sup>RIVM, National Institute for Public Health, Bilthoven, Netherlands.

**Rationale:** Assessing the risks of exposure to hazardous chemicals in emergency situations and decision-making on individual medical treatment is not straightforward. We therefore evaluated the use of physiologically based pharmacokinetic (PBPK) models in this context, taking DCM as an example. DCM is toxic by inhalation and can cause mild to serious health effects.

**Methods:** In a clinical trial approved by the Hospital Medical Ethical Board, six healthy volunteers were individually exposed to DCM for 1 hour. The volunteers had to apply a paint stripper to a surface without air mask, in a closed room. Eighteen blood samples were drawn ( $t = -1$  to 48h post-dose). Whole blood DCM concentrations and percentages of carboxyhemoglobin (% HbCO) were measured using GC. The DCM air concentration in the room was continuously monitored by a Miran 1B2 infrared spectrophotometer. Experimental blood DCM concentrations and % HbCO were subsequently compared to the predictions of a previously published PBPK DCM model.

**Results:** The DCM external dose (area under the exposure-time curves) ranged between 175 and 390 ppm\*h (equal to 608 - 1354 mg\*h/m<sup>3</sup>). DCM blood concentrations reached maximum levels at the end of the exposure ( $t = 1$ h) and ranged between 0.25 and 5.1 mg/L. Increase in % HbCO was delayed (maxima reached between 2 and 6 h) and ranged between 0.4 and 2.3 %. The predicted DCM blood concentration ranged between 1.55 and 4.20 mg/L at  $t = 1$  h and the predicted % HbCO ranged between 3.1 and 4.1 % at  $t > 1.5$  h. The general form of the concentration-time profiles was well predicted, especially in the elimination phase of DCM from blood.

**Conclusion:** The model was found to fit experimental DCM blood concentrations reasonably well but should be refined for % HbCO. Such a PBPK model might be helpful in case many individuals are acutely exposed to DCM and for whom HbCO monitoring is not available.

#### **PS 2050 Specificity Protein (Sp) 1 Transcription Factor Modulates Long Noncoding RNA Expression in Liver Cancer Cells.**

S. Gandhi<sup>1,2</sup> and S. H. Safe<sup>2,3</sup>. <sup>1</sup>College of Medicine, Texas A&M College of Medicine Health Sciences Center, Houston, TX; <sup>2</sup>Institute of Biosciences and Technology, Texas A&M College of Medicine Health Sciences Center, Houston, TX; <sup>3</sup>Department of Veterinary Physiology and Pharmacology, Texas A&M College of Medicine Health Sciences Center, Houston, TX.

Hepatocellular carcinoma is one of the most prevalent forms of cancer worldwide and it exhibits highly invasive and metastatic properties. Recent studies have shown that of the small proportion of the genome that is transcribed only about 1.4% encodes for protein-coding genes. Of the remaining vast majority of transcripts that do not encode protein, long noncoding RNAs (lncRNAs) have recently gained attention because of their pivotal role in disease. lncRNAs are a class of transcripts

longer than 200 nucleotides and have been characterized as having both tumor suppression and oncogenic functions in many types of cancers. Although their mechanisms of action remain largely unknown, many lncRNAs are regulated by transcription factors in a tissue-specific manner. Specificity protein (Sp) transcription factors Sp1, Sp3, and Sp4 are overexpressed in many tumors, and regulate expression of genes required for cancer cell and tumor growth, survival, angiogenesis, and inflammation. Sp proteins are the targets of many conventional and alternative chemotherapeutic drugs, and therefore further study of their functions is of great interest. In this study, we examined the role of Sp transcription factors in regulating lncRNAs in liver cancer cells. Using HepG2 and Huh-7 cells as models, we investigated the effects of Sp downregulation on the expression of several lncRNAs as well as cell growth and survival. Downregulation of Sp transcription factors by RNA interference or by drugs that target these proteins identified a set of lncRNAs in liver cancer cells that are modulated by Sp transcription factors. Further studies are underway to examine the specific functions of these lncRNAs in liver cancer growth and metastasis as well as their utility as diagnostic biomarkers.

#### **PS 2051 The Third Trimester: The Critical Phase of the Deleterious Effects of Cadmium in Pregnancy.**

J. I. Anetor, P. Tawari-Eebi, M. Charles-Davies and A. Arowojolu. *Chemical Pathology, College of Medicine, University of Ibadan, Ibadan, Nigeria.*

Environmental cadmium (Cd) is rising globally particularly in the developing countries. Reports indicate that the deleterious effects of Cd may occur at lower levels than hitherto thought. The effects of Cd on female reproduction particularly in pregnancy has received only measured attention and these reports did not delineate the phases of pregnancy at which adverse effects may be critical. One hundred and sixty subjects (125 pregnant; 35 non-pregnant), were studied. Pregnant subjects were classified into three trimesters: 1st (35), 2nd (35) & 3rd (55). Cadmium, Cu, Zn, Fe, Se, Serum proteins were determined in all subjects. Third trimester subjects were followed until delivery. Cadmium levels were similar in the 1st & 2nd trimesters but significantly increased in the 3rd trimester compared to controls and 1st & 2nd trimesters. Zinc level was significantly decreased in the 3rd trimester compared with the 1st & 2nd trimesters. Importantly, Cd was inversely related to Zn. Thirty-two (58%) subjects delivered normal weight babies, 19 (35%) delivered babies with low birth weight (LBW). Four (7%) delivered babies with high birth weight. Women with LBW babies had significantly higher Cd and lower Zn levels as well as low BMI. Cadmium, Zn, Se all correlated inversely with neonatal birth weight (NBW). Cadmium and Se strongly correlated inversely with NBW ( $r = -0.7$ ,  $p = 0.000$ ;  $r = -0.31$ ,  $p = 0.02$ ) respectively. Zinc also correlated directly with NBW. These data suggest that the third trimester with the lowest Zn level also had the highest Cd level (Cd is a metabolic antagonist of Zn). It appears the critical phase that Cd may elicit its toxic effect in pregnancy is the 3rd trimester and low Zn level may be the driving factor. The third trimester is therefore the phase to target in risk assessment, communication and management.

#### **PS 2052 Ethanol Is a Significant Cofactor in HAART-Induced Hepatotoxicity.**

H. Donde<sup>1</sup>, S. Ghare<sup>1</sup>, J. Zhang<sup>1</sup>, I. Kirpich<sup>1</sup>, S. Joshi-Barve<sup>1</sup>, C. McClain<sup>1,2</sup> and S. Barve<sup>1</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY.

Highly Active Antiretroviral Therapy (HAART) has led to a significant increase in the life expectancy of HIV patients; however, there are significant side effects including lipodystrophy and hepatotoxicity. Alcohol abuse is highly prevalent in HIV infected individuals and hence may be a significant negative cofactor in HAART induced hepatotoxicity.

The present study examines the mechanisms underlying HAART and alcohol induced hepatotoxicity. The effects of HAART drugs (azidothymidine, and Indinavir sulphate) in combination with alcohol were examined both *in vitro* (H4IIEC3- a rat hepatoma cell line) and *in vivo*. Individual treatments of H4IIEC3 cells with alcohol and AZT showed a certain level of hepatotoxicity which was significantly increased in combinatorial treatment of alcohol and AZT. These data indicate that alcohol can induce and further enhance HAART-induced cytotoxicity. Alcohol and HAART drug interactions and hepatotoxicity were also assessed *in vivo* using an animal model of chronic alcohol feeding. Mice were pair-fed liquid diets (Lieber DeCarli) containing 35% of calories as alcohol (alcohol-fed, AF) or as isocaloric maltose-dextrin (pair-fed, PF). HAART treatment groups received AZT (30mg/kg BW) and IDV (50mg/kg BW) by oral gavage for 5 weeks. Animals exposed to both alcohol and HAART developed increased visceral adiposity compared to pair-fed animals, suggesting disturbances in lipid metabolism in these mice. Lipodystrophy was also evidenced by macro and microvesicular steatosis in the livers; elevated liver triglycerides and free fatty acids. Additionally, animals receiving combinations of alcohol and HAART exhibited increased inflammation and greater hepatic neutrophil infiltration.

Overall, our data demonstrate that alcohol exacerbates HAART hepatotoxicity, and is a significant cofactor in the development of hepatic steatosis and liver injury.

**PS 2053 Acute Exposure to Acrolein, a Ubiquitous Environmental Pollutant, and Anti-HIV HAART Medication Leads to Hepatotoxicity.**

S. Ghare<sup>1</sup>, H. Donde<sup>1</sup>, S. Joshi-Barve<sup>1</sup>, C. McClain<sup>1,2</sup> and S. Barve<sup>1</sup>.

<sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY.

Highly Active Antiretroviral Therapy (HAART) is the current treatment for HIV infection. Although HAART leads to a significant increase in the life expectancy of patients with HIV; the prolonged use of HAART causes hepatotoxicity. This has become a significant clinical problem which leads to discontinuation of therapy in turn causing HIV virus reactivation and the development of AIDS. Additionally, environmental pollutants are known to significantly impact general health as well as therapeutic outcome; however their contribution to HAART therapy-induced liver toxicity is unknown. Acrolein is a common environmental, food and water pollutant and a major component of cigarette smoke. It is also produced endogenously via lipid peroxidation and cellular metabolism. The present study examines the potential impact of acute acrolein exposure on the hepatotoxic effects associated with HIV medication. A well characterized human hepatoma cell line (HepG2) model system was used to investigate the combined cytotoxic effects of acrolein along with HAART drug, azidothymidine (AZT). HepG2 cells were treated with various concentrations of acrolein and HAART drugs either individually or in combination. Our results showed that acute exposure to either acrolein or HAART drugs had minimal to no effect on hepatocyte survival. However acrolein exposure enhanced the AZT- induced apoptotic death in HepG2 cells. Acrolein also sensitized hepatocytes to AZT- induced mitochondrial dysfunction, as shown by mitochondrial membrane depolarization and ATP depletion. Notably, acrolein and AZT responsive epigenetic modifications at the FasL promoter were observed, leading to a marked enhancement in FasL gene expression, a known death ligand for hepatocyte and liver damage. Overall, the data suggest that exposure to environmental pollutant acrolein has the potential to exacerbate AZT- induced hepatotoxicity, and increase the severity of drug induced liver injury. This work was supported by NIH grants.

**PS 2054 Solubility Enhancement Studies for a Potential Cyanide Antidote.**

M. Negrito, K. Kovacs, M. Ancha, M. Jane, S. Lee, S. Angalakurthi, S. Rasheed and I. Petrikovics. *Chemistry, Sam Houston State University, Huntsville, TX.*

Present studies focused on the solubility enhancement for the sulfur donor methyl propyl trisulfide (MPTS) to develop an intramuscular formulation for treating cyanide (CN) intoxication. Various FDA approved co-solvents (ethanol, polyethylene glycols (PEG 200, PEG 300, PEG 400) and propylene glycol (PG)), and surfactants (Cremophor EL, Cremophor RH40, polysorbate 80, sodium cholate and sodium deoxycholate) and their combinations were applied to enhance the solubility of the lipophilic MPTS. For solubility determination GC-MS methods were developed. The maximum solubility of MPTS was found at 90% ethanol of over 170 mg/ml. The maximum solubility of over 40 mg/ml was achieved with 20 % Cremophor EL. The combination of the surfactant 20% Cremophor EL and the co-solvent 75% ethanol lead to a synergistic solubilizing effect with the solubility reaching over 400 mg/ml of MPTS.

The in vitro efficacy studies for the MPTS vs. thiosulfate (TS), determined by measuring the thiocyanate formation spectrophotometrically, showed that MPTS is a significantly superior sulfur donor than TS. Similarly, the preliminary in vivo efficacy studies, determined on a therapeutic mice model and expressed as Antidotal Potency Ratios (APR), the ratio of CN LD50 with and without the test antidote(s), showed that MPTS is superior to TS. The combination of MPTS + TS showed a synergistic effect (APR= 3.6).

**PS 2055 Chemical Hazards Emergency Medical Management (CHEMM): Chemical Specific Acute Patient Care Guidelines for Prehospital and Emergency Department/Hospital Management.**

P.J. Hakkinen<sup>1</sup>, D. Siegel<sup>2</sup>, A. Maier<sup>3</sup>, F. Chang<sup>1</sup>, A. Wullenweber<sup>3</sup>, J. Strawson<sup>3</sup>, A. Willis<sup>3</sup>, P. Nance<sup>3</sup>, O. Kroner<sup>3</sup> and R. Sandhu<sup>3</sup>. <sup>1</sup>National Library of Medicine (NLM)/National Institutes of Health (NIH), Bethesda, MD; <sup>2</sup>National Institute of Health (NIH)/National Institute of Child Health and Human Development, Bethesda, MD; <sup>3</sup>Toxicology Excellence for Risk Assessment, Cincinnati, OH.

Chemical Hazards Emergency Medical Management (CHEMM) is an online and downloadable interactive tool. It is designed to enable first responders, first receivers, other healthcare providers, and planners to plan for, respond to, recover from, and mitigate the effects of mass-casualty incidents involving chemicals. Content has been developed via NLM staff, CHEMM contractors, and Federal government and non-Federal government subject matter experts (SMEs). CHEMM includes chemical-specific, acute patient care guidelines for pre-hospital and emergency department/hospital management for exposures to selected groups of chemicals. The information is divided into sections for response in the Hot Zone, Decontamination Zone, and Support Zone/Treatment Area, and each chemical page includes chemical specific information on substance identification, rescuer protection, triage, pediatric/geriatric/obstetric vulnerabilities, clinical symptoms, antidotes, and more. The first version of CHEMM was released in mid-2011, with recent efforts including the addition of over 50 new chemicals with the types of information noted above.

**PS 2056 Manganese Accumulation in the Brain of Asymptomatic Welders and Its Functional Consequences.**

E. Lee<sup>1</sup>, M. R. Flynn<sup>2</sup>, G. Du<sup>1</sup>, M. Lewis<sup>1</sup> and X. Huang<sup>1</sup>. <sup>1</sup>Neurology, Pennsylvania State University, Hershey, PA; <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Manganese, a neurotoxicant that is concentrated in welding fumes, may play a role in neurodegenerative processes such as Parkinsonism.

In the present study, we examined possible brain biomarkers of manganese exposure in asymptomatic welders using state-of-the-art MRI techniques and correlated imaging findings with functional measures (neuropsychological tests). Sixteen welders and 16 age- and education-matched controls comprised the current sample. For welders, increased welding hours were associated with higher T1 relaxation rates in amygdala, caudate nucleus, hippocampus, putamen, and orbitofrontal white matter in addition to traditionally reported globus pallidus, reflecting increased accumulation of manganese. The higher hours in welding were also associated with greater T1-weighted intensity values in caudate nucleus and hippocampus for welders. Subgroup analysis of welders who were highly exposed to welding compared to controls with no lifetime exposure to welding indicated that welders had higher T1 relaxation rates in globus pallidus and putamen consistent with current literature.

Correlation analyses of MRI results and neuropsychological tests revealed that performance on set shifting tasks (stroop and visual-verbal tests) were negatively correlated with T1-weighted intensity values in orbitofrontal white and grey matter for all subjects. In addition, executive function (the D-KEFS tower test) also was correlated negatively with T1-weighted intensity values in amygdala, caudate nucleus, hippocampus, putamen, and globus pallidus. Moreover, welders with high welding exposure showed decreased working memory performance and associated increased T1-weighted intensity values.

These results suggest that brain regions other than the globus pallidus, e.g., the caudate nucleus and/or hippocampus, also may reflect sensitively manganese exposure. In addition, there may be some cognitive decline associated with manganese deposition in brain.

**PS 2057 Ethanol-Induced Reductions of Antimicrobial Peptide LL-37 in THP-1 Cells and Bal Fluid of Ethanol Fed Mice.**

M. McCaskill, H. Hottor, M. Sapkota and T. Wyatt. *Department of Environmental, Agricultural, Occupational Health, University of Nebraska Medical Center, Omaha, NE.*

The most common infections plaguing the pulmonary system outside of common viral infections such as Rhinovirus and Influenza are Haemophilus influenzae, Klebsiella pneumonia, Burkholderia repacia, Bordetella pertussis, and Mycobacterium tuberculosis. Respiratory infection incidence has been directly correlated to circulating levels of vitamin D. Vitamin D is required for antimicrobial peptide LL-37 production and function in the lung. As a result, antimicrobial LL-37 production is correlated with respiratory function and health. C57Bl6 mice

were exposed to ethyl-alcohol via the Meadows-Cook model for 6 weeks. Mice were also fed Diallyl Disulfide (DADS) at 1uM/gram of feed, and 4000IU of cholecalciferol in their daily diet. THP-1 human acute monocytic cell line were pre-treated with 80mM alcohol for 24 hours, and treated with 1uM of DADS, and 100nM of 1,25 dihydroxy vitamin D for 6, 12, 24 hours. Eighty mM alcohol exposed THP-1 cells displayed a 53% reduction in the cellular supernatant of LL-37. The 6 hour exposure of DADS attenuated the alcohol induced reduction of cellular supernatant LL-37. The 6 hour treatment of 1,25 dihydroxyvitamin D also attenuated the reduction LL-37 in the supernatant of THP-1 cells. In the BALF of the 6 week alcohol fed mice, 1,25 dihydroxyvitamin D was reduced by 70%. In the in-vivo model DADS exposure completely abrogated the alcohol induced reduction of BALF LL-37. This data displays the propensity of alcohol to affect the ability of THP-1's (pre-monocyte cell model) to produce an antimicrobial peptide LL-37. This may be related to the disturbances in 1,25 dihydroxy vitamin D in the pulmonary epithelium as reflected by reductions of BALF of alcohol fed mice. The ability of DADS and vitamin D to attenuate this alcohol induced reduction of LL-37 in the THP-1 cells, and BALF of chronically alcohol fed mice may assist with novel treatment options for human chronic alcohol related respiratory infection severity and rates.

**PS 2058 Utility of Intranasal Fentanyl Powder Formulation: Pharmacokinetics-Pharmacodynamics Relationship in Rhesus Monkeys.**

K. Yunomae, N. Yanagida, M. Nishizono, T. Kamenosono, S. Haruta, Y. Ooshima, H. Sameshima, K. Fukuzaki and R. Nagata. *Shin Nippon Biomedical Laboratories (SNBL), Ltd., Kagoshima, Japan.*

The recent survey conducted by the American Pain Foundation revealed that breakthrough pain posed the greatest challenge to the quality of life (QOL) of cancer patients. The fentanyl buccal tablet, a self-administration formulation, is used at present to relieve breakthrough pain rapidly. However, a new formulation that possesses much quicker pain relief is required to improve the QOL. SNBL has developed an intranasal fentanyl powder formulation (TRF) with the applied "µco System", an intranasal drug delivery system technology. The purpose of this study was to investigate the utility of TRF by comparing the absorption properties and time of onset of action after administration of TRF with those of the commercial buccal tablet. [Methods] Six male rhesus monkeys with body weights 5.4-8.0 kg were used. The plasma fentanyl levels were analyzed by LC/MS/MS. The tail withdrawal latency (TWL) procedure using 50°C water was conducted to evaluate antinociception of fentanyl following administration (8 µg/kg) of fentanyl in 3 forms: TRF (intranasal), intravenously injectable formulation, and buccal tablet. [Results] T<sub>max</sub> and C<sub>max</sub> after administration of TRF were 12.8 min and 2.6 ng/mL, respectively, and were much quicker and higher than the corresponding values for the buccal tablet (50.8 min and 1.1 ng/mL). TRF prolonged the TWL. The effect continued for 25 min from just after nasal administration, similar to that of the intravenously injectable formulation. The effect of the buccal tablet on TWL was noted only at 45 min after buccal administration, suggesting a slow onset of action. [Conclusion] TRF showed a quicker nociceptive effect due to a more rapid nasal absorption of fentanyl in comparison with the buccal tablet. These results indicated that TRF would be a useful formulation for rapidly relieving breakthrough pain in cancer patients with self-administration.

**PS 2059 Better Prediction of Immunogenicity of Biopharmaceuticals, Is It Possible?**

G. M. van Mierlo<sup>3</sup>, F. J. Tielen<sup>2</sup>, R. Klein Entink<sup>1</sup>, A. Penninks<sup>3</sup>, M. Sauerborn<sup>3</sup>, S. Folkertsma<sup>1</sup>, E. Reefman<sup>2</sup> and B. Fabriek<sup>1</sup>. <sup>1</sup>*Quality and Safety, TNO, Zeist, Netherlands;* <sup>2</sup>*Metabolic Health Research, TNO, Leiden, Netherlands;* <sup>3</sup>*Toxicology Applied Pharmacology, TNO Triskelion, Zeist, Netherlands.* Sponsor: R. Woutersen.

A major drawback of biologicals is the possible induction of immunogenicity upon clinical use, that may result in a safety issue and/or a reduction of drug efficacy. Anti-drug antibodies (ADA) are determined as a measure of immunogenicity. Current preclinical models have proven lack of predictivity for clinical immunogenicity. Therefore, there is a need for better methods to predict which drugs are likely to induce immunogenicity in clinical trials.

Based on historical data of immunogenicity, information on structurally, therapeutically and/or 'mode-of-action' similar compounds can be obtained to establish the translational aspects these models. We selected interferon alfa, beta and TNF-inhibitors as model compounds (13 in total) for which the public domain (FDA reviews, BLA, NDA, EMEA, pubmed) was scavenged for immunogenicity related information. The Information consisted of physical chemical properties, formulation aspects (including stability data), preclinical animal toxicity data, clinical data (study specifics and ADA occurrences and effect).

Due to the lack of information on in vitro immunogenicity in literature, we decided to generate these data for the 13 selected compounds. We performed autologous ex vivo human T-DC co-cultures and established T cell proliferation and DC maturation as response markers.

A logistic regression model has been developed relating physical chemical, animal and in vitro information to immunogenicity, where immunogenicity has been defined as two dimensional: the prevalence in the general population and the potency of the substance (dose-response sensitivity). In a statistical analysis of the model, together with expert information, important predictive factors for immunogenicity were successfully identified.

In conclusion, retrospective analysis of various characteristics and preclinical data from on-market biological can provide us with insight in the mechanism of immunogenicity.

**PS 2060 Improved Efficacy of Delivery of Antigen Using a Novel Injection Device in the Rabbit.**

N. Hebert<sup>1</sup>, S. Garipey<sup>1</sup>, I. Brochu<sup>1</sup>, A. Caron-Laramée<sup>2</sup>, M. Brouillette<sup>2</sup> and C. Hébert<sup>2</sup>. <sup>1</sup>*Charles River, Sherbrooke, QC, Canada;* <sup>2</sup>*University of Sherbrooke, Sherbrooke, QC, Canada.* Sponsor: M. Vézina.

Needle-free injector devices show a novel, improved and safer alternative to more classical intramuscular injection immunization protocols.

Two routes of administration [intramuscular (IM) versus intradermal (ID) injection; with a gene-gun type needle-free injector device] were compared in rabbits and the immunogenicity response, together with any potential toxicity were evaluated following immunization with a plasmid coding for the Hepatitis B surface protein (HbSAg) when administered up to three times (Days 1 and 29 [and Day 43; intradermal only]).

Overall, there were no differences between routes of administration when body temperature, body weight, food consumption, selected coagulation and clinical chemistry parameters, and C-Reactive proteins were compared over a period of 43 days. At necropsy, there were no organ weight changes or any adverse macroscopic observations. Based on the magnitude of antibody response and the number of animals mounting a response, a more robust immune response was observed in animals immunized with the injector delivery method (ID). Only 17% of animals receiving the IM injection showed detectable levels of anti-HbSAg antibodies, compared to 50% of animals receiving the ID injection. Furthermore, anti-HbSAg levels in animals administered ID were generally higher than the IM responder. In conclusion, these results suggest that a needle-free injector device shows a safe alternative to intramuscular injection with an increased efficacy when using in immunization regimens.

**PS 2061 Development of a Protocol to Determine the T Cell Dependent Antibody Response (TDAR) to KLH in the Mouse—A Comparison between the CD-1 and C57BL/6N Strains.**

S. Kirk, A. Luccock and K. Troth. *Covance Laboratories Ltd., Harrogate, United Kingdom.*

Pre-clinical safety assessment of biopharmaceuticals may require testing in a specific strain of mouse, when this is the only species where the test material is pharmacologically active. This can present challenges when evaluating immunotoxicity due to known differences in immune responses that exist between different strains. In this study we developed a robust TDAR protocol in the CD-1 mouse then attempted to transfer a similar protocol for use in the C57BL/6N strain.

Initially CD-1 mice were immunised twice intravenously, 1 week apart, at KLH dose levels of 0.3 or 80 mg/kg/challenge. Cyclosporin was also tested at 20 and 100 mg/kg/day in order to establish a positive control. KLH and cyclosporin dose levels of 80 mg/kg and 100 mg/kg respectively, were not tolerated resulting in several premature decedents. A strong IgM and IgG response was observed at the 0.3 mg/kg dose level. Cyclosporin administration at 20 mg/kg/day was sufficient to suppress this response in females only. Cyclosporin administration was tested at 60 mg/kg/day, which proved adequate to suppress the immune response to KLH in both sexes. This protocol was tested in C57BL/6N mice, but failed to produce a robust antibody response. Based on a protocol provided by another lab, C57BL/6N mice were challenged subcutaneously with KLH at 0.1 mg/kg in alum on Day 1 then challenged with KLH only at 0.05mg/kg on Day 7. Control group mice were tested in parallel, without the use of alum. A strong IgM and IgG anti-KLH response was noted in both sexes, most notably in females. In the control group, only the females produced a robust anti-KLH response.

In conclusion, we have established a robust immunisation protocol to measure the TDAR response in CD-1 mice and a suitable positive control to suppress the response. An immunisation protocol in the C57BL/6N mouse was also established

however the use of an adjuvant was required to produce a strong anti-KLH response. Further work to establish a suitable dose level of cyclosporin in C57BL/6N mice is still required.

## **PS 2062 T Cell Dependent Antibody Responses in the Rat: Forms and Sources of Keyhole Limpet Hemocyanin Matter.**

H. Lebecq<sup>1</sup>, M. B. Hock<sup>2</sup>, J. Sundsmo<sup>3</sup>, D. Mytych<sup>2</sup>, H. Chow<sup>3</sup>, L. Carlock<sup>1</sup>, M. K. Joubert<sup>2</sup> and J. L. Bussiere<sup>2</sup>. <sup>1</sup>Amgen, Seattle, WA; <sup>2</sup>Amgen, Thousand Oaks, CA; <sup>3</sup>Stellar Biotechnologies, Port Hueneme, CA.

The T-cell dependent antibody response (TDAR) is a functional assay used in immunopharmacology and immunotoxicology to assess the ability to mount an antibody (IgM and/or IgG) response to immunization. Keyhole limpet hemocyanin (KLH) is extensively used as immunogen of choice both in nonclinical and clinical settings. Native KLH is comprised of high molecular weight (HMW) assemblies (>600-800 kDa) of KLH subunit dimers. It is not known how the different forms (HMW vs. subunit) and manufacturing processes (commercial sources) may impact the nature of anti-KLH immune responses (e.g., magnitude and inter-animal variability). Anti-KLH IgM and IgG responses were studied in female Sprague-Dawley rats immunized on days 1 and 22 with 100 µg of HMW KLH from two different sources or subunit KLHs from three different sources without co-injection with any adjuvant. Dose analysis and biophysical characterization of KLH formulations were conducted. Anti-KLH IgM and IgG responses were measured on days 1, 8, 15, 22, 29, 36, and 43 using a proprietary indirect electrochemiluminescence immunoassay. The two HMW KLH preparations showed a greater number of sub-visible particles (2-150 µm size range) than the three subunit KLHs. All HMW KLHs and all subunit KLHs were equivalent on SEC (hydrodynamic volume), PAGE (size and charge) and SDS-PAGE (molecular radius). Robust primary and secondary anti-KLH IgG and IgM responses were detected for both sources of HMW KLH. The subunit KLH immunizations resulted in lower IgG and IgM responses, with the exception of Stellar Biotechnologies subunit KLH which produced a robust secondary response. Inter-animal variability for IgM and IgG responses was lower with HMW KLH than with subunit KLHs. In conclusion, different forms and sources of KLH are associated with different magnitudes and inter-animal variabilities in IgM and IgG responses, a critical finding to take into consideration when designing TDAR studies for proper immunotoxicology or immunopharmacology testing.

## **PS 2063 Use of the T Cell-Dependent Antibody Response to Evaluate Immunostimulation.**

M. S. Piché<sup>1</sup>, J. Shenton<sup>2</sup>, C. Dumont<sup>1</sup>, R. Bourgeois<sup>1</sup>, I. Brochu<sup>1</sup>, A. J. Grenier<sup>1</sup>, E. Marcotte<sup>1</sup>, L. Durette<sup>1</sup>, M. Poirier<sup>1</sup>, L. de Haan<sup>2</sup> and L. LeSautour<sup>1</sup>. <sup>1</sup>Immunology, Charles River, Montréal, QC, Canada; <sup>2</sup>Medimmune, Cambridge, United Kingdom.

**Purpose:** The T-cell-dependent antibody response (TDAR) has traditionally been used to evaluate immunosuppression. The purpose of this study was to evaluate whether the TDAR following immunization with the T-dependent antigen (TDA) KLH, has utility for evaluating pharmacologically-mediated immunostimulation in cynomolgus monkeys. Recent advances in the development of immunostimulatory therapeutics, primarily T-cell stimulating biologics with cross-reactivity limited to the cynomolgus monkey, have presented a need for pharmacodynamic assays capable of measuring increased T-cell activation in monkeys.

**Methods:** Instead of immunizing the monkeys with 10 mg of KLH, an immunization dose used for evaluating immunosuppression, monkey were immunized twice (1 month apart) with either 0.1 mg or 1.0 mg of KLH in the presence or absence of adjuvants as model immunostimulants. The subsequent antibody response to KLH was measured in the serum following both immunizations, while the cellular response was measured by ELISpot following the second immunization after *ex vivo* challenge of peripheral blood cells with KLH.

**Results:** Immunostimulation by the adjuvant, defined as an increased magnitude of the TDAR, was more clearly demonstrated in monkeys dosed with 0.1 mg of KLH as compared to monkeys dosed with 1 mg of KLH. In addition, a strong KLH-induced IFN-γ response and a mild IL-5 response were elicited following KLH immunization in the presence of the model immunostimulants; however, the cytokine responses were not consistently observed across all animals.

**Conclusion:** Although further validation using known immunostimulatory therapeutics (as opposed to adjuvants) is required, it is clear that monitoring enhanced antibody responses and possible *ex vivo* cytokine responses following low dose immunization with KLH may present an opportunity to evaluate pharmacologically-mediated immunostimulation in cynomolgus monkeys.

## **PS 2064 Assessment of Hepatitis B Surface Antigen and Tetanus Toxoid-Specific T Cell-Dependent Antibody Responses in Cynomolgus Monkeys.**

B. Wang<sup>1</sup>, D. A. DeVona<sup>1</sup>, M. P. Bernard<sup>1</sup>, Q. Wang<sup>2</sup>, C. Gleason<sup>3</sup>, H. G. Haggerty<sup>1</sup> and W. J. Freebern<sup>1</sup>. <sup>1</sup>Immunotoxicology, Bristol-Myers Squibb, New Brunswick, NJ; <sup>2</sup>Rutgers University, New Brunswick, NJ; <sup>3</sup>Global Biometric Sciences, Bristol-Myers Squibb, Syracuse, NY.

Assessment of T-cell-dependent antibody responses (TDAR) is implemented in nonclinical safety testing to evaluate test article effect on immune function. Robust ELISA-based assays to analyze hepatitis B surface antigen (HBsAg)- and tetanus toxoid (TT)-specific antibodies in serum from cynomolgus monkeys immunized with HBsAg and TT were developed. Assay optimization included evaluation of vaccination doses (Engerix B [HBsAg] at 10 and 20 µg, human pediatric and adult doses; TT Adsorbed at 5 flocculation units) and dosing regimen, post-immunization blood collection times, capture reagents and concentrations thereof, initial test serum dilutions, detection antibody dilutions, and incubation times. HBsAg- and TT-specific IgG and IgM endpoint titers (EPT) were analyzed pretest and weekly up to 6 weeks post-immunization to evaluate antibody response kinetics to these antigens. In brief, HBsAg or TT (0.2 or 0.03 µg/well, respectively) is adsorbed overnight onto a 96-well microtiter plate followed by incubation with an initial test serum dilution of 1:5 or 1:50 and titrated 3x to final dilutions of 1:295245 or 1:2952450 for HBsAg or TT-specific antibody analyses, respectively. Bound HBsAg or TT specific-antibodies are detected using a 1:500 or 1:1000 dilution of alkaline phosphatase-conjugated goat anti-human Ig (total, IgM or IgG). After substrate addition and colorimetric analysis, an EPT is calculated. Following primary immunization, peak HBsAg IgM- and IgG-specific responses were observed 22 and 28 to 35 days post immunization, respectively. HBsAg-specific IgG EPT did not generally increase from primary peak response after a second challenge. Since the study monkeys were immunized with TT prior to purchase, a TT IgM-specific response was not detected. TT-specific IgG responses peaked 15 days post on-study immunization.

## **PS 2065 Development of a Delayed Type Hypersensitivity (DTH) Model in Cynomolgus Monkeys.**

G. Bannish<sup>1,5</sup>, H. Babbe<sup>2</sup>, A. Curran<sup>6</sup>, L. A. Coney<sup>5</sup>, L. Hall<sup>3</sup>, J. Zhou<sup>3</sup>, J. Ma<sup>4</sup>, M. Perpetua<sup>1</sup>, J. Doughty<sup>1</sup>, A. Beavis<sup>1</sup> and M. Scully<sup>2</sup>. <sup>1</sup>Biologics and Biomarker Analysis, Huntingdon Life Sciences, East Millstone, NJ; <sup>2</sup>Janssen R&D, LLC, Radnor, PA; <sup>3</sup>Janssen R&D, LLC, Raritan, NJ; <sup>4</sup>Janssen R&D, LLC, La Jolla, CA; <sup>5</sup>Group Strategic Marketing, Huntingdon Life Sciences, Huntingdon, United Kingdom; <sup>6</sup>Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ. Sponsor: C. Auletta.

We have developed an improved delayed type hypersensitivity (DTH) model to assess the cellular immune response. Animals were sensitized with three antigens, keyhole limpet hemocyanin (KLH), *Candida Albicans* (CA), and Tetanus Toxoid (TT) emulsified in incomplete Freund's adjuvant (IFA). These antigens were administered subcutaneously on 3 to 5 occasions over 1 to 2 weeks, followed by a resting period of 1 month. Antigenic challenge was administered intra-dermally with reduced amounts of antigen and in the absence of IFA adjuvant, and at multiple sites with individual antigens or a combined cocktail. Specific IgG responses to each of the antigens were detected. Slight erythema and induration were observed at some sites and some animals, most prominent at 48 hours and with KLH or cocktail. Histological evaluations detected a more intense cellular response with KLH and the combination than TT or CA at both 48 and 72 hours post challenge. Mononuclear cell infiltration (CD3 labeled lymphocytes and CD68 labeled macrophages) was observed in biopsies from CA (3 of 4 animals), TT (3 of 4 animals), KLH (all animals) and the cocktail (all animals), with maximal responses occurring at the 48 and 72 hour time points. Flow cytometry was performed on samples from blood, bone marrow, spleen, and lymph nodes to assess regular and activated immune cell subsets, including evaluation of naïve T lymphocytes (CD95-CD28+) and central memory T lymphocytes (CD95+CD28+) throughout the course of the study. In summary, these findings are consistent with infiltration of cytotoxic T lymphocytes into the challenge site, which is a hallmark of a classical DTH response.

**PS 2066 Validation of a 7-Color Flow Cytometry Panel for Lymphocyte Phenotyping in Peripheral Blood from Cynomolgus Monkeys.**

S. Eble<sup>1</sup>, B. Wang<sup>1</sup>, D. A. DeVona<sup>1</sup>, C. Thompson<sup>1</sup>, C. Gleason<sup>2</sup>, H. G. Haggerty<sup>1</sup>, W. J. Freebern<sup>1</sup> and M. P. Bernard<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb, New Brunswick, NJ; <sup>2</sup>Global Biometric Sciences, Bristol-Myers Squibb, Syracuse, NY.

Standard peripheral blood immunophenotyping is often implemented in nonclinical safety testing to evaluate potential test article effects on specific lymphocyte population cell counts. The purpose of this study was to validate a robust, resource efficient, high throughput 7-color flow cytometry panel for the identification of T, B, and NK cells in cynomolgus monkey blood. In brief, whole blood was aliquoted into wells (2.2 mL capacity) of a 96-deep well block, washed with PBS, and incubated with fluorophore-conjugated, cell-marker specific antibodies. Following red blood cell lysis, subsequent paraformaldehyde fixation of leukocytes and addition of counting beads, detection of immunostaining was performed using a BD FACSCanto II flow cytometer. Total lymphocytes were identified by side light scatter and CD45 immunostaining and the CD45+ lymphocyte subpopulations were characterized as follows: total T cells (CD16-CD3+), helper T cells (CD16-CD3+CD4+CD8-), cytotoxic T cells (CD16-CD3+CD8+CD4-), double positive T cells (CD16-CD3+CD8+CD4+), double negative T cells (CD16-CD3+CD8-CD4-), B cells (CD16-CD20+), and NK cells (CD3-CD16+CD159a-, CD3-CD16-CD159a+, and CD3-CD16+CD159a+). The inter-assay, intra-assay, and inter-analyst precision estimates based on absolute numbers of lymphocyte subpopulations (calculated using counting beads) were all within 20% (%CV; coefficient of variation). Validation testing demonstrated antibody specificity and minimal fluorescence carryover between samples. Whole blood stability (ie prior to immunostaining) was demonstrated for up to 24 hours at ambient temperature and the fixed samples were determined to be stable for up to 24 hours at 5 ± 4°C prior to flow cytometric analysis. Based on the results from this validation study, it was determined that the 7-color flow cytometry panel described herein reliably and precisely identifies T, B, and NK cells in cynomolgus monkey whole blood.

**PS 2067 Testing the Use of CD107a and IFN-γ As Markers of Cynomolgus Cytotoxic T Lymphocyte Activation.**

L. Anest, A. Guerrero, M. Fort and P. Narayanan. *Discovery Toxicology*, Amgen, Seattle, WA.

Cytotoxic T lymphocytes (CTLs) are key effector cells, in the immune system, that play an important role in anti-viral host defense and cancer immune-surveillance. Non-human primates, especially cynomolgus macaques, are the closest surrogates for detecting immunosuppressive properties of targeted anti-inflammatory therapeutics in human. While qualified methods exist to measure CTL function in humans and rodents, there are few assays currently available for detection of changes in CTL function in response to drug exposure in cynomolgus macaques. Herein, we present an adaptation of a flow cytometry-based human CTL degranulation assay for characterization of cynomolgus macaque CTL function. This is based on detection of lysosomal-associated membrane protein 1 (CD107a) on the surface of degranulated CTL in conjunction with the secretion of IFN-γ which allows for the identification of fully activated CTL. Briefly, whole blood samples from cynomolgus macaques were stimulated in vitro with staphylococcal enterotoxin B (SEB) for six hours, then stained for the detection of intracellular IFNγ and surface expression of CD3, CD4, CD8 and CD107a prior to analysis on a flow cytometer. Whole blood samples from naïve cynomolgus macaques (n = 11) were tested to establish a range of dual positive CD107a+IFNγ+ CTL (0.04-1.58% of CD3+CD4-CD8+ T cells) in response to SEB stimulation. Next, a longitudinal study was completed to determine the intra-animal variation of CD107a+IFNγ+ CTL responses in 4 cynomolgus macaques by collecting samples at 2-3 week intervals over a two month period. CTL activation in response to SEB stimulation demonstrated a %CV of 31-57% over the course of the study. The direct addition of an immunosuppressive compound, cyclosporine A, to WB suppressed IFN-γ secretion but not degranulation of CTL in response to SEB in a concentration-dependent manner. The ability to quantify the CTL functional responses in cynomolgus macaques may be a useful tool for determining any immunomodulatory effects of drug candidates in pre-clinical safety studies on this important lymphocyte subset.

**PS 2068 Validation of Assays for Phagocytic Function of Polymorphonuclear Neutrophils and Monocytes in Whole Blood from Cynomolgus Macaque.**

M. Perpetua<sup>1</sup> and G. Bannish<sup>2,1</sup>. <sup>1</sup>Biologics and Biomarker Analysis, Huntingdon Life Sciences, East Millstone, NJ; <sup>2</sup>Group Strategic Marketing, Huntingdon Life Sciences, East Millstone, NJ.

Phagocytosis constitutes an essential arm of host defense against bacterial and fungal infections. The process can be subdivided into phagocyte chemotaxis to sites of inflammation, binding to foreign agents, ingestion of opsonized bacteria, and intracellular killing by oxygen-dependent and oxygen-independent mechanisms. We have assessed several of these functions in whole blood from cynomolgus macaque using commercially available kits designed for human use. Tests included intra-assay precision, inter-assay precision, processed stability, sample stability, and inter-analyst variability. The percent coefficient of variation was lower for granulocytes than monocytes, typically 1% versus 10% or less in the ingestion assay. Respiratory burst following stimulation with phorbol 12-myristate 13-acetate (PMA), opsonized bacteria, or the chemotactic peptide N-formyl-Met-Leu-Phe (fMLP) was within ranges established for human whole blood. The PMA stimulant was high and consistently > 95% above unstimulated negative control values, the fMLP was low (< 5%), and opsonized bacteria induced a high percentage of stimulated granulocytes (>95%) but lesser stimulated monocytes (~60%). The highest CV values occurred in tests of oxidizing monocytes for inter-assay (19%), processed stability (19%), and sample stability (15%), but were otherwise typically below 5%. Overall these results determine the ability to use these assays for analysis of phagocytic function in cynomolgus macaque under GLP conditions.

**PS 2069 Flow Cytometry Immunophenotyping of Lymphocyte Subsets in a Large Cohort of Beagle Dogs.**

J. Descotes<sup>2</sup>, C. Mimouni<sup>1</sup>, J. Legrand<sup>1</sup> and R. Forster<sup>1</sup>. <sup>1</sup>Marketing, CiToxLAB, Evreux, France; <sup>2</sup>Poison Center, Lyon, France.

Since the dog is a major non-rodent species used in regulatory drug safety studies, there is a growing need to generate historical immunological background data to interpret the results of nonclinical immunotoxicity studies in dogs. We have initiated the compilation of data on peripheral blood lymphocyte subsets in a large cohort of male and female naïve Beagle dogs of at least 6 months of age. Venous blood samples of approximately 0.5 ml were collected from fasted animals in the morning. Immunophenotyping analysis of B lymphocytes, total T lymphocytes, T CD4+ and CD8+ lymphocytes with commercial BD Pharmingen fluorescent antibody reagents (BD Biosciences, France) is performed using a Navios 10-color flow cytometer with the Navios v1 software (Beckman Coulter, France). Flow count® fluorospheres are added to each sample prior to flow cytometry analysis for direct determination of lymphocyte subset absolute counts. At writing, validated results are available on 40 males and 50 females. Results obtained in males and females, respectively, are presented as percentage of gated cells and mean (± standard deviation) of absolute count of each lymphocyte subset/μl: B lymphocyte percentage (21.3% & 18.5%) and absolute count (604.4±185.5 & 495.5±171.5); total T lymphocyte percentage (60.8% & 64.1%) and absolute count (1719.6±599.4 & 1728.5±334.9); T CD4+ lymphocyte percentage (41.0% & 43.6%) and absolute count (1180.4±399.7 & 1159.3±228.1); T CD8+ lymphocyte percentage (12.7% & 12.2%) and absolute count (360.2±136.6 & 324.6±106.9). Stored samples from additional animals (total of 100 animals from each sex) are being processed, which will very shortly constitute the largest cohort of data on peripheral blood lymphocyte subsets in the naïve Beagle dog.

**PS 2070 Development of Molecular Classifiers for Distinguishing between True Sensitizers and False Positives in the Local Lymph Node Assay.**

D. R. Boverhof<sup>1</sup>, D. Adenuga<sup>1</sup>, M. Woolhiser<sup>1</sup>, I. Kimber<sup>2</sup>, R. Dearman<sup>2</sup>, M. Black<sup>3</sup> and R. S. Thomas<sup>3</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>University of Manchester, Manchester, United Kingdom; <sup>3</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Recent publications have highlighted certain chemistries which yield false positive responses in the LLNA when compared with guinea pig and human data. Toxicogenomics was applied to provide molecular characterization of the LLNA responses with the goal of developing classifiers for predicting true skin sensitizers. Auricular lymph node gene expression responses were evaluated in female CBA mice exposed to equipotent doses of 9 known chemical sensitizers and 7 false positives per the standard LLNA dosing regimen. Lymph nodes were analyzed for 3HTdR incorporation on study day 6 and gene expression responses on study days

4 and 6. Subsequent to data filtering, a comprehensive cross-validation model comparison using 84 different statistical classification methods was performed to identify expression-based classifiers for each chemical class (sensitizers and false positives) and time point. The predictive performance of the models was evaluated using five-fold cross-validation. The gene lists from the top performing model for each chemical class and time point were subsequently confirmed and refined using quantitative RT-PCR. The top performing day 4 classifiers had AUC values of 0.904 and 0.926 for sensitizers and false positives, respectively, while the day 6 classifiers showed higher AUC values of 0.962 and 1.00 for sensitizers and false positives, respectively. The optimal day 6 classifier gene list included 44 and 30 genes for sensitizers and false positives, respectively, with 19 overlapping genes. The 55 total genes displayed functional relevance to sensitization and irritation responses and both classifiers are now being evaluated against a series of new chemistries to independently assess model performance. Overall these data highlight the potential utility of molecular classifiers for distinguishing between sensitizers and false positives.

**PS 2071 Development of an *Ex Vivo* BrdU-Labeling Procedure for the Murine LLna.**

D. M. Lehmann<sup>1</sup>, C. Copeland<sup>1</sup>, E. H. Boykin<sup>1</sup>, S. J. Quell<sup>2</sup>, L. Copeland<sup>1</sup> and W. C. Williams<sup>1</sup>. <sup>1</sup>NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>Independent, Research Triangle Park, NC.

The murine local lymph node assay (LLNA) is widely used to identify chemicals that may cause allergic contact dermatitis. Exposure to a dermal sensitizer results in proliferation of local lymph node T cells, which has traditionally been measured by in vivo incorporation of [3H]methyl thymidine (3HTdR). A more recent non-isotopic variation of the assay utilizes bromodeoxyuridine (BrdU) incorporation in vivo. To eliminate the need for animal injections, we developed an ex vivo labeling procedure. BALB/c mice were dosed topically on the dorsum of both ears for 3 consecutive days with vehicle or one of 3 concentrations of eugenol (EUG), cinnamaldehyde (CA), hexyl cinnaminic aldehyde (HCA), nickel sulfate (NiS), isopropanol (IP) or lactic acid (LA). On day 5, lymph nodes were harvested, and single-cell suspensions were labeled ex vivo with 3HTdR or BrdU. Lymphocyte proliferation was determined by scintillation counting or BrdU ELISA, respectively. Concentration-dependent increases in ear thickness and lymphocyte proliferation were observed for EUG, CA and HCA, but none of the doses tested resulted in excessive skin irritation. The results of both the ex vivo 3HTdR and ex vivo BrdU assays correctly identified EUG, CA and HCA as dermal sensitizers according to the criteria outlined in the Globally Harmonized System for Classification and Labeling of Chemicals. As anticipated, non-sensitizers IP and LA did not induce a positive threshold response in either assay. Furthermore, a positive threshold response was not obtained for the false negative chemical NiS in either assay. The results of both ex vivo assays are in close agreement with those of the in vivo BrdU labeling procedure. We conclude that the ex vivo BrdU labeling method offers predictive capacity comparable to the other previously established LLNA protocols while eliminating animal injections and the use of radioisotope. This abstract does not represent EPA policy.

**PS 2072 A Proteomics Approach to Elucidate the Role of Nrf2 in Primary Bone-Marrow-Derived Dendritic Cells of Mice upon Activation by Contact Allergens.**

A. Haase<sup>1</sup>, F. Mussotter<sup>1</sup>, Z. El Ali<sup>2</sup>, S. Kerdine-Römer<sup>2</sup>, J. Tomm<sup>3</sup>, M. Pallardy<sup>2</sup>, M. von Bergen<sup>3</sup> and A. Luch<sup>1</sup>. <sup>1</sup>Federal Institute for Risk Assessment (BfR), Berlin, Germany; <sup>2</sup>University of Paris-Sud, INSERM UMR-996, Paris, France; <sup>3</sup>Department of Proteomics and Metabolomics, Helmholtz Centre for Environmental Research (UFZ), Leipzig, Germany.

Contact sensitizers are low molecular weight compounds, which can prompt dendritic cells in the skin to subsequently activate naïve T-cells in draining lymph nodes. Often these compounds are electrophilic and lead to activation of the Keap1/Nrf2 pathway. We aimed to further elucidate the underlying molecular mechanisms of skin sensitization and to identify putative biomarkers. We used bone marrow-derived dendritic cells (BMDC) from CD34+ progenitor cells from wild-type or Nrf2 -/- mice. Cells were treated for 8 h with different contact allergens: cinnamaldehyde (CA), 1-chloro-2,4-dinitrobenzene (DNCB), nickel sulfate (NiSO<sub>4</sub>) or with SDS as an irritant control. Analysis was done using 2D gels and ESI-MS/MS. Protein spots were considered as differentially expressed if they changed at least 1.5-fold ( $p < 0.05$ ). While treatment with 250 and 400 µM nickel and 100 µM SDS hardly had any effects, CA and DNCB led to significant changes in protein expression. We found 9 and 27 spots upregulated with 50 and 100 µM CA, respectively. For 5 and 10 µM DNCB 14 and 35 spots were upregulated, respectively. Some of those were not detected in Nrf2 -/- cells, indicating a Nrf2-dependent regulation. More than 90% of the proteins could be identified. Some of those have been already characterized as

Nrf2-dependent such as glutathione S-transferases, glutamate cysteine ligase, or catalase. We also identified other proteins involved in oxidative stress, signal transduction pathways, basic cellular pathways and also heat shock proteins. Some of them were not inducible in Nrf2 -/- cells and were not previously described as Nrf2-dependent. We could confirm Nrf2 activation in the response of mouse BMDC upon exposure to contact sensitizers. We could identify interesting potential biomarkers, some of which should be studied in more detail in the future.

**PS 2073 Nrf2-Dependent and -Independent Effects of tBHQ on Early T Cell Activation.**

C. E. Rockwell<sup>1</sup>, P. E. Fields<sup>3</sup>, C. D. Klaassen<sup>2</sup>, J. W. Zagorski<sup>1</sup>, A. E. Turley<sup>1</sup> and H. Dover<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS; <sup>3</sup>Pathology & Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS.

Nrf2 is a transcription factor that is activated by cellular stress from various sources, including oxidative stress and electrophiles. In response to cell stress, Nrf2 upregulates a battery of cytoprotective genes. In addition to this role, Nrf2 has also been shown to have immunomodulatory effects, including anti-inflammatory effects in innate immune cells and effects on T cell differentiation. The purpose of the present studies was to determine the role of Nrf2 in cytokine production and other events associated with early T cell activation. The present studies demonstrate that the Nrf2 activator, tBHQ, causes a significant decrease in the early production of IFN $\gamma$  and IL-2 in anti-CD3/anti-CD28-activated splenocytes from both wild-type and Nrf2-null mice. Interestingly, splenocytes from Nrf2-null mice produced increased levels of IFN $\gamma$ , but decreased levels of IL-2, as compared to those from wild-type mice. In addition to IL-2 and IFN $\gamma$ , the effects of tBHQ on other genes that are upregulated after T cell activation were investigated. In contrast to IL-2 and IFN $\gamma$ , tBHQ caused only modest effects on the upregulation of CD25 and CD69, which are also induced during early T cell activation. Treatment of activated splenocytes with tBHQ also inhibited calcium influx. Collectively, the current studies suggest that tBHQ inhibits early production of IFN $\gamma$  and IL-2 and that this effect is at least partially Nrf2-independent. These studies also suggest that Nrf2 promotes IL-2, but inhibits IFN $\gamma$ , at early time points after T cell activation. (This work was funded by NIH grant: ES018885.)

**PS 2074 Activation of Nrf2 by TBHQ Inhibits IL2 Production, but Not CD69 Expression, in Human Jurkat T Cells.**

J. W. Zagorski<sup>1,2</sup>, A. E. Turley<sup>2</sup>, K. R. Vandenberg<sup>2</sup>, J. Compton<sup>2</sup>, H. E. Dover<sup>2</sup> and C. E. Rockwell<sup>2,1</sup>. <sup>1</sup>Cellular and Molecular Biology, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor that is activated by cell stress, such as electrophilic and oxidative stimuli. Once activated, Nrf2 translocates to the nucleus and induces the transcription of its target genes, including HMOX and NQO1. Previously, it has been shown that Nrf2 skews CD4+ T cell differentiation in primary murine T cells, however the role of Nrf2 in human T cells is largely uncharacterized. Therefore, the purpose of the present studies was to determine the effects of Nrf2 activation upon early events of CD4+ T cell activation, in human Jurkat T cells. Treatment of Jurkat cells with the Nrf2 activator, tBHQ (5 µM), significantly decreased both transcript and protein production of IL-2. Similarly, a modest reduction of CD25 induction by tBHQ was observed, but CD69 expression remained unaffected. Nuclear translocation of c-fos and c-jun (transcription factors that regulate IL-2) was not affected by tBHQ treatment. In contrast, cells pretreated with 1 µM and 5 µM tBHQ showed both a delay of and decrease in Ca<sup>2+</sup> influx stimulated by anti-CD3/anti-CD28. Collectively, the current studies suggest a differential effect of tBHQ on early events of CD4+ T cell activation, and these effects are at least partially due to inhibition of Ca<sup>2+</sup> influx into the cell. (This work is supported by NIH grant: ES018885)

**PS 2075 Inhibition of Early Cytokine Production by the Nrf2 Activator, tBHQ, in Human Primary Blood Mononuclear Cells.**

A. E. Turley<sup>1,2</sup>, J. W. Zagorski<sup>1</sup> and C. E. Rockwell<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

tBHQ (tert-butylhydroquinone) is a common food preservative and a known Nrf2 (nuclear factor erythroid 2-related factor 2) activator. Nrf2 is a ubiquitously expressed transcription factor responsive to cell stress that regulates many cytoprotec-

tive and detoxification genes. In addition, Nrf2 has been shown to have anti-inflammatory properties and to modulate the activity of numerous immune cell types, including T cells. The purpose of the present studies was to characterize the role of Nrf2 during T cell activation in primary blood mononuclear cells isolated from human whole blood. The induction of several genes associated with early T cell activation, including IL-2, IFN- $\gamma$ , CD25 and CD69, was investigated in PBMCs treated with tBHQ prior to T cell activation. Treatment with tBHQ inhibited production of the early cytokines IL-2 and IFN- $\gamma$ , in a dose-dependent manner. Compared to the cytokines, induction of the cell surface markers CD25 and CD69 was less sensitive to tBHQ, with expression inhibited only at the highest concentration of tBHQ. The effects of tBHQ on protein expression of IL-2, IFN- $\gamma$ , CD25, and CD69 correlated with the mRNA expression of these genes. Consistent with Nrf2 activation, tBHQ treatment also caused induction of the Nrf2 target genes Hmox-1, Nqo1, and Gclc. Collectively, these studies demonstrate that tBHQ inhibits early cytokine production by anti-CD3/anti-CD28-activated PBMCs while only modestly decreasing CD25 and CD69 induction. Overall, these data suggest that Nrf2 may differentially modulate the early events of T cell activation in primary human T cells. (This work is supported by NIH grant ES018885)

**PS 2076 Diethylstilbestrol (DES)-Regulated microRNA-30a May Induce Autophagy by Regulating Beclin1 in Thymic Cells of Neonatal Mice.**

N. P. Singh, U. P. Singh, I. K. Abbas, P. Nagarkatti and M. Nagarkatti. *Pathology, Microbiology, and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

Prenatal exposure to DES is known to cause changes in immune functions thereby increasing susceptibility to autoimmune diseases in humans. Experimental studies have also indicated that prenatal exposure to DES affects thymic T cells. Our laboratory has been investigating DES-regulated miR profile in fetal thymocytes following prenatal exposure. Of the 608 miRs examined by performing high-throughput miR arrays with thymocytes on gestational day 18 (GD18) of C57BL/6 mice exposed to DES, we observed more than 60 miRs that were up- or down-regulated (>1.5-fold) when compared to vehicle treated group. Upon further analyses, we observed significant downregulation (>2.0 fold) of miR-30a in fetal thymocytes post DES exposure. miR-30a has been shown to regulate Beclin 1 (BECN1) expression affecting autophagic activity. In the current study, therefore, we examined whether miR-30a that was down regulated in fetal thymocytes post DES exposure plays a role in autophagy vis a vis immune dysfunction in neonatal mice. Recent studies have suggested that autophagy in the thymic epithelium is dispensable for negative selection of autoreactive T cells. Upon analysis of miR-30a by Real-Time PCR, we observed significant (more than 2-fold) downregulated expression of miR-30a in fetal thymocytes but upregulated expression of BECN1. We further characterized miR-30a for its binding affinity with BECN1 3'UTR region. Our studies demonstrated significant blocking of BECN1 expression in the presence of miR-30a and the effect of miR-30a was reversed in the presence of DES. Together, these data demonstrate that prenatal exposure to DES can cause alterations in thymocyte differentiation through dysregulation in miR-30a leading to altered BECN1 expression that in turn may influence the mechanisms of autophagy in fetal thymocytes. (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

**PS 2077  $\Delta^9$ Tetrahydrocannabinol (THC) Rescues Mice from Staphylococcal Enterotoxin B (SEB)-Induced Acute Lung Injury (ALI) and Subsequent Mortality by the Induction of Regulatory T Cells and the Down-Regulation of microRNA-182.**

R. Rao, P. Nagarkatti and M. Nagarkatti. *University of South Carolina, Columbia, SC.*

Acute Lung Injury (ALI) is characterized by infiltration of lymphocytes in the lung, edema, Acute Respiratory Distress Syndrome (ARDS), and death. In this study, Staphylococcal Enterotoxin B (SEB) was used to induce ALI in mice. SEB is a superantigen that activates T cells expressing V $\beta$ 8, which leads to activation of ~20% of T-cells and massive release of pro-inflammatory cytokines leading to the induction of ALI/ARDS. We tested the hypothesis that  $\Delta^9$ Tetrahydrocannabinol (THC), a cannabinoid known for its anti-inflammatory properties can rescue mice from SEB induced mortality. Intranasal followed by intraperitoneal administration of SEB resulted in death of mice, while THC treatment rescued them from mortality. SEB exposure induced vascular leak in the lung, which was reduced by THC treatment. SEB administration resulted in the infiltration of lymphocytes (CD3 $^+$ , V $\beta$ 8 $^+$ ,

NK, NKT, MDSC and macrophages) in the lung and THC treatment led to the decrease in their absolute cell numbers. Interestingly, THC treatment caused an induction of CD4 $^+$ Foxp3 $^+$  T-cells in the lung, indicating a role for regulatory T-cells in the amelioration of SEB induced inflammation. Additionally, SEB exposure led to the induction of miR-182 that caused a downregulation in Foxo1 expression leading to clonal expansion of T-cells. THC treatment however, decreased miR-182 expression indicating that THC might mediate its effects in part through the down-regulation of miR-182. Cytokine analysis showed that while SEB exposure led to the increase of IL-2 and MCP-1 in the serum and IFN- $\gamma$  and IL-6 in the Bronchoalveolar lavage fluid (BALF), THC treatment resulted in a decrease in these cytokines. Together, our data demonstrates that THC can rescue mice from SEB induced ALI and death. (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20 RR032684 and VA Merit Award BX001357)

**PS 2078 Identification of microRNA That Affect Multiple Pathways of TCDD-Induced T Cell Dysregulation.**

P. Mehrpouya, P. Nagarkatti and M. Nagarkatti. *Department of Pathology, Microbiology and Immunology, University of South Carolina School of Medicine, Columbia, SC.*

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD), an environmental contaminant, is well known for inducing severe toxicity including immunosuppression. We examined the mechanisms by which TCDD affects the T cell response to Staphylococcal enterotoxin B (SEB). SEB, a superantigen, activates ~20% of T cells via V $\beta$ 8 T cell receptor, causes a robust release of pro-inflammatory cytokines. We injected C57BL/6 mice with SEB in footpads and treated i.p with vehicle or TCDD. Our studies showed that TCDD treatment of SEB-activated lymphocyte led to a decrease in V $\beta$ 8 $^+$  T cells in compare to vehicle and causes an increased induction of apoptosis in SEB-activated T cells. TCDD led to induction of FoxP3 $^+$  T regulatory cells (Tregs) and suppression of pro-inflammatory cytokines, IFN- $\gamma$ , TNF- $\alpha$  and IL-6 while increasing the expression of the anti-inflammatory cytokine, IL-10. Showing the role of microRNA (miR) in TCDD-induced immune dysregulation, we performed high throughput miR analysis. Following TCDD administration, 36 miRs were up-regulated while 50 were down-regulated. In silico analysis demonstrated that several pathways were affected including induction of apoptosis, cytochrome P450 expression and Treg differentiation. We validated the role of selected miR following vehicle or TCDD treatment of SEB-activated LN cells. miR-31, complementary to the 3'-UTR of the target gene Foxp3, was down regulated in the TCDD treated group which is validated by RT-PCR. miR-351 directed against the target gene CYP1A1, was down-regulated in the TCDD treated group which suggests that TCDD acts as an AhR ligand causing increased CYP1A1 expression as well as Tregs induction. miR-21 targets the pro-apoptotic targets, Fas and FasL was down-regulated, which results in TCDD-mediated toxicity. Our studies demonstrated that TCDD affects miR expression that acts through several mechanisms to cause immune dysregulation. (Supported by NIH grants P01AT003961, P20 RR032684, R01AT006888, R01ES019313, R01MH094755 and VA Merit Award BX001357)

**PS 2079 Quantitative Phosphoproteomic Analysis of the Dynamic Signaling Network Mediating Proinflammatory Response in the Spleen of Mice under Deoxynivalenol-Induced Ribotoxic Stress.**

X. Pan<sup>1,2</sup>, D. Whitten<sup>3</sup>, C. Wilkerson<sup>1,3</sup> and J. Pestka<sup>2,4</sup>. <sup>1</sup>Department of Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Proteomics Core Facility, Michigan State University, East Lansing, MI; <sup>4</sup>Department of Food Science and Human Nutrition, Michigan State University, East Lansing, MI.

The trichothecene mycotoxin deoxynivalenol (DON) is a widely-studied model ribotoxin that targets the innate immune system and has public health significance due to its common contamination of human and animal food. Induction of proinflammatory genes in the spleen by DON is known to involve activation of transcription factors mediated by rapid phosphorylation of mitogen-activated protein kinases (MAPKs). To further understand how phosphorylation of proteins leads to the onset of proinflammatory response, stable isotope dimethyl labeling-based proteomics was applied to quantitatively profile the immediate ( $\leq 30$  min) phosphoproteome changes in the spleen of mice orally exposed to a toxicologically relevant dose of DON. A total of 90 phosphoproteins indicative of novel phosphorylation events were significantly modulated by DON. In addition to critical branches and

scaffolds of MAPK signaling being affected, DON exposure altered phosphorylation of proteins that mediate PI3K/AKT, B cell receptor and T cell receptor-linked pathways and DNA methylation. Gene ontology analysis indicated that DON exposure affected biological processes such as cytoskeleton organization, regulation of apoptosis and immune system development, which could modulate cell adhesion and lymphocyte function, setting the stage for the proinflammatory response. Fuzzy c-means clustering analysis further revealed that DON evoked several distinctive temporal profiles of the regulated phosphopeptides. These results should shed light on mechanisms of the immunotoxicity of ribotoxins and could ultimately lead to novel strategies for countering the adverse actions of such agents.

## PS 2080 Targeted Proteomic Analysis of Phospho-Lyn in Hg Intoxicated B Cells.

J. A. Caruso<sup>1</sup>, P. M. Stemmer<sup>1</sup>, M. J. McCabe<sup>2</sup> and A. J. Rosenspire<sup>3</sup>. <sup>1</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI; <sup>2</sup>Environmental Medicine, University of Rochester, Rochester, NY; <sup>3</sup>Immunology and Microbiology, Wayne State University, Detroit, MI.

Network and key node analysis of proteins undergoing Hg(2+)-induced phosphorylation and dephosphorylation in Hg intoxicated mouse WEHI 231 B cells identified Lyn as the top scoring node. Lyn is a Src family protein tyrosine kinase known to be intimately involved in the B Cell Receptor (BCR) signaling pathway. Under normal signaling conditions the tyrosine kinase activity of (mouse) Lyn is controlled by phosphorylation, primarily of two well known canonical regulatory tyrosine sites, Y397 and Y508. However Lyn has multiple tyrosines, threonines and serines, which have not so far been determined to play a major role under normal signaling conditions, but are potentially important targets for phosphorylation following Hg(2+) exposure. In order to determine how Hg(2+) intoxication modulates the phosphorylation of additional residues in Lyn, a targeted MS assay was developed. Initial mass spectrometric surveys of purified Lyn identified seven phosphorylated amino acid residues (6 tyrosines and 1 serine). A targeted quantitative assay was then developed from these results using the multiple reaction monitoring (MRM) strategy. WEHI 231 cells were treated with Hg, pervanadate, or anti-mu antibody (to stimulate the BCR), and cell stimulation confirmed by anti-phosphotyrosine western blots. Whole cell lysates from these same samples were then separated by 1D SDS-PAGE and the regions containing Lyn were selected for analysis. In gel digestion produced tryptic peptides that were analyzed on a TSQ Vantage MS system using a Lyn-specific MRM method that targeted 11 peptides and 6 phosphopeptides. Data indicate that several Lyn sites are subject to Hg(2+)-induced phosphorylation. However Y117 and Y194 were especially susceptible, suggesting that their phosphorylations may be important mediators of Hg immunotoxicity. Supported by NIEHS: R21ES019228

## PS 2081 Penicillium Mycotoxins Alter the Expression of Genes Coding Enzymes That Regulate Epigenetic Programming in Bovine Macrophages.

S. Oh<sup>1</sup>, R. Cliff<sup>2</sup>, C. G. Balch<sup>1</sup>, B. S. Sharma<sup>1</sup>, H. J. Boermans<sup>2</sup>, S. Haladi<sup>3</sup> and N. A. Karrow<sup>1</sup>. <sup>1</sup>Animal & Poultry Science, University of Guelph, Guelph, ON, Canada; <sup>2</sup>Biomedical Sciences, University of Guelph, Guelph, ON, Canada; <sup>3</sup>Alltech Inc., Guelph, ON, Canada.

Penicillium mycotoxins (PM) are natural immunomodulatory contaminants that accumulate in grains, crops, fruits, and fermented products, especially during post harvest periods, due to improper storage and harvesting methods. In this study, the expression of genes coding key enzymes involved in epigenetic regulation was assessed using a bovine macrophage cell line (BoMac). BoMac were activated with bacterial lipopolysaccharide (LPS) and exposed for 6 hr to the following PM: citrinin (CIT), ochratoxin A (OTA), patulin (PAT), mycophenolic acid (MPA), penicillic acid (PA), or a combination of one of the above with OTA at the concentration that inhibits BOMAC cell proliferation by 25% (IC25). Messenger RNA was isolated and real-time PCR analysis was performed to assess mycotoxin-induced changes in the expression of DNA methyltransferases (DNMTs), histone demethylases (JMJD3 and UTX), histone acetylases (CBP/p300), histone deacetylases (HDACs), and histone ubiquitin ligase (BMI1). LPS-induced expression of DNMT3a was augmented by OTA+PA, while DNMT3b expression was reduced by PA, OTA+PA and CIT+OTA. JMJD3 expression was induced by PA but down-regulated by OTA+PA. CBP/p300 expression was reduced by all individual mycotoxins as well as OTA+MPA and OTA+PA, and BMI1 expression was reduced by MPA, OTA+MPA and OTA+PA. The expression of HDAC1 was reduced by CIT, MPA and PA, while HDAC2 expression was induced by CIT+OTA and OTA+PAT. Lastly, HDAC3 expression was reduced by MPA, PA, CIT+OTA,

OTA+PAT, OTA+MPA and OTA+PA. These findings propose a potential novel regulatory mechanism by which PM can modulate bovine macrophage gene expression and function.

## PS 2082 Genipin-Induces Cyclooxygenase-2 Expression through Upregulating NF-κB, C/EBP and AP-1 Signaling Pathways in Murine Macrophages.

T. Khanal, H. Kim, J. Choi and H. Jeong. Pharmacy, Chungnam National University, Daejeon, Republic of Korea.

Genipin, the aglycone of geniposide, exhibits anti-inflammatory and anti-angiogenic activities. Cyclooxygenase-2 (COX-2) acts as a link between inflammation and carcinogenesis through its involvement in tumor promotion. In the present study, we examined the effect of genipin on COX-2 gene expression and analyzed the molecular mechanism of its activity in murine RAW 264.7 macrophages. Furthermore, genipin dose-dependently increased the levels of COX-2 protein and mRNA. These results demonstrate that genipin induced COX-2 expression via NF-κB and AP-1 activation. Moreover, genipin increased the luciferase reporter gene activity in cells transfected with a COX-2 promoter. Transient transfections utilizing COX-2 promoter deletion constructs and COX-2 promoter constructs, in which specific enhancer elements were mutagenized, revealed that the NF-κB, C/EBP and AP-1, were predominant contributors to the effects of genipin. Together, these results suggest that genipin induces the expression of COX-2 in Raw 264.7 macrophages, and the induction is related with activation of NF-κB and AP-1 signaling pathway. Taken together, these findings suggest that genipin is related biological activities and induced inflammation.

## PS 2083 The Role of Transcription Factor FoxO1 in Asbestos-Induced Apoptosis of MT-2 Cells.

H. Matsuzaki<sup>1</sup>, S. Lee<sup>1</sup>, M. Maeda<sup>2</sup>, N. Kumagai-Takei<sup>1</sup>, Y. Nishimura<sup>1</sup> and T. Otsuki<sup>1</sup>. <sup>1</sup>Department of Hygiene, Kawasaki Medical School, Kurashiki, Japan; <sup>2</sup>Laboratory of Functional Glycobiology, Department of Biofunctional Chemistry, Division of Agricultural and Life Science, Graduate School of Environmental and Life Science, Okayama University, Okayama, Japan.

Asbestos is known to cause mesothelioma and lung cancer. We previously reported that asbestos affects not only mesothelial and lung epithelial cells, but also anti-tumor immune system. Regulatory T cells, Treg, produce inhibitory cytokines to suppress anti-tumor immune system. MT-2 cells were cultured with asbestos for 8 months and employed as Treg model exposed to asbestos. MT-2 cells exposed to asbestos showed higher viability after treatment with high concentration of asbestos than original MT-2 cells, and was designated as MT-2Rst. Total RNA were prepared from MT-2Rst and original MT-2 cells, respectively, and mRNA expressed in these cells were analyzed by using a micro array containing 41,000 human genes. FoxO1, forkhead transcription factor, was found to decrease in MT-2Rst cells. We generate FoxO1 knock-down MT-2 cells with shRNA. FoxO1 shRNA reduced population of apoptotic cells after treatment with asbestos, whereas did not alter basal apoptotic ratio. These results suggest that FoxO1 play a role in regulation of asbestos-induced apoptosis, and down-regulation of FoxO1 in MT-2Rst is involved in its resistance to asbestos.

## PS 2084 BCL-6 and SHP-1: Putative Regulators of TCDD-Mediated Impaired Human B Cell Activation.

A. Phadnis<sup>1,2</sup>, R. B. Crawford<sup>2,3</sup>, R. S. Thomas<sup>4</sup> and N. E. Kaminski<sup>2,3</sup>. <sup>1</sup>Genetics, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>4</sup>Hamner Institute for Health Sciences, Research Triangle Park, NC.

The environmental contaminant 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is known to cause suppression of humoral immune responses. Evidence from epidemiological studies performed in dioxin-contaminated areas suggest associations between exposure to dioxin-like compounds and increased incidence of non-Hodgkin's lymphoma (NHL) in human subjects. We have observed that TCDD-treatment of CD40L and cytokine-activated human peripheral blood B cells leads to suppression of B cell activation. Hence, in order to elucidate the molecular mechanisms underlying impaired B cell activation by TCDD, we focused on two candidate genes – SHP-1, a protein tyrosine phosphatase that inhibits signaling in

activated B cells and BCL-6, a transcriptional repressor of B cell activation and differentiation also mutated in NHL. SHP-1 was identified through a genomic analysis of AHR binding in TCDD-treated mouse B cells. To evaluate the potential involvement of SHP-1 in this process, time-course measurements were performed and SHP-1 mRNA and protein levels were induced at day 3 in presence of TCDD. In several donors, we also observed a TCDD concentration-dependent increase in protein levels of SHP-1. With respect to BCL-6, we observed decreased downregulation of protein levels compared to control cells. When BCL-6 and SHP-1 levels were measured simultaneously in human B cells, an increase in the double positive (SHP-1hi BCL-6hi) population was seen in the presence of TCDD. This increase in SHP-1 and BCL-6 levels was observed in several TCDD-sensitive human donors and the changes were concentration-dependent. Collectively, these results suggest that the regulators, BCL-6 and SHP-1 may be involved in the TCDD-mediated suppression of human primary B cell activation. (Supported in part by NIH R01 ES002520 and P42 ES004911)

## PS 2085 Paradox of Epithelial Early Growth Response 1 in Epithelial Inflammatory Signaling under Ribosomal Insults.

K. Do, H. Choi, J. Kim, S. Park, C. Oh and Y. Moon. *Lab. of Mucosal Exposome and Biomodulation, Department Microbiology and Immunology, Pusan National University School of Medicine and Medical Research Institute, Yangsan, Republic of Korea.*

Regulation of gut epithelial NF- $\kappa$ B expression and activity are crucial for preventing overstimulation of pro-inflammatory response following exposure to commensal bacteria. To determine whether the EGR-1 modulates epithelial NF- $\kappa$ B signaling, we investigated the effects of epithelial EGR-1 on responses to bacterial NF- $\kappa$ B-activating lipopolysaccharide (LPS) in intestinal epithelial cells under ribosomal stress. Although nuclear translocation of NF- $\kappa$ B was observed in the cells exposed to LPS, chemokine expression was slightly affected. In contrast, simultaneous exposure to LPS and ribosomal insults decreased epithelial NF- $\kappa$ B activities, but chemokine expression was super-induced. Similar to our previous study, ribosomal insults-induced EGR-1 mediated induction of pro-inflammatory chemokines in the intestinal epithelial cells. Mechanistically, mucosal ribosomal insult-triggered EGR-1 mediated PPARG induction, which blocked NF- $\kappa$ B activation by LPS. Taken together, EGR-1 regulates pro-inflammatory NF- $\kappa$ B activation by LPS via EGR-1-induced PPARG although EGR-1 is a positive mediator of chemokine induction by mucosal ribosomal insult in gut epithelial cells (This study was carried out with the support of National Joint Agricultural Research Project of RDA (project number PJ008405032012) RDA, Republic of Korea).

## PS 2086 TCDD-Induced Modulation of Ig Expression in a Human B Lymphocyte Cell Line.

B. Johnson, J. Liu and C. E. Sulentic. *Pharmacology & Toxicology, Wright State University, Dayton, OH.*

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a potent environmental toxin known to inhibit immunoglobulin (Ig) gene expression in various animal studies. We have identified the mouse 3'Igh regulatory region (3'IghRR) as a sensitive transcriptional target of TCDD that may mediate inhibition of Ig expression. Interestingly, the hs1,2 enhancer of the human 3'IghRR is polymorphic and has been associated with a number of autoimmune diseases. In contrast to the inhibitory effects of TCDD on the mouse hs1,2, the human hs1,2 is activated by TCDD. Whether this species difference in hs1,2 modulation translates to the 3'IghRR and Ig expression is unknown. The sensitivity of the antibody response to TCDD-induced suppression in animal models suggests that human B-cells could be a sensitive target of TCDD; however, very few studies have evaluated the effect of TCDD on human B-cell function and Ig expression and none have evaluated the human 3'IghRR. The objective of this study was to characterize the CL-01 human B lymphocyte cell line as a potential human cellular model to determine the relationship between the AhR, 3'IghRR, Ig expression and class switch recombination. Our results support expression of a functional AhR in the CL-01 cells. TCDD treatment also induced transcriptional activity of luciferase reporters regulated by each allele of the polymorphic human hs1,2 enhancer. Additionally, the CL-01 cells can be activated to express Ig by ligands for the Toll-like receptor 9 (TLR9) and this activation appears to be sensitive to TCDD-induced modulation. Future studies will evaluate the role of the hs1,2 polymorphism in 3'IghRR activation, Ig expression and CSR and in the effects of TCDD on these processes. Since TCDD represents a large class of chemicals found in the environment, diet, and pharmaceuticals, understanding chemical-induced modulation of the human 3'IghRR and hs1,2 enhancer may provide a clue to the etiology of autoimmune diseases associated with the hs1,2 polymorphism. (Supported by NIEHS R01ES014676)

## PS 2087 Comparison of the Effects of Deoxynivalenol and Tributyltin Oxide to That of Model Compounds Inducing Endoplasmic Reticulum Stress, Ribotoxic Stress and T Cell Activation.

P. C. Schmeits<sup>1</sup>, M. R. Katika<sup>1</sup>, A. A. Peijnenburg<sup>1</sup>, H. van Loveren<sup>2</sup> and P. Hendriksen<sup>1</sup>. <sup>1</sup>Toxicology and Effect Monitoring, RIKILT Institute of Food Safety, Wageningen, Netherlands; <sup>2</sup>Laboratory for Health Protection Research, National Institute of Public Health and the Environment, Bilthoven, Netherlands.

Two common immunotoxicants, the mycotoxin deoxynivalenol (DON) and the organotin compound tributyltin oxide (TBTO), were previously studied for their effects on the human Jurkat transcriptome. DON induces ribotoxic stress and both DON and TBTO induces ER stress, oxidative stress, calcium mediated signalling, NFAT and NF $\kappa$ B pathways, T cell activation and apoptosis. The present study aimed to confirm this finding by comparing the effects of DON and TBTO on mRNA expression in Jurkat cells to that of positive controls inducing ribotoxic stress (anisomycin), ER stress (thapsigargin) and T cell activation (PHA and ionomycin).

Jurkat cells were exposed for 6 hours to subcytotoxic concentrations of DON, TBTO, anisomycin, thapsigargin, ionomycin and PHA. RNA was isolated and hybridised on Affymetrix U133 Plus 2.0 Arrays. Effects on mRNA expression were analysed on the level of individual genes or on the level of pathways.

The gene expression profiles of anisomycin and DON were almost identical confirming that DON and anisomycin both induce ribotoxic stress and act via the same mechanism. Anisomycin and DON upregulated the processes of ribosomal function, RNA biosynthesis, T cell activation and apoptosis. Genes were similarly affected by thapsigargin and TBTO confirming that both compounds induce ER stress. Both TBTO and thapsigargin upregulated genes involved in RNA biosynthesis, ER stress, T cell activation and oxidative stress, and downregulated ribosomal function. Another group of genes were upregulated by TBTO and not affected by the other compounds and are involved in DNA packaging and nucleosome assembly. As expected, ionomycin induced genes involved in T cell activation. In contrast, PHA did not affect any pathway. In conclusion we showed that DON induces ribotoxic stress and TBTO induces an endoplasmic reticulum stress response.

## PS 2088 Bidirectional Impact of Atrazine-Induced Elevations in Progesterone (P4) on the LH Surge in the Ovariectomized (OVX), Estradiol (E2)-Primed Rat.

J. M. Goldman<sup>1</sup>, L. K. Davis<sup>2</sup>, A. S. Murr<sup>1</sup> and R. L. Cooper<sup>1</sup>. <sup>1</sup>Endocrine Toxicology Branch, Toxicology Assessment Division, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Impact Pharmaceutical Services, Research Triangle Park, NC.

Multiple daily exposures to the herbicide atrazine (ATRZ) have been reported to suppress the luteinizing hormone surge (LHS) in female rats. Exposure has also been found to elevate P4 concentrations, and an increase in P4 is known to have a different directional effect on LH depending on its temporal association to the surge. Consequently, the present study focused on the effects of ATRZ dose and exposure duration on the LHS in OVX, E2-primed Long-Evans rats. ATRZ was administered by gavage (1300h), and serial tail blood samples were taken at 1400, 1600, 1800 & 2000h following 1, 2 & 4 days of exposure. An initial study with 0 & 100 mg/kg (previously demonstrated to suppress the LHS after multiple treatments) significantly enhanced the afternoon LH surge peak & area under the curve (AUC) in response to a 1-day exposure, an effect consistent with kisspeptin genetic expression in the brain anteroventral periventricular region. In contrast, 4 daily treatments caused a significant suppression in both measures, whereas no effects were present following 2 days of dosing. After a 1-day treatment, prompt & marked elevations in serum P4 concentrations, attributable to adrenal secretion, were present at both 30 minutes & 1 hour, but by the 4th day a marked decline was present at 1 hour. A dose-response assessment was subsequently conducted with 0, 10, 30 & 100 mg/kg ATRZ for 1 & 4 days. At 1 day, 100 mg/kg caused similar elevations in circulating P4, the LH peak & AUC, whereas 4 daily exposures resulted in a shift to a reduced AUC. No effects on the surge were observed with 10 or 30 mg/kg at 1 or 4 days. This influence on the LHS indicates that the effectiveness of ATRZ in inducing P4-associated bidirectional shifts in LH depends on both the dosage administered and importantly on the temporal association of exposure to the appearance of the surge. (This abstract does not represent EPA policy.)

## PS 2089 Chloroethylaziridine: An Ovotoxic Metabolite of Cyclophosphamide?

J. A. Madden and A. F. Keating. *Iowa State University, Ames, IA.*

Phosphoramidate mustard (PM) has been implicated as the ultimate ovotoxic metabolite of the chemotherapeutic agent cyclophosphamide, however, studies suggest that in extra-ovarian tissues PM can spontaneously metabolize to a volatile

cytotoxic compound, chloroethylaziridine (CEZ). To our knowledge, CEZ toxicity has not been characterized directly in the ovary. Postnatal day 4 (PND4) Fisher 344 (F344) rat ovaries were cultured in media containing vehicle control (1% DMSO; CT) in the absence or presence of PM (60  $\mu$ M) or CEZ. CEZ-treated ovaries were those that were present in the same incubator as PM-treated (60  $\mu$ M) ovaries, thus receiving exposure to the volatile metabolite. Additionally, the requirement of ovarian tissue for CEZ formation was evaluated by adding PM (60  $\mu$ M) to wells that did not contain an ovary to determine any ovotoxic impact on ovaries that were in control media in the same incubator. Following 6 days of culture, follicle types were classified and counted in all treatments. Relative to control, PM and CEZ caused primordial follicle loss ( $P < 0.05$ ), with PM being more ovotoxic ( $P < 0.05$ ) than CEZ (CT -  $426.7 \pm 28.88$ ; PM -  $86.33 \pm 9.9$ ; CEZ -  $260 \pm 30.0$ ). Small primary follicle depletion only occurred following PM exposure ( $P < 0.05$ ), not CEZ, relative to CT (CT -  $103.3 \pm 16.95$ ; PM -  $3.67 \pm 1.45$ ; CEZ -  $83.67 \pm 7.8$ ). In the absence of ovarian tissue, CEZ spontaneously arose from PM, and depleted ( $P < 0.05$ ) both primordial (CT -  $377.5 \pm 53.24$ ; CEZ -  $82.75 \pm 29.93$ ) and small primary follicles (CT -  $85.0 \pm 21.91$ ; CEZ -  $24.5 \pm 6.4$ ), relative to control. Thus, ovarian tissue is not a requirement for CEZ generation from PM. This study supports that CEZ is a novel ovotoxicant that warrants further characterization in the ovary to understand its contributions to the detrimental effects of chemotherapy on female fertility. The volatility and toxicity of CEZ is particularly concerning for chemotherapy patients and their families as well as the medical professionals caring for these patients (Supported by ES016818).

**PS 2090 Role of Connexin Proteins during the Ovarian Response to 7, 12-Dimethylbenz[*A*]Anthracene Exposure in Rat Ovaries.**

S. Ganesan and A. E. Keating. *Animal Science, Iowa State University, Ames, IA.*

7,12-dimethylbenz[*a*]anthracene (DMBA) is an ovotoxic polycyclic aromatic hydrocarbon liberated through burning of organic matter. Connexin (CX) 43 and 37 are gap junction proteins providing granulosa:granulosa and granulosa:oocyte communication, respectively, and are essential for follicle survival. CX43 can inhibit chemical-induced apoptosis and low CX43 expression correlates with increased granulosa cell apoptosis. An acute single DMBA exposure to cultured postnatal day 4 (PND4) F344 rat ovaries caused loss of both large primary and secondary follicles at a concentration of 12.5 nM DMBA, while a higher concentration, 75 nM, resulted in only large primary follicle loss 8 days after exposure. This study investigated CX protein involvement during the ovarian response to DMBA exposure. PND4 F344 rat ovaries were cultured for 4 days followed by single exposures of vehicle control (1% DMSO) or DMBA (12.5 nM or 75 nM) and the culture was maintained for 4 or 8 days for Cx43 and Cx37 mRNA or protein quantification ( $n = 3$ ; 6-10 ovaries/pool) and localization ( $n = 3$ ). After 4 days, Cx37 mRNA was increased ( $P < 0.05$ ) by 12.5 nM (3.5-fold) and 75 nM (1.5-fold) DMBA exposures, while, conversely, Cx43 was decreased (12.5 nM - 0.94-fold; 75 nM - 0.70-fold;  $P < 0.05$ ). After 8 days, Cx37 and Cx43 mRNA decreased (12.5 nM - 0.99 and 0.95-fold; 75 nM - 0.85 and 0.95-fold;  $P < 0.05$ ), regardless of DMBA concentration, compared to control. CX43 protein was located between the granulosa cells of all follicle stages, while CX37 was present in the oolemma. After 8 days, decreased ( $P < 0.05$ ) CX37 (12.5 nM - 13%) and CX43 (12.5 nM - 8%; 75 nM - 23%) proteins were observed. These data support an initial increase in Cx37 and Cx43 mRNA as part of the ovarian protective response to DMBA exposure, while the decrease after 8 days of DMBA exposure is likely a reflection of the loss of follicular viability induced by DMBA. (Supported by ES016818 to AFK and AAUW fellowship to SG).

**PS 2091 Endocrine Modulation Potential of Steroids for Possible Applications in Contraception.**

K. Kim, A. Wang and K. L. Steinmetz. *SRI International, Menlo Park, CA.*

The objective of this study was to evaluate novel steroids for selective endocrine modulation potential using high-throughput in vitro screening cell-based and receptor binding systems. Steroids were tested for their potential to bind and modulate activity of the androgen receptor (AR), estrogen receptor (ER), progesterone receptor (PR), and glucocorticoid receptor (GR). For cell-based assays, a reporter gene construct of each hormone response element upstream of the luciferase reporter gene promoter was stably or transiently transfected into mammalian cells and luciferin used for light generation. Relative hormone-responsive activity was quantified by measuring light produced. In the cell-based system, the orally active androgens dimethandrolone (DMA, CDB-1321) and 11 $\beta$ -methyl-19-nortestosterone (CDB-4746) showed androgenic, progestational, anti-estrogenic, and anti-glucocorticoid activities. Their esterified prodrugs, DMAU (DMA-17 $\beta$ -undecanoate, CDB-4521) and 11 $\beta$ -methyl-19-nortestosterone 17 $\beta$ -dodecylcarbonate

(CDB-4754) were less progestational and anti-estrogenic than DMA and CDB-4746, respectively. In contrast, testosterone (CDB-0111) and testosterone 17 $\beta$ -undecanoate (CDB-3122) only showed androgenic activities. The AR binding system showed that the prodrugs have almost no receptor binding capacity compared with the parent drugs. Levonorgestrel (CDB-0107), a progestational compound used in emergency contraceptive pill, and its esterified prodrug, levonorgestrel-17 $\beta$ -butanoate (LB, CDB-1830) showed androgenic, strong progestational and anti-estrogenic, and weak anti-glucocorticoid activities. In conclusion, we have screened steroids for endocrine modulating activity. For esterified prodrugs, liberation of the parent drug by ester cleavage appears essential for biological activity. This work is supported by NICHD Contract N01-HD-9-0014.

**PS 2092 Dioxin-Produced Imprinting of Sexual Immaturity through Fixing the Status of a Reduction in the Hypothalamic Expression of Gonadotropin-Releasing Hormone.**

T. Takeda<sup>1</sup>, M. Fujii<sup>1</sup>, J. Taura<sup>1</sup>, M. Yamamoto<sup>2</sup>, M. Himeno<sup>2</sup>, Y. Ishii<sup>1</sup> and H. Yamada<sup>1</sup>. <sup>1</sup>Graduate School of Pharmaceutical Sciences, Kyushu University, Fukuoka, Japan; <sup>2</sup>Faculty of Pharmaceutical Sciences, Nagasaki International University, Sasebo, Japan. Sponsor: Y. Kumagai.

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) causes a number of disorders in reproduction and development. Our previous studies have revealed that single treatment of pregnant Wistar rat with TCDD (1  $\mu$ g/kg, orally) reduces the pituitary synthesis of gonadotropin in perinatal pups, leading to not only a reduction in gonadal steroidogenesis but also the imprinting of sexual immaturity such as defects in sexual behaviors after growing up. However, the reason why the attenuation of pituitary gonadotropin imprints sexual immaturity remains largely unknown. To address this issue, we performed a DNA microarray analysis to identify target gene the altered expression of which is linked to dioxin-induced sexual immaturity, using the hypothalami of 70 days-old male pups. The result showed that TCDD causes alterations in the expression of many genes in the hypothalamus (up: 332, down: 283). Among them, we focused on a reduction in gonadotropin-releasing hormone (GnRH) gene, because this hormone plays a pivotal role in the regulation of sexual behaviors. Further analysis indicated that a reduction in GnRH mRNA emerges from postnatal day 4 which is involved in the critical period for the brain organization/differentiation stimulated by sex-steroids. The cerebral level of GnRH protein in the pups was also reduced by maternal exposure to TCDD, although the hypothalamic content remained unchanged. Intracerebroventricular infusion of GnRH into the TCDD-exposed pups after their growing up restored many defects in sexual behaviors. These results together with our previous findings suggest that maternal exposure to TCDD impairs the maturation of GnRH neurons in the offspring by reducing steroidogenesis at fetal and neonatal stage, and this is the origin for imprinted defects in sexual behaviors at adulthood owing to a permanent reduction in GnRH expression.

**PS 2093 Bisphenol A Down-Regulates Cytochrome P45011a1 prior to Inhibiting Steroidogenesis in Mouse Antral Follicles.**

J. Peretz and J. A. Flaws. *Comparative Biosciences, University of Illinois, Urbana, IL.*

Bisphenol A (BPA) is an endocrine disrupting chemical used in polycarbonate plastic products and the epoxy resin lining of food and beverage cans. Once released from these products, BPA readily enters the body and affects physiological processes such as steroidogenesis. Previous studies in our lab have shown that exposure to BPA decreases sex steroid hormone levels in mouse antral follicles. The current study was designed to expand these findings by testing the hypothesis that BPA first decreases the mRNA expression levels of cytochrome P45011a1 (side chain cleave; *Scx*), which then leads to decreased sex steroid hormone production. To test this hypothesis, antral follicles were mechanically isolated from adult cycling mice, individually cultured in supplemented  $\alpha$ -minimum essential medium, and treated with either vehicle control (DMSO) or various concentrations of BPA (1, 10, or 100  $\mu$ g/mL). Follicles and media were collected at various time-points between 6h and 96h. Exposure to BPA10  $\mu$ g/mL and 100  $\mu$ g/mL significantly decreased progesterone levels beginning at 24h and continuing throughout culture compared to DMSO (24h:DMSO:4.86 $\pm$ 2.25; BPA10:1.62 $\pm$ 0.82; BPA100:0.95 $\pm$ 0.06 ng/mL;  $n=5-6$ ;  $p \leq 0.05$ ). Exposure to BPA10  $\mu$ g/mL and 100  $\mu$ g/mL significantly decreased androstenedione, testosterone, and estradiol levels at 72h and 96h compared to DMSO. Further, exposure to BPA10  $\mu$ g/mL and 100  $\mu$ g/mL decreased expression of *Scx* beginning at 18h and continuing throughout culture compared to DMSO. These data suggest that BPA decreases expression of *Scx* as early as 18h and that this reduction in *Scx* leads to a decrease in progesterone production by 24h, followed by a decrease in androstenedione, testosterone, and estradiol production at

later time points. Therefore, BPA exposure targets *Sec* and thus, inhibits the conversion of cholesterol to pregnenolone, resulting in the decreased sex steroid hormone levels of BPA-exposed antral follicles.

**PS 2094 Di(2-Ethylhexyl) Phthalate Alters the Expression of Phosphatidylinositol 3-Kinase Signaling Proteins Involved in Early Ovarian Folliculogenesis In Vivo.**

P. R. Hannon and J. A. Flaws. *Department of Comparative Biosciences, University of Illinois, Urbana, IL.*

Di(2-ethylhexyl) phthalate (DEHP) is a common plasticizer in consumer, building, and medical products containing polyvinyl chloride. Widespread production and use in everyday items represent a public health concern as humans are exposed to DEHP via ingestion, inhalation, and dermal contact. Large doses of DEHP harm ovarian function; however, the effects of DEHP on the ovary at environmentally relevant doses are unknown. Our group has shown that 30 day exposure to relatively low doses of DEHP accelerates recruitment of primordial follicles to the primary stage of development. Immature follicles at this stage rely on intrinsic ovarian factors and proper regulation of the phosphatidylinositol 3-kinase (PI3K) signaling pathway for primordial follicle survival, quiescence, and activation of folliculogenesis. Since DEHP accelerates primordial follicle activation, we tested the hypothesis that 30 day treatment with DEHP alters the expression of intrinsic ovarian factors, specifically those involved in the PI3K signaling pathway. To test this hypothesis, CD-1 mice (post-natal day 39) were orally dosed with tocopherol stripped corn oil (vehicle control) or DEHP (20 µg/kg/day, 200 µg/kg/day, 20 mg/kg/day, and 200 mg/kg/day) daily for 30 days. Whole ovaries and ovarian tissue with antral follicles removed were subjected to gene expression analysis by qPCR (n=4/group). In the whole ovary, DEHP increased the mRNA expression of *Kit* at the 20 µg/kg dose, and decreased the mRNA expression of *Pten* and *Foxl2* at the 20 mg/kg dose and *Kit*, *Pten*, *Rps6*, and *Tsc1* at the 200 mg/kg dose (e.g. *Tsc1* vehicle: 1.05±0.19; 200 mg/kg: 0.5±0.02; p≤0.05). In ovarian tissue with antral follicles removed, DEHP decreased the mRNA expression of *Mtorc1* at the 200 µg/kg and 20 mg/kg doses. These data suggest that DEHP alters the expression of factors involved in early folliculogenesis, specifically in PI3K signaling. Furthermore, the dysregulation of PI3K signaling could lead to adverse acceleration of early folliculogenesis. Supported by R01 ES019178.

**PS 2095 Humoral Immunity in Infant Cynomolgus Monkeys: Control Background Data.**

S. Oneda<sup>1</sup>, N. Lalayeva<sup>1</sup>, R. Watson<sup>1</sup>, N. Makori<sup>1</sup>, P. Franklin<sup>1</sup>, T. Beck<sup>1</sup>, K. Fukuzaki<sup>1</sup> and R. Nagata<sup>2</sup>. <sup>1</sup>SNBL USA, Ltd., Everett, WA; <sup>2</sup>Shin Nippon Biomedical Laboratories, Ltd., Tokyo, Japan.

**Background:** Developmental immunotoxicity (DIT) evaluations are performed to determine if the test article has an immunotoxic effect on the developing immune system. T-cell dependent antibody response (TDAR) to keyhole limpet hemocyanin (KLH) is one of the methods to assess DIT in the nonhuman primate. Differences in KLH-specific IgM and IgG responses within animal age and animal origin were evaluated in infant cynomolgus monkeys (*Macaca fascicularis*, hereafter Cynos).

**Methods:** KLH was administered by intramuscular injection to infant Cynos twice. The initial KLH injection (1st dose) occurred postnatal days (PND) 90, 120, 180, or 270. The second KLH injection (boost, 2nd dose) occurred 2 to 3 months after the 1st dose (PND180, 180, 240, and 330, respectively). The origins of the Cynos were Indonesian (Island, IL) and Cambodian (Mainland, ML). Serum samples were obtained prior to each KLH injection and once weekly for 4 weeks following each KLH injections. KLH-specific serum IgM and IgG levels were measured using ELISA methods.

**Results:** IgM elevated rapidly after the 1st and 2nd doses. The highest IgM in IL (69.2 and 73.6 µg/mL after the 1st and 2nd doses, respectively) was 24-27% lower than ML (95.2 and 96.4 µg/mL). IgG elevated gradually after the 1st dose but rapidly after the 2nd dose. The highest IgG after the 1st dose in IL (34.5 µg/mL) was 24% lower than ML (45.2 µg/mL). After the 2nd dose, the highest IgG in IL (1339.7 µg/mL) was 39% higher than ML (941.7 µg/mL). The profiles (patterns) of IgM and IgG were similar between IL and ML. IgM was clearly low on PND90/180 group when compared with PND120/180 while IgG was comparable. There were no notable differences in IgM and IgG between PND120/180 and PND180/240 groups. Both IgM and IgG were highest in PND270/DB330 group at most time points.

**Conclusion:** There were no remarkable differences in TDAR results between animal origins. It is recommended that TDAR assessment be conducted in 4 month or older infants.

**PS 2096 Bisphenol A Treatment of Cultured Mouse Ovarian Antral Follicles May Affect the Aryl Hydrocarbon Receptor Signaling Pathway.**

A. Ziv-Gal, Z. R. Craig, W. Wang and J. A. Flaws. *Comparative Biosciences, University of Illinois, Urbana, IL.*

Bisphenol A (BPA) is a commonly used plasticizer in the manufacture of polycarbonate plastics. Previous studies indicate that BPA exposure has toxic effects on the female reproductive system. For example, BPA (50-100 µg/ml) inhibits growth and steroidogenesis in cultured adult mouse antral follicles. Nevertheless, not much is known about the underlying mechanism. The aryl hydrocarbon receptor (AHR) is a ligand activated transcription factor that regulates cellular processes in the ovary including transcriptional activation of cytochrome P450, family 1, subfamily B, polypeptide 1 (*Cyp1b1*). Interestingly, previous studies have shown that *in-utero* BPA treatment alters expression levels of AHR signaling pathway related genes in mouse embryonic ovaries. Hence, our current study was designed to examine whether the toxic effects of BPA observed in adult mouse antral follicles are mediated by the AHR signaling pathway. We hypothesized that BPA treatment of cultured adult mouse antral follicles alters expression levels of *Ahr*, aryl hydrocarbon receptor nuclear translocator (*Arnt*), aryl hydrocarbon receptor repressor (*Ahrn*), and *Cyp1b1*. To test this hypothesis, we mechanically isolated antral follicles from mouse ovaries (C57BL/6) and cultured them in vehicle control or BPA (0.001-50 µg/mL) for 24 and 96 hours. At the end of the cultures, follicles were further processed for gene expression analyses. Our results indicate that at 24 hours, BPA 50 µg/mL treatment significantly decreased *Ahrn* and *Cyp1b1* expression levels compared to the control group (p≤0.05). At 96 hours, BPA treatment (0.001-10 µg/mL) did not alter expression levels of any of the examined genes compared to the control group. These data suggest that relatively low doses of BPA do not affect the expression levels of selected AHR related genes. A high dose of BPA (50 µg/mL) may affect the expression of selected genes in the AHR signaling pathway as early as 24 hours. Supported by: NIH ES019178 (JAF), NIH K99ES021467 (ZRC), the Environmental Toxicology Scholar Program (WW, AZG).

**PS 2097 Oral Two-Generation Reproduction Toxicity Study with Synthetic Amorphous Silica, NM200 in Wistar Rats.**

A. Wolterbeek<sup>1</sup>, S. Schneider<sup>2</sup>, R. Landsiedel<sup>2</sup>, D. de Groot<sup>1</sup>, I. Waalkens<sup>1</sup>, M. Wouters<sup>3</sup>, R. van Ee<sup>3</sup> and H. van de Sandt<sup>1</sup>. <sup>1</sup>TNO, Zeist, Netherlands; <sup>2</sup>BASF, Ludwigshafen, Germany; <sup>3</sup>TNO, Eindhoven, Netherlands. Sponsor: R. Woutersen.

Safety assessments must complement the technological progress in engineering of new nanomaterials.

Although the current test guidelines on developmental and reproductive toxicity are generally able to determine hazards, their specific application to nanomaterials needs to be evaluated. The results of a two-generation reproduction toxicity study (OECD 416) with NM200 are presented here.

Male and female Wistar Han rats (28 per group) were treated by oral gavage with NM-200 (supplied by Joint Research Centre, Italy) at dose levels of 0, 100, 300 and 1000 mg/kg body weight/day for two consecutive generations (premating 10 weeks, mating 2 weeks, gestation and lactation 3 weeks each). The nanostructured material was tested 'as delivered' and aggregates were not artificially broken down. The nanomaterial particle size distribution was characterized. Body weight and food consumption were measured regularly. Reproductive (including estrus cycle evaluation and sperm analysis) and developmental (including sexual maturation) parameters were measured and at sacrifice (reproductive) organs and tissues were sampled for histopathological analysis.

Oral administration of synthetic amorphous silica, NM-200 up to 1000 mg/kg bw/day had no adverse effects on the reproductive performance of rats or on the growth and development of the offspring into adulthood for two consecutive generations.

The systemic distribution of the silica particles will be studied in various target organs of F1-generation animals, both by chemical analysis and by electron microscopy. Measurement of uptake and organ burdens could be valuable additions to OECD standard test guidelines when applied to the hazard assessment of nanomaterials.

This study was sponsored by CEFIC (LRI-N3 project) and monitored by Monika Maier, Evonik Industries AG, Hanau, Germany on behalf of ASASP a CEFIC Sector group.

**PS 2098 Toxicological Profile and Tolerability of Pixantrone (Pixuvri) in Newborn Mice Comparative Study with Doxorubicin (DOX).**

A. M. Giusti<sup>1</sup>, P. A. Colombo<sup>1</sup>, M. Longo<sup>1</sup>, P. Della Torre<sup>1</sup>, A. Morisetti<sup>2</sup>, C. Allievi<sup>2</sup> and J. Singer<sup>3</sup>. <sup>1</sup>Accelera, Nerviano Milano, Italy; <sup>2</sup>CTI Advisor, Milano, Italy; <sup>3</sup>Cell Therapeutics, Seattle, WA.

Pixuvri at the doses of 15 and 27 mg/kg/day was given intraperitoneally to juvenile mice on Post Natal Days 10, 13, 17, 20, 35, 39 and 42 to assess its toxicological profile. Particularly, heart, bone marrow, liver and kidneys toxicity was evaluated for early and late onset.

DOX at 3 mg/kg/day was given as a comparator. Animals were sacrificed at the end of treatment and after 4- or 8-week of observation (DOX terminated after 4-week). Pixuvri up to 27 mg/kg/day was better tolerated than DOX at a dosage nine times lower (3 mg/kg/day) DOX induced a marked reduction in bodyweight gain and a cumulative mortality higher than 50% in pups, survivors being however sacrificed pre-term due to severe decay of their health conditions. Bone marrow toxicity was comparable between Pixuvri at low dose and DOX, whereas more pronounced effects were observed with Pixuvri 27 mg/kg/day, but recoverable after 4 or 8 weeks off-dose. Pixuvri was measurable in plasma up to 2 and occasionally to 6 h. after administration. After repeated treatments C<sub>max</sub> and AUC increased proportionally with the dose and no accumulation was seen. No significant gender difference was observed. Toxicity to thymus and reproductive organs was observed with both test items while no nephro- or hepatotoxicity was detected. Cardiotoxicity was negligible up to 27 mg/kg/day of Pixuvri in females, and quoted as minimal in high dose males at 4- and 8-week of recovery. The cardiotoxicity of DOX, assessed at the end of treatment and 4-week after, was lower than that of Pixuvri, although a significant reduction in heart weight was observed at the end of treatment sacrifice. Notably, for DOX it was not possible to assess the onset and severity of cardiotoxicity at the last timepoint of 8-week, that is definitely the most indicative of late cardiotoxicity. In conclusion, Pixuvri was better tolerated than DOX in newborn and young animals, all reaching adulthood, suggesting Pixuvri as a possible alternative to DOX for pediatric use.

**PS 2099 Murine Uterine Receptivity Markers Are Affected by Particulate Air Pollution in a Dose Response Manner.**

K. R. Castro<sup>1</sup>, G. Ribeiro Jr<sup>1</sup>, M. Peres<sup>1</sup>, P. Saldiva<sup>1</sup>, M. Matsuda<sup>2</sup> and M. M. Veras<sup>1</sup>. <sup>1</sup>Pathology - LIM05, University of São Paulo, São Paulo, Brazil; <sup>2</sup>Oftalmology - LIM33, University of São Paulo, São Paulo, Brazil. Sponsor: S. Barros.

It is of concern that exposure to air pollutants (AP) negatively affects reproductive function. Recently, we observed that AP is associated with increased rates of implantation failures (IF) in mice. The uterus requires a subtle collaboration of a variety of factors including: cytokines (LIF), adhesion and antiadhesion (MUC-1) molecules and hormonal induced morphological changes (e.g. decidualization, epithelial changes) to become receptive. The aim of this study was to investigate if increased IF due to chronic exposure to PM<sub>2.5</sub> could be related to changes in uterine receptivity. To test this, female mice (n=10/group) were continuously exposed (45 days) to either filtered air (AF) or 2 different daily exposure doses of concentrated ambient particles (600 and 1200 µg/m<sup>3</sup> of PM<sub>2.5</sub>). Estrous cyclicity was evaluated 2 weeks before mating and at 4.5 dpc females were euthanized and the following outcomes were evaluated: ovarian and uterine weight, number of corpora lutea, uterine histopathology and LIF and MUC-1 expression by qPCR and immunohistochemistry. We observed that the effects are dose dependent, being more pronounced in the higher dose. Results have shown that estrous cyclicity is affected by a reduction in the duration of the cycle accompanied by an extended diestrus. Ovarian weights are increased but there was no significant change in the number of CL. The histopathological evaluation of the uterus indicated a decrease in the volume and thickness of the endometrium. In both exposed groups, increased diameter and thickness of the glandular and luminal epithelium were seen. No significant alteration was observed in the expression of MUC-1 but there was significant suppression of LIF during the implantation window. In conclusion, exposure to PM<sub>2.5</sub> could have significant negative effects on endometrial receptivity by affecting the fine regulation of proliferation and differentiation (decidualization) of uterine cells mediated by LIF expression.

**PS 2100 Functional Assessment of Sexual Maturity in Female Cynomolgus Monkey (*Macaca fascicularis*).**

C. Luetjens and G. F. Weinbauer. Covance Laboratories GmbH, Muenster, Germany.

Selection of suitable criteria for assessing sexual maturity in the female long-tailed macaque (*Macaca fascicularis*) has yielded conflicting results. The present retrospective work investigates whether the presence of two consecutive menstrual bleedings hallmarks complete sexual maturation. Daily vaginal swabs were collected from 1175 Asian and 660 Mauritian origin animals and the records were used to assess the ovarian cycle pattern and seasonality. Animals were housed socially. The swabs were rated from no to heavy menstruation. Menstrual cycle length was categorized (C1, C2, and C3) depending on the cycle length difference between consecutive cycles to distinguish normal cycling females from females with prolonged cycle length. Data from 12446 cycles, comprising 1-38 cycles/animal were correlated with animal age and body weight. Mean cycle duration was 32.4 days. No seasonal differences were detected. The bleeding length for Mauritian animals (median 2.9 days) was significantly longer than for the Asian animals (median 2.6 days) and the bleeding severity differed also significantly (Mauritian animals: median 3.0; Asian animals: median 2.5). Among the 1835 females under study, 784 had single prolonged cycles and were in the category C2 or C3 whereby the Asian animals had three times more prolonged cycles. At arrival at our facility the average Mauritian origin animals were significantly heavier ( $3.75 \pm 0.62$  kg) than the Asian females ( $n=3.25 \pm 0.58$  kg) although the Asian animals were significantly older ( $4.74 \pm 1.18$  years) compared to Mauritian animals ( $4.01 \pm 0.58$  years). This investigation indicates that the onset of sexual maturity is different depending on female cynomolgus monkey origin. However, cycle lengths of the majority of cynomolgus monkeys appeared rather consistent and the cycle category was predictable. This information has to be taken into consideration in the planning phase of studies under the ICH guideline S6(R1) (ICH, 2011) in which the use of sexually mature animals have become part of toxicity studies.

**PS 2101 Air Pollution Accelerate Atherosclerosis Progression on Predisposed Mice.**

M. Peres<sup>1</sup>, K. R. Castro<sup>1</sup>, N. Costa<sup>1</sup>, G. Ribeiro Jr<sup>1</sup>, F. César<sup>2</sup>, M. Cavalcante<sup>2</sup>, D. Abdalla<sup>2</sup>, P. Saldiva<sup>1</sup> and M. M. Veras<sup>1</sup>. <sup>1</sup>Pathology, University of São Paulo, São Paulo, Brazil; <sup>2</sup>Toxicology, University of São Paulo, São Paulo, Brazil. Sponsor: S. Barros.

Exposure to urban particulate air pollution is linked to cardiovascular diseases including atherosclerosis. In this study we investigated if gestational (G) and/or post-natal (P) exposure to PM<sub>2.5</sub> is associated with aortic plaque formation in susceptible individual. LDLr<sup>-/-</sup> mice were exposed during pregnancy to either filter or polluted air (daily exposure dose=600 µg/m<sup>3</sup> of PM<sub>2.5</sub>) using a Harvard Particle Concentrator. After weaning, male pups were subdivided and 4 groups were formed according to the exposure period (G or PN). No hypercholesterolemic diet was given to the animals. After 20 weeks of exposure, we assessed non-invasively the size of atherosclerotic plaque (AP) in the aortic arch by ultrasound biomicroscopy. Then, aortic roots were collected and the expression of genes involved in plaque formation and progression was assessed by qPCR (VCAM, ICAM, PCAM, IL-1β, IL-6, IL-10, INFγ, MCP-1, CD36, MMP-1, MMP-9, TIMP-1 and TIMP-2). Birth weight was reduced in animals exposed to PM<sub>2.5</sub> during G period (less 11%). Groups exposed to PM<sub>2.5</sub> presented greater AP areas and there was an interaction effect ( $p<0.001$ ) between G and P exposures and the size the plaque ( $r=-0.43$ ,  $p<0.01$ ). Expression of IL-1β and IL-6 (proatherogenic cytokines) were higher in exposed groups and IL-10 expression (antiatherogenic cytokines) was reduced. Expression of adhesion molecules and genes involved in plaque destabilization were reduced (VCAM, MMP2, TIMP1 and 2). In most of the cases differences in genes expression were associated with G exposure to PM<sub>2.5</sub> but there were also interaction effects with P exposure. For other genes no differences were observed. Results demonstrate how environmental pollution can negatively influence intrauterine environment, impair fetal development and along with postnatal chronic exposure predispose susceptible individuals to atherosclerotic plaque formation later in life. Imbalance between pro- and anti-inflammatory cytokines might account for the progression of atherosclerosis due to PM<sub>2.5</sub> exposure.

**PS 2102 Brominated Diphenyl Ether-47 Induces Oxidative Stress-Stimulated Pro-Inflammatory Pathways in Human Extravillous Trophoblasts.**

H. Park and R. Loch-Carus. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Preterm birth is associated with significant infant morbidity and mortality. Although the etiology of preterm birth is not fully determined, critical roles of oxidative stress and inflammation are implicated. Polybrominated diphenyl ethers (PBDEs) are widely used flame retardant compounds. Brominated diphenyl ether (BDE)-47 is one of the most prevalent PBDE congeners found in human breast milk, serum and placenta. Despite the presence of PBDEs in human placenta, the effects of PBDEs on pregnancy are poorly understood. The present study investigated BDE-47-induced oxidative stress and the role of oxidative stress on BDE-47-stimulated pro-inflammatory responses in a human extravillous trophoblast cell line, HTR-8/SVneo. HTR-8/SVneo cells were exposed to 5, 10, 15 and 20  $\mu$ M BDE-47 for 4 h and reactive oxygen species (ROS) generation was measured using the dichlorofluorescein (DCF) assay. Inhibition of ROS formation was measured after pre-treatment for 1 h with deferoximine (DFO), an iron-chelating antioxidant. To determine oxidative stress-mediated activation of inflammatory pathways by BDE-47, HTR-8/SVneo cells were pretreated with 1 mM DFO for 1 h prior to BDE-47 treatment for 24 h, or co-treated with 100  $\mu$ M ( $\pm$ )- $\alpha$ -tocopherol for 24 h. Cytokine release was analyzed by enzyme-linked immunosorbent assay. Treatment of HTR-8/SVneo cells with 15 and 20  $\mu$ M BDE-47 increased DCF fluorescence compared with solvent controls, indicating increased ROS formation. When cells were pretreated with DFO, BDE-47-stimulated DCF fluorescence was decreased. Pre- or co-treatment with DFO and ( $\pm$ )- $\alpha$ -tocopherol prevented BDE-47-induced interleukin-6 release. These data indicate that BDE-47-induced cytokine release in HTR-8/SVneo cells depended on ROS formation. Because inflammation occurring at gestational tissues during pregnancy has been associated with preterm birth, further research is needed to ascertain potential relevance of these findings to pregnancy and preterm labor.

**PS 2103 One-Generation Reproduction Study of Isobornyl Acetate in Rats, with an Evaluation through Sexual Maturity in the F1 Generation.**

V. T. Politano<sup>1</sup>, E. M. Lewis<sup>2</sup>, A. M. Hoberman<sup>2</sup>, R. M. Diener<sup>3</sup> and A. Api<sup>1</sup>.  
<sup>1</sup>Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ; <sup>2</sup>Charles River Laboratories, Horsham, PA; <sup>3</sup>Argus International, Inc., Horsham, PA.

Isobornyl acetate, a widely used fragrance ingredient, was administered to male and female rats (25 rats/sex/dose) at dosages of 0, 30, 100, and 300 mg/kg/day. Administration via gavage of the test material or the vehicle, corn oil, began before the cohabitation period (83 days for males; 14 days for females), through cohabitation (maximum 14 days), until the day before sacrifice (males) or day 25 of presumed gestation (females that do not deliver) or day 22 of lactation. F1 generation rats selected for continued evaluation were sacrificed on day 60 ( $\pm$  3) postpartum. There were no treatment-related deaths at any dosage level tested. Excess salivation was observed in P generation male rats at 300 mg/kg/d and P generation females at 100 and 300 mg/kg/d. Mean body weights, body weight gains and feed consumption values were comparable among the dosage groups. There were 23, 22, 24, and 22 pregnant rats in the four dosage groups; all pregnant rats delivered litters. All natural delivery and litter observations were comparable. There were no treatment-related clinical signs, gross lesions or changes in body weight, body weight gains, feed consumption, or organ weights in the male and female F1 generation rats at any dosage level tested. Sexual maturation was unaffected in the F1 generation. Based on the results of this study, the no-observable-adverse-effect-level (NOAEL) for toxicity of isobornyl acetate is 300 mg/kg/day. The reproductive NOAEL in the P generation rats and the NOAEL for viability and growth of the F1 generation offspring is greater than or equal to 300 mg/kg/day. This dose is 2000 times greater than the conservatively calculated exposure (assuming 100% dermal absorption) to isobornyl acetate from fragrance use.

**PS 2104 Di (2-Ethylhexyl) Phthalate Is Not Genotoxic to Oocytes, but May Induce Apoptosis in Two-Cell Zygotes.**

S. Vargas-Marín, L. Vega, M. Solís-Heredia, B. Ramos-Robles, B. Quintanilla-Vega and I. Hernández-Ochoa. *Department of Toxicology, Cinvestav-IPN, Mexico City, Mexico.*

Di (2-ethylhexyl) phthalate (DEHP) is a phthalate found in food packaging, toys, medical equipment, among others. DEHP decreases the fertile capacity of the oocyte by interfering with its progression through meiosis and impairing embryo

development. Since DEHP is genotoxic to different cell types, we suggest that the decrease in the fertile capacity of the oocyte is also attributed to the genotoxic effect of DEHP. This study evaluated whether in vivo exposure to DEHP causes DNA damage in oocytes, and if this damage persists in the zygote. Female CD1 mice (n = 6 per group) were exposed orally to DEHP (20, 200 and 2000 mg/kg/d) or vehicle (corn oil tocopherol-stripped) every 24 h for 3 estrous cycles. The minimal dose of DEHP was based on the reference dose established by the Environmental Protection Agency (EPA). 5-fluorouracil (1  $\mu$ M) was used as positive control. Following treatments, mice on estrus received equine chorionic gonadotropin hormone (eCG; 5 IU) ip, 48 h later mice received hormone human chorionic gonadotropin (hCG; 5 IU) and 16 h post-hCG mice were either euthanized to collect eggs or bred with a fertile proved male mouse to collect zygotes. Oocytes were incubated with hyaluronidase to remove cumulus cells and then with Tyrode solution to remove the zona pellucida. Denuded oocytes were used to evaluate viability by staining with propidium iodide/Hoechst 33342 and DNA damage by comet assay. Viability was expressed as percentage live cells and DNA damage was assessed as the Olive Tail Moment (OTM). No significant differences in viability or OTM were observed among groups. Two-cell zygotes from mice exposed to 2000 mg/kg/d DEHP were used to assess the induction of micronuclei (MN) by staining with Hoechst 33342. DEHP did not induce MN in the zygote, however, intra-cytoplasmic prolongations resembling cell death by apoptosis were observed. These data suggest that DEHP is not genotoxic to oocytes, but it could elicit apoptosis in two-cell zygotes and thus contribute to reduced fertility. Conacyt-Mexico CB-167678.

**PS 2105 Inhaled Ambient Particulate Matter Induces Preterm Birth and Low-Birth Weight in a Mouse Model of Pregnancy.**

J. L. Blum, L. Chen and J. T. Zelikoff. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Recent epidemiologic evidence has linked exposure to elevated levels of particulate matter (PM) in air pollution to preterm birth (PTB), low birth weight (LBW), and small for gestational age babies. However, several questions remain unanswered including mechanisms of action (MOA), gestational windows of vulnerability, and most active PM size and composition. To begin to better understand how PM exposure impacts fetal development, timed-pregnant B<sub>6</sub>C<sub>3</sub>F<sub>1</sub> mice were exposed whole body from gestational day (GD) 0.5 (morning of confirmed breeding) through GD17.5 to concentrated PM<sub>2.5</sub> (CAPs, at 15-times of ambient concentration) at our site in Tuxedo, NY or to filtered air (FA) for 6hr/day, 7days/wk. The daily average CAPs concentration throughout exposure was 163.8  $\pm$  99.6  $\mu$ g PM/m<sup>3</sup>. Based on EPA standards for PM<sub>2.5</sub> of 35  $\mu$ g/m<sup>3</sup>/24 hr, our 24 hr time-weighted average (i.e., 6.8  $\mu$ g/m<sup>3</sup>) is relevant for many U.S. urban centers. Exposure to CAPs in this study reduced the duration of gestation by 0.5 days (compared to FA controls), which is comparable to a 1 wk decrease in human pregnancy bringing birth close to the PT category (i.e., <37 wk). Concomitant with the observed PTB were both an 11.4% decrease in birth weight and 2.5% decrease in crown-to-rump length (CRL) at birth and at postnatal day 1. Neonates born to CAPs-exposed dams remained lighter than their filtered-air counterparts through the 21 days of nursing, though daily rates of weight gain were equal to that of FA controls. Exposure to airborne PM had no effect on conception rate, maternal weight gain during pregnancy, offspring anogenital distance, or sex ratio compared to FA control. These studies are the first to provide biological plausibility for the epidemiologic evidence demonstrating an association between PM exposure and PTB/LBW. The same recently-developed mouse model will be used in future studies to determine MOA and PM sensitive gestational "windows" of vulnerability. Supported by March of Dimes and NIEHS NYU Center ES000260.

**PS 2106 In Utero Exposure to Bisphenol A Increases Germ Cell Apoptosis in the Neonatal Mouse Ovary.**

W. Wang, Z. R. Craig, J. Peretz and J. A. Flaws. *Comparative Bioscience, University of Illinois, Urbana, Urbana, IL.*

Bisphenol A (BPA) is a known endocrine disruptor that is widely used as a synthetic plasticizer to harden polycarbonate plastics and epoxy resin. However, BPA can leach from plastic products into the food and water of consumers, leading to human exposure to BPA on a daily basis. The objective of this study was to examine the effects of prenatal BPA exposure on early ovarian development in mice. Pregnant dams (6 per treatment group) were orally dosed with tocopherol stripped corn oil (vehicle control) or BPA (0.5 and 50  $\mu$ g/kg/day) daily starting on gestation day 11 and continuing throughout pregnancy. After birth, neonatal ovaries were collected and subjected to histological evaluations and gene expression analyses. Our results show that the selected doses of BPA affected ovarian development differently. Specifically, compared to vehicle controls, BPA 0.5  $\mu$ g/kg/day treatment increased the number of healthy germ cells present in germ cell nests and increased

the number of primordial follicles, suggesting that BPA at this dose prevents apoptosis of germ cells, which is critical for the formation of the primordial pool. In contrast, BPA 50 µg/kg/day significantly increased the numbers of apoptotic germ cells, indicating BPA at this dose might accelerate germ cell apoptosis. To explore why the selected doses of BPA affect early ovarian development differently, we compared the expression of various apoptotic factors in the treatment groups. BPA 0.5 µg/kg/day increased the expression of the pro-apoptotic factor Bad and selected anti-apoptotic factors (Mcl-1, Bcl21), and the ratio of Bcl2/Bax, but decreased the expression of the pro-apoptotic factor Bik. In contrast, BPA 50 µg/kg/day significantly increased the expression of the pro-apoptotic factor Bak1. Collectively, these data suggest that in utero exposure to BPA affects early ovarian development, but that selected doses of BPA affect ovarian development differently. Supported by: NIH T32ES007326 (WW), NIH P20ES018193 (JAF), NIH K99ES021467 (ZRC).

**PS 2107 Enhanced Pre-Postnatal Toxicity Study of AMG 162 Administered by SC Injection to Pregnant Cynomolgus Monkeys with up to 6-Months Postnatal Evaluation.**

J. L. Bussiere<sup>1</sup>, R. Boyce<sup>1</sup>, I. Pyrah<sup>1</sup>, D. Branstetter<sup>2</sup>, M. Loomis<sup>1</sup>, C. Farmin<sup>3</sup>, L. Chouinard<sup>4</sup>, G. Elliott<sup>5</sup>, A. Varela<sup>4</sup> and G. Chellman<sup>5</sup>. <sup>1</sup>Amgen Inc., Thousand Oaks, CA; <sup>2</sup>Amgen Inc., Seattle, WA; <sup>3</sup>Genentech Inc., S. San Francisco, CA; <sup>4</sup>Charles River -PCS, Montréal, QC, Canada; <sup>5</sup>Charles River -PCS, Reno, NV.

AMG 162 is a fully human IgG2 monoclonal antibody that inhibits bone resorption by targeting RANKL, an essential mediator of osteoclast formation, function, and survival. Monthly SC injection of pregnant cynomolgus monkeys with 0 or 50 mg/kg AMG 162 from ~GD20 until parturition resulted in test article-related effects on the pregnant females and their offspring. In the pregnant females, there were reductions in biomarkers of bone turnover, increased stillbirths, one instance of dystocia, and one stillbirth following maternal signs of hypocalcemia. Lactation, mammary gland histomorphology, and fetal growth were comparable in controls and the AMG 162 group. In infants exposed in utero, there was increased postnatal mortality, decreased body weight gain, decreased growth/development, and decreased biomarkers of bone turnover from birth to 10 weeks of age. AMG 162-related effects in infants were present in bones (osteoclast hypoplasia, nonproliferative hyperostosis, physal hypertrophy, and decreased marrow space), normally erupted teeth (dysplasia and malalignment), lymph nodes (most absent), and in multiple tissues (extramedullary hematopoiesis). Signs of infection in multiple tissues were detected in 3 infants that underwent unscheduled necropsy. In infants necropsied at 6 months of age, there was full recovery from all bone-related changes observed earlier postpartum with some AMG 162-related effects persisting (absent/decreased size of lymph nodes, extramedullary hematopoiesis, dental dysplasia). One AMG 162-exposed infant, in which there had been recovery from pharmacological effects, had minimal to moderate mineralization of multiple tissues. In general, the effects observed in mothers and infants were consistent with the pharmacological action of AMG 162.

**PS 2108 Impact of Feed Choice When Performing Generational Reproduction Studies.**

A. Milius, R. Read, J. Waldschmidt and D. Dandekar. *Toxicology, Xenometrics, Stilwell, KS.*

The selection of an appropriate lab diet is extremely important for reproduction (repro) studies. In our lab, Purina Mills (PM) Rodent Diet 5002 has been the standard feed for all rodent repro studies for over 22 years. Our lab has not veered from this diet as a strong historical control exists with its utilization. A new diet, Harlan Teklad® (HT) Global 16% Protein Rodent Meal 2016CM, was recently introduced for use in an extended one-generation study. This feed was recommended by the supplier based on its use in other labs for repro studies and it meets the qualifications stated in guidelines of the Endocrine Disruptor Screening Program. Per guidelines, the Genistein-equivalent content of genistein plus daidzein (aglycone forms) of each batch of feed must be ≤ 300 µg/g vs. ~300 – 550 µg/g in the standard diet used in the past studies. During the delivery phase of the study, an increased incidence of pup mortality was noted in all groups including the control group. An increased incidence of pups with no milk in their stomach was also noted in all groups. Upon further evaluation, it was discovered that the feed was occluding the nostrils of many of the pups, thereby interfering with the suckling process. The general physical appearance of the HT feed was very similar to the PM, so feed-related differences due to physical form were not anticipated. However, after discovering the cause of mortalities relating to the feed, it was then noted that the texture of this feed was much finer (similar to talcum powder). Therefore, while a specific feed may be suitable for many repro & developmental study types, the same feed may not be suitable for those study types where offspring are reared. While the HT may be an excellent feed source for many repro & developmental study types, we did not consider this feed type to be suitable for our one-generation study.

Although, our findings are based on one experience in our lab, our findings demonstrate that a cautious approach should be taken when making changes in study design as any changes can be crucial to study outcome and interpretation of results.

**PS 2109 In Vitro Exposure to Di-n-Butyl Phthalate (DBP) Decreases the Expression of Cell Proliferation Transcripts in Cultured Mouse Ovarian Antral Follicles.**

Z. R. Craig, T. DelValle, W. Wang and J. A. Flaws. *Comparative Biosciences, University of Illinois, Urbana, IL.*

Di-n-butyl phthalate (DBP) is commonly found in consumer products such as plastics, cosmetics, insecticides and oral medications. We have shown previously that DBP (1000 µg/mL) inhibits growth and causes death of mouse antral follicles treated in vitro. Furthermore, we have shown that DBP may do so by altering the expression of important cell cycle regulators and causing an imbalance in the expression of key members of the *Bcl2* family, markers for the intrinsic apoptotic pathway. However, no studies have evaluated the effects of DBP on other cell proliferation markers or the extrinsic apoptotic pathway. The purpose of this study was to further investigate the mechanisms by which DBP inhibits follicle growth and causes antral follicle death. We hypothesized that DBP decreases the expression of cell proliferation genes such as *Mki67*, *Pcna*, and *Igf1*, and also increases the expression of *Fas*, a marker for the extrinsic apoptotic pathway. To test our hypothesis, antral follicles were isolated from adult CD-1 mice (32-37 days old) and individually exposed (n= 8-12/culture) to DBP (1-1000 µg/mL) or vehicle (dimethylsulfoxide, DMSO) for 24 h. Following culture, follicles were subjected to qPCR analysis for the expression of *Mki67*, *Pcna*, *Igf1*, and *Fas*. DBP treatment (100 and 1000 µg/mL) decreased the expression of *Mki67* and *Igf1* compared to control follicles (p<0.05). DBP treatment did not alter the levels of *Pcna* transcript when compared to control follicles, while *Fas* mRNA was undetectable in all treatment groups. Decreased expression of the cell proliferation genes *Mki67* and *Igf1* further supports that DBP-induced inhibition of antral follicle growth involves a defect in follicular cell proliferation. Also, undetectable *Fas* suggests that the extrinsic apoptotic pathway may not be involved under these conditions. Supported by NIH grants K99ES021467 (ZRC), R01ES019178 (JAF), T32ES007326 (WW) and the Billie Field Fellowship in Reproductive Biology (WW).

**PS 2110 Evaluating Benzo[a]pyrene Effects on Steroidogenesis and Reproduction.**

E. T. Booc<sup>1</sup>, C. Thornton<sup>1</sup>, X. Fang<sup>1</sup>, A. Lister<sup>2</sup>, D. MacLachy<sup>2</sup> and K. L. Willett<sup>1</sup>. <sup>1</sup>Pharmacology, University of Mississippi, University, MS; <sup>2</sup>Biology, Wilfrid Laurier University, Waterloo, ON, Canada.

Benzo[a]pyrene (BaP) is a polycyclic aromatic hydrocarbon (PAH) that has been implicated in modulating aromatase enzyme function. This effect has potential to interrupt normal reproductive function by causing imbalances in homeostatic androgen and estrogen levels. The aim of this study was to use a fish model, *Fundulus heteroclitus*, in order to assess whether BaP caused a significant change in steroid concentrations that could negatively alter additional reproductive biomarkers. Adult fish were exposed to waterborne BaP concentrations of (0, 1 or 10 µg/L) for 28 days. Males and females were combined for the second half of the exposure (days 14-28) in order to quantitate egg production and fertilization rates. BaP exposure did significantly reduce male gonad somatic index (GSI) and egg fertilization at 10 µg/L. Testosterone concentrations in males were significantly reduced at the high BaP dose averaging only 355 pg/mL plasma versus 2510 pg/mL in the controls. Also, estradiol concentrations in the females were significantly reduced at 1 and 10 µg/L BaP averaging 4070 and 3350 pg/mL plasma respectively compared to 7540 pg/mL plasma in the controls. Sperm concentrations, egg production, male liver somatic index (LSI), and female GSI and LSI were not altered. BaP exposure at these environmentally relevant concentrations caused negative alterations to both molecular and phenotypic biomarkers associated with reproduction. Our next goal is to assess if these parental effects will cause permanent changes in subsequent generations of progeny. (Supported by NIEHS R03 ES018962)

**PS 2111 Comparison of Estrogen Mixtures In Vitro vs In Vivo.**

B. Hannas, J. R. Furr, L. E. Gray and V. S. Wilson. *RTB, US EPA, Research Triangle Park, NC.*

Numerous sources contribute to widespread contamination of drinking water sources with both natural and synthetic estrogens, which is a concern for potential ecological and human health effects. In vitro screening assays are valuable tools for identifying mechanisms of toxicity but in vitro results cannot be directly extrapolated to in vivo exposures since most in vitro assays do not account for metabolism,

distribution and excretion or other systemic toxicities. In this study, we highlight some of the limitations associated with using *in vitro* estrogen transcriptional activation assays for predicting *in vivo* action of xenoestrogens. In particular, we compared the ability to predict the uterine growth response (uterotrophic assay, UA) to estrogens, administered to the rat orally either individually or as mixtures, using an *in vitro* estrogen transcriptional activation (TA) assay (T47D-kbluc cell line). We demonstrated that a binary mixture of bisphenol-AF (BPAF) + Methoxychlor in the UA conforms to dose additive (DA) estrogenicity, whereas the degree of estrogenicity of this mixture is underestimated by the TA assay. In contrast, the TA assay responded to a binary mixture of benzylbutyl phthalate (BBP) + BPAF in a DA manner, whereas, the UA displayed no estrogenic response to this mixture. These data illustrate the limitations associated with making *in vivo* predictions based on *in vitro* assay data for compounds that are metabolically inactivated *in vivo* in the liver, gut or other tissues or activated by the liver *in vivo*. Ongoing efforts related to this study include characterizing individual dose response curves and mixture estrogenicity for additional estrogens *in vitro* and *in vivo*. These data will be used to make predictions from the *in vitro* assay to the *in vivo* response to exposure to the compounds. This information is critical for valid interpretation of *in vitro* screening assay results. Disclaimer: Abstract does not necessarily reflect U.S.EPA policy.

**PS 2112 Bisphenol A May Affect the Fertilizing Ability of Mouse Oocytes via Mechanisms Involving Events from Sperm Penetration into the Oocyte to Formation of 1-Cell Zygote.**

B. Ramos-Robles<sup>1</sup>, M. Sánchez-Gutiérrez<sup>2</sup>, S. Vargas-Marín<sup>1</sup>, D. Acuña-Hernández<sup>1</sup>, B. Piña-Guzmán<sup>3</sup> and I. Hernández-Ochoa<sup>1</sup>. <sup>1</sup>Department of Toxicology, Cinvestav-IPN, Mexico City, Mexico; <sup>2</sup>Instituto de Ciencias de la Salud, UAEH, Pachuca, Mexico; <sup>3</sup>Departamento de Bioprocesos, UPIBI-IPN, Mexico City, Mexico.

The cumulus cells surrounding the oocyte expand before ovulation to allow oocyte maturation, and to facilitate sperm cell to penetrate the oocyte. It has been demonstrated that bisphenol A (BPA), a plasticizer that leaches from plastics into food and water, alters the expansion of cumulus cells. Since we have shown that BPA decreases the ability of oocytes, surrounded by cumulus cells, to be fertilized by sperm cells, this study examined whether BPA affects the fertilizing ability of oocytes through effects on cumulus cells, oocyte penetrability by sperm cells or zygote development to 8-cell stage. Female C57BL/6J mice (n = 6-8 per group) were exposed orally to BPA (50 µg/kg/d), diethylstilbestrol (10 µg/kg/d, positive control) or corn oil during 3 estrous cycles every 24 h. Following treatments, mice on estrus received equine chorionic gonadotropin hormone (5 IU) ip, 48 h later mice received hormone human chorionic gonadotropin (hCG; 5 IU) and 16 h post-hCG mice were either euthanized to collect oocytes and perform *in vitro* fertilization or bred with a fertility proven male mouse to collect zygotes. Percentage of fertilized oocytes decreased in BPA-treated mice compared to control regardless of the presence or absence of cumulus cells surrounding the oocyte. Percentage of penetrated oocytes by sperm cells decreased in BPA-treated mice compared to control, but additional independent experiments are needed to validate these last data. The numbers of 2-, 4- and 8-cell zygotes were similar in BPA-treated mice and control. Our data confirm the detrimental effect of BPA on the reproductive capacity of oocytes, and further suggest that BPA alters the fertilizing ability of oocytes via decreasing the oocyte penetrability and/or via mechanisms that involve events from sperm penetration into the oocyte to the formation of 1-cell zygote. Conacyt-Mexico CB-167678.

**PS 2113 Amphoteric Fluorotelomer-Based Surfactant: 28-Day Subchronic and One-Generation Reproductive Toxicity in Rats.**

J. O'Connor<sup>1</sup>, T. L. Serex<sup>1</sup> and R. C. Buck<sup>2</sup>. <sup>1</sup>Haskell, DuPont, Newark, DE; <sup>2</sup>Chemicals & Fluoroproducts, DuPont, Wilmington, DE.

An amphoteric fluorotelomer-based surfactant in glycol solvent mixture and water was evaluated in a 28-day oral gavage study (OECD 407) with a 28-day recovery subset and a one-generation reproduction study subset (OECD 422). Groups of 20 Crl:CD(SD) rats were dosed with vehicle (deionized water) containing 0, 10, 50, or 200 mg/kg/day test substance. Dams were allowed to deliver and rear their offspring until postnatal day (PND) 4. Litter examinations were determined at birth and on PND 4. For the subchronic and recovery evaluations, gross postmortem examinations were performed on selected rats and selected organs were weighed and/or retained for histopathological examination. There were no test substance related deaths or clinical observations, no effects on body weight or nutritional parameters, no effects on neurobehavioral endpoints, clinical pathology, reproductive performance, or on offspring at any dose. Test substance-related changes occurred at ≥ 50 mg/kg/day in the kidneys of male rats and in the nose of male and female rats. Increased hyaline droplets consistent with alpha2u globulin were noted at ≥ 50 mg/kg/day in the cortical tubules of males after 28 days of administration, and were

also observed in the P1 males after 45 days of test substance administration. Increased hyaline droplet accumulation was not present in the recovery males. Low incidences of nasal olfactory epithelium degeneration/atrophy were present in the 28-day and/or P1 rats at 200 mg/kg/day in males, and at ≥ 50 mg/kg/day in females. Olfactory lesions were reversible; the human relevance of this effect is unknown. No test substance-related changes were present in the nose of the 200 mg/kg/day recovery groups. Under these study conditions, the systemic toxicity NOAEL was 10 mg/kg/day based on histopathologic effects observed in the noses and kidneys of male rats at 200 mg/kg/day and in the noses of female rats at ≥ 50 mg/kg/day. The NOAEL for reproductive toxicity and effects on offspring was 200 mg/kg/day, the highest dose tested.

**PS 2114 Effects of Zearalenone with or without Proprietary Binders on Vaginal Morphology of Prepubertal Gilts.**

D. Bradley, T. J. Evans, D. Ledoux and G. Rottinghaus. University of Missouri, Columbia, MO.

The xenoestrogenic mycotoxin, zearalenone (ZEA), can cause hyperestrogenism in prepubertal gilts, resulting in changes in the size, structure, and, potentially, function of the female reproductive tract. Objectives of the present study were to: 1) evaluate ZEA-induced changes in the vaginal epithelium using morphologic parameters and 2) determine whether proprietary binders can ameliorate the xenoestrogenic effects of ZEA. Thirty prepubertal gilts were assigned to five treatment groups. The gilts were housed individually and fed either a control diet, the same control diet with an added 1.5 mg of ZEA per kg of feed, or the ZEA-contaminated diet with Binder A, B, or C added. Animals were humanely sacrificed on Day 21 and portions of the reproductive tracts were removed and fixed in formalin. Image analysis software was used to measure total vaginal lumen circumference, as well as the total length of vaginal epithelium exhibiting hyperplasia and/or squamous metaplasia. The mean vaginal luminal circumference of the cross sections was greater in ZEA-treated groups and the controls, with or without binder. Likewise, the mean percentage of hyperplastic vaginal epithelium was also higher in the ZEA-treated groups, regardless of the presence of binder. There was a tendency for two of the binders to have ameliorative effects on the percentage of vaginal epithelium undergoing ZEA-induced squamous metaplasia. It is clear that treatment with ZEA affected the morphometric parameters evaluated. While none of the binders appeared to ameliorate the ER-α estrogen receptor-mediated effects of ZEA, those effects of ZEA and its metabolites involving ER-β estrogen receptors, such as squamous metaplasia, were reduced by two of the binders. The results of this experiment demonstrated how morphometric parameters can be used to assess the effects of xenoestrogens, such as ZEA, and the potentially receptor-dependent ameliorative effects of proprietary binders.

**PS 2115 Effect of Bisphenol A (BPA) and Ethinyl Estradiol (EE2) in the Gene Expression of Estrogen Receptors (ER) and ER-Related Receptors in the Rat Prostate and Mammary Gland.**

L. Camacho, M. Basavarajappa, R. Prabhu, S. M. Lewis, M. M. Vanlandingham and K. Deldos. NCTR, US FDA, Jefferson, AR.

Tissue and temporal expression of receptors involved in estrogen signaling and their modulation by hormonally active agents are hypothesized to influence the long term effects of such agents; however, these expressions are poorly defined. NCTR Sprague-Dawley rats were dosed from gestation day 6 until parturition by oral gavage and their pups were directly dosed by the same route from postnatal (PND) 1 to 90. Dose groups included naïve and vehicle controls, BPA (2.5 µg-300 mg/kg body weight (bw)/day), and EE2 (0.5 and 5.0 µg/kg bw/day). The expression level of genes coding for nuclear ERs (Esr1 and 2), ER-related receptors (Esrra, b, and g), and G-protein-coupled ER (Gper) was analyzed in the whole prostate and female mammary gland at PND 4 and 90. Quantitative real-time RT-PCR was used and data was expressed as % Gapdh expression level. The most highly expressed receptor in PND 4 prostate was Esrra and its expression was also high in adult prostate (3 and 30% Gapdh, respectively). The expression of Esr2, which encodes ERβ, was only 0.1% Gapdh in PND 4 prostate, but increased to 40% Gapdh at PND 90. The expression of the other receptor genes was 1% Gapdh or less and was not affected by age (Esr1 > Esrrg > Gper > Esrrb). Neither BPA nor EE2 affected the expression of the receptor genes analyzed in the prostate under our conditions. In the mammary gland, the most expressed gene analyzed was ERα-coding gene Esr1 (6% Gapdh), while the least expressed gene was Esr2 (0.05% Gapdh), at both PND 4 and 90. At PND 4, Esrrg was slightly (<2x) induced by the low EE2 dose, relative to vehicle control. In the PND 90 mammary gland, both EE2 doses induced ~3x the expression of Esr2, while the expression of Esrrb was induced ~3.5x by the low, but not high, EE2 dose. BPA did not alter the expression of the genes analyzed in the mammary gland. Our data suggest that the expression of these receptors is tissue-specific and that BPA and EE2 differentially modulate their expression. IAG FDA 224-12-0003/NIH ES12013.

**PS 2116 A Combined Repeated Dose and Reproductive/Developmental Toxicity Screening Study of Perfluoroundecanoic Acid in Rats.**

A. Ono<sup>1</sup>, M. Ikeya<sup>2</sup>, T. Suzuki<sup>3</sup>, T. Nishimura<sup>4</sup>, T. Kawamura<sup>1</sup>, M. Takahashi<sup>1</sup>, M. Matsumoto<sup>1</sup>, H. Kato<sup>1</sup>, M. Hirata-Koizumi<sup>1</sup> and A. Hirose<sup>1</sup>. <sup>1</sup>Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Bozo Research Center Inc., Tokyo, Japan; <sup>3</sup>Tokyo Metropolitan Institute of Public Health, Tokyo, Japan; <sup>4</sup>Teikyo Heisei University, Chiba, Japan.

Perfluoroalkyl carboxylic acids are one of environmental contaminants which have received attention because of their possible effects on wild life and human health in recent years. In order to obtain the initial risk information on the toxicity of perfluoroundecanoic acid (PFUnA (C11)), we conducted the repeated dose and reproductive/developmental toxicity screening test. PFUnA was administered by gavage to rats at 0 (vehicle: corn oil), 0.1, 0.3 or 1.0 mg/kg/day. Males were dosed for 42 days beginning 14 days before mating and females were dosed from 14 days before mating to day 4 of lactation. During the dosing period, body weight gain was inhibited in both sexes at 1.0 mg/kg/day. In this group, there was a decrease in fibrinogen in both sexes and shortening of activated partial thromboplastin time in males. Blood biochemical examination revealed an increase in BUN and decrease in total protein in both sexes and increases in ALP and ALT and decrease in albumin in males at 1.0 mg/kg/day. The relative liver weight was increased in males at 0.3 mg/kg/day and above and in females at 1.0 mg/kg/day, and histopathologically, centrilobular hypertrophy of hepatocytes was observed in both sexes at 0.3 mg/kg/day and above. Focal necrosis and diffuse vacuolation of hepatocytes were also found in the 1.0 mg/kg/day group. Regarding the reproductive/developmental toxicity, the body weight of pups at birth was lowered and body weight gain for 4 days after birth was inhibited at 1.0 mg/kg/day while no dose-related changes were found in the other reproductive/developmental parameters. Based on these findings, the NOAELs for the repeated dose and reproductive/developmental toxicity are considered to be 0.1 mg/kg/day and 0.3 mg/kg/day, respectively.

**PS 2117 The Detrimental Effect of Bisphenol A on Mouse Two-Cell Zygote May Depend on the Dose.**

T. Moore-Ambriz<sup>1</sup>, D. Acuña-Hernández<sup>1</sup>, B. Ramos-Robles<sup>1</sup>, S. Vargas-Marín<sup>1</sup>, M. Sánchez-Gutiérrez<sup>2</sup> and I. Hernández-Ochoa<sup>1</sup>. <sup>1</sup>Department of Toxicology, Cinvestav-IPN, Mexico City, Mexico; <sup>2</sup>Instituto de Ciencias de la Salud, Universidad Autónoma del Estado de Hidalgo, Pachuca, Mexico.

Early development of the zygote begins with the first cleavage that forms diploid cells and it depends on the contribution of paternal gametes. Bisphenol A (BPA) is an environmental compound that may leach from plastics into food or water. Some studies have shown that BPA alters embryonic development but they mostly focus on effects at later stages of development. This study evaluated the effect of an *in vivo* exposure to different doses of BPA on the formation of two-cell zygotes. Female mice C57BL/6J (39 days old) (n = 6-16 per group) were orally exposed to BPA (0.05, 0.5 and 50 mg/kg/d) or corn oil (tocopherol-stripped, negative control) for 3 estrous cycles every 24 h. Following treatments, mice on estrus received equine chorionic gonadotropin hormone (5 IU) ip, 48 h later mice received hormone human chorionic gonadotropin (hCG; 5 IU) and 16 h post-hCG mice were bred with a fertility proven male mouse to collect two-cell zygotes. Zygotes were stained with Hoechst 33342 and classified for abnormalities such as cell lysing and cytoplasmic prolongations. Mice treated with all doses of BPA had lower percent of fertilized oocytes compared to control, but zygote abnormalities were observed from the dose of 0.5 mg/kg/d BPA. Specifically, two-cell zygotes from mice exposed to 0.5 mg/kg/d BPA had higher percent of cell lysing or cytoplasmic prolongations compared to control, and two-cell zygotes from mice exposed to 50 mg/kg/d BPA had higher cytoplasmic prolongations compared to control. Our data suggest that BPA alters the formation of 2-cell zygote causing abnormalities depending on the dose. Conacyt-Mexico CB-167678.

**PS 2118 Body Burden and Preliminary Effects in Rats following Low-Dose Drinking Water Exposure to a VOC Mixture during Pregnancy and Adolescence.**

A. J. Filgo<sup>1,3</sup>, D. M. Chambers<sup>2</sup>, E. M. Quist<sup>1,4</sup>, B. C. Blount<sup>2</sup> and S. E. Fenton<sup>1</sup>. <sup>1</sup>NTP Laboratory, DNTP, NIEHS, NIH, DHHS, Research Triangle Park, NC; <sup>2</sup>National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA; <sup>3</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>4</sup>Comparative Biomedical Sciences, College of Veterinary Medicine, NC State University, Raleigh, NC.

Volatile organic compounds (VOCs) such as benzene, trichloroethylene, trans-1,2, dichloroethylene, tetrachloroethylene, and vinyl chloride are common industrial solvents used in a number of cleaning agents and solvents. Ingestion or inhalation

are the most common routes of reported environmental or occupational exposures to VOCs. In the US, spikes in birth defects, infant mortality, reproductive cancers and leukemia have occurred in areas where high levels of VOCs were detected in drinking water supplies. Here, time-pregnant Harlan Sprague Dawley rats and their offspring were given access to water containing mixtures of these 5 VOCs at concentrations 5, 10 and 50 times those detected in contaminated US drinking water (Sonnenfeld et al., 2001). Dams and pups were exposed from gestation day (GD) 10 until sacrifice. Blood was collected under hermetic conditions to determine VOC body burden in both dams (GD13, 15, 20 and postnatal day (PND)15, 21) and pups (PND15, 21, 28, 48). In exposed dams, low levels of VOCs were detected in the blood during pregnancy and increased during lactation. Dose dependent changes among each compound was also evident. Blood levels did not plateau, and differences in VOC body burden were attributed to the varying amounts of water consumed. Pup VOC levels also varied with changing body weight, milk and water consumption. At necropsy, pup body, liver and spleen weights were recorded and various tissues were collected for further analysis. VOC-exposure had no effect on selected organ weights or body/organ weight ratios. Morphological changes in the mammary gland were detected and were most prominent in male mammary tissue. Disclaimer: This abstract does not necessarily reflect NIEHS and CDC policy.

**PS 2119 The Inhibin B (InhB) Response to the Testicular Toxicants Mono-2-Ethylhexyl Phthalate (MEHP), 1, 3 Dinitrobenzene (DNB) or Carbendazim (CBZ) following Short-Term Repeat Dosing in the Male Rat.**

W. Breslin<sup>1</sup>, A. Paulman<sup>2</sup>, D. Sun-Lin<sup>1</sup>, K. M. Goldstein<sup>1</sup> and A. Derr<sup>2</sup>. <sup>1</sup>Eli Lilly and Company, Indianapolis, IN; <sup>2</sup>Covance Laboratories Inc., Greenfield, IN.

The objectives of this study were to evaluate the utility of plasma InhB as a biomarker of testicular injury in adult rats using the known Sertoli cell toxicants MEHP, DNB or (CBZ). The studies were run under conditions of short-term repeat dosing similar to that which would be used in early stage drug development to screen and prioritize drug candidates. The short-term high-dose exposure paradigm also allowed for assessment of changes in InhB as an early indicator of testicular injury. Following oral gavage administration of the compounds for 2 or 7 days, the rats were evaluated for clinical signs, body weight, food consumption, organ weights, plasma hormone levels, and gross and microscopic pathology of selected organs. MEHP, DNB, and CBZ produced a range of testicular toxicity characterized by minimal exfoliation of germ cells as demonstrated by increased cellular debris in the epididymis (MEHP) to more severe and dose/duration responsive Sertoli cell vacuolation, germ cell degeneration, and multinucleated giant cells of germ cell origin (DNB and CBZ). The slight to moderate Sertoli and germinal cell injuries did not correlate with significant changes in plasma InhB levels following 2 or 7 days of exposure. However, moderate to severe injury to germinal epithelium following up to 7 days of exposure, but not after a 2 day exposure, correlated with decreased in plasma InhB levels and less consistently with increases in plasma follicle stimulating hormone (FSH). In conclusion, under the conditions of these studies, changes in InhB were not an effective early onset marker of testicular toxicity or an effective marker for slight to moderate levels of acute injury and only reflected more severe disruption of spermatogenesis. Changes in plasma InhB and FSH were poorly correlated except in some instances of moderate to marked testicular toxicity.

**PS 2120 Poor Correlation between Rat Testis Histology and Serum Inhibin B after Treatment with Two Drug Candidates.**

W. J. Reagan<sup>1</sup>, R. E. Chapin<sup>1</sup>, J. A. Alvey<sup>1</sup>, R. A. Goldstein<sup>1</sup>, M. G. Dokmanovich<sup>1</sup>, K. Johnson<sup>2</sup> and F. J. Geoly<sup>1</sup>. <sup>1</sup>Drug Safety R&D, Pfizer, Inc, Groton, CT; <sup>2</sup>Arbor Analytics, Ann Arbor, MI.

Serum Inhibin B was measured in two studies of known-testis-toxic drug candidates. Study 1 was for a Hepatitis C candidate, and utilized a 10 week dosing period, followed by mating and necropsy of half of each group, and then a 12 week recovery period for the remaining 15 rats/group. At the end-of-dosing post-mating necropsy, 6 of 15 high-dose males had testis lesions (germ cell loss, degeneration); Inhibin B was significantly reduced in all animals in that group. The mid-dose group had no testis lesions but significantly reduced mean serum Inhibin B. After the 12 week recovery, 9/15 high-dose males showed damage in testes, and no mid-dose animals had testis lesions. Mean serum Inhibin B in all treated groups at recovery was not different from controls. Inhibin B appeared to both over-report and under-report testis damage in Study 1. Study 2 was an acute pathogenesis study for an antibacterial compound, using control and two dose levels and multiple time-points (days 5, 8, 15, 22, and then untreated until day 71). At each timepoint blood was sampled from all remaining rats and 5/group were killed for histologic evaluation. The low-dose group developed minimal to moderate lesions, while

serum Inhibin B was never changed. The high-dose animals progressed quickly from minimal lesions to being broadly and moderately affected (germ cell death, cell absence, disorganization); serum Inhibin B levels were reduced at days 8 and 15 only. In this study, Inhibin B appeared less sensitive than histology, except with marked testis damage, when Inhibin B was routinely low. Serum Inhibin B both over-reported damage (being reduced in the absence of lesions) and under-reported testis damage (being normal in the presence of testis lesions) in these two studies. We conclude that across both of these studies, there was a poor correlation between changes in serum levels of Inhibin B and testis histopathology.

**PS 2121 Assessment of Inhibin B As a Biomarker of Testicular Injury following Administration of Carbendazim, Cetrorelix, or 1, 2-Dibromo-3-Chloropropane in Wistar Han Rats.**

L. S. Her, A. M. Mineo, J. A. Phillips, M. S. Thibodeau and J. S. Moffit.  
*Nonclinical Drug Safety US, Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT.*

Although histopathology is considered the gold standard for assessing testicular toxicity in the nonclinical setting, identification of non-invasive biomarkers for testicular injury are necessary to improve safety monitoring capabilities for clinical trials. Inhibin B has been investigated as a potential noninvasive biomarker for testicular toxicity. The present study investigates the correlation of Inhibin B serum levels in Wistar Han rats with the onset and reversibility of testicular histopathology from classical testicular toxicants, carbendazim (CBZ), cetrorelix acetate (CTX), and 1,2-dibromo-3-chloropropane (DBCP). The dosing paradigm was selected with Interim (Day 8), Drug (Day 29), and non-dosing Recovery (Day 58) Phases. Monitoring of serum Inhibin B was not effective at predicting the onset of CBZ- or CTX-mediated testicular pathology in rats. Inhibin B level was reduced by DBCP administration at the end of the Drug Phase only, acting as a leading indicator of the onset of testicular toxicity, prior to the onset of germ cell depletion. However, since Inhibin B was decreased at the end of the Dosing Phase and the onset of testicular pathology occurred without any additional dosing in the Recovery Phase, it is unclear if monitoring Inhibin B would provide sufficient advanced warning of the onset of testicular pathology. Furthermore, FSH was decreased and the ratio of Inhibin B/FSH was increased with DBCP administration in the Interim Phase, but not in the Drug or Recovery Phases. Although the Inhibin B/FSH ratio was a leading indicator of testicular pathology, the effective window for monitoring may be narrow. Conclusion: Inhibin B has limited predictive capacity as a leading testicular biomarker in rats.

**PS 2122 The Inhibin B Response in Male Rats Treated with a GnRH Agonist and an Endothelin Receptor Antagonist.**

T. Mitchard, M. Coulson, S. Bickerton, J. Harris, C. Betts and J. Stewart.  
*Safety Assessment, AstraZeneca R&D, Macclesfield, United Kingdom. Sponsor: R. Roberts.*

The testis shows a moderate frequency as a preclinical toxicity target organ. This is primarily detected by histopathology and there is a need to identify circulating biomarkers to enable longitudinal monitoring and facilitate safe progression of compounds into the clinic. Inhibin B is primarily synthesized by the Sertoli cells and regulates pituitary FSH release through a negative feedback loop. This study was part of a HESI-sponsored initiative to evaluate inhibin B as a marker of spermatogenic dysfunction in the rat.

Inhibin B was measured in male Han Wistar rats (10 weeks old) administered vehicle or an endothelin receptor antagonist (ET-An) orally for 28 days or a GnRH agonist (GnRH-A) as a subcutaneous implant on Day 1. Ten animals/group/time point were killed on Days 4, 8, 15 and 29 (controls on Days 15 and 29), for testes weights and histopathology. In-life blood samples were taken on Days 4, 8, 15 and 29 to measure inhibin B, FSH and LH, and at necropsy for the same hormones plus testosterone.

Plasma inhibin B showed a wide concentration range in control animals (group means 76.4 to 184.2 pg/mL; individual animals 17.8 to 381 pg/mL). GnRH-A caused decreased testes weights plus degenerative testicular pathology from Day 4 with partial recovery by Day 29. Statistically significant reductions in inhibin B were observed at all time points and appeared to track the development and partial recovery of the pathology (generally <50 pg/mL on Days 4 to 15; group mean 92 pg/mL on Day 29). ET-An produced an increase in testes weights and a non-degenerative lesion of minimal tubular dilatation. There was a trend for lower inhibin B values (30 to 50%) at all time points, including on Day 4 when tubular dilatation was not yet evident. Overall, we conclude that following GnRH-A administration, inhibin B showed a good correlation with testicular pathology for GnRH-A, and following ET-An administration appeared to give a signal that might reflect changes in tubular function in the absence of degenerative pathology.

**PS 2123 Inhibin B As a Marker of Sertoli Cell Damage and Spermatogenic Disturbance in the Rat.**

T. Pfaff<sup>2</sup>, G. F. Weinbauer<sup>1</sup>, J. Rhodes<sup>3</sup> and M. Bergmann<sup>4</sup>. <sup>1</sup>Covance Laboratories GmbH, Muenster, Germany; <sup>2</sup>AiCuris GmbH & Co. KG, Wuppertal, Germany; <sup>3</sup>Covance Ltd., Harrogate, United Kingdom; <sup>4</sup>Department for Anatomy, Giessen, Germany.

This study was designed to determine the effects of Compound A on the fertility and early embryonic development in the male rat over a 15-19 weeks treatment and a 19 weeks treatment free period in control and 30, 60 and 180 mg/kg dose groups (n =22/group). Compound A in a dose-dependent manner induced various degrees of spermatogenic alterations compatible with Sertoli cells being the primary target, e.g. inter- and intracellular Sertoli cell vacuolization and altered cellular morphology followed by germ cell degeneration and marked reduction of epididymal sperm numbers. Blood-testis barrier remained intact (electron microscopy and hyperosmotic fixation test) until germ cells disappeared. Mating behaviour and weights of androgen-dependent prostate and seminal vesicles remained unaffected. Inhibin B levels correlated only with moderate to severe spermatogenic alterations. Ten animals with inhibin B levels below detection limit were encountered and five of these animals were fertile in week 19 but following another 15 weeks without treatment, animals were rendered infertile and inhibin B levels remained undetectable. In the rat, inhibin B only reflects major spermatogenic alterations and markedly reduced inhibin B levels might indicate irreversibility of these alterations and even infertility.

**PS 2124 The Inhibin B Response to Testicular Toxicants Ethylene Glycol Monomethyl Ether or Dibromoacetic Acid in Male Rats.**

B. Enright<sup>1</sup>, B. Torseni<sup>1</sup>, H. Lorenz<sup>2</sup> and K. Whitney<sup>1</sup>. <sup>1</sup>Abbott Laboratories, Abbott Park, IL; <sup>2</sup>Abbott GmbH & Co. KG, Ludwigshafen, Germany. Sponsor: R. Yeager.

This study was conducted as part of an ILSI-HESI consortium effort to assess the utility of circulating inhibin B as an early biomarker of testicular toxicity in rats. Two known testicular toxicants were selected for use in this study: ethylene glycol monomethyl ether (EGME) and dibromoacetic acid (DBAA). EGME (200 mg/kg/day), DBAA (250 mg/kg/day) or vehicle control (0.2% hydroxypropyl methylcellulose [HPMC]) were administered orally to male rats for 3, 6, or 14 consecutive days. On study days 4, 7, and 15, serum was collected for evaluation of inhibin B levels from all surviving animals and a subset of animals was necropsied from each of the control, EGME, and DBAA groups. Administration of EGME resulted in spermatocyte degeneration in late stage tubules and spermatocyte depletion to stage III on day 4, progressing to loss of spermatocytes and round spermatids to stage VI by day 7 and continued germ cell loss and degeneration of elongating spermatids by day 15. Inhibin B levels among EGME-treated animals progressively decreased relative to their respective controls at all time points. Administration of DBAA was associated with spermatid retention at all three time points and abnormal residual bodies at days 7 and 15. Inhibin B levels among DBAA-treated animals decreased progressively relative to their respective controls on days 7 and 15. The results of this study indicated that serum inhibin B levels in rats provided a signal of testicular toxicity for each of these known testicular toxicants administered at high levels; however, histopathology provided the earliest evidence of toxic effects.

**PS 2125 The Inhibin B Response to the Testicular Toxicant, 1, 3 Dinitrobenzene in Rats and the Analytical Evaluation of Inhibin B ELISA Kit.**

N. Bogdan<sup>1</sup>, M. Sonce<sup>1</sup>, M. Singer<sup>1</sup>, L. Hall<sup>1</sup>, S. Bryant<sup>1</sup> and P. Vinken<sup>2</sup>. <sup>1</sup>Drug Safety Sciences, Janssen Research and Development, LLC, Raritan, NJ; <sup>2</sup>Drug Safety Sciences, Janssen Research and Development, LLC, Beerse, Belgium.

**Background:** This work is part of an ILSI-HESI consortium effort to evaluate the analytical performance of a second generation ELISA kit and also to assess the utility of circulating inhibin B (InhB) as an early biomarker of testicular toxicity in rats. **Methods:** A commercially available InhB ELISA was used to assess for dilution linearity, frozen stability and serum/plasma comparison. Reference ranges were generated for male Sprague Dawley rats. To evaluate the biological utility of InhB, 1, 3-dinitrobenzene (DNB), a Sertoli cell toxicant, was orally administered to male rats for 2 or 5 consecutive days at 2 or 6 mg/kg/day. On Days 1 and 2, serum was collected for evaluation of InhB and follicle stimulating hormone (FSH) from all rats treated for 2 days, and on Days 1, 3 and 5 from all rats treated for 5 days. At the end of treatment, testes were weighed and examined histologically. **Results:** There

was no difference between serum or plasma InhB values and they were stable out to 12 weeks when stored at -20°C and -80°C. Dilution linearity was acceptable up to 32-fold. An age-related decline of InhB levels was seen between 6 and 9 weeks of age after which levels were stable up to 20 weeks. DNB caused a time-dependent increase in incidence and severity of testicular findings characterized by degeneration of the germinal epithelium, loss of pachytene spermatocytes and vacuolization of the Sertoli cells. InhB levels decreased only with the high dose treatment on Day 5 and without any associated changes in FSH. **Conclusions:** Overall, the InhB assay performed well under our conditions; however it is important to be aware of the biological variability and low control values observed by some other laboratories. In our study, a change in serum InhB levels was detected only in association with moderate/severe testicular toxicity, and is therefore considered of limited value as an early biomarker for Sertoli cell toxicity.

**PS 2126 The Inhibin B (InhB) Response to the Testicular Toxicants Hexachlorophene, Ethane Dimethane Sulfonate (EDS), Dibutylphthalate (DBP), Nitrofurazone, DL-Ethionine, 17-Alpha Ethinylestradiol, 2, 5-Hexanedione, or Carbendazim (CBZ) following Short-Term Dosing in the Male Rat.**

L. P. Saldutti<sup>1</sup>, Z. Erdos<sup>1</sup>, K. Pearson<sup>1</sup>, M. Goedken<sup>2</sup>, K. Menzel<sup>1</sup>, K. Turner<sup>3</sup> and W. E. Glaab<sup>1</sup>. <sup>1</sup>Merck Pharmaceuticals, West Point, PA; <sup>2</sup>Merck Pharmaceuticals, Kenilworth, NJ; <sup>3</sup>Research Triangle Institute, Research Triangle Park, NC.

**Background:** Inhibin B is a hetero-dimer glycoprotein that down regulates follicle stimulating hormone and is produced predominantly by the Sertoli cells. The potential correlation between changes in plasma Inhibin B and Sertoli cell toxicity was evaluated in male rats administered various testicular toxicants in 8 separate studies. Inhibin B fluctuations over 24 hours were also measured. **Methods:** For the testicular toxicity studies, five to eight Sprague-Dawley, Wistar, or Wistar-Han rats ranging from 8 to 13 weeks of age were administered 1 of 8 testicular toxicants for 1 to 29 days (depending on the compound). The 8 testicular toxicants were DL-Ethionine, dibutyl phthalate, nitrofurazone, 2,5-hexanedione, 17-alpha ethinylestradiol, ethane dimethane sulfonate, hexachlorophene, and carbendazim. For the 24-hour time period, plasma was collected by an automatic blood sampler. **Results:** Histomorphologic testicular findings were seminiferous tubule degeneration (STD), aspermatogenesis, and interstitial cell degeneration. Across the 8 testicular toxicants tested there were varying degrees of correlation between decreases in Inhibin B and STD and aspermatogenesis. In an ROC exclusion model analysis, where treated samples without histopathology were excluded, performed on all studies except EDS (Leydig cell toxicant), Inhibin B showed a sensitivity of 72% at 90% specificity, demonstrating the potential value of Inhibin B as a biomarker of testicular toxicity. **Conclusion:** Decreases in Inhibin B showed a good correlation with Sertoli cell toxicity. As anticipated, there was no correlation between decreases in Inhibin B and Leydig cell toxicity (interstitial cell degeneration). A pattern of Inhibin B secretion could not be identified over a 24 hour time period.

**PS 2127 Simvastatin and Dipentyl Phthalate Lower Testosterone Production and Exhibit Dose Additive Effects on the Fetal Testis via Distinct Mechanistic Pathways.**

B. Beverly<sup>1</sup>, C. Lambright<sup>1</sup>, J. R. Furr<sup>1</sup>, H. Sampson<sup>1</sup>, B. McIntyre<sup>2</sup>, P. M. Foster<sup>2</sup>, G. S. Travlos<sup>2</sup>, V. S. Wilson<sup>1</sup> and L. E. Gray<sup>1</sup>. <sup>1</sup>US EPA, ORD, NHEERL, TAD, Research Triangle Park, NC; <sup>2</sup>NIH, NIEHS, NTP, Research Triangle Park, NC.

Sex differentiation of the mammalian reproductive tract is a highly regulated process that is driven, in part, by fetal testosterone (T) production. In utero exposure to phthalate esters (PE) during sex differentiation can result in reproductive tract malformations in rats. PE alter the expression of genes associated with steroid synthesis/transport and cholesterol biosynthesis. Simvastatin (SMV) is a cholesterol-lowering drug that interferes with cholesterol biosynthesis. As cholesterol is a precursor for steroid biosynthesis, we proposed that like PE, maternal exposure to SMV during the critical period of sex differentiation would lower fetal T production and result in corresponding alterations in cholesterol- and androgen-mediated gene expression. Timed pregnant Sprague Dawley rats were dosed orally with 15.6, 31.25, or 62.5 mg/kg/d SMV from GD14-GD18. Testicular T production on GD18 was measured by RIA and changes in gene expression in fetal testes and livers were assessed by quantitative rt-PCR. Circulating lipid concentrations were also measured in dams and fetuses. SMV lowered fetal testicular T production and altered several genes involved in cholesterol biosynthesis in the fetal liver. Triglycerides, LDL, HDL, and total cholesterol were also lowered significantly in the fetal circulation, while lipids in the dam were not. Unlike PE, SMV did not

alter genes associated with sexual differentiation or development. In a second experiment, dams were dosed with 62.5 mg/kg/d SMV, 50 mg/kg/d dipentyl phthalate (DPeP, a PE), or a mixture of both. SMV and DPeP reduced fetal T production to 38.6 and 42.3% of the control values, respectively, but the SMV/DPeP mixture reduced T production to 20.9% of control. These studies suggest that although SMV and DPP affect two different pathways, they exhibit dose additive effects within the fetal testis.

**PS 2128 Postnatal Effects of Dipentyl Phthalate on Male Rat Reproductive Development.**

J. R. Furr and L. E. Gray. NHEERL, Toxicity Assessment Division, Reproductive Toxicology Branch, United States EPA, Research Triangle Park, NC.

We conducted several in utero, ex vivo and in vitro studies to characterize the relative potencies of a series of phthalates on fetal rat testis testosterone production and gene expression. Dipentyl phthalate (DPeP) was the most potent of the active chemicals in its effect on fetal testis endocrine function. Although these studies have pointed to the overall potency of DPeP, little literature exists defining its dose-response curve in vivo. The objective of this study was to determine if the potency of DPeP on fetal testis endocrine function was predictive of the ability of the chemical to induce reproductive tract malformations in male rats. We treated timed-pregnant Sprague-Dawley rats 0, 11, 33, 100 or 300 mg DPeP/kg/d, from GD 8-18 and examined the postnatal development of the male offspring. Male offspring of treated dams displayed decreased AGD, increased nipple retention, incomplete preputial separation, decreased sperm production, hypospadias, undescended testes, malformations of the testes, ventral prostate, and seminal vesicles, reduced body weight (300 mg/kg/day) and reduced postnatal survival. Phthalate syndrome (PS) malformations were seen in about 9%, 44% and 100% of the F1 male offspring at 33, 100 and 300 mg/kg/d, dosage levels that reduced fetal T production by 35%, 77% and 93% respectively. Also of note were skull malformations in highest treatment group in the form of malocclusions and incomplete zygomatic ossification. These results indicate the DPeP is about 3.5 fold more potent in inducing the PS in F1 male rats than is DEHP and demonstrate that the relative potencies for disrupting fetal testis endocrine function can be used to predict some the postnatal reproductive effects of this class of endocrine disruptors. **Disclaimer:** This abstract doesn't necessarily reflect USEPA policy. Supported in part by NTP/NIEHS IA# RW-75-92285501.

**PS 2129 Changes of Expression Levels of Oxidative Stress-Related Genes in Mouse Epididymides by Neonatal Exposure to Low-Dose Decabromodiphenyl Ether.**

M. Nakamoto<sup>1</sup>, H. Miyaso<sup>1</sup>, M. Komiyama<sup>1</sup>, Y. Matusno<sup>1,2</sup> and C. Mori<sup>1,2</sup>. <sup>1</sup>Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba-shi, Japan; <sup>2</sup>Center for Preventive Medical Science, Chiba University, Chiba-shi, Japan.

Decabromodiphenyl ether (decaBDE), one of polybrominated diphenyl ethers (PBDEs), is the most famous flame retardant and is used in worldwide. In a previous study, we identified adverse effects of neonatal decaBDE exposure on mouse epididymides, for example decrease of epididymal weight. On the other hand, neonatal exposure to diethylstilbestrol (DES), artificial estrogenic compounds, also causes several adverse effects on epididymides. DES exposure causes the decrease of epididymal weight, morphological abnormality, and the lasting change of expression levels of several genes. Molecular mechanisms for induction of harmful effects by decaBDE exposure remain unclear. Since many studies have reported that PBDEs have estrogenic activity, this activity may contribute to induction of adverse effects of decaBDE exposure. This study was carried out to examine how effects are caused in epididymides by neonatal decaBDE exposure, and elucidate molecular mechanisms of adverse effects by decaBDE exposure. Administration of decaBDE was performed subcutaneously at 0.25 mg/kg body weight/day, on postnatal days 1 to 5. At 12 weeks of age, epididymides were histologically examined and gene expression was analyzed using DNA microarray and real-time PCR. Our data showed that 1) no histological change was observed on epididymal tissues by neonatal decaBDE exposure, differently from that of DES, 2) decaBDE exposure could not induce the change of expression levels of genes which were affected by DES, but caused changes of expression levels of some oxidative stress related genes in mouse epididymides, 3) the expression level of Ubiquitin C (Ubc) increased in decaBDE-exposed mouse epididymides. Our presented data suggest the possibility that increase of oxidative stress is related to elicitation of harmful effects in decaBDE-exposed mouse epididymides.

## PS 2130 Structural Changes in Various Organs of Male Rats Caused by Long-Term Oral Administration of Chlorpyrifos.

S. Tripathi and A. K. Srivastav. *Department of Zoology, DDU Gorakhpur University, Gorakhpur, India.*

- Wistar rats (male) were divided into two groups — group A (GA) served as control and group B (GB) were daily administered orally chlorpyrifos (Anu Products Ltd., India) at a dose of 5 mg/kg b wt. Rats were sacrificed on 1st, 2nd, 4th, 6th, and 8th week after initiation of the experiment. Left testis and duodenum were excised and fixed in aqueous Bouin's solution. The tissues thus fixed were routinely processed for histological studies. Chlorpyrifos treatment caused degeneration in seminiferous tubules and thus inhibit the spermatogenesis in rats. Few seminiferous tubules lack the germinal epithelium. After exposure to chlorpyrifos the morphological observations of duodenum showed an increased mucous cell activity, disruption and sloughing of duodenal villar cells, lymphocytic infiltration and degeneration of cells. In conclusion the findings of the present study indicate that the organophosphate – chlorpyrifos can inhibit spermatogenesis and provoke degenerative features in the duodenum of rats and thus severely affect these organs.

## PS 2131 Assessment of Phthalate-Induced Changes in Fetal Rat Testis Gene Expression Using a rt-PCR Array.

C. Lambright<sup>1</sup>, H. Sampson<sup>2</sup>, J. R. Furr<sup>1</sup>, B. Hannas<sup>1</sup>, N. Evans<sup>1</sup>, L. E. Gray<sup>1</sup> and V. S. Wilson<sup>1</sup>. <sup>1</sup>ORD/RTD, US EPA, Research Triangle Park, NC; <sup>2</sup>ORISE/US EPA Fellow, Research Triangle Park, NC.

Phthalate esters (PE) such as diethyl hexyl phthalate (DEHP) produce reproductive malformations in male rodents by reduction of testosterone (T) production and gene expression after dams are exposed during the critical period of sexual differentiation. We investigated the effects of seven PE known to reduce fetal T production and further evaluated gene expression using novel SABiosciences PCR arrays. Each array tests for 84 genes either involved in phase one drug or lipoprotein transport and cholesterol metabolism/synthesis. Timed pregnant Sprague-Dawley rats were orally dosed with individual phthalates from gestational day (GD) 14-18. On GD 18, testes were collected from 3 fetuses per dam and cultured for 3 hours. Medium was collected and T values measured by RIA. Remaining testes were pooled by litter, RNA extracted, cleaned, quantified, and evaluated for gene expression using PCR arrays. PE were DiHP (750 mg/kg), Dihexyl (750 mg/kg), DPP (100 mg/kg), DiBP (900 mg/kg), DiNP (1500 mg/kg), DCHP (0, 100, 300, 600, or 900 mg/kg), and DEHP (750 mg/kg). Of the 84 genes on the Drug Metabolism arrays, four were significantly reduced: Cyp11b1, Cyp11a1, Cyp17a1, and ALDH2. Cyp11a1 and Cyp17a1 are involved in T synthesis, while Cyp11b1 aids in the production of cortisol and corticosterone. Using the lipoprotein/cholesterol arrays, we identified 10 genes that were significantly altered that are involved in cholesterol biosynthesis (such as APOC3, Dhcr24/7, EBP, MVK, Tm7sf2). These data support that PE effects in the fetal testis are not limited to alterations in androgen synthesis and include genes for other hormones (Insl3), growth factors, steroid transport proteins, and multiple genes involved in cholesterol synthesis. Disclaimer: This abstract doesn't necessarily reflect USEPA policy. Supported in part by NTP/NIEHS IA # RW-75-92285501-1 and fellowship administered jointly between EPA/DOE and the Oak Ridge Institute for Science and Education.

## PS 2132 Modulation by Antioxidants of Chemotherapeutic Drugs-Induced Alterations in Steroidogenic Enzyme Activities in the Testis.

N. Kilarkaje<sup>1</sup> and M. Al-Bader<sup>2</sup>. <sup>1</sup>Department Anatomy, Faculty of Medicine, Kuwait University, Safat, Kuwait; <sup>2</sup>Physiology, Faculty of Medicine, Kuwait University, Safat, Kuwait.

Combined treatment of bleomycin, etoposide and cisplatin (BEP) is a 'gold standard' therapy for several types of cancers. These drugs impair testicular functions, although the effects on Leydig cell steroidogenic enzymes are not known. We investigated the effects of the drugs on the enzymes and putative modulation by antioxidants of the drug effects. Male Wistar rats (13-15 week-old; N=5/group) were treated with either water (G1), or an antioxidant cocktail (AO; G2:  $\alpha$ -tocopherol [100 mg/kg], L-ascorbic acid [50 mg/kg], Zn [40 mg/L] and Se [100  $\mu$ g/L, po]), or BEP+AO (G4). In G3 and G4, E and P were given from day 1-5 and B on days 2, 9 and 16 of each cycle. The rats were anesthetized with ether and sacrificed by CO<sub>2</sub> asphyxiation the next day. The gene expressions were quantified by ReT-PCR by using specific primers. The expression of the proteins was evaluated by Western blotting and confocal microscopy. Data were compared by one way ANOVA and LSD test and p<0.05 was considered significant. The gene expressions of Cyp17a1,

P450scc, StAR and Scarb1 were up-regulated and that of Cyp19a1,  $\beta$ -hsd and 17 $\beta$ -hsd were down-regulated in G3 and G4. In G2, Cyp19a1,  $\beta$ -hsd, 17 $\beta$ -hsd and StAR expressions were down-regulated (p<0.05). The protein levels of LHR and  $\beta$ -HSD were unaffected, whereas that of StAR were up-regulated, and that of P450scc, 17 $\beta$ -HSD, Cyp17a, and Cyp19a were down-regulated in G2-G4 compared to G1 (p<0.05). No significant protective effects of the AO were observed, except on Cyp17a and Cyp19a. All proteins were localized in the cytoplasm. In conclusion, the drugs affect both gene and protein expressions of steroidogenic enzymes in Leydig cells and the antioxidants have limited protective effects (Supported by Kuwait University Grant # MA02/08, GM01/01 and GM01/05).

## PS 2133 Comparison of Fetal Testosterone Production in Various Tissues of the Male Sprague-Dawley Rat Dosed *In Utero* with Dipentyl Phthalate during the Critical Window of Sexual Differentiation.

K. R. Tatum-Gibbs<sup>1</sup>, J. R. Furr<sup>2</sup>, C. Lambright<sup>2</sup>, N. Evans<sup>2</sup>, B. Hannas<sup>2</sup>, B. W. Riffle<sup>1</sup>, H. Sampson<sup>1</sup>, A. K. Hotchkiss<sup>3</sup>, V. S. Wilson<sup>2</sup> and L. E. Gray<sup>2</sup>. <sup>1</sup>ORISE, US DOE, Oak Ridge, TN; <sup>2</sup>Reproductive Toxicology, US EPA, Research Triangle Park, NC; <sup>3</sup>NCEA, US EPA, Research Triangle Park, NC.

Phthalate esters are high-production volume chemicals used in the manufacture of numerous plastics and consumer products, which generates major concern for potential human exposure and environmental contamination. Several studies have demonstrated adverse effects associated with phthalate exposure administered during the critical window of sexual differentiation on the development of the male reproductive system, many of which can be attributed to a decrease in fetal testosterone (T) production. However, there is very little information regarding reduction in fetal T in tissues other than the testes and the "Point of Departure" as it relates to the relationship between reductions in fetal T levels and resultant postnatal male reproductive malformations. Therefore, the objective of the current study was to assess fetal T production in various tissues following in utero exposure to dipentyl phthalate (DPeP) to determine the relationship between reductions in fetal T with the postnatal reproductive male malformations. DPeP was given to timed pregnant Sprague-Dawley rats via oral gavage on gestation days (GDs) 14-18 at doses of 11, 33, 100, or 300 mg/kg/d (n=3); controls received the vehicle corn oil. At GD 18 dams were necropsied and fetal specimens (plasma, testes, reproductive tract, and whole body) were recovered for extraction of T using Solid Phase Extraction (SPE). We found the dose response curves for T production (media extraction) were very similar to the extracted T levels in the testes and serum. However, preliminary results suggest the dose response curves for the reproductive tract and whole body may be quite different from those of testes and serum T levels. This abstract does not reflect U.S. EPA policy. Supported by EPA/NTP IA # RW-75-922-85501

## PS 2134 Cumulative Effects of a 9 Phthalate Mixture on Charles River-Sprague-Dawley (CR-SD) Fetal Rat Testis Testosterone (T) Production and Gene Expression.

V. S. Wilson, J. R. Furr, C. Lambright, B. Hannas and L. E. Gray. *Reproductive Toxicology Branch, US EPA, ORD, NHEERL, TAD, Research Triangle Park, NC.*

*In utero* exposure to mixtures of 2 to 5 phthalate esters (PE) with similar modes of action have been shown to inhibit male reproductive development in a dose-additive fashion. Further when PE were administered to pregnant dams during the period of sexual differentiation, when reproductive malformations were observed in male offspring they correlated to significant reductions in fetal T levels. We have observed that a mixture of 9 PE administered on gestation day (GD) 14-18 to Harlan SD rats (dilutions of a fixed ratio mixture; top dose of 80 mg DEHP, DiHP, DiBP, DBP, BBP, DCHP, D(hexyl)P, D(heptyl)P, and 10 mg DPeP/kg/d) reduced fetal T production in a dose additive manner (Hannas et al, 2011). The current study compared the sensitivity of the fetal testis of CR-SD to the Harlan SD rat for disruption of testis T production and gene expression of the 9 PE mixture. A pilot postnatal study with Harlan SD rats (administered at the top dose and 67, 33, 17, and 8% of the top dose) the high dose group produced a high incidence of phthalate syndrome malformations accurately predicted by dose addition modeling, but far in excess of that predicted by response addition. The CR-SD rat (ED50 = 38% of top dose) was slightly less sensitive to disruption than the Harlan SD rat (ED50 = 26%) for fetal T production. Results demonstrate that mixtures of 9 PE behave in a manner accurately predicted by dose addition modeling. Thus considering PE hazard identification on an individual basis, without inclusion of other PE, could underestimate the risk posed by a mixture of PEs. Future postnatal 9 PE studies are planned in the CR-SD rats to determine the point of departure correlation between

reduced fetal T levels and the resultant postnatal male reproductive malformations. Disclaimer: This abstract does not necessarily reflect USEPA policy. Supported in part by NTP/NIEHS Interagency Agreement # RW-75-92285501.

## **PS 2135 Impact of Clinically Relevant Cisplatin Treatment on the Undifferentiated Spermatogonia Population and Niche.**

J. Harman and J. Richburg. University of Texas at Austin, Austin, TX.

A typical clinical cisplatin (CDDP) regimen consists of repeated cycles of 5-7 daily low dose injections followed 1-2 week recovery period; and while effective, often results in prolonged, sometimes permanent, infertility. Theoretically, undifferentiated spermatogonia (undiff-Sp), including spermatogonial stem cells (SSCs), should repopulate the testis after exposure has ceased. We hypothesize that SSC mitotic activity increases following the initial exposure to CDDP, rendering SSCs increasingly susceptible to CDDP-induced injury during subsequent cycles. We examined changes in the adult C57 undiff-Sp population and niche at days 1, 8 and 16 of the recovery period following a clinically-relevant course of 1 cycle (2.5 or 5.0 mg/kg/d) and 2 cycles (2.5 mg/kg/d) of intraperitoneal CDDP. Histological examination of the testis epithelium showed an increase in damage correlating with exposure dose and cycle number. Apoptosis was measured via TUNEL and found to increase during the recovery period following 1 cycle of 2.5mg/kg and 5.0mg/kg (300%), as well as 2 cycles of 2.5mg/kg (400%) CDDP compared to controls. Immunohistochemistry (IHC) was performed using antibodies specific for FOXO1 (undiff-Sp marker) and GDNF (critical SSC niche protein secreted by Sertoli cells). Analysis of FOXO1 showed a reduction in undiff-Sp during the recovery period following 1 cycle of 2.5 (50%) and 5.0mg/kg CDDP (66%), as well as 2 cycles of 2.5mg/kg CDDP compared with controls (50%); followed by a return to numbers equal with or surpassing controls at 16d recovery. IHC analysis of GDNF revealed a general increase in expression, prominently along the basal membrane, during the recovery period in all treatment groups. These data suggest that a greater dose of CDDP in a single cycle of exposure causes a greater impact on the functional stem cell pool and its niche and multiple cycles of exposure result in a still greater impact than an equivalent cumulative dose. Future experiments focus on whether CDDP exposure targets the SSCs, the Sertoli cells, or both.

## **PS 2136 Using a Rat Primary Epididymal Cell Model to Evaluate Drug-Induced Inflammation and Granulomas.**

K. Stachek<sup>2</sup>, W. Nowland<sup>1</sup>, T. Winton<sup>1</sup>, S. Kumpf<sup>1</sup>, S. N. Campion<sup>1</sup>, R. E. Chapin<sup>1</sup> and M. E. Hurtt<sup>1</sup>. <sup>1</sup>Drug Safety Research and Development, Pfizer Inc., Groton, CT; <sup>2</sup>College of Pharmacy, University of Rhode Island, Kingston, RI.

Epididymal inflammation and sperm granuloma formation have been detected in vivo in Sprague Dawley (SD) rats following various treatments. The objective of this in vitro primary rat cell model is to identify compounds that cause epididymal inflammation and granulomas using minimal compound and fewer animals. We had previously found that more potent granulomagens produced larger increases in transcript levels for the IL6 and GRO cytokines (3 to 10-fold increases), while less potent and negative compounds produced smaller (less than or equal to 2X) or no increases. We evaluated the marketed phosphodiesterase type 4 inhibitors, ibudilast (I), roflumilast (R), and the active metabolite roflumilast N-oxide (RNO), which are known to cause sperm granulomas in rats. Primary cultures of mixed epididymal epithelial cells were isolated and plated on Matrigel 24-well plates and exposed to increasing concentrations of test compounds. 24 hours post dosing, we measured mitochondrial metabolic activity using the MTS assay and cell lysates were evaluated for IL6, GRO, and IL10 gene expression by qRT-PCR at the IC20 (80% MTS activity). R and RNO were poorly soluble, which limited the in vitro exposure levels. Perhaps for this reason, modest increases in IL-6 and GRO were seen with R and RNO treatment (1.2- and 1-fold for R, 1.6- and 1.9-fold for RNO) while MTS activity was not reduced. However, treatment with ibudilast resulted in larger increases in IL-6 and GRO, 2.7- and 2.9-fold respectively at the IC20, consistent with its in vivo activity. The results of this study demonstrate that this primary epididymal culture model detects inflammatory signals that reflect the in vivo activity of at least one of these compounds in rats.

## **PS 2137 Evaluation of an In Vitro Model of Spermatogenesis for Predicting Testicular Toxicity.**

K. M. Goldstein<sup>1</sup>, M. Perrard<sup>2</sup>, P. Durand<sup>2</sup>, T. K. Baker<sup>1</sup> and D. E. Seyler<sup>1</sup>. <sup>1</sup>Investigative Toxicology, Eli Lilly & Co., Indianapolis, IN; <sup>2</sup>Kallistem, Lyon, France. Sponsor: C. Thomas.

Due to the complex physiology of the testes, *in vitro* models have been largely unsuccessful at predicting testicular toxicity *in vivo*. These models often bear limited resemblance to *in vivo* cellular organization. We evaluated an *in vitro* model (Hue et

al 1998) that forms tight junctions similar to the blood-testis-barrier (BTB), and supports spermatogenesis through meiosis II (secondary spermatocytes) and the formation of round spermatids. We used this *in vitro* model to evaluate the toxicity of four known testicular toxicants: Bisphenol A (BPA), 2-Methoxyacetic acid (MAA), 1,3-Dinitrobenzene (DNB), and Lindane in pre-pubertal rat seminiferous tubule cultures treated with compound for 28 days. Formation of the BTB (tight junctions) was measured by transepithelial electrical resistance (TEER) every 2 days. Cells were collected weekly for flow cytometric analysis to measure total viability and cell counts for each stage of spermatogenesis. Concentrations for each chemical were selected to approximate those shown to produce *in vivo* testicular effects. BPA and DNB decreased dramatically the TEER in a dose and time-dependent manner, whereas the effects of MAA and Lindane were less marked and transitory, even at the higher concentrations tested. Cell viability was slightly, if any, modified by the compounds; this was due most likely to the phagocytic activity of the Sertoli cells. All compounds induced dramatic dose-dependent diminutions of the populations of spermatocytes I and II, and round spermatids. It is important to note that the well-known specific toxic effects of MAA and DNB on pachytene spermatocytes were easily reproduced by this *in vitro* model. Combined, these assays not only predicted testicular toxicity *in vivo*, but also identified whether the compound directly targets the Sertoli cells or germ cells. With further validation, this cell model may be applicable as a screen to minimize running long-term live-phase studies.

## **PS 2138 Vinclozolin Alters the Testosterone Homeostasis by Regulating the Rat Liver Cytochrome P450.**

D. C. Escobar-Wilches, C. L. Zazueta-Beltran, M. L. Lopez-Gonzalez and A. Sierra-Santoyo. Toxicology, CINVESTAV-IPN, Mexico City, Mexico.

The Vinclozolin (V) is a well-characterized anti-androgenic fungicide in several species. The V is able to produce a complex pattern of induction, suppression and inhibition of cytochrome P450 (CYP) isoforms in mammals. The alteration of liver CYP expression can modify the testosterone biotransformation pattern. The objective of this work was to assess the effect of V on liver CYP expression and its repercussion on serum and urine levels of testosterone and its metabolites. Male Wistar adults rats were orally administered 100 mg/kg/d V for 7 d suspended in corn oil. After last dose the urine of 24 h was collected and animals were sacrificed and the blood was obtained by cardiac puncture. The liver was processed to obtain microsomes for enzyme assays and protein content analysis of different CYP isoforms. The testosterone and its metabolites were extracted from plasma and urine was processed by enzymatic hydrolysis using  $\beta$ -glucuronidase/sulphatase and analyzed by HPLC. V exposure increased 25% the liver relative weight and was accompanied by an increase of 40.3% of total CYP content. The liver immunoreactive protein content of CYP1A1, 1A2, 2A, 2B1 and 3A2 increased 6.5-, 16.4-, 2.3-, 6.5- and 1.5-fold, respect to the non-treated group. The protein content of CYP2E1 was not affected by V. Enzyme activities of EROD, MROD, PROD and PNPB significantly increased 3.0-, 6.4-, 64.3- and 1.6-fold, respectively. In V-treated animals testosterone levels increased 80-fold in serum and 150-fold in urine. V affected the testosterone biotransformation pattern, androstenedione levels increased in serum and urine 54- and 3.6-fold, respectively; 6-DHT increased 112-fold in urine. Other testosterone metabolites were not affected. These results indicate that V regulates liver CYP expression and alters the testosterone biotransformation pattern. In addition, they also suggest an alteration on testosterone homeostasis which may represent another mechanism of action for V. These results will provide further insight into the relationship between toxicity and V exposure.

## **PS 2139 Sperm mRNAs Are Molecular Markers of Testicular Injury in Rats.**

L. Anderson<sup>1</sup>, E. Dere<sup>2</sup> and K. Boekelheide<sup>1</sup>. <sup>1</sup>Department of Pathology and Laboratory Medicine, Brown University, Providence, RI; <sup>2</sup>Department of Urology, Rhode Island Hospital, Providence, RI.

Traditional endpoints used to measure male reproductive toxicity in humans, including semen and hormone analysis, are insensitive and unreliable; those used to monitor toxicity in animal studies, while sensitive, are not easily translatable to humans. It is therefore necessary to develop sensitive and reliable molecular biomarkers of testicular injury that can be used to both monitor human reproductive function and compare animal studies with human exposures.

**Objective:** This sub-chronic dose response study aimed to build on existing data that identified 12 mRNA transcripts that were altered in the sperm following exposure to single doses of the Sertoli cell toxicants 2,5-hexanedione (2,5-HD) or carbendazim (CBZ).

**Methods:** Adult male Fisher 344 rats were either exposed to 0, 0.14%, 0.21%, or 0.33% 2,5-HD in the drinking water for three months, or exposed by daily oral gavage to 0, 30, 50, or 70 mg/kg CBZ in corn oil for three months. Body and organ weights were obtained, and quantifiable histopathological parameters (homogenization resistant spermatid head counts and retained spermatid head counts) were measured. Sperm mRNAs were measured by qRT-PCR arrays.

**Results:** At doses that produced no-to-low levels of testicular injury, as assessed by organ weights and histopathology, a total of eight mRNA transcripts were altered in the cauda epididymal sperm. Four of the transcripts were significantly increased at the highest dose of HD, with clusterin increased in a dose responsive manner at all doses of HD. Six of the transcripts were significantly altered after exposure to CBZ, with clusterin also increased in a dose responsive manner at all doses of CBZ.

**Conclusions:** Our data indicate that sperm mRNA transcripts are sensitive markers of testicular toxicity. The clusterin transcript in particular may be a more sensitive indicator of Sertoli cell injury than the most sensitive histopathological endpoint.

## PS 2140 Effect of Neonatal Exposure to Decabromodiphenyl Ether on Transcript Levels of Splicing Factors in Mouse Testes.

H. Miyaso<sup>1</sup>, N. Nakamura<sup>2</sup>, Y. Matsuno<sup>3,1</sup>, M. Komiya<sup>1</sup> and C. Mori<sup>1,3</sup>.

<sup>1</sup>Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan; <sup>2</sup>Department of Pharmacology, Physiology and Toxicology, Marshall University, Huntington, WV; <sup>3</sup>Center for Preventive Medical Science, Chiba University, Chiba, Japan.

Decabrominated diphenyl ether (decaBDE) is one of flame retardants and is used in worldwide. Our previous study found postnatal exposure to decaBDE had adverse effect to male reproduction in mice. Mice were injected subcutaneously 0.025, 0.25, and 2.5 mg/kg decaBDE during postnatal day 1-5 and evaluated at 12 weeks of age. In 0.025, and 0.25 mg/kg dose groups, the number of Sertoli cells was reduced significantly. Thyroid hormones (THs) are key players for Sertoli cells development. We identified that the transcript levels of TH receptor  $\alpha$  (Thra) decreased significantly in testes of 0.025 mg/kg decaBDE dose group, while no change of TH levels was observed between control and all dose groups. Moreover, we found the ratio of Thra1/Thra2 level decreased in 0.025 and 0.25 mg/kg dose groups compared to control group. The ratio of Thra1/Thra2 level is known to be varied by the change physiologically, and the ratio of heterogeneous ribonucleoprotein (hnRNP) A1 (hnrnpa1): serine/arginine-rich splicing factor 1 (Srsf1) is related to Thra1/Thra2 level. However, no change was observed in hnrnpa1: Srsf1 level between control and dose groups. Therefore, we hypothesized other splicing factors may be involved in decrease of Thra1/Thra2 level. In this study, the transcript levels of hnRNP F (hnrnpf) and hnRNP H1 (hnrnp1) were examined by real-time PCR. Mice were dosed by above described method, and testes were collected at 12 weeks of age. Our data showed the decrease in transcript level of hnrnpf in 0.025 mg/kg dose group, and decrease of hnrnp1 level in 0.25 and 2.5 mg/kg dose groups compared to the control group. Our study suggests that hnrnpf and hnrnp1 are also involved in the decrease of Thra1/Thra2 ratio by neonatal decaBDE exposure.

## PS 2141 RSPOs Counteract TCDD Inhibition of Canonical Wnt Signaling during Fetal Mouse Prostate Development.

A. Branam<sup>1,2</sup>, N. M. Davis<sup>1,2</sup>, R. W. Moore<sup>1,2</sup>, A. J. Schneider<sup>1,2</sup>, C. M. Vezina<sup>1,3</sup> and R. E. Peterson<sup>1,2</sup>. <sup>1</sup>University Wisconsin-Madison, Madison, WI; <sup>2</sup>Pharmacy, UW-Madison, Madison, WI; <sup>3</sup>Comparative Biosciences, UW-Madison, Madison, WI.

Prostatic buds are derived from the urogenital sinus (UGS) and later form into the prostate ductal network in adult mammals. In utero TCDD exposure causes mispositioning and reductions in dorsal and lateral prostatic bud numbers and prevents formation of ventral buds leading to ventral prostate agenesis. Here we examined canonical Wnt signaling following TCDD exposure in vitro. We found multiple components of the pathway (Lef1, Tcf1, Wif1, Lgr5) to be downregulated by TCDD. R-spondins (RSPOs) are promoters of canonical Wnt signaling but their mechanism for activating the canonical Wnt pathway is not fully understood. Previously, we demonstrated RSPO2 and RSPO3 promote prostatic bud development and addition of these proteins can rescue the effects of TCDD on prostatic bud growth. We now further examined the mechanism of RSPO activation of the Wnt pathway in the UGS by studying the extracellular Wnt antagonists, DKKS, and determining their effects on budding in vitro and examining LGRs, which are putative RSPO receptors, by studying mRNA expression between vehicle and TCDD treated UGSs. Both mechanisms of Wnt activation by RSPOs have been demonstrated in other systems; however, it remains unclear if RSPOs preferentially

act through one mechanism over the other. Our results showed little effect on prostate bud number following treatment with DKK1 and DKK2. We found both Lgr4 and Lgr5 mRNA expression in the basal epithelium (BE) where prostatic buds form and additionally we found a decrease by TCDD in Lgr5 mRNA levels in vitro. These results suggest that RSPOs bind to LGRs located in the BE of the UGS to initiate prostate bud formation. Together, these data illustrate that TCDD inhibits multiple components of the Wnt signaling pathway and that the combined inhibition of these components significantly contributes to the inhibitory budding phenotype caused by TCDD. (Grant support: NIH ES01332, T32 ES007015)

## PS 2142 Sensitivity of Toxicological Endpoints to Detect Alterations in the Male Reproductive System of Nonhuman Primates.

G. D. Cappon<sup>1</sup>, D. Potter<sup>1</sup>, M. E. Hurr<sup>1</sup>, G. F. Weinbauer<sup>2</sup> and C. J. Bowman<sup>1</sup>. <sup>1</sup>Pfizer Worldwide Research & Development, Groton, CT; <sup>2</sup>Covance Laboratories GmbH, Muenster, Germany.

The assessment of the potential for a compound to cause toxicity to male reproductive processes relies heavily on histopathology and organ weights of the reproductive tissues. This is even more so with biologics where non-human primates (NHP) is the only relevant species and evaluation of functional fertility is impractical. To address this shortcoming ICH S6(R1) included a trigger for the addition of non-routine endpoints to NHP studies in cases where there is reproductive cause for concern. To determine the sensitivity of these endpoints to perturbation we performed a power analysis of routine and triggered endpoints. The analysis was done on control data from sexually mature Asian and Mauritian sourced NHP used in toxicity studies at Covance Laboratories GmbH. The power calculations were performed with a 2 sample two-sided T-test ( $\alpha=0.05$ ) assuming 3 NHP/group and the number of observations ranged from 98 to 472 per endpoint. For reproductive organ weights the power to detect a 50% change from control was 30%, 35%, 18% and 13% for testes, epididymides, prostate, and seminal vesicle, respectively. For testicular volume the power to detect a 50% change was ~ 30%, with slight differences depending on the method (caliper or ultrasound). For seminal analysis the power to detect a 50% change was 6%, 6%, 66% and 41% for ejaculate weight, sperm count, sperm motility, and sperm morphology (percent normal), respectively. For male hormone data the power to detect a 50% change was 10%, 30%, 7% and 78% for testosterone, inhibin B, luteinizing hormone, and follicle stimulating hormone, respectively. Given samples sizes of 3 per treatment group, and the magnitude of biological variability observed for these endpoints, the ability to draw conclusions about potential toxicity will be limited for most endpoints. Consequently, great care should be taken in the choice of endpoints added to general toxicity studies to assess the male reproductive system.

## PS 2143 Contribution of PI3K/Akt/DAF-16 Activity in *C. elegans* to Gene-Environment Interactions following MeHg Exposure.

S. J. Fretham and M. Aschner. *Pediatric Toxicology, Vanderbilt University Medical Center, Nashville, TN.*

Neither genetic nor environmental factors completely explain the etiology and progression of dopaminergic (DAergic) neurodegeneration in Parkinson's disease (PD). This study examines PI3K/Akt signaling as a mechanistic link between environmental and genetic factors known to contribute to PD. Specifically the interaction between methylmercury (MeHg) exposure, a ubiquitous neurotoxin, and PARK7 (DJ-1), an autosomal recessive PD gene. PI3K/Akt signaling is highly conserved and regulates many aspects of neuronal survival and function. MeHg exposure has been shown to activate PI3K/Akt signaling and DJ-1 modifies PTEN activity, an upstream regulator of PI3K/Akt. Mutant and transgenic *Caenorhabditis elegans* (*C. elegans*) strains were used to determine if PI3K/Akt responsiveness and loss of DJ-1 increases MeHg vulnerability. Strains used include: wild type (WT) Bristol N2; strains null for daf-16, age-1, daf-18, djr-1.1, and djr-1.2; and a strain overexpressing DAF16::GFP. Synchronous L1 populations were treated with 0-40  $\mu$ M MeHg for 30 minutes followed by assessment of survival and basal slowing (a dopamine-dependent feeding behavior). Compared to WT worms, increased PI3K/Akt activity resulting from genetic loss of daf-18 (PTEN homolog) and daf-16 (FOXO homolog) led to increased death and lower lethal dose (LD50) values following MeHg treatment while decreased PI3K/Akt activity through loss of age-1 (PI3K homolog) and overexpression of DAF-16::GFP increased survival. Loss of djr-1.1 or djr-1.2 (PARK7 homologs) did not affect survival. Basal slowing was significantly reduced in WT worms following 20  $\mu$ M but not 10  $\mu$ M MeHg treatment ( $p<0.01$ ). Basal slowing in worms lacking djr-1.1 but not djr-1.2, was decreased by 10  $\mu$ M and 20  $\mu$ M MeHg, suggesting that loss of djr-1.1 increases DAergic sensitivity to MeHg. Collectively, these findings demonstrate that MeHg-induced

PI3K/Akt activation contributes to toxicity and that MeHg impairs DAergic behavior, an effect that is enhanced by loss of *djr-1.1*. (Work supported by NIEHS R01-07331 and NIEHS T32-ES007028).

**PS 2144 Low-Dose Postnatal MeHg Exposure Alters mRNA Levels of Rat Brainstem Glutamate Receptors and Voltage Gated Calcium Channels.**

A. Colón-Rodríguez, R. K. Hajela, S. Escudero, Y. Yuan and W. D. Atchison. *Pharm/Tox, Michigan State University, East Lansing, MI.*

Methylmercury (MeHg) hastens the onset of motor paralysis in SOD-1 G93A mice, a genetic model of Amyotrophic Lateral Sclerosis (ALS), suggesting a gene-environment interaction in a genetically susceptible animal model. Associated with this are alterations in  $[Ca^{2+}]_i$  and glutamate receptor (GluR) function, both of which are suggested targets for MeHg toxicity. The goal of this study was to determine if MeHg alters mRNA levels of voltage gated  $Ca^{2+}$  channels (VGCCs), NMDA, or AMPA receptors. We measured mRNA levels of the pore forming  $\alpha_1$  subunit of L, N, P/Q and R type VGCCs, NR1 and NR2A subunits of NMDA receptors and GluR2 and GluR3 subunits of AMPA receptors. Determining if MeHg alters levels of these ion channels could contribute to understanding of MeHg-induced alteration in  $[Ca^{2+}]_i$  in motor neurons. Postnatal day 5 rats were treated sc with 0.75 or 1.5 mg/kg/day MeHg for 15 or 30 days (d), then stopped for a clearing period of 30 d. Quantitative real time PCR was performed on reverse transcript of RNA isolated from 10 mg of brainstem tissue, a region rich in motor neurons. MeHg treated animals had higher levels of GluR2, GluR3 and NR2A at 15 d in both 0.75 and 1.5 mg/kg/day exposure. MeHg induced an increase in the levels of all GluR subunits studied. It was highest at 30 d, and more pronounced in the 0.75 mg/kg/day exposure. GluR2 was the most affected subunit. At 60 d, levels of all GluR subunits were increased but at levels similar to those seen at 15 d of exposure. With the exception of  $\alpha_{1A}$ , levels of all VGCC  $\alpha_1$  subunits were higher at 0.75 mg/kg/day MeHg exposure on 15 and 30 d and lower at 60 d. At 15 d 1.5 mg/kg/day MeHg increased levels of all VGCC  $\alpha_1$  subunits except  $\alpha_{1E}$ . At 30 d the level was even higher for all of the  $\alpha_1$  subunits, but returned to levels similar to those at 15 d after the clearing period. The increase in the level of GluR subunits and most of the VGCCs could contribute to the alteration in  $Ca^{2+}$  homeostasis induced by MeHg on motor neurons. Supported by NIH grants R01ES03299 and R25NS065777.

**PS 2145 Effects of Chronic Postnatal Methylmercury Exposure on mRNA Expression of Calcium Regulatory Proteins in Adult Mouse Brain Stem.**

J. A. Musser<sup>1,2</sup>, A. Colón-Rodríguez<sup>1</sup> and W. D. Atchison<sup>1,2</sup>. <sup>1</sup>Department Pharmacology/Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Methylmercury (MeHg) causes marked alterations in neuronal  $[Ca^{2+}]_i$  homeostasis through its interaction with membrane ion channels such as voltage-gated  $Ca^{2+}$  channels (VGCCs), and  $Ca^{2+}$  permeable ligand-gated channels-NMDA (NMDAR) and AMPA receptors (AMPA). Chronic postnatal exposure to MeHg hastens the onset of Amyotrophic Lateral Sclerosis-like phenotype in the SOD1G93A genetically susceptible mouse model via glutamate-mediated excitotoxicity. The underlying mechanism of MeHg effects on brainstem motor neurons remains unclear. In this study we focused on examining the effects of chronic MeHg exposure on mRNA expression of the pore-forming  $\alpha_1$  subunits of the L ( $\alpha_{1L}$ ), N ( $\alpha_{1N}$ ), P/Q ( $\alpha_{1P/Q}$ ) and R-type ( $\alpha_{1R}$ ) VGCCs, NR1 and NR2 subunits of the NMDAR, GluR2 and GluR3 subunits of the AMPAR,  $Ca^{2+}$  binding proteins calbindin D28K and parvalbumin, and glutamate transporter EAAT2, all of which can modulate  $[Ca^{2+}]_i$  homeostasis. Eleven week old male ICR mice were exposed to 0, 0.5 or 5 ppm MeHg in drinking water *ad libitum* for 6 mos. Total RNA was extracted from 10 mg of brainstem and reverse transcription PCR performed. Quantitative real time PCR was performed on reverse transcript (cDNA) to measure expression of the target genes. Exposure to 0.5 ppm MeHg induced a decrease in the expression of the AMPAR subunits,  $Ca^{2+}$  binding proteins and the  $\alpha_1$  subunit of the N- and P/Q-type VGCCs. NMDAR expression at 0.5 ppm MeHg exposure was not altered for the NR1 subunit but was increased for NR2. At 5 ppm MeHg decreased expression of GluR2, EAAT2, calbindin D28K, parvalbumin, and all of the VGCC subunits. Expression of AMPAR subunit GluR3 was increased at 5ppm exposure. These results support the idea that MeHg-induced increase in  $[Ca^{2+}]_i$  on brainstem motor neurons is due to the glutamate receptors (greater GluR2 expression, and NR2 expression), or inefficient  $Ca^{2+}$  buffering (decrease in the  $Ca^{2+}$  binding proteins and EAAT2 transporter). VGCCs may not contribute to the alteration in  $[Ca^{2+}]_i$  induced by MeHg because their expression was decreased. Supported by NIH grants R01ES03299 and R25NS065777.

**PS 2146 Perinatal Exposure to Low-Dose Methylmercury Induces Dysfunction of Motor Coordination with Decreases in Synaptophysin Expression in the Cerebellar Granule Cells of Rats.**

M. Fujimura. *Basic Medical Sciences, National Institute for Minamata Disease, Minamata, Japan.* Sponsor: A. Naganuma.

Methylmercury (MeHg) is an environmental pollutant that is toxic to the developing central nervous system (CNS) in children, even at low exposure levels. Perinatal exposure to MeHg is known to induce neurological symptoms with neuropathological changes in the CNS. However, the relationship between the neurological symptoms and neuropathological changes induced in offspring as a result of exposure to low-dose MeHg is not well defined. In the present study, neurobehavioral analyses revealed that exposure to a low level of MeHg (5 ppm in drinking water) during developmental caused a significant deficit in the motor coordination of rats in the rotating rod test. In contrast, general neuropathological findings, including neuronal cell death and the subsequent nerve inflammation, were not observed in the region of the cerebellum responsible for regulating motor coordination. Surprisingly, the expression of synaptophysin (SPP), a marker protein for synaptic formation, significantly decreased in cerebellar granule cells. These results showed that perinatal exposure to low-dose MeHg causes neurobehavioral impairment without general neuropathological changes in rats. We demonstrated for the first time that exposure to low-dose MeHg during development induces the dysfunction of motor coordination due to changes of synaptic homeostasis in cerebellar granule cells.

**PS 2147 Striatal Synaptosome Mitochondrial Function Is Not Altered following a 6mo MeHg Treatment in Male BALB/c Mice.**

S. M. Fox<sup>1,2</sup> and W. D. Atchison<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Methylmercury (MeHg) is a potent environmental neurotoxicant that causes cell-type specific damage in the cerebellum in a calcium ( $Ca^{2+}$ ) dependent manner. The developmental effects of MeHg have been widely explored. However, the effects of chronic exposure in adults have not been characterized. The ability of MeHg to cause cell-type specific damage due to alterations in  $Ca^{2+}$  regulation raises the possibility that other subsets of neurons with vulnerability that depends on  $Ca^{2+}$  regulation could be sensitive to MeHg. This study focused on investigating the effects of chronic MeHg treatment on the mitochondrial function of nigrostriatal dopamine (NSDA) neurons. These neurons exhibit a unique physiological phenotype; they autonomously generate action potentials in the absence of synaptic input. The spontaneous action potentials rely on the influx of  $Ca^{2+}$  through Cav1.3, L-type  $Ca^{2+}$  channels. We also investigated whether co-treatment with isradipine, a  $Ca^{2+}$  channel antagonist, would protect against MeHg-mediated damage. Beginning at 3mo, male BALB/c mice were given 5ppm Hg as MeHg in their drinking water alone or were co-treated with 2ppm isradipine in their food for 6mo. Following the 6mo treatment period mouse weight gain was normal and there were no phenotypic changes. Mitochondrial function was measured in synaptosome preparations from NSDA neurons using the Extracellular Flux Analyzer (Seahorse Biosciences). Mitochondrial basal respiration, ATP production rate, maximal respiration, and spare capacity were examined. No alterations were seen in any measure of mitochondrial function in animals treated with MeHg alone or in animals co-treated with isradipine ( $n \geq 4$ ,  $p$  values=0.8494, 0.1019, 0.9178, 0.8227 respectively). These studies have demonstrated that mitochondrial function of striatal synaptosomes is unchanged following a 6mo MeHg treatment. The effects of a 12mo MeHg treatment are currently being pursued. This work was supported by a ViCTER supplement to R01ES03299.

**PS 2148 Identification and Characterization of Plasma Membrane and Intracellular Transporters Involved in MeHg-Induced Whole Animal and DA Neuron Pathology.**

N. VanDuyn and R. M. Nass. *Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Methylmercury (MeHg) exposure from occupational, environmental, and food sources is a significant threat to public health. Recent epidemiological and vertebrate studies suggest that MeHg exposure may contribute to the propensity to develop Parkinson's disease (PD). We have developed a novel *C. elegans* model of MeHg toxicity and have shown that low, chronic exposure confers dopamine (DA) neuron degeneration, and that the toxicity is partially dependent on the phase II antioxidant transcription factor SKN-1/Nrf2. Aims/Objectives: In this study we

asked what genes are involved in MeHg-induced animal and DA neuron pathology. Methods: We utilized a reverse genetic screen, immunofluorescence, transgenic *C. elegans*, RT-PCR, ICP-MS, Western analysis, and neuronal morphology analysis to characterize expression, localization and the role that SKN-1, MPT-1, and MIT-1 play in MeHg-induced whole animal and DA neuronal death. Results: Over 17,000 genes were screened for whole animal sensitivity to MeHg, and 92 genes were identified (90% have strong human homologues) that affect whole animal and/or DA neuron pathology. Here we report detailed analysis of several transporters. Specifically, genetic knockdown of MPT-1 results in 40% of animals showing DA neurodegeneration relative to 0% in WT animals following 500 nM MeHg exposure for 4 days. Genetic knockdown of transporters MPT-1 and MIT-1 following high levels of MeHg exposure (10uM) results in 0% and 2% viability, respectively, compared to 100% in WT animals. Inductively Coupled Plasma Mass Spectrometry (ICP-MS) studies show that MPT-1 knockdown results in 2-fold higher Hg levels relative to WT, while MIT-1 contain 60% less than WT. We also provide evidence for differential cellular localization. Conclusions: This study describes a novel whole genome reverse genetic screen that has identified a number of molecular transporters and proteins involved in MeHg resistance. Support: NIEHS ES014459 and ES003299 to RN, and EPA STAR Graduate Fellowship to NVD.

## PS 2149 Biochemical Alterations of Rat Brain Mitochondrial Enzymes Induced by Aluminium Chloride.

R. Venugopal<sup>1</sup>, K. Arumugam<sup>1</sup>, V. Dhasal<sup>1</sup>, P. Subbarayalu<sup>2</sup> and S. Viswanadhapalli<sup>3</sup>. <sup>1</sup>Zoology, K.M. Centre for Post Graduate Studies, Puducherry, India; <sup>2</sup>Greehey Children's Cancer Research Institute, University of Texas Health Science Center at San Antonio, San Antonio, TX; <sup>3</sup>Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Aim: The present study was planned to investigate the effect of aluminium chloride (AlCl<sub>3</sub>) on enzyme activities in the mitochondrial fractions of the brain of male albino rats. Methods: Adult male albino rats were administered AlCl<sub>3</sub> at two different doses, 50 mg and 100 mg/kg body weight, orally, daily for 45 days. At the end of the experimental period the animals were sacrificed, the brain was removed and mitochondrial fractions were isolated. Antioxidant enzymes like catalase, superoxide dismutase, glutathione peroxidase, glutathione reductase and glutathione-S-transferase were estimated in the brain extract. Other biochemical markers were also studied. Results: AlCl<sub>3</sub> administration had no effect on the body weight and brain weight. Almost all the antioxidant enzymes studied were markedly diminished in the brain of AlCl<sub>3</sub> treated animals. The lipid peroxidation and hydrogen peroxide were significantly increased. The activities of acid phosphatase and alkaline phosphatase were significantly increased. The activities of Ca<sup>++</sup> ATPase, Mg<sup>++</sup> ATPase and Na<sup>+</sup> K<sup>+</sup> ATPases were decreased by the AlCl<sub>3</sub> treatment in the brain. However, the influence was found to be more in 100 mg treated when compared to 50 mg AlCl<sub>3</sub> treated rats. The activity of acetylcholinesterase was diminished while the lactate dehydrogenase activity increased after aluminium treatment. Conclusion: The present study suggests the toxicity of aluminium by inducing the oxidative stress and adverse alterations in the brain metabolism and possible interference in brain coordination processes.

## PS 2150 Effects of Mercuric Chloride on Cell Surface Expression of Dopamine Transporter in PC12 Cells.

C. Hui, A. Carpi and S. Cheng, *Scicnes, John Jay College of Criminal Justice, New York, NY.*

Mercury compounds are known to have a ubiquitous nature due to their ability to move through the biogeochemical cycle and food web. Organic and inorganic forms of mercury generally target different organ systems of the body while biotransformation after exposure can result in the bioaccumulation of various species of the element. Divalent mercury (Hg<sup>2+</sup>) can be found within the brain following exposure to the mercury vapor of dental amalgams and after extended exposure to methyl mercury. Dopamine transporter protein (DAT) has been implicated as a link between neurotoxicity following exposure to 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Increases in DAT expression on the cell membrane have been shown to result in amplified sensitivity to MPTP. The in vitro effect of mercuric chloride (HgCl<sub>2</sub>) on the cell surface expression of DAT in stably transfected DAT expressing PC12 cells was studied. Cell viability (MTT assay) following treatment with 0.5ppm HgCl<sub>2</sub> and 1-methyl-4-phenylpyridinium (MPP<sup>+</sup>) the active metabolite of MPTP, was observed to result in an additive increase in toxicity compared with treatment with MPP<sup>+</sup> alone. Using immunocytochemistry and Western blot, DAT surface expression was seen to increase following HgCl<sub>2</sub> (0.2-2.0ppm) exposure which exhibited a biphasic pattern with the maximum expression observed at 0.5 ppm when compared to the control. With null function DAT mutant, cell viability following exposure to HgCl<sub>2</sub> and MPP<sup>+</sup> showed an absence of the increase in toxicity observed at 0.5ppm originally observed in the wild

type control cells. The results show that HgCl<sub>2</sub> is able to increase DAT surface expression in a concentration dependent manner and as a result, exposure could trigger subsequent increased susceptibility to pesticides such as MPTP that use the DAT system as pathway of toxicity.

## PS 2151 Changes in Gene Induction Associated with Lead Acetate Mediated Oxidative Stress and Mitochondrial Dysfunction in Neuronal PC12 Cells.

H. Kim<sup>1</sup>, Z. Paras<sup>1</sup>, G. Tsai<sup>1</sup>, M. J. Kim<sup>1</sup>, M. Shakarjian<sup>1,2,3</sup> and D. E. Heck<sup>1</sup>. <sup>1</sup>New York Medical College, Valhalla, NY; <sup>2</sup>Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ; <sup>3</sup>Environmental and Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Lead is a major environmental heavy metal toxin that affects brain development and impairs cognition in children and adults. Despite extensive research, molecular mechanisms underlying neurotoxicity mediated by lead are not well understood. Previous studies have shown that ROS production caused by lead exposure decreases cellular antioxidant defense networks in the brain. In the present studies, we evaluated lead-mediated alterations in oxidative stress pathways in PC12 cells. Using H2DCFDA in conjunction with flow cytometry, we found that lead exposure increased ROS production up to 2.7-fold (3 hr, 1 nM to 10 μM); this effect was associated with mitochondrial membrane potential changes which were 60% lower after 24 hour treatment with 1 μM PbAc<sub>2</sub>. Using QPCR, we observed that exposure to lead resulted in the induction of anti-oxidant genes including MnSOD, catalase, NQO1, HO-1 and GST-M1). QPCR analysis also revealed induction of genes that are indicators of Ca<sup>2+</sup> flux (TRPV1), inflammation (COX-2, IL-1 β, TNFα), and apoptosis (bcl-2, bax, caspase-3). Relative mRNA for signaling kinases ERK(p42/p44), SAPK/JNK and PKC-δ were increased while that for p38MAPK was decreased. Taken together our results suggest that lead treatment of PC12 cells enhances cellular ROS levels, negatively impacts the anti-oxidant gene profile and the mitochondrial membrane potential of PC12 cells, upregulates expression of genes critical for inflammation and apoptosis and alters expression of critical cellular signaling kinases. We speculate that changes in the expression of antioxidant enzymes and signaling kinases are important in lead-mediated neurotoxicity. (Supported by AR055073)

## PS 2152 Effects of Pb<sup>2+</sup> in the Neural Differentiation of Mouse Embryonic Stem Cells.

F. J. Sanchez-Martin and A. Puga, *Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

Exposure to environmental agents during embryonic life is suspected to modify the epigenetic mechanisms that regulate the gene expression patterns that control development. The resulting changes in gene expression may affect lineage differentiation and extend into adulthood, well beyond the time when the organism was exposed to the agents. This paradigm provides a testable molecular basis for the Barker hypothesis, which proposes that there is a fetal origin of adult disease. Lead (Pb) is a ubiquitous environmental toxicant whose possible effects, especially at early ages of development, include reduction of cognitive functions and IQ, behavioral effects, attention deficit and hyperactivity disorder. We are using neural differentiation of mouse embryonic stem cell (mESC) to determine the molecular changes taking place during embryogenesis and neurodevelopment as a consequence of long-term exposure to Pb<sup>2+</sup>. We find that after differentiation of mESC into neuronal cells, cultures express many neuronal markers, including *Tubb3*, *Syp*, *Gap43* and *Hud*, and do not express the glial marker *Gafp*. Furthermore, the cells express *Vglut1*, a marker of glutamatergic neurons. Incubation with Pb<sup>2+</sup> during differentiation reduces the expression of the calcium-dependent exon IV of *Bdnf* and alters the expression pattern of other neural genes but does not alter the morphology of the neuron and the expression of *Tubb3*. Thus, we conclude that after differentiation of mESC in vitro, we can obtain pure cultures of glutamatergic neurons whose gene expression patterns are changed by Pb<sup>2+</sup> exposure. These cells should provide an useful substrate to analyze the mechanisms of toxicity of environmental neurotoxicants. Supported by NIH grant R21 ES020048.

**PS 2153 Developmental Lead (Pb<sup>2+</sup>) Exposure and Mutant DISC1 Interact to Produce Schizophrenia-Like Neurobehavioral Abnormalities and Brain Volume Changes in Mice: A Gene-Environment Interaction Study.**

T. R. Guilarte<sup>1,3</sup>, J. L. McGlothlan<sup>1</sup>, B. Abazyan<sup>2</sup>, C. Yang<sup>2</sup>, K. Hua<sup>3</sup>, S. Mori<sup>3</sup> and M. Pletnikov<sup>3</sup>. <sup>1</sup>Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, NY; <sup>2</sup>Psychiatry, Johns Hopkins School of Medicine, Baltimore, MD; <sup>3</sup>Radiology, Johns Hopkins School of Medicine, Baltimore, MD.

The glutamatergic hypothesis of schizophrenia suggests that hypoactivity of the NMDA receptor (NMDAR) is an important factor in the pathophysiology of schizophrenia and related mental disorders. The environmental developmental neurotoxicant lead (Pb<sup>2+</sup>) is a potent and selective antagonist of the NMDAR and two recent human studies have suggested an association between prenatal Pb<sup>2+</sup> exposure and the increased likelihood of expressing a schizophrenic phenotype later in life. Schizophrenia and other major mental disorders likely result from interactions between genetic risk factors and adverse environmental insults. We evaluated the neurobehavioral consequences of Pb<sup>2+</sup> exposure in mice with inducible expression of mutant Disrupted-in-Schizophrenia-1 (DISC1), a candidate gene for major psychiatric diseases. We hypothesize that mutant DISC1 and Pb<sup>2+</sup> exposure synergistically interact to produce an exaggerated phenotype in mutant mice. Mutant DISC1 and control mice born by the same dams were raised and maintained on normal or Pb<sup>2+</sup> diet. We tested animals in a series of behaviors associated with schizophrenia and performed volumetric MRI measurements of the brain. We found that the interaction between developmental Pb<sup>2+</sup> exposure and mutant DISC1 produced a significantly greater increase in locomotor activity, impaired pre-pulse inhibition of the acoustic startle that was abrogated by D-serine and exacerbated responses to MK-801, an NMDAR antagonist. Compared to control unexposed mice, mutant exposed animals had significantly larger lateral ventricles. Our data suggest that interactions between Pb<sup>2+</sup> and mutant DISC1 may synergistically produce schizophrenia-like behavioral alterations and brain volume changes in mice. [Supported by grant # ES06189-18S1 to TRG]

**PS 2154 Reduced Parvalbumin Expression in the Striatum, Frontal Cortex, and Hippocampus after Developmental Pb<sup>2+</sup> Exposure: Examining Early Life Pb<sup>2+</sup> Exposure As a Risk Factor for Schizophrenia.**

K. Stansfield<sup>1</sup>, K. Ruby<sup>2</sup>, J. L. McGlothlan<sup>1</sup> and T. R. Guilarte<sup>1</sup>. <sup>1</sup>EHS, Columbia University, NYC, NY; <sup>2</sup>Lake Erie College of Osteopathic Medicine, Erie, PA.

The calcium-binding protein, parvalbumin (PV), is expressed in GABAergic interneurons and is implicated in working memory and associative learning. Decreased PV expression is observed in schizophrenia patients and also in animal models of schizophrenia. N-methyl-D-aspartate receptor (NMDAR) antagonists are used to model certain aspects of schizophrenia in animal models and NMDAR antagonists decrease PV levels and the number of PV-positive interneurons, suggesting that NMDAR function plays a role in the expression of PV interneurons and in schizophrenia. Lead (Pb<sup>2+</sup>) is a potent NMDAR antagonist that has been implicated in the etiology of schizophrenia, therefore we examined the effect of developmental Pb<sup>2+</sup> exposure on PV cell density in the striatum and PV protein expression in the striatum, hippocampus and frontal cortex of rats developmentally exposed to Pb<sup>2+</sup>. A trend of decreased PV positive cell density was observed at all levels of the striatum, however a statistically significant decrease (t11=2.2; p = 0.005) in cell density was found in the caudal striatum of Pb<sup>2+</sup>-treated rats relative to controls. Additionally, PV protein expression measured by western blot was significantly reduced in the striatum (t22=3.3; p = 0.003), frontal cortex (t7 = 2.25, p = 0.05) and hippocampus (t10 = 2.31, p = 0.04) of rats developmentally exposed to Pb<sup>2+</sup>. Overall, these findings indicate that early life Pb<sup>2+</sup> exposure decreases the number of PV positive neurons in the striatum, and reduces the expression of PV in the striatum, frontal cortex and hippocampus. The data suggests a relationship between Pb<sup>2+</sup> induced NMDAR hypoactivity and PV expression, implicating a potential association between developmental Pb<sup>2+</sup> exposure and the expression of a schizophrenia phenotype later in life. [This work was supported by NIEHS grant # ES006189 to TRG]

**PS 2155 Effects of Developmental Lead Exposure on Associative Learning and Memory Are Modified by Sex, Developmental Window of Exposure, and Level of Exposure.**

D. Anderson, W. Mettill, S. Kidd and J. Schneider. Thomas Jefferson University, Philadelphia, PA.

Trace fear conditioning is a variant of fear conditioning in which a neutral conditioned stimulus (CS) is paired with an aversive unconditioned stimulus (UCS). Trace conditioning includes a "trace" interval of several seconds separating the CS and UCS. Learning the CS-UCS association across this interval and the consolidation of the memory requires participation of both the hippocampus and medial prefrontal cortex (mPFC). Long-term storage of information associating temporally disconnected events occurs in the mPFC in parallel with memory storage in the hippocampus. The current research investigated the extent to which these processes are affected by developmental Pb exposure. Long Evans dams were fed Pb-containing food (RMH 1000 with or without added Pb acetate: 0, 150, 375, 750 ppm) prior to breeding and stayed on the same diet through weaning at postnatal day 25 (perinatal exposure group (Peri)). Other animals were exposed to the same doses of lead but exposure started on postnatal day 1 and continued through postnatal day 25 (early postnatal exposure group (EPN)). Beginning at postnatal day 45, animals were placed in the trace fear conditioning apparatus. Conditioning trials (CS tone-UCS shock pairings) were repeated six times during an 18 min training period. Freezing behavior was measured during the trace period. Retention testing occurred 24/48 hrs and 10 days later to assess memory consolidation and long-term memory. At the lowest level of exposure, EPN-exposed females were more impaired at short and long-term retention than were Peri-exposed females; the opposite effect was observed in males. In females, the lowest level of exposure had the greatest disruptive effect on retention. In males, the highest level of exposure had the greatest disruptive effects on retention. These data suggest complex responses of the brain to developmental Pb exposure with likely different molecular effects in hippocampus and PFC that vary with sex and timing and level of exposure. Supported by NIH RO1-ES015295.

**PS 2156 Sex- and Hemisphere-Dependent Neurochemical Changes Produced by Lead, Prenatal Stress, and the Combination.**

D. A. Cory-Slechta, D. Weston, S. Liu and J. L. Allen. Environmental Medicine, University of Rochester Medical School, Rochester, NY.

Brain lateralization, important to mediation of cognition and 'multi-tasking', is disrupted in attention deficit disorder and schizophrenia. Altered brain lateralization could play a role in the corresponding cognitive and attention deficits associated with both low level lead (Pb) exposure and prenatal stress (PS). This study examined laterality of mesocorticolimbic (frontal cortex, nucleus accumbens, striatum, midbrain) monoamines and amino acids (frontal cortex only) that mediate such behavioral functions, both under normal (control) conditions, and in response to lifetime Pb (0 or 50 ppm), PS (restraint stress on gestational days 16-17) or Pb+PS in rats. Sex-dependent differences in brain laterality were seen even in control rats, as noted in frontal cortex, striatum and midbrain monoamines and frontal cortex amino acids. Hemispheric differences in Pb ± PS effects were most notable in males, as seen in frontal cortex and striatum, but particularly in midbrain, where Pb+PS, but neither alone, significantly reduced right hemispheric levels of homovanillic acid and norepinephrine, with similar trends in serotonin. In contrast, no Pb+PS effects were found in left hemisphere. Pb+PS, but neither alone, reduced frontal cortex dopamine and increased dopamine turnover in left hemisphere of males, whereas in the right hemisphere, Pb, PS and Pb+PS reduced frontal cortex dopamine and Pb alone increased dopamine turnover. The only suggestive Pb+PS hemispheric difference in females was increased right but not left hemisphere frontal cortex GABA. Thus Pb, PS and Pb+PS can differentially influence mesocorticolimbic neurotransmitter function both by hemisphere and sex. Such differences are likely to contribute to associated sex-related alterations in behavioral outcomes, such as our previously reported contrasting effects on learning accuracy produced by Pb+PS in males vs. females. The findings also underscore the significance of defining the hemisphere used for assay in experimental studies for evaluation of CNS mechanisms of behavior.

**PS 2157 Sex-Dependent Changes in the Effects of Lead and Prenatal Stress on Impulsivity and Neurochemical Substrate.**

H. Weston, D. Weston, S. Liu, J. L. Allen and D. A. Cory-Slechta. Environmental Medicine, University of Rochester Medical School, Rochester, NY.

Both lead (Pb) exposure and prenatal stress (PS) adversely affect cognition and attention. Impulsivity is one diagnostic component of attention deficit, and enhanced impulsivity has been related to multiple neuropsychiatric disorders. This

study examined whether combined Pb+PS would enhance impulsivity compared to either alone, as well as potential associated mechanisms using rats exposed to 0 or 50 ppm Pb from 2 mos prior to breeding through lactation with/without PS on gestational days 16-17. Impulsivity was assessed in a delay of reward paradigm that provides a choice between an immediate but small reward or a larger but delayed reward, with delay time increased across test sessions. Choice of the long delay typically declines with increasing delay time. In males, PS, particularly with Pb, delayed this transition, consistent with impulsivity of choice. A trend towards increased omission of trial initiation responding was also noted in males. Females showed no changes. Adverse effects in males may be related to reduced nucleus accumbens dopamine (DA) function and reduced frontal cortex, nucleus accumbens and striatal serotonergic (5HT) function, as found in 2 mos old male littermates of behaviorally-tested rats; effects less evident in females. The transitory nature of the behavioral changes in males may arise from the 'enriching' effects of behavioral testing: post-testing, Pb + PS increased levels of striatal DA and 5HT and metabolites, and of nucleus accumbens DOPAC, norepinephrine and 5HT in males, consistent with a reversal of pre-testing neurochemical changes. These findings demonstrate a preferential vulnerability of males to PS-induced impulsive choice that is enhanced by concurrent Pb exposure and which may arise from early reductions in mesocorticolimbic DA and 5HT function. As impulsivity is considered to play a central role in attention deficit, gambling, substance abuse and personality disorder, the findings have significant public health implications. Supported by EPA Grant RD 83457801.

**PS 2158 Investigation of the Combined Neurotoxicity of Developmental Iron Deficiency and Lead Exposure.**

A. Greminger<sup>1</sup>, D. A. Cory-Slechta<sup>1</sup> and M. Mayer-Proschel<sup>2</sup>. <sup>1</sup>Environmental Medicine, University of Rochester, Rochester, NY; <sup>2</sup>Biomedical Genetics, University of Rochester, Rochester, NY.

Iron deficiency (ID) and Lead (Pb) exposure are widespread public health problems that continue to affect women and children with similar risk factors, as well as produce similar neurotoxic effects on the developing CNS. Although studies of these insults singularly suggest a potential for enhanced neurotoxicity in their combination, previous work has failed to address this in relevant animal models, and consistent data from human cohorts are lacking. We utilized a maternal iron-deficient dietary model in the presence or absence of Pb-exposure to examine the possible synergism of ID and Pb during offspring neurodevelopment. Offspring of each exposure were assessed using hematologic parameters, as well as tissue Pb levels. Our data show that maternal Pb-only exposure did not cause anemia in either the dam or the offspring throughout development. In combination with ID, Pb did not decrease hematocrit levels in offspring beyond those of ID-only, arguing against the notion that Pb causes or worsens ID. However, the presence of ID significantly increased blood and tissue Pb levels by more than 50% in the dams and offspring compared to animals exposed to the same Pb levels in the absence of ID. Our data suggest that maternal non-anemic ID strongly increases absorption of Pb into the CNS of offspring underscoring the importance of non-anemic ID as a susceptibility factor to environmental Pb toxicity. To determine the functional impact of ID + Pb we measured overall brain maturation using the auditory brain stem response. We found significant decreases in neuronal conduction velocity in all three exposure groups (Pb-only, ID-only and ID + Pb) compared to control offspring at PND40. However, the combination of ID + Pb did not result in synergistic increases over either insult alone at this age or decibel level (70dB). Additional analysis at different ages and stimulation levels is required to determine if this lack of synergy may be due to compensatory mechanisms or is restricted to later in development.

**PS 2159 Bcl-xL-Mediated Remodeling of Rod and Cone Photoreceptor (PR) Synaptic Mitochondria (mt) After Postnatal Lead Exposure (PLE): Structure and Function.**

D. A. Fox<sup>1</sup>, G. A. Perkins<sup>2</sup>, M. H. Ellisman<sup>2</sup> and J. E. Johnson<sup>3</sup>. <sup>1</sup>Univ. Houston, Houston, TX; <sup>2</sup>Univ. California: San Diego, La Jolla, CA; <sup>3</sup>Univ. Houston-Downtown, Houston, TX.

PLE produces rod-selective apoptosis (blocked by Bcl-xL) and persistent scotopic-mesopic ERG and vision deficits in man and animals. Rod, but not cone, inner segment mt were considered the target: albeit PR synaptic mt were not examined. Thus, we determined the effects of PLE on these mt and if Bcl-xL provided protection. C57BL/6 mice pups had PLE during lactation by dams drinking Pb water. [BPb] was 10-20 µg/dL and at control level by 60 doa. EM, 3-D electron tomography, and oxygen consumption (QO2) studies were done at 70 doa: control, transgenics overexpressing Bcl-xL in PRs, PLE and Bcl-xL/PLE groups. In PLE, rod spherule and cone pedicle mt were swollen, cristae structure changed, and the no.

of segments/crista and fraction of cristae with multiple segments (branching) increased. In PLE, mt cristae surface area and volume (abundance) decreased in spherules and increased in pedicles. PLE remodeling of spherule mt produced smaller cristae with more branching, whereas pedicle mt had larger cristae with more branching and increased cristae junction diameter. PLE decreased dark-adapted PR and PR synaptic terminal QO2. In Bcl-xL/PLE, spherules still had decreased abundance; pedicles still had increased branching, crista segments/volume and crista junction diameter; and PR and synaptic QO2 only partially recovered. These findings reveal cellular and compartmental differences in the structure, vulnerability and remodeling of rod and cone inner segment and synaptic mt to PLE: consistent with findings that synaptic mt are more sensitive to calcium overload, oxidative stress and ATP loss than non-synaptic mt. These PLE alterations likely underlie the persistent scotopic-mesopic deficits, and stress the importance of examining synaptic dysfunction after developmental insults and preventing synaptic degeneration even if apoptosis is blocked.

**PS 2160 Alpha-Synuclein-Mediated Activation of c-Abl and Dopamine Depletion in Dopaminergic Neuronal Cells Treated with Iron-Oxide Nanoparticles or Methamphetamine.**

S. Lantz<sup>1</sup>, Z. K. Binienda<sup>1</sup>, L. Mohammed Saeed<sup>1,2</sup>, B. Robinson<sup>1</sup>, M. G. Paule<sup>1</sup>, A. S. Burris<sup>2</sup>, S. F. Ali<sup>1</sup> and S. Z. Imam<sup>1</sup>. <sup>1</sup>FDA/NCTR, Jefferson, AR; <sup>2</sup>Nanotechnology Center, University of Arkansas, Little Rock, AR.

Mutations in the alpha-synuclein gene have been associated with autosomal dominant forms of Parkinson's disease (PD). Transgenic mice that over-express the human alpha-synuclein gene (primarily the point mutations A53T and A30P), develop neurological impairments similar to those of PD. Previous studies in our laboratory have shown that oxidative-stress-mediated activation of the tyrosine kinase, c-Abl, results in an increase in the phosphorylation of parkin, an important E3 ubiquitin ligase that assists in the clearance of proteins destined for proteasomal degradation. Here, we show that treatment with iron-oxide nanoparticles or methamphetamine results in activation of c-Abl, observed via the measurement of phospho-Abl. Additionally, an over-expression of alpha-synuclein protein in SHSY-5Y neuroblastoma cells was observed after these treatments. A 45% increase in the expression of alpha-synuclein was observed in SHSY-5Y cells treated with iron oxide nanoparticles (10 and 30 nanometers) at a concentration of 10 µg/ml. Similarly, a 55% increase in the expression of alpha-synuclein protein was observed 24 h after exposure to 500 µM methamphetamine. In addition, a significant depletion in dopamine was observed after treatment with either iron oxide nanoparticles or methamphetamine (55% and 65%, respectively), suggesting that both the over-expression of alpha-synuclein and excess dopamine might generate oxidative stress, which is one of the major pathways of c-Abl activation. These results suggest that the over-expression of alpha-synuclein and dopamine depletion after exposure to iron oxide nanoparticles or methamphetamine contribute to oxidative-stress mediated activation of c-Abl, thus initiating events that may lead to dopaminergic neuronal cell death.

**PS 2161 Identification of Iron Regulatory Proteins Differentially Expressed in Brains with Alzheimer Disease by Quantitative Proteomics.**

B. D. Minjarez<sup>1</sup>, L. Valero<sup>2</sup>, A. D. Rios-Perez<sup>4</sup>, M. Sanchez del Pino<sup>2</sup>, R. Mena<sup>3</sup> and J. P. Luna-Arias<sup>1</sup>. <sup>1</sup>Biología Celular, CINVESTAV, Mexico City, Mexico; <sup>2</sup>Proteómica, Centro de Investigación Príncipe Felipe, Valencia, Spain; <sup>3</sup>Fisiología, Biofísica y Neurociencias, CINVESTAV, Mexico City, Mexico; <sup>4</sup>Toxicología, CINVESTAV, Mexico City, Mexico.

Alzheimer's disease (AD) is the most common form of dementia affecting around 24.3 million people worldwide. As a consequence of the rapid demographic ageing, AD has become one of the most severe progressive socio-economical and medical burdens facing countries all over the world. AD brains are characterized by the presence of extracellular deposits of amyloid-β-containing plaques and intracellular neurofibrillary tangles (NFTs) composed of paired helical filaments of hyperphosphorylated Tau. AD is considered to be the result of complex events involving both genetic and environmental factors. Among them, two remarkable factors are oxidative stress and mitochondrial damage. Postmortem examinations of human brain tissue have demonstrated that iron concentrations are increased in the brains of AD patients compared to controls. The main goal of this study was the identification of proteins showing different expression levels in AD, using iTRAQ-protein labeling

and, identification and quantitation of peptides by tandem mass spectrometry. We identified more than 721 polypeptides, where some iron regulatory proteins were found up-regulated such as Ferritin light chain, Ferritin heavy chain and Melanotransferrin. In addition, several proteins involved in redox regulation also found such as Peroxiredoxin, Superoxide dismutase, Oxidation resistance protein 1, were up-regulated in AD brains in comparison to a normal brain. This approach will give us landscape of the proteome of AD brains that could be useful for the potential identification of AD biomarkers that may be involved in oxidative damage.

## PS 2162 Prediction of Drug-Induced Liver Injury Using High-Content Screening Assay of Rat Hepatocytes.

M. Chen<sup>1</sup>, T. Chun-Wei<sup>1</sup>, Q. Shi<sup>1</sup>, L. Guo<sup>1</sup>, H. Fang<sup>2</sup>, L. Shi<sup>1</sup> and W. Tong<sup>1</sup>. <sup>1</sup>US FDA, NCTR, Jefferson, AR; <sup>2</sup>ICF International at NCTR, US FDA, Jefferson, AR.

Drug induced liver injury (DILI) is a leading cause for drug failures in clinical trials and for post-approval drug withdrawals. This fact implies that the current animal-based approaches do not provide a sufficiently reliable assessment of DILI; therefore, there is an increased interest to develop new approaches for identifying hepatotoxicity, especially those that can be applied in the early drug discovery. In this study, we assessed the feasibility of using high content screening (HCS) assays of rat primary hepatocytes to predict the human specific hepatotoxicity of pharmaceuticals. We developed a predictive model using a commercial HCS assay on 8 cellular parameters that were relevant to hepatotoxicity mechanisms including cell loss, nuclear size, DNA damage, apoptosis, lysosomal mass, DNA fragmentation, mitochondrial potential, and steatosis. The model's performance was assessed both by internal cross-validations using a library of 108 drugs with human-specific hepatotoxicity annotations and by further external validation using an additional sixteen drugs. In the leave-one-drug-out cross-validation, the HCS assay-based predictive model yielded accuracy of 68% with sensitivity of 77% and specificity of 50%, which is significantly higher than that by chance and better than the quantitative structure-activity relationship (QSAR) model developed using the same set of drugs in accuracy. The results from the external validation showed that eight out of nine of the most-DILI-concern drugs (with 89% sensitivity) and four out of seven no-DILI-concern drugs (with 57% specificity) were correctly predicted. Our findings suggest that the HCS assay of rat hepatocytes can potentially approach useful for hepatotoxicity screening for drug discovery.

## PS 2163 Oral Toxicity Study of the Novel Optimized HCV Protease Inhibitor in Rats and Monkeys.

Z. J. Zhan<sup>1</sup>, H. Yan<sup>1</sup>, S. McPherson<sup>2</sup>, S. Neu<sup>3</sup> and Q. He<sup>2</sup>. <sup>1</sup>AB Pharma Ltd., Shanghai, China; <sup>2</sup>WuXi AppTec Co. Ltd., Suzhou, China; <sup>3</sup>Vet Path Services, Inc., Mason, OH.

ZN2007, a novel highly potent HCV-NS3 protease inhibitor with excellent PK and stability properties, was orally administered as sodium salt (ZN2007Na) to cynomolgus monkeys at 25, 500, or 1000 mg/kg/day for 14 days followed by a 7-day recovery period; and rats at 50, 500, or 1000 mg/kg/day for 28 days followed by a 14-day recovery period.

The monkeys were treated with ZN2007Na formulated in 20% (w/v) sulfolbutylether-B-cyclodextrin (SBECD) at 25, 500, and 1000 mg/kg/day for 14 days. No death occurred in 14-day study, and only some soft and/or watery stools were observed in all monkeys including both control and test article-treated groups through the dosing phase. This was considered to be related to the vehicle as it was seen in controls and has been reported in scientific publications (Stella and He, 2008). Abnormal stools were resolved from Day 16 through the recovery period. In rats, no death occurred in 28-day GLP study, and some mild to moderate salivation was the only test article-related finding in males at  $\geq 500$  mg/kg/day, and females at  $\geq 50$  mg/kg/day, respectively. There were no any test article-related changes in mortality, body weight, food consumption, ophthalmic examinations, clinical pathology parameters, electrocardiography (ECG), hematology, coagulation, serum chemistry, and also no any test article-related effects observed on both macroscopic and microscopic examinations for all tested animals at any dose levels (25, 50, 500, or 1000 mg/kg/day) in rats and monkeys, respectively. Moreover, there were no any side effects determined with other protease such as hERG, Cytochrome P450, etc. Based on the above findings, it is concluded that the NOAEL was 1000 mg/kg/day in rats. At NOAEL, the mean values of C<sub>max</sub> and AUC<sub>0-24h</sub> were 24350 ng/mL and 71400 h\*ng/mL in rats. So far, a number of toxicity studies were conducted at WuXi AppTec, and the preclinical safety data of inhibitor ZN2007Na in both rats and monkeys strongly support the safe use conditions for AB Pharma team to file IND for clinical trials in USA by the end of 2012.

## PS 2164 Physicochemical Properties and Compound Accumulation in Lysosomes and Mitochondria.

S. Lu<sup>1</sup>, A. Sista<sup>2</sup>, P. Hoerter<sup>2</sup>, B. Jessen<sup>1</sup> and Y. Will<sup>3</sup>. <sup>1</sup>Drug Safety Research & Development, Pfizer Inc, San Diego, CA; <sup>2</sup>Pharmaceutical Sciences, Pfizer Inc, San Diego, CA; <sup>3</sup>Compound Safety Prediction, Pfizer Inc, Groton, CT.

Eukaryotic cells are highly compartmentalized composing various functionally distinct, membrane-enclosed subcellular organelles such as lysosomes and mitochondria. Unwanted accumulation in nontarget sites can interact with organelle components, resulting in structural and functional changes, potentially leading to toxicity. Physicochemical properties have been shown to be a contributing mechanism for compound accumulation in cells and even organelles. In this study, we examined the relationship between physicochemical properties such as partition coefficient (logP) and acid dissociation constant (pKa) and lysosomal compound accumulation. Our data demonstrate a clear association of basic (basic pKa > 6) and lipophilicity (logP > 2) with lysosomal compound accumulation. We also showed this accumulation was derived by the low pH in the lysosomes. In addition our data revealed membrane perturbation by the compounds with similar physicochemical properties. In an effort to understand how physicochemical properties can contribute to mitochondrial compound accumulation we selected a set of basic compounds and measured their logD (partition coefficient) at neutral (7.4) and acidic (4.7) pH. The majority of basic compounds with acidic logD (at pH 4.7) > 0.3 induced more toxicity in HepG2 cells cultured in galactose than in cells cultured in high glucose-containing media, indicating mitochondrial liability associated with these compounds. This data supports the hypothesis that compounds with relatively pH-insensitive permeability selectively accumulate into mitochondria. Interestingly, certain compounds such as nefazodone and nicardipine were shown to carry both, lysosomal and mitochondria liabilities. In summary, our data indicate that physicochemical properties alone can contribute to both, lysosomal and mitochondrial compound accumulation. How this contributes to in vivo organ toxicity needs to be further elucidated.

## PS 2165 Lack of Retinal Pathology in a BACE1 Knockout Mouse or in Rats after Intravitreal Injections of BACE1 Inhibitors.

C. Somps, C. Houle, T. Brown, J. Harney, J. Brady and D. Karanian. Drug Safety, Pfizer Global R&D, Groton, CT.

The  $\beta$ -site amyloid precursor protein (APP)-cleaving enzyme 1 (BACE1) is a target of tremendous focus and development interest for the treatment of Alzheimer's disease. While initial characterization reports of BACE1 knockout (KO) mice suggest that BACE1 is a safe target for modulation (Roberds et al., 2001; Lou et al., 2001), more recent studies present evidence of retinal pathology (Cai, et al., 2012). Additionally, oral administration of a selective BACE1 inhibitor to rats has been associated with retinal changes after chronic dosing, including accumulation of auto-fluorescent material in the retinal pigment epithelium (RPE) and degeneration of photoreceptors in associated retina (May, et al., 2011). To address these concerns we evaluated the retinas in BACE1 homozygous KO mice from an in-house colony. With the goal of enabling a shorter duration screening paradigm for ocular toxicity, we also evaluated the retinas from rats after a single intravitreal injection of BACE1 inhibitors or non specific protease inhibitor at high (~10  $\mu$ M) intraocular concentrations. We found that 3-month old BACE1 KO mice are viable and without organ or clinical pathology distinctions from wild-type (wt) littermates. Ocular evaluation by H&E staining indicated that the retinas of the BACE1 KOs were unremarkable when compared to wt mice. Ophthalmic examinations, as well as light and fluorescent microscopy following intravitreal injections of BACE1 inhibitors, revealed no significant differences in the retinas or RPE between control and treated rats 1-8 days post-injection. In summary, our results support those of others indicating retinal pathologies reported with BACE1 inhibitors are not related to downregulation of BACE1 activity. Additionally, short duration intravitreal exposure to high concentrations of selective BACE1 inhibitors or nonspecific protease inhibition was not associated with detectable retinal pathology, and thus may not be a reliable model for predicting retinal toxicity of BACE1 inhibitors.

## PS 2166 Peptide Analysis Using Dry Blood Spot Technology Combined with Mass Spectrometry for Toxicology Studies: A Practical Approach for Minimizing Animal Use.

W. Ruddock, P. Aughton, J. Chapdelaine and G. Bain. ITR Laboratories Canada, Baie-D'Urfe, QC, Canada.

Scope: The amount of preclinical research based on peptides is constantly growing, however the difficulties of reliably analyzing this type of molecule leads to a major challenge in obtaining reliable toxicokinetic data. Combining the latest technology

related to dried blood spots and mass spectrometry provides many advantages even though the initial method development is more arduous than for typical small molecules of less than 1000 daltons.

**Experimental Procedures:** The peptide calcitonin-salmon was chosen based on it being readily available from Sigma Aldrich and that its molecular weight is higher than normally monitored by mass spectrometry since it consists of thirty-two amino acid linear polypeptide. The compound is dosed by oral gavage at 10 mg/kg to CD-1 mice, and 8 mL of blood collected by tail clipping every two minutes. The blood is immediately transferred to Whatman 903 filter paper and allowed to dry before placing with desiccant and refrigerating. The dry blood samples are then punched out, and calcitonin-salmon is extracted from the spots and injected. The chromatographic conditions were developed using reverse phase chromatography and detection using a triple quadrupole API 4000 mass spectrometer with electrospray ionization to monitor the parent and fragment ions of both calcitonin-salmon and its analog internal standard.

**Conclusions:** Results show that this approach provides a toxicokinetic profile with timepoints every two minutes whilst allowing a considerable reduction in mice required for a study and giving a full profile for each individual animal. This work shows that preliminary TK data may be obtained based on 3R principles even for peptide analysis, an area that still has room for much improvement using dry blood spot sample analysis.

## **PS 2167 Early and Progressive Changes in the Urinary Biomarker Profile of Cisplatin-Induced Kidney Injury in Cynomolgus Macaques.**

Y. Chen<sup>1</sup>, W. Luo<sup>2</sup>, H. Yu<sup>4</sup>, Q. Qin<sup>4</sup>, J. Qiao<sup>4</sup>, F. Chang<sup>1</sup>, D. Thurman<sup>1</sup>, M. Pinches<sup>3</sup>, S. Gales<sup>3</sup>, N. Barrass<sup>3</sup>, J. Valentin<sup>3</sup>, L. B. Kinter<sup>1</sup> and R. A. Bialecki<sup>1</sup>. <sup>1</sup>AstraZeneca R&D, Waltham, MA; <sup>2</sup>Discovery Statistics, Waltham, MA; <sup>3</sup>AstraZeneca R&D, Alderley Park, United Kingdom; <sup>4</sup>Shanghai Institute of Materia Medica, Shanghai, China.

Cisplatin-induced nephrotoxicity has been characterized in animals and humans. New urinary biomarkers may enable early or parallel detection of drug-induced kidney injury (DIKI) in non-rodent models. Our aims were to: 1) determine if a human renal biomarker panel can detect early DIKI when compared with traditional biochemical and histological indices; 2) monitor progressive cisplatin-mediated changes in DIKI biomarkers over 20 days in cynomolgus macaques. Animals (3M/3F per group) were treated with a single dose of cisplatin (2.5 mg/kg i.v. infusion; groups 1/2/4/5) or saline (groups 3/6) on day 1. Toxicokinetic profile was determined on day 1. Blood and urine samples were collected predose and postdose (days 1, 4, 9, 15, 20) for comparing changes in plasma chemistry, urinalysis and urinary DIKI biomarkers. Renal tissue was examined microscopically at different intervals. Results indicated cisplatin produced progressive renal histologic changes from subtle findings on day 2 to maximum effects on day 21. Traditional renal markers significantly increased in plasma creatinine (8-fold), BUN (3-fold), urinary glucose (5-fold), protein (3-fold) and enzymes (GGT, NAG) between day 4-9 but resolved by day 15 when renal pathology appeared more severe. Four new biomarkers (clusterin, calbindin, lipocalin, Tamm-Horsfall protein) changed progressively and significantly from day 4 to 20 days to parallel development of renal histologic injury. Importantly,  $\beta$ -2 microglobulin was significantly increased before subtle renal damage observed on day 2 and increased progressively over 20 days to parallel histologic changes, suggesting this is the most sensitive biomarker for detection of onset and potentially prodromal cisplatin-induced kidney injury in cynomolgus macaques.

## **PS 2168 A Case Study for Exploring Rodent Models to Assess Risk of Hypotension.**

M. Pannirselvam, D. Hodges, J. Jones, J. Prezioso, K. Tanner, H. Gao, E. Inett, F. Berlioz-Seux, C. Barnes, G. Smith, M. Sanders, U. Germann and D. Brewster. Vertex Pharmaceuticals, Cambridge, MA.

A cardiovascular (CV) safety pharmacology study in telemetered conscious dogs evaluating Compound-A (CPD-A), an anti-cancer agent, demonstrated a dose- and time-dependent decrease in mean arterial blood pressure (MAP), most likely attributable to off-target PDE3 inhibition. At 20 mg/kg p.o. CPD-A, MAP was reduced by ~30% from the baseline within 1-hour of dosing and this effect persisted ~12 hours. The objective of this study was to identify a rodent model that would best mimic the dog CV response to CPD-A. We investigated CPD-A (at doses up to 120 mg/kg, p.o.) in conscious, telemetered rats and detected no meaningful acute effects on MAP, although a moderate tachycardia was observed. Upon repeated daily dosing of 120 mg/kg QD to rats, CPD-A led to a mild decrease in MAP on Day 3 when compared to pre-dose baseline and time-matched vehicle controls. As

in the acute study, a moderate tachycardia was observed. To maximize exposure, a single intravenous bolus administration of 20 mg/kg CPD-A was investigated. This resulted in a significant MAP drop and a moderate reflex tachycardia. Based on these data, we hypothesized that a difference in sympathetic tone and baroreflex sensitivity between dog and rat may underlie the species difference in cardiovascular response observed after single oral administration of CPD-A. To explore this possibility, we also assessed CPD-A in isoflurane-anesthetized rat model to decrease sympathetic tone and baroreflex response. Continuous infusion of CPD-A at 10 and 20 mg/kg/hr led to a gradual decrease in MAP of up to 15 and 45%, respectively, and a mild bradycardia at the highest dose. As an alternative to the rat, we also evaluated a urethane-anesthetized guinea pig model. Infusion of 10 mg/kg CPD-A over 10 min resulted in a gradual drop in MAP accompanied by reflex tachycardia. These studies suggest the anesthetized rat or guinea pig offered good in vivo screening alternatives for this compound class.

## **PS 2169 MDR1, MRP2 and BCRP Transporter Gene Knockout in CACO-2 Cells.**

K. E. Sampson, J. Blasberg, A. Brinker, J. Pratt, N. Venkatraman, Y. Xiao, M. Bourner and D. C. Thompson. Sigma-Aldrich, St. Louis, MO.

**Purpose:** Membrane transporters P-glycoprotein (P-gp, MDR1), MRP2, and BCRP play a role in drug disposition and can mediate drug-drug interactions leading to safety/toxicity concerns. The goal of this study was to selectively knock out these drug transporter genes in a subclone of Caco-2 cells (C2BBE1) using zinc finger nuclease (ZFN) technology.

**Methods:** ZFN pairs targeting specific transporter genes were nucleofected into C2BBE1 cells. Stable clones were isolated and sequenced at gene target sites. Transport function in wild type (WT) and knockout (KO) cell lines was tested in bidirectional assays using probe substrates at 5  $\mu$ M for 2 hr at 37°C. Contents of both wells were analyzed for drug content using LC/MS-MS, and permeability was calculated for both directions. Lucifer yellow permeability was measured to verify monolayer integrity.

**Results:** ZFN-transfected clones were sequenced and the genotype was confirmed for disruptions in each allele. In bidirectional transport assays to confirm loss of transporter function, the efflux ratios (ER) for digoxin and erythromycin were reduced from 17.7 and 16.8 in the WT cells to 1.4 and 1.0 in the MDR1 KO cells, respectively. The ER for estrone 3-sulfate and nitrofurantoin were reduced from 22.7 and 13.2 in the WT to 1.8 and 1.7 in the BCRP KO cells, respectively. The ER for 5(6)-carboxy-2',7'-dichlorofluorescein was reduced to 2.0 in the MRP2 KO from 32.0 in the WT cells. Double knockout cell lines (MDR1/BCRP KO, MDR1/MRP2 KO, and MRP2/BCRP KO) were used to identify substrates of multiple transporters. Cimetidine was confirmed as a substrate of both P-gp and BCRP using the MDR1/BCRP KO cell line. Fexofenadine transport required P-gp and a basolateral MRP transporter such as MRP3, but not MRP2.

**Conclusions:** Stable single and double KO cell lines of human efflux transporters were successfully generated and characterized for loss of function using model substrates. These cell lines may be useful in clarifying complex drug-transporter interactions without reliance on the selectivity of chemical inhibitors.

## **PS 2170 Target Promiscuity and Physicochemical Properties Contribute to Pharmacologically-Induced ER-Stress.**

E. Koslov-Davino, X. Wang and T. Schroeter. Pfizer, Groton, CT. Sponsor: N. Greene.

In vivo toxicity of drug candidates remains a major problem in the pharmaceutical industry, and is a significant cause of late stage attrition. As a consequence predictive in vitro assays are developed and put in place early in the discovery pipeline to aid compound selection. Endoplasmic reticulum stress (ER-stress) has been implicated in many disease states, as well as compound-induced organ toxicities. We explored the role of ER-stress as a general mechanism of toxicity by utilizing a high-throughput in vitro assay to screen 318 chemically diverse Pfizer proprietary compounds with known in vivo toxicity outcome for nuclear accumulation of spliced X-Box Binding Protein 1 (XBP1s), a key transcription factor of the Unfolded Protein Response (UPR). We examined the correlation between physicochemical properties, such as molecular weight, pKa, lipophilicity, topological polar surface area, and passive permeability, as well as target promiscuity, between XBP1s hits and non-hits and found that lipophilicity, target promiscuity and low passive permeability significantly contributed to ER-stress. In addition, we have shown that compounds which cause ER-stress in the form of XBP1s activation at concentrations below 40  $\mu$ M have a more than four times greater chance of causing in vivo toxicity at 10  $\mu$ M plasma exposure.

**PS 2171 Enhancing the Safety of Antiviral Compounds by Assessing Mitochondrial and Nuclear Transcriptional Regulation Using a Multiplex Branched DNA Screen.**

M. Crosby and Y. P. Dragan. *Global Safety Assessment, AstraZeneca Pharmaceuticals LP, Waltham, MA.*

The development of antiviral therapeutics can be hindered by the fact that they can lead to liver, renal, and cardiac injury. One antiviral strategy focuses on inhibiting the transcription of viral nucleic acids via nucleoside analog reverse-transcriptase inhibitors (NRTIs). NRTIs may cause toxicity due to mitochondrial DNA incorporation (mtDNA) and/or inhibition of DNA polymerase  $\gamma$  (*Nature Rev Drug Disc* 2003, 2: 812-22; *Expert Opin Drug Metab Toxicol* 2010, 6:1493-604). Functionally, such types of therapeutics may affect mtDNA transcription and replication, resulting in downstream defects in oxidative phosphorylation and mitochondrial biogenesis, which can lead to compromised organ function. The strategies for ensuring mitochondrial safety include examining changes in mitochondrial biogenesis, metabolism, toxicity, and assaying for specific enzymatic activities in the electron transport chain. While these assays answer important functional questions, they may not necessarily pick up subtle changes with respect to DNA transcription and replication, which can lead to the downstream functional changes. The development of a multiplex, branched DNA (bDNA) assay to assess gene transcription in the mitochondria, as well as in the nucleus has the advantage of detecting a total of eight transcripts in a single lysate. This significantly reduces the cost, time, and consumables that would be needed for traditional qRT-PCR. Studies using human liver epithelial cells treated with a selected group of nucleoside reverse transcriptase inhibitors, including 2',3'-dideoxyinosine, 2',3'-dideoxy-3'-thiacytidine, and 3'-azido-3'-deoxythymidine indicate that this technology may be applied to support the selection of compounds in pharmaceutical programs interested in pursuing nucleoside reverse transcriptase inhibitors as a part of their antiviral strategy.

**PS 2172 Comparison of In Vitro Models for Prediction of Hepatotoxicity of Pharmaceutical Drug Candidates.**

C. McGinnis<sup>1</sup>, T. Sachnik<sup>1,2</sup>, X. Ang<sup>1,3</sup>, J. Johnson<sup>4</sup>, E. Viturro<sup>2</sup> and A. Odermatt<sup>3</sup>. <sup>1</sup>Non-Clinical Safety, Hoffmann-La Roche, Basel, Switzerland; <sup>2</sup>Technische Universität München, Munich, Germany; <sup>3</sup>Division of Molecular and Systems Toxicology, University of Basel, Basel, Switzerland; <sup>4</sup>Hepregen Corporation, Medford, MA.

Liver toxicity is one of the foremost reasons for failure of a drug candidate to reach the clinic. It is also a leading cause for market withdrawals, FDA warnings and modifications of use for current medications. As a result, In vitro hepatocyte-specific studies using cells from preclinical species and also human donors are being investigated to allow for prediction of DILI during the early phase of drug discovery. During this project several novel in vitro models were studied for their potential to detect liver toxic compounds. A high-throughput, 384-well based assay with two-dimensional monocultures of rat or human primary hepatocytes was validated and implemented with ATP depletion as a cellular endpoint. Data obtained from more than 30 commercial and proprietary compounds were compared to results obtained from 3T3 mouse fibroblasts as a non-metabolically competent model. Species-related, and cell type-dependent differences were determined and overall predictability compared to more advanced cell culture models such as a micropatterned hepatocyte co-culture model called HepatoPacTM, as well as a 3D hepatocyte spheroid culture using a Roche developed Hanging Droplet Culture Plate. In depth analysis of the species-, cell- and culture-dependent in vitro results were put into context with underlying mode of actions and dose-effect relationships. This work formed part of a B.Sc. project work carried out by Thomas Sachnik, and M.Sc. project work carried out by Xiaoman Ang.

**PS 2173 Bioassays to Explore Mitochondrial Functions and Anticancer Drug Toxicity.**

E. Robert, P. Picamal and N. A. Compagnone. *Department of Toxicology, ICDD, Meyreuil, France.* Sponsor: Y. Will.

The mitochondria have been identified as one of the major players in previously unrecognized drug-induced hepatic injuries. Hepatotoxicity is the main reason for drug withdrawal in clinical phases and post-marketing. Identifying early mitochondrial toxicities is thus essential to increase the chances of success in drug development. We have developed a panel of integrated functional bioassays aiming at measuring the different functions of the mitochondrial possibly associated with

mitochondrial toxicity in a high throughput and robust manner. Three major axes were explored using cell-based bioassays: the bioenergetics, the redox status and the mitochondrial DNA depletion. First, measurements of the dioxygen consumption, cellular ATP level, extracellular lactate release with regard to cell viability, were multiplexed using fluorescence and luminescence methods. The identification of mitochondrial liabilities associated to hepatotoxicity was largely improved compared to the literature. Secondly, considering that the redox status is associated to drug toxicity, we measured the modulation of the mitochondrial ROS production and antioxidant defenses in response to drugs. Finally, due to its proximity to the electron transport chain and its lack of histones, mitochondrial DNA constitutes a potential target for drug-induced damages. The mitochondrial DNA content was quantified using high content analysis. We performed all the bioassays on HepG2 cells. We tested a panel of drugs that have been marketed, known to be responsible or not for mitochondrial liabilities associated or not to liver and/or cardiac injuries. The tested compounds were classified according to mechanisms of toxicity we detected and compared to the literature. Mitochondrial liabilities can be identified with a predictivity of 84%. Coupling early indicators of mitochondrial dysfunction to late predictors of cytotoxicity provides more relevant and complete information on drug-induced mitochondrial injuries capable of reducing the large space of false negative left by existing methodologies.

**PS 2174 Glucose-Induced Gene Expression Changes Influence Barrier Function in Human Retinal Pigment Epithelial (RPE) Cells.**

G. L. Gong, L. Lecureux and L. D. Lehman-McKeeman. *BMS, Princeton, NJ.*

The RPE forms a blood-retinal barrier in the back of the eye, and alterations in this barrier can adversely affect vision. In the present work, ARPE-19 cells were cultured in physiologically-relevant glucose levels (5 mM) and high glucose conditions (25 mM) for a period up to 3 weeks. Permeability, assessed by apical-basolateral flux of FITC-labeled dextran, was  $10 \pm 1$  ng/ml/min in normal glucose and  $6 \pm 0.3$  ng/ml/min in high glucose, suggesting an increase in barrier function. High glucose also increased mRNA levels of pigment-epithelial-derived factor (PEDF) about 5-fold, while decreasing VEGF-A mRNA levels about 2-fold; these changes correlated with secreted levels of these growth factors, which increased 2.3-fold and decreased 2.8-fold, respectively, in culture medium. High glucose levels increased expression of sphingosine-1-phosphate receptor 1 (S1P1) in ARPE-19 cells more than 3-fold within 1 week of treatment, a change that was maintained during 3 weeks of exposure, whereas expression of S1P3 decreased in a time-dependent manner to nearly 7-fold lower levels after 3 weeks. mRNA levels of tight junction proteins zonula occludens-1 and claudin-1 were unchanged after 1 week of high glucose conditions, but decreased at 3 weeks by 2- and 8-fold respectively. The results of the present study indicate that, in ARPE-19 cells, high glucose conditions affect transcellular permeability and alter expression of proteins involved in tight junction regulation. Moreover, S1P1 and S1P3 genes, which are known to play critical roles in regulating the integrity of endothelial cell barrier function, may also contribute to the regulation of retinal barrier function in RPE cells.

**PS 2175 Towards an Integrated Risk Assessment of Hepatotoxic Drugs via Covalent Binding and Cellular Stress in Primary Hepatocytes.**

M. Teppner<sup>1</sup>, F. Boess<sup>1</sup>, B. Ernst<sup>2</sup> and A. Paehler<sup>1</sup>. <sup>1</sup>Non Clinical Safety, Hoffmann-La Roche Ltd., Basel, Switzerland; <sup>2</sup>Institute of Molecular Pharmacy, University of Basel, Basel, Switzerland.

**Introduction**

Idiosyncratic DILI is of concern to drug development as it occurs rarely but with severe outcome. Early biomarkers for DILI besides covalent binding (CVB) are warranted to classify problematic drugs in vitro. Here we present on complementary endpoints in primary hepatocytes that may early identify cellular damage.

**Methods**

Primary hepatocytes were treated with DILI drugs under attenuated oxidative stress via enzymatic in situ generation of H<sub>2</sub>O<sub>2</sub> up to 24 h. CVB was determined by <sup>14</sup>C binding, prostaglandins via quantification by LC-MS/MS in addition to ATP and LDH release. Expression profiles of Nrf2 regulated genes were created by qPCR analysis

**Preliminary Results**

In hepatocytes generating H<sub>2</sub>O<sub>2</sub>, CVB was significantly exaggerated (13-fold for troglitazone; 20-fold for diclofenac) as compared to controls indicating further peroxidase activation of initially formed reactive metabolites. Significant increase of prostaglandin isomers was observed at lower drug concentrations and at earlier time points than changes in ATP and LDH. In rat hepatocytes prostaglandins E<sub>2</sub> /

15(R) D2 increased by 3.3 / 2.3-fold for FeNTA and 3.0 / 2.0-fold for troglitazone at 6 h. In human hepatocytes, this increase was 3.6 and 3.8-fold respectively for troglitazone with no effect on LDH or ATP.

mRNA levels indicate the activation of several keap/Nrf2 regulated genes such as NAD(P)H dehydrogenase (7.7-fold) and GSH-S-transferase  $\alpha 2$  (6.1-fold) after 24 h for troglitazone. Heme oxygenase 1 (64.1-fold) as well as GSH-S-transferase  $\pi 1$  (12.3-fold) showed a transient induction after treatment with FeNTA.

#### Conclusions

The presented methods are useful for an early identification of DILI liabilities. Besides CVB, cellular stress in hepatocytes may contribute to development of DILI; here prostaglandins are sensitive biomarkers. mRNA levels give insight into the mechanism of toxicity. The in situ generation of H<sub>2</sub>O<sub>2</sub> provides a supportive tool by attenuating response that is specific to drug treatment.

### PS 2176 Aneugenicity Associated with Aurora Kinase Inhibition in a Novel Series of JAK1-Selective Kinase Inhibitors.

E. Harstad, K. Ford, M. Zak, R. Mendonca, S. Ubhayakar, G. Deshmukh, J. Kenny, W. Blair and D. Diaz. Genentech, South San Francisco, CA.

JAK1 inhibition imparts therapeutic benefit in inflammatory diseases, in particular rheumatoid arthritis. A novel series of JAK1-selective molecules was discovered eliminating anemia associated with JAK2 inhibition. In preclinical lead optimization screening, a metabolism-independent aneugenic micronucleus (MN) signal was discovered using a high-content micronucleus test (HC-MNT) in CHO cells. The objectives of this study were to: 1) determine the predictivity of the HC-MNT vs the manual MN assay in normal human mononuclear cells, 2) elucidate the mechanism of aneugenicity, and 3) develop an in silico toxicophore screen to eliminate MN formation. Over 80 JAK1 inhibitors were tested in the HC-MNT, and 20 were tested in the manual MN assay, with 89% positive predictive value in this series of molecules. Results from the HC-MNT indicated an aneugenic signature (based on cytotoxicity indices) that was confirmed via standard centromeric FISH staining in the manual assay. Bone marrow MN evaluations rats confirmed the in vivo relevance of the in vitro MN finding. Selected molecules tested also confirmed the lack of clastogenicity in vitro and in vivo. Aurora kinase inhibition was evaluated as a known microtubule-dysfunction mechanism leading to aneugenicity. In functional cellular assays, Aurora A inhibition was confirmed at high concentrations. Aurora A cellular IC<sub>50</sub>s were consistent with concentrations producing aneugenicity in vitro and in vivo, suggesting a relationship between Aurora A inhibition and aneugenicity exhibited by these compounds. In silico docking identified key interacting residues important for Aurora A binding, allowing Aurora A potency to be screened out prior to chemical synthesis. In summary, these experiments demonstrate the fidelity of the HC-MNT assay with the in vitro and in vivo MN assays for aneugenicity in this chemical series and enabled development of a toxicophore model to eliminate Aurora A liabilities.

### PS 2177 Evaluation of High Content Mechanism Screening As a Prediction Tool for Organ Toxicity.

W. Pennie<sup>2</sup>, S. Lu<sup>1</sup>, C. Stock<sup>3</sup>, J. Gilbert<sup>2</sup> and Y. Will<sup>2</sup>. <sup>1</sup>Drug Safety research and Development, Pfizer Inc, San Diego, CA; <sup>2</sup>Compound Safety Prediction, Pfizer Inc, Groton, CT; <sup>3</sup>Apredica, Watertown, MA.

Attrition due to drug safety remains a serious problem for the pharmaceutical industry. Extensive efforts are made to develop early predictive in vitro screens to assist in selecting compounds with a more desirable safety profile. Since cardiac and hepatic toxicity remain the top causes of compound attrition, much focus has been on building predictive assays for such toxicities. One platform is high content screening performed in an organ relevant cell line to assess a variety of mechanistic toxicity parameters. We have recently shown that general cytotoxicity screening such as ATP measurement in organ specific cell lines can not accurately predict specific organ toxicity. Here we wanted to understand if by choosing more mechanistic parameters we could differentiate compounds with different organ toxicities. In the current study we selected >50 compounds with known human hepatic or cardiac toxicity. These were tested in both H9C2 cells (cardiac panel) and primary rat hepatocytes (hepatic panel) using high content mechanism screening. We found that the majority of compounds, regardless of their designated organ toxicities, displayed similar effects on the two panels tested. Only a small number of compounds demonstrated differential activity in the two panels (eg. nimesulide was only toxic in the hepatic panel). Our results indicate that sophisticated high content mechanism screening in itself is still a poor predictor for differentiating cardiac and hepatic toxicity. More organ relevant endpoints, such as BSEP/MRP assessment for hepatotoxicity and ion channel pharmacology and beating changes for cardiac injury, might increase this prediction. Whether 3-dimensional tissues or stem cell approaches will provide more realistic cell models also remains to be seen. At this

point our high content screening approach can detect potential liabilities, identify mechanism of injury, and at the most provide a Therapeutic Index projection if exposure data are accurately projected.

### PS 2178 Consequences of Mrp2 Deficiency for Diclofenac-Induced Toxicity in Rat Intestine *In Vitro*.

X. Niu, D. van de Vegte, M. Langelaar, I. de Graff and G. Groothuis. Pharmacy, Groningen Research Institute of Pharmacy, Groningen, Netherlands.

Diclofenac (DCF), a widely used non-steroidal anti-inflammatory drug (NSAID), is associated with high prevalence of severe intestinal side-effects. The reactive metabolite diclofenac acylglucuronide (DAG) formed in the liver, and transported by bile into the intestine was reported to be involved in the intestinal injury, based on the observation that Mrp2 deficient (TR-) rat intestine was less sensitive to DCF toxicity due to the reduced biliary transport and intestinal exposure to DAG. However, it is not clear what are the direct consequences of Mrp2 deficiency in the intestine itself. Previously we reported that DCF was toxic in the rat intestine *in vitro* without the presence of liver metabolites. Therefore, using precision cut intestinal slices (PCIS), we compared wild type (WT) and Mrp2 deficient (TR-) rat intestine *in vitro*, by studying direct toxicity, DCF disposition and intracellular glutathione concentration.

PCIS from WT and TR- rats were incubated with a concentration range of DCF. DCF induced similar dose-dependent toxicity and 200  $\mu$ M DCF caused a significant decrease of ATP in both strains of rats indicating that the intestine from TR- rat is not intrinsically less sensitive to DCF toxicity.

As glutathione is a substrate of Mrp2, Mrp2 deficiency may influence its accumulation and thereby the DCF induced toxicity. Intestinal GSH level in the TR-rats was significantly lower than in WT rats but did not make the TR- rat intestine more vulnerable.

In both strains, hydroxyl DCF as well as DAG were detected as the main intestinal metabolites after 5 hours incubation, less amount was excreted into the medium by PCIS of the TR- rats. The study of DCF disposition is ongoing with using chamber.

In conclusion, the TR- rat intestine is not intrinsically less sensitive to DCF toxicity and the lower GSH level does not make it more vulnerable. Less intestinal metabolites are excreted by the PCIS of TR- rats, but whether this is due to lower production or lower excretion ability needs to be further validated.

### PS 2179 Effects of Nicotinamide Phosphoribosyltransferase (NAMPT) Inhibitors on Platelet Development.

J. Singh<sup>1</sup>, T. Zabka<sup>1</sup>, H. Uppal<sup>1</sup>, D. Diaz<sup>1</sup>, J. Tarrant<sup>1</sup>, E. Clarke<sup>2</sup>, T. Lin<sup>1</sup>, N. La<sup>1</sup>, B. McCray<sup>1</sup>, T. Nguyen<sup>1</sup>, P. Dhawan<sup>1</sup>, E. Doudement<sup>1</sup>, A. Kauss<sup>1</sup>, D. Dambach<sup>1</sup> and D. Misner<sup>1</sup>. <sup>1</sup>Safety Assessment, Genentech, South San Francisco, CA; <sup>2</sup>ReachBio, Seattle, WA.

BACKGROUND: Nicotinamide adenine dinucleotide (NAD) is an essential cofactor in glycolysis. Cancer cells have increased energy demands due to proliferation. Nicotinamide phosphoribosyltransferase (NAMPT) catalyzes the rate-limiting step of NAD synthesis, and is up-regulated in many cancer types. Thus, NAMPT inhibitors (NAMPTi) have the potential to treat cancer. Clinical trials with NAMPTi APO866 and GMX1778 failed to reach projected efficacious doses due to thrombocytopenia. We assessed the effects of NAMPTi on megakaryocyte development in vitro and evaluated hematopoietic effects including platelet production in rats. We also tested the hypothesis that nicotinic acid (NA), which replenishes NAD via a NAMPT-independent pathway, mitigates the hematopoietic effects of NAMPTi.

METHODS: Human megakaryocyte lineage cells were cultured from mononuclear cells (containing CD34+ progenitor cells) in vitro for 14 days in the presence of NAMPTi alone or with NA co-treatment. The differentiation, proliferation and survival of megakaryocytes were evaluated functionally (by colony formation) and cell viability was determined biochemically (by ATP levels). Rats were dosed for 4-14 days with NAMPTi alone or co-treated with NA. Bone marrow effects were evaluated by complete blood count with white cell differential and histopathology of hematopoietic tissues.

RESULTS: NAMPTi reduced the functional (colony forming) and biochemical (ATP) viability of megakaryocytes in vitro. This effect tracked with NAMPTi potency and was mitigated by NA co-treatment. NAMPTi caused cellular depletion of hematopoietic tissues and decreases in circulating reticulocytes, red blood cells and lymphocytes in rats. There was no significant reduction in circulating platelets. Hematopoietic effects in rats were partially mitigated by NA co-treatment. Thus, NA may mitigate NAMPTi-mediated thrombocytopenia in the clinic.

**PS 2180 Structural Optimization of the Rac GTPase Inhibitor EHOp-016.**

E. Velez, E. Hernandez and C. Vlaar. *University of Puerto Rico Medical Science Campus, San Juan, Puerto Rico.*

The Rho GTPase Rac family are intracellular signaling proteins that control gene expression and various cellular functions including invasion and metastasis, cell cycle progression and apoptosis. Furthermore, they have been reported to be implicated in cancer initiation and progression. Rac1 is a member of the Rho family GTPases associated with lamellipodia or invadopodia causing invading cells to migrate, and is activated via association with Guanine Exchange Factors (GEFs), among which Vav2. Increase Rac1 activation has been associated with increased breast and brain cancer cell proliferation and invasion. Therefore, one main goal is to focus on the design of novel Rac inhibitors for the development of anticancer drugs. Previously, our laboratory synthesized EHOp-016, which was demonstrated to be the first known inhibitor of Vav2-Rac1 interaction in MDA-MB-435 metastatic cancer cells at low micromolar concentrations. In order to reduce the toxicity and increase the potency, we utilized molecular docking to design novel EHOp-016 derivatives. The carbazole group of EHOp-016 appeared to be required for inhibitory activity, and thus was maintained as a core fragment in further design. It appeared from the docking experiments that replacement of the central pyrimidine ring with other building blocks that orient the potential inhibitors into a U-shaped conformation, provided the best docking results. Novel molecules, that according to docking results bind much better to Rac1 than EHOp-016 will be presented, and the specific interactions leading to increased binding will be discussed. As the compounds were designed to be easily accessible via laboratory synthesis, these proposed improved inhibitors of Rac activity could lead to novel antimetastatic cancer therapies.

**PS 2181 Role of Renal Cytochrome P450 Isozymes in the Bioactivation of 3, 5-Dichloroaniline *In Vitro*.**

C. Racine, T. Ferguson, S. Bakshi, D. Preston, D. Anestis and G. Rankin. *Pharmacology, Physiology and Toxicology, Marshall University, Huntington, WV.*

Chlorinated anilines are common intermediates in the production of agricultural chemicals, dyes, industrial compounds, and pharmaceuticals. Some chloroanilines can induce nephrotoxicity in vivo and in vitro. Previous studies have shown 3,5-dichloroaniline (3,5-DCA, 1.0 mM) induced nephrotoxicity in isolated renal cortical cells (IRCC) following 90 min exposure. Studies from our lab have also shown IRCC pretreated with non-selective cytochrome P450 (CYP) inhibitors [piperonyl butoxide (1.0 mM) and metyrapone (1.0 mM)] partially attenuated 3,5-DCA toxicity, suggesting that CYPs may play a role in 3,5-DCA bioactivation. The purpose of the present study was to further explore the role of CYP mediated 3,5-DCA bioactivation using an in vitro rat model. IRCC were obtained from male Fischer 344 rats. IRCC (4 x 10<sup>6</sup> cells/ml; 3mL) were incubated with shaking for 90 min with either dimethyl sulfoxide (DMSO) or 3,5-DCA (1.0mM). IRCC were pretreated with various CYP inhibitors [isoniazid (1.0 mM), ketoconazole (0.1 mM), omeprazole (0.01 mM), diethyldithiocarbamate (DEDTCa; 0.1 mM), oleanomycin triacetate (0.5 mM), or sulfaphenazole (0.1 mM)] and cytotoxicity was determined by measuring lactate dehydrogenase (LDH) release. Pretreatment with DEDTCa, omeprazole, and sulfaphenazole partially attenuated 3,5-DCA induced nephrotoxicity, while ketoconazole, isoniazid, oleanomycin triacetate did not alter 3,5-DCA induced nephrotoxicity. Studies in rats have shown that DEDTCa, omeprazole, and sulfaphenazole are effective inhibitors of the CYP2C family isozymes. These results suggest that 3,5-DCA is bioactivated via multiple pathways, one of which involves the CYP2C family. (Supported in part by NIH Grant 8P20GM103434 to the West Virginia IDeA Network for Biomedical Research Excellence)

**PS 2182 Studying Drug Effects on Renal Tubular Secretion of Creatinine with a Novel Cellular Model Coexpressing Major Creatinine Transporters OAT2, OCT2, OCT3 and MATE1.**

J. X. Zhang, M. S. Warren, J. Huang and Y. Huang. *Optivia Biotechnology Inc., Menlo Park, CA.*

Serum creatinine level is a commonly used surrogate measure for glomerule damage and kidney function evaluation. It is well known that creatinine clearance in the kidney is through free glomerular filtration and transporter mediated excretion in proximal tubule. Inhibiting these transporters can result in transient increase in plasma creatinine level, which can lead to false interpretation of glomerular damage.

Recently, we have identified that, in addition to OCT2 and MATE1, OAT2 and OCT3 can play major role on creatinine secretion. This finding led to development of a novel cellular model co-expressing all four transporters, for modeling active creatinine secretion in the kidney.

Using the model, we tested drugs with reported incidence of increasing serum creatinine. Most of these drugs inhibited B>A transcellular transport of [C14]Creatinine to different extent, suggesting they are able to block active tubular secretion of creatinine in vivo. It is noteworthy that Cimetidine, which has been previously demonstrated by us as a pan-inhibitor of all four transporters, was able to completely abolish creatinine transport; whereas trimethoprim, which is not an OAT2 inhibitor, only resulted in partial inhibition. These results are in good accordance with clinical studies that higher dosage of Cimetidine can completely block active creatinine secretion in proximal tubule whereas there is no statistically difference in serum creatinine level in patients under moderate- and high-dose of trimethoprim. Furthermore, salicylic acid, which was tested at clinically relevant concentrations, also exhibited a dose-dependent and substantial inhibitory effect on creatinine transport, which suggested that in addition to potentially causing damage to renal tubules, partial blockage of active creatinine secretion could also contribute to serum creatinine level increase caused by salicylic acid, possibly through inhibiting OAT2 and/or MATEs transporters.

**PS 2183 Proximal Tubular Transport of Mercuric Species following Compensatory Tubular Hypertrophy.**

C. Bridges<sup>1</sup>, D. W. Barfuss<sup>2</sup>, L. Joshee<sup>1</sup> and R. K. Zalups<sup>1</sup>. <sup>1</sup>*Division of Basic Medical Sciences, Mercer University, Macon, GA;* <sup>2</sup>*Department of Biology, Georgia State University, Atlanta, GA.*

Chronic kidney disease (CKD) is characterized by a progressive and permanent loss of functioning nephrons. As nephrons are lost, vascular, glomerular and tubular changes occur in remaining nephrons in an attempt to compensate for this loss. These changes lead to glomerular and tubular hypertrophy, hyperperfusion and hyperfiltration. We have hypothesized that tubular hypertrophy and hemodynamic changes resulting from CKD may increase the exposure of individual nephrons to nephrotoxins, such as mercury, and thus may increase the susceptibility of these nephrons to toxic compounds. To test this hypothesis we compared the transport of mercuric species in individually perfused proximal tubules isolated from normal (Sham) or uninephrectomized (NPX) rabbits. Kidneys of NPX rabbits undergo significant hypertrophy in the two weeks following surgery. Tubules isolated from NPX rabbits were larger in diameter than those from Sham rabbits. When the perfusion rate was increased in normal tubules, as a way in which to mimic hyperperfusion, we observed an increase in tubular accumulation of mercury. When tubules from Sham and NPX rabbits were perfused with cysteine-S-conjugates of mercury, we found that tubular accumulation of mercury was greater in tubules from NPX animals. Similarly, luminal disappearance flux ( $J_p$ ) of mercury was greater in tubules from NPX animals. Taken together, our data suggest that hypertrophic changes in proximal tubules may lead to an increased ability and/or tendency of proximal tubules to take up and accumulate nephrotoxins such as mercury.

**PS 2184 Suramin Attenuates Hyperglycemia-Induced Renal Oxidative Stress, Inflammation and Fibrosis in Rats.**

M. Korrappati<sup>1</sup>, B. E. Shaner<sup>1</sup>, B. A. Neely<sup>2</sup>, J. L. Alge<sup>2</sup>, J. M. Arthur<sup>2,3</sup> and R. G. Schnellmann<sup>1,3</sup>. <sup>1</sup>*Drug Discovery and Biomedical Sciences, MUSC, Charleston, SC;* <sup>2</sup>*Medicine, Division of Nephrology, MUSC, Charleston, SC;* <sup>3</sup>*Veterans Administration Medical Center, Charleston, SC.*

Hyperglycemia-induced oxidative stress, inflammation and fibrosis increase susceptibility of diabetic kidneys to nephrotoxic agents. Because development of novel agents that act early to prevent progression of hyperglycemia-induced changes is important, we examined the efficacy and mechanism(s) of suramin in hyperglycemia-induced renal injury before manifestation of overt histological damage. Two groups of male Sprague Dawley rats received streptozotocin (STZ) and one group, saline. Three weeks later one STZ group received suramin (10 mg/kg). All animals were euthanized one week later (4 weeks). While there was a decrease in creatinine clearance between controls and STZ ± suramin rats, there was no difference in creatinine clearance between STZ rats ± suramin intervention. LC-MS/MS-based analysis revealed increases in urinary proteins that are early indicators of diabetic nephropathy (DN) (e.g. cystatin C, clusterin, cathepsin B, and retinol binding protein 4 and peroxiredoxin-1) in the STZ group and were blocked by suramin. Endothelial intracellular adhesion molecule-1 (ICAM-1) activation, leukocyte infiltration and inflammation; transforming growth factor-β1 (TGF-β1) signaling; TGF-β1/SMAD-3-activated fibrogenic markers fibronectin-1, alpha-smooth muscle actin and collagen 1A2; activation of pro-inflammatory and pro-fi-

brotic transcription factors nuclear factor  $\kappa$ B (NF- $\kappa$ B) and signal transducer and activator of transcription factor-3 (STAT-3), respectively, were all increased in STZ rats and suramin blocked these changes. Therefore, delayed administration of suramin attenuated urinary markers of DN, inflammation by blocking NF- $\kappa$ B activation/ICAM-1-mediated leukocyte infiltration and fibrosis by blocking STAT-3-TGF- $\beta$ 1/Smad-3 signaling, supporting the potential use of suramin in development of diabetes-induced kidney injury.

## PS 2185 Resveratrol Alters Subcellular Changes in Oxidative Stress Mediated by Cisplatin in Rat Renal Tissue.

M. Valentovic<sup>1</sup>, J. G. Ball<sup>1</sup>, J. Wolfe<sup>1</sup>, S. Van Meter<sup>1</sup>, M. Wright<sup>1</sup>, B. Lamyathong<sup>2</sup> and B. Brown<sup>1</sup>. <sup>1</sup>Pharmacology, Physiology and Toxicology, Marshall University School of Medicine, Huntington, WV; <sup>2</sup>Wheeling Jesuit University, Wheeling, WV.

The cancer chemotherapeutic agent cisplatin is associated with a 33% incidence of diminished renal function. Interventions to reduce renal toxicity are important in improving patient outcome. Resveratrol (RES) is a phytochemical found in grapes, cranberries and nuts. RES has been recognized as a natural agent possessing anti-cancer and antioxidant properties. This study investigated RES attenuation of cisplatin renal in vitro toxicity and focused on differences between cytosolic and mitochondrial oxidative stress mediated by cisplatin. Male Fischer 344 rats (200-250 g) were anesthetized, with isoflurane and the kidneys were isolated. Renal cortical slices were prepared and pre-incubated with 30  $\mu$ l ethanol (VEH) or 30  $\mu$ g/ml resveratrol (RES, final concentration) for 30 min at 37°C. Tissue were subsequently incubated for a maximum of 120 min with 0, 75, or 150  $\mu$ g/mL cisplatin. Loss of membrane integrity was evaluated as leakage of lactate dehydrogenase (LDH). Oxidative stress and nitrosative stress was assessed in kidney homogenate as well as in subcellular fractions of mitochondria and cytosol. Oxidative stress was measured by protein carbonyl formation using an Oxyblot. Nitrosative alterations were assessed using 3-nitrotyrosine formation by western blot. LDH leakage required a 120 min exposure to cisplatin. An increase in protein carbonyls as detected by Oxyblot, was increased by cisplatin and totally prevented by RES. RES also decreased protein carbonyls in tissue not exposed to cisplatin. Our findings showed that a 30 min RES pre-incubation diminished cisplatin renal toxicity and that protein carbonyl and 3-nitrotyrosine and early changes in oxidative stress prior to the onset of loss of membrane integrity. (Supported by NIH Grants INBRE 3P20RR016477-09S4; 5P20RR016477 and 8P20GM103434 to the West Virginia IDeA Network for Biomedical Research Excellence).

## PS 2186 Diglycolic Acid Induces Cytotoxicity in Human Proximal Tubule Cells via Preferential Inhibition of Succinate Dehydrogenase and Oxidative Phosphorylation.

G. M. Landry, C. L. Dunning, T. V. Dupree, M. J. Hitt and K. McMartin. Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.

Diethylene glycol (DEG) is an organic solvent used in common consumer products, thus allowing for increased risk for exposure. DEG metabolism produces two primary metabolites, 2-hydroxyethoxyacetic acid (2-HEAA) and diglycolic acid (DGA). DGA, not DEG or 2-HEAA, produces proximal tubule cell necrosis leading to acute renal failure, the hallmark of DEG poisoning. Studies were designed to assess whether the mechanism for DGA-induced cytotoxicity involves disruption of cellular metabolic processes resulting in mitochondrial dysfunction. DGA induces severe ATP depletion in human proximal tubule (HPT) cells that occurs prior to significant cell death. HPT cells pretreated with increasing DGA concentrations showed significant decreases in oxygen consumption suggesting that DGA acts as an oxidative phosphorylation inhibitor, rather than a mitochondrial electron transport chain uncoupler. Co-incubation of DGA with the antioxidant,  $\alpha$ -tocopherol significantly reduced DGA-induced reactive oxygen species (ROS) formation, but did not reduce ethidium homodimer uptake or lactate dehydrogenase release, two measures of necrotic cell death, suggesting that ROS production is not a cause, but a consequence of DGA-induced cell death. DGA treatment also significantly and preferentially inhibits succinate dehydrogenase activity, but has no effect on other citric acid cycle enzyme activities. Intracellular transport studies utilizing DGA in competition with <sup>14</sup>C-succinate determined an approximate IC<sub>50</sub> value of 175 mmol/L. This value suggests that DGA-induced cytotoxicity is not due to substrate starvation of cells, but rather inhibition of metabolic processes, which occur at much lower DGA concentrations. These results indicate that DGA produces proximal tubule cell death by specific inhibition of mitochondrial-mediated processes resulting in decreased energy production and oxygen utilization.

## PS 2187 Chronic Ethanol Ingestion in Mice Induces Renal Inflammation and Injury through the Platelet-Activating Factor Receptor.

C. Latchoumycandane<sup>1</sup>, J. Liu<sup>1</sup>, L. E. Nagy<sup>2</sup> and T. M. McIntyre<sup>1</sup>. <sup>1</sup>Department of Cellular and Molecular Medicine, Lerner Research Institute, Cleveland Clinic, Cleveland, OH; <sup>2</sup>Department of Pathobiology, Lerner Research Institute, Cleveland Clinic, Cleveland, OH.

Ethanol exposure increases circulating oxidized phospholipids in rats and in alcoholic steatohepatitis patients, although the biological role of circulating oxidized phospholipids remains unclear. Platelet-activating factor (PAF), and some oxidized phospholipids, activate the Platelet-activating factor receptor (PAFR). We hypothesized that PAFR contributes to renal inflammation and injury after ethanol ingestion. In this study we find that mice fed a Lieber-DeCarli ethanol diet had increased levels of circulating PAF, and the pro-apoptotic oxidatively truncated phospholipid azelaoyl-PC. Most strikingly, PAFR-null mice had less infiltrating neutrophils, oxidized phospholipids and TUNEL positive cells in kidney as compared to wild-type (wt) mice fed with ethanol diet. Blood urea nitrogen and serum creatinine, renal functional markers, increased after ethanol exposure in wt mice but not in PAFR-null mice. The renal fibrosis marker,  $\alpha$ -smooth muscle actin was increased in ethanol-fed wt mice, but not in PAFR-null mice. Kidney injury molecule-1 (KIM-1), a marker for proximal tubular injury, is increased during acute renal injury, and we find higher expression of KIM-1 in the proximal tubules of ethanol fed wt mice as compared to PAFR-null mice. These results suggest that PAF and bioactive PAF-like oxidized phospholipids promote renal inflammation, acute injury, and renal fibrosis. These events completely depend on a functional PAFR. This demonstrates a novel mechanism of PAFR in alcoholic renal injury.

## PS 2188 Nephrotoxicity of Epigenetic Inhibitors Used for the Treatment of Cancer.

N. E. Scholpa, M. Moore and B. S. Cummings. Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Several studies exist investigating the anti-neoplastic activity of epigenetic inhibitors. In contrast, fewer studies have investigated the toxicity of epigenetic inhibitors in non-target organs, such as the kidney. Even fewer have investigated both the anti-neoplastic activity and toxicity of epigenetic inhibitors under similar conditions. This study determined the anti-neoplastic activity and nephrotoxicity of epigenetic inhibitors In Vitro. The therapeutic efficacy of epigenetic inhibitors was first determined in human prostate cancer cells (PC-3 and LNCaP) using the DNA methyltransferase inhibitor 5-azacytidine (5-Aza) and the histone deacetylase inhibitor trichostatin A (TSA). Cells were also treated with carbamazepine (CBZ), an anti-convulsant with histone deacetylase inhibitor-like properties. 5-Aza, TSA, or CBZ alone (0-100  $\mu$ M) did not induce decreases in MTT staining in PC-3 or LNCaP cells after 48 hr. In contrast, docetaxel, a frontline chemotherapeutic, did induce concentration-dependent decreases in MTT staining after just 24 hr. Treatment of prostate cancer cells with CBZ prior to docetaxel exposure decreased MTT staining in LNCaP cells, but neither TSA nor 5-Aza altered MTT staining compared to cells exposed to docetaxel alone. Treatment of normal rat kidney (NRK) and human embryonic kidney 293 (HEK293) cells with the same concentration of epigenetic inhibitors used in prostate cancer cells significantly decreased MTT staining after 48 hr. The epigenetic inhibitors were generally more toxic than the nephrotoxic bromate (0-400 ppm), and TSA and 5-Aza pretreatment increased the cytotoxicity of BrO<sub>3</sub><sup>-</sup> in NRK cells. Increased cytotoxicity in NRK cells correlated to alterations in epigenetic markers such as histone phosphorylation and to alterations in the methylation of the cyclin-dependent-kinase inhibitor protein p21. Collectively, these data suggest that epigenetic inhibitors can induce nephrotoxicity at doses that are therapeutically relevant in prostate cancer cells In Vitro.

## PS 2189 hTERT-Immortalized Renal Proximal Tubule Epithelial Cells: A Model for Testing Cadmium's Role in the Development of Renal Cancer.

B. R. Simon. Global Environmental Health Sciences, Tulane University, New Orleans, LA. Sponsor: J. Wickliffe.

The incidence of renal cell carcinoma (RCC) has steadily increased in the United States over the past three decades. Therefore, it is critical that scientists are better able to understand contributing factors. Cadmium (Cd) is a recognized carcinogen and widespread environmental contaminant. The kidney is a known target organ of Cd toxicity, however the mechanistic role(s) that Cd plays in the development of RCC has not been described. Renal proximal tubule epithelial cells (RPTECs) are specifically affected by Cd because of their propensity to reabsorb Cd from filtrate

leading to bioaccumulation. In order to elucidate the mechanisms by which Cd acts, we aim to characterize a newly developed cell line derived from renal proximal tubule epithelial cells of a healthy human male donor (RPTEC/TERT1). Our goal is to establish this new in vitro system for future toxicological and cancer research by characterizing the RPTEC/TERT1 cell line and utilizing them to conduct biologically relevant exposure studies. We will explore these goals through exposure experiments to binary mixtures of two common environmental contaminants, Cd and benzo(a)pyrene (B[a]P). Our preliminary results demonstrate that these cells are sensitive to both compounds separately over a wide range of exposure levels. Additionally, the characteristic Cd-interacting protein, metallothionein I/II, exhibits a Cd-specific protein response, which supports its ability to function as expected, based on in vivo evidence. The RPTEC/TERT1 cell line expresses metabolic biotransformation enzymes necessary for processing polycyclic aromatic hydrocarbons (PAHs) which is exemplified by their sensitivity to the representative PAH, B[a]P. Future experiments will further characterize DNA repair capacity of the RPTEC/TERT1 cell line and the development of mutagenic lesions when exposed to binary mixtures of sub-cytotoxic doses of Cd and B[a]P. This work will provide mechanistic support and augment current scientific knowledge regarding the development of RCC and exposure to xenobiotic mutagens and carcinogens.

**PS 2190 BUN and Serum CRE Alterations in Higa and BALB/c Mice after Subacute Administration of Fluoride via Drinking Water.**

T. Kido<sup>1,2</sup>, M. Tsunoda<sup>2</sup>, C. Sugaya<sup>2</sup>, H. Yanagisawa<sup>1</sup> and Y. Aizawa<sup>3</sup>. <sup>1</sup>Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, Japan; <sup>2</sup>Preventive Medicine, Kitasato University School of Medicine, Sagami-hara, Japan; <sup>3</sup>Kitasato University, Tokyo, Japan.

Fluoride (F) is known as an environmental pollutant. Because F is filtered by the kidney, mice with impaired renal function may be affected more significantly by F. IgA nephritis is the most common chronic glomerulonephritis. High IgA (HIGA) mice have been used as a model of IgA nephritis. The effects of fluoride on BUN and serum creatinine (CRE) of HIGA and BALB/c mice after subacute administration via drinking water were examined in this study to get basic information of the toxic effects of F on the mice with IgA nephritis. F was administered to HIGA and BALB/c mice, aged 11-12 weeks at 0, 50, 100, and 150 ppm in their drinking water for 4 weeks. The blood was sampled from the tail artery once a week. The BUN and CRE in the serum was determined by the kits. For the BUN levels in the HIGA mice, after one week from the beginning of the exposures, the mean BUN in the 50-ppm group was significantly higher than those in the 100- and 150-ppm groups. At 2 weeks, the mean value of BUN in the 100-ppm group was significantly higher than those in the 0- and 50-ppm groups. For the BALB/c mice, there were no significant differences among the groups. For the CRE in the serum of HIGA mice, after 1 week, the mean CRE in the 50-ppm group was significantly higher than those in the 100- and 150-ppm groups. For the BALB/c mice, after 3 weeks, the mean CRE in the 50-ppm group was significantly higher than those in the 0- and 100-ppm groups. The alterations in the BUN and CRE in the serum observed in the HIGA and BALB/c mice may indicate the toxic effects of F on the kidney. However, the alterations were not dose-dependent, and the effects of F on the kidney of HIGA mice were not as significant as those on kidney of the BALB/c mice. The toxic effects of F on the kidney were not enhanced in the HIGA mice at 11 to 12 weeks of age.

**PS 2191 Performance Evaluation of Urinary Complement Biomarker for the Immune-Mediated Glomerular Injury.**

M. Ko<sup>1</sup>, E. Nagiec<sup>2</sup>, D. Fix<sup>3</sup>, B. L. Homer<sup>2</sup> and A. John-Baptiste<sup>1</sup>. <sup>1</sup>Drug Safety, Research & Development, Pfizer, San Diego, CA; <sup>2</sup>Drug Safety, Research & Development, Pfizer, Cambridge, MA; <sup>3</sup>Drug Safety, Research & Development, Pfizer, Groton, CT. Sponsor: W. Huang.

With the increased focus on protein biotherapeutic development in recent years, glomerular injury has become a significant risk factor. In order to monitor this risk in preclinical and clinical drug development reliable, sensitive and specific biomarkers are greatly needed. Currently urinary albumin and total protein are the most commonly used diagnostic biomarkers for monitoring both tubular and glomerular injury. Rat passive Heymann nephritis (PHN) is a model of glomerular injury characterized by subepithelial immune complex deposits, along with deposition of C5b-9 and ensuing proteinuria (Pippin et al., 2009). Schulze et al. established that elevated urinary C5b-9 was associated with glomerular immune deposit formation in this model (1989, Kidney International, 35, 60-68). Consequently, we evaluated the performance of commercially available Quidel human and USCN rat C5b-9 ELISA kits on urine samples. Zymosan-activated plasma or serum samples from non-human primate (NHP) and rat, respectively, were used as positive

controls. The linear detection range of the standard curve, dilution effect, matrix effect, albumin interference, and inter-assay variability were assessed as performance parameters for the kits. In addition, a rat PHN study was conducted, and the urine samples were analyzed with USCN C5b-9 ELISA kits. The results showed poor performance of the kits, demonstrated by greater than  $\pm 30\%$  analytical recovery for dilution effects, urine matrix effects, albumin interference, and greater than 25% coefficient of variation for inter-assay variability. Moreover, using Urinary Stabilizing Buffer (Argutus Medical Ltd, Dublin, Ireland) did not improve the performance. Therefore, we could not demonstrate an association between the C5b-9 positively-stained glomeruli and urinary C5b-9 level in the rat PHN study. We concluded that Quidel and USCN kits performed poorly for the detection of urinary C5b-9 in rat and NHP urine.

**PS 2192 Miniaturized Multiplex Protein Nanoarray Assays for Early Detection of Drug-Induced Nephrotoxicity in Mice and Rats.**

A. W. Kherzai, R. G. Sanedrin, P. Han, N. A. Amro, R. Helfrich, S. Aziz, N. Patel, D. Mikos and H. Jamil. *Nano BioDiscovery, Nanoink INC, Skokie, IL.* Sponsor: S. Devi.

Drug-induced toxicity is the major cause of kidney damage. The previous methods for measuring drug induced injury, namely serum creatinine and blood urea nitrogen, have been found inadequate. Recently the FDA and EMEA have qualified a panel of biomarkers that is highly useful in the early identification and characterization of kidney injury.

Here we report the development of highly sensitive and small sample volume NanoArray multiplex assays for early detection of drug-induced nephrotoxicity in mouse and rat in-vivo models based on dip-pen nanolithography (DPNTM) using a NanoArrayer 3000TM. This instrument enables the production of highly reproducible micro- to nano-scale arrays of proteins which occupy an area approximately 100 times smaller than conventional microarrays. The reduced array area results in reduced reagent and sample requirement and increased sensitivity due to reduced analyte depletion. For a multiplexed sandwich ELISA, arrays of specific capture antibodies are printed on activated glass slides. Samples of as little as 2-4  $\mu$ l can be incubated over the arrays in 48 and 96 well format. The slides are then incubated with specific biotinylated detection antibodies followed by fluorescently labeled Streptavidin. The fluorescence is measured with a high resolution fluorescence scanner.

The multiplex assays were developed and validated for mouse (Albumin, Clusterin, Cystatin C, KIM-1, and EGF) and rat biomarkers panels (Albumin, Clusterin, Cystatin C, KIM-1, B2MG and TFF3) and showed high sensitivity and specificity. The assay was used to detect and quantify renal injury biomarkers in urine samples obtained from normal and drug compromised rats. The low volume sample requirements in conjunction with the extremely high sensitivity, selectivity, and reproducibility help enable longitudinal studies on individual rodents thus saving significant study costs and providing better toxicity data than other conventional methods used for preclinical and clinical safety and toxicity studies.

**PS 2193 Magnetic Resonance Imaging (MRI) Assessment of Renal Glomerular Filtration Rate (GFR).**

M. Uteng<sup>1</sup>, A. Mahl<sup>1</sup>, A. Piaia<sup>1</sup>, J. Cunliffe<sup>1</sup>, E. Persohn<sup>1</sup>, E. Tritto<sup>1</sup>, D. Leduc<sup>1</sup>, P. Moulin<sup>1</sup>, N. Shangari<sup>1</sup>, S. Chibout<sup>1</sup>, A. Wolf<sup>1</sup>, L. Li<sup>1</sup>, E. Pognan<sup>1</sup> and N. Beckmann<sup>2</sup>. <sup>1</sup>Novartis Institutes for BioMedical Research, Novartis, Basel, Switzerland; <sup>2</sup>Global Imaging Group, Novartis, Basel, Switzerland.

MRI of kidneys after administration of the contrast agent, gadolinium-tetra-azacyclo-dodecanetetra-acetic acid (Gd-DOTA), has been reported as a promising method for assessment of GFR. However, there is little literature on the sensitivity of this method compared to standard assessments in non-clinical trials of drug development. To this end, we have conducted a study with the aim to determine the sensitivity of MRI as a method for detection of GFR in rodents.

Sprague-Dawley rats were treated with Adefovir as positive control, and Telbivudine and Entecavir as negative controls for nephrotoxicity. The rats were treated daily by oral gavage for 4 weeks with 10X and 25X human equivalent exposure doses (HED) of compounds. After 3, 10 and 28 days treatment, GFR was assessed by MRI and creatinine clearance rate, while renal toxicity was assessed by urinary kidney biomarkers, clinical biochemistry parameters in blood and urine, histopathology, electron microscopy and gene expression profiling. Impairment of GFR was detected by MRI showing delayed time-to-peak signal of Gd-DOTA clearance in the renal cortex of animals treated with 25X HED Adefovir on day 28. These results correlated with histopathological observations of cortical tubular degeneration. Moreover, renal toxicity was also confirmed by urinary kidney biomarkers (e.g Kim1), and by down-modulation of renal tubular associated

genes. On the other hand, the creatinine filtration rate did not reveal any significant changes. Animals treated with Telbivudine and Entecavir showed neither renal impairment nor toxicity for the entire study duration. In conclusion, these results demonstrated that MRI is a sensitive method for non-invasive detection of GFR changes and that this technique may be a good alternative to the standard measurements of creatinine filtration in non-clinical investigative studies.

## PS 2194 Identification of 3-Indoxyl Sulfate As an Early Biomarker for Nephrotoxicant-Induced Acute Kidney Injury.

A. Won<sup>1</sup>, T. Kim<sup>1</sup>, Y. Shin<sup>1</sup>, B. Lee<sup>2</sup>, S. Kim<sup>3</sup> and H. Kim<sup>1</sup>. <sup>1</sup>College of Pharmacy, Pusan National University, PUSAN, Republic of Korea; <sup>2</sup>College of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea; <sup>3</sup>Department of Chemistry and Chemistry Institute for Functional Materials, Pusan National University, Busan, Republic of Korea.

The identification of new biomarkers of acute kidney injury (AKI) is important for the detection of drug-induced kidney damage. Various serum or urinary biomarkers have been used to detect AKI, but these biomarkers have shown poor sensitivity and specificity. In this study, we compared the sensitivity of a new metabolomic biomarker, 3-indoxyl sulfate (3-IS), with traditional biomarkers for the diagnosis of AKI using the area under the receiver operating characteristic (ROC) curve. Sprague-Dawley male rats were allocated to several groups. Each group was administered either a single dose of cisplatin (20 mg/kg, i.p.), continuous injection of cyclosporin A (10 mg/kg, i.p.), mercury chloride (1.5 mg/kg, i.p., and 7.5 mg/kg, i.p.), or gentamicin (60 mg/kg, s.c.). Urine and plasma samples were collected 1, 3, and 7 days after last injection of nephrotoxicants. Urine and blood biochemical parameters involved in kidney toxicity were measured. We also measured 3-IS levels in the serum, urine, and kidney using HPLC. In the nephrotoxicants-treated rats, blood urea nitrogen (BUN) and serum creatinine (sCr) levels were slightly increased. The 3-IS levels were significantly reduced in the urine of rats treated with cisplatin and other nephrotoxicants. In contrast, 3-IS levels were significantly elevated in the serum and kidneys of nephrotoxicants-treated rats. The 3-IS is produced by bacterial metabolism of tryptophan in the intestine, followed by oxidation and sulfation in the liver. The 3-IS is mainly excreted via active secretion by the organic anion transporter (OAT) in the proximal tubule. Thus, reduced urinary 3-IS levels can reflect proximal tubule injury. These results suggest that urinary 3-IS may be used as an alternative to traditional biomarkers to predict AKI.

## PS 2195 A Quantitative High-Throughput Screening Platform for Predictive Kidney Toxicity.

M. Adler<sup>1</sup>, E. Gottwald<sup>1</sup>, B. Goodwin<sup>2</sup>, M. Xia<sup>2</sup> and V. S. Vaidya<sup>1</sup>. <sup>1</sup>Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; <sup>2</sup>National Center for Advancing Translational Sciences, National Institutes of Health, Bethesda, MD.

Drug and environmental chemical-induced kidney toxicity plays an important role in the high incidence and prevalence of kidney injury in both hospitalized and non-hospitalized patients, which in many circumstances can be prevented or at least minimized by predictive toxicity screening. The goal of this study was to develop a cell-based quantitative high throughput screening (qHTS) platform with two aims: 1) to identify a more biologically relevant *in vitro* system for prediction of human kidney toxicity than currently used immortalized cells and 2) to identify a sensitive, specific, robust and translatable biomarker of kidney toxicity since *in vivo* biomarkers such as kidney injury molecule-1 do not respond *in vitro*. We used primary human proximal tubular epithelial cells (HPTEC) and observed that these cells in a monolayer possess human tubular epithelial characteristics like 1) formation of domes; 2) expression of zonula occludens-1, cytokeratin 18 by immunostaining; 3) a wide range of efflux and influx transporters including aquaporin 1, megalin, organic cation transporter 2, multidrug resistance protein 2, P-glycoprotein by semi-quantitative PCR and 4) activity of brush-border enzymes like alkaline phosphatase, and  $\gamma$ -glutamyl-transferase. We found that hemeoxygenase-1 (HO-1) mRNA and protein levels significantly increased in a concentration-dependent manner (tested over 6-point concentration curve) following exposure to structurally and mechanistically diverse kidney toxicants such as cisplatin, gentamicin, cyclosporin A and cadmium chloride and correlated well with cytotoxicity. HO-1 expression remained unchanged following treatment of HPTEC with non-kidney toxic compounds (e.g. carboplatin), demonstrating its specificity. Our results demonstrate the relevance and potential use of HPTEC in a qHTS platform using HO-1 as a biomarker for predictive safety assessment of drugs and environmental chemicals.

## PS 2196 Systems Biology Approach Identifies Transcriptional Regulator of Kidney Injury Molecule-1.

A. K. Ajay<sup>1,3</sup>, T. Kim<sup>2,3</sup>, P. J. Park<sup>2,3</sup>, V. Ramirez<sup>1,3</sup> and V. S. Vaidya<sup>1,3</sup>. <sup>1</sup>Renal Division, Brigham and Women's Hospital, Boston, MA; <sup>2</sup>Centre for Biomedical Informatics, Harvard Medical School, Boston, MA; <sup>3</sup>Department of Medicine, Harvard Medical School, Boston, MA.

Kidney injury molecule-1 (KIM-1) is the highest upregulated gene following kidney ischemic or toxic insult and functions as a phosphatidylserine receptor to internalize apoptotic cells. Owing to lack of information about regulation of KIM-1, we used genome-wide expression data following kidney ischemia reperfusion injury (IRI) in rats and utilizing ChIP enrichment analysis and kinase enrichment analysis we identified STAT3 and checkpoint kinase 1 (Chk1) as a potential transcription factor and kinase regulating KIM-1. Then we performed an extensive biological validation of the bioinformatics predictions and report that reactive oxygen species generation following IRI upregulates Chk1 that binds to STAT3 phosphorylating it at Ser727, which further binds to KIM-1 promoter for its transcription. We observed temporal association among pSTAT3, pChk1 and KIM-1 using immunoblotting and immunostaining in rat kidneys following IRI and in human kidneys from patients with kidney injury. To prove transcriptional regulation of KIM-1 by STAT3 we used i) primary human proximal tubular epithelial cells (HPTEC) and showed a significant increase (1.5 fold) in KIM-1 mRNA and protein following STAT3 activation. Conversely we used human renal carcinoma cell line (769 P) expressing high pSTAT3/KIM-1 and found 2-fold decrease in KIM-1 following STAT3 siRNA transfection. Furthermore, we confirmed that STAT3 binds on KIM-1 promoter in i) rat kidneys (10 fold by ChIP assay) following IRI; ii) HPTECs transfected with KIM-1-luciferase plasmid (3-fold by STAT3 activation) and iii) 769 P cells transfected with STAT3 siRNA (2-fold decrease). The binding of Chk1 to STAT3 was observed using immunoprecipitation in HPTEC by hydroxyurea (Chk-1 activator). These results reveal Chk1-STAT3 as one of the key pathways regulating KIM-1 transcription.

## PS 2197 Kidney miRNAs Show Age and Sex Differences in Expression during the Rat Life Cycle.

J. C. Kwekel, V. Desai, T. Han, C. L. Moland and J. C. Fuscoe. *Personalized Medicine Branch, US FDA, National Center for Toxicological Research, Jefferson, AR.*

Increasing evidence for epigenetic mechanisms of gene regulation has fueled interest in the role of miRNAs in toxicogenomics for biomarker discovery. While relatively immature in comparison to other genomic resources, the growing knowledge base of individual miRNAs and their putative gene targets allows for large scale inquiry into more comprehensive, genome-wide analysis of miRNA expression. Kidney tissues in the F-344 rat model system were examined over the life cycle for the purpose of evaluating miRNAs with putative roles in drug metabolism and kidney disease. miRNA expression was characterized at 2, 5, 6, 8, 15, 21, 78, and 104 weeks of age in both sexes using Agilent 8x15k rat miRNA microarrays containing multiple probes for 677 unique miRNAs. Five animals per sex and age were used for a total of 80 samples. Agilent's Feature Extraction software was used for initial analysis and processing of the raw data and 224 miRNAs were found to be expressed in the kidney in at least one age and sex. Combined filtering criteria of 1.5 fold change and  $p < 0.05$  (2-way ANOVA) revealed 105 miRNAs (47%) exhibiting differential expression by age or sex. Principal component analysis (PCA) showed PC1 accounted for 21% of the variability among the 105 differentially expressed miRNAs in a pattern consistent with age-specific effects. 12 miRNAs showed increased expression at 78 and 104 weeks, consistent with an aging-related effect (e.g. miR-142-3p, miR-223). Although no large scale, sex-related patterns were evident from the PCA, some miRNAs showed sex-specific patterns of expression (e.g. miR-204, miR-499, miR-183). miR-499 has been implicated in regulation of mitochondrial dynamics through direct targeting of calcineurin. Collectively, these results comprise one of the first large-scale characterizations of global miRNAs in the kidney over the entire rat life cycle and show age- and sex-related differences that may impact susceptibility to adverse effects in the kidney.

## PS 2198 Mice Deficient in microRNA-155 Have Greater Susceptibility to Cisplatin-Induced Kidney Toxicity.

K. L. Pellegrini, V. Bijol and V. S. Vaidya. *Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Although originally identified as an oncogenic factor, microRNA-155 (miR-155) has also been found to be upregulated in macrophages and dendritic cells in response to a range of inflammatory stimuli and required for the activation of Th17 cells. We have previously shown miR-155 to be significantly upregulated following

ischemic or toxic insult to the kidney and the objective of this study was to further investigate the role of miR-155 in regulating kidney injury. Male miR-155<sup>-/-</sup> (KO) and wild type C57BL/6J (WT) mice were injected intraperitoneally with 20 mg/kg of cisplatin and sacrificed at 0, 24, 48, 72, 96 and 120 h (n = 5/timepoint) for the collection of blood and kidneys. Blood urea nitrogen (BUN) and serum creatinine (Scr) were measured to determine kidney function, and kidney injury molecule (KIM-1) mRNA, histopathology (necrosis) and TUNEL staining (apoptosis) were measured to determine the extent of proximal tubular injury.

The miR-155<sup>-/-</sup> mice had significantly higher kidney dysfunction as evidenced by more than 2-fold higher levels of BUN and Scr in the KO mice as compared to WT by 48 h. The KO mice also had significantly higher KIM-1 mRNA levels (3-fold) than the WT that remained higher than WT through to 120 h. Necrosis and apoptosis were significantly increased in the kidneys of KO mice as compared to WT mice throughout the time course, and mortality of approximately 60% was observed for the miR-155<sup>-/-</sup> mice as compared to 20% for the WT mice by 120 h. These results demonstrate that miR-155<sup>-/-</sup> mice are highly susceptible to cisplatin-induced kidney toxicity. Tumor protein 53 induced nuclear protein 1 (TP53INP1), which phosphorylates p53 to induce apoptosis, has previously been identified as a direct target of miR-155. We hypothesize that miR-155 is repressing the levels of TP53INP1 (and in turn, the induction of apoptosis) in the kidneys of C57BL/6J mice treated with cisplatin, and that the dysregulation of TP53INP1 in miR-155<sup>-/-</sup> mice promotes the induction of apoptosis, resulting in higher levels of kidney injury.

## PS 2199 Urinary microRNAs As Translational Biomarkers to Detect Acute Kidney Injury.

K. Ramachandran, J. Saikumar, S. S. Waikar and V. S. Vaidya. *Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

MicroRNAs (miRNAs) are a family of short, single stranded, non coding RNA molecules that direct the expression of nearly 60% of all protein coding genes. Extracellular miRNAs, identified in 14 different body fluids, have been proposed as biomarkers of disease and organ damage due to their stability, sensitivity, specificity and ease of detection. Previously, we identified 3 miRNAs (miR-21, -155 and -18a) that were upregulated following ischemic injury and gentamicin induced nephrotoxicity in rats. Human urinary levels of miR-21 and -155 were able to distinguish patients with and without acute kidney injury (AKI). The aim of our current study was to profile the human miRNome in the urine of patients with or without AKI to identify a panel of urinary miRNAs that can serve as sensitive and specific indicators for kidney injury. To estimate the fraction of miRNAs present in the urine, we used the Human miRNome miScript miRNA PCR Array from Qiagen (miRBase version 18 containing ~1900 miRNAs) on urines pooled from 6 patients with AKI and 6 healthy controls. Samples were collected from patients admitted in the Intensive Care Unit (ICU) with a rise in serum creatinine of 100% over baseline. Using a cycle threshold (Ct) range of 19-30, miRNAs that were expressed in both, or in either one of the diseased or healthy pools were selected. All miRNAs that had Ct values >30 in both the sample sets were considered as 'Not Expressed' and eliminated. Thus, we designed a customized array of the 378 detected miRNAs and analyzed the 12 urine samples (6 AKI and 6 healthy) individually. We found 52 miRNAs that were upregulated >5-fold in the AKI patients as compared to the controls and 33 candidate miRNAs (out of 52) were selected using a standard deviation cut-off of 1.5. Further evaluation of these candidate miRNAs for sensitivity, specificity, stability, reproducibility and robustness in an expanded cohort of patients with or without kidney damage will help in establishing the value of urinary miRNAs as non-invasive biomarkers for kidney injury.

## PS 2200 Genetic Reduction in Fibrinogen Protects from Progression of Acute Kidney Injury to Chronic Kidney Disease.

F. Craciun, A. K. Ajay and V. S. Vaidya. *Department of Medicine, Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

The incidence of acute kidney injury (AKI) is increasing and recent studies emphasize the significantly higher risk of developing chronic (CKD) and end-stage kidney disease for AKI survivors. We have shown that mRNA and protein expression in the kidney as well as urinary fibrinogen (Fg) is significantly increased following AKI in mice, rats and humans. Furthermore, we have demonstrated that Fg heterozygosity in mice reduces plasma Fg to 75% of the normal circulating levels, protecting from AKI and promoting faster resolution of kidney damage. Therefore, we hypothesized that Fg heterozygosity would protect from AKI to CKD progression. To test this we used a Folic acid (250 mg/kg, single sq injection) induced AKI to CKD progression model in wildtype (Fg+/+), heterozygous (Fg+/-) and Fg defi-

cient (Fg-/-) mice on Balb/c background and the mice were sacrificed at days 1 and 14 following administration (n=4-6/time point/group). At day 1 there was significant kidney dysfunction as assessed by blood urea nitrogen (112, 73 and 65 mg/dL for Fg+/+, Fg+/- and Fg-/- respectively) and serum creatinine (0.7, 0.6, 0.3 mg/dL for Fg+/+, Fg+/- and Fg-/- respectively), indicating protection in Fg+/- and Fg-/. Kidney mRNA levels of Kidney injury molecule-1 (marker of proximal tubular injury) were significantly higher for Fg+/+ (80 fold) than Fg+/- (46 fold) and Fg-/- (55 fold) as compared to uninjured mice. By day 14 these markers of acute injury reverted to normal but there was increased kidney mRNA expression of fibrosis markers fibronectin (9, 4 and 8 fold in Fg+/+, Fg+/- and Fg-/- respectively) and collagen (8, 3 and 9 fold in Fg+/+, Fg+/- and Fg-/- respectively) when compared to uninjured mice, with only Fg+/- showing protection. This was confirmed histologically by Masson's trichrome staining. We conclude that a lowered but not completely abolished level of Fg protects from AKI to CKD progression, providing a therapeutic target that could benefit AKI survivors.

## PS 2201 Urinary Levels of N-Acetyl-β-D-Glucosaminidase (NAG), Glutathione-S-Transferase (GST), Blood Lead and Plasma Creatinine As Early Indicators of Lead Nephropathy in Occupationally Exposed Subjects.

I. O. Omotosho<sup>1</sup> and G. O. Ademowo<sup>2</sup>. <sup>1</sup>Chemical Pathology, College of Medicine, University of Ibadan, Ibadan, Nigeria; <sup>2</sup>Institute of Advanced Medical Research, College of Medicine, University of Ibadan, Ibadan, Nigeria.

Lead (Pb) toxicity remains a public health problem. Although early diagnosis is paramount for meaningful intervention particularly in occupationally exposed subjects, the diagnosis of Pb poisoning at early stage remains a problem even in developed economies. This work addressed this issue by expressing urinary levels of NAG and GST as exponents of concentrations of conventional renal function markers (creatinine, urea and uric acid) and blood Pb. The result of exponential expression of these results showed a definite pattern particularly in occupationally exposed subjects relative to confirmed chronic renal failure subjects and control. When these figures were compared logarithmically, definite hyperboles for the control, the occupationally exposed and the CRF were observed; the importance of this in early diagnosis of lead nephropathy is to be discussed. Based on these, we propose hypothesis that can be used in the early identification of renal tubular damage especially in subjects occupationally exposed to lead using this logarithmic model.

## PS 2202 Early Postnatal Gentamicin Treatment Reduces Glomerular Number in Extra Uterine Growth Restricted Wistar Rats.

R. R. Bueters, A. Klaasen, L. P. van den Heuvel and M. F. Schreuder. *Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.* Sponsor: F. Russel.

Introduction: Nephrogenesis is the process that leads to the formation of nephrons and ceases around the 36th week of gestation in man, without the possibility of additional formation later in life. A lower number of nephrons have been associated with an increased chance at chronic kidney disease development. In the Netherlands alone, almost 8% of all children are born preterm, and many are treated with drugs or suffer from extra uterine growth restriction (EUGR) that may potentially reduce nephron formation. In this study we investigated the impact of gentamicin and ceftazidime on kidney development w/o EUGR.

Methods: Wistar rats were allocated to either normal size litters (12 pups) or increased size litters (20 pups), the last resulting in EUGR. Both cohorts were divided in control and intervention groups where animals were administered 0.9% NaCl, 4 mg/kg gentamicin or 5 mg/kg ceftazidime via intraperitoneal route from post natal day 2-8. At day 8 and 35, animals were sacrificed and the kidneys were collected. Day 8 kidneys were examined for mRNA expression in a selection of targets, proliferation, apoptosis and general histopathology. Total glomerular count (estimated using stereology) and glomerular generation count were performed in kidneys collected at day 35.

Results: Gentamicin treatment in combination with EUGR resulted in 20% less glomeruli compared to sham treatment. EUGR animals had less body weight, but showed parallel growth compared to non-growth restricted animals, indicating a successful working model. No clear distinctions were noted in mRNA expression levels, glomerular generation count or general histopathology. The proliferation/apoptosis balance is currently under investigation.

Conclusion: Early postnatal gentamicin treatment in combination with EUGR tends to decrease the total glomerular number in Wistar rats, of which the pathways were not clarified yet. The long term clinical sequelae are still unclear.

**PS 2203 Resistance to Dioxin-Induced Hydronephrosis in a Mouse Strain Having Unresponsive Microsomal Prostaglandin E Synthase-1.**

K. Aida-Yasuoka, W. Yoshioka, T. Kawaguchi, S. Ohsako and C. Tohyama.  
*University of Tokyo, Tokyo, Japan.*

**Background:** The majority of dioxin toxicity is governed by aryl hydrocarbon receptor (AhR), and the degree of toxicity is affected by its allele type. It is known that AhRb1 and AhRb2 are responsible for marked manifestation of dioxin toxicity, but that AhRd is not. Our previous works 1, 2) showed that COX-2 and microsomal prostaglandin E synthase-1 (mPGES-1), an inducible form of PGE2 synthase, are critical factors in the pathogenesis of hydronephrosis (HN), and suggested the presence of the possible strain difference in the development of HN between C57BL/6J and BALB/c. Thus, we here examined the incidence of dioxin-induced hydronephrosis (HN) in mouse pups of these strains to clarify causative factors that bring out a strain difference in dioxin-induced HN.

**Methods:** Two strains of mice, C57BL/6J and BALB/c, harboring b1 and b2 alleles, respectively, were administered 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), at an oral dose of 15 µg/kg, 1 day after birth, to expose pups with TCDD via lactation. Kidneys were collected on postnatal day 7 for histology and gene expression analysis by quantitative RT-PCR.

**Results:** Incidence of HN was approx. 60% in C57BL/6J and 0% in BALB/c despite the comparable induction levels of CYP1A1 in the both strains. There was no strain difference in COX-2 mRNA abundance. A strain difference in mPGES-1 mRNA abundance was found comparable to the HN incidence. Gene expression of early growth response 1 (Egr-1), that activates mPGES-1 transcription, was increased in C57BL/6J, but not in BALB/c. In addition, mRNA of aquaporin 2, a water channel, that absorbs water at the collecting duct, was decreased in C57BL/6J and increased in BALB/c.

**Conclusions:** Although both C57BL/6 and BALB/c have dioxin-sensitive receptors, this study demonstrates that strain difference in the incidence of TCDD-induced HN in mouse pups can be partly explained by distinct expression differences in mPGES-1. It is also suggested that Egr-1 may modulate the induction of mPGES-1.

**PS 2204 Escape from Toxic Island: Learning Toxicology Concepts through Informational Posters and a Board Game.**

D. Hardej<sup>1,2</sup>, L. Hoffman<sup>1,2</sup> and A. R. Scharz<sup>1</sup>. <sup>1</sup>Mid-Atlantic Society of Toxicology (MASOT), Bordentown, NJ; <sup>2</sup>Pharmaceutical Sciences, St. John's University, Queens, NY.

Escape from Toxic Island is a program that was developed by the MASOT Education and Outreach Committee to teach toxicology concepts to school aged children. The program is composed of informational posters containing basic toxicology concepts followed by a board game with toxicology questions. Answers to many of the questions were contained in the posters and children were encouraged to use them to obtain correct answers as they moved along the game board. One of the informational posters contained basic definitions and toxicology concepts such as routes of exposure, signal words used in the labeling of toxic substances and government agencies that regulate toxicity. The second poster explored toxicity in and around the home and included information about cleaning products, pesticides, and car care products. The program was developed by the Chair of the MASOT Education and Outreach Committee. Review of the informational posters and game board was accomplished by Education and Outreach Committee members who represent academia, industry and government experts in toxicology to ensure relevancy and accuracy of information. In step with the success of the Inspector Tox program developed 2 years ago by this committee, island themed costumes and props were utilized. Toxic Island's resident pirate, Captain Tox, assisted with instruction and game play. Incorrect answers were cheerfully corrected after "walking the plank". The audience for the program resulted from a joint effort of St. John's University and the Afterschool All Stars Program. The Afterschool All Stars provides free programs to roughly 80,000 children in need in 13 different cities in the continental U.S. and Hawaii. Volunteers were recruited from MASOT, St. John's faculty, and graduate and undergraduate toxicology students. Learning outcomes for the program are based on responses made to questions posed on the game board. Respondents who answered incorrectly to game board questions were encouraged to explore the informational posters for correct answers.

**PS 2205 A C. elegans Dose-Response Protocol and Inquiry Lab in an Undergraduate Toxicology Course.**

M. J. Pomeroy-Black. *Biology, LaGrange College, LaGrange, GA.*

In order to prepare students for a multi-week research project, it is essential to allow them to practice the protocols that will be used in the project. Using *C. elegans*, students initially observed normal behavior and identified the developmental stages of the organisms. Students then practiced transferring *C. elegans* between plates and explored various endpoints that could be used in their research project, including avoidance, locomotion and feeding. During the next lab session pairs of students were given protocols for a dose-response lab activity in which they were assigned a compound, performed a dilution series, and used the dry drop test as a measure of avoidance. Data were compiled and statistically analyzed after the lab. After establishing this basis of knowledge the students designed and conducted their own experiment for the remainder of the semester. Student pairs wrote a research proposal based on a literature search, gathered preliminary data in the lab and embarked on several replications of their experiment. Students analyzed their data using an ANOVA and presented their research as a poster session to the broader community.

**PS 2206 The Best of the Worst: A Novel Approach to Teaching Environmental Toxicology.**

C. P. Curran. *Biological Sciences, Northern Kentucky University, Highland Heights, KY.*

Curriculum development for undergraduate toxicology courses taught is challenging, because of the varied preparation and background of students enrolled. Students are typically majoring in environmental science, chemistry, or biology, and each discipline has unique program requirements. Environmental toxicology courses present even greater challenges for students without a solid grounding in ecology or biochemistry. A novel course was developed at Northern Kentucky University, focused on problem-based learning and team-based learning to engage students in identifying and understanding environmental toxicology issues in their local communities and in a variety of ecosystems (polar, temperate and tropical). Sample activities such as "What is the Worst Environmental Problem in the World?" will be explained along with the pedagogical underpinnings of the curriculum design. Student satisfaction with the course was extremely high (4.8 on a 5.0 scale), indicating this course could be a model for other undergraduate educators.

**PS 2207 Risk Assessment Capstone Project for Seniors in an Undergraduate Toxicology Program.**

S. M. Ford. *College of Pharmacy & Allied Health Professions, St. Johns University, Jamaica, NY.*

Capstone projects are intensive, active learning exercises for seniors to apply their knowledge and skills to a complex problem in their discipline. The projects vary in form and function. They may be done in teams or by individual students; the tasks may be self-selected or assigned. Planning and implementation are student-directed under supervision of faculty. Outcome of the work may be a written document and/or an oral presentation. The scope should be substantial, utilize critical thinking, and draw upon the learning objectives of the major. In our BS Toxicology program, seniors are assigned a risk assessment in the course Regulatory Toxicology and Risk Assessment. They are given a hypothetical disaster, involving a population exposed to a chemical through air, water, food, soil, or medication. Ideally the chemical chosen is one for which the toxicological data is sparse, so that students must evaluate the agent based on its properties and chemical class. The scenario includes the amount released, the exposed population, and the media of exposure. The result of the project is a written risk analysis, a website, and presentation of their findings to the College. The capstone project requires the students to utilize the facts and concepts of toxicology in an analytical manner, and apply the skills of writing, oral communication, and teamwork to a realistic situation. The public presentation informs the larger university community on the process of toxic risk assessment.

**PS 2208 Development of a Summer Undergraduate Research Program in Toxicology and Environmental Health Sciences.**

L. M. Aleksunes<sup>1,3</sup>, L. Liang<sup>2,3</sup>, E. Caswell<sup>2</sup> and D. L. Laskin<sup>1,3</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Department of Health Systems and Policy, University of Medicine and Dentistry of New Jersey-School of Public Health, Piscataway, NJ; <sup>3</sup>NIEHS Center for Environmental Exposures and Disease, Piscataway, NJ.

Exposure to research opportunities in toxicology and environmental sciences is key to the development of the next generation of scientists. The Community Outreach and Engagement Core of the NIEHS Center for Environmental Exposures and Disease at the University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School and Rutgers University has developed a summer research fellowship program to promote toxicology and environmental sciences as careers in biomedical research. The program consists of 10-week basic science and translational research experiences for undergraduates and was also designed to include weekly events including laboratory safety and responsible conduct of research training, a field trip to a pharmaceutical company, career development and research seminars and student presentations. Participants of the 2012 summer research program ranked the field trip as the most valuable weekly activity followed by presentations from toxicologists and environmental health scientists. Based on pre- and post-survey results, over 60% of respondents reported that a career as a scientific researcher was most appealing based upon satisfaction from doing research, the perceived benefit of scientific knowledge to the community, and an overall interest in science. In addition, 87.5% of respondents will continue to pursue research after completion of the summer research program. This includes five students pursuing Ph.D. degrees beginning in 2012 or 2013. A summer research program engages undergraduate students in full-time research experiences and provides unique opportunities to promote toxicology and environmental sciences as research areas for the next generation of scientists and enhances career development skills. Supported by ES020721, ES005022, and ASPET SURF.

**PS 2209 Incorporation of Toxicology and Risk Assessment Principles into an Environmental Health Course.**

R. N. Phalen. *Health Science, CSUSB, San Bernardino, CA.* Sponsor: T. Dodd-Butera.

Environmental health deals with a multitude of public health issues ranging from sanitation to hazardous materials to air and water quality. Practitioners are largely involved in the regulatory side of protecting public health, which requires an intimate understanding of toxicology and risk assessment. However, many of the identified deficiencies with risk assessment are perpetuated by the educational curricula. For example, chemical hazards are introduced to students and evaluated by regulators on a case-by-case basis, often based on one toxicological endpoint alone. Strong emphasis is placed on making comparisons of reference doses to exposure estimates without regard to the effect of uncertainties associated with inadequate data. High uncertainty alone could result in selection of a more toxic substance over one less studied. A unique class project was created to give environmental health students, our future regulators, an improved perspective on how toxicological information can be used to make informed decisions that best protect human health and well-being. The multi-step exercise focuses on a decision made by the World Health Organization to bring DDT back into use to fight malaria. Students work in groups to collect chemical, toxicological, efficacy, and economic aspects of a common pesticide used for mosquito control. The class then comes together to compare and discuss the group results and select the best pesticide option for the impacted region. A semi-quantitative risk management tool is also used for a more objective determination. Lastly, a surprise change in one circumstance causes perspectives to change and the outcome is a completely different conclusion. The end result is a sophisticated interaction of ideas and concepts, which motivates students to start thinking about how there is more to toxicology than lethal doses and dose-response curves, and that there is more to risk assessment than hazard quotients. A detailed description of the project and handouts will be provided.

**PS 2210 Poisoning Principles: Clinical Toxicology and Undergraduate Nursing Education.**

T. Dodd-Butera<sup>1</sup> and M. Broderick Pritty<sup>2</sup>. <sup>1</sup>Nursing, CSU San Bernardino, College of Natural Sciences, San Bernardino, CA; <sup>2</sup>California Poison Control System, San Diego, CA.

According to the American Association of Poison Control Center's (AAPCC) annual report (2010), 601,197 human exposures to toxicants resulted in management in a health care facility. Therefore, education concerning clinical toxicology and

poisonings is essential in preparation of future healthcare professionals. This abstract describes an educational program for undergraduate nurses delivered through a collaboration with a regional Poison Control Center (PCC) and a local university. Undergraduate nursing students were assigned to a clinical toxicology rotation and were required to participate in didactic educational modules addressing principles of toxicokinetics, such as the ADME (absorption, distribution, metabolism, and exposure) model, prior to the PCC rotation. During the rotation, clinical toxicology approaches to the poisoned patient were reviewed. Attendance at a journal club at the poison center was included, covering topics such as: environmental exposures, chemicals, drug overdoses, and unintentional poisonings. A lecture on lead toxicity was then given to the entire class, including those undergraduate students in other rotations. The program culminated with all students participating in a poster session addressing clinical toxicology and other environmental health experiences. Students were required to evaluate the entire course, including the PCC rotation. Students reported an increase in knowledge and awareness about the role of toxicology and environmental health in their professional development. In addition, the knowledge gained could be applied to bedside nursing to evaluate the role of poisoning and antidote use, along with toxicology principles, for treatment and care of patients utilizing healthcare facilities. Recommendations for future programs include integrating toxicology into didactic and clinical experiences of undergraduate nursing students within all rotations, and across healthcare and scientific disciplines.

**PS 2211 Coal Ash Material Safety—A Health Risk-Based Evaluation of USGS Coal Ash Data from Five US Power Plants.**

L. J. Bradley. *AECOM, Chelmsford, MA.*

Over 42% of the estimated 130 million tons of coal ash produced annually in the US is put into beneficial use, and is material that is not placed in disposal facilities. However, these uses are threatened by USEPA's potential regulation of coal ash as a hazardous waste, and by constant references to "toxic coal ash" by the press in response to environmental groups' writings. Therefore, a detailed health-risk based evaluation was conducted of coal ash data released in a report by the US Geological Survey. Eight robust coal ash data sets were selected as representing material that could be put into beneficial use from five US power plants each utilizing a different source of coal. The evaluation was conducted by comparing constituent concentrations in coal ash to risk-based screening levels developed by the USEPA that are protective of a child's direct exposure to residential soils (including ingestion, dermal contact and inhalation routes of exposure). These screening levels are considered by the Agency to be protective for daily exposure by humans (including sensitive groups) over a lifetime. Coal ash percentiles (10th-90th) were compared directly to the screening levels, and in a more detailed evaluation, upper-bound exposure point concentrations were used in a cumulative risk screening process. Constituent concentrations in coal ash were also compared to USGS background concentrations in soils in the US. The results indicate that with few exceptions constituent concentrations in coal ash are below screening levels for residential soils, and are similar in concentration to background US soils. Because exposure to constituents in coal ash used in beneficial applications, such as concrete, road base, or structural fill would be much lower than assumed for a residential soil scenario, these uses should also not pose a direct contact risk to human health.

**PS 2212 Provisional Advisory Levels (PALs) for Chloroethanol (Ethylene Chlorohydrin).**

S. Milanez<sup>1</sup>, P. M. McGinnis<sup>2</sup>, L. Koller<sup>3</sup> and F. Adeshina<sup>4</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN; <sup>2</sup>RG York and Associates, Syracuse, NY; <sup>3</sup>Environmental Health & Toxicology, Corvallis, OR; <sup>4</sup>US EPA, Washington DC.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hour, 30-day, 90-day, and 2-year durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance, but are intended for use at the discretion of risk managers in emergency situations when site-specific risk assessments are not available. The PAL document for chloroethanol was developed based on the SOP and QAPP requirements.

Chloroethanol (2-chloroethanol; ethylene chlorohydrin), is a colorless, combustible liquid with a faint ether-like odor, and is soluble in water and organic solvents. It is a high production volume chemical that is used as an industrial solvent and a chemical manufacturing intermediate. It is formed when ethylene oxide is used to sterilize polyvinyl chloride plastics and to fumigate foods. Humans and animals exposed by inhalation or orally exhibited CNS, GI, and respiratory symptoms, and had post-mortem lesions in numerous internal organs. All PALs were derived using rat

data because the human data were not adequate; the animal data were generally consistent among species and with the limited human data. Developed PAL values for oral exposure are 35 mg/L as the PAL 1 for 24 hours; 110 mg/mL as the PAL 2 for 24 hours, and 30 and 90 days; 230 mg/L as the PAL 3 for 24 hours; and 160 mg/L as the PAL 3 for 30 and 90 days. PALs derived for inhalation exposure are 0.26 ppm and 0.78 ppm as the 24-hour PAL 2 and PAL 3, respectively. For 30 and 90 days, the inhalation PAL 1 is 0.0015 ppm and the PAL 2 is 0.015 ppm. Other oral and inhalation PAL values were not developed due to insufficient data.

#### **PS 2213 Provisional Advisory Level (PAL) Development for Lewisite and Sulfur Mustard.**

C. Bast<sup>1</sup>, R. Young<sup>2</sup>, P. M. McGinnis<sup>3</sup>, C. Baird<sup>4</sup> and F. Adeshina<sup>5</sup>. <sup>1</sup>Oak Ridge National Laboratory (ORNL), Oak Ridge, TN; <sup>2</sup>ORNL, Oak Ridge, TN; <sup>3</sup>RG York & Associates, Syracuse, NY; <sup>4</sup>US Army Public Health Command, Aberdeen, MD; <sup>5</sup>US EPA, Washington DC.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, 90-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site specific risk assessments are not available. Application of PAL protocols has been performed for lewisite and sulfur mustard to estimate inhalation exposure limits; oral PAL values are not recommended (NR) due to insufficient data. PAL values for the vesicants, lewisite and sulfur mustard, are based on ocular effects in humans and animals or lethality thresholds in rodents.

Lewisite inhalation PAL 1, 2, and 3 values are NR, 0.01, and 0.037 mg/m<sup>3</sup>, respectively, for 24-hr; and NR for 30-/90-d and 2-yr.

Sulfur mustard inhalation PAL 1 values are 0.00083 mg/m<sup>3</sup> for 24-h and 0.00010 mg/m<sup>3</sup> for 30-d/90-d and 2-yr. PAL 2 values are 0.0042 mg/m<sup>3</sup> for 24-h, 0.0029 mg/m<sup>3</sup> for 30-d, and 0.00097 mg/m<sup>3</sup> for 90-d and 2-yr. PAL 3 values are 0.088 mg/m<sup>3</sup> for 24-h and NR for 30-d/90-d and 2-yr.

#### **PS 2214 Provisional Advisory Level (PAL) Development for Fentanyl.**

C. S. Wood<sup>1</sup>, C. Baird<sup>2</sup>, L. Koller<sup>3</sup> and F. Adeshina<sup>4</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN; <sup>2</sup>US Army Public Health Command, Aberdeen, MD; <sup>3</sup>Environmental Health and Toxicology, Corvallis, OR; <sup>4</sup>US EPA, Washington DC.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, 90-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. Minimum data requirements must be met or a value may be considered NR (not recommended). PALs have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site specific risk assessments are not available. Application of PAL protocols has been performed for fentanyl to estimate oral and inhalation exposure limits.

Fentanyl is a highly potent, synthetic opioid used clinically as an analgesic and anesthetic. Dose-response information from humans showed that effects were similar between children and adults. The magnitudes of sedation and analgesia were positively correlated with dose. Side-effects included pruritus, nausea, vomiting, headache, bradycardia, vertigo and respiratory depression leading to decreased oxygen saturation at higher doses. Oral PALs were based on adverse side-effects in humans. Oral PAL 1 and 2 values are 0.03 and 0.23 mg/L respectively, for 24-hr/30-d/90-d; oral PAL 3 and all 2-yr values are NR. Inhalation exposure resulted in sedation and respiratory depression. Inhalation PAL 1, 2, and 3 values are NR, 0.0037, and 0.11 mg/m<sup>3</sup> respectively, for 24-h. The 30-d/90-d/2-yr inhalation PALs are NR.

#### **PS 2215 Development of a Chronic Reference Concentration for Decalin.**

L. D. Stuchal, R. E. Weil and S. M. Roberts. Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL.

Decalin is a naturally occurring dicycloalkane present in crude oil and produced as a product of combustion. Its ability to solubilize oils and fats makes it useful in paints, cleaning fluids, gasoline, and varnishes. Because of its widespread use in

many types of commercial products, decalin is ubiquitous in the environment and exposure by the general public is of concern. Neither oral nor inhalation toxicity values are currently available for decalin in published sources despite recurring point and non-point source releases. To derive a reference concentration (RfC) for decalin, inhalation toxicity studies were reviewed using a weight-of-evidence approach. A two-year mouse inhalation study conducted by the National Toxicology Program was chosen as the critical study for the derivation of the chronic RfC. In this study, a significant increase in the occurrence of hepatotoxicity was detected at the highest concentration tested (400 ppm) in male mice. Benchmark dose modeling was utilized to derive a point of departure for hepatic necrosis, syncytial alteration, and erythrophagocytosis. For data not amenable to modeling, a point of departure was derived using the no observable adverse effect level (NOAEL). The most sensitive adverse effect, syncytial alteration resulted in a BMDL<sub>10</sub> of 7.8 ppm using the Log-logistic model. A chronic RfC for decalin of 0.08 mg/m<sup>3</sup> was calculated by conversion of the BMDL<sub>10</sub> to a human equivalent continuous inhalation concentration of 1.4 ppm (7.9 mg/m<sup>3</sup>) using a dosimetric adjustment factor of 1 and application of a total uncertainty factor of 100. The chronic decalin RfC was derived despite several toxicity database limitations, including a small number of chronic inhalation studies and uncertainty regarding reproductive effects. Future research on decalin toxicity is needed to better characterize the adverse effects associated with its chronic inhalation.

#### **PS 2216 Weight-of-Evidence Evaluation of Methyl Methacrylate Olfactory Effects in Humans and Derivation of an Occupational Exposure Level.**

M. Pemberton<sup>1</sup>, L. A. Bailey<sup>2</sup> and L. R. Rhomberg<sup>2</sup>. <sup>1</sup>Systox, Cheshire, United Kingdom; <sup>2</sup>Gradient, Cambridge, MA.

Methyl methacrylate (MMA) causes olfactory effects in rodents that are considered relevant to humans. Recent scientific studies have focused on understanding the apparent lack of species concordance between the rodent and occupational studies. We have applied the hypothesis-based weight-of-evidence (HBWoE) approach to evaluate the concordance of the available data and the hypothesis that the observed difference in sensitivity between rats and humans may be the result of physiological and biochemical differences. Our WoE analysis integrated several lines of evidence [animal, human, mode of action (MoA), and toxicokinetics data] and found: 1) acute and chronic rat and mouse MMA inhalation studies consistently indicate degenerative lesions of the main olfactory region as the most sensitive endpoint; 2) numerous studies support an MoA for MMA involving high concentrations of carboxylesterase activity in nasal epithelial tissue that metabolizes MMA to methyl acrylic acid (MAA), an organic acid with irritative and corrosive properties; 3) carboxylesterases are a group of non-specific enzymes that are widely distributed throughout the body in animals and humans; 4) toxicokinetic studies and a physiologically based pharmacokinetic (PBPK) model describing inhalation dosimetry of MMA in the upper respiratory tract (URT) of rats and humans point to differences in nasal morphology and biochemistry that help reconcile these differences as species-specific manifestations of a common toxicological process, and predict a rat-to-human dosimetry adjustment factor (DAF) of 3 to 8, consistent with observed lower sensitivity in humans compared to rats; and 5) worker studies, although somewhat limited, consistently suggest a no observed adverse effect level (NOAEL) for URT irritation, including olfactory dysfunction, of 50 ppm. We derived MMA occupational exposure levels (OELs) from animal data (ranging from 28-118 ppm) and human data. Overall, our WoE analysis supports use of the human data for derivation of an MMA OEL of 50 ppm.

#### **PS 2217 An Updated Dose-Response Evaluation of Aldrin and Dieldrin.**

E. Hooker, H. J. Gibb and K. G. Fulcher. Tetra Tech Sciences, Arlington, VA.

The United States Environmental Protection Agency (USEPA) reviewed the cancer and non-cancer effects of the organochlorine insecticides, aldrin and dieldrin, in the late 1980's. The results of those assessments are reported by USEPA's Integrated Risk Information System (IRIS). These assessments include reference dose (RfD) values of 0.00003 and 0.00005 mg/kg-day and cancer slope factor values of 17 and 16 (mg/kg-day)<sup>-1</sup> for aldrin and dieldrin, respectively. The USEPA methods for dose-response analysis have changed in the decades since these evaluations were done. The dose-response analyses of cancer and non-cancer health effects of aldrin and dieldrin were re-evaluated using current methodology, including benchmark dose (BMD) analysis (BMDs Version 2.2 software) and current body weight scaling. A literature review was updated to determine the most appropriate adverse effect endpoints. Using current methodology and information, the cancer slope factors for aldrin and dieldrin were estimated to be 3.4 and 7.0 (mg/kg-day)<sup>-1</sup>, respectively (i.e., about 5 and 2.3 fold lower risk than previous assessments). The current analyses estimated RfD values of 0.0001 and 0.00008 mg/kg-day for aldrin

and dieldrin, respectively (both higher than previous assessments). Because aldrin and dieldrin are no longer used as pesticides in the United States, they are a low priority for additional review by the USEPA. However, because they are persistent and still detected in environmental samples, quantitative risk assessments based on the best available methods are required. Several national and international health assessment organizations (e.g., WHO) do not consider aldrin and dieldrin to be human carcinogens. Recent epidemiologic studies do not demonstrate a causal association between aldrin and dieldrin and human cancer risk. These re-evaluations, based on current methodologies and available data, suggest that these two compounds pose a lower human health risk than currently reported by USEPA.

**PS 2218 Benzene: Development of a 24-Hour, Health-Protective Comparison Value.**

J. T. Haney. *Toxicology Division, Texas Commission on Environmental Quality, Austin, TX.*

Texas has the most extensive volatile organic compound (VOC) ambient air monitoring network in the nation. As part of that network, the TCEQ collects every sixth-day, 24-hour canister VOC data. These data are used to calculate annual averages for comparison to chronic, health-protective Air Monitoring Comparison Values (AMCVs) (i.e., RfC-like values for noncarcinogenic effects, 1E-05 excess risk levels for cancer effects). In regard to acute exposure durations, however, the TCEQ typically has only 1-hour AMCVs, which while conservative are not designed to evaluate 24-hour sample results. Thus, the development of 24-hour, health-protective AMCVs would allow the TCEQ to more fully utilize 24-hour VOC data for the evaluation of potential public health concerns. The TCEQ has developed a proposed 24-hour AMCV for benzene since it is a ubiquitous VOC of both agency and public interest. Critical effect dose-response data for hematotoxicity from mouse studies indicate an effect level range of 10-100 ppm for subacute exposure (e.g., 6-8 hours per day, 5-10 days). A point of departure (POD) from these studies was used to develop the 24-hour value. The total number of exposure hours exceeds 24 hours for all these subacute studies and available toxicokinetic information indicates the time between the intermittent daily exposures would not allow for clearance of benzene's hematotoxicity-implicated metabolites (e.g., hydroquinone, hydroquinone glucuronide, catechol) from the bone marrow as evidence suggests they are not readily excreted. Using the same POD (LOAEL of 10.2 ppm) and uncertainty factors (total UF of 100) as the TCEQ used to derive its 1-hour AMCV (180 ppb) but without duration adjustment (based on toxicokinetic considerations) results in a conservative 24-hour, health-protective AMCV of 100 ppb. This value is well below even chronic human hematotoxicity observed adverse effect levels (e.g., 7.2-13.6 ppm). The proposed 24-hour AMCV is considered sufficiently conservative for the adequate protection of public health and would significantly complement TCEQ health effect evaluations of ambient air data.

**PS 2219 Derivation of a Guidance Limit for Cadmium in Children's Jewelry: Health Canada's Perspective.**

G. Barrett<sup>1</sup>, P. Chantal<sup>2</sup>, S. Wright<sup>3</sup>, P. Chowhan<sup>4</sup>, P. Pelletier<sup>1</sup>, H. Ryan<sup>1,2</sup> and J. Field<sup>1</sup>. <sup>1</sup>*Toxicology and Flammability Risk Assessment Unit, Consumer Product Safety Directorate, Health Canada, Ottawa, ON, Canada;* <sup>2</sup>*Product Safety Laboratory, Consumer Product Safety Directorate, Health Canada, Ottawa, ON, Canada;* <sup>3</sup>*Compliance and Enforcement Division, Consumer Product Safety Directorate, Health Canada, Ottawa, ON, Canada;* <sup>4</sup>*Risk Management Strategies Division, Consumer Product Safety Directorate, Health Canada, Ottawa, ON, Canada.* Sponsor: G. Chen.

It has been demonstrated that swallowed jewellery items may become lodged in the stomach, and morbidity and mortality have been associated with jewellery containing lead. Due to its inherent toxicity, the use of cadmium to make costume jewellery may pose an analogous threat. In the absence of reliable human toxicity data, the results from animal studies were used to derive an oral acute provisional minimal risk level (pMRL) of 0.0732 mg/kg bw for cadmium. Health Canada analyzed approximately 200 children's jewellery samples that were judged small enough to fit into a child's mouth for cadmium content. A subset of these samples were also subjected to migration testing, which revealed no consistency between the total amount of cadmium in a sample, and the amount that might be released in the simulated physiological environment of the stomach over an extended period (such as in the case of a piece of jewellery lodged in the stomach over several days). Since standardized migration testing cannot accurately predict the amount of cadmium that might leach out of a sample under such circumstances, the use of total cadmium content to derive a guideline is considered the most health-protective approach. Limiting total cadmium content to 130 ppm removes variables that interfere with migratable cadmium quantification (such as the thickness and composition of the surface plating, and elemental composition of the amalgam) and is protective of the scenario of an ingested piece of jewellery lodged in the stomach for an extended period of time.

**PS 2220 Assessment of Risks to the US Population Posed by Exposure to Gold and Ceramic Dental Restorations.**

R. E. Peters<sup>1</sup>, M. Richardson<sup>2</sup>, S. Clemow<sup>3</sup>, K. James<sup>1</sup> and S. D. Siciliano<sup>1</sup>. <sup>1</sup>*University of Saskatchewan, Saskatoon, SK, Canada;* <sup>2</sup>*Stantec Consulting Ltd., Ottawa, ON, Canada;* <sup>3</sup>*SNC-Lavalin Environment, Ottawa, ON, Canada.* Sponsor: L. Weber.

There is significant mercury exposure from dental amalgam used in restorative practice. However, little is known about the chemical exposures and risks of alternative dental restorative materials. Thus, it is difficult for clinicians to weigh the performance, risks, and benefits of dental amalgam to alternate restorative materials. Here we provide the first population-level risk assessment for gold alloy and ceramic restorative materials. Employing the US National Health and Nutrition Examination Survey (NHANES) data from 2001 to 2004, we assessed the exposure of adults to the components of gold alloy and ceramic dental restorations in the US general population. Three specific exposure scenarios were considered: 1) all restorations were either gold alloy or ceramic; 2) all crowns were gold alloy or ceramic; and 3) 11% of fillings were either gold alloy or ceramic, in 30% of the population. Silver appears to be the most problematic component of gold alloy restorations, due to a combination of relatively high toxicity and high proportional composition. Based on the toxicity of silver and its proportional content in gold dental alloys, it was estimated that adults could possess an average of 4 tooth surfaces restored with gold before exceeding the Reference Exposure Level (REL) for silver. Lithium appears to be the most problematic component of dental ceramics. All other ceramic components considered resulted in estimated daily doses well below their respective RELs. Based on the toxicity of lithium and its proportional content in dental ceramics, it was estimated that adults could possess an average of 16 tooth surfaces restored with ceramics before exceeding the REL for lithium. Relative to dental amalgam and gold alloys, ceramics present the fewest and lowest chemical exposures and risks.

**PS 2221 Development of an Oral Cancer Slope Factor for Acrylamide Based on Tumors Relevant to Humans.**

J. D. Urban<sup>1</sup>, C. M. Thompson<sup>2</sup>, R. Deskin<sup>3</sup>, M. Waite<sup>3</sup> and L. C. Haws<sup>1</sup>. <sup>1</sup>*ToxStrategies, Inc., Austin, TX;* <sup>2</sup>*ToxStrategies, Inc., Houston, TX;* <sup>3</sup>*Cytex Industries, Inc., Woodland Park, NJ.*

Acrylamide is an industrial chemical used mainly in the production of polyacrylamides. Acrylamide and polyacrylamides have many uses, including uses as flocculants and flow control agent for enhancing oil production from wells, in the production of dyes, organic chemicals, contact lenses, cosmetics and toiletries, in sugar refining, and as a chemical grouting agent and soil stabilizer. Acrylamide is also commonly present in fried foods and the primary route of human exposure in the general population is diet. In their most recent risk assessment for acrylamide, USEPA developed an oral cancer slope factor (OSF) of 0.5 (mg/kg-day)<sup>-1</sup> based on a 2-year drinking water study that reported increased incidences of thyroid tumors and tunica vaginalis mesotheliomas (TVMs) in male F344 rats. However, there is considerable evidence that F344 rats are particularly susceptible to TVMs, and therefore TVMs may not be relevant to humans. As such, our objective was to evaluate the overall weight of the evidence regarding each tumor type and to derive an OSF for acrylamide based on those tumors relevant to humans. Among the tumors induced by acrylamide (thyroid tumors, TVMs, mammary gland tumors, CNS tumors), thyroid and mammary gland tumors were considered most relevant to humans. Using the rat OSF for the combined increased incidences of thyroid and mammary gland tumors observed in female F344 rats, we derived a human OSF using a rat-to-human dose metric conversion factor based on serum levels of the primary acrylamide metabolite, glycidamide (widely considered to be the putative proximal carcinogen). The final human OSF for combined thyroid and mammary gland tumors was determined to be 0.09 (mg/kg-day)<sup>-1</sup>. This OSF suggests a lower cancer potency for acrylamide based on target tissues more relevant to humans. It should be noted however, the FDA and NTP just completed a 2-year, multi-species drinking bioassay and the results of this study may impact future OSF estimates for acrylamide.

**PS 2222 An Evaluation of the Human Carcinogenic Potency of Methyl Tert-Butyl Ether (MTBE): Considering New Data and Mode of Action.**

P. Sheehan and K. Bogen. *Exponent, Oakland, CA.*

The carcinogenic potency of MTBE was initially evaluated by State of California scientists in 1999 based on a gavage study with rats (Belpoggi et al. 1995, 1997, 1998) and inhalation studies with rats and mice (Bird et al. 1997). Potency was estimated at that time using a linearized multistage model. Since then, an additional

rodent cancer bioassay of MTBE in drinking water (Dodd et al. 2011), several genotoxicity and mutagenicity studies, evaluations of MTBE metabolites formaldehyde and tert-butyl alcohol (TBA), as well as other studies providing information on MTBE's mode of action have been reported. In addition, the U.S. Environmental Protection Agency (EPA) declared the data on lymphomas and leukemias from Belpoggi et al. (Ramazzini Institute) as unreliable for risk assessment raising additional uncertainty about California's potency estimate. The new data and remaining reliable historic rodent bioassay data were used to re-evaluate the cancer potency or slope factor (CSF) of MTBE considering mode of action (MOA). The overwhelming majority of studies indicate that neither MTBE nor TBA is genotoxic. In stark contrast, formaldehyde is clearly genotoxic, but when generated by MTBE metabolism is efficiently detoxified to preclude elevating background levels and associated genotoxic damage. Based on genotoxicity and MOA analyses, the most likely CSF for MTBE is zero, unless chronic exposures induce target-tissue toxicity including in sensitive individuals. A corresponding expected CSF value for MTBE conditional on a linear MOA was estimated to be 0.000018 per mg MTBE per kg body weight per day for a chronically exposed adult. If MTBE is carcinogenic to humans, then it is extremely weak relative to other chemical carcinogens evaluated by EPA.

**PS 2223 Development of a 24-Hour Air Monitoring Comparison Value (AMCV) for 1, 3-Butadiene and Comparison of 1-Hour, 24-Hour, and Chronic AMCVs to Observed Adverse Effect Levels.**

R. L. Grant and R. E. Jones. *Toxicology Division, Texas Commission on Environmental Quality (TCEQ), Austin, TX.*

The TCEQ develops AMCVs, which are considered safe concentrations of chemicals in air, to determine whether 1-hour (hr) or annual average chemical concentrations in ambient air exceed levels of potential concern for adverse health effects. Previously for 1,3-butadiene (BD), a 1-hr AMCV of 1,700 ppb was derived based on a mouse developmental study (6 hr/day exposures, gestational days 6-15). A chronic AMCV of 9.1 ppb was derived based on a 1 in 100,000 excess risk for leukemia mortality from an epidemiological study in styrene-butadiene workers. To calculate annual ambient air concentrations, the TCEQ collects a significant amount of 24-hr monitoring data that are not directly comparable to the 1-hr or chronic AMCV. Therefore, the TCEQ has developed a 24-hr AMCV for BD to evaluate the potential for health effects from 24-hr exposure. The same mouse study used for the 1-hr AMCV was judged to be the critical study for the 24-hr AMCV based on mode-of-action and toxicokinetic data. The 6-hr human equivalent point of departure (POD-HEC) of 51,300 ppb was duration adjusted (Haber's rule with  $n = 1$ ) to calculate the 24-hr POD-HEC of 12,800 ppb. The proposed 24-hr AMCV is 430 ppb after application of total uncertainty factors of 30. The TCEQ has developed guidelines to derive observed adverse effects levels (OAEs) based on available dose response data to better communicate to risk managers and the public the margin of safety between OAEs and AMCVs. For the 6- and 24-hr AMCVs, the acute OAE is 66,000 ppb (the central estimate POD-HEC for 5% decrease in fetal weight loss). The 1-hr AMCV of 1700 ppb is 39 times lower than the acute OAE and the 24-hr AMCV of 430 ppb is 150 times lower. The long-term OAE is 10,000 ppb (the lowest average occupational exposure concentration where the likelihood ratio test that slope = 0 was statistically significant for different maximum levels of cumulative BD ppm-years for leukemia deaths). The chronic AMCV of 9.1 ppb is 1,100 times lower than the chronic OAE.

**PS 2224 Health-Based 24-Hour Air Monitoring Comparison Value (AMCV) for Acrolein in Ambient Air: Comparison to Air Monitoring Data Collected in Texas.**

A. Jenkins. *Toxicology Division, Texas Commission on Environmental Quality, Austin, TX.*

Acrolein is of national and state interest because it is ubiquitous, is difficult to analyze in ambient air, and concentrations causing eye and respiratory irritation are low. In 2011, a follow-up special monitoring project for acrolein was conducted by the USEPA at a school near a building products manufacturing facility in Texas. Ten 24-hour (hr) ambient air samples were collected in canisters downwind of a facility known to emit acrolein and analyzed using an improved method. The follow-up project was done in response to finding that acrolein canister results can be affected by the canister cleaning method and calibration gas standards. The TCEQ has previously derived 1-hr and chronic health-protective AMCVs for acrolein in order to evaluate air monitoring data. In order to evaluate the 24-hr data collected at the school and at two other permanent monitoring sites in Texas, the TCEQ has developed a proposed 24-hr AMCV to better evaluate the potential for adverse health effects. Acrolein's toxicity is mainly concentration dependent and levels causing adverse effects are similar in humans and animals. The same rat study used to

develop the chronic AMCV was selected as the critical study for derivation of the 24-hr AMCV since interim histopathology was performed after various exposure durations (e.g., 6 hr/day for 4, 14, 30, and 65 days) which encompassed the 24-hr duration of interest. A no-observed-adverse-effect level of 200 ppb was identified from the key study for all exposure durations based on the absence of nasal epithelial hyperplasia. Based on a mode-of-action analysis, no duration adjustment was necessary. After correcting for animal-to-human dosimetric differences, the 24-hr human equivalent point of departure was 37.4 ppb. Total uncertainty factors of 30 were applied to calculate the 24-hr AMCV of 1.2 ppb. In comparison, the 1-hr AMCV for acrolein is 4.8 ppb and its chronic AMCV is 0.22 ppb. No concentrations exceeding the 24-hr AMCV using the improved canister method have been reported at monitoring sites in Texas.

**PS 2225 Protection against Toxic Effects of Arsenic by Vitamin E: Characterization of Transplacental Arsenic Species and Effects.**

A. Sampayo-Reyes<sup>1</sup>, R. Marcos<sup>2</sup> and A. Hernandez<sup>2</sup>. <sup>1</sup>*Departamento de Toxicogenética, Centro de Investigación Biomédicas del Noreste, Monterrey, Mexico;* <sup>2</sup>*Departament de Genètica i de Microbiologia, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Millions of people world-wide are exposed to arsenic (As) via drinking water. As is biotransformed for excretion, and the CH<sub>3</sub> groups necessary for such metabolism are also essential to DNA methylation. Pregnant women methylate As more efficiently to protect the fetus from immediate toxicity, but at the risk of later epigenetic deregulation. Thus, preventing early-life As exposure may be critical for the health of future generations. In order to evaluate early-life exposure to arsenic, pregnant hamsters were exposed to 50 and 100 ppm of arsenite via drinking water at the 0th and 8-9th day of gestation. Co-treatment with 8.5 mg/Kg/day of selenite or 6 mg/Kg/day of vit E was also carried out to assess whether those compounds exert any As-transplacental protective role. To characterize arsenic speciation during pregnancy, fetus development, unweaning and adulthood, As species were measured in the urine and/or organs by HPLC-ICP/MS. Teratogenic effects of transplacental arsenic were analyzed observing both reabsorptions and embryo anomalies, and in utero As-exposed litters were followed-up to evaluate tumor incidence at the adult stage. Characterization of arsenic species indicates that fetuses and unweaned offspring are As-exposed through placenta and milk, showing a speciation profile similar to that in mothers. Results demonstrate a teratogenic As effect in a dose and time-of-gestation dependent manner, and a noticeable protective effect of both selenite and vit E.

**PS 2226 Approaches for Deriving an OEL for Peracetic Acid and Occupational Risk Management Considerations.**

N. Pechacek<sup>1</sup>, A. Maier<sup>2</sup> and L. T. Haber<sup>2</sup>. <sup>1</sup>*Ecobal, St. Paul, MN;* <sup>2</sup>*Toxicology Excellence for Risk Assessment, Cincinnati, OH.*

To provide perspective on current and proposed occupational exposure limits (OELs) for peracetic acid (PAA; CAS 79-21-0) we evaluated PAA toxicity with the aim of understanding uncertainties and their implications for the resulting OEL. The database for PAA is limited and no single study is definitive. Two unpublished reports on human exposures to PAA provide some concentration-response data, indicating that a sensitive acute effect of PAA exposure is eye and respiratory tract irritation, but the studies differ quantitatively. These differences are not surprising, in light of the differences in exposures (apparently pure PAA vapor vs. an aerosol of a mixture), the subjective nature of the reporting, and the likely small sample sizes. The studies are also limited by the lack of clear concentration-duration-response data. Nonetheless, the studies provide a reasonable estimate of the threshold for the onset of irritation in humans in the range of 0.53 mg/m<sup>3</sup> for up to 3 hours and 1.56 mg/m<sup>3</sup> for up to 45 minutes. RD50 (concentration estimated to cause a 50% depression in respiratory rate) data in mice and rats provide additional information on the irritant potency of PAA. The RD50 in mice was 17 mg/m<sup>3</sup> for pure PAA vapor and 12 mg/m<sup>3</sup> for a commercial mixture. The rat RD50 was 21.5 to 24.1 mg/m<sup>3</sup>. Based on the array of human data and the RD50 values in rodents, we calculated potential TWA OELs ranging from 0.26 to 1.56 mg/m<sup>3</sup>. A similar range of 0.62 – 2 mg/m<sup>3</sup> is found among the published OELs, and any of these values could be justified as protective of worker health given the uncertainties in the data and the precision of the OEL methodology. More definitive sensory irritation studies would further clarify selection of a value in this range. Given the extant data, the ultimate OEL choice within a range of reasonable values is a policy-based risk management decision, not a scientific one. The optimal time averaging approach is also not clearly established by the data; however, a combination of a TWA with a STEL is the recommended risk management option.

**PS 2227 An Inhalation Risk Assessment for Measured Ambient Air Concentrations of 6:2 Fluorotelomer Alcohol.**

T. L. Serex<sup>1</sup>, M. W. Himmelstein<sup>1</sup>, R. C. Buck and M. H. Russell. *E.I. duPont de Nemours & Co. Inc., Wilmington, DE.*

6:2 Fluorotelomer Alcohol (CAS# 647-42-7, 1-Octanol-3,3,4,4,5,5,6,6,7,7,8,8,8, tridecafluoro-, 6:2 FTOH) is a raw material used for manufacturing surfactant and polymeric products. 6:2 FTOH vapor phase inhalation is a potential exposure route. The aim of the current investigation was to 1) compare the oral and inhalation repeated-exposure toxicity data to confirm systemic toxicity, target organs, and lack of an exposure route effect, 2) confirm similar metabolic and toxicokinetic profiles via both exposure routes, and 3) conduct an inhalation risk assessment for reported ambient air concentrations. In an inhalation range-finder (5-days) and a 28-day inhalation toxicity study, the profile of 6:2 FTOH and its metabolites in plasma under controlled inhalation exposure was investigated as well as the systemic toxicity and target organs. These studies provided a basis for toxicity comparison, plasma metabolites, and dosimetry between inhalation and oral dosing. Similar toxicity, metabolic and toxicokinetic profiles via both exposure routes was confirmed. Benchmark Dose Analysis (BMD) was conducted on the subchronic toxicity endpoints to determine the most sensitive effect and the corresponding BMD associated with this effect. Based on this analysis, the corresponding human equivalent dose (HED) was calculated to be 1.4 mg/kg bw/day. An additional assessment factor of 2 was applied to extrapolate from the subchronic exposure to a chronic exposure and resulted in a final HED of 0.7 mg/kg bw/day. An equivalent air concentration was determined using an allometric scaling factor to arrive at a human equivalent concentration (HEC) of 2.5 mg/m<sup>3</sup>. This HEC was then divided by the reported indoor and outdoor air concentrations to arrive at a margin of exposure (MOE). MOEs calculated for inhalation exposure to indoor or outdoor air ranged from 1.1E+05 to 2.5E+07. This assessment indicates there is no human health risk expected even at the highest ambient air concentrations of 6:2 FTOH reported.

**PS 2228 Derivation of an Occupational Exposure Limit for Inorganic Borates Using a Weight of Evidence Approach.**

M. J. Vincent<sup>1</sup>, A. Maier<sup>1</sup>, E. Hack<sup>2</sup>, P. Nance<sup>1</sup> and W. Ball<sup>3</sup>. <sup>1</sup>TERA, Cincinnati, OH; <sup>2</sup>The Henry Jackson Foundation, Bethesda, MD; <sup>3</sup>Rio Tinto Minerals, Greenwood Village, CO.

Inorganic borates are encountered in many settings worldwide, spurring international efforts to develop exposure guidance (U.S. EPA 2004; WHO 2009; ATSDR 2010) and occupational exposure limits (OEL) (ACGIH 2005, MAK 2011). We derived an updated OEL to reflect new data and current international risk assessment frameworks. We assessed toxicity and epidemiology data on inorganic borates to identify relevant adverse effects. International risk assessment frameworks (IPCS 2005; IPCS 2007) were used to evaluate endpoint candidates: reproductive toxicity, developmental toxicity, and sensory irritation. For each endpoint, a preliminary OEL was derived and adjusted based on consideration of toxicokinetics, toxicodynamics, and other uncertainties. Dose-response modeling supported selection of the point of departure for each endpoint. Developmental toxicity was the most sensitive systemic effect. An OEL of 1.6 mg B/m<sup>3</sup> was estimated for this effect based on a point of departure (POD) of 63 mg B/m<sup>3</sup> with an uncertainty factor (UF) of 40. Sensory irritation was considered to be the most sensitive effect for the portal of entry. An OEL of 1.4 mg B/m<sup>3</sup> was estimated for this effect based on the identified POD and an UF of 1. Reproductive effects are not the most sensitive basis for OEL derivation. An OEL of 1.4 mg B/m<sup>3</sup> was derived as an 8-hour TWA based on sensory irritation potential. The OEL is expected to protect from systemic toxicity endpoints.

**PS 2229 US EPA Decabromodiphenyl Ether Alternatives Hazard Assessment Results.**

J. Rhoades<sup>1</sup>, M. Kawa<sup>1</sup>, E. Lavoie<sup>2</sup>, C. Baier-Anderson<sup>2</sup> and J. Tunkel<sup>1</sup>. <sup>1</sup>SRC, Inc., East Syracuse, NY; <sup>2</sup>US EPA, OPPT, DfE, Washington DC.

The U.S. Environmental Protection Agency (US EPA) Design for Environment (DfE) Program undertook a chemical alternatives assessment for decabromodiphenyl ether (decaBDE) as part of the Action Plan for Polybrominated Diphenyl Ethers (PBDEs) published in December 2009. DfE convened a multi-stakeholder partnership to explore the human health and environmental profiles of functional and viable alternatives to decabromodiphenyl ether (decaBDE). The partnership identified ~ 30 functional alternatives to decaBDE. The hazard assessment for decaBDE and the alternatives used DfE hazard evaluation criteria to assign hazard designations for human health toxicity, ecological toxicity and environmental fate endpoints. The alternatives included a range of flame retardant

chemistries including both halogenated and non-halogen organic substances, inorganic materials, polymeric and non-polymeric substances and novel, new to market substances. Some alternatives were well characterized for all endpoints, while others were lacking data. Analog data, predictive models, structural alerts and expert judgment were used to make hazard designations for endpoints with data gaps. Trends for human health, ecological toxicity and fate characteristics were indicated in a number of the alternatives and are described in the poster. In general, molecular size ranges, molecular structures, and/or functional groups were found to be most influential on the hazard designations. A novel component of this assessment was the evaluation of higher molecular weight polymers for their human health and ecological toxicity based on their low potential for bioavailability and variability in low molecular weight components. Effective hazard assessment approaches of hazard criteria coupled with decision-making protocols are practical tools for businesses to use early in materials selection processes and will contribute to more sustainable product development. The resulting hazard profiles should be of value to manufacturers making substitution decisions in preparation for the upcoming decaBDE phase out.

**PS 2230 Predicting Bioavailability of Arsenic in Mining Soils.**

V. L. Mitchell<sup>1</sup>, N. T. Basta<sup>2</sup>, S. W. Casteel<sup>3</sup>, S. Whitacre<sup>2</sup>, L. E. Naught<sup>3</sup> and P. A. Myers<sup>1</sup>. <sup>1</sup>Toxic Substances Control, Cal EPA, Sacramento, CA; <sup>2</sup>Ohio State University, Columbus, OH; <sup>3</sup>University of Missouri, Columbia, MO.

Arsenic (As) is a naturally occurring element in soil and a key chemical of concern at former mine sites in California. Risk assessment calculations typically utilize default oral toxicity values, which are based on ingestion of readily soluble forms of As such as sodium arsenate (NaAs). However, mining soils in California are relatively high in iron hydroxide phases that bind As strongly, resulting in reduced solubility/bioavailability. The juvenile swine model is an approved, but often cost prohibitive, method for determining the relative bioavailability (RBA) of As in soils compared to that of NaAs. RBAs can be used to adjust toxicity criteria, resulting in a more accurate site-specific risk assessment. In vitro methodologies have proven to be useful surrogates for in vivo feeding studies in predicting bioavailability for other metals but lack precision for arsenic, particularly in high iron content soils. Six soil samples collected from Empire Mine State Historic Park (total As 302-12,041 mg/kg) were analyzed in the juvenile swine model. RBAs ranged from 4 to 20%. Gastrointestinal modeling correlated but underestimated RBA (1-9%). Sequential chemical extraction procedures (SEP) were applied to fractionate the As in soils into (F1) non-specifically sorbed; (F2) specifically sorbed; (F3) amorphous and poorly-crystalline oxides of Fe and Al; (F4) well-crystallized oxides of Fe and Al and residual As phases. The results of these extractions demonstrated that the sum of non-specifically sorbed and specifically sorbed arsenic (F1+F2) was similar to the predicted in vitro bioaccessibility while F1+F2+F3 is a conservative estimate of the in vivo RBA (10-50%). SEP could prove to be a cost-effective and valuable screening tool for estimating in vivo RBA. In summary, the assumption of 100% bioavailability of As in mining soils grossly overestimates exposure and risk to human health. Adjustments for As bioavailability in these materials and similar mining wastes provides a more accurate assessment of human exposure.

**PS 2231 A Quantitative Risk Assessment of 1-Bromopropane, Based on Tumor Data.**

D. A. Dankovic<sup>1</sup> and G. Dotson<sup>2</sup>. <sup>1</sup>Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH; <sup>2</sup>Document Development Branch, CDC/NIOSH, Cincinnati, OH.

The "green" movement has resulted in the introduction of several new "environmentally-friendly" substitutes into commerce, including 1-bromopropane (1-BP; CAS no. 106-94-5). Although use of 1-BP is intended to minimize ozone depletion, occupational exposure is of concern. Case studies, occupational exposure assessments, and epidemiological investigations have suggested that workplace exposure to 1-BP may be associated with neurological, reproductive, and hematological effects. Previous quantitative risk assessments of 1-BP have been based on toxicological studies of these and other non-cancer endpoints. This poster presents a quantitative risk assessment based on a NTP chronic bioassay, in which rats and mice were exposed to 125-500 or 62.5-250 ppm 1-BP, respectively, for up to 2 years. Inhalation of 1-BP produced alveolar/bronchiolar adenomas and carcinomas in female mice, adenomas of the large intestine in female rats, and keratoacanthoma/squamous cell carcinoma of the skin in male rats. Benchmark concentrations (BMC) and lower 95% confidence limits (BMCL) estimates at the 1 in 1000 response level (0.1%) were based on a previously published model average procedure. The BMC (BMCL) estimates were 0.85 (0.41) ppm for alveolar/bronchiolar adenoma + carcinoma; 13.5 (2.76) ppm for large intestine adenomas; and 3.73 (1.44) ppm for keratoacanthoma + squamous cell carcinoma of the skin. The BMC

(BMCL) estimates were extrapolated to humans on a (body weight)<sup>0.75</sup> basis, assuming a 45-year occupational exposure. Human-equivalent concentrations for a 1 in a 1000 lifetime added risk at the various tumor sites are 0.39 (0.19) ppm, for lung tumors; 6.17 (1.26) ppm for intestinal tumors; and 1.75 (0.68) ppm for skin tumors. These results suggest that even sub-ppm occupational exposures to 1-BP may pose an increased risk of cancer.

*The findings and conclusions in this report are those of the authors and do not necessarily represent the views of the National Institute for Occupational Safety and Health.*

## **PS** 2232 Human Health Risk Assessment of Inhaled Acudyne™ Shine Polymer in Hair Care Products.

S. M. Krieger, W. Shade, R. Sura, J. A. Hotchkiss and G. A. Hazelton. *The Dow Chemical Company, Midland, MI.*

ACUDYNE™ Shine is one of a family of acrylic polymers used in hair care product applications such as gels/mousses, and pump or aerosol sprays at concentrations up to 7 wt% to enhance the properties of the product. The pattern of use provides a potential for inhalation exposure to both consumers and salon workers. Sprague Dawley rats were exposed 6 h/day, 5 d/wk, for two- or 13-wks to ACUDYNE™ polymer concentrations of 0, 2, 11, and 100 mg/m<sup>3</sup> or 0, 1, 8, and 82 mg/m<sup>3</sup>, respectively, to provide toxicologic data for human risk assessment. A simulated consumer/occupational exposure monitoring study was conducted to determine typical breathing zone aerosol concentrations during product use. In the 13-wk study, no treatment-related changes in daily clinical observations, functional tests, ophthalmology, urinalysis, hematology, clinical chemistry, or coagulation parameters were observed. Males and females exposed to 82 mg/m<sup>3</sup> ACUDYNE™ had increased mediastinal and tracheobronchial lymph nodes, higher absolute and relative lung weights, and chronic-active bronchiolar-alveolar inflammation after 13-wks of exposure. Females also had decreased feed consumption and body weight gains. The No Adverse Effect Concentration was 8 mg/m<sup>3</sup> for males and females. Assuming 100% deposition, the inhaled dose of ACUDYNE™ polymer at an aerosol concentration of 8 mg/m<sup>3</sup> was estimated to be 0.47 mg/gm lung/day in rats. Based on a rat-to-human inhalation dosimetry factor of 24-32, the human equivalent inhaled dose at the same aerosol concentration was estimated to be 11.3 to 15.1 mg/gm lung/day. Results of the exposure monitoring study indicated breathing zone concentrations of respirable aerosol particles of 0.38 and 0.11 mg/m<sup>3</sup> and daily polymer lung deposition of  $\leq 0.19$  and  $\leq 0.44$   $\mu$ g/gm lung for consumer and occupational exposure scenarios, respectively. Based on the calculated human equivalent margin of exposure of  $> 25,000$  to  $150,000$  for all exposure scenarios, repeated daily inhalation exposure to ACUDYNE™ Shine polymer in hairspray formulations poses no significant human health risk.

## **PS** 2233 Derivation of Acceptable Drinking Water Levels for Bromine and Bromide-Releasing Antimicrobial Agents.

J. C. English, V. S. Bhat and C. J. McLellan. *NSF International, Ann Arbor, MI.*

Elemental bromine is the active ingredient in brominating cartridges, and is registered for disinfection of drinking water aboard ships and oil drilling platforms. Since bromine disproportionates in water to bromide (stable) and hypobromite (unstable) ions, this assessment applies specifically to inorganic bromide, whereas health-based guideline values for bromate and organic bromine compounds have been developed elsewhere. Repeated oral exposure in various mammalian species is associated with central nervous system effects expressed as behavioral and EEG changes. Repeated oral dosing also causes a hypothyroid effect that is specific to rats and not observed clinically. In a rat three-generation study with NaBr administered via the diet, the NOAELs for reproductive and parental effects were 48 and 12 mg Br/kg-day, respectively. In oral developmental toxicity studies, the NOAELs for both parental and developmental effects were 77 and 196 mg Br/kg-day, in rats and rabbits, respectively. Chronic administration of KBr or methyl bromide via the diet of rats did not result in treatment-related adverse findings. There is extensive clinical experience with various bromide salts based on their historical use as sedative-hypnotics and in treatment of seizure disorders. When male and female volunteers were administered NaBr capsules for 12 weeks, there was a small effect on EEGs that was reproducible but within normal limits. Serum T4, T3, and related hormone levels remained within normal limits. The most sensitive effect was gastric irritation expressed as nausea that occurred shortly after the ingestion of the capsules, but no longer occurred when the capsules were taken with a meal. Based on the absence of sedation and EEG changes within normal limits, the human systemic NOAEL was 7 mg Br/kg-day. Using a 10x uncertainty factor to account for intraspecies variability, an RfD of 0.7 mg/kg-day was determined for bromide, which corresponds to a Total Allowable Concentration of 12 mg/L in drinking water and accounts for exposure of the general population to bromide from the diet.

## **PS** 2234 Low-Level Arsenic in Drinking Water and Bladder Cancer Risk: Meta-Analysis Update and Risk Assessment Implications.

J. S. Tsuji<sup>1</sup>, D. D. Alexander<sup>2</sup> and V. Perez<sup>3</sup>. <sup>1</sup>Exponent, Bellevue, WA; <sup>2</sup>Exponent, Boulder, CO; <sup>3</sup>Exponent, Chicago, IL.

A published meta-analysis of relevant case-control and cohort studies was updated with two recent studies to further examine the association between low-level arsenic exposure and bladder cancer risk, and whether meta relative risks (mRR) differed significantly from bladder cancer risks predicted in a 2001 report by the National Research Council (NRC). Cancer risk estimates from NRC (2001), which are based on data from southwestern Taiwan, form the basis of the U.S. Environmental Protection Agency's 2010 proposed cancer slope factor for assessing arsenic cancer risks. Our updated meta-analysis of nine studies improved the precision of the previous estimate (mRR = 1.11; 95% CI: 0.95–1.30), with no significant association observed between low-level arsenic exposure and bladder cancer (1.07; 0.95–1.26; p-heterogeneity = 0.54). RRs for never-smokers in the individual studies and the mRR were consistently below 1.0 (0.83; 0.65–1.06; p-heterogeneity = 0.89). Thus, exposure misclassification/regression to the null cannot explain the lack of a significant positive relationship for never-smokers. The mRR was modestly elevated for ever-smokers, but not significantly, with heterogeneity among studies (1.19; 0.95–1.45; p-heterogeneity = 0.04). To evaluate the independent effect of arsenic in comparison to NRC (2001) risk estimates for the U.S., the mRR for bladder cancer in never-smokers was compared to RRs predicted by NRC (2001) at various water concentrations within the low-level studies and for less than lifetime exposures. The collapsed category mRR for never smokers was 0.82 (0.62–1.10) (using cut-points in individual studies near 50 ppb) and was compared to RRs calculated for non-smokers in the U.S. based on NRC (2001). The 95% CI did not include NRC predicted RRs at 20 or 50 ppb, even for half lifetime exposures (RRs of 1.14 and 1.31, respectively). Results of low-level studies differed significantly from, and were inconsistent with, risks predicted by NRC (2001) for non-smokers including those with less than lifetime exposure.

## **PS** 2235 A Chronic Oral Reference Dose for Hexavalent Chromium.

C. M. Thompson<sup>1</sup>, C. R. Kirman<sup>2</sup>, D. M. Proctor<sup>3</sup>, M. Suh<sup>4</sup>, S. M. Hays<sup>4</sup>, L. C. Haws<sup>5</sup> and M. A. Harris<sup>1</sup>. <sup>1</sup>ToxStrategies, Katy, TX; <sup>2</sup>Summit Toxicology, Orange Village, OH; <sup>3</sup>ToxStrategies, Rancho Santa Margarita, CA; <sup>4</sup>Summit Toxicology, Allenspark, CO; <sup>5</sup>ToxStrategies, Austin, TX.

Intestinal tumors have been observed in mice (but not rats) following chronic exposure to high concentrations of hexavalent chromium [Cr(VI)] in drinking water. Mice (but not rats) also exhibit histological lesions consistent with intestinal wounding, specifically villous blunting and crypt hyperplasia—collectively termed diffuse hyperplasia. Recent mode of action studies support that these tumors were indeed the result of chronic wounding and regenerative hyperplasia to repair the intestinal mucosa. Herein, we develop an oral reference dose (RfD) that is protective of the tumor precursor lesion (diffuse hyperplasia), and therefore is protective of intestinal cancer. A rodent physiologically based pharmacokinetic (PBPK) model was used to predict internal dose measures for chromium in the duodenum, jejunum, and ileum of mice under the conditions of the 2-year bioassay. These internal dose metrics together with corresponding incidences for diffuse hyperplasia in each intestinal segment were used to characterize the dose-response relationship for the small intestine in a single plot containing a robust dataset with as many as 24 data points. Points of departure (PODs) were derived using benchmark dose modeling and global nonlinear regression, with models providing acceptable fits differing  $< 3$ -fold. Human equivalent lifetime average dose values were estimated for each POD using two different methods of extrapolation with the human PBPK model for chromium. Dividing the PODs by uncertainty factors (UFs) of 10-30 yields a range of 8 RfD values (2 modeling approaches  $\times$  2 human equivalent dose methods  $\times$  2 UF values). The resulting RfD range is protective against diffuse hyperplasia, and is therefore protective of both noncancer and cancer effects in the small intestine. This range of RfD values leads to acceptable Cr(VI) concentrations in drinking water that are greater than those typically found in drinking water sources ( $\leq 5$   $\mu$ g/L).

## **PS** 2236 Mode-of-Action Evaluation for Hexavalent Chromium-Induced Lung Cancer.

D. M. Proctor<sup>1</sup>, M. Suh<sup>1</sup>, C. M. Thompson<sup>2</sup> and M. A. Harris<sup>2</sup>. <sup>1</sup>ToxStrategies, Rancho Santa Margarita, CA; <sup>2</sup>ToxStrategies, Katy, TX.

Inhalation of hexavalent chromium [Cr(VI)] has been associated with increased lung cancer risk among workers of certain industries, but no well recognized or published mode of action (MOA) exists. Although it has been suggested that

Cr(VI) acts by a mutagenic MOA because it damages DNA in vitro and in some in vivo tests, several recent reviews have concluded that Cr(VI) is only weakly mutagenic and that genetic/epigenetic changes resulting in genomic and/or microsatellite instability, inflammation, oxidative stress and deregulation of repair mechanisms play a role in carcinogenicity. Further, recent data for mouse small intestinal cancers caused by Cr(VI) in drinking water support a cytotoxic MOA involving chronic intestinal wound and healing. Using the modified Hill Criteria, we have reviewed kinetic, human, animal, and mechanistic data to develop a lung cancer MOA; evaluated plausibility, dose-response, and temporal concordance; and considered alternative MOAs. Among workers with an observed increase in lung cancer, respiratory tissue irritation and inflammation were common clinical findings, and in animal studies irritation and inflammation precede tumor formation in dose ( $\geq 50$   $\mu\text{g}/\text{m}^3$ ) and time (within 30 days), suggesting that cytotoxicity and inflammation are early key events. The overall evidence supports that Cr(VI) induces lung cancer by a non-mutagenic MOA involving oxidative stress, cytotoxicity, and inflammation, causing oxidative DNA damage, epigenetic DNA modifications and genomic instability, occurring at the high exposure concentrations. Further, extracellular Cr(VI) reduction in the lung limits absorption and may introduce non-linearity in the extrapolation of tissue dose from high to low exposures. Based on these findings, the risk assessment for inhalation exposure to Cr(VI) should consider intensity-based dose metrics and non-linear low dose extrapolation approaches.

**PS 2237 A Screening Level Assessment of the Health and Environmental Hazards of Organohalogen Flame Retardants.**

D. A. Eastmond, V. S. Bhat and K. Capsel. *Environmental Toxicology Graduate Program, University of California, Riverside, CA.*

Organohalogen flame retardants are extensively used in both industrial and consumer products. However, relatively little is known about the potential of many of these chemicals to cause adverse health and environmental effects. To address this, we conducted a health and environmental hazard screening of almost 100 brominated or chlorinated flame retardants based on the GreenScreen® or Quick Chemical Assessment Tool (QCAT®) methodologies. Priority consideration was given to human health hazards such as carcinogenicity (including mutagenicity and genetic toxicity), reproductive or developmental toxicity, endocrine disruption, and acute mammalian toxicity. Environmental hazards given priority consideration included acute aquatic toxicity, persistence, and bioaccumulation. Using publicly available information, each hazard category was assigned a concern level (low, moderate, high, or very high) based on pre-defined numerical ranges, such as no-observed adverse effect levels, and hazard classification schemes from authoritative sources, when available. Less than 10% of the screened chemicals had empirical data to assess each priority hazard category. Where empirical data were not identified, structure activity relationship (SAR) models were relied upon to predict hazard potential. After assigning concern levels for each priority health effect, each chemical received a score, similar to a report card (A, B, C, D, or F). The majority of the screened chemicals received either a D or F grade due to empirical data suggesting high hazard, SAR model predictions, and/or excessive data gaps. Carcinogenicity was the most prominent potential health hazard identified based on empirical data. The most prevalent data gap was endocrine disruption due to the lack of identified empirical data or computer models able to predict this hazard. This study highlights the limited toxicity information available for these widely used chemicals, and indicates that more testing and oversight is critically needed to identify safer alternatives for fire prevention.

**PS 2238 Air Quality and Human Health Risks Along the Texas Gulf Coast.**

T. Bredfeldt and D. McCant. *Toxicology, Texas Commission On Environmental Quality, Austin, TX.*

There are several urban and industrial regions along the Texas Gulf Coast that house some of the largest ports in the US, numerous refineries, thousands of chemical/petrochemical facilities and manufacturing plants. Given its dense population and industrial activity, monitoring and regulation of air quality in these regions is critical for protection of human health. The TCEQ has developed the largest ambient air monitoring network in the US to measure cumulative emissions in the area. In the coastal regions alone, there are more than 47 fixed-site air monitors (17 AutoGCs and 30 canisters), some of which have been operational for 20 years. Acrolein, benzene, 1,3-butadiene, and formaldehyde are considered air toxics of greatest concern. To evaluate risks associated with these air toxics, we collected site-specific concentrations of these four chemicals and evaluated them from both an acute and chronic health perspective by comparing them to TCEQ health-protective values called ambient air monitoring comparison values (AMCVs). We calculated average annual concentrations measured by 1-h AutoGC or 24-h canister and

found that concentrations of these air toxics have steadily declined. Using long-term average concentrations of these air toxics, we calculated long-term risks to be within our acceptable risk goal ( $< 1 \text{ E-5}$ ) or a hazard quotient ( $< 1$ ) for the majority of monitoring sites. The long-term average benzene concentration at Lynchburg Ferry and Huisache monitors reached concentrations that resulted in risk (1.8 and 1.1 E-5, respectively) slightly above our risk goal. To better understand dynamics of air toxics at sites with a history of exceeding the long-term AMCV, we used 1-h AutoGC data to characterize ambient conditions contributing to exceedances. We found exceedances of the respective acute AMCVs to be rare. Instead, a few ( $< 30\%$ ) hourly concentrations influenced the average concentration thereby causing long-term exceedances. The decline in air toxics concentrations due to improved monitoring and regulations has now resulted in air toxics at acceptable levels at all monitors in the coastal region.

**PS 2239 Assessment of Potential Perchlorate Exposures from the Use of Household Chlorine Bleach.**

T. Lewandowski<sup>1,2</sup>. <sup>1</sup>*Gradient, Seattle, WA;* <sup>2</sup>*Health and Nutrition Sciences, Brooklyn College/City University of New York, Brooklyn, NY.*

US Government surveys have indicated that perchlorate ( $\text{ClO}_4$ ) occurs at low levels (generally below 4  $\mu\text{g}/\text{L}$ ) in many U.S. public water supplies systems. Although small amounts of perchlorate in water may be due to natural processes, the higher concentrations of perchlorate found in some drinking water supplies (up to 100  $\mu\text{g}/\text{L}$ ) are believed to be the result of past use of  $\text{ClO}_4$  in aeronautics, explosives and/or fireworks, which subsequently affected nearby water bodies or watersheds. The potential health consequences of exposure to low concentrations of  $\text{ClO}_4$  in drinking water remain controversial, with disputed epidemiology findings and questions about the relevance of animal study data to humans. Because a small amount of  $\text{ClO}_4$  is produced by the normal decomposition of chlorate in household chlorine bleach, we examined whether the use of bleach under various scenarios could lead to exposures associated with possible health effects. We considered bleach of different ages and different label strengths and used a temperature- and time-sensitive model to estimate the decomposition of chlorate to  $\text{ClO}_4$ . Predicted  $\text{ClO}_4$  concentrations in bleach ranged from 1 to 34  $\text{mg}/\text{L}$ . The exposure scenarios considered addressed the use of bleach for household laundry, emergency water decontamination, "shock treatment" of private drinking water wells, and regular treatment of water in private swimming pools. In each case, our analysis indicated that potential exposures to  $\text{ClO}_4$  from the use of chlorine bleach would be well below levels associated with potential health effects. For example, the maximum  $\text{ClO}_4$  exposure of a pregnant woman drinking water sanitized with chlorine bleach in an emergency decontamination situation was estimated at 0.2  $\mu\text{g}/\text{kg}\cdot\text{day}$ , 35 times less than the dose associated with minimal effects on iodide uptake in humans. Thus the presence of  $\text{ClO}_4$  as a decomposition product in household bleach does not pose an adverse health risk for consumers.

**PS 2240 Derivation of a Reference Dose for Resorcinol.**

B. H. Magee. *Risk Assessment, ARCADIS, Chelmsford, MA.*

Resorcinol is a common chemical used in industry. US EPA has no final or provisional toxicological criteria for resorcinol. In 2004, a critical analysis of the toxicological database was performed with the purpose of deriving a scientifically reasonable Reference Dose (RfD). Key studies, critical effect(s) and associated doses (No Observed Adverse Effect Levels (NOAELs) and/or Lowest Observed Adverse Effect Levels (LOAELs) are identified and adjusted using uncertainty factors (UFs) to determine an oral RfD.

The analysis of available information from epidemiological studies and animal studies at the time established the one-generational dose range finding study conducted by WIL Research Laboratories (WIL, 2003) and sponsored by the Resorcinol Task Force (RTF) as the definitive study from which to derive the RfD. It identified thyroid toxicity as the critical effect of resorcinol exposure and 61  $\text{mg}/\text{kg}\cdot\text{day}$  as the NOAEL. The derived RfD was 2  $\text{mg}/\text{kg}\cdot\text{day}$ . The RfD was endorsed and approved by a Toxicology Excellence for Risk Assessment (TERA) Independent Peer Review Panel and approved by the Pennsylvania Department of Environmental Protection's (PaDEP's) Cleanup Standards Science Advisory Board ("CSSAB") in 2004.

Soon after that time, a full two-generational reproductive toxicity study was completed (WIL, 2005) and published (Welsch et al., 2008). The NOAEL from this definitive study for the same critical effect was 375  $\text{mg}/\text{kg}\cdot\text{day}$ , and the corresponding RfD is 13  $\text{mg}/\text{kg}\cdot\text{day}$  using the WIL (2005) results, thus indicating that the RfD of 2  $\text{mg}/\text{kg}\cdot\text{day}$  endorsed by the TERA Panel and approved by PaDEP in 2004 was health-protective.

Meanwhile, other regulatory regimes, such as REACH have focused on a more limited list of critical effects in order to derive the relevant Derived No Effect Levels (DNELs) for the development of Chemical Safety Assessments. This can lead to

outcomes which differ from those outlined above and are often even more conservative. This paper explores the background to these divergences and highlights that the context under which an RfD or DNEL is developed has a significant bearing on the final determination made.

**PS 2241 Risk Estimates for Dioxins, Furans, and PCBs in Edible Fish and Shellfish at the San Jacinto River Waste Pits, Texas, USA.**

E. S. Williams, S. Usenko and B. W. Brooks. *Environmental Science, Baylor University, Waco, TX.*

From the 1960s to the early 1980s, paper process wastes were disposed of at a pits site on the San Jacinto River. Eventually the pits subsided into the river, spreading polychlorinated dioxins, furans, and biphenyls into the adjacent aquatic ecosystem. Consumption advisories have been in place for local fish and shellfish since 1990. The San Jacinto River Waste Pits site was identified during a Total Maximum Daily Loads process, and was added to the National Priorities List in 2008. Previous efforts to characterize bioaccumulation of chlorinated compounds on the site included sampling of sediment and thirteen species of fish and shellfish. During the sampling period, numerous persons were observed fishing on or near the site. Important fish and shellfish consumed from the area appear to be clams (*Mercenaria* spp.), blue crabs (*Callinectes sapidus*), and black drum (*Pogonias cromis*). Mean TCDD concentrations in clams, crabs, and fish from the site were 28, 3.6, and 2.25 pg/g wet weight, respectively. TCDF was the only other dioxin/furan congener detected, but ten dioxin-like PCBs were observed in these samples. Excess lifetime cancer risk estimates posed by consumption of contaminated fish and shellfish were calculated using default exposure parameters; risk estimates for reasonable maximum exposures ranged from  $1.2 \times 10^{-5}$  to  $1.51 \times 10^{-4}$ . Risks in excess of  $10^{-4}$  under these parameters are associated only with consumption of clams from the site, and lower exposure frequency would be expected. Considerations of spatial sampling sufficiency, multiple exposure scenarios, associated risk estimates, and analysis of uncertainty will be presented.

**PS 2242 Evaluation of the Glyphosate Developmental Toxicity Database: Absence of Potential for Cardiovascular Malformations.**

A. Williams, G. Kimmel, C. Kimmel and J. DeSesso. *Exponent, Alexandria, VA.*

The herbicide glyphosate has undergone multiple safety tests for developmental toxicity in rats and rabbits. The European Commission's 2002 review of available glyphosate data (European Commission, 2002; BBA, 1998-2000) discusses, in particular, specific heart defects observed in individual rabbit developmental toxicity studies, but describes the evidence for a potential causal relationship as equivocal. The present assessment was undertaken to analyze the body of information generated from the seven unpublished rabbit studies submitted to European regulatory agencies in order to determine if glyphosate poses a risk for cardiovascular malformations. In addition, the results of six unpublished developmental toxicity studies in rats were considered. Five of the seven rabbit studies (dose range: 10-500 mg/kg/day) were GLP- and testing guideline-compliant for the era in which the studies were performed; a sixth study predated testing and GLP guidelines, but generally adhered to these principles. The seventh study was judged inadequate. In each of the adequate studies, offspring effects occurred at or above doses that caused maternal toxicity. An integrated evaluation of the six adequate studies, using conservative assumptions, demonstrated that neither the overall malformation rate nor the incidence of cardiovascular malformations increased with dose up to the point where severe maternal toxicity was observed (generally  $\geq 150$  mg/kg/day). Random occurrences of cardiovascular malformations were observed across all dose groups (including controls) and did not exhibit a dose-response relationship. In the six rat studies (GLP and testing guideline compliant; dose range: 30-3500 mg/kg/day), a low incidence of sporadic cardiovascular malformations was reported that was clearly not related to treatment. In summary, assessment of the entire body of the developmental toxicity data reviewed fails to support a potential risk for increased cardiovascular defects as a result of glyphosate exposure during pregnancy.

**PS 2243 Oral Risk Assessment for Isooctane—A Class-Based Approach Using the Surrogate n-Hexane.**

B. Wang<sup>1</sup>, P. Undesser<sup>2</sup> and M. Whittaker<sup>1</sup>. <sup>1</sup>ToxServices LLC, Washington DC; <sup>2</sup>Water Quality Association, Lisle, IL.

Isooctane is a volatile liquid commonly found in gasoline. It is principally released into the environment via the manufacture, use and disposal of products associated with the petroleum industry. Although the most likely route of human exposure to

this chemical is through inhalation, products such as polyethylene pipes used for distribution of drinking water can release it in water, and it has high oral absorption. NSF/ANSI 61 Annex A (2012) risk assessment guideline was used to determine an acceptable level of isooctane in drinking water. Weight of evidence indicates that isooctane is not mutagenic or carcinogenic. All the available repeated dose oral studies are short term in nature and the majority was designed to address the  $\alpha 2u$ -globulin-associated renal toxicity, which is specific to male rats and not relevant to humans. Thus, insufficient data are available to establish an oral reference dose (RfD) for isooctane. Since isooctane is categorized into the aliphatic EC5 (equivalent carbon) to EC8 fraction of petroleum hydrocarbons, a class based approach was taken. Most of the limited oral studies available for the chemicals in this fraction were performed on n-hexane. Relevant critical health effects with n-hexane exposure are peripheral neuropathy, reduced body weight and testicular atrophy. Many groups and agencies used n-hexane as a representative of this fraction, which is known to significantly overestimate the toxicity of these chemicals, and different RfD values were derived for n-hexane using different approaches. After comparing these assessments, we chose to use the most conservative, duration-adjusted lowest observed adverse effect level of 407 mg/kg/day established from a subchronic gavage study in rats, and a composite uncertainty factor of 3000 to calculate the RfD of 0.12 mg/kg/day for isooctane. Based on this value, a total allowable concentration of 840  $\mu\text{g/L}$  was derived. This drinking water action level is protective of public health since it used the more toxic n-hexane to fill the data gap, and it has a margin of exposure of over 15,000.

**PS 2244 Deriving Dermal Safe Harbor Levels for DEHP Relevant to Consumer Products for Adults.**

T. Jonaitis, J. W. Card and L. Haighton. *Intertek Cantox, Mississauga, ON, Canada.*

Di(2-ethylhexyl)phthalate (DEHP), a plasticizer in various consumer products, is listed as a chemical known to the State of California to cause cancer and reproductive toxicity. The Proposition 65 Safe Harbor Levels (SHL) for DEHP include a Maximum Allowable Dose Level (MADL) for DEHP, specific to the oral route, of 410  $\mu\text{g/day}$  for adults (58  $\mu\text{g/day}$  for infant boys; 20  $\mu\text{g/day}$  for neonatal boys). The No Significant Risk Level (NSRL) for cancer of 310  $\mu\text{g/day}$ , while not route-specific, was based on an oral study. While DEHP in children's toys is of concern due to mouthing behavior, most 60-day notices of violation for DEHP are related to consumer products intended for adults. Thus, there is a need for realistic, dermal-specific SHLs and accurate calculations of exposure. From studies on dermal absorption of DEHP from plastic film (present at 25.5 mg/cm<sup>2</sup> of film, or 40.37% w/w) applied to the skin of rats (used as a conservative estimate of migration of DEHP from a product into the human body since rats have a higher dermal absorption than humans), a maximum dermal absorption of 0.1% was determined. Comparatively, the reported oral bioavailability of DEHP is 25%. Using these values, the dermal MADL would correspond to 102,500  $\mu\text{g/day}$  for adults (410  $\mu\text{g/day} \times 0.25$  oral absorption fraction/0.001 dermal absorption) and the dermal NSRL would be 77,500  $\mu\text{g/day}$ . From the same study, a dermal absorption rate of DEHP from the plastic was calculated to be approximately 0.24  $\mu\text{g/cm}^2/\text{hour}$  for the rat which corresponds to 0.016  $\mu\text{g/cm}^2/\text{hour}$  for humans, given observed species differences. This value can be used to calculate dermal exposures with correction for differing concentrations. Also, a migration rate of 1.4  $\mu\text{g/cm}^2/\text{hour}$  can be used to determine the DEHP skin loading for estimating transfer of DEHP from a consumer product onto the hands, and then directly and indirectly to the mouth for comparison to the oral SHLs. In summary, route-specific SHLs are considered useful for realistically estimating risks associated with exposure of adults to DEHP from consumer products.

**PS 2245 Microfluidic Steroidogenesis Assays for *In Vitro* Toxicant Screening.**

A. B. Theberge<sup>1,2,3</sup>, E. Berthier<sup>4</sup>, C. J. Hedman<sup>5</sup>, B. P. Casavant<sup>2</sup>, N. P. Keller<sup>1,4</sup>, W. A. Bushman<sup>1,3</sup> and D. J. Beebe<sup>1,2</sup>. <sup>1</sup>Molecular and Environmental Toxicology, University of Wisconsin-Madison, Madison, WI; <sup>2</sup>Biomedical Engineering, University of Wisconsin-Madison, Madison, WI; <sup>3</sup>Urology, University of Wisconsin-Madison, Madison, WI; <sup>4</sup>Medical Microbiology and Immunology, University of Wisconsin-Madison, Madison, WI; <sup>5</sup>Institute for Clinical and Translational Research, University of Wisconsin-Madison, Madison, WI. Sponsor: C. Bradfield.

Many endocrine disrupting compounds act by interrupting steroidogenesis, thus disrupting subsequent processes that rely on steroids for signaling such as hormone-mediated pathways crucial for development. High-throughput in vitro assays are required to identify such compounds efficiently. Liquid chromatography-mass spectrometry (LC-MS) is a gold standard technique for steroid characterization and quantification, but traditional methods for steroid extraction with organic solvents, typically used to remove matrix components prior to LC-MS, require many manual

steps, thus presenting a bottleneck for steroid analysis. To expedite steroid extraction, we developed an integrated microfluidic device consisting of a bottom channel for cell culture and a top channel in which steroids are extracted directly from culture media into organic solvent. The top channel is accessible with a pipette or robot liquid handler, which can be used to transfer the sample to an LC-MS autosampler for analysis. We extracted cortisol solutions of known concentration to demonstrate consistent extraction over a range of biologically relevant concentrations spanning two orders of magnitude. We validated this microfluidic system with the human adrenocortical cell line H295A, demonstrating that these cells produce steroids in microculture and respond to cAMP, a known stimulant of steroidogenesis. Microfluidic extraction was used to isolate a panel of steroids including cortisol, cortisone, 11-deoxycortisol, and testosterone, which were quantified using LC-MS. In addition to high-throughput toxicant screening, the microfluidic platform holds great potential for steroidogenesis assays with limited samples, such as primary cells. Funded by NIH T32ES007015.

**PS 2246 An Improved *In Vitro* Method for Determining Chemical Effects on Steroidogenesis Using LC/MS/MS to Monitor Multiple Steroid Hormones Combined with Gene Expression.**

C. M. Toole<sup>1</sup>, H. Wagner<sup>1</sup>, K. Lewis<sup>2</sup> and J. M. McKim<sup>1</sup>. <sup>1</sup>*CeeTox, Inc., Kalamazoo, MI*; <sup>2</sup>*OpAns, LLC, Durham, NC*.

Steroid hormones play vital roles in development. Environmental compounds can impact the steroidogenic pathway producing a wide range of effects. Quantifying multiple steroids from a single biological sample, coupled with gene expression of the enzymes that form them, allows for a better evaluation of these effects. The human adrenal H295R cell line is currently used by the Environmental Protection Agency (EPA) to screen for chemical effects on steroidogenesis by evaluating production of Estradiol (E2) and Testosterone. Following EPA guidelines, 22(R)-hydroxycholesterol (22RHC) can be added (20–40  $\mu$ M) to the culture medium to increase basal production of E2. Addition of 22RHC to the H295R culture medium bypasses steroidogenic acute regulatory protein (StAR). To evaluate the induction mechanism of 22RHC, H295R exposures were conducted using both 22RHC and forskolin, a known inducer of steroidogenesis. 22RHC and forskolin were administered to cells at 0.4, 1, 4, 10, 20 and 40  $\mu$ M and 0.03, 0.2, 0.3, 1, 3 and 10  $\mu$ M, respectively for 48 hr. RT-PCR was used to quantitate the expression of 9 steroidogenic genes and LC/MS/MS was used to measure hormone levels of 12 steroids. Forskolin was found to upregulate mRNA of CYP11B2, HSD3B2, CYP21A2, CYP17A1, CYP19A1 in a dose-dependent manner. StAR mRNA was also increased at the highest exposure concentration. No significant upregulation of mRNA was observed in the 22RHC-exposed cells within the solubility limit. Steroid levels from LC/MS/MS displayed first and zero order enzyme kinetics. LC/MS/MS results showed that 22RHC exposures significantly increased early event markers (e.g., progesterone, pregnenolone, DOC, and 11 DOC), whereas forskolin exposures resulted in higher levels of most steroids. These results demonstrate that steroid genes are not regulated by a positive feedback loop in 22RHC exposed cells. This study shows that evaluation of multiple steroid levels combined with gene expression provides a more complete picture of steroidogenesis.

**PS 2247 Mapping Pathways of Endocrine Disruption in MCF-7 Cells: 2D and 3D Culture Systems.**

M. M. Vantangoli, S. Hall and K. Boekelheide. *Brown University, Providence, RI*.

It is becoming increasingly important to identify endocrine-active compounds early in toxicity testing, placing weight on the use of in-vitro screening. Currently, the pathways of endocrine disruption are being mapped in response to estrogenic compounds. In this study, human breast adenocarcinoma MCF-7 cells are being utilized to map pathways of endocrine disruption following exposure to estrogenic endocrine-active compounds. Our study utilizes two models, a 2-dimensional system representative of classical in-vitro studies, and a scaffold-free 3D culture system. Both systems follow a protocol that includes 72 hours of growth in media containing 10% FBS for 72 hours, followed by 48 hours in media containing 5% stripped serum. Treatments with compounds of interest begin following the 48 hours. Preliminary data shows that our 2D system is responsive to estrogenic compounds including estradiol, DES and BPA across several endpoints, including cell proliferation and protein expression. Over a range of concentrations of estradiol (0.01nM–100nM) and times (1, 3, 6, and 12 hours) analysis of gene expression showed increases in classical estrogen responsive genes including progesterone receptor (1.5–3.5 fold), cathepsin D (1.5–2 fold), estrogen-inducible pS2 (1.5–4 fold) and GREB1 (4–14 fold) at concentrations as low as 0.01nM estradiol. These results were also shown by Western blotting, with time-dependent increases in pS2 and

GPR30 following estradiol stimulation. Our 3D system exhibits cell-contacts and morphology that may play an important role in evaluating toxicities of estrogenic endocrine-active compounds. Here, we show the potential use of both 2D and 3D culture of MCF-7 cells to assess the estrogenic activities of suspected endocrine-active compounds.

**PS 2248 Cell-Specific Control of Estrogen Response Mechanisms in HeLa-9903 and T47D-KBluc Cell Lines.**

D. Blakeman, B. Meyer, A. Hulett, J. M. McKim and C. M. Toole. *CeeTox, Inc., Kalamazoo, MI*.

Estrogen signaling can be adversely affected by endocrine disrupting chemicals via agonism or antagonism. Cell lines capable of detecting agonism and antagonism are useful screening tools for determining estrogenic activity of chemicals. Transcriptional effects of the Estrogen Receptor (ER) are modulated by interactions with coregulatory proteins that function as either coactivators (agonism) or corepressors (antagonism). Selective ER modulators (SERMs), such as tamoxifen, favor recruitment of corepressors that inhibit transcriptional activity. In different tissues, tamoxifen can have partial-agonist-antagonist activities which may be related in part to the milieu of ER coactivators and corepressors in these tissues. To further elucidate effects of SERMs on transcriptional activity, agonism and antagonism was evaluated using reporter gene assays in two cell types, hER $\alpha$ -HeLa-9903, derived from a human cervical tumor, and T47D-KBluc, stably transfected breast cancer cells. Cells were acclimated in 96-well plates and exposed for 24 hr to tamoxifen (TAM), 4-OH tamoxifen (4HTAM), raloxifen (RALOX), estradiol (E2), dihydrotestosterone (DHT), corticosterone (CORT), or 17-methyltestosterone (MT). Cytotoxicity, luminescence, and solubility were measured. An agonist response was demonstrated for TAM, RALOX and 4HTAM in hER $\alpha$ -HeLa-9903 cells, but not T47D-KBluc. Antagonism also showed distinct results for the two cell types where T47D-KBluc cells demonstrated a potential additive effect with 4-HTAM and the maximal response was 4-fold higher than E2. RALOX and TAM also demonstrated enhanced responses in hER $\alpha$ -HeLa-9903 cells. Because T47D-KBluc cells have endogenous ER $\alpha$  and ER $\beta$ , and hER $\alpha$ -HeLa-9903 cells have exogenous ER $\alpha$ , coupled with the fact that corepressors and activators may be different in breast and cervical tissues, the resulting mechanisms controlling agonism and antagonism may be regulated, at least partially, by separate and distinct gene signaling mechanisms. These findings show that measuring estrogenic activity in two cell lines may provide a more accurate assessment of estrogen response.

**PS 2249 Profiling of ER $\alpha$ -Coregulator Binding As a Means for Functional Classification of Unknown Endocrine Disruptors.**

R. Houtman<sup>1</sup>, S. Wang<sup>2,3</sup>, J. M. Aarts<sup>2,3</sup>, W. Westerink<sup>4</sup>, B. J. Blaauboer<sup>5</sup>, T. Bovee<sup>2</sup> and R. van Beuningen<sup>1</sup>. <sup>1</sup>*PamGene International BV, Den Bosch, Netherlands*; <sup>2</sup>*RIKILT-Institute of Food Safety, Wageningen UR, Wageningen, Netherlands*; <sup>3</sup>*Division of Toxicology, Wageningen UR, Wageningen, Netherlands*; <sup>4</sup>*Wil Research, Den Bosch, Netherlands*; <sup>5</sup>*Division of Toxicology, Institute for Risk Assessment Sciences, Utrecht, Netherlands*.

Testing chemicals for their endocrine-disrupting potential, e.g. interference with estrogen receptor alpha (ER $\alpha$ ) signaling, is an important aspect of chemical safety profiling. Due to drawbacks of in vivo testing, the development of in vitro alternatives has a high priority. In a previous study, we have demonstrated an in vitro assay which profiles binding of (un)liganded nuclear receptors to a microarray of coregulator-derived peptides, as a good candidate. Here, a set of 13 model compounds, US-EPA recommended for ER $\alpha$  gene reporter assay proficiency testing, was used to assess reproducibility, robustness and added value of our assay. ER $\alpha$ -coregulator binding profiles in the presence of a concentration series of each compound were generated. With a median coefficient of variation of 5% and excellent correlation ( $R^2=0.99$ ) between duplicate measurements, the uncertainty level of the peptide microarray was well within the range observed for other commonly used in vitro ER functional assays. Per compound, a dose-response curve for each ER $\alpha$ -coregulator interaction was constructed. Our results show correct prediction of estrogenicity for 12 out of 13 tested compounds. The potency ranking for 9 out of the 10 ER-agonists exactly matched that for transcriptional activation as reported by ICCVAM and US-NIEHS with excellent correlation ( $R^2=0.98$ ). Moreover, unsupervised classification (Hierarchical clustering, Euclidean distance, average linkage) with the compound-characteristic ER $\alpha$ -coregulator binding profiles results in structurally related compounds to cluster together, whereas the steroid test compounds having an aromatic A-ring were separated from those with a cyclohexene A-ring. This latter feature should be exploited to build a prediction model to enable classification of unknown toxicants by comparison with pre-profiled references.

**PS 2250 Validation of the Yeast Estrogen and Yeast Androgen Screens for Endocrine Active Substances: Interlaboratory Ring Trial.**

C. Woitkowiak<sup>1</sup>, T. Ramirez<sup>1</sup>, H. Hüner<sup>1</sup>, C. Schönlau<sup>2</sup>, H. Hollert<sup>2</sup>, S. Broschke<sup>3</sup>, O. Zierau<sup>3</sup>, G. Vollmer<sup>3</sup>, M. Jäger<sup>4</sup>, A. Poth<sup>4</sup>, E. Higley<sup>5</sup>, M. Hecker<sup>5</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>RWTH, University of Aachen, Aachen, Germany; <sup>3</sup>Technical University Dresden, Dresden, Germany; <sup>4</sup>Harlan Cytotest Cell Research GmbH, Roßdorf, Germany; <sup>5</sup>University of Saskatchewan, Saskatoon, SK, Canada.

Endocrine disruptor compounds (EDCs) are a group of natural or synthetic compounds that have the capacity to interact with the endocrine system of living organisms and consequently causes adverse health effects in an intact organism, or its progeny, or (sub)populations. Due to the impact that this interaction could have on human health, there is an increasing interest in assessing the risk of the exposure to EDCs. Currently, several *in vitro* and *in vivo* assays have been developed and few of them validated and regulatory accepted. For instance, the US EPA developed the Endocrine Disruptor Screening Program, which has been recently implemented. For the program a large number of experimental animals will be still use used even for testing some of the *in vitro* assays. Herein, we performed the inter-laboratory validation of two robust models that addresses agonistic and antagonist effect at the human hormone receptor, the YES (Yeast Estrogen Screen) and the YAS (Yeast Androgen Screen). Both assays are non-animal alternatives to the estrogen and androgen receptor binding assays proposed in the EDSP and OECD Conceptual Framework. The ring trial is the final experimental part of the validation process at the European Center for Validation of Alternative Methods (ECVAM). A set of 24 blinded compounds (7 estrogens and 6 androgens of diverse potency, 3 anti-estrogens, 3 anti-androgens and 5 negative compounds) have been tested in five different laboratories. The analysis of the first phase of this ring-trial already demonstrates a high reproducibility for both methods among the different participating laboratories.

**PS 2251 Comparison of the Manual and Quantitative High-Throughput Versions of the BG1Luc Estrogen Receptor Transactivation Test Method.**

P. Ceger<sup>1</sup>, W. Casey<sup>2</sup>, J. Strickland<sup>1</sup>, L. Rinckel<sup>1</sup> and W. Stokes<sup>2</sup>. <sup>1</sup>ILS, Inc., Research Triangle Park, NC; <sup>2</sup>NTP/NICEATM, NIEHS, Research Triangle Park, NC.

NICEATM conducted an international validation study of the BG1Luc estrogen receptor (ER) transactivation (TA) test method. The test method evaluation report was reviewed and the method accepted by U.S. regulatory agencies and the Organisation for Economic Co-operation and Development. In 2011, NICEATM nominated the BG1Luc ER TA to Tox21 to be evaluated for adaptation into a quantitative high throughput screening (qHTS) assay. The Tox21 collaboration, an effort by the National Toxicology Program, NIH Chemical Genomics Center, Environmental Protection Agency, and Food and Drug Administration, was formed to advance toxicity testing by shifting from traditional *in vivo* tests to *in vitro* methods. A major goal of Tox21 is to prioritize chemicals for in-depth toxicity testing. One method for prioritization is the use of qHTS assays using cell- and biochemical-based assays to construct concentration-response curves for thousands of chemicals. The Tox21 consortium adapted the BG1Luc ER TA manual method to a qHTS format, making it the first assay validated for regulatory use to be adapted to Tox21. Data from qHTS assays have been generated for approximately 10,000 chemicals in both the agonist and antagonist versions of the qHTS assay. Seventy-six chemicals had been tested in both the manual and qHTS methods. Data from both methods were used to evaluate the degree to which classifications of test chemicals in the BG1 manual and qHTS methods matched reference classifications (accuracy) and the degree to which chemical classifications were identical between the two methods (concordance). Except for a few discrepancies attributable to different test concentrations used in the two methods, the BG1Luc ER TA manual and qHTS methods produced almost identical results in terms of accuracy, with a high degree of concordance. Supported by ILS staff under NIEHS contract N01-ES-35504.

**PS 2252 Reconstructed Vaginal-Ectocervical and Endocervical Tissue Models for HSV-2, Chlamydia, and Gonorrhea Infections.**

T. Landry<sup>1</sup>, K. LaRosa<sup>1</sup>, J. Pudney<sup>2</sup>, R. Ingalls<sup>2</sup>, D. Anderson<sup>2</sup>, P. Hayden<sup>1</sup>, M. Klausner<sup>1</sup> and S. Aychunie<sup>1</sup>. <sup>1</sup>MatTek Corporation, Ashland, MA; <sup>2</sup>Boston Medical School, Boston, MA.

Despite extensive efforts, limited success has been achieved in developing tissue models for sexually transmitted infections (STIs) such as herpes simplex virus 2 (HSV-2), Chlamydia trachomatis (Ct), and Neisseria gonorrhea (Ng). We devel-

oped highly differentiated, normal human 3-dimensional (NHu-3D) vaginal-ectocervical (EpiVaginal™) and endocervical tissues models for STI infections. Immunohistochemistry and quantitative real time PCR were used to characterize the ectocervical tissues to monitor HSV-2 infection. Infection of the endocervical tissue model by the infectious elementary body (EB) of Ct was assessed by quantitative cultures. ELISA assays were used to quantify TNF- $\alpha$  release in response to Ng and Toll-Like Receptor (TLR) ligands. Results showed that the EpiVaginal tissue expresses nectin-1, a receptor for HSV-2, and infection experiments showed that the tissue model was infectable with HSV-2. Similar to the *in vivo* situation, infection of the vaginal-ectocervical tissue model with HSV-2 caused a separation of the epithelium from the lamina propria layer ("blister formation"). The results were confirmed by DNA PCR. The data from Ct infected endocervical tissues showed a cyclic level of EBs which were: 1) present at 12 hrs, representing bacteria that failed to be taken up by the cells, 2) not detectable at 24 hrs, all intracellular EBs might have been converted to the replicative reticular bodies (RB) and are therefore are not cultivatable, and 3) present at 40 hr, RBs have been converted back to EBs completing the first cycle. Furthermore, the reconstructed endocervical tissues respond to Ng infection and TLR ligands by secreting TNF- $\alpha$  into the culture medium. In conclusion, new *in vitro* reconstructed ectocervical and endocervical tissue models have been developed for HSV-2, Ct, and Ng infections. The models can be used to study the safety and efficacy of candidate therapeutics aimed at preventing or neutralizing HSV-2, Chlamydia, or gonorrhea infections.

**PS 2253 Combining Pathway-Based *In Vitro* Assays to Prioritize 1848 Environmental Chemicals for Estrogenic Potential.**

D. Rotroff<sup>1,2</sup>, D. Reif<sup>1</sup>, N. S. Sipes<sup>1</sup>, T. B. Knudsen<sup>1</sup>, P. Kothia<sup>1</sup>, M. Martin<sup>1</sup>, K. Houck<sup>1</sup> and R. Judson<sup>1</sup>. <sup>1</sup>NCCT, EPA, Research Triangle Park, NC; <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

There are thousands of environmental chemicals subject to regulatory decisions for endocrine disrupting potential. Due to the resources required to perform traditional toxicity tests, high-throughput screening (HTS) assays have emerged as a viable tool for chemical prioritization. The ToxCast and Tox21 programs have tested 1848 chemicals in a broad screening panel of 19 assays for estrogen receptor (ER) agonist and antagonist activity. These assays screen for ER activity by profiling effects on ligand binding or cellular changes across a diverse array of assay types (e.g. receptor binding, protein complementation, transcriptional activation, and cell growth) and cell types (T47D, BG1, HEK293T, CHO-K1, HeLa). The protein complementation assays were run with and without S9 to determine metabolic potential. Assays were assigned to assay-groups to distinguish ER mechanisms (i.e. agonism, antagonism, metabolic activation/deactivation, ER $\alpha$ /ER $\beta$  activation). Concentration response data for each chemical was normalized to 17 $\beta$ -estradiol, scaled for differences in assay sensitivity, and fit to a Hill model. A composite concentration response curve for each chemical-group combination was created from curve fitting parameters to develop a weight-of-evidence metric for estrogenicity. Composite curve efficacy, potency, and "goodness of fit" were used to rank chemicals and distinguish putative partial agonists from discordant assay results. In a separate analysis, uterotrophic assay results (39 chemicals) were used to characterize composite curve predictivity using logistic regression. Overall, of the original 1848 chemicals 22 were active in at least 13 HTS ER agonist assays, including known ER agonists, 4-nonylphenol, and DES. 347 chemicals were active in at least 3 HTS ER agonist assays, indicating the need for assays measuring multiple biologically plausible ER mechanisms in order to confidently prioritize chemicals for estrogenicity. This abstract does not necessarily reflect Agency policy.

**PS 2254 Identification of Compounds That Activate Aryl Hydrocarbon Receptor Using a qHTS Platform.**

N. R. Miller<sup>1</sup>, R. Huang<sup>1</sup>, K. Houck<sup>2</sup>, M. S. Denison<sup>3</sup> and M. Xia<sup>1</sup>. <sup>1</sup>NCGC, NIH, Rockville, MD; <sup>2</sup>EPA, Research Triangle Park, NC; <sup>3</sup>Environmental Toxicology, University of California, Davis, Davis, CA.

The basic helix-loop-helix perARNT-SIM (bHLH-PAS) superfamily of transcription factors plays an important role in mediating the biological response to endogenous and xenobiotic small molecules. The Aryl hydrocarbon receptor (AhR) is a prominent member of the bHLH-PAS, and is crucial to adaptive responses to environmental changes. AhR mediates cellular responses to environmental pollutants such as aromatic hydrocarbons through induction of phase I and II enzymes but also crosstalks with other nuclear receptor signaling pathways. To identify potential AhR ligands as part of the Tox21 collaboration, we have optimized and miniaturized a cell-based AhR luciferase reporter gene assay in the recombinant human HepG2 cell line HG2L7.5c1 into a 1536-well plate format. We have validated this assay by screening a library of 1280 pharmacologically active compounds (LOPAC) plus 88 Tox21 chemicals in triplicate using a quantitative HTS (qHTS) platform.

From the primary screen, we have identified a group of relatively potent compounds including known AhR agonist indirubin-3'-oxime; CGS-15943, an adenosine receptor antagonist; the cyclin-dependent kinase inhibitor kenpaullone; the amiloride analogue phenamil; and the gastric proton pump inhibitor omeprazole. Validation of the cell-based assay on our integrated robotics system gave a signal to background ratio of 5 and average Z' factors of 0.4, that indicates this assay is suitable for qHTS of the Tox21 10K library. These findings support the utility of a cell-based AhR luciferase assay system for the high-throughput detection of compounds activating the AhR signal transduction pathway. Supported by EPA Interagency Agreement Y3-HG-7026-03.

**PS 2255 Comet and Nucleotide Postlabeling Results in the Chicken Egg Genotoxicity Assay.**

A. M. Jeffrey<sup>1</sup>, U. Deschl<sup>2</sup>, J. Duan<sup>1</sup>, K. D. Brunnemann<sup>1</sup>, E. Vock<sup>2</sup>, M. J. Iatropoulos<sup>1</sup> and G. M. Williams<sup>1</sup>. <sup>1</sup>Department of Pathology, New York Medical College, Valhalla, NY; <sup>2</sup>Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany.

For the chicken egg genotoxicity assay, an *in vitro* alternative model for assessing genotoxicity, we used white leghorn chicken (*Gallus gallus*) egg fetal livers before full development of the nervous system. Injections were made on days 9, 10 and 11, the last 3 hours before termination. Livers were harvested for the COMET assay for DNA strand breaks and nucleotide postlabeling for DNA adducts. To deliver test substances, a variety of vehicles were evaluated, covering the range (from hydrophilic to hydrophobic) of solubility, using the endpoint of viability of the embryo-fetus. The following suitable vehicles were selected, i.e., 50 µl of deionized water, 50 µl of 0.5% aqueous methylcellulose, and 50 µl 20% Solutol HS15 for hydrophilic, amphiphilic, and hydrophobic substances, respectively. Test substances were injected with a 1 ml plastic BD syringe using a 0.4 mm x 13 mm needle. Following the injection into the air sac, the eggs were sealed with paper tape. Test compounds included diethylnitrosamine (hydrophylic) and 2-acetylaminofluorene (hydrophobic). The eggs were incubated and maintained at 37° ± 0.5° C and 60% ± 5% relative humidity. On day 11, the shells of viable eggs were opened at the blunt end, and the allantochorionic membrane was retracted to allow access to the entire anterior (visceral) aspect of the chicken fetus via the yolk sac. Fetal weights, were recorded after removal of the surrounding excess yolk. The abdominal cavity was opened and the entire liver was removed and weighed. Diethylnitrosamine (0.25 - 4.0 mg cumulative dose per egg) and 2-acetylaminofluorene (0.1-0.6 mg) were tested over a dose range and subsequent alkaline COMET assays were conducted on isolated liver cells. Both compounds gave a positive dose response with plateaus occurring at the higher doses. In addition, 2-acetylaminofluorene was positive in the nucleotide postlabeling assay and showed patterns of DNA adducts similar to those previously observed in turkey eggs and rats.

**PS 2256 Development of Hazard Evaluation Support System (HESS) and the Attached Database (HESS DB) for Repeated-Dose Toxicity of Chemical Substances.**

T. Yamada<sup>1</sup>, T. Abe<sup>1</sup>, R. Hasegawa<sup>1</sup>, Y. Sakuratani<sup>1</sup>, J. Yamada<sup>1</sup>, T. Yamashita<sup>2</sup>, Y. Yamazoe<sup>3</sup>, O. Mekenyan<sup>4</sup>, A. Hirose<sup>5</sup> and M. Hayashi<sup>6</sup>. <sup>1</sup>Chemical Management Center, National Institute of Technology and Evaluation, Tokyo, Japan; <sup>2</sup>BioIT Business Development Office, Fujitsu Limited, Chiba, Japan; <sup>3</sup>Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan; <sup>4</sup>Laboratory of Mathematical Chemistry, University "Prof. Assen Zlatarov" Bourgas, Bourgas, Bulgaria; <sup>5</sup>Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan; <sup>6</sup>BioSafety Research Center, Iwata, Japan.

Repeated-dose toxicity (RDT) is one of the key regulatory endpoints in the hazard assessment of chemical substances. The data is nationally and internationally utilized for the chemical management. On the other hand, reduced animal testing is desired for economic and animal welfare reasons. Herein, we developed Hazard Evaluation Support System database (HESS DB). HESS DB is a new toxicity database of RDT studies for about 500 chemicals, most of which have been conducted in accordance with Good Laboratory Practice Principles under Japanese Chemical Substance Control Law. Moreover, the DB includes available reference information on Absorption, Distribution, Metabolism, and Excretion (ADME) and toxicological mechanism for some of those chemicals. It is useful for checking the availability of toxicity test data and for setting the animal test conditions with related information of structural analogs. Additionally, chemicals showing similar histopathological changes can be efficiently searched with the DB. The DB is linked to simultaneously developed Hazard Evaluation Support System (HESS), which is compatible with OECD QSAR Toolbox and has a supportive function to group structural analogs with toxicity data. Combination use of HESS and HESS DB supports to perform category approach to predicting the primary toxicity of

untested chemicals in a transparent and interpretable manner. HESS and HESS DB are freely provided in the website of NITE (<http://www.safe.nite.go.jp/english/kasinn/qsar/hess-e.html>).

**PS 2257 Mitochondrial Bioenergetics and Drug-Induced Toxicity in a Panel of Mouse Embryonic Fibroblasts with Mitochondrial DNA Single Nucleotide Polymorphisms.**

C. V. Pereira<sup>1</sup>, P. J. Oliveira<sup>1</sup>, Y. Will<sup>2</sup> and S. Nadanaciva<sup>2</sup>. <sup>1</sup>CNC- Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal; <sup>2</sup>Pfizer Inc, Groton, CT.

Mitochondrial DNA (mtDNA) variations including single nucleotide polymorphisms (SNPs) have been proposed to be involved in idiosyncratic drug reactions. However, current *in vitro* and *in vivo* models lack the genetic diversity seen in the human population. Our hypothesis is that different cell strains with distinct mtDNA SNPs may have different mitochondrial bioenergetic profiles and may therefore vary in their response to drug-induced toxicity. Therefore, we used an *in vitro* system composed of four strains of mouse embryonic fibroblasts (MEFs) with mtDNA polymorphisms. We sequenced mtDNA from embryonic fibroblasts isolated from four mouse strains, C57BL/6J, MOLF/Eij, CZECHII/Eij and PERA/Eij, with the latter two being sequenced for the first time. The bioenergetic profile of the four strains of MEFs was investigated at both passage 3 and 10. Our results showed that there were clear differences among the four strains of MEFs at both passages, with CZECHII/Eij having a lower mitochondrial robustness when compared to C57BL/6J, followed by MOLF/Eij and PERA/Eij. Seven drugs (nefazodone, ketoconazole, tolcapone, flutamide, tamoxifen, imipramine and troglitazone) known to impair mitochondrial function were tested for their effect on the ATP content of the four strains of MEFs in both glucose- and galactose-containing media. Our results showed that there were strain-dependent differences in the response to some of the drugs. We propose that this model is a useful starting point to study compounds that may cause mitochondrial off-target toxicity in early stages of drug development, thus decreasing the number of experimental animals used.

**PS 2258 Assessment of Drug-Induced Inhibition of Fatty Acid Oxidation in Intact Cells.**

S. Nadanaciva, L. Qiu and Y. Will. Pfizer Inc, Groton, CT.

Fatty acid oxidation in mitochondria is an important metabolic pathway for energy generation in the heart and in organs such as the liver and muscle during fasting. Drug-induced inhibition of fatty acid oxidation in the liver can lead to microvesicular steatosis or macrovesicular steatosis and eventually to liver failure. Moreover, since the liver is the supplier of energy in the form of glucose (via gluconeogenesis) and ketone bodies to other organs, inhibition of fatty acid oxidation in the liver can lead to a deficiency in the energy supply for extra-hepatic tissues. Fatty acid oxidation in intact cells has traditionally been assayed by measuring the production of tritiated water from labeled fatty acids such as tritiated palmitate. In order to circumvent the use of radio-labeled material, we assessed fatty acid oxidation in intact cells by measuring the effect of palmitate, a long-chain fatty acid, on cellular oxygen consumption in an XF96 extracellular flux analyzer. We observed an increase in the oxygen consumption of cells such as c2c12 mouse myoblasts, HepG2 cells (a liver-derived carcinoma cell line) and hepatocytes upon palmitate addition. Etomoxir, an inhibitor of carnitine palmitoyltransferase-1 (an enzyme catalyzing the rate-limiting step of long-chain fatty acid entry into mitochondria) inhibited respiration. In a proof-of-concept study, we assessed the effect of drugs (amiodarone, tamoxifen, tianeptine and perhexiline) that are known to inhibit mitochondrial fatty acid oxidation. Our results showed that the measurement of drug-induced changes in cellular oxygen consumption in the presence of palmitate is a convenient method by which to assess inhibition of fatty acid oxidation in cells.

**PS 2259 Cytotoxicity and Genotoxicity of 2, 6-dichloro-3-methyl-1, 4-benzoquinone (DCMBQ) Involves Reactive Oxygen Species Production *In Vitro*.**

C. F. McGuigan, X. Li and X. Le. Division of Analytical & Environmental Toxicology, University of Alberta, Edmonton, AB, Canada.

Halobenzoquinones (HBQs) were recently identified as drinking water disinfection byproducts. Computational toxicity predictions have identified the HBQ 2,6-dichloro-3-methyl-1,4-benzoquinone (DCMBQ) as a potential carcinogen; however, little toxicity information is available. The normal BJ human fibroblast cell line (CRL-2522) was utilized to perform *in vitro* assays to examine the cytotoxicity, genotoxicity, and reactive oxygen species production capability of DCMBQ. Real-time cell electronic sensing (RT-CES) showed a concentration-dependent decrease

in cell index, indicative of cytotoxicity, after exposure to 12.5-50  $\mu$ M DCMBQ over a 72-hour period. Using the alkaline comet assay, a significant genotoxic effect (one-way ANOVA,  $p < 0.05$ ), indicated by increased tail moment, was observed in cells exposed to  $\geq 20 \mu$ M DCMBQ for 24 hours. To further determine the mechanism of toxicity, reactive oxygen species (ROS) production was measured using the fluorophore DCFDA (2',7'-dichlorofluorescein diacetate) in cells exposed to DCMBQ (5-50  $\mu$ M) for 2-72 hours. Significant time and concentration-dependent increases in ROS were observed (two-way ANOVA,  $p < 0.05$ ) for  $\geq 15 \mu$ M DCMBQ at 24 hours of exposure but as early as 4 hours of exposure for 50  $\mu$ M DCMBQ. This effect was significantly reduced by the addition of N-acetylcysteine (NAC), a ROS scavenger. Likewise, simultaneous addition of NAC to cells treated with highly genotoxic concentrations of DCMBQ in the alkaline comet assay reduced tail moment values to those comparable with untreated control groups. Based on these results, we conclude that DCMBQ is cytotoxic and genotoxic under these experimental conditions, and these effects are due at least in part to ROS production. As DCMBQ has been detected in finished drinking water samples, additional testing is urgently required to determine potential effects on human health.

## PS 2260 Intra- and Interlaboratory Validation Studies on Reactive Oxygen Species Assay for Photosafety Evaluation of Pharmaceuticals.

T. Toda<sup>1</sup>, S. Onoue<sup>2</sup>, Y. Seto<sup>2</sup>, H. Takagi<sup>3</sup>, N. Osaki<sup>3</sup>, S. Kawakami<sup>4</sup>, Y. Matsumoto<sup>5</sup>, Y. Iwase<sup>6</sup>, T. Yamamoto<sup>6</sup>, S. Wakuri<sup>7</sup>, K. Hosoi<sup>8</sup>, K. Nakamura<sup>1</sup> and H. Kojima<sup>9</sup>. <sup>1</sup>Shionogi & Co., Ltd., Osaka/Tokyo, Japan; <sup>2</sup>University of Shizuoka, Shizuoka, Japan; <sup>3</sup>Taisho Pharmaceutical Co., Ltd., Saitama, Japan; <sup>4</sup>Asahi Kasei Pharma Corporation, Shizuoka, Japan; <sup>5</sup>Aska Pharmaceutical Co., Ltd., Kanagawa, Japan; <sup>6</sup>Mitsubishi Tanabe Pharma Corporation, Saitama/Chiba, Japan; <sup>7</sup>Hatano Research Institute, Food and Drug Safety Center, Kanagawa, Japan; <sup>8</sup>Santen Pharmaceutical Co., Ltd., Nara, Japan; <sup>9</sup>National Institute of Health Sciences, Tokyo, Japan.

A reactive oxygen species (ROS) assay was previously developed for photosafety evaluation of pharmaceuticals. Although outcomes from the previous multicenter validation study were indicative of satisfactory transferability, reproducibility, and predictive capacity of the ROS assay using Atlas Suntest CPS/CPS plus solar simulators, the feasibility of different solar simulators for the ROS assay has never been elucidated. Herein, in 4 participating laboratories, 2 standards and 42 coded chemicals, including 23 phototoxins and 19 non-phototoxic drugs/chemicals, were assessed by the ROS assay using Seric SXL-2500V2 solar simulators with the aim of evaluating the compatibility of different solar simulators for the ROS assay. In the ROS assay on quinine (200  $\mu$ M), a typical phototoxic drug, the intra- and inter-day precisions (coefficient of variation; CV) were found to be 1.7–9.4% and 2.7–6.9%, respectively. The inter-laboratory CV for quinine averaged 13.2% for singlet oxygen and 7.1% for superoxide. The ROS assay on 42 coded chemicals (200  $\mu$ M) provided no false negative predictions as compared to the in vitro/in vivo phototoxicity, although several false positives appeared. These results were regarded as a convincing demonstration that the ROS assay is compatible with, and can be adapted to, other available suitable solar simulators without losing performance.

## PS 2261 Investigating the Role of Mitochondrial Dysfunction in Zoniporide Toxicity.

P. Rana, S. Rachel and Y. Will. *Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT.*

Zoniporide, an inhibitor of the Na<sup>+</sup>-H<sup>+</sup> exchanger-1 was developed for the reduction of myocardial ischemic injury in acute coronary syndromes, in the high-risk surgical setting, and secondary for prevention in patients with ischemic diseases. A 28-days intravenous infusion rat study revealed target organ toxicity of the sciatic nerve, spinal cord, and stomach injury (Pettersen et al., 2008). Due to insufficient efficacy, zoniporide was discontinued after the phase 2 clinical trial. We have previously reported that zoniporide seems to affect mitochondrial function (Rana et al., 2011) here, we expand on our studies by investigating further mechanisms that could lead to this mitochondrial disturbance.

We tested zoniporide in rat liver mitochondria for its inhibition of mitochondrial respiration and conducted mitochondrial swelling experiments to study possible mitochondrial permeability transition pore (MPT) effects of zoniporide. We further tested this compound in H9c2 cells growing in glucose and galactose media and measured ATP depletion and Caspase 3/7 levels. Finally, we tested zoniporide on the flux analyzer and measured immediate effect on mitochondrial respiration and glycolytic rates. In the cell based assays, we tested zoniporide alone and in the presence of Cyclosporine A (CSA), which has been known to close the MPT. We observed that zoniporide did not inhibit mitochondrial respiration in rat liver isolated mitochondria. However, at 24 h, there was more than a 3-fold difference between glucose/galactose IC<sub>50</sub>, suggesting an effect on a mitochondrial target.

This was further confirmed using a flux analyzer, where there was decrease in oxygen consumption rate (OCR) which was accompanied by increase in extra cellular acidification rate (ECAR) suggesting that cell injury is primarily mitochondria targeted as cells switches respiration from mitochondrial OXPHOS to glycolysis. Co-incubation with CSA had a rescue effect on Caspase3/7 levels in galactose growing cells. In summary, we believe that zoniporide induced cell injury includes primarily mitochondria by causing MPT.

## PS 2262 Validation of an HTS-Amenable Assay to Detect Drug-Induced Mitochondrial Toxicity.

R. Swiss<sup>1</sup>, A. L. Niles<sup>2</sup>, J. J. Cali<sup>2</sup> and Y. Will<sup>1</sup>. <sup>1</sup>Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT; <sup>2</sup>Promega, Madison, WI.

Drug-induced mitochondrial dysfunction has been shown to contribute to organ toxicity and late stage attrition. Therefore, testing for drug-induced mitochondrial dysfunction pre-clinically is vitally important and has the ability to greatly impact the success of a potential drug candidate. Several assays have been developed but are hampered for high-throughput screening because they either require special reagents, isolated mitochondria or specialized equipment.

Here we validate in 384-well format, a dual parameter assay that measures both cytotoxicity and mitochondrial toxicity simultaneously during very short exposure durations using standard detection methods. In this assay, cytotoxicity is measured by evaluating cell membrane integrity via the presence or absence of a distinct protease activity associated with necrosis.

For our initial evaluation, K562 cells were grown in both glucose-supplemented media and galactose-supplemented media and were tested in parallel. The objective was to see how many mitochondrial toxicants this cell-based assay would be able to detect.

We validated the assay using the classical mitochondrial toxicants antimycin A, CCCP and, oligomycin, as well as two drugs known to have mitochondrial liabilities (nefazodone, and flutamide) as well as the non-specific detergent digitonin, in a 384-well plate format with a 2 hour exposure.

We determined the assay to have excellent reproducibility with less than 3 fold differences between IC<sub>50</sub> values form day to day. Once the assay was validated, we screened a set of 75 commercial compounds that included compounds known to cause different organ toxicities and with known or unknown mitochondrial liabilities. Our screening data identified that compounds could be sorted into 7 different categories based on the calculated IC<sub>50</sub>s of each condition, the cytotoxicity measurement in both glucose and galactose-grown cells and the ATP measurement in both media conditions. Our results are currently evaluated for their sensitivity and specificity in comparison to other existing assays.

## PS 2263 Establishing a Link between Redox Cycling and Cell Death for Quinone and Flavin Chemotypes.

L. Jones, P. Rana, R. Swiss, R. Naven and Y. Will. *Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT.*

Oxidative stress is one of the major mechanisms of drug induced toxicity. One electron reduction of oxidants generates reactive oxygen species (ROS) via redox cycling. In biological systems, the flavo enzymes mediate the transfer of electrons to the quinone by reducing it to the semiquinone. Recently, we evaluated flavin analogues for their ability to redox cycle and tried to establish their association to toxicity. We investigated menadione (a quinone analogue) and toxoflavin (a flavin analogue) for its attribution to its redox cycling activity that leads to oxidative stress which eventually leads to cell death.

In our proof of concept study, we investigated the redox cycling capability of menadione and toxoflavin by utilizing a biochemical assay that measures the H<sub>2</sub>O<sub>2</sub> produced through redox cycling of compounds. Next, we tested these compounds in THLE cells using high content imaging to assess the production of ROS using dihydro ethidium (DHE). In addition, we measured glutathione and ATP levels in THLE cells. Next, we wanted to know if we could rescue the detrimental effects of redox cycling on cell health, by incubation with two different antioxidants. One of them was catalase, which effectively dismantles hydrogen peroxide with water as a byproduct, the other was N-acetyl-cysteine (NAC), which minimizes oxidative stress.

Here, we report that both, menadione and toxoflavin redox cycle and produce hydrogen peroxide (ROS), both in the biochemical assay as well as in the cell based assay. Glutathione levels were also depleted with both of these compounds. Furthermore, the ROS formation and glutathione depletion lead to cell injury that is measured by ATP depletion. Catalase was able to dismantle H<sub>2</sub>O<sub>2</sub> in the biochemical assay. In the cell based assay, ROS, glutathione and ATP effects were recovered in the presence of NAC. In summary, we established the involvement of redox cycling of quinones and flavin chemotypes to toxicity in THLE cells

**PS 2264 Identification and Characterization of Potential Mitochondrial Liabilities Using a Multitiered *In Vitro* Rat Primary Hepatocyte Screening Paradigm.**

D. D. Baker, B. D. Jeffy and M. A. Breider. *Exploratory Toxicology, Celgene, Inc., San Diego, CA.*

A tier I rat primary hepatocyte multi-endpoint cytotoxicity assay (MECA) system is an effective tool to assess and rank order compounds on predicted potential to induce toxicity in repeat-dose *in vivo* rat toxicology studies. Our MECA system utilizes three primary biochemical endpoint assays: an ATP assay for cell viability, a lactate dehydrogenase (LDH) assay for membrane integrity and a WST-1 assay for mitochondrial function. A positive signal in the WST-1 assay should be further characterized with a Tier II specific assessment of sub-mitochondrial toxicity. To determine potential mitochondrial liabilities, our Tier II mechanistic assessment includes a JC-1 assay for Mitochondrial Pore Transition (MPT) status, a 2',7'-dichlorofluorescein diacetate (DCFDA) assay for reactive oxygen species (ROS) production, a Caspase 3/7 assay for apoptosis, and a Seahorse XF24™ assay system to determine functional oxidative phosphorylation (mitochondrial respiration). HMG-CoA reductase inhibitors (statins) are compounds that lower cholesterol and reduce cardiovascular disease. There has been increasing evidence that some statins may affect mitochondrial function, leading to adverse effects such as myopathy or rhabdomyolysis. We investigated the effects of multiple statins, including simvastatin, on various mitochondrial functional endpoints. Tier I screening of the statins in primary rat hepatocytes identified a general mitochondrial liability with a 50% decrease in WST-1 throughout the concentration range. In Tier II assays demonstrated that simvastatin treatment induced hepatocellular apoptosis at high concentrations and lowered both basal mitochondrial respiration and maximal respiration compared to control at non-cytotoxic concentrations. These data corroborate the decreased WST-1 reading and suggesting impaired electron transport chain function. A multi-tiered approach is essential to fully characterize potential mitochondrial dysfunction and add predictive value to *in vitro* toxicology screens in early phases of drug discovery.

**PS 2265 Impact of Exposure Profile on Toxic Response Using Hepatocytes (HepaRG) Cocultured with Intestinal Cells (Caco-2).**

K. Yuki, N. Ikeda, T. Kasamatsu and N. Nishiyama. *Kao Corporation, Haga-gun Tochigi, Japan.* Sponsor: *J. Avalos.*

[Background, Purpose] To develop an alternative method to *in vivo* toxicity studies, a general approach would be to extrapolate key markers identified in the early stage of the *in vivo* toxic response into an *in vitro* system. Under *in vivo* conditions, a test substance is absorbed, distributed, and/or metabolized before reaching target cells, whereas in an *in vitro* system, compounds are directly exposed to target cells and metabolic activation might or might not be involved. To address the impact of the significant difference of chemical exposure profiles between *in vivo* and *in vitro* systems, we have developed a co-culture system consisting of HepaRG cells and Caco-2 cells as a model for hepatocytes, where the system simulates intestinal absorption and liver metabolism processes.

[Methods] The toxic responses of the co-culture system toward four chemicals (acetaminophen, carbon tetrachloride, amiodarone, and EGCg) reported to have a hepatotoxic effect were compared to the single culture HepaRG system.

[Results] Co-culturing with Caco-2 cells increased ALB and CYP expression in HepaRG cells. Although treatment with each test chemical changed LDH and GSH activity in both culture systems, dosages of EGCg were very different for similar toxic effects. Monitoring of EGCg concentration and GSH activity revealed a two-fold lower EGCg Cmax, a 10-fold higher AUC (0-24), and reduction of GSH activity after 12 hr for the co-culture system.

[Discussion, Conclusion] This study demonstrated that the exposure profile of test substances may affect the toxic response of cultured cells. It is important to develop *in vitro* models that reflect the *in vivo* exposure conditions.

**PS 2266 Combinatorial High-Throughput Gene Transfection on a Chip for Metabolism-Induced Toxicity Screening.**

M. Lee<sup>4</sup>, S. Kwon<sup>1</sup>, D. Lee<sup>2</sup>, D. Shah<sup>1</sup>, B. Ku<sup>2</sup>, D. S. Clark<sup>3</sup> and J. S. Dordick<sup>1</sup>. <sup>1</sup>Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY; <sup>2</sup>Central R & D Institute, Samsung Electro-Mechanics Co., Suwon, Republic of Korea; <sup>3</sup>Department of Chemical and Biomolecular Engineering, University of California Berkeley, Berkeley, CA; <sup>4</sup>Solidus Biosciences, Inc., San Francisco, CA.

Variation in metabolic enzyme expression among segments of the human population may cause deviations from the expected pharmacokinetic profile of a drug, resulting in idiosyncratic toxicity or a lack of efficacy. Cell lines that stably express

metabolic enzymes are emerging tools for prediction of these rare clinical events; however, it is difficult to create and maintain a library of stable cell lines that mimics the diversity of metabolic profiles. To address this need, we have developed a "Transfected Enzyme and Metabolism Chip" (or TeamChip) for high-throughput analysis of systematic drug metabolism and toxicology. The TeamChip is prepared by infecting an array of miniaturized 3-D cell cultures on a micropillar chip with varying concentrations of recombinant adenoviruses carrying genes for different metabolic enzymes in a microwell chip, which generates an array of cell cultures with differentiated metabolizing capabilities. As a proof of concept, we have demonstrated the controlled expression of individual drug-metabolizing enzymes (CYP3A4, 2D6, 2C9, 1A2, 2E1, and UGT1A4) in THLE-2 human liver cell line on the chip by altering the multiplicity of infection of the various recombinant adenoviruses. The expression levels of the metabolizing enzymes on the chip were determined by in-cell immunofluorescence assays and the activity of the expressed enzymes in THLE-2 cells were tested with fluorogenic dyes. By printing the 6 recombinant adenoviruses into the microwell chip in a combinatorial way, we were able to achieve 144 combinations of multiple metabolic enzymes expressed in THLE-2 cells on a single TeamChip. Finally, 6 model compounds that were shown to be hepatotoxic, in some cases idiosyncratically and withdrawn from the market, were tested to simulate enzyme-specific hepatotoxicity.

**PS 2267 Validation of High-Throughput and High-Content (HT/HC) Assays to Support 21st Century Toxicity Evaluations.**

R. Becker<sup>1</sup>, G. Patlewicz<sup>2</sup>, T. Simon<sup>3</sup>, K. Goyak<sup>4</sup>, R. Phillips<sup>4</sup>, J. Rowlands<sup>5</sup> and S. Seidel<sup>6</sup>. <sup>1</sup>American Chemistry Council, Washington DC; <sup>2</sup>DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE; <sup>3</sup>Ted Simon LLC, Winston, GA; <sup>4</sup>ExxonMobil Biomedical Sciences Inc., Annandale, NJ; <sup>5</sup>The Dow Chemical Company, Midland, MI; <sup>6</sup>Dow Corning Corporation, Midland, MI.

Advances in high throughput and high content (HT/HC) methods have the potential to improve the efficiency and the effectiveness of toxicity evaluations and risk assessments. However, scientific confidence in these methods and their prediction models must be formally established before use in regulatory decision making. Traditional validation approaches that define relevance, reliability, sensitivity and specificity may not be readily applied since a number of these methods are proprietary; HT/HC methods may use one of a kind robotics; although run individually, these assays are likely to be used as a group or battery for decision making and, HT/HC methods are not exact replacements for *in vivo* testing. Building on the frameworks developed in the 2010 Institute of Medicine Report on Biomarkers and the OECD 2007 Report on (Q)SAR Validation, we present frameworks that can be adapted to address the validation challenges of HT/HC methods. These require explicit specification of context and purpose of use such that scientific confidence can be defined to meet different applications (e.g., a lesser degree of confidence may be acceptable for priority setting compared to that required to support hazard characterization, or classification/labeling). We recommend that a specific validation strategy be developed and implemented for HT/HC assays and their prediction models, focused on the specific biological response of interest. We discuss how anchoring the assays and their prediction models to Adverse Outcome Pathways should facilitate the interpretation of results and support scientifically defensible fit-for-purpose applications. To build scientific confidence, data should be publicly disseminated and assay results and prediction models should be subjected to independent scientific peer review.

**PS 2268 Performance Evaluation of Publicly Available QSAR Software Platforms for Toxicology Endpoints: Case Study Involving VEGA, OPENTOX, and OECD QSAR Toolbox.**

S. Bobst<sup>1</sup> and M. Vracko<sup>2</sup>. <sup>1</sup>Product Safety, Nexeo Solutions LLC, The Woodlands, TX; <sup>2</sup>Laboratory of Chemometrics, National Institute of Chemistry, Ljubljana, Slovenia.

Several Quantitative Structure Activity Relationship (QSAR) software methods are available for public use. QSAR methods are gaining greater acceptance as an alternative to animal testing, to fill data gaps for hazard communications (e.g. the U.N. Globally Harmonized System for chemical labeling) and data submissions for regulatory requirements (e.g. the European chemical regulation known as REACH). QSAR software models are constructed using data systems involving molecular descriptors, specific to toxic endpoints, and reference databases comparing known data references, with unknown data points. VEGA, OPENTOX, and OECD QSAR Toolbox are three software platforms widely known and publicly available. The analysis displays the performance of the software programs with a poly aromatic hydrocarbon (PAH) test data set. Variation in software performance, including specificity (false negatives), sensitivity (false positives), and strength of prediction (regression) is evaluated against the test case data. The comparative analysis provides insight into the criteria and requirements for determining which software

platform maybe most appropriate for specific endpoints for unique chemical categories. Such analysis assists industry stakeholders in planning the use of QSAR models for hazard communication, regulatory compliance, and sustainable life cycle management.

**PS 2269 Use of a Cell-Based Assay to Monitor the Stability of the Tox21 10K Compound Library.**

R. Huang<sup>1</sup>, J. Zhao<sup>1</sup>, M. Xia<sup>1</sup>, K. L. Witt<sup>2</sup>, K. Houck<sup>3</sup>, R. R. Tice<sup>3</sup>, D. Dix<sup>3</sup> and C. P. Austin<sup>1</sup>. <sup>1</sup>NCATS/NIH, Rockville, MD; <sup>2</sup>NTP, NIEHS/NIH, Research Triangle Park, NC; <sup>3</sup>NCCT, EPA, Research Triangle Park, NC.

In Tox21 Phase II, a collection of ~10K compounds ([http://www.epa.gov/ncct/dstox/sdf\\_tox21s.html](http://www.epa.gov/ncct/dstox/sdf_tox21s.html)) is being screened against a battery of nuclear receptor and stress response pathway assays. Knowing the identity and purity of each substance and its stability in dimethylsulfoxide (DMSO), the solvent of choice, is critical to the interpretation of assay results. In the screening protocol, a copy of the 10K library, maintained in the Tox21 robotics facility at room temperature (RT), is used in multiple assays over a 4-month period. In addition to an ongoing analytical analysis on the library at time 0 and 4 months, the complete results of which will not be available until mid 2013, we evaluated compound stability using the p53-beta lactamase reporter gene (p53-BLA) assay to monitor biological activity. This assay was selected because it is a highly reproducible (>95%) cell-based assay with a relatively high hit rate (16%). The library was tested 1 day, 2 weeks, 2, 4, and 6 months after being placed on the robot. The number of compounds that showed a significant change in activity (loss or gain) as an indication of compound degradation at each time point compared to the freshly thawed library (day one) reached a plateau of 1.7% of the 10K library at approximately 4 months. Most of the change in activity appeared to occur within the first 2 weeks and included compounds such as dinoterb, bithionol and captafol. Results show that the majority of compounds are relatively stable at RT for up to 6 months, with the caveat that the compounds inactive against p53 (i.e., the majority of the library) were not captured by this method. This study is the first attempt to use a cell-based assay to systematically monitor the stability of a large-scale, environmentally focused compound library. The results can be used to determine when to replace the library plates, and they also serve to validate the quality of the Tox21 production screen process – from compound storage and handling to robotic operations and assay performance.

**PS 2270 Application of Metabolomics *In Vitro* for Identification of Toxicological Modes of Action.**

T. Ramirez<sup>1</sup>, N. Bordag<sup>2</sup>, W. Mellert<sup>1</sup>, H. G. Kamp<sup>1</sup>, T. Walk<sup>2</sup>, R. Looser<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>metanomics, berlin, Germany.

The demand for the use of alternatives to animal testing has increased in the last years, not only due to new regulations, such as REACH or the 7th Amendment of the cosmetic directive, but also because they can be used for toxicological screening during compound development. The use of state-of-the-art technologies combined with cellular *in vitro* models represents a new opportunity to obtain comprehensive information about the toxicological mode of action of compounds being in commerce and most importantly for compounds under development. Metabolomics is a versatile technology with multiple potential applications in safety profiling and has been considered as the alternative to elucidate the molecular basis of toxicity. Moreover, the combination of *in vitro* systems coped to this technology may on one hand enable the acquisition of quantitative information about the multi-parametric metabolic response of the cellular systems in normal and patho-physiological conditions and on the other hand, it represents a major step towards non-animal alternatives in toxicology. Herein, we report on the extracellular metabolic profile (secretome) of HepG2 cells after the exposure to chemicals compounds with well-known toxic profile and differ modes of action. The obtained metabolic fingerprint allowed for a clear distinction between the tested toxicological modes of action. These results may majorly contribute to the future elucidation of the biochemical events underlining the toxic modes of actions of chemical compounds without animal testing.

**PS 2271 Functional Genomics Approach in Yeast and the DT40 Avian Cell Line Identify Conserved Mechanisms of Trichloroethylene Toxicity.**

V. De La Rosa and C. Vulpe. University of California, Berkeley, Berkeley, CA.

Trichloroethylene (TCE) is an industrial solvent and a common drinking water contaminate. Previous studies have identified the TCE metabolite DCVC as responsible for increased kidney toxicity and renal cancer, yet the molecular events

mediating renal toxicity an cancer remain controversial. Our studies in yeast provide a foundation for identifying potential mechanisms of TCE renal toxicity and to establish an alternative model for identifying mechanisms of toxicity in humans. A functional genomics approach in yeast identified DNA damage and repair pathways important in response to DCVC exposure. Specifically, mutagenic translesion synthesis (TLS) and nucleotide excision repair (NER) pathways were found to play important roles in DCVC toxicity. This data suggests DCVC may cause direct DNA damage that elicits a mutagenic repair response. Follow-up studies were conducted in the DT40 avian cell to assess if the mutagenic DNA repair response is conserved in higher eukaryotes. The viability of DNA repair mutants was significantly decreased particularly for TLS and NER mutants. Furthermore, western blot analysis showed initiation of TLS repair after DCVC exposure. These results support a conserved DNA damage and mutagenic repair mechanism mediating DCVC renal toxicity. Additionally the results support a functional genomics approach in yeast as a viable model for identifying mechanisms of toxicity in higher organisms, including humans.

**PS 2272 The Value of Pharmacological Data to Support Systemic Acute Toxicity Evaluation of Compounds: A Profile Analysis.**

R. R. Note, H. Noçairi, L. Bourouf, G. Ouedraogo and J. Cotovio. *Department for The Development of Predictive Models and Methods, L'Oréal, Aulnay sous Bois, France.* Sponsor: E. Dufour.

Developing alternatives in the area of acute systemic toxicity implies combination of multiple parameters. We showed that integration of cell-death data, pharmacological profiles and physico-chemical properties resulted in a significant improvement of the LD50 prediction model originally developed by CeeTox. In order to reduce the false negative rate, correcting factors were applied to the model; this included considerations of a clear dose-response effect, the magnitude of the response and the number of receptors responding. A decrease of the LD50 parameter was expected the cited criteria were met. At a LD50 threshold of 500 mg/kg, the predictive performances of the so called V1 model were extremely encouraging with an overall concordance of 88%\*.

The purpose of the study is to get a better understanding of the data generated on the selection of 13 CNS and Heart receptors potentially playing a causative role in the toxic effect. The analysis of the profiles observed with the set of 73 public domain chemicals was completed as follows:

- Comparison of the LD50 values estimated via the different models (V0, V1, experimental)

- Toxicological categorization based upon the LD50 threshold of 500 mg/kg

- Identification of the receptors most responding and understanding of their biological relevance

No variation of the LD50 values was observed for 43 chemicals while an increase or a decrease was assigned to 10 and 20 chemicals respectively. As expected, the decrease in the LD50 value made the model more predictive for 16 out of the 20 compounds. With regards to the toxic compounds, the receptors most responding were a subset of 5 CNS and heart receptors (M2, alpha2, beta1, GABA, N neuronal). Next step will consist of checking the relevance of such receptors for a set of proprietary chemicals. As such, we could envisage the development of a more economical and pragmatic model that would be useful for early screening purposes.

\*SOT 2010, SOT 2011, SOT 2012

**PS 2273 Development of *In Vitro* Organotypic 3D Epithelial Models for High-Throughput Screening of Toxicological, Immunological and Developmental Signaling Pathways.**

C. Mankus, G. Jackson, J. Bolmarcich, P. Hayden and M. Klausner. *Mattek Corporation, Ashland, MA.*

Currently, there is a growing need for moderate to high-throughput toxicological assays that provide mechanistic information regarding cellular targets and signaling pathways. Here, we describe the development of *in vitro* organotypic 3D skin (EpiDerm™) and airway (EpiAirway™) models with the added feature of luciferase based transcription factor (TF) reporter functions. To produce the models, early passage normal human epidermal keratinocytes and tracheal epithelial cells were transduced with lentiviral vectors containing the TF response elements linked to luciferase. Stably transduced cells were selected by puromycin resistance, expanded several passages and cryopreserved to produce large pools of cells for organotypic model production. To date, reporters for 6 stress response pathways, including oxidative stress, DNA damage, metal stress, MAPK/inflammation, NFκB and xenobiotic stress have been developed in both the EpiDerm™ and EpiAirway™ models. Each model has demonstrated a dose response to positive control test articles including, TBHQ, Nutlin-3, ZnCl<sub>2</sub>, PMA, TNFα and TCDD, respectively, with an average induction of 3-15 fold over vehicle when luciferase activity in tissue

extracts was quantified using a microplate luminometer. TF reporters can be assembled in custom 96-well arrays for screening of unknown test compounds and monitoring of cell signaling pathway activity. Using this format, 3 test articles and a negative control (N=3) can be tested against 8 stress pathways in a single assay resulting in a heat map-like profile of pathway activation. The ultimate goal of the project is to develop a panel of 14 TF reporter models for both skin and airway models that can be assembled into custom 96-well high-throughput arrays as well as additional individual tissue formats. Results from these initial 6 models indicate that EpiDerm™ and EpiAirway™ reporter models will provide novel tools for conducting mechanistic human toxicological studies.

## PS 2274 *In Vitro* Predictive Toxicology for Breast Cancer.

R. Rudel<sup>1</sup>, J. Ackerman<sup>1</sup> and C. Vulpe<sup>2</sup>. <sup>1</sup>Silent Spring Institute, Newton, MA; <sup>2</sup>University of California, Berkeley, CA.

Identifying chemicals that increase breast cancer (BC) risk could help prevent BC, but rodent bioassays are expensive. In vitro and computational methods are being developed to predict adverse effects with limited in vivo testing. The present work aims to develop in vitro methods to predict chemicals that can increase BC risk. Animal and human studies suggest that both genotoxic carcinogens and certain hormone exposures increase BC risk. Our initial goal is to identify in vitro tests that predict mammary gland carcinogens (MCs) in rodent bioassays, since few breast carcinogens have been studied in humans. We have previously identified 208 chemicals causing mammary tumors in rodents in at least one study. We used the Chemical Carcinogenesis Research Information System (CCRIS) to compare genotoxicity profiles for MCs with 27 'non-carcinogens' (nonCs) that did not show increased tumors at any site in National Toxicology Program bioassays. We included five assay types: bacterial mutagenicity, and in vitro and in vivo micronuclei and chromosomal aberration. Data from at least one of these were available for 158 MCs and 22 nonCs. We found that most MCs are genotoxic: 87% were positive in >15% of CCRIS entries within any assay type, with or without metabolic activation (MA), while 10% were consistently negative (i.e., no study was positive). In comparison, 59% of nonCs were consistently negative. Since many in vitro predictive toxicity programs do not include MA, we also evaluated whether MA was needed for genotoxicity. Without MA, the MCs that were consistently negative for genotoxicity increased from 10% to 24%, and the number consistently positive (i.e., positive in >15% of entries in every assay type) dropped from 66% to 48%. In conclusion, a high percentage of MCs are consistently genotoxic but 10% are negative in all tests. Without activation almost 25% of the MCs would be consistently negative. The relationship between genotoxicity and cancer has been extensively discussed, but to our knowledge this is the first focus on breast cancer. Future work will extend to other in vitro endpoints.

## PS 2275 *In Vitro* to *In Vivo* Extrapolation Using Data from ToxCast.

M. DeVito<sup>1</sup>, S. S. Auerbach<sup>1</sup>, A. Merrick<sup>1</sup>, K. L. Witt<sup>1</sup>, K. Janardhan<sup>3</sup>, D. Malarkey<sup>1</sup>, H. Nagai<sup>1</sup>, I. Shah<sup>2</sup>, C. Corton<sup>2</sup> and R. Judson<sup>2</sup>. <sup>1</sup>NTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>ORD, US EPA, Research Triangle Park, NC; <sup>3</sup>ILS, Research Triangle Park, NC; <sup>4</sup>Nihon Nohayaku Co. Ltd., Tokyo, Japan.

Using data from the USEPA ToxCast Phase I, a model was developed to predict non-genotoxic rat liver carcinogens. The model predicts that chemicals that activate PPAR $\alpha$ , increases in oxidative stress as measured by H2AX phosphorylation, decreases in MCP-1 or are anti-androgens in vitro are likely to induce rat liver tumors through non-genotoxic mechanisms. The present study evaluated the concordance of these in vitro responses to in vivo effects. The studied chemicals were either positive in the predictive model and were rat liver carcinogens (acetochlor, carbaryl, perfluorooctanoic acid (PFOA), 2,5-Pyridinedicarboxylic acid dipropyl ester (2,5-PCDA), simazine); positive in the model but were negative in a rat bioassay (bisphenol A, flusilazole) or were negative in the model and in vivo (triclosan). Using the highest dose from the cancer bioassay, male Sprague-Dawley rats were exposed by gavage to chemicals for 4d and euthanized 4h after the last dose. Livers were removed for gene array analysis. Serum MCP-1 levels were determined. In vitro and in vivo, PPAR $\alpha$  was activated by PFOA and acetachlor. Triclosan was positive in vivo, but not in vitro. None of the chemicals altered serum MCP-1 in vivo (2,5-PCDA and simazine, were positive in vitro). Carbaryl and bisphenol A induced H2AX phosphorylation in vitro but were not positive in vivo. Bisphenol A, acetochlor and flusilazole showed anti-androgen activity in vitro and in vivo. While negative in vitro, 2,5-PCDA, PFOA, carbaryl and triclosan altered androgen responsive genes in vivo. Carbaryl and acetochlor induced oxidative stress in vitro but not in vivo. In contrast, triclosan induced oxidative stress responsive genes in vivo but not in vitro. PPAR $\alpha$  pathway activation has a good concordance in vitro and in

vivo. Results for anti-androgenicity, MCP-1 and oxidative stress were much less concordant between in vitro and in vivo. This abstract does not necessarily reflect the policies or views of NIH or the USEPA.

## PS 2276 The *In Vitro* 3T3 Neutral Red Uptake Phototoxicity Test: What to Do with UVB Absorbers?

D. B. Learn, M. D. Schwartz, M. E. Dougherty and A. M. Hoberman. Center for Photobiology, Charles River Laboratories Preclinical Services, Horsham, PA.

The literature suggests and conventional wisdom holds that Ultraviolet B (UVB) is highly cytotoxic to the Balb C 3T3 fibroblast cell line used in the OECD 432 3T3 NRU Phototoxicity Test and thus the assay is not appropriate for test materials that absorb primarily in the UVB portion of the spectrum. The choice of an appropriate light source and filtering is always a critical factor in this or any assay, and, while this Guidance recommends an Ultraviolet A (UVA) dose of 5 J/cm<sup>2</sup>, the UVB dose (if any) or limit of exposure is not addressed. To define the sensitivity of the cells to UVB and evaluate if indeed their sensitivity precluded the use of UVB, we evaluated the Guidance-required cell viability, OD<sub>540</sub> absorption, and other endpoints with increased UVB (290 – 300 nm) exposure by removing the tissue culture plate lid during exposure using a xenon arc solar simulator. This direct (uncovered) exposure increased the UVB irradiance from approximately 19 mJ/cm<sup>2</sup> to approximately 32 mJ/cm<sup>2</sup>, concomitant with the recommended 5 J/cm<sup>2</sup> UVA dose. While cell survival was modestly reduced, the resulting IC<sub>50</sub>, OD<sub>540</sub> absorption, PIF, and MPE endpoints from this enhanced UVB exposure alone and response to Chlorpromazine indicate no adverse effect on the validity of the assay and acceptable Guidance-defined results under these exposure conditions. This additional ability to test UVB absorbers provides all the advantages of the assay to this subset of test materials, enhances this step in the preclinical process of drug discovery and further establishes the robustness of the assay as a valid step in preclinical drug development.

## PS 2277 Comparison of Multiple Assay Formats to Measure Kinase Inhibitor Activity.

K. Leach and D. Puppala. Compound Safety Prediction, Pfizer, Groton, CT.

Protein phosphorylation is a key mechanism for controlling cellular functions, and protein kinase inhibitors show good efficacy as oncology therapeutics. Currently there are 15 marketed kinase inhibitors, with many more in clinical trials. A key component of drug discovery efforts for these inhibitors is the optimization of kinase selectivity, since a greater degree of promiscuity is associated with a greater risk of safety concerns. A wide variety of biochemical and cellular kinase assays which utilize multiple technologies are available for testing compounds and determining kinase activity, and an important consideration is the translation across these assays. A set of 14 Pfizer kinase inhibitors with different primary kinase targets were profiled across three different types of assays: biochemical kinase assays measuring peptide substrate phosphorylation; ActivX technology, which measures specific binding to kinases within a cell lysate; and cell-based kinase assays, measuring endogenous substrate phosphorylation. The biochemical assays were conducted at Km levels of ATP, with nonphysiological peptide substrates, while the cellular assays utilized intact cells and cellular levels of ATP. A comparison of results across these platforms against three different kinases, aurora, abl or glycogen synthase kinase beta, was carried out and the results demonstrate a high degree of congruency with the cellular kinase activity and the Activ X technology. For this set of compounds, there was less agreement between the biochemical versus cellular kinase assays. These results suggest that utilization of high throughput biochemical assays can be used to provide an initial determination of kinase activity, but that followup testing under more physiological conditions using the ActivX technology, or cellular assays, is required to fully assess kinase inhibitor activity.

## PS 2278 Mouse Cecal Microbiota Converts Monomethylarsonic Acid (MMA) to an Array of Oxy- and Thio-Arsenical Metabolites.

M. J. Kohan<sup>2</sup>, D. J. Thomas<sup>2</sup>, T. Pinyavev<sup>1</sup>, M. Mantha<sup>1</sup>, K. M. Herbin-Davis<sup>2</sup> and J. T. Creed<sup>1</sup>. <sup>1</sup>MCEARD, NERL, US EPA, Cincinnati, OH; <sup>2</sup>ISTD, NHEERL, US EPA, Research Triangle Park, NC.

The metabolism of arsenicals markedly affects their tissue distribution and retention as well as the toxic and carcinogenic effects of this metalloid. Metabolism of arsenicals by the microbiota of the gastrointestinal tract has been shown to convert inorganic and dimethylated arsenicals to various methylated species. Here, anaerobic microbiota from ceca of adult female C57BL/6 mice was incubated with 20,

200, 1000, or 2000 parts per billion (ppb) MMA for up to 48 hours at 37°C. Samples of supernates from reaction mixtures were taken for arsenic speciation by HPLC-ICP-MS. MMA was converted to monomethylated mono- (MMMTA), di- (MMDTA), and tri- (MMTTA) thiolated species. In addition, MMA was also converted to dimethylated mono- (DMMTA) and di- (DMDTA) thiolated species. After 48 hours, DMDTA was the predominant metabolite in reaction mixtures containing 20, 200, or 1000 ppb MMA. In reaction mixtures containing 2000 ppb MMA, MMDTA was the predominant metabolite of MMA. These results show that anaerobic microbiota from mouse cecum includes organisms that efficiently methylate MMA and can convert oxyarsenicals into homologous thioarsenicals. The presumptive source of sulfur used for conversion of oxyarsenicals into thioarsenicals is hydrogen sulfide produced by the microbiota through dissimilatory sulfate reduction. Conversion of methylated oxyarsenicals into methylated thioarsenical during preabsorptive metabolism may influence the transport of ingested arsenic across the gastrointestinal barrier thereby affecting the systemic distribution, fate, and effects of arsenic. (This abstract does not reflect U.S. EPA policy).

## PS 2279 Paraoxonase Activity in Subchronic Low-Level Inorganic Arsenic Exposure.

O. Ademuyiwa<sup>1</sup>, O. K. Afolabi<sup>1</sup>, A. D. Wusu<sup>1</sup>, O. O. Ogunrinola<sup>1</sup>, E. O. Abam<sup>1</sup>, D. O. Babayemi<sup>1</sup>, E. A. Balogun<sup>1</sup> and O. O. Odukoya<sup>2</sup>.  
<sup>1</sup>Biochemistry, Federal University of Agriculture, Abeokuta, Nigeria; <sup>2</sup>Chemistry, Federal University of Agriculture, Abeokuta, Nigeria.

Epidemiological evidences indicate close association between inorganic arsenic exposure via drinking water and cardiovascular diseases. While the exact mechanism of this arsenic-mediated increase in cardiovascular risk factors remains enigmatic, studies indicate a role for paraoxonase (PON) in cardiovascular diseases. To study the association between inorganic arsenic exposure and cardiovascular diseases, rats were exposed to sodium arsenite (50, 100 and 150ppm) and sodium arsenate (100, 150 and 200ppm) in their drinking water for 12 weeks. PON activities towards paraoxon (PONase) and phenylacetate (AREase) in plasma, lipoproteins, liver and brain microsomal fractions were determined. Inhibition of PONase and AREase in plasma and HDL characterised the effects of the two arsenicals. While arsenite inhibited PONase by 33% (plasma) and 46% (HDL) respectively, arsenate inhibited the enzyme by 41 and 34% respectively. AREase activity was inhibited by 52 and 48% by arsenite; the inhibition amounted to 72 and 67% respectively by arsenate. The pattern of inhibition in plasma and HDL indicates that arsenite induced a dose-dependent inhibition of PONase whereas arsenate induced a dose-dependent inhibition of AREase. In the VLDL, arsenate inhibited PONase and AREase while arsenite inhibited PONase. In the hepatic and brain microsomal fractions, only the PONase enzyme was inhibited by the two arsenicals. The inhibition was more pronounced in the hepatic microsomes where a 70% inhibition was observed at the highest dose of arsenate. Microsomal cholesterol was increased by the two arsenicals resulting in increased cholesterol/phospholipid ratios. Our findings indicate that decreased PON activity observed in arsenic exposure may be an incipient biochemical event in the cardiovascular effects of arsenic. Modulation of PON activity by arsenic may also be mediated through changes in membrane fluidity brought about by changes in the concentration of cholesterol in the microsomes.

## PS 2280 Comparative Early Oncogenic Effects of Cadmium and Arsenic in Human Lung Epithelial Cells.

R. J. Person, E. J. Tokar and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Cadmium (Cd) and inorganic arsenic (iAs) are known human lung carcinogens. In this study, we compare development of in vitro cellular models of human lung cancer induced by Cd or iAs. We have shown chronic, low-level (5  $\mu$ M) Cd (as CdCl<sub>2</sub>) induces an acquired cancer phenotype in human lung epithelial cells (HPL-1D) after 20 weeks of continuous exposure. Here we compare an iAs model in development to this previously developed Cd model. The HPL-1D cells that were used are an immortalized, non-tumorigenic human peripheral epithelial cell and were used with both agents. HPL-1D cells were chronically exposed to non-toxic levels of Cd (5  $\mu$ M) or iAs (2  $\mu$ M) and over 20-26 weeks of chronic exposure signs of oncogenic transformation were assessed. Matrix metalloproteinase-2 (MMP-2) activity, colony formation in soft agar, invasion and expression of cancer relevant genes were used to assess oncogenic phenotype in these cell models. By 26 weeks of continuous iAs exposure, secreted MMP-2 significantly increased to 147% of control, near levels typical of a cancer phenotype. In comparison, after only 20 weeks of Cd exposure, MMP-2 levels increased to 358% of control and cell invasion and colony formation increased by more than 3-fold compared to control cells, all indicating an oncogenic phenotype. Following iAs exposure (26 weeks) increases were seen in MT-1A (768% of control) and MT-2A (614% of control) expression, similar to that

seen with Cd transformation. Expression of epithelial-to-mesenchymal transition marker *VIMENTIN* increased to 323% of control with chronic iAs exposure. High *VEGF* oncogene expression is often seen in lung adenocarcinomas and after 26 weeks of chronic iAs treatment expression increased to 4.3-fold above control. The SLC39A8 (ZIP 8) transporter, which is known to influx Cd, though increased by Cd transformation was unchanged in chronic iAs exposure. Thus, it appears that both Cd and iAs can induce early signs of transformation in human lung epithelial cells, although some gene expression is inorganic specific.

## PS 2281 Metallothionein Blocks Arsenic-Induced Oxidative DNA Damage.

W. Qu and M. P. Waalkes. NTP, NIEHS, NIH, Research Triangle Park, NC.

Metallothionein (MT) plays an important role in detoxication of inorganics. Inorganic arsenic is a toxic metalloid and a human carcinogen that may act, in part, by causing oxidative DNA damage (ODD). MT can limit ODD induced by other inorganic carcinogens, like cadmium. Although MT can mitigate arsenic toxicity *in vivo*, how MT impacts arsenic-induced ODD has not been defined. Here, we studied ODD induced by acute arsenic treatment *in vitro* and the effects of cellular MT using cells that poorly express MT (MT-I/II double knockout; called MT-null cells) compared to parental wild-type (WT) MT competent cells. MT-null and WT cell lines were first exposed to arsenite (NaAsO<sub>2</sub>) for 24 h to assess cytotoxicity. Arsenic was much less cytotoxic in WT cells (LC<sub>50</sub> = 11.0  $\pm$  1.3  $\mu$ M, mean  $\pm$  SEM) than MT-null cells (LC<sub>50</sub> = 5.6  $\pm$  1.2  $\mu$ M). Arsenic-induced ODD was measured by the immuno-spin trapping method which measures DNA radicals after conversion to stable DNA nitrones *in situ*. Arsenic treatment (1 or 5  $\mu$ M; 24 h) induced much less ODD in WT cells (121% and 141% of control, respectively) than in MT-null cells (202% and 260%). In WT cells arsenic caused concentration-related increases in MT expression (transcript and protein), and in metal-activated transcription factor 1 (MTF1), a requirement for induced MT gene expression by arsenic. In contrast, in MT-null cells, the basal levels of MT were very low and were not increased by arsenic. Transfection of MT-I into MT-null cells markedly reduced arsenic-induced ODD. Two important transport genes, *Mrp1* and *Mrp2*, showed increased expression in WT cells but not MT-null cells. Arsenic caused concentration-related increases in the oxidant defense genes, *HO-1* and *GSTA2* in both WT and MT-null cells, but to much higher levels in WT cells. Thus, MT protects against arsenic-induced ODD in MT competent cells potentially by multiple mechanisms including direct sequestration and scavenging oxidant radicals. MT-competent cells are more adept at activating metal transport systems and oxidant response genes, although the role of MT in these responses is unclear.

## PS 2282 Increase Blood Pressure, Changes of Left Ventricular Geometry, and Function in Children Environmentally Exposed to Inorganic Arsenic.

C. Osorio-Yañez<sup>1</sup>, J. Ayllon-Vergara<sup>2</sup>, L. Arreola-Mendoza<sup>3</sup>, G. Aguilar-Madrid<sup>4</sup>, E. Hernández-Castellanos<sup>1</sup>, A. Barrera-Hernández<sup>1</sup>, L. C. Sanchez-Peña<sup>1</sup> and L. M. Del Razo<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav-IPN, D.F., Mexico; <sup>2</sup>Español Hospital, D.F., Mexico; <sup>3</sup>CIEMAD-IPN, D.F., Mexico; <sup>4</sup>Health and Work, IMSS, D.F., Mexico.

Hypertension is a known cardiovascular risk factor to develop final cardiac events and epidemiologic studies in adults have been related hypertension with inorganic arsenic (iAs) exposure. Left ventricular mass (LVM) increase is a potent predictor of cardiovascular morbidity and mortality and it is stimulated by higher blood pressure as well as impaired myocardial contractile performance. Ejection fraction (EF) has been employed as a good index of global systolic function. The aim of this study was evaluate the association between iAs exposure, blood pressure, and echocardiographic parameters in children. In this cross-sectional study 170 children (3-14 years old) chronically exposed to iAs through drinking water were recruited in iAs-endemic area of central part of México. LVM and EF were derived from echocardiography and blood pressure was measured by standard protocols. Total arsenic in urine (UtAs) was significant associated with systolic ( $\beta$ =2.65;  $p$ =0.056) and diastolic ( $\beta$ =0.012;  $p$ =0.019) blood pressure in multivariate regression models adjusted by age, gender and body mass index. Indeed, diastolic blood pressure was associated with cumulative arsenic exposure ( $\Sigma$ AsE; ppb\*year) through drinking water ( $\beta$ =0.003;  $p$ =0.002). Notably, LVM (g) was significant associated with  $\Sigma$ AsE ( $\beta$ =15.43;  $p$ =0.002) in adjusted multivariate model. Diastolic prehypertension was present in 48%, concentric remodeling was presented in 60% [normal LVM and relative wall thickness (RWT)  $\geq$ 0.43] and LVM concentric hypertrophy defined as LVM  $>$ 88.9 g/m<sup>2</sup> and RWT  $\geq$ 0.43 were presented in 7% (11 children). Moreover, EF was inversely associated with UtAs  $>$  35ng/ml ( $\beta$ =-3.21;  $p$ =0.036) in adjusted multivariate analyses. In conclusion, iAs exposure would be able to cause diastolic prehypertension, increase of LVM and decrease of EF in children, given evidence of possible cardiovascular disease in early-life exposure.

**PS 2283 Reduction of Dimethylarsenate to the Supertoxic Dimethylarsenite by Rats and Rat Liver Cytosol.**

Z. Gregus and B. Némethi. *University of Pécs, Pécs, Hungary.*

Dimethylarsinic acid (DMA<sub>V</sub>) is the major urinary metabolite of inorganic arsenic in humans and most animals. DMA<sub>V</sub> is weakly cytotoxic, however, it is reduced to dimethylarsinous acid (DMA<sub>III</sub>) which is over 100 times more toxic. Although glutathione S-transferase omega 1 (GSTO1) catalyzes the reduction of DMA<sub>V</sub>, its role in DMA<sub>V</sub> reduction in vivo or in cell extracts is uncertain. We studied the reduction of DMA<sub>V</sub> to DMA<sub>III</sub> in rats and in rat liver cytosol to better understand its mechanism. To assess DMA<sub>V</sub> reduction in rats, we devised a novel procedure. This is based on following the time course of the accumulation in the blood of the RBC-bound dimethylarsenic (DMA<sub>s</sub>), which represents DMA<sub>III</sub>. Therefore, we serially measured the RBC-bound DMA<sub>s</sub> in the blood of DMA<sub>V</sub>-injected anesthetized rats with ligated renal pedicles. These studies indicated that reduction of DMA<sub>V</sub> to DMA<sub>III</sub> was rapid, as in 90 min 31% of the injected 50 µmol/kg DMA<sub>V</sub> dose was converted to DMA<sub>III</sub> that was sequestered by the circulating erythrocytes. Pretreatment of rats with glutathione (GSH) depletors (phorone or BSO) delayed the elimination of DMA<sub>V</sub> and the accumulation of RBC-bound DMA<sub>s</sub>, whereas the methyltransferase inhibitor PAD was without effect. Reduction of DMA<sub>V</sub> by rat liver cytosol was assayed by extraction of DMA<sub>III</sub> from the incubations of cytosol with DMA<sub>V</sub> and quantification by HPLC-HG-AFS. We found that reduction of DMA<sub>V</sub> required cytosolic protein and GSH and was inhibited by thiol reagents, GSSG and dehydroascorbate. Although thioredoxin reductase (TrxR) inhibitors (aurothioglucose and trivalent antimony) inhibited cytosolic DMA<sub>V</sub> reduction, TrxR plus NADPH alone or when added to the cytosol failed to support DMA<sub>V</sub> reduction. On ultrafiltration of the cytosol through a 3 kDa filter, the reducing activity in the retentate was lost but was largely restored by NADPH. Such experiments also indicated that the reducing enzyme was larger than 100 kDa, and was not GSTO1. In summary, reduction of DMA<sub>V</sub> to the supertoxic DMA<sub>III</sub> in rats and rat liver cytosol is rapid and GSH dependent, yet its mechanism is still elusive.

**PS 2284 Fibronectin Expression in Human Bladder Cells (UROtsa) Exposed to or Malignantly Transformed by Arsenic or Cadmium.**

A. R. Klinger<sup>1</sup>, M. E. Jenó<sup>1</sup>, K. J. Wilt<sup>1</sup>, H. M. Hewitt<sup>1</sup>, X. Zhou<sup>2</sup>, S. Somji<sup>2</sup>, S. H. Garrett<sup>2</sup>, D. A. Sens<sup>2</sup> and J. R. Dunlevy<sup>1</sup>. <sup>1</sup>Anatomy, University of North Dakota, Grand Forks, ND; <sup>2</sup>Pathology, University of North Dakota, Grand Forks, ND.

Fibronectin is an extracellular matrix glycoprotein that is present in nearly all connective tissues as well as a soluble protein within the blood. The main functions of fibronectin relate to cellular adhesion, cell migration, and cell signaling. In the bladder, fibronectin is found within the lamina propria, blood vessels, nerves, and smooth muscle basement membrane. Fibronectin is present at very low levels in the normal bladder epithelium but in bladder carcinomas it has been found to be substantially increased in expression and/or present in oncofetal alternatively spliced forms. This has led to several studies of fibronectin as a potential prognostic marker in bladder cancer. The purpose of the current study is to validate initial microarray studies that indicated strong differential expression of fibronectin in UROtsa bladder cells transformed with cadmium compared to non-malignant UROtsa cells. Fibronectin mRNA and protein were found to be increased in 6 of 7 cadmium transformed cell lines as well as in 5 of 6 arsenic transformed cell lines compared to the non-transformed parent cells. The ability of fibronectin expression to be altered epigenetically by histone acetylation or DNA methylation or directly by exposure to arsenic or cadmium was also examined. Fibronectin mRNA and protein was found to consistently decrease during 24-72 hours exposure to arsenic but was not consistently changed by short term exposure to cadmium. The results of this study show that alternations in fibronectin expression may correlate with transformation of bladder cells exposed to heavy metals.

**PS 2285 Gene Expression Changes Induced by Various Arsenicals In Vitro.**

P. R. Dodmane, L. L. Arnold, K. L. Pennington and S. M. Cohen. *Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE.*

Inorganic arsenic (IA) is a human urinary bladder, skin and lung carcinogen. The mechanism by which IA induces tumors is unknown. IA is metabolized to methylated arsenicals and excreted in urine. In vitro trivalent arsenicals are more cytotoxic than pentavalent forms. Multiple studies have documented a range of arsenic-induced gene changes in vivo and in vitro, but the dose response is unclear. In this

study, the dose response for IA and effects of various arsenicals for gene expression changes was evaluated in human bronchial epithelial cells (HBEC). Primary HBEC were exposed to 0.1, 1, 5 or 10 µM of As<sub>III</sub>, 1 µM MMA<sub>III</sub> and 1.4 µM DMA<sub>III</sub> for 24 h and 5.8 µM As<sub>III</sub> for 72 h. Increasing concentration of As<sub>III</sub> showed increasing number of differentially expressed genes (DEG) correlating with increasing cytotoxicity. The lowest As<sub>III</sub> used, 0.1 µM, did not induce any DEG, whereas there were 7, 101 and 1735 DEG at 1, 5 and 10 µM As<sub>III</sub>, respectively. Pathway analysis showed only IFN signaling and pattern recognition receptor pathways (PRRP) being altered with 1 µM As<sub>III</sub>. IFN signaling was also altered with 5 µM As<sub>III</sub> in addition to NRF2-mediated oxidative stress response (NOSR) and IL-17A signaling. Ten µM As<sub>III</sub> altered NOSR in addition to glutamate metabolism, cell cycle/G1/S check point regulation, p53 signaling and AhR signaling. DMA<sub>III</sub> induced 2 DEG and MMA<sub>III</sub> induced 268 DEG. DMA<sub>III</sub> induced lesser cytotoxicity compared to MMA<sub>III</sub>. MMA<sub>III</sub> induced canonical pathways of hepatic stellate cell activation, LXR/RXR activation, atherosclerosis signaling, PRRP and IFN signaling pathways. As<sub>III</sub> for 72 h induced 71 DEG that represented similar signaling pathways as observed at 24 h. These data suggest that arsenic at lower concentrations induces inflammatory and oxidative stress responses whereas at higher concentrations it altered multiple cellular pathways that control cell cycle and cell proliferation. NOAEL for As<sub>III</sub> appears to be between 0.1 to 1 µM. All arsenicals tested altered similar signaling pathways in HBEC and were similar to urothelial cells and keratinocytes.

**PS 2286 Effects of Treatment with Dimethylarsinous Acid (DMAIII) on the Urinary Bladder Epithelium of Female Arsenic Methyltransferase (As3mt) Knockout Mice and C57Bl/6 Mice.**

L. L. Arnold, P. R. Dodmane, K. L. Pennington and S. M. Cohen. *Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE.*

Chronic exposure to inorganic arsenic (InAs) is carcinogenic to the human urinary bladder. It produces urothelial cytotoxicity and proliferation in rats and mice. DMA<sub>V</sub>, a major methylated urinary metabolite of InAs, is a rat bladder carcinogen. DMA<sub>III</sub> was shown to be the likely urinary metabolite of DMA<sub>V</sub> inducing urothelial changes and is postulated to be one of the active metabolites of InAs. To evaluate potential DMA<sub>III</sub>-induced urothelial effects, it was administered to As3mt knockout mice which cannot methylate arsenicals. Female C57Bl/6 wild type and As3mt knockout mice (10/group) were administered DMA<sub>III</sub>, 77.3 ppm in water for four weeks. Urothelial effects were evaluated by light and scanning electron microscopy (SEM) and immunohistochemical detection of bromodeoxyuridine (BrdU). DMA<sub>III</sub> significantly increased the BrdU labeling index in the knockout group compared to control and to the treated wild type group. DMA<sub>III</sub> induced a greater increase in the incidence of simple hyperplasia in knockout mice (4/10) compared to wild type mice (2/10). All treated knockout mice had more and larger intracytoplasmic granules, compared to the treated wild type mice. Changes in SEM classification were not significant. In conclusion, DMA<sub>III</sub> induces urothelial toxicity and regenerative hyperplasia in mice and most likely plays a role in inorganic arsenic-induced urothelial changes. However, in mice, DMA<sub>V</sub> does not induce hyperplasia, suggesting that urinary concentrations of DMA<sub>III</sub> do not reach cytotoxic levels in DMA<sub>V</sub>-treated mice.

**PS 2287 Arsenite Inhibits DNA Repair through S-Nitrosation of Poly (ADP-Ribose) Polymerase 1.**

X. Zhou, K. L. Cooper, L. G. Hudson and K. Liu. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

Arsenic, a widely distributed carcinogen, is known to significantly amplify the impact of other carcinogens such as ultraviolet radiation and benzo(a)pyrene at low, non-cytotoxic concentrations. Evidence from our lab and others suggests inhibition of DNA repair could be an important mechanism of arsenic co-carcinogenesis. We recently demonstrated that reactive nitrogen species (RNS) induced by arsenic may play an important role in inhibition of PARP-1 activity, but the role of RNS in the mechanism of arsenic inhibition is not clear. In this work, we show that As(III)-induced RNS caused S-nitrosative modification on cysteine residuals of Poly(ADP-ribose) polymerase (PARP)-1, a key DNA repair protein in base excision repair. We found that similar to the effect of a NO donor, As(III) treatment in HaCat cells induced S-nitrosation on PARP-1 protein. This S-nitrosation of PARP-1 could be reduced by L-NAME (nitric oxide synthase inhibitor), c-PTIO (nitric oxide scavenger) or ascorbic acid. In addition, As(III) treatment lead to zinc loss and activity inhibition of PARP-1 protein isolated from cells. Importantly, we confirmed that S-nitrosation happened on zinc finger DNA binding domain of PARP-1 protein using biotin-switch assay. Taken together, these results show that arsenite induces S-nitrosation on zinc finger DNA binding domain of PARP-1 via generation of NO, leading to zinc loss and activity inhibition of PARP-1. These findings provide novel insight into the molecular mechanism of As inhibition of PARP-1.

**PS 2288 Paradoxical Effects of Ongoing Arsenic Exposure on an Arsenic-Transformed Bladder Cancer Model.**

F. Zhao, S. Pacheco, A. Gandolfi and W. T. Klimecki. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Epidemiology studies have shown a strong link between chronic arsenic exposure and bladder cancer. An immortalized human urothelial cell line, UROtsa has been widely used as a model of arsenic-induced bladder toxicity. Chronic exposure to 1uM sodium arsenite transforms UROtsa to a cancerous cell line, URO-ASSC. This phenotype is stable with no further arsenite selection, and URO-ASSC is typically assayed for malignancy without arsenite exposure. In the absence of arsenite, we found that both UROtsa and URO-ASSC demonstrate constitutive autophagy. Recent evidence suggests that autophagy is a survival mechanism for cancer. This led us to hypothesize that disrupting autophagy could reduce malignant potential in URO-ASSC. We found that URO-ASSC accumulates LC3II protein levels 3.4 fold faster compared to UROtsa when autophagic flux was blocked with bafilomycin A1 in a 2-hour time course, suggesting a higher rate of autophagic turnover in URO-ASSC. Impairing autophagy in URO-ASSC by siRNA against ATG7 resulted in 65% reduction of anchorage-independent growth, a key phenotype of arsenic-induced malignant transformation. Surprisingly, when we reintroduced URO-ASSC cells to 1uM of arsenite exposure, LC3-II levels and autophagic flux were reduced by 50%, suggesting that ongoing exposure to arsenite impairs autophagy. This autophagy impairment was also associated with a 55% reduction in soft agar growth in the presence of 1uM arsenite. These *in vitro* experiments provide insight into the complex effect of arsenic exposure on the process of autophagy and its relationship to arsenite-induced malignancy. Furthermore, these studies raise the possibility that ongoing arsenic exposure may suppress malignant growth concurrently with establishing the malignant phenotype, perhaps in part through modulating the autophagic pathway. The translational impact of this finding could have bearing on human populations such as those in Chile, that transition from periods of sustained arsenic exposure to periods in which arsenic exposure has been mitigated.

**PS 2289 Effects of Arsenic on Expressions of Ube2d Family and Accumulation of p53 in Renal Tubular Cells and Vascular Endothelial Cells.**

M. Satoh<sup>1</sup>, J. Lee<sup>1</sup>, M. Tokumoto<sup>1,2</sup>, Y. Fujiwara<sup>1</sup> and C. Watanabe<sup>3</sup>. <sup>1</sup>*School of Pharmacy, Aichi Gakuin University, Nagoya, Japan;* <sup>2</sup>*Showa Pharmaceutical University, Tokyo, Japan;* <sup>3</sup>*Graduate School of Medicine, University of Tokyo, Tokyo, Japan.*

Arsenic is an environmental pollutant that induces apoptosis in various tissues. However, underlying molecular mechanisms of arsenic-induced apoptosis are not clear. Recently, we have found that apoptosis through the overaccumulation of p53 is involved in cadmium toxicity in rat proximal tubular cells (NRK-52E cells). Moreover, gene expressions of Ube2d family, which conjugate ubiquitin to p53 and drive p53 to be degraded, are suppressed by cadmium in NRK-52E cells. In this study, we examined the involvement of gene expressions of Ube2d family (Ube2d1, Ube2d2, Ube2d3 and Ube2d4) and accumulation of p53 in arsenic toxicity, using model cells of vascular endothelia and renal tubules. In NRK-52E cells, NaAsO<sub>2</sub> (As[III]) decreased mRNA levels of Ube2d family except Ube2d3 and increased protein levels of p53. Interestingly, although protein levels of p53 were markedly increased by As[III], mRNA levels of UBE2D family were not decreased by this metalloid in human brain microvascular endothelial cells (HBMECs). In human proximal tubular cells (HK-2 cells), As[III] slightly increased protein levels of p53 with low-dose treatment. However, mRNA levels of UBE2D family were not decreased by As[III] in HK-2 cells. Moreover, mRNA levels of p53 were decreased by As[III] in HBMECs and HK-2 cells. Our findings suggest that As[III] increases cellular protein levels of p53, mediating tissue- or cell-specific pathways for p53 stability.

**PS 2290 A Common Arsenic (+3 Oxidation State) Methyltransferase (AS3MT) Polymorphism Affects Urinary Metabolite Profiles of Arsenic in a US Population.**

D. J. Thomas<sup>4</sup>, Z. Drobna<sup>1</sup>, M. Styblo<sup>1</sup>, R. L. Calderon<sup>2</sup>, X. Lu<sup>3</sup>, X. Le<sup>3</sup> and E. E. Hudgens<sup>2</sup>. <sup>1</sup>*Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*EPHD, NHEERL, US EPA, Research Triangle Park, NC;* <sup>3</sup>*Environmental Health Sciences, University of Alberta, Edmonton, AB, Canada;* <sup>4</sup>*ISTD, NHEERL, US EPA, Research Triangle Park, NC.*

AS3MT catalyzes methylation of inorganic arsenic (iAs) forming mono- (MAs) and di- (DMAs) methylated products that mediate some of the toxic and carcinogenic effects associated with chronic iAs exposure. Therefore, the catalytic efficiency of

AS3MT may be an important determinant of risk associated with chronic iAs exposure. Concentrations of iAs, MAs, and DMAs in urines from residents of Churchill County, Nevada, were used to calculate primary (MAs/iAs) and secondary (DMAs/MAs) methylation indices (MI). AS3MT genotypes were determined for 198 individuals selected on the basis of lowest and highest secondary MIs. The incidence of an AS3MT polymorphism (rs11191439) that replaces a methionyl residue in position 287 with a threonyl residue (M287T) affected the secondary MI. For the M287T polymorphism, median values for secondary MIs were 6.5 in 150 individuals homozygous for wild-type AS3MT, 2.8 in 43 individuals heterozygous for wild-type and mutant alleles, and 2.4 in 5 individuals homozygous for the M287T polymorphism. In contrast, median values for primary MIs were unaffected by this polymorphism. Two intronic variants (T35587C and G35991A) reported to alter the levels of MAs and DMAs in other studies did not alter primary and secondary MIs in this population. These results indicate that the common M287T polymorphism of AS3MT is associated with altered profiles of methylated arsenicals in urine from individuals chronically ingesting iAs in drinking water. Linkages among AS3MT genotype-dependent alterations in urinary arsenical profiles, the catalytic properties of AS3MT variants, and disease susceptibility require further examination. (This abstract does not reflect U.S. EPA policy).

**PS 2291 Arsenic Increases Atherosclerosis by LXR $\alpha$ -Dependent and LXR $\alpha$ -Independent Mechanisms.**

M. Lemaire<sup>1</sup>, C. A. Lemarié<sup>2</sup>, M. Flores Molina<sup>1</sup> and K. K. Mann<sup>1</sup>. <sup>1</sup>*Oncology, Lady Davis Institute for Medical Research, McGill University, Montréal, QC, Canada;* <sup>2</sup>*Medicine, Lady Davis Institute for Medical Research, McGill University, Montréal, QC, Canada.*

Arsenic exposure has been linked to atherosclerosis; however, molecular mechanisms involved in arsenic-enhanced atherosclerosis are unknown. Previously, we have shown *in vitro* and *in vivo* that arsenic inhibits transcriptional activation of the liver X nuclear receptors (LXR), key regulators of macrophage lipid homeostasis. Here, we evaluated the role of LXR $\alpha$  in arsenic-induced atherosclerosis using the ApoE<sup>-/-</sup> mouse model. In ApoE<sup>-/-</sup> mice, 200 ppb arsenic increased atherosclerosis plaque size after 13 weeks. In contrast, LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup> mice do not show increased plaque size following arsenic exposure, indicating that arsenic may enhance atherosclerosis in an LXR $\alpha$ -dependent manner. In the ApoE<sup>-/-</sup> mice, we saw significant changes in plaque composition, and thus in LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup>, we assessed plaque staining of: 1) lipid deposition and macrophage content and 2) collagen composition and smooth muscle cell content. Interestingly, arsenic decreases macrophages in LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup>, where no change was observed in ApoE<sup>-/-</sup> exposed mice. However, arsenic increased lipids in both genotypes, suggesting impaired macrophage cholesterol efflux capacity and subsequent lipid accumulation. Secondly, we observed that arsenic decreased collagen content in LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup> and ApoE<sup>-/-</sup> to the same extent, but arsenic increased smooth muscle cells, a major collagen producing cell type, in the LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup>, while they were decreased in ApoE<sup>-/-</sup>. This indicates that LXR $\alpha$  may be involved in maintaining matrix integrity. In fact, arsenic-exposed LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup> plaques had increased matrix metalloproteinase (MMPs) activity compared to both control LXR $\alpha$ <sup>-/-</sup>ApoE<sup>-/-</sup> and ApoE<sup>-/-</sup>, which could be responsible for both the decrease in plaque collagen and the smooth muscle cells invasion. Our observations suggest that arsenic may be increasing atherosclerosis formation through LXR inhibition, but it may alter plaque composition in a LXR independent manner.

**PS 2292 Induction of Cytochrome P450 1A1 (CYP1A1) by Pentavalent Methylated Arsenicals in Human Hepatoma HepG2 Cells.**

A. Anwar-Mohamed, O. Elshenawy and A. O. El-Kadi. *University of Alberta, Edmonton, AB, Canada.*

Arsenic (As[III]) is a worldwide environmental pollutant and a human carcinogen. It is well recognized that the carcinogenicity of As[III] is largely dependent on the methylation levels (monomethyl, dimethyl, and trimethyl) that are present during the process of metabolism in mammals. Oxidative methylation, is based on the findings that As[III] is sequentially converted to monomethylarsonic acid (MMA(V)), dimethylarsinic acid (DMA(V)), and trimethylarsine oxide (TMA(V)) in both humans and in laboratory animals such as mice and rats. Activation of the aryl hydrocarbon receptor (AhR) ultimately leads to the induction of the carcinogen activating enzyme cytochrome P450 1A1 (CYP1A1). Therefore, in this study we examined the effects of co-exposure to MMA(V), DMA(V), or TMA(V) in the absence and presence of the AhR ligand, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), on the expression of CYP1A1 in HepG2 cells. Our results showed that

treatment of HepG2 cells with MMA(V), DMA(V), or TMA(V) alone significantly induces CYP1A1 mRNA, protein, and catalytic activity levels. Furthermore, when the cells were co-exposed to MMA(V), DMA(V), or TMA(V) in the presence of TCDD, there was further potentiation of the TCDD-mediated induction of CYP1A1 mRNA, protein, and catalytic activity levels. In addition, MMA(V), DMA(V), and TMA(V) in the absence and presence of TCDD induced the AhR-dependent XRE-driven luciferase reporter activity, suggesting an AhR-dependent mechanism. In conclusion, this is the first demonstration that As(III) metabolites, MMA(V), DMA(V), and TMA(V) induce CYP1A1 mRNA, protein, and catalytic activity levels in an AhR-dependent mechanism and represents a novel mechanism by which As(III) causes carcinogenicity. Supported by NSERC Discovery Grant RGPIN 250139-12.

**PS 2293 Comparative Oxidation State Specific Analysis of Arsenic by High-Performance Liquid Chromatography-Inductively Coupled Plasma-Mass Spectrometry and Hydride Generation-Cryotrapping-Atomic Absorption Spectrometry.**

J. Currier<sup>1</sup>, R. Saunders<sup>2</sup>, L. Ding<sup>2</sup>, W. M. Bodnar<sup>3</sup>, P. Cable<sup>3</sup>, T. Matoušek<sup>4</sup>, J. Creed<sup>5</sup> and M. Styblo<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>4</sup>Institute of Analytical Chemistry of the ASCR, Brno, Czech Republic; <sup>5</sup>Microbiological and Chemical Exposure Assessment Research Division, NERL, US EPA, Cincinnati, OH.

Several methods are used for quantifying the toxic inorganic arsenic (iAs) metabolites, methylarsonous acid (MAs<sup>III</sup>) and dimethylarsinous acid (DMAs<sup>III</sup>), including reversed-phase high-performance liquid chromatography-inductively coupled plasma-mass spectrometry (HPLC-ICP-MS) and hydride generation-cryotrapping-atomic absorption spectrometry (HG-CT-AAS). While HG-CT-AAS has consistently detected these arsenicals in biological samples, HPLC-ICP-MS has provided contradictory results. Here, we compare the capacities of both methods to detect and quantify MAs<sup>III</sup> and DMAs<sup>III</sup> in an in vitro methylation system containing recombinant human arsenic (+3 oxidation state) methyltransferase (AS3MT), S-adenosyl methionine, a non-thiol reductant tris(2-carboxyethyl)phosphine, and arsenite (iAs<sup>III</sup>) or MAs<sup>III</sup> as substrates. HPLC separation of the in vitro methylation mixture resulted in significant losses of MAs<sup>III</sup> and DMAs<sup>III</sup> with total arsenic recoveries below 25%. Ultrafiltration showed that both MAs<sup>III</sup> and DMAs<sup>III</sup> are bound to AS3MT. Oxidation of the mixture with H<sub>2</sub>O<sub>2</sub> prior to HPLC separation increased arsenic recoveries to ~95% but oxidized MAs<sup>III</sup> and DMAs<sup>III</sup>, thus preventing quantification of these metabolites. In contrast, direct HG-CT-AAS analysis revealed large quantities of MAs<sup>III</sup> and DMAs<sup>III</sup> and high total arsenic recoveries (>72%) after cysteine treatment. These data suggest that HPLC-ICP-MS can provide false-negative results when used for analysis of MAs<sup>III</sup> or DMAs<sup>III</sup> in biological samples containing protein at concentrations as low as those commonly found in human urine.

**PS 2294 The Retention of Trivalent Arsenic Metabolites in Urothelial Cells Is Associated with Markers of As Exposure and Diabetes.**

M. Styblo<sup>5</sup>, J. Currier<sup>1</sup>, C. González-Horta<sup>2</sup>, L. M. Del Razo<sup>3</sup>, B. Sánchez-Ramírez<sup>2</sup>, L. Ballinas-Casarrubias<sup>2</sup>, G. G. García-Vargas<sup>4</sup>, M. C. Ishida<sup>2</sup>, R. Saunders<sup>2</sup>, Z. Drobna<sup>2</sup> and D. Loomis<sup>6</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Universidad Autónoma de Chihuahua, Chihuahua, Mexico; <sup>3</sup>CINVESTAV-IPN, Mexico City, Mexico; <sup>4</sup>Universidad Juárez del Estado de Durango, Durango, Mexico; <sup>5</sup>University of Nebraska Medical Center, Omaha, NE; <sup>6</sup>Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Chronic exposure to inorganic arsenic (iAs) in drinking water has been linked to an increased prevalence of diabetes. Laboratory evidence suggests that methylarsonous acid (MAs<sup>III</sup>) and dimethylarsinous acid (DMAs<sup>III</sup>) that are formed in the course of iAs metabolism contribute to the diabetogenic effects of iAs exposure. However, no data are available on tissue concentrations of these toxic metabolites in humans. Here, we used a newly developed hydride generation(HG)-cryotrapping(CT)-inductively coupled plasma-mass spectrometry method with limits of detection of 0.04-2 pg As to examine the retention of tri- and pentavalent metabolites of iAs in urinary bladder exfoliated cells (BECs) isolated from urine of 343 residents of Chihuahua, Mexico who ingest drinking water contaminated with up to 400 ppb As. The urinary metabolites of iAs were measured by HG-CT-atomic absorption

spectrometry. The sum of As species in BECs ranged from 0.8 to 3,137 pg As/10,000 cells. Notably, iAs was the major species retained in BECs (~66% of total As). MAs<sup>III</sup> and DMAs<sup>III</sup> accounted for 8 and 2% of total As. We found positive statistically significant correlations between the concentrations of As species in BECs and in urine ( $r = 0.12-0.55$ ,  $p < 0.001$ ). When adjusted for age, sex, and BMI, trivalent arsenicals retained in BECs were significantly correlated with markers of diabetes, fasting plasma glucose (FPG) and 2-hour plasma glucose (2HPG) ( $r = 0.13-0.20$ ,  $p < 0.001$ ). Urinary iAs, MAs, and DMAs also correlated with FPG and 2HPG ( $r = 0.15-0.21$ ,  $p < 0.001$ ). Thus, both urinary metabolites of iAs and the metabolites retained in BEC can be used as biomarkers of the diabetogenic effects of iAs exposure.

**PS 2295 Oxidation State Specific Analysis of Arsenic Species in Tissues of Wildtype and Arsenic (+3 Oxidation State) Methyltransferase (As3mt) Knockout Mice.**

C. Douillet<sup>2</sup>, J. Currier<sup>1</sup>, R. Saunders<sup>2</sup>, Z. Drobna<sup>2</sup> and M. Styblo<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC.

As3mt catalyzes the conversion of inorganic arsenic (iAs) to methylated metabolites, including methylarsonite (MAs<sup>III</sup>) and dimethylarsinite (DMAs<sup>III</sup>). While this enzyme is critical for the detoxification of ingested iAs, MAs<sup>III</sup> and DMAs<sup>III</sup> are more toxic than iAs. The As3mt-KO mice can thus be used to explore the role of MAs<sup>III</sup> and DMAs<sup>III</sup> in the adverse effects of iAs exposure. Wild-type (WT) C57BL/6 mice exposed to 50 ppm As as arsenite (iAs<sup>III</sup>) in drinking water developed diabetes characterized by impaired glucose tolerance without insulin resistance. Methylated arsenicals were detected in tissues maintaining glucose homeostasis, but the oxidation state of As was not determined. Our recently developed HG-CT-AAS method for the oxidation state specific speciation of As in complex biological matrices was used to compare retention of tri- and pentavalent As species in tissues of WT and As3mt-KO mice drinking water with iAs. As3mt-KO mice were exposed to 0, 15, 20, 25 or 30 ppm and WT mice to 50 ppm As as iAs<sup>III</sup> for 4 weeks. As3mt-KO mice retained almost exclusively iAs; iAs<sup>III</sup> was the most prevalent species in liver, pancreas, adipose, lung, heart, and kidney, ranging from 53 to 74% of total As. Methylated arsenicals did not exceed 10% of total As in any tissue. Tissues of WT mice retained iAs and methylated arsenicals; iAs<sup>III</sup>, MAs<sup>III</sup> and DMAs<sup>III</sup> represented 55-68% of the total As in the liver, pancreas, and brain. High levels of MAs<sup>III</sup> were found in the intestine and intestinal content of WT, but not As3mt-KO mice, suggesting that intestinal bacteria are not a major source of methylated As species. Our results indicate that internal total As doses in tissues critical to glucose homeostasis (liver, pancreas, skeletal muscle, adipose) equivalent to WT mice can be achieved in As3mt-KO mice after exposure to 25 and 30 ppm As. Future studies will compare the diabetogenic effects of iAs exposure in WT and As3mt-KO mice.

**PS 2296 Photo-Activatable GFP-Labeled Rat Glucocorticoid Receptor (paGFP-rGR) As Model to Study Effects of Arsenic on Endocrine Receptor Activation and Cellular Localization.**

S. K. Schmalig<sup>1,3</sup>, F. Zandbergen<sup>1</sup>, A. Adebayo<sup>1,2</sup>, C. M. Connolly<sup>1,4</sup>, V. Chatikavanij<sup>1</sup>, J. E. Bodwell<sup>5</sup> and J. W. Hamilton<sup>1,2</sup>. <sup>1</sup>Marine Biological Laboratory, Woods Hole, MA; <sup>2</sup>Brown University, Providence, RI; <sup>3</sup>Bridgewater State University, Bridgewater, MA; <sup>4</sup>Valdosta State University, Valdosta, RI; <sup>5</sup>Dartmouth Medical School, Lebanon, NH.

Exposure to arsenic (As) is associated with an increased risk of many serious illnesses including several types of cancer, type 2 diabetes, cardiovascular disease, and reproductive and developmental problems. Previous research showed that As can act as an endocrine disruptor, altering the regulation of gene expression by numerous nuclear hormone receptors, including the Glucocorticoid Receptor (GR). At very low doses (0.05-1  $\mu$ M) As enhanced hormone-mediated, GR-regulated gene expression by 2- to 3-fold. Conversely, at intermediate non-cytotoxic concentrations (1-5  $\mu$ M) As inhibits receptor-mediated gene expression. We have hypothesized that these differential effects reflect separate mechanisms with different targets and that the inhibited activation could be caused by 1) altered rate of hormone receptor translocation to the nucleus, 2) altered number of receptors that translocate, 3) altered steady-state nuclear levels of receptor (e.g., by decreases in nuclear export), 4) altered efficiency of receptor function, or some combination of these. To test this, we used HEK293 cells to generate a cell line stably expressing rat GR fused to photo-activatable Green Fluorescent Protein (HEK293-paGFP-rGR), allowing

for intracellular tracking of GR using microscopy. The paGFP-rGR behaves biochemically in a similar manner as native GR. PaGFP-rGR mediates hormone-induced gene expression and microscopy showed that the rate and extent of nuclear translocation of paGFP-rGR increase in a concentration dependent manner in response to synthetic glucocorticoid. We found that intermediate As concentrations reduce this translocation. (Funded by NIH-NIEHS SRP (P42 ES007373), NSF REU (0115378), and NIH-NRSA (2 T32 ES 7272-21))

## PS 2297 **In Utero Arsenic Exposure and Epigenetic Changes in the Mouse Liver: Comparisons with Transcriptional Modulation.**

K. Bailey<sup>1</sup>, D. Rojas<sup>2</sup>, Z. Drobna<sup>3</sup> and R. C. Fry<sup>1,2</sup>. <sup>1</sup>*Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>3</sup>*Department of Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Chronic exposure to high levels of iAs in drinking water is associated with cancers of the skin, urinary bladder, lung, liver, and prostate in humans. Exposure to iAs during fetal development has been of particular concern as this developmental time point is often particularly sensitive to the effects of environmental toxicants. In C3H and CD1 mice, iAs acts as a complete transplacental carcinogen in which male offspring born to pregnant CH3 and CD1 females exposed to 85 ppm iAs in drinking water during the latter part of gestation [gestational day (GD) 8-18] have an increased incidence of hepatocellular carcinomas (HCCs) in adulthood, a major form of cancer associated with chronic iAs exposure in humans. Analyses of normal-appearing liver tissue from transplacentally-exposed newborns and adults with liver tumors have previously reported perturbations in gene expression and/or global DNA methylation levels and suggested these alterations may contribute to iAs-associated liver carcinogenesis. Here, we examined the gene expression profiles of >35,000 transcripts and the DNA methylation levels of >15,000 CpG islands associated with gene promoters of fetal male CD1 mice (GD 18) transplacentally exposed to a hepatocarcinogenic dose (85 ppm) of iAs (GD 8-18). Compared to vehicle-exposed mice, we observed statistically significant changes in the transcriptome (308 transcripts) and DNA methylome (191 gene promoters) in gestationally-exposed fetal males ( $p < 0.05$ , 1.3-fold change vs. controls). Surprisingly, when using these same criteria for the identification of changes in DNA methylation and transcript levels, there were no common genes. These results suggest alterations in the DNA methylome may not necessarily be predictive of changes in gene expression and the relevance of these alterations in disease development warrant further study.

## PS 2298 **Arsenic Compromises Airway Epithelial Barrier Properties in Primary Mouse and Immortalized Human Cell Cultures.**

C. L. Sherwood<sup>1,4,5</sup>, A. Liguori<sup>1,4,5</sup>, C. Olsen<sup>1,4</sup>, C. Lantz<sup>2,4,5</sup>, J. L. Burgess<sup>4,6</sup> and S. Boitano<sup>1,3,4</sup>. <sup>1</sup>*Arizona Respiratory Center, AZ Health Sciences Ctr, Tucson, AZ;* <sup>2</sup>*Cell and Molecular Medicine, AZ Health Sciences Ctr, Tucson, AZ;* <sup>3</sup>*Physiology, AZ Health Sciences Ctr, Tucson, AZ;* <sup>4</sup>*Southwest Environmental Health Sciences Ctr, University of Arizona, Tucson, AZ;* <sup>5</sup>*Bio5 Institute, University of Arizona, Tucson, AZ;* <sup>6</sup>*Mel & Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ.*

Arsenic is a lung toxicant that can lead to respiratory illness through inhalation and ingestion. Lung effects from arsenic exposure include lung cancer and obstructive lung disease, as well as reductions in lung function and immune response. As a key player in innate immune defense, airway epithelial cells provide a barrier that protects underlying tissue from inhaled particulates, pathogens, and toxicants. In animal and human studies, arsenic ingestion can lead to altered lung function suggestive of epithelial barrier dysfunction. In this report, we evaluated the effects of a five-day exposure to environmentally relevant levels of arsenic (i.e.,  $< 4 \mu\text{M}$  as Na-arsenite; equivalent to  $\sim 300 \text{ ppb}$ ) on airway epithelial barrier properties. In a primary mouse tracheal epithelial (MTE) cell model we found that both micromolar ( $3.9 \mu\text{M}$ ) and sub-micromolar ( $0.8 \mu\text{M}$ ) arsenic concentrations reduced transepithelial resistance, a measure of barrier function. Immunofluorescent staining of arsenic-treated MTE cells showed altered localization patterns of barrier proteins claudin-1 and occludin at cell-cell contacts. In order to better quantify arsenic-induced changes in barrier molecular components we used the same arsenic exposure on an immortalized human bronchial epithelial cell line (16HBE14o-). We found that arsenic increased the protein expression of claudins -4, -5, and -7 as well as the mRNA levels of claudin-7 in 16HBE14o- cells. Additionally, micromolar levels of arsenic resulted in altered phosphorylation of occludin. In summary, exposure to environmentally relevant levels of arsenic can alter both the structure and function of airway epithelial barrier constituents and, consequently, basic innate immune defense in the airway.

## PS 2299 **Associations of Single Nucleotide Polymorphisms and Haplotypes in Arsenic [+3 Oxidation State] Methyltransferase (AS3MT) with Arsenic Metabolism: A Case Study in Arsenic Contaminated Areas from Vietnam.**

T. Agusa<sup>1</sup>, T. Kunito<sup>2</sup>, N. M. Tue<sup>1</sup>, V. M. Lan<sup>3</sup>, T. B. Minh<sup>4,5</sup>, P. K. Trang<sup>3</sup>, J. Fujihara<sup>6</sup>, H. Takeshita<sup>6</sup>, S. Takahashi<sup>1</sup>, P. H. Viet<sup>3</sup>, S. Tanabe<sup>1</sup> and H. Iwata<sup>1</sup>. <sup>1</sup>*Center for Marine Environmental Studies (CMES), Ehime University, Matsuyama, Japan;* <sup>2</sup>*Shinshu University, Matsumoto, Japan;* <sup>3</sup>*Center for Environmental Technology and Sustainable Development (CETASD), Vietnam National University, Hanoi, Vietnam;* <sup>4</sup>*Faculty of Chemistry, Vietnam National University, Hanoi, Vietnam;* <sup>5</sup>*United Nations Industrial Development Organization (UNIDO), Hanoi, Vietnam;* <sup>6</sup>*Shimane University Faculty of Medicine, Izumo, Japan.*

To understand associations of single nucleotides polymorphisms (SNPs) and haplotypes in arsenic [+3 oxidation state] methyltransferase (AS3MT) with arsenic metabolism, we investigated local residents from arsenic-contaminated areas of Vietnam. Analysis of 18 SNPs revealed that there were four haplotype (HT) groups (HT1; AS3MT 03963 – 06144 – 12390 – 14215 – 35587 – 37950, HT2; AS3MT 04602 – 35991, HT3; AS3MT 05913 – 09749 – 27215, HT4; AS3MT 358903 – 37853) in this population. Urinary monomethylarsonic acid (MMA)/inorganic As (IA) and MMA/dimethylarsinic acid (DMA) ratios were used as indicators of arsenic metabolism. AS3MT 12590 genotype and HT2 and 4 groups were significantly associated with MMA/IA. On the other hand, MMA/DMA was explained by AS3MT 07395, 08979, 12590, and 14458 genotypes. Because association of AS3MT 14458 with arsenic metabolism observed in this study was consistent with other populations in other previous studies, this SNP may significantly affect the metabolism regardless ethnicity.

## PS 2300 **Mechanism of Arsenic Carcinogenesis in Normal Human Lung Cells.**

H. Xie<sup>1,2,3</sup>, J. Wise<sup>1,2,3</sup>, S. Martin<sup>1</sup> and S. Huang<sup>1</sup>. <sup>1</sup>*Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME;* <sup>2</sup>*Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME;* <sup>3</sup>*Applied Medical Sciences, University of Southern Maine, Portland, ME.*

Arsenic originates from both geochemical and numerous anthropogenic activities including mining, combustion of fossil fuels, wood preservation, agriculture and metallurgy. Exposure of the general public to significant levels of arsenic is widespread. Arsenic is a well-documented human carcinogen. Long-term exposure to low levels of arsenic in drinking water have been linked to bladder, lung, kidney, liver, prostate, and skin cancer. Among them, lung cancer is of great public concern. However, little is known about how arsenic causes lung cancer and few studies have considered effects in normal human lung cells. The purpose of this study was to determine the cytotoxicity and genotoxicity of arsenic in human primary bronchial fibroblast (NHBF) and epithelial cells (NHBE). Our data show that arsenic induces a concentration-dependent increase in cell death after short (24 h) or longer (120 h) exposures. Arsenic induces concentration-dependent but not time-dependent increase in chromosome damage in fibroblasts. No chromosome damage is induced after either 24 h or 120 h arsenic exposure in epithelial cells. Using comet assay and gamma-H2A.X foci forming assay, we found that 24 h or 120 h exposure to arsenic induces increases in DNA double strand breaks in both cell lines. These data indicate that arsenic is cytotoxic and genotoxic to human lung primary cells. However, the mechanism of arsenic-induced genotoxicity could be different in bronchial epithelial cells than that in fibroblasts. This work is supported by NIEHS grant R15ES021587 (H.X.) and by NIEHS grant ES016893 (J.P.W.). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

## PS 2301 **Gene Expression Alterations among Adults with Chronic Arsenic Exposure in Bangladesh.**

Y. Chervona<sup>1</sup>, A. Muñoz<sup>1</sup>, T. Kluz<sup>1</sup>, M. V. Gamble<sup>2</sup> and M. Costa<sup>1</sup>. <sup>1</sup>*Environmental Medicine, New York University School of Medicine, New York, NY;* <sup>2</sup>*Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, NY.*

Background: Exposure to arsenic (As) is associated with an increased risk of several cancers, as well as, cardiovascular disease, and childhood neuro-developmental deficits. Arsenic compounds are weakly mutagenic, but can alter DNA methylation and post-translational histone modifications (PTHMs) levels, as well, gene expression.

Methods: Water and urinary arsenic, as well as, gene expression profiles were analyzed in peripheral blood mononuclear cells (PBMCs) from a subset of participants (N=20) of a folate clinical trial in Bangladesh (FACT study). Gene expression profiling was performed using Affymetrix exon ST 1.0 arrays. Differentially expressed genes were identified in a global analysis and real-time PCR was used to validate the expression findings.

Results: Expression analysis revealed that a total of 561 and 1198 genes had a change in expression ( $p=0.05$ ) with increasing arsenic exposure, in males and females respectively. When examined together (N=20), 177 genes had a  $> 1.25$  fold change in expression. The analysis revealed that some genes appear to be gender specific (i.e. adenosylhomocysteinase (AHCY), oxoglutarate (alpha-ketoglutarate) dehydrogenase (lipoamide) (OGDH), lysine (K)-specific demethylase 5C/D (JARID1C/D), and SET domain containing (lysine methyltransferase) 7, while others changed in the same direction among both males and females (i.e. potassium voltage-gated channel, Isk-related family, member 3 (KCNE3), elongation factor, RNA polymerase II, 2 (ELL2), NADH dehydrogenase (ubiquinone) 1 beta sub-complex, 8 (NDUFB8), lactate dehydrogenase D (LDHD). Moreover, both males and females exhibited a decrease in the expression of DNA repair genes with increasing arsenic exposure.

Conclusion: Chronic exposure to As is associated with gender specific alterations in gene expression profiles of Bangladeshi adults.

## **PS 2302 Changes in Regulation of Lipid Metabolism from Low-Dose Arsenic Exposure.**

A. Adebayo<sup>1,2</sup>, F. Zandbergen<sup>2</sup> and J. W. Hamilton<sup>1,2</sup>. <sup>1</sup>Brown University, Providence, RI; <sup>2</sup>Marine Biological Laboratory, Woods Hole, MA.

Arsenic (As) is naturally present in the environment, and it can be found at various levels in drinking water resulting from contamination of groundwater. Exposure to As is a major health concern because it is associated with an increased risk of various diseases such as type II diabetes, cardiovascular disease (CVD), several types of cancer, and reproductive and developmental problems. Type II diabetes and CVD are in turn associated with altered blood lipid levels and obesity. Indeed, excess adipose tissue and altered blood lipid levels have been shown to be strong predictors for development of type II diabetes and CVD. Previous cell culture studies have shown that arsenic affects adipogenesis, and a recent *in vivo* study found that arsenic exposed dams displayed alterations in overall lipid metabolism and triglyceride levels. In the current study, we developed a model to investigate changes in transcription factors involved in regulating lipid metabolism. We exposed adult male C57BL/6J mice to 0, 10, or 100 ppb As in drinking water for 6 weeks, and then isolated various tissues from these mice in the fed or fasted state. We analyzed expression of genes and proteins involved in lipid metabolism and regulation in adipose tissue and liver using quantitative PCR and western blotting. Our results show alterations in expression of transcription factor SREBP-1c and its target genes, including diglyceride acyltransferase (DGAT2) and fatty acid synthase (FAS). These results indicate that arsenic can alter the expression of genes and proteins involved in fatty acid synthesis and triglyceride production, which may contribute to how arsenic exposure may cause metabolic imbalances in exposed individuals.

(Funded by NIH-NIEHS Superfund Research Program (P42 ES007373), and NIH-NRSA Training Grant (2 T32 ES 7272-21))

## **PS 2303 Survey of Arsenic in Drinking Water in the Southern Gobi Region of Mongolia.**

P. B. Olkhanud<sup>1</sup> and E. K. Silbergeld<sup>2</sup>. <sup>1</sup>Department of Environmental Health Sciences, HSUM, Ulaanbaatar, Mongolia; <sup>2</sup>Department of Environmental Health Sciences, JHSPH, Baltimore, MD.

Arsenic (As) is a naturally occurring toxicant of global concern. The extent of As content in ground water, however, has not been fully assessed in Mongolia, where all drinking water is sourced from groundwater. Mongolia is currently experiencing rapid mining development, especially in the southern region, which is triggering population growth that will drive increasing water demand for safe drinking water. Moreover, the high prevalence of As exposure and As related diseases just across the border in northern China further highlights the necessity for relevant studies in Mongolia. Thus, this study attempts to determine As concentrations in water sources near the Oyu Tolgoi mine in the Southern Gobi region of Mongolia and investigate its relationship with area, type and depth of the well, and develop a geo-statistical map describing the spatial pattern of As concentration in the drinking water sources. The results of our study show that the current and the potential future exposure to As in the Southern Gobi region of Mongolia is significant. In terms of current exposures, almost half of the Herder's wells that are currently in use and 16.4% of the Monitoring boreholes contain As levels above the World Health Organization's recommended level. The results also indicate different levels of As concentrations in the water from different types of tube-wells even in the same area

and a decreasing tendency of As concentration with increasing well depth suggesting different aquifers in that region. Overall, As in the drinking water sources in the Southern Gobi region of Mongolia is a critical public health issue, especially given the current mining boom in this region.

## **PS 2304 The Role of miRNA-29B in Dysregulation of Mesenchymal Stem Cell Differentiation to Adipocytes by Low-Dose Arsenic Exposure.**

K. Beezhold, L. R. Klei, Y. Garciafigueroa and A. Barchowsky. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Human exposure to environmental toxicants is a well-known cause of disease and low chronic exposure may contribute significantly to longitudinal risk of chronic diseases. Pathogenic mechanisms for many environmental toxicants remain poorly defined, which limits development of effective interventions to protect against environmentally-derived chronic diseases. Low dose exposure to trivalent arsenic (AsIII) in drinking water is a major public health concern that contributes to a number of diseases and pathologies, including cardiovascular and metabolic diseases. While progress has been made in the understanding of the pathogenic signaling events contributing to arsenic-induced disease, many responsible mechanisms have not been elucidated. Control of miRNA expression and action presents a promising new means for understanding downstream effects of arsenic exposure; however, there are few reports of how arsenic regulates expression of miRNA and impacts their function. Our preliminary data indicated induction of miR-29 in white and brown adipose tissue isolated from arsenic exposed (100 µg/L in drinking water for 2 wk) mice and in human adipose-derived mesenchymal stem cells (hMSC) as arsenic inhibited adipocyte differentiation. Further analysis via real-time PCR revealed a 2-3 fold induction of miR-29b following arsenic exposure in hMSCs. The miR-29 family has been indicated by multiple studies to be involved in cardiovascular and metabolic diseases, with reduced stem or progenitor cell differentiation capacity believed to be a fundamental means for disease progression. Analysis of downstream proteins by western blot indicates that C/EBP- $\zeta$ , an inhibitor of adipogenesis, is upregulated in arsenic treated cells and this upregulation is diminished in cells stably expressing an inhibitor of miR-29b. These data show that exposure to low-dose arsenic effects expression of miRNA in hMSCs, negatively affecting their ability to properly differentiate into adipocytes. Supported by NIEHS grant R01ES013781.

## **PS 2305 Human Exposure to Arsenic in Drinking Water Is Associated with Increased Protein Halogenation in Blood and Sputum.**

R. Zangar<sup>1</sup>, R. Lantz<sup>2</sup>, R. B. Harris<sup>2</sup>, J. L. Burgess<sup>2</sup>, M. K. O'Rourke<sup>2</sup>, M. M. Montenegro<sup>3</sup>, M. M. Matzke<sup>1</sup>, B. Webb-Robertson<sup>1</sup> and J. G. Pounds<sup>1</sup>. <sup>1</sup>PNNL, Richland, WA; <sup>2</sup>University of Arizona, Tucson, AZ; <sup>3</sup>Instituto Tecnológico de Sonora, Tucson, Mexico.

Chronic arsenic exposure to environmentally high levels ( $> 200$  ppb) in geologically contaminated drinking water has been correlated with increased incidence of chronic lung disease, including cough, bronchitis, shortness of breath and obstructive or restrictive lung disease. However, the effects of chronic arsenic exposures at lower levels (e.g.,  $< 100$  ppb), which are prevalent in the United States and near the current EPA MCL of 10 ppb, have not been well studied. Eosinophils and neutrophils are associated with lung disease, and these granulocytes selectively secrete peroxidases that halogenate protein tyrosines. A custom ELISA microarray platform was used to measure the halogenation of 24 individual proteins in paired sputum and serum samples from 55 subjects in 4 Mexican cities with differing arsenic levels. Eighteen halogenated proteins were significantly correlated (Spearman's rank correlation,  $p < 0.05$ ) between the two fluids (highest  $r$  value  $-0.58$ ). Halogenated protein results were compared to total arsenic levels in urine using multiple linear regression, accounting for the study participants' age, BMI and resident city. The total urine arsenic was significantly associated ( $P \leq 0.05$ ) with the halogenation of 7 proteins in both plasma and serum (MMP1, 2 and 9, EGFR, VEGF, HBEGF, TGF $\alpha$ ) and 11 additional sputum-only proteins (PDGF, E-selectin, EGF, SP-A, leptin, HGF, CD14, IGF1, RANTES, TNF, ceruloplasmin) proteins. These results support the conclusion that environmental arsenic exposure is associated with elevated markers of pulmonary granulocyte activity. Replication in an independent study population is warranted to confirm our results. Supported by P42 ES4940, P30 ES006694, P50 CA095060, and U54 ES016015.

**PS 2306 Evaluating Arsenic Speciation in Fish, Shellfish, and Seaweed Using LC-ICPMS.**

B. D. Laird and L. Chan. *Department of Biology, University of Ottawa, Ottawa, ON, Canada.*

**Rationale & Objectives:** Risk due to dietary arsenic (As) exposure is speciation dependent. For example, although elevated As concentrations are commonly observed in fish, shellfish, and seaweed, the health risks are generally assumed to be low due to the predominance of organoarsenicals (e.g. arsenobetaine). However, little speciation data is available to support this assumption for many types of seafood. The objective of the research described in this poster is to fill this data gap by quantifying the relative contribution of various As species for a variety of store-bought seafood samples.

**Methodology:** Seafood samples were purchased from several supermarkets for As speciation analysis using Liquid Chromatography Inductively Coupled Plasma Mass Spectrometry (LC-ICP-MS). The samples included cherry stone clams, oyster shell clams, tiger prawn, halibut, mackerel, ling cod, marlin, snapper, yellow grouper, and Porphyra seaweeds. Extraction of As species was performed with a methanol-ammonium carbonate solution using a DigiPREP block digestion system. Quantified As species included As(III), As(V), arsenobetaine, arsenocholine, dimethylarsinic acid, and monomethylarsonic acid.

**Results:** Total As concentrations ranged between 6 (king mackerel) and 135 (ling cod)  $\mu\text{g g}^{-1}$  (d.w.). The main contributor to As concentrations tended to be arsenobetaine, which ranged between 35% (yellow grouper) and 100% (king mackerel). As(V) was not a significant contributor (<1%) to total As concentrations in any of the samples.

**Conclusions:** Arsenobetaine was the major As species in most of the seafood samples tested. Future work will be done to assess whether As speciation in foods is modified when digested in simulated gastrointestinal fluids.

**PS 2307 Reduction of Arsenite-Enhanced Ultraviolet Radiation DNA Damage by Supplemental Zinc.**

K. L. Cooper, B. S. King, M. M. Sandoval, K. Liu and L. G. Hudson. *Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.*

Arsenic is a recognized human carcinogen and there is evidence that arsenic augments the carcinogenicity of DNA damaging agents such as ultraviolet radiation (UVR) thereby acting as a co-carcinogen. Inhibition of DNA repair is one proposed mechanism to account for the co-carcinogenic actions of arsenic. We and others find that arsenic interferes with the function of certain zinc finger DNA repair proteins. Furthermore, we reported that zinc reverses the effects of arsenic in cultured cells and a DNA repair target protein, poly (ADP-ribose) polymerase-1. The study objective was to determine whether zinc ameliorates the effects of arsenite on UVR-induced DNA damage in human keratinocytes and in an in vivo model. In order to investigate the potential zinc effects, normal human epidermal keratinocytes (HEKn) and SKH-1 hairless mice were exposed to arsenite, zinc or both before solar-simulated (ss) UVR exposure. Poly (ADP-ribose) polymerase activity and DNA damage in each treatment group were measured in normal human keratinocytes by immunocytochemistry and mutation frequencies at the hprt locus were measured. DNA damage was assessed by immunohistochemical staining of skin sections isolated from SKH-1 hairless mice. Cell-based findings demonstrate that ssUVR-induced DNA damage and mutagenesis are enhanced by arsenite, and supplemental zinc partially reverses the arsenite effect. In vivo studies confirm that zinc supplementation decreases arsenite-enhanced DNA damage in response to ssUVR exposure. From this data we can conclude that zinc offsets the impact of arsenic on ssUVR-stimulated DNA damage in cells and in vivo. This suggests that zinc supplementation may provide a strategy to improve DNA repair capacity in arsenic exposed human populations.

**PS 2308 Arsenic-Stimulated Adipose Fat Metabolism Is Mediated by G-Protein Coupled Receptors.**

Y. Garciafigueroa, L. R. Klei and A. Barchowsky. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Consumption of low to moderate levels of arsenic (As(III)) promotes a number of diseases that may stem from dysfunctional adipose tissue and glucose metabolism. As(III) inhibits adipocyte differentiation and insulin-stimulated glucose uptake. However, little is known of the impacts of As(III) on adipose lipid storage and lipolysis, as well as mechanisms through which As(III) affects lipolysis. We recently demonstrated that As(III)-inhibited human mesenchymal stem cell (hMSC) differentiation to adipocytes was mediated by G-protein coupled endothelin-1 receptors and hypothesized that a similar mechanism signals for As(III)-stimulated fat mobilization and utilization in mature adipocytes. To test this hypothesis, adipocytes

(identified by perilipin-coated, Nile red positive lipid droplets) derived from primary hMSC were exposed to 1  $\mu\text{M}$  As(III) for 24 to 72 h. As(III) stimulated lipolysis within 24 h relative to untreated adipocytes and caused a progressive loss of perilipin and lipid droplets over 72 h. As(III)-stimulated lipolysis was not associated with an increase in cAMP. However, pre-incubation of the adipocytes with the Gi-inhibitor, Pertussis toxin (Ptx), attenuated As(III)-stimulated lipolysis and lipid droplet loss. Selective inhibition of Gi-coupled endothelin-1 type A and B receptors (EDNRA/EDNRB) also attenuated the effects of As(III), but inhibition of other adipose Gi-coupled receptors involved in fat metabolism was ineffective. The endothelin receptors have different roles in the As(III) responses, since EDNRA inhibition was more effective in preserving lipid droplets and perilipin expression while blocking either endothelin receptor attenuated As(III)-stimulated lipolysis. These findings provide additional evidence that As(III) effects on adipogenesis, adipose cell function, and lipid metabolism are mediated through stimulation of specific G-protein coupled receptors. Supported by NIEHS grant R01ES013781 and R01ES013781-S1.

**PS 2309 Autophagy Is a Cell Self-Protective Mechanism against Arsenic-Induced Cell Transformation.**

G. Chen, T. Zhang and Y. Qi. *University of Kentucky, Lexington, KY.*

Subchronic exposure to arsenic increases the incidence of human cancers, such as skin, lung, colon and rectal cancer. The mechanism for arsenic-induced tumorigenesis is still not clear. It is generally believed that DNA damage and genomic instability, generated by arsenic-promoted oxidative stress, account largely for this process. The major sources of reactive oxygen species (ROS) are arsenic-damaged mitochondria. Autophagy is a catabolic process functioning in turnover of long-lived proteins and dysfunctional organelles such as mitochondria. Defects of autophagy under stress conditions promote genomic instability and increase the risk of tumorigenesis. In the present study using a human bronchial epithelial cell line, BEAS-2B cells, we investigated the role of autophagy in arsenic-induced cell transformation, an important step in arsenic tumorigenesis. Our results show that subchronic arsenic exposure induces BEAS-2B cell transformation accompanied with increased ROS generation and autophagy activation. However, the patterns for ROS and autophagy alteration are different. Arsenic exposure generated a prolonged and steady increase of ROS levels, while the activation of autophagy, after an initial boost by arsenic administration, decreases in response to subchronic arsenic exposure, although the activity is still higher than a non-treated control. Further stimulation of autophagy increases mitochondria turnover and decreases ROS generation as well as arsenic-induced cell transformation. Contrarily, inhibition of autophagy activity decreases mitochondria turnover and enhances arsenic-induced ROS generation and cell transformation. In addition, the mTOR signaling pathway is involved in arsenic-mediated autophagy activation. Our results suggest that autophagy is a cell self-protective mechanism against arsenic-induced cell transformation.

**PS 2310 In Utero Low-Level Arsenite Exposure Alters Blood Biochemistry in Adult Mice Predisposing for Liver Steatosis.**

P. Sanchez Soria<sup>1</sup>, S. Quach<sup>1</sup>, R. N. Hardwick<sup>1</sup> and T. D. Camenisch<sup>1, 2, 3</sup>.

<sup>1</sup>College of Pharmacy, University of Arizona, Tucson, AZ; <sup>2</sup>Steele Children's Research Center, University of Arizona, Tucson, AZ; <sup>3</sup>Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ.

Chronic exposure to low levels of arsenic in drinking water has been strongly correlated to higher incidence of hypertension as well as other cardiovascular diseases. Additionally, recent animal studies have shown that chronic exposure to 100 parts per billion (ppb) sodium arsenite resulted in a significant increase in systolic blood pressure, and a similar increase was observed in diastolic blood pressure. Additionally, mice exposed to arsenic developed concentric left ventricular hypertrophy. In order to explore the mechanisms of arsenic-related adult disease, we wanted to evaluate how in-utero exposure contributes to the development of disease, later in adulthood. Mice were exposed to either 100 ppb in-utero, or sodium chloride (control) and were maintained for 34 weeks through adulthood. Blood biochemistry analysis was done, and organs were harvested for histological assessment, as well as protein and RNA studies. Results show that mice exposed to arsenic in-utero had significantly elevated blood glucose levels, as well as significantly higher cholesterol, LDL and HDL levels with no significant change in weight, when compared to control mice. Furthermore, liver enzymes alkaline phosphatase (ALP), alanine transaminase (ALT), and aspartate transaminase (AST) were elevated in the in-utero exposed mice, when compared to controls. Consistent with these results, oil red-o stain of liver sections show moderate steatosis and higher lipid content in the arsenic treated animals. Taken together, these results show that exposure to arsenic early in life may predispose for the development of metabolic diseases as well as cardiovascular ones.

## PS 2311 Arsenic Impairs Adult Muscle Stem Cells and Skeletal Muscle Integrity.

A. Roperti<sup>1</sup>, D. Stoltz<sup>2</sup>, B. Goodpaster<sup>3</sup>, E. Brown<sup>4</sup>, G. Distefano<sup>4</sup>, A. Barchowsky<sup>5</sup> and F. Ambrosio<sup>4</sup>. <sup>1</sup>Bioengineering, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Medicine, University of Pittsburgh, Pittsburgh, PA; <sup>4</sup>Physical Medicine and Rehabilitation, University of Pittsburgh, Pittsburgh, PA; <sup>5</sup>Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.

Arsenic (As(III))-contaminated drinking water is a global health concern as chronic As(III) exposure increases risk for a number of cancers, diseases, and disabilities. As(III) exposure is associated with skeletal muscle weakness, impaired gait, and fatigue. While As(III) and other metals impact embryonic stem cells and development, it is not clear how As(III) impairs adult stem cell functions in tissue maintenance and regeneration. We hypothesized that As(III) exposure affects adult skeletal muscle stem cell (MuSC) metabolism and function to disrupt muscle maintenance and repair capacity. To investigate this hypothesis, we examined muscle integrity, MuSC metabolism, and phenotype in hind limb muscles isolated from mice exposed to 0 or 100 µg/L As(III) for 5 weeks. Histological analysis demonstrated disrupted muscle bundles with perivascular fatty inclusions and ultrastructural analysis revealed large, fused muscle cell mitochondria in As(III) exposed mice relative to control. MuSC isolated from the As(III) mice and cultured without As(III) for multiple doublings retained a phenotype with mitochondrial myopathy, autophagy, uncoupled oxidative phosphorylation, and impaired differentiation. This phenotype was a maladaptation to stress, as As(III) altered growth kinetics and resistance to oxidative stress. The phenotype and altered growth kinetics were reproduced in primary human MuSCs. These findings suggest that direct effects on MuSC mitochondrial phenotype, metabolism, and differentiation underlies muscle impairment observed following As(III) exposures. Supported by NIEHS grant R01 ES0136781, NIH K12 for Physical and Occupational Therapists (K12 HD055931) and NIA grant K01 1K01AG039477.

## PS 2312 Arsenic Induces Premature Senescence and Vascular Calcification *In Vivo* and *In Vitro*.

V. Sorribas, C. Sosa and A. Martin-Pardillos. *Laboratory of Molecular Toxicology, University of Zaragoza, Zaragoza, Spain.* Sponsor: A. Anadon.

Arsenic is a natural vasculotoxic agent with ubiquitous exposure to both, human and animals. Several mechanisms have been proposed to explain the vascular toxicity of arsenic. This work describes new mechanisms that affect the vascular smooth muscle cells (VSMC): stress-induced premature senescence (SIPS), dedifferentiation, and medial vascular calcification.

Rat aortic VSMC were treated with 1-100 µM of sodium arsenate (AsV), arsenite (AsIII), monomethylarsonic acid, or dimethylarsinic acid. None of the treatments induced VSMC calcification in the presence of 1 mM inorganic phosphate (Pi), but 1 µM AsIII increased calcification when induced with 2.5 mM Pi. Cytotoxicities of the four arsenic species were assayed with an LDH assay and acridine orange/ethidium bromide staining. Results revealed that the calcification increase with AsIII was accompanied by a rise in cytotoxicity due to simultaneous incubation with 2.5 mM Pi. This calcification increase was also observed in the aortas of an established vascular calcification model: 5/6 nephrectomized rats fed with a high Pi diet and treated with vitamin D3. Several known mechanisms that might explain arsenic toxicity in our experimental model were discarded: apoptosis, oxidative stress, and inflammasome activation. Nevertheless, both senescence-associated β-galactosidase (SA β-gal) activity and p21 expression were increased by AsIII, which reveals the induction of SIPS. AsIII also caused dedifferentiation of VSMC, as shown by the reduced expression of the VSMC markers SM22α and calponin. Senescence and similar patterns of gene expression were also observed in the aortas of healthy rats treated with 50 ppm AsV in drinking water for one month. In conclusion, both the premature senescence in aortic VSMC with phenotypic dedifferentiation and the increase of Pi-induced calcification are novel mechanisms of arsenic vasculotoxicity observed *in vitro* and *in vivo*.

## PS 2313 Prolonged iAs Exposure Leads to Aberrant Insulin Signaling in L6 Myocytes.

I. L. Druwe, J. J. Sollome, J. Gonzales and R. R. Vaillancourt. *Department of Pharmacology & Toxicology, The University of Arizona, Tucson, AZ.*

Diabetes mellitus is a metabolic syndrome characterized by inappropriate production of insulin or the inability of cells to respond to insulin. It is estimated that by the year 2050, 1 in 3 U.S. adults will have diabetes mellitus. Insulin is the principal hormone involved in lowering blood glucose and functions by suppressing liver

gluconeogenesis and glycogenolysis and by stimulating the glucose uptake in skeletal muscle and adipocytes. Recent epidemiological studies both in the USA and abroad have linked chronic ingestion of low levels of inorganic arsenic (iAs), an environmental toxicant, to the onset of diabetes mellitus. Although these observations have been met with some skepticism, there are few mechanistic studies to elucidate the mechanisms by which iAs perturbs insulin signaling. The few studies that have been performed have focused namely on adipocyte *in-vitro* models. Here we show that L6 myocytes, an insulin responsive cell line, exposed to low doses of iAs (0.25 to 2 µM) for 4 or 7 days showed a decreased insulin stimulated glucose uptake but no decrease in phospho-AKT or phospho-AS160. In addition, we found that phospho-ERK signaling decreased, while phospho-p38 MAPK signaling increased in response to prolonged iAs treatment. Interestingly enough increased p38 MAPK activity has been associated with insulin resistance. These data support the epidemiological evidence that chronic exposure to low, physiologically relevant levels of arsenite can contribute to insulin resistance and type 2 diabetes, and that the mechanisms involved are different than those produced by iAs in adipocyte cell models. And while the etiology of type 2 diabetes has yet to be elucidated these data show that in addition to pharmacological treatment and lifestyle modifications, environmental exposures should also be considered when evaluating the etiology of type 2 diabetes.

## PS 2314 Gene Expression Changes Associated with Chronic Low-Level Monomethylarsonous Acid Exposure in Human Urothelial Cells.

M. Medeiros<sup>1</sup>, T. Minh le<sup>1</sup>, D. J. Troup<sup>1</sup>, P. Novak<sup>2</sup> and A. Gandolfi<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, University of Arizona, Tucson, AZ; <sup>2</sup>Biology Centre ASCR, Institute of Plant Molecular Biology, Ceske Budejovice, Czech Republic.

Bladder cancer has been associated with chronic arsenic exposure. Monomethylarsonous acid [MMA(III)] is a metabolite of inorganic arsenic and has been shown to transform a human urothelial cell line (UROtsa). It was used as a model arsenical to examine the mechanisms of arsenical-induced malignant transformation of urothelium. A microarray analysis was performed to assess the transcriptional changes in UROtsa from chronic 50 nM MMA(III) exposure that leads to transformation at three months. The analysis revealed only minor changes in gene expression at one and two months of exposure, contrasting with substantial changes observed at three months of exposure. To assess the changes occurring between 2 and 3 months of exposure, incremental analysis was performed for 29 genes, covering 7 distinct pathways (mitogenic, PI3K/AKT, apoptosis, JAK/STAT, oxidative stress, DNA repair, and inflammation), that were found changed at 3 months of exposure based on the gene array analysis. Between 2 and 3 months of exposure, progressive alterations in the expression of several genes (i.e., PDGFRA, COX2, XAF1) were observed. These alterations are being correlated with expected phenotypic changes (i.e., hyper-proliferation, colony formation in soft agar) in the transforming cells. Since short-term exposure (up to two months) has not been shown to induce transformation, the gene expression changes observed for cultures treated up to 3 months and beyond suggest that a stress-threshold exists. This study was supported by the Superfund Basic Research Program Grant (NIH grant ES04940) from National Institute of Environmental Health Sciences, and the Trainee in Toxicology and Toxicogenomics (NIEHS grant ES007091). Additional support from NIH grant CA23074, and NIEHS grant ES06694.

## PS 2315 Multidrug Resistance Protein 1 Confers Resistance to Organic Arsenic Compound in HL-60 Cells.

H. Narenmandula, S. Xu and Y. Zhang. *Department of Pharmacology, Toxicology, and Biochemical Pharmaceutics, Zhejiang University, Hangzhou, China.* Sponsor: D. Thomas.

Arsenic trioxide is established as one of most effective drugs for treatment of patients with acute promyelocytic leukemia (APL). However, non-promyelocytic leukaemia HL-60 cells is exhibit resistant to As2O3, and little is known about the underlying resistance mechanism for As2O3 and its biomethylation products, namely, monomethylarsonous acid (MMAIII) on the treatment of tumors. In the present study, we investigated the molecular mechanisms underlying iAsIII and its intermediate metabolite MMAIII-induced anticancer effects in the HL-60 cells. Here, we show that the HL-60 cells exhibit resistance to inorganic iAsIII (IC50=10 µM), but are relatively sensitive to its intermediate MMAIII (IC50=3.5 µM). Moreover, we found that the multidrug resistance protein 1 (MRP1), but not MRP2, are expressed in HL-60 cells, which reduced the intracellular arsenic accumulation, and conferred resistance to inorganic iAsIII and MMAIII. Pretreatment of HL-60 with MK571, an inhibitor of MRP1, significantly increased iAsIII and MMAIII-induced cytotoxicity and arsenic accumulations, suggesting that the expression of MRP1/4 may lead to HL-60 cells resistance to trivalent arsenic compounds.

## PS 2316 Integrative Toxicopathological Evaluation of Aflatoxin B1 Exposure in F344 Rats.

G. Qian<sup>1</sup>, F. Wang<sup>1</sup>, L. Tang<sup>1</sup>, M. E. Massey<sup>1</sup>, N. J. Mitchell<sup>2</sup>, J. Su<sup>1</sup>, J. H. Williams<sup>3</sup>, T. D. Phillips<sup>2</sup> and J. Wang<sup>1</sup>. <sup>1</sup>Environmental Health Science, University of Georgia, Athens, GA; <sup>2</sup>Veterinary Integrative Biosciences, Texas A&M University, College Station, TX; <sup>3</sup>Peanut Collaborative Research Support Program, University of Georgia, Griffin, GA.

An integrative evaluation of the toxicopathological effects of aflatoxin B1 (AFB1) was conducted in this study. Briefly, male F344 rats were orally exposed to a single-dose of AFB1 at 0, 50, 250 or 1000 µg/kg body weight (BW) or repeated-dose of AFB1 at 0, 5, 10, 25 or 75 µg/kg BW for up to 5 weeks. Biochemical and histological changes were assessed together with the formation of AFB1-lysine adduct (AFB-Lys) in serum and liver foci positive for placental form glutathione S transferase (GST-P+). In single-dose protocol, serum AST, ALT and ALP were dose-dependently elevated with maximal changes (> 100 folds) appeared at 3-day after treatment. Animal that received 250 µg/kg AFB1 showed concurrent bile duct proliferation, necrosis and appearance of GST-P+ hepatocytes at 3-day while the pre-neoplastic GST-P+ foci appeared after 1-week. Neither liver GST-P+ hepatocytes nor foci were induced by 50 µg/kg AFB1 treatment. In repeated-dose protocol, bile duct proliferation and liver GST-P+ foci co-occurred after 3-week, followed by proliferation foci formation after 4-week and dramatic ALT, AST and CK elevations after 5-week exposure in animals received 75 µg/kg AFB1. Liver GST-P+ hepatocytes and foci appeared in a dose- and time-dependent manner, low dose of AFB1 (5 µg/kg) did not induce liver GST-P+ foci formation throughout the experiment. Serum AFB-Lys increased temporally at low doses (5-25 µg/kg) and reached a maximum after 2-week exposure at 75 µg/kg group, consistent with liver histological changes that may affect the adduct formation. This integrative study demonstrates that liver GST-P+ cells and foci are sensitive biomarkers for AFB1 toxic effect and correlated with bile duct proliferation and biochemical alterations in F344 rats, which hold promise as potential target for future intervention strategies.

## PS 2317 Ethoxyquin Protective Effect against Aflatoxins Chronic Intoxication in Laying Hens.

A. G. Valdivia<sup>1</sup>, M. C. De Luna<sup>1</sup>, R. Ortiz<sup>1</sup>, A. Martinez de Anda<sup>1</sup>, T. Quezada<sup>1</sup>, F. Jaramillo<sup>2</sup> and J. Reyes<sup>3</sup>. <sup>1</sup>Agricultural Sciences Centre, Aguascalientes Autonomous University, Aguascalientes, Mexico; <sup>2</sup>Physiology and Toxicology, Basic Sciences Centre of UAA, Aguascalientes, Mexico; <sup>3</sup>Cellular Physiology, Research and Advanced Studies Centre of IPN, Mexico City, Mexico.

Ethoxyquin (EQ) is a synthetic compound used to prevent lipid oxidation and preserve the nutritional quality of feed. EQ can increase the expression of some enzymes detoxification system. Aflatoxins (AFs) are toxicogenic and carcinogenic common food contaminants that affect human health and productivity in poultry. The aim was to evaluate the EQ ability to decrease the toxic effect of AFs chronic dietary intake in laying hens. At 14 weeks age, 360 Leghorn Hy-Line hens were subjected to experimental chronic intoxication (0.00, 0.50, 1.00 and 1.50 mg AFs/kg BW) for 72 weeks, with and without EQ (500 mg/kg feed). The EQ feed was well accepted by hens and alone did not alter egg production, feed daily intake and feed efficiency index. Dietary AFs consumption decreased of performance of hens and produced pathological and biochemical alterations. However, EQ diminished the AFs induced changes in macro and microscopic architecture of liver and kidneys, plasma total protein, hepatic/renal reduced glutathione, specific enzyme activity of glutathione, gamma-glutamyl, alanine and aspartate transferases, which suggests the presence a EQ chemopreventive effect against AFs toxic effects in laying hens.

## PS 2318 Aflatoxin Exposure in Human Populations of Uganda.

M. Kang<sup>1</sup>, P. Nkurunziza<sup>2</sup>, R. Muwanika<sup>3</sup>, G. Qian<sup>1</sup>, L. Tang<sup>1</sup>, J. Seeley<sup>2</sup>, J. Williams<sup>1</sup> and J. Wang<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>British Medical Research Council Uganda Unit, Entebbe, Uganda; <sup>3</sup>Rakai Health Science Program, Entebbe, Uganda.

Aflatoxins (AF) exposure and aflatoxicosis as well as chronic hepatocarcinogenic effects in human populations are serious global public health threats, especially for the developing world. In this study human serum samples (n=1931) from two existing cohort studies conducted in Uganda were measured for AFB1-lysine adduct. In samples (n=725) from the General Population Cohort (GPC), 90% (651/725) had detectable AFB1-lysine adduct with a median of 1.61 pg/mg albumin, ranged from 0.40 to 253.11 pg/mg albumin. In samples (n=1,206) from Rakai Community Cohort (RCC), 85% (1025/1206) had detectable AFB1-lysine adduct with a median of 3.19 pg/mg albumin, ranged from 0.41 to 167.04 pg/mg albumin. Levels of AFB1-lysine adduct in the RCC samples are significantly higher

than those in the GPC samples ( $p < 0.05$ ). Temporal patterns of AFB1-lysine adduct in these two distinct human populations were further evaluated in samples collected at 3-year interval since the initiation of the cohorts. Detection rates of AFB1-lysine adduct in GPC varied over time: 94% in 1989, 100% in 1992, 84% in 1995, 80% in 1998, 72% in 2001, 93% in 2004, 97% in 2007, and 94% in 2010 with median (range) of 1.77 (0.43-22.46), 2.44 (1.02-5.06), 0.83 (0.41-18.60), 0.89 (0.41-6.02), 1.15 (0.41-11.55), 1.77 (0.41-14.80), 1.92 (0.40-30.89), and 2.29 (0.47-253.11) pg/mg albumin, respectively. Detection rates of AFB1-lysine adduct in RCC also varied: 71% in 1994, 96% in 1996, 91% in 1999, 50% in 2002, 92% in 2005, 89% in 2008, and 90% in 2011 with median (range) of 2.44 (0.41-94.79), 1.16 (0.41-555.33), 1.19 (0.45-122.51), 5.08 (0.51-30.92), 3.58 (0.41-67.56), 3.22 (0.45-117.96), and 2.60 (0.43-167.04) pg/mg albumin, respectively. Levels of AFB1-lysine adduct in samples from these two cohort studies were further assessed with various demographic parameters. These results demonstrated the temporal patterns of AF exposure in rural human populations of Uganda.

## PS 2319 Immunological and Pathomorphological Study of Combined Effects of Fumonisin B1 and Ochratoxin A on Pigslets.

M. Mwanza<sup>1,2</sup>, M. M. Dutton<sup>2</sup> and S. D. Stoev<sup>3</sup>. <sup>1</sup>Animal Health, North West University, Mmabatho, South Africa; <sup>2</sup>Food, Environment and Health Research Group, Faculty of Health Science, University of Johannesburg, Johannesburg, South Africa; <sup>3</sup>Department of General and Clinical Pathology, Faculty of Veterinary Medicine, Trakia University, Trakia, Bulgaria.

In this study, two experiments (*in vivo* and *in vitro*) were carried out to study the effects on OTA and FB1 on pigs mononuclear cells as well as on live pigs to assess the effects of these mycotoxins on their health with particular reference to the immune system and pathomorphological changes. The *in vitro* study showed a time vs concentration decrease of pigs mononuclear cells were used the MTT assay and exposed to 5 and 40 ng/ml for ochratoxin A and 5 and 40 µg/ml of FB1 at 12, 24 and 48 hrs. While the *in vivo* study showed the ochratoxin A induced highest cell viability decrease as compared to FB1 when exposed singularly, whereas exposure to both mycotoxins simultaneously showed further reduction of cell viability. In the *in vivo* study was done with mycotoxic nephropathy induced in eighteen young pigs with mouldy diets containing 0.5 ppm ochratoxin A (OTA) and/or 10 ppm fumonisin B1 (FB1) for three months. The most obvious damage provoked by OTA was seen in the kidneys, as expressed by the strong degenerative changes in proximal tubules and fibrosis in kidneys, FB1 was found to induce an increase in permeability of vessels mainly in lung, brain, cerebellum or kidneys and slight to moderate degenerative changes in kidneys. The exposure to both mycotoxins simultaneously revealed synergistic pathomorphological changes characterized by the combination of the main lesions provoked by each mycotoxin alone, being stronger in their expression when administered together. In addition, Exposure to both mycotoxins and their combination showed induced humoral immune response in all experimental pigs shown by decrease in antibody titers.

## PS 2320 Deoxynivalenol (DON)-Induced Secretion of the Gut Satiety Hormone Cholecystokinin (CCK) in the STC-1 Enteroendocrine Cell Model Is Mediated by the Calcium Sensing Receptor (CaSR) and Transient Receptor Potential Ankyrin-1 (TRPA1).

H. Zhou<sup>1</sup> and J. Pestka<sup>1,2,3</sup>. <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.

The trichothecene mycotoxin deoxynivalenol (DON, vomitoxin) causes anorexia and emesis in part by inducing gut satiety hormone secretion by enteroendocrine cells of the gastrointestinal tract. To elucidate mechanisms for these effects, we employed the STC-1 enteroendocrine cell model, which can be induced by DON to secrete the gut satiety peptide cholecystokinin (CCK). We initially found that intracellular calcium mobilization was evoked in STC-1 cells by DON in a concentration- and time-dependent manner, generating sustained sinusoidal oscillations that preceded CCK secretion. Pretreatment with EGTA, a chelator of Ca<sup>2+</sup>, was found to block CCK secretion. Pretreatments with the CaSR (calcium sensing receptor) antagonists, NPS 2143 or Calhex 231 or TRPA1 (transient receptor potential ankyrin-1) antagonist HC 030031 were found to suppress DON-induced Ca<sup>2+</sup> mobilization and CCK release. Both sets of these inhibitors worked in an additive fashion. Furthermore, preincubation with 1) phospholipase C inhibitor, U73122, 2) inositol 1,4,5 triphosphate receptor (IP3R) blocker, 2-aminoethyl diphenylborinate, 3) the transient receptor potential melastatin-5 (TRPM5) inhibitor, triphenylphosphine oxide (TPPO), or 4) the L-type voltage-sensitive Ca<sup>2+</sup> channel (L-type VSCCs) blocker, nitrendipine could also significantly attenuate

DON-induced CCK release in STC-1 cells. The results suggest that DON might induce CCK release in enteroendocrine cells by increasing CaSR sensitivity to extracellular  $[Ca^{2+}]_0$  which mediates increased  $[Ca^{2+}]_i$  influx via L-type-VSCCs  $Ca^{2+}$  and TRPA1 cation channels. DON-induced calcium and hormonal responses demonstrated herein might ultimately contribute to anorexia and emesis potentially as a protective mechanism following ingestion of the toxin.

## PS 2321 Red Clover Exhibits Multifaceted Activity on Breast Cancer Cells.

B. M. Dietz, J. Eskra, M. Darji, S. Chen, G. F. Pauli and J. L. Bolton.  
*Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL.*

An increased breast cancer risk for postmenopausal women taking hormone therapy has been demonstrated by the Women's Health Initiative. Botanical dietary supplements, including red clover products, are commonly used to alleviate menopausal symptoms but still lack efficacy and safety studies. Red clover isoflavones, such as biochanin A and genistein, have been promoted for their cancer preventive activity, in part due to genistein's ER $\beta$  selective activity. Other studies suggested possible side effects in estrogen sensitive tissue due to genistein's ER $\alpha$  mediated estrogenicity. This study examines these controversial claims by performing several estrogenic assays with a well-characterized clinical red clover extract and pure isoflavones. Proliferation experiments in ER+ breast cancer cells (MCF-7) showed that the effect of the red clover extract on cell proliferation is highly concentration dependent and has a bell-shaped curve: Low- and high concentrations (30 - 100 ng/mL and > 5  $\mu$ g/mL, respectively) reduced cell proliferation, whereas intermediate amounts (300 ng/mL - 1  $\mu$ g/mL) increased it. The pure isoflavones, genistein and biochanin A, exhibited similar bell-shaped dose dependencies. Low- (10 nM) and high isoflavone concentrations (> 10  $\mu$ M) decreased cell proliferation, whereas cell survival increased at 300 nM - 1  $\mu$ M. These findings are in agreement with prior reports of genistein preferentially binding to ER $\beta$  at 6 - 20 nM and to ER $\alpha$  at ~300 nM, which may explain the dose-dependent effects of the isoflavones and the extract. Supporting the proliferation results, ERE-luciferase and gene induction assays showed that red clover extract at 300 ng/mL - 1  $\mu$ g/mL mimics estradiol and might, therefore, have similar adverse effects if consumed in higher quantities. These findings highlight the importance of correct dosing for isoflavone-containing products and the relevance of dose considerations to ensure safety of botanical dietary supplements.

## PS 2322 Occurrence of T-2 Toxin, HT-2 Toxin and Zearalenone in Retail Foods in Japan.

T. Yoshinari<sup>1</sup>, K. Aoyama<sup>2</sup>, M. Nakajima<sup>3</sup>, M. Taniguchi<sup>3</sup>, H. Takeuchi<sup>4</sup>, S. Hashiguchi<sup>5</sup>, S. Kai<sup>6</sup>, S. Tabata<sup>7</sup>, T. Tanaka<sup>8</sup> and Y. Sugita-Konishi<sup>1</sup>. <sup>1</sup>National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Food and Agricultural Materials Inspection Center, Sendai, Japan; <sup>3</sup>Nagoya City Public Health Research Institute, Nagoya, Japan; <sup>4</sup>Mie Prefecture Health and Environment Research Institute, Mie, Japan; <sup>5</sup>Kawasaki City Institute for Public Health, Kawasaki, Japan; <sup>6</sup>Kanagawa Prefectural Institute of Public Health, Kanagawa, Japan; <sup>7</sup>Tokyo Metropolitan Institute of Public Health, Tokyo, Japan; <sup>8</sup>Kobe Institute of Health, Kobe, Japan.

Fusarium toxins are a group of mycotoxins produced by many kinds of Fusarium species, and frequently detected in field crops such as wheat, barley, maize and corn. They cause mycotoxicosis, a serious health hazard to humans and domestic animals. Therefore, collecting the information about fusarium toxin contamination in daily foods is crucial. Occurrence data of deoxynivalenol, a major fusarium toxin, have been collected in worldwide, but that of other toxins is limited. In this study, we examined foods from Japanese retail shops for contamination with three kinds of fusarium toxins, T-2 toxin, HT-2 toxin and zearalenone. Food samples were extracted with methanol-water (75 : 25). After filtration, the extract was diluted five times with phosphate buffered saline, and subjected to a DZT MS-PREP Immunoaffinity column. The toxins were quantified by LC-MS/MS. In 2011, a total of 196 samples of 12 different products were examined. In corn grits (20 samples) and tear grass (20 samples), more than 1 ng/g of T-2 toxin on average was detected. In barley, breakfast cereal, cookie, corn grits, tear grass and wheat, more than 1 ng/g of HT-2 toxin on average was detected (The sample sizes were 10, 10, 10, 20, 20 and 40, respectively). The maximum concentration of the sum of T-2 and HT-2 toxin was 48.9 ng/g in corn grits. In corn grits, red bean (10 samples) and tear grass, more than 5 ng/g of zearalenone on average was detected. These results showed that the highly toxic trichothecene mycotoxins, T-2 and HT-2 toxin were contaminated in retail foods in Japan. Especially contributors of these toxins are breakfast cereal, tear grass and wheat.

## PS 2323 In Vitro Metabolism and Interaction of Zearalenone and Its Metabolites in Mammalian Cells.

G. Font<sup>1</sup>, E. Tatay<sup>2</sup>, G. Meca<sup>3</sup> and M. Ruiz<sup>4</sup>. <sup>1</sup>Preventive Medicine, University of Valencia, Burjassot, Spain; <sup>2</sup>Preventive Medicine, University of Valencia, Burjassot, Spain; <sup>3</sup>Preventive Medicine, University of Valencia, Burjassot, Spain; <sup>4</sup>Preventive Medicine, University of Valencia, Burjassot, Spain.

Zearalenone (ZEA) is a non-steroidal estrogenic mycotoxin produced by Fusarium sp. fungi. ZEA is rapidly absorbed and metabolized to  $\alpha$ -Zearalenol ( $\alpha$ -ZOL) and  $\beta$ -Zearalenol ( $\beta$ -ZOL) in the liver; therefore mixtures of these mycotoxins may be simultaneously in biological systems and cause human health risk. The objectives of this study were: a) to compare the cytotoxicity of ZEA,  $\alpha$ -ZOL and  $\beta$ -ZOL alone or in combination in hamster ovary (CHO-K1) and human hepatoma (HepG2) cells using the MTT assay after 24, 48 and 72h of exposure, b) to evaluate the interactions of mycotoxins mixtures in both cell lines by the isobologram analysis and, c) to study the in vitro metabolism of ZEA in both types of cells using liquid chromatography coupled to the mass spectrometry detector-linear ion trap (LC-MS-LIT). The IC50 values obtained for individual mycotoxins range from 59.4 to >100.0  $\mu$ M, from 30.0 to 33.0  $\mu$ M and from 55.0 to >75.00  $\mu$ M in CHO-K1 cells and from 70.0 to >100.0  $\mu$ M, from 20.6 to 26.0  $\mu$ M and from 38.4 to >100.0  $\mu$ M in HepG2 cells for ZEA,  $\alpha$ -ZOL and  $\beta$ -ZOL, respectively. Isobologram analysis provides a combination index (CI) value to determine the type of interaction that occurs. The interactions of ZEA and its metabolites became slightly synergism at low levels (CI from 0.34  $\pm$  0.10 to 0.81  $\pm$  0.33) followed by additive effect (CI from 0.80  $\pm$  0.18 to 8.54  $\pm$  7.76) and turned into antagonism (CI from 1.41  $\pm$  0.16 to 26.17  $\pm$  20.72). The metabolism assays demonstrated that no conversion of ZEA in  $\alpha$ -ZOL and  $\beta$ -ZOL was detected. However, other metabolites products of ZEA,  $\alpha$ -ZOL and  $\beta$ -ZOL were generated in both cell lines.

## PS 2324 Role of Peptide YY3-36 (PYY) and 5-Hydroxytryptamine (5-HT) in Emesis Induction by Deoxynivalenol (Vomitoxin).

M. Bates<sup>1</sup>, W. Wu<sup>1,5</sup>, S. Bursian<sup>3,2</sup>, B. Flannery<sup>1</sup>, H. Zhou<sup>1</sup>, J. Link<sup>3</sup>, H. Zhang<sup>5</sup> and J. Pestka<sup>1,2,4</sup>. <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Animal Science, Michigan State University, East Lansing, MI; <sup>4</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI; <sup>5</sup>College of Veterinary Medicine, Nanjing Agricultural University, Nanjing, China.

Deoxynivalenol (DON, vomitoxin), a trichothecene mycotoxin produced by Fusarium, frequently contaminates cereal grains causing reported outbreaks of human and animal food poisoning making it a relevant public health concern. Although these outbreaks have the rapid onset of emesis as a common hallmark, the mechanisms for this adverse effect are not fully understood. Recently, our laboratory has demonstrated that the mink (Neovison vison) is a suitable small animal model for investigating trichothecene-induced emesis. We employed the mink to determine the role of gut satiety hormone peptide YY3-36 (PYY3-36) and neurotransmitter 5-hydroxytryptamine (5-HT) in DON-induced vomiting. Emesis induction following intraperitoneal exposure to DON at 100 and 250  $\mu$ g/kg bw initiated within 15 to 30 min which persisted for up to 120 min. Measurement of DON in plasma by ELISA revealed that the emetic period correlated with distribution and clearance of the toxin. Significant elevations in both PYY3-36 (30 to 60 min) and 5-HT (60 min) were observed during emesis. Pretreatment with the Y2 receptor antagonist JNJ-31020028 attenuated PYY- and DON-induced emesis. The 5-HT3 receptor antagonist granisetron was found to completely suppress induction of vomiting by cisplatin, a known 5-HT inducer, as well as DON. Interestingly, granisetron pretreatment could partially block PYY3-36-induced emesis. Taken together, the results presented here suggest that both PYY3-36 and 5-HT play contributory roles in DON-induced emesis.

## PS 2325 Dietary Inclusion of Montmorillonite Clay Mitigates Bioavailability of Aflatoxin, Fumonisin and Aflatoxin/Fumonisin Mixtures in Fischer 344 Rats.

N. J. Mitchell<sup>1</sup>, K. Xue<sup>2</sup>, A. Marroquin-Cardona<sup>1</sup>, K. A. Brown<sup>1</sup>, S. E. Elmore<sup>1</sup>, S. Lin<sup>2</sup>, L. Tang<sup>2</sup>, J. Wang<sup>2</sup> and T. D. Phillips<sup>1</sup>. <sup>1</sup>College of Veterinary Medicine, Texas A&M University, College Station, TX; <sup>2</sup>Department of Environmental Health Sciences, University of Georgia, Athens, GA.

Aflatoxins (AFs) have been linked to hepatocellular carcinoma and mortality in humans and animals. Chronic AF exposure, particularly in developing countries, is a significant problem that continues to contribute to public health issues in communities burdened by poor economic status and food scarcity. One possible strategy to

improve food safety is to reduce exposures to AF using montmorillonite clay which binds AFs in the GI tract, and decreases bioavailability of these toxins. Our recent work in Ghana has shown that communities at risk for AF exposure are also at high risk for fumonisin (FB) exposure. In this study, montmorillonite clay was tested for FB<sub>1</sub> binding capacity in combination with AFB<sub>1</sub> in a rodent model. Fisher-344 rats were gavaged once with 0.125 mg AFB<sub>1</sub>/kg b.w. and/or 25 mg FB<sub>1</sub>/kg b.w. following an acclimation period with feed containing clay additive. Urine samples were collected at 12 hr time intervals for 72 hr following gavage and were analyzed for AF and FB biomarkers. Lower AFM<sub>1</sub> and FB<sub>1</sub> levels in the urine were indicative of reduced absorption of the parent compounds through the GI tract and into the circulation. AFM<sub>1</sub> and FB<sub>1</sub> excretion peaked between 12-24 hr and quickly declined by 36 hr. Addition of clay at 0.25%, 0.5% and 2% w/w feed decreased AFM<sub>1</sub> excretion by 88-97% at the 12 hr time point, indicating highly effective binding. Clay treated animals also had a reduction in FB<sub>1</sub> excretion, but to a lesser extent than the AFM<sub>1</sub> biomarker (i.e. 41-80%). When in combination both AFM<sub>1</sub> and FB<sub>1</sub> binding occurred, but capacity was decreased by almost half, suggesting that AFB<sub>1</sub> and FB<sub>1</sub> are competing for similar binding sites on the clay. This study indicates that inclusion of montmorillonite clay in contaminated diets can reduce bioavailability of both AFs and FBs in populations at high risk for mycotoxin exposure. ### PS 2326 Development and Validation of an Analytical Method for Vomitoxin in Gavage Dose Formulations Used in Rodent Toxicology Studies.

J. C. Blake<sup>1</sup>, D. P. Coleman<sup>1</sup>, J. Gilliam<sup>1</sup>, M. A. Silinski<sup>1</sup>, R. A. Fernando<sup>1</sup>, C. S. Smith<sup>2</sup>, B. Collins<sup>2</sup> and V. G. Robinson<sup>2</sup>. <sup>1</sup>RTI International, Research Triangle Park, NC; <sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC. Sponsor: K. Levine.

Vomitoxin, also known as deoxynivalenol (DON), is a trichothecene mycotoxin produced by certain types of *Fusarium* fungi. It occurs predominantly in grains such as corn, wheat, barley, and rice, and has been shown to have great stability during storage, processing, and cooking of food. Because of the potential for widespread contamination of food and exposure to farmers through inhalation, the National Toxicology Program is investigating the toxicity of vomitoxin. Thus, the current study was undertaken to develop and validate a formulation analysis method for vomitoxin in deionized water as a gavage vehicle for use in toxicology studies. Important objectives of an analytical method for supporting a toxicological study are to insure that the correct test article is being administered at the specified dose concentrations and that the dose formulations are stable. To achieve these objectives, an Ultra Performance Liquid Chromatography (UPLC) method was developed and validated for analysis of vomitoxin in deionized water. Sample preparation involves a simple dilution with water and addition of an internal standard solution (2,6-dimethylphenol in acetonitrile). The method was successfully validated over the range 1.5 to 720 µg/mL. The limit of detection was estimated as 0.2 µg/mL and the limit of quantitation was estimated as 0.8 µg/mL. Assessment of formulation stability, at ambient and refrigerated storage conditions, over a 42-day period was evaluated. Dose simulation stability testing was also conducted to evaluate the formulations stability for at least three hours under simulated dosing conditions. In addition, analysis period stability of the analytical preparations was assessed. This method will be used to support toxicology studies of vomitoxin conducted by the National Toxicology Program.

### PS 2327 Comparative Hepatic Glutathione S-Transferase Mediated Detoxification of Aflatoxin B1 in Chickens.

B. R. Bunderson<sup>1</sup>, C. Rowe<sup>1</sup>, S. J. Lamont<sup>2</sup> and R. A. Coulombe<sup>1</sup>. <sup>1</sup>Toxicology Graduate Program, Utah State University, Logan, UT; <sup>2</sup>Department of Animal Science, Iowa State University, Ames, IA.

Efficiency of hepatic glutathione S-transferase (GST)-mediated conjugation of bioactivated aflatoxin B1 (AFB1) is critical to species resistance to this toxic and carcinogenic mycotoxin. Poultry are among the most susceptible animals, and domestic turkeys are especially susceptible, a condition we have shown to be associated with a deficiency of AFB1-detoxifying GSTs. Chickens are more resistant than domestic turkeys, yet little is known about their hepatic GST detoxification capabilities. In this study, we compared hepatic GST-mediated detoxification of prototype substrates 1-chloro-2,4-dinitrobenzene (CDNB), 1,2-dichloro-4-nitrobenzene (DCNB), ethacrynic acid (ECA), and cumene hydroperoxide (CHP) and toward the exo-AFB1-8,9-epoxide (AFBO) in livers of Broiler, Fayoumi, and Leghorn chickens. All breeds had equivalent GST activities, except Fayoumi, which was significantly lower toward CDNB. Broiler, Fayoumi, and Leghorn had similar GST-mediated conjugation activities toward AFBO (6.5 ± 0.2, 6.1 ± 0.6, 6.4 ± 0.2

pmol/min/mg, respectively). This level of hepatic AFB1 detoxification is substantially more than that in livers of domestic turkeys, which are more susceptible than chickens to AFB1. These data support previous findings that in vitro conjugation of AFB1 by GST is an accurate predictive marker species resistance to this mycotoxin. Supported in part by NRI Competitive grant 2007-35205-17880 from the USDA-NRI Animal Genome Project.

### PS 2328 Bisphenol A (BPA) Levels in Liquid Supernatants of Canned Foods Determined by Highly Sensitive BPA ELISA.

H. Kim<sup>1,2</sup>, A. Joiaim<sup>1</sup>, D. Kaplan<sup>1</sup>, K. Friedrich<sup>1</sup> and D. Putt<sup>1</sup>. <sup>1</sup>Detroit R&D, Inc., Detroit, MI; <sup>2</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.

BPA [2,2-(4,4'-dihydroxydiphenyl)propane], an endocrine disruptor, mimics the action of 17β-estradiol (E2) in mammals, increasing the risk of hormone-related health problems such as early puberty, infertility, breast, ovarian and prostate cancers and insulin resistance. Fetuses and newborns are most vulnerable to the BPA toxicity. Recently, BPA levels of canned soup solids were measured by LC/MS/MS (detection limit, 2 ng/g) and it was found that the soup solids contained 10 to 80 ng/g BPA. A subsequent study revealed that the group that consumed a 12-ounce serving/day, for 5 days of canned soups, excreted 19-fold higher BPA in urine (mean, 21 ng/ml) compared with the control group that consumed same amounts of fresh soups (mean, 1.1 ng/ml). BPA in liquid supernatants of canned foods contain ~10-fold lower levels of BPA compared to the solids. To screen BPA in supernatants, a highly sensitive and facile BPA ELISA has been developed after production of BPA polyclonal antibodies by immunization of a goat with carboxylalkyl-derivatized BPA conjugated to KLH. The detection limit of the BPA ELISA was 1 pg. Whereas anti-BPA slightly cross-reacted with BPB, it did not cross-react with BPS, BPF or resveratrol, which are structurally similar to BPA. Ten-fold diluted supernatants of canned soups were applied to BPA ELISA. Supernatants obtained from 3 kinds of soups (3 cans/each kind of soup, 9 data points) produced by first company contained 9.56 ± 0.96 ng/ml, 9.07 ± 0.38 ng/ml and 10.38 ± 0.83 ng/ml of BPA, similar to ~8.70 ng/ml of BPA levels in supernatants from second company. A negative control, supernatants of canned vegetables from third company, contained extremely low levels of BPA (0.05 ± 0.02 ng/ml), suggesting use of BPA-free can linings. These results demonstrate that the competitive BPA ELISA is suitable for measurements of BPA leaching from the epoxy film-coated cans using liquid supernatants from canned foods.

### PS 2329 Perinatal BPA Exposure at Low Doses Impairs Oral Tolerance and Immunization to Ovalbumin in Offspring Rats at Adulthood.

S. Ménard, V. Braniste, M. Leveque, C. Lencina, M. Naturel, L. Moussa, S. Sekkal, C. Harkat, E. Gaultier, V. Theodorou and E. Houdeau. INRA, Toulouse, France. Sponsor: D. Zalko.

Aims: Bisphenol A (BPA) used in food packaging impacts gut epithelial barrier after perinatal exposure. Because antigen sampling by gut epithelium drives mucosal immune response, our aim was to address the consequences of perinatal BPA exposure at low doses on oral tolerance and immunization at adulthood. Methods: Dams were treated per os from gestation day 15 to pup weaning with BPA [0.5, 5 or 50 µg/kg/d] or vehicle (corn oil). Female offsprings (day 45) were used to assess para- and transcellular jejunal permeability by Ussing chambers, and immune response to ovalbumin (OVA) after either oral tolerance, immunization or oral challenge. Results: Perinatal BPA exposure decreased jejunal paracellular permeability by 2-fold at 0.5 and 50 µg/kg/d, and by 3-fold at all doses for transcellular permeability (p<0.05). BPA exposure at 5 and 50 µg/kg/d increased anti-OVA IgG titers after an oral tolerance protocol (116±62x103 and 86±29x103 respectively vs 7.2±2.2 x103 in controls; p<0.04). Anti-OVA IgG titers were only increased at 5 µg/kg/d after OVA immunization. Enhanced humoral response in rats exposed to 5 µg/kg/d was associated with higher IFNγ secretion by spleen in OVA-sensitized (2-fold) and MLN of OVA-tolerized (20-fold) rats (p<0.05). Finally, oral OVA challenge in BPA group increased MPO activity (316±34 vs 184±22 U/g protein in controls; p<0.05), IFNγ concentration (2-fold, p<0.05), and decreased TGFβ concentration (3-fold, p<0.05) in the colon, indicating inflammation. Conclusion: Perinatal exposure to low doses of BPA decreased jejunal paracellular and transcellular permeability, and impaired oral tolerance and immunization to dietary antigens at adulthood. BPA treatment during perinatal period affects intestinal homeostasis in a nonlinear dose-response relationship. These results suggest that perinatal period is a critical window for BPA exposure that may trigger food intolerance in later life.

**PS 2330 Perinatal BPA Exposure at Low Doses Impairs Immune Homeostasis and Promotes Intestinal Parasite Infection in Young Rats.**

V. Theodorou, S. Ménard, C. Lencina, M. Leveque, M. Olier, V. Braniste, M. Naturel, S. Sekkal, C. Harkat and E. Houdeau. *INRA, Toulouse, France.*  
Sponsor: *D. Zalko.*

**Aims:** Perinatal exposure to 5µg/kg/day of the food contaminant bisphenol A (BPA) impaired oral tolerance in adult rats (see Ménard et al, abstract 1). Herein, we aimed to address the consequences of BPA perinatal exposure on immune homeostasis in young rats at weaning, i.e. oral tolerance, systemic immunization with ovalbumin (OVA) and parasitic infection. **Methods:** Dams were given per os from gestational day 15 to pup weaning BPA [5µg/kg/d] or vehicle (corn oil). Weaned female offspring (day 25) were used to assess para- and trans-cellular jejunal permeability by Ussing chambers, and immune responses following oral tolerance or immunization to OVA, or after infection with a gut nematode *Nippostrongylus brasiliensis* (N bras). **Results:** Perinatal treatment with BPA did not affect intestinal permeability or humoral response (anti-OVA IgG titers) following either oral tolerance or immunization in D25 rats. However, a decrease of OVA-induced IFNγ secretion was observed in spleen of OVA-sensitized rats (53±15 vs 317±162 pg/ml; p<0.05) and in mesenteric lymph nodes of OVA-tolerized rats (3.9±2.3 vs 19±14 pg/ml; p<0.05). The lack of cellular response to food antigens questioned the ability of BPA-exposed rats to clear intestinal infections. A 3-fold increase in N bras living larvae was observed in the intestine of BPA-exposed rats compared to controls (2817±689 vs 757±291 larvae/g of faeces, respectively; p<0.05), but no significant change in myeloperoxidase activity into jejunal tissues. **Conclusion:** Perinatal exposure to low dose of BPA did not affect humoral response to the food antigen OVA in juvenile rats. However, a decrease of OVA-induced IFNγ secretion in BPA-exposed rats emphasized a lack of specific cellular response to food antigens. Finally, perinatal BPA treatment evoked an increased risk to intestinal parasitic infection without triggering an inflammatory response, demonstrating impaired immune defence in early life stages.

**PS 2331 Perinatal Peripubertal Exposure to Bisphenol-A Increases Hepatic Steatosis in Immature and Adult Mice.**

P. Shimpi<sup>1</sup>, A. Donepudi<sup>1</sup>, V. More<sup>1</sup>, M. Paranjpe<sup>2</sup>, S. DaFonte<sup>2</sup>, B. Rubin<sup>2</sup> and A. L. Slitt<sup>1</sup>. <sup>1</sup>*Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI;* <sup>2</sup>*Sackler School of Graduate Biomedical Sciences, Tufts University, Boston, MA.*

While diet and physical activity remain the predominant reason for development of obesity and obesity-related disease, there is some concern that environmental exposure to chemicals may be a predisposing factor. Bisphenol A (BPA), a component used in the manufacturing of certain plastics and plastic resins, can leach into food and/or drink from food and beverage containers. High urinary BPA levels have been positively associated with general and abdominal obesity in human populations. In rodents, developmental BPA exposure increases body weight and fatty liver (steatosis). The purpose of this study was to uncover potential mechanisms by which perinatal-peripubertal (PNPP) exposure to BPA increases liver steatosis. Pregnant CD-1 mice were administered 25 or 250 µg BPA/kg/day (BPA25, BPA250, respectively) via osmotic pump, and then after weaning on PND 20, the resulting daughters were exposed to BPA via drinking water up through PND 35. Tissues were collected at PND32 and at 39 weeks of age. Livers were analyzed for triglyceride content, stained with Oil Red O and relative mRNA expression was quantified by qPCR. At PND32, BPA25 and 250 increased liver Oil Red O staining compared to controls. BPA25, but not BPA250, increased protein expression for lipogenic enzymes, (Acc-1 and Fas) but did not significantly increase lipogenic gene expression. In adult mice, BPA25, but not BPA250, increased Oil Red O staining. BPA25 increased Acc-1 expression, whereas BPA250 increased Srebp1-c, Acc-1, and Fas. Protein expression was not changed. In conclusion, PNPP exposure to BPA had some effect in promoting steatosis and pro-steatotic gene expression in immature and adult female mice, but the exact mechanism by which BPA promotes steatosis remains unclear.

**PS 2332 Leaching of Chemicals with Estrogenic Activity from BPA-Free Materials after Common Use Stresses.**

G. D. Bittner<sup>2,1,3</sup>, C. Z. Yang<sup>2</sup>, M. Stoner<sup>2</sup> and D. Klein<sup>1</sup>. <sup>1</sup>*PlastiPure, Inc., Austin, TX;* <sup>2</sup>*CertiChem, Inc., Austin, TX;* <sup>3</sup>*University of Texas, Austin, TX.*

Since 2007, many consumer products are no longer made from polycarbonate (PC) plastics because of widespread concern about the estrogenic activity (EA) of bisphenol-A (BPA). However, BPA-Free plastics have not been thoroughly vetted by most

product manufacturers to ensure that they do not release other chemicals that have EA. We have used, robotized MCF-7 and BG1Luc assays currently undergoing validation by ICCVAM/NICEATM to quantify the total EA in chemicals leaching from a various widely-available plastic resins used to make consumer products and packaging. This study expands the prior work of Yang et al, 2011(EHP 119:989-998). We assayed the total EA in chemical mixtures leaching from unstressed and stressed polycarbonate (PC), polypropylene (PP), polyethylene (PE), cyclic olefin copolymer(COC), and polyethylene terephthalate glycol-modified (PETG - Tritan™) plastic resins. Plastic resins were subjected to simulated common-use stresses of dishwashing, microwaving, and sunlight, and then extracted for ~ 72 hours at 37 degrees Celsius by saline (hydrophilic) or ethanol (hydrophobic) solvents. The total EA in these leachates were then quantified and EA-specific responses were validated by conducting confirmation assays. EA positive determinations were made on samples with values 3 standard deviations or more higher than vehicle controls. Using these criteria, Tritan PETG and PC resins were consistently significantly positive for EA. PE and PP samples often tested positive for EA, but some consistently had no detectable EA. Most COC resins consistently had no detectable EA. Our data show that BPA-Free often does not mean EA-Free, i.e., that leaching of chemicals having EA from the plastic resins is often not addressed by simply choosing BPA-Free materials.

**PS 2333 Microsomal Metabolism of Asarone Isomers.**

A. T. Cartus and D. Schrenk. *Food Chemistry and Toxicology, University of Kaiserslautern, Kaiserslautern, Germany.*

The alkenylbenzenes alpha-asarone (aA; CAS 2883-98-9), beta-asarone (bA; CAS 5273-86-9), and gamma-asarone (gA; CAS 5353-15-1) are constituents of various plants, e.g. *Acorus calamus* (Sweet Flag) and some peppers. Both, aA and bA are carcinogenic to rodents and exhibit genotoxic effects in vitro. Neither genotoxicity nor carcinogenicity of gA have been evaluated so far. Several allylic alkenylbenzenes such as safrole, estragole and methyleugenol are well known genotoxic carcinogens, whereas their propenyl analogues are not. This suggests that an allylic side chain, and therefore the capability for the formation of an 1'OH metabolite, may be a basic prerequisite for the carcinogenicity of those compounds. However, the propenyl compounds aA and bA are an exception of that "allylic rule". We suggest the ortho-methoxy groups of aA and bA to be a key structural element for the mode of action of their carcinogenicity.

We investigated the metabolism of aA, bA and gA using liver microsomes from different species (including human). Identity of metabolites was confirmed by LC-MS/MS and 1H-NMR spectroscopy in comparison with synthesized reference standards.

Our results show that the side chain hydroxylation of aA and gA was the predominating metabolic step leading to E-3'OHA (from aA) and 1'OHA (from gA), respectively, together with the formation of side-chain dihydrodiols, for which the epoxides may be the precursors. To a smaller extent, we found enzymatically formed secondary metabolites derived from the alcohols like 3'oxoA and 1'oxoA, but no corresponding carboxylic acids. Furthermore, we found the corresponding mono-demethylated phenolic metabolites. These results are comparable to our prior results on phase I metabolism of methylisoeugenol and methyleugenol. In contrast, bA showed a more complex pattern of metabolites: in addition to Z-3'OHA, the unexpected direct formation of 1'OHA was proven. This metabolic step, possibly facilitated by steric attraction of the Z-configured bA side chain and the ortho-methoxy substituent, may explain the carcinogenicity of bA, but not of aA, where no 1'OH metabolite was found.

**PS 2334 Histamine in Scombrototoxin Fish Poisoning: Toxicology, Epidemiology and Dose-Response Analysis.**

Y. Zang and P. M. Bolger. *US FDA, College Park, MD.*

Histamine plays important physiological functions such as immune responses and gastric acid secretion. However, ingestion of fish containing large amounts of spoilage-originated histamine can result in scombrototoxin fish poisoning (SFP), a common chemical-originated food poisoning that affects cardiovascular, gastrointestinal and neurological systems. Fish importing countries have established various regulations and limits for histamine in fish and fishery products to protect consumers. However, many limits were established in a pre-quantitative risk assessment era. An assessment of toxicological and epidemiological data indicates that though other biogenic amines might also play a role in the etiology of SFP, histamine is the most significant causative agent. Due to limitations of the disease-reporting system, the epidemiology-based dose-response approach is not suitable in developing a safety limit of histamine in fish. Instead, a dose-response analysis was conducted

based on human oral challenge studies selected. Both the NOAEL and BMD assessments identified 50 mg of histamine per meal as the dose where either adverse effects were not noted or the estimate of additional risk (lower confidence level) was low. At this level healthy adults would not be expected to exhibit any of the symptoms associated with SFP. This dosage level will not apply to children and individuals with a specific sensitivity to histamine. In addition, this level was derived from data on small number of subjects. While the variation of response appears to be reflected in the study results, further studies would be most helpful in refining this threshold value. Using a conservative serving size of 250 g fish meat/meal, the maximum concentration of histamine in fish that should not cause an adverse effect was calculated as 200 ppm. Compliance sampling plan can be derived based on this threshold level to ensure a desirable level of protection of the public health.

**PS 2335 Carrageenan-Induced Disruption of Mucosal Barrier via Regulation of Proinflammatory NF- $\kappa$ B and Early Growth Response Gene 1: A Mechanistic Implication of Food-Borne Inflammatory Bowel Disease.**

J. Kim, H. Choi, K. Do, S. Park and Y. Moon. *Laboratory of Mucosal Exposome and Biomodulation, Department of Microbiology and Immunology, Pusan National University School of Medicine and Medical Research Institute, Yangsan, Republic of Korea.*

The widely used food additive carrageenan (CGN) has been shown to induce intestinal inflammation, ulcerative colitis-like symptoms, or neoplasm in the gut epithelia in animal models, which are also clinical features of human inflammatory bowel disease. In this study, the effects of CGN on pro-inflammatory transcription factors NF- $\kappa$ B and early growth response gene 1 product (EGR-1) were evaluated in terms of human intestinal epithelial barrier integrity. Both pro-inflammatory transcription factors were elevated by CGN and only NF- $\kappa$ B activation was shown to be involved in the induction of pro-inflammatory cytokine interleukin-8. Moreover, the integrity of the in vitro epithelial monolayer under the CGN insult was maintained by both activated pro-inflammatory transcription factors NF- $\kappa$ B and EGR-1. Suppression of NF- $\kappa$ B or EGR-1 aggravated barrier disruption by CGN, which was associated with the reduced gene expression of tight junction component zonula occludens 1 and its irregular localization in the epithelial monolayer (This work was supported by the Basic Science Research Program through the National Research Foundation of Korea, funded by Ministry of Education, Science, and Technology Grant 2012R1A1A2005837)

**PS 2336 Comparison of the Estrogenic Activity of Licorice Species with Hops in Botanical Dietary Supplement Formulations for Women's Health.**

A. Hajirahimkhan, C. Simmler, Y. Yuan, D. Nikolic, S. Chen, B. M. Dietz, G. F. Pauli, R. B. van Breemen and J. L. Bolton. *Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL.*

The Women's Health Initiative showed an increased risk of breast cancer for menopausal women taking hormone therapy. As a result, many women have turned to botanical supplements to manage menopausal symptoms, although there is limited data about their efficacy and safety. Our previous studies demonstrated estrogenic and chemopreventive properties for hops (*Humulus lupulus*). The goal of the current study was to compare the estrogenic effects of three common licorice species (*Glycyrrhiza glabra*, *Glycyrrhiza uralensis*, *Glycyrrhiza inflata*) with those of hops. Methanol extracts of the licorice species showed a dose-dependent induction of an estrogen responsive alkaline phosphatase in endometrial cancer cells with *Glycyrrhiza uralensis* being the most potent. Compared to hops, the activity of the licorice species was significant but less pronounced. Similar results were obtained in an estrogen response element (ERE)-luciferase reporter assay in breast cancer cells. The licorice constituent, liquiritigenin, was the major ligand of estrogen receptor (ER) in pulsed ultrafiltration mass spectrometry of the licorice extracts. Competitive binding assay using purified human ERs showed liquiritigenin as a selective ligand of ER $\beta$ . In comparison to 8-prenylnaringenin (8-PN), the major estrogenic principle of hops, liquiritigenin had lower affinity to both ERs. Liquiritigenin was less active than 8-PN in the induction of alkaline phosphatase and ERE-luciferase. Isoliquiritigenin, the precursor chalcone of liquiritigenin, demonstrated significant activity in these estrogenic assays, while xanthohumol, the precursor of 8-PN, did not exhibit estrogenic effects. The estrogenic activity of isoliquiritigenin was partially associated with its cyclization to liquiritigenin. These data suggest that licorice species are moderately estrogenic and are worthwhile further exploration as effective and safe dietary supplements to alleviate menopausal symptoms.

**PS 2337 Acrylamide and Acrolein: Heat-Induced Contaminants in Food.**

G. Eisenbrand<sup>1</sup>, N. Watzek<sup>1</sup>, D. Scherbl<sup>1</sup>, M. Baum<sup>1</sup>, F. Berger<sup>1</sup>, U. Fuhr<sup>2</sup>, O. Doroshenko<sup>2</sup>, D. Tomalik-Scharte<sup>2</sup> and E. Richling<sup>1</sup>. <sup>1</sup>*Chemistry, Division of Food Chemistry and Toxicology, Kaiserslautern, Germany;* <sup>2</sup>*Pharmacology, University Hospital of Cologne, Cologne, Germany.*

The genotoxic carcinogen (IARC class 2A) acrylamide (AA) is a food contaminant formed by thermal treatment of food. This applies as well to acrolein (AC) an  $\alpha,\beta$ -unsaturated aldehyde grouped into IARC group 3B. Whereas human dietary exposure levels to AA are well established and range between about 0.5-5  $\mu$ g/kg bw/d, exposure to AC is much less investigated. After uptake, AA is partly metabolised into the genotoxic glycidamide (GA). GA forms DNA adducts, primarily at N7 of guanine (N7-GA-Gua). AA, GA and AC are conjugated to glutathione (GSH) and excreted via urine as mercapturic acids (MA).

AA was given by gavage in single doses of 0.1-10,000  $\mu$ g/kg bw to female rats. Formation of urinary MAs and of N7-GA-Gua DNA adducts in liver, kidney and lung was measured 16 h after application using HPLC-MS/MS. At the lowest dosage (0.1  $\mu$ g AA/kg bw), N7-GA-Gua adducts were below the limit of detection in any organ tested. At 1  $\mu$ g/kg bw, enhanced adduct levels were found in kidney (~1 adduct/10<sup>8</sup> nucleotides) and lung (< 1 adduct/10<sup>8</sup> nucleotides), but not in liver. At 10 and 100  $\mu$ g/kg bw, adducts were found in all three organs not significantly different to those found at 1  $\mu$ g AA/kg bw (about 1-2 adducts/10<sup>8</sup> nucleotides). In two pilot intervention studies, MAs of AA and AC were monitored after ingestion of test meals of 150 g self-made potato chips (1 mg AA, 13 volunteers, study 1) and of 175 g commercially available potato chips (44  $\mu$ g AA and 5  $\mu$ g AC, 5 volunteers, study 2). Urinary MA contents were determined by HPLC-MS/MS for up to 72 h (study 1), respectively 24 h (study 2). Total excretion of AC-related MA exceeded that of AA-related MA by factors of about 12 (study 1) to 4 (study 2). These results suggest markedly higher exposure to AC than to AA from heat treated potato based foods representing a major source of dietary exposure to AA. They mandate further research to broaden the database on dietary AA and AC.

**PS 2338 Sex Hormone Modulation of Long-Term Induction and Short-Term Inhibition of CYP1A1/2 by Genistein in HepG2/C3A Cells.**

Y. Liu<sup>1,3</sup>, T. Flynn<sup>1</sup>, M. Ferguson<sup>2</sup> and M. Garcia<sup>1</sup>. <sup>1</sup>*Division of Toxicology, Center for Food Safety and Applied Nutrition, US FDA, Laurel, MD;* <sup>2</sup>*Division of Public Health and Biostatistics, Center for Food Safety and Applied Nutrition, US FDA, College Park, MD;* <sup>3</sup>*Oak Ridge Institute for Science and Education, Oak Ridge, TN.*

Genistein is widely consumed in soy products and dietary supplements for its reported beneficial health effects including cancer prevention. However, there have been conflicting data suggesting that genistein ingestion has both anticancer and cancer promoting activities. Cytochromes P4501As (CYP1A) play key roles in the metabolic activation of many carcinogens. Since genistein has both anti-estrogenic and estrogenic activities, sex-specific factors could also contribute to its biological activities. In the current study, human hepatoma HepG2/C3A cells were cultured in media with defined human sex hormone profiles to investigate CYP1As inhibition and induction by genistein. In male hormone supplemented cells, CYP1A1 and CYP1A2 gene expression and activities were induced to higher extent compared with female hormone supplemented cells after either  $\beta$ -naphthoflavone or genistein treatment. However, basal gene expression of CYP1A1 and CYP1A2 were higher in female- than in male-hormone supplemented cells. In the inhibition studies, CYP1A activities were significantly lower in the male-specific medium than in female specific medium. The results showed that genistein could exert both long-term (3-day) induction and short-term (1-hr) inhibition effects on CYP1A activities in vitro which could explain the inconsistent cancer-related reports. Furthermore, there were significant differences in both the inductive and inhibitory effects of genistein between the male- and female-specific media suggesting that sex hormones, in physiological concentrations and ratios, can modulate the effects of genistein on CYP1A gene expression and activities in a human liver cell line.

**PS 2339 Safety Evaluation of Optimash BG from T. Reesei for Use in Grain, Brewing, and Carbohydrate Processing.**

N. K. Muntean, V. Sewalt and Q. Bui. *DuPont Industrial Biosciences, Palo Alto, CA.*

Optimash BG is a cellulase enzyme used in grain processing (for the production of potable alcohol and brewing) and glucose production from starch. The enzyme, endoglucanase 2, is produced from a recombinant modified strain of *Trichoderma reesei*. A battery of toxicology studies was conducted to investigate its potential to

cause adverse effects in humans using methods complying with OECD guidelines. All studies were conducted according to OECD Principles of Good Laboratory Practice. Acutely, Optimash BG is not an eye irritant, a very mild skin irritant, and not toxic by ingestion with an oral LD50 greater than 2000 mg/kg bw. Optimash BG is not a mutagen, a clastogen, or an aneugen. In the *in vitro* cytogenetic test using cultured human lymphocytes cells, Optimash BG did not induce chromosomal aberrations (both structural and numerical) in the presence and absence of metabolic activation (S-9 mix) up to the highest concentration (5000 ug TP/ml). No mutagenic activity was noted in the Ames assay in the presence and absence of S-9 mix up to 5000 ug TP/plate. In a repeated 90 days oral (gavage) in Wistar rats, no biological or statistical differences were observed. Also, no treatment-related changes in the hematology and clinical chemistry were noted at study termination. The NOAEL was established at 80 mg total protein/kg bw/day (97.6 mg TOS/kg bw/day). Under the worst-case scenario that Optimash BG is applied at the maximum rate and the enzyme is neither destroyed nor removed during processing, the use of the enzyme in grain processing, carbohydrate processing and brewing is not expected to result in adverse effects to humans. With a margin of safety of 258 and a pADI of 39%, the use of Optimash BG is not of toxicological concern.

### PS 2340 A 13-Week Subchronic Toxicity Study of Glycidol Fatty Acid Esters in F344 Rats.

T. Toyoda<sup>1</sup>, Y. Cho<sup>1</sup>, S. Onami<sup>1</sup>, J. Akagi<sup>1</sup>, A. Nishikawa<sup>2</sup> and K. Ogawa<sup>1</sup>.  
<sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.

Glycidol fatty acid esters (GEs) have been recently identified as food process contaminants in refined edible oils. Although there is toxicological concern arising from potential release of glycidol from parent esters during digestion in the gastrointestinal tract, little is known about *in vivo* toxicity of GEs. In the present study, subchronic toxicity of two types of GEs, oleate and linoleate esters, was investigated with administration at concentrations of 0, 225, 900 and 3600 ppm (equivalent molar concentration to 800 ppm glycidol) in drinking water for 13 weeks to male and female F344 rats. For comparison, treatment with 200 and 800 ppm of glycidol was also performed. Body weight gain of both sexes was markedly reduced with 800 ppm glycidol compared to the controls, and the cause was considered at least partly related to decreased water consumption. Hematological data showed significant increase of MCV in 800 ppm glycidol females and decrease of WBC in 3600 ppm oleate ester females. In serum biochemistry, increase of total cholesterol and potassium and decrease of ALT were detected in 800 ppm glycidol males, 3600 ppm linoleate ester males, and 800 ppm glycidol females, respectively. Serum creatinine levels in both sexes were decreased in the 800 ppm glycidol group. Relative weights of kidney and spleen were significantly increased in 200 and 800 ppm glycidol males and 800 ppm females. In addition, increase of relative kidney weights was also found in 3600 ppm oleate ester males. On histopathological assessment, increased cell debris was observed in the epididymal ducts of 800 ppm glycidol males, but not in ester groups. Although more detailed analysis will be needed to clarify any testicular toxicity of glycidol and *in vivo* genotoxicity of GEs, our results suggest that oleate and linoleate esters might be less toxic to F344 rats than glycidol itself.

### PS 2341 Modes of Action Underlying Citrinin-Induced Renal Carcinogenesis.

K. Kuroda<sup>1</sup>, M. Watanabe<sup>2</sup>, Y. Ishii<sup>1</sup>, S. Takasu<sup>1</sup>, K. Matsushita<sup>1</sup>, A. Kijima<sup>1</sup>, K. Ogawa<sup>1</sup>, T. Nomi<sup>3</sup>, A. Nishikawa<sup>3</sup>, Y. Sugita-Konishi<sup>2</sup> and T. Umemura<sup>1</sup>.  
<sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Division of Microbiology, National Institute of Health Sciences, Tokyo, Japan; <sup>3</sup>Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.

Citrinin (CTN), a mycotoxin produced by *Penicillium* and *Aspergillus*, is known to induce renal tumors in rats; however, the involvement of genotoxic mechanisms remains unclear. To evaluate the genotoxic potential of CTN, reporter gene mutation, comet, and micronucleus assays were performed. For the reporter gene mutation assay, groups of 5 male *gpt* delta rats were given CTN at doses of 20 and 40 mg/kg by gavage for 28 days to extirpate the kidneys 3 days after the last dosing. For the comet and micronucleus assays, groups of 5 male F344 rats were treated with CTN at the same doses by gavage for 2 days to extirpate the kidneys or bone marrow, respectively. In the reporter gene mutation assay, the high dose (40 mg/kg) was decreased to 30 mg/kg on day 4 because of severe weight loss. The results of the reporter gene mutation and comet assays suggested that CTN did not induce DNA damage and subsequent gene mutations. Positive result was obtained only in the micronucleus assay, which might result from numerical chromosomal aberrations

due to microtubule dysfunction by CTN. Therefore, it seems likely that non-genotoxic mechanisms are involved in CTN-induced carcinogenesis. In kidney samples from *gpt* delta rats, increases in the labeling indices of proliferating cell nuclear antigen (PCNA)-positive cells and mRNA expression levels of cell cycle-related genes (i.e., *cyclin E1*, *cyclin A2*, *cyclin B1*, and *E2F1*) were observed at all doses, despite the fact that the low dose showed no toxicological effects. Accordingly, the promotion of cell cycle progression observed in the kidneys of CTN-treated rats may have resulted from a direct mitogenic function of CTN. Increased phospho-ERK levels observed at all doses indicated that CTN is a promising candidate trigger for induction of the cell cycle; however, further investigation of the detailed pathway appears warranted.

### PS 2342 The Dynamics of a Harmful Algal Bloom and Paralytic Shellfish Toxins in Juneau, Alaska.

D. W. Chamberlin<sup>1</sup>, G. L. Eckert<sup>2</sup> and S. L. Tamone<sup>3</sup>. <sup>1</sup>Department of Biology, Appalachian State University, Boone, NC; <sup>2</sup>School of Fisheries and Ocean Sciences, University of Alaska Fairbanks, Juneau, AK; <sup>3</sup>Department of Natural Sciences, University of Alaska Southeast, Juneau, AK. Sponsor: G. LeBlanc.

Paralytic shellfish poisoning (PSP) is a deadly neurological syndrome resulting from the ingestion of shellfish containing high levels of paralytic shellfish toxins (PSTs), and approximately seven cases of PSP are reported in Alaska annually. The main component of PSTs is the neurotoxin saxitoxin, which is produced by the dinoflagellate *Alexandrium* sp. In June and July 2012 during this summer undergraduate project at the University of Alaska Southeast, plankton tows, seawater samples, and bivalve samples revealed a significant bloom of *Alexandrium* and subsequent toxin event in seawater and bivalves. Saxitoxin was extracted from the water column by filtering 1L of seawater and sonicating the filter for one hour in diH<sub>2</sub>O. The concentration of saxitoxin in seawater, measured using ELISA, ranged from 26 ug/L to 230 ug/L during the bloom. Nine species of bivalves, *Saxidomus giganteus*, *Mytilus trossulus*, *Clinocardium nuttalli*, *Protothaca staminea*, *Mya truncata*, *Mya arenaria*, *Tresus capax*, *Mactromeris polynyma*, and *Hiatella artica*, were sampled for saxitoxins using ELISA following soft tissue homogenization and extraction. Two species, *Mytilus trossulus* and *Saxidomus giganteus*, exceeded the regulatory limit for saxitoxin, 80 ug/100g wet wt. *Mytilus trossulus* saxitoxin concentrations ranged from 67 to 215 ug/100g, while *S. giganteus* ranged from 143 to 279 ug/100g. After the bloom, concentration of saxitoxin in the seawater and *M. trossulus* decreased, at a rate of 5.7ug/day, but remained elevated in *S. giganteus*. The concentration of saxitoxin in *M. trossulus* was below the FDA regulatory limit of 80ug/100g wet wt. 26 days after the bloom of *Alexandrium* was detected. Recreational harvest of bivalves in Alaska is not regulated for PSP; however, these results suggest that PSP risk is very high, particularly for *S. giganteus*.

### PS 2343 Acute and 28-Day Oral Toxicity Evaluation of siRNAs and Longer Double-Stranded RNAs in Mice.

J. S. Petrick<sup>1</sup>, B. S. Wahle<sup>2</sup>, W. M. Moore<sup>1</sup>, R. Shah<sup>1</sup>, D. Eveleigh<sup>3</sup>, J. H. Sherman<sup>1</sup>, W. F. Heydens<sup>1</sup> and S. L. Lemke<sup>1</sup>. <sup>1</sup>Monsanto Company, St. Louis, MO; <sup>2</sup>Xenometrics, LLC, Stilwell, KS; <sup>3</sup>Asuragen, Inc, Austin, TX.

RNA interference is being used in agricultural biotechnology as a selective tool for developing crop traits. There are numerous biological barriers to uptake and activity of ingested nucleic acids that are ubiquitous components of animal diets. To evaluate the potential for adverse effects of dietary double stranded RNAs (dsRNAs), we conducted oral toxicity studies in mice with a pool of four 21-mer small interfering RNAs (siRNAs) and a 218 base pair dsRNA targeting the mouse ortholog of vacuolar ATPase (vATPase). When dsRNA targeting the insect ortholog of vATPase is expressed in corn plants, they are insecticidal against corn rootworm. Test materials were administered to CD-1 mice by oral gavage in a single dose acute toxicity study at 2000 mg/kg and in a 28 day repeat dose oral toxicity study at 1, 10, and 100 mg/kg. *Torula* yeast RNA was included as a control in both studies. There was no impact of treatment on body weight, food consumption, clinical observations, or gross pathology in the acute toxicity study. The acute NOAELs for both the siRNAs and dsRNA were 2000 mg/kg, the highest doses tested. In the 28-day study, there were no treatment-related adverse effects on body weight, food consumption, clinical observations, clinical chemistry, hematology, gross pathology, or micropathology. The NOAELs in the 28 day study for both the siRNAs and dsRNA were 100 mg/kg, the highest doses tested. In summary, siRNAs and longer dsRNAs with 100% sequence identity to mouse vATPase do not result in adverse effects when administered orally to mice in a large dose. These results are consistent with the current body of knowledge that exogenous dsRNA molecules in food, even those with sequences identical to human and/or animal genes, are safely consumed.

## PS 2344 The Global Burden of Disease Caused by Arsenic in Food.

S. Oberoi, A. Barchowsky and F. Wu. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Arsenic is a ubiquitous, naturally occurring metalloid that poses a significant human cancer risk. While water consumption provides the majority of human exposure to arsenic, naturally occurring levels of arsenic in grains, vegetables, meats and fish, as well as through food processed with water containing arsenic (e.g. cooking rice) present a significant exposure to millions of individuals worldwide. To estimate the global burden of diseases attributable to toxic inorganic arsenic in food, we first evaluated the weight of evidence that supports a causal role for arsenic in a number of cancers and non-cancer disease endpoints. We determined that there was substantial evidence from large epidemiological studies that arsenic causes skin, lung, and bladder cancer in humans. The body burden of toxic arsenicals from foods is difficult to estimate and highly variable due to the natural distribution of arsenic in soils and water and the complication posed by multiple toxic inorganic and organic arsenicals, as well as non-toxic organic arsenicals contributing to total arsenic levels. Therefore we used GEMS/FAO-STAT estimates of food consumption in thirteen global clusters and JECFA reported measurements of total and inorganic arsenic in different foods to determine the upper and lower boundaries of foodborne inorganic arsenic exposures. We converted previously reported slope factors for arsenic related bladder, lung, and skin cancers that were based on water exposure to calculate the annual risk of the cancer incidence in males and females within each GEMS cluster. These cluster incidence estimates were summed to generate global estimates of 9,129 to 119,176 additional cases of bladder cancer, 11,844 to 121,442 of lung cancer, and 17,882 to 183,358 of skin cancer worldwide that are attributable to inorganic arsenic in food. These estimates indicate that foodborne arsenic contributes to a significant, but low level of global disease burden. *Supported by the WHO Foodborne Disease Burden Epidemiology Reference Group, Chemical Toxicology Task Force.*

## PS 2345 Hydrogen Peroxide Levels in Freshly Brewed Coffee and Effects on Storage.

S. N. Uppu<sup>2</sup>, B. London<sup>1</sup>, S. N. Murthy<sup>1</sup> and R. M. Uppu<sup>1</sup>. <sup>1</sup>*Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA;* <sup>2</sup>*Science, Dutchtown High School, Geismar, LA.*

Coffee originating in the 15<sup>th</sup> century from Ethiopia is one of the heavily consumed beverages. Although there are studies on caffeine and other components of coffee such as cafestol, the presence of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) in coffee was not known till recently as it was confined to scientific community and some informed public. It is a general belief that H<sub>2</sub>O<sub>2</sub> is formed only after long periods of storage or with certain roasting practices. The present study focused on dispelling the myths of H<sub>2</sub>O<sub>2</sub> in coffee. We first measured H<sub>2</sub>O<sub>2</sub> in freshly brewed coffee from different companies by ferrous oxidation-xylenol orange binding (FOX) method. Following this, we examined the time dependent accumulation of H<sub>2</sub>O<sub>2</sub> and its changes with temperature. Further, H<sub>2</sub>O<sub>2</sub> was estimated in coffee obtained from several local vendors. Contrary to the general belief that the accumulation of H<sub>2</sub>O<sub>2</sub> is an aging phenomenon of coffee, we found this toxicant even in freshly brewed coffee. This was true for all brands tested, and H<sub>2</sub>O<sub>2</sub> content increased upon storage. The highest increase was seen in coffee stored on the hot plate compared to the ones kept at room temperature/in cold. The H<sub>2</sub>O<sub>2</sub> content of coffee from different vendors ranged between 0.29 and 0.82 mM, which is 5- to 20-fold higher than the typical H<sub>2</sub>O<sub>2</sub> concentrations at which significant cytotoxic effects have been reported for assay systems using neuroblastoma and other cell types. Our findings shed new light on the probable toxic effects of a commonly consumed beverage like coffee, and the time and temperature dependent variations of keeping. While there are documented benefits of consumption of coffee, the H<sub>2</sub>O<sub>2</sub> mediated toxic effects are critical and have also to be borne in mind. Future studies are warranted to delineate the contribution of H<sub>2</sub>O<sub>2</sub> in the healthy well being of individuals who consume coffee extensively [Funding support from NSF (grant HRD-1043316) and the US Department of Education (grant PO31B040030) is acknowledged. Corresponding author's email: rao\_uppu@subr.edu].

## PS 2346 Toxicologic Evaluation of the Calcium Binding Protein Apoaquorin.

P. Marone<sup>1</sup>, M. R. Bauter<sup>1</sup>, H. Hofman-Huther<sup>2</sup> and D. Moran<sup>3</sup>. <sup>1</sup>*Toxicology, Eurofins Product Safety Laboratories, Dayton, NJ;* <sup>2</sup>*BSL Bioservice Scientific Laboratories GmbH, Planegg, Germany;* <sup>3</sup>*Quincy Bioscience, Madison, WI.*

The present study evaluated the mutagenic and toxicologic potential of a proprietary calcium binding jellyfish protein, Apoaquorin. The test article was investigated for its potential to induce gene mutations according to a plate incorporation

and pre-incubation test by Salmonella typhimurium strains TA98, 100, 1535, and 1537 and E.coli WP2uvrA at concentrations of 31.6, 100, 316, 1000, 2500, and 5000 µg/plate with and without metabolic activation. No toxic effects, precipitation or biologically relevant increases in revertant colony numbers of the test item were noted in any of the five tester strains used up to the highest dose group evaluated with and without metabolic activation in experiments I and II. Therefore, Apoaquorin did not cause gene mutation by base pair changes or frameshifts in the genome of the strains used and was considered to be non-mutagenic in the bacterial reverse mutation assay. In a 90-day oral gavage study including dose levels of 0, 92.6, 462.9, and 926.0 mg/kg/day in Sprague-Dawley rats, there were no adverse clinical, body weight, body weight gain, food consumption, food efficiency, or clinical- or histo-pathology changes associated with the administration of Apoaquorin. Therefore, the no-adverse-effect level (NOAEL) for Apoaquorin administered orally over 90 days was 926.0 mg/kg/day (666.7 mg/kg/day, based on an concentration of 722mg/g or 72% active ingredient) the highest dose tested, for male and female Sprague-Dawley rats.

## PS 2347 Toxicological Evaluation of a High-Purity Transresveratrol from an Alternative Synthetic Route.

J. A. Edwards, M. Beck and P. Beilstein. *Product Safety, DSM Nutritional Products, Kaiseraugst, Switzerland.* Sponsor: A. Davidovich.

trans-Resveratrol is a naturally-occurring, polyphenolic compound found predominantly in grapes. resVida (≥ 99.0% trans-resveratrol manufactured by DSM) has previously been assessed for safety based on toxicity studies (Williams et al, 2009) and obtained self-GRAS status in 2008. An alternative manufacturing process is now available in which trans-resveratrol is obtained with the same high purity of ≥ 99.0% but with different trace components to those in the original manufacturing process. Several of these new resveratrol-related by-products are found in nature (for example trans-pterostilbene). A safety assessment of the new process trans-resveratrol and its by-products was undertaken. The assessment process comprised:

- Identification of the new by-products
- Literature review for information on new by-products
- In silico analysis (DEREK) for toxic alerts of new by-products
- Structural analogue comparisons where appropriate
- In silico analysis (METEOR) for likely metabolism of newly identified by-products
- Ames tests (Salmonella Typhimurium Reverse Mutation Assays) with representative and spiked batches (to maximal specification level) of the new process material
- Definition of a new upper limit specification for newly identified by-products

Information presented from this process includes summarized data from the Ames test, which showed no mutagenic potential, with or without S9. From the assessment of all this information it was concluded that ≥ 99.0% trans-resveratrol produced from the alternative route is safe and suitable for use within the marketing limits defined in the GRAS evaluation of the original process material.

Williams LD, Burdock GA, Edwards JA, Beck M, Bausch J (2009) Safety studies conducted on high-purity trans-resveratrol in experimental animals, Food Chem Toxicol 47(9):2170-2182.

## PS 2348 A 28-Day Gavage Study of 2-Methylfuran in Male Fischer 344 Rats.

S. S. Gill<sup>1</sup>, M. Kavanagh<sup>1</sup>, W. Cherry<sup>1</sup>, M. Barker<sup>1</sup>, M. Weld<sup>2</sup> and G. M. Cooke<sup>1</sup>. <sup>1</sup>*TRD, Health Canada, Ottawa, ON, Canada;* <sup>2</sup>*Chemical Health Hazard Assessment Division, Health Canada, Ottawa, ON, Canada.* Sponsor: R. Mehta.

In thermally treated products, a series of alkylated furan derivatives have been found, in particular 2-substituted alkylfurans such as 2-methylfuran. These methyl analogues are metabolically activated in a similar fashion as the parent furan, yielding highly reactive unsaturated dialdehydes. There is limited toxicological data available for 2-methyl furan which makes conducting a risk assessment difficult. This pilot study was designed to determine the dose range of 2-methylfuran for future subchronic studies needed to determine a NOAEL. Male Fischer 344 rats 5-6 weeks of age were administered 2-methylfuran by gavage to final concentrations of 0, 0.4, 1.5, 3, 6, 12, or 25mg/kg bw/day. The animals were weighed daily prior to gavage. Food consumption was measured on a weekly basis. The liver was the primary target organ which developed dose-dependent toxicity. Relative liver weights were increased by 42% at 25 mg/kg bw/day. Histological changes in the liver were observed at 0.4, 1.5, 3, 6, 12 and 25 mg/kg bw/day. These changes were not accompanied by clinical changes in serum liver enzyme markers such as ALT, ALP and AST. Clinical biochemistry markers for kidney were altered but these were not accompanied by histological changes. At 25 mg/kg bw/day, spleen weights were increased and the prostate was significantly increased in size. Some hematological parameters were also altered. In this pilot study, the liver was the major target organ

for 2-methylfuran as indicated by changes in gross, histological and clinical parameters. Although there were changes in the weights of other organs including prostate, kidneys and spleen, these were not accompanied by histological changes. The results of this study will be used to conduct a future subchronic study to establish a NOAEL for risk assessment purposes.

**PS 2349 Characterization of Bacterial Mutagenicity QSAR Predictions of Food Additives to Support Safety Assessments in a Regulatory Setting.**

K. P. Cross<sup>1</sup>, G. J. Myatt<sup>1</sup>, K. Arvidson<sup>2</sup> and K. Muldoon-Jacobs<sup>2</sup>. <sup>1</sup>Leadscope, Inc., Columbus, OH; <sup>2</sup>Center for Food Safety and Applied Nutrition, US FDA, College Park, MD.

Assessment of food additive safety at the U.S. FDA has utilized quantitative SAR (QSAR) analysis models for endpoints ranging from genetic toxicity, reproductive and developmental toxicity to rodent carcinogenicity. However, many of the QSAR models in routine use were originally developed for drug and industrial chemical assessments. Consequentially a performance assessment on their use for compounds of interest to FDA CFSAN was undertaken. A set of approximately 4000 compounds of interest to CFSAN was assembled and used to characterize the performance of a QSAR model developed for predicting overall Salmonella mutagenicity. The test set was used to assess the suitability of the chemical space of the model for predicting food additive compounds. Overall performance statistics for accuracy, sensitivity, specificity and domain of applicability were measured. Structural classes were identified through compound clustering based on structural fingerprints that were well-predicted, poorly predicted, and not able to be predicted. Additionally, a set of public structural alerts that represent different mutagenic toxicophores was assembled and used to help more precisely quantify performance. Variation in performance was observed across different toxicophores, providing a detailed picture of the model's strengths and weaknesses from a structural perspective in assessing food additives.

**PS 2350 The Role of Palmitoylation in Chemical and Microbial Toxicity: Signal Pathways, Protein Binding and Trafficking.**

I. A. Ross and C. S. Kim. *Toxicology, US FDA, Laurel, MD.* Sponsor: T. Flynn.

Multicellular organisms use chemical messengers to transmit signals among organelles and to other cells. Relatively small hydrophobic molecules such as lipids are excellent candidates for this signaling purpose. In most proteins, palmitic acid and other saturated and some unsaturated fatty acids are esterified to the free thiol of cysteines and to the N-amide terminal. This process enhances the surface hydrophobicity and membrane affinity of protein substrates and play important roles in modulating protein trafficking, stability, and sorting. Protein palmitoylation has been involved in numerous cellular processes, including signaling, apoptosis, and neuronal transmission. The palmitoylation process is involved in diseases such as Huntington's disease, various cardiovascular and T-cell mediated immune disorders, and cancer. Our study on lipopolysaccharide and deoxynivalenol treatment to rats provides insights on the role of protein palmitoylation in chemical and microbial toxicity. In the liver of animals treated with 10 mg/kg DON, palmitic acid decreased by 22% between 3 and 24 hr and increased 24% between 24 and 72 hr as compared to the controls. LPS at 83 µg/kg caused 54% decrease in elaidic acid between 3 and 24 hr, and 7% between 24 hr and 72 hr while stearic acid decreased 33% between 3 and 24 hr and 60% between 24 and 72 hr as compared to the controls. Palmitate is a component of the LPS of Gram-negative bacteria. The bacterial outer membrane enzyme lipid A palmitoyltransferase PagP confers resistance to host immune defenses by transferring a palmitate chain from a phospholipid to the lipid A component of LPS. PagP is sensitive to cationic antimicrobial peptides (CAMP) which are included among the products of the Toll-like receptor 4 (TLR4) signal transduction pathway. This modification of lipid A with a palmitate appears to both protect the pathogenic bacteria from host immune defenses and attenuate the activation of those same defenses through the TLR4 signal transduction pathway.

**PS 2351 Compartment-Regulated Expression of Macrophage-Inhibitory Cytokine 1 under Mucosal ER Stress.**

S. Park, H. Choi, K. Do, J. Kim and Y. Moon. *Lab. of Mucosal Exposure and Biomodulation, Department Microbiology and Immunology, Pusan National University School of Medicine and Medical Research Institute, Yangsan, Republic of Korea.*

Endoplasmic reticulum (ER) stress causes global translational arrest during protein biosynthesis. In spite of global translational arrest, the critical stress responsive genes, including macrophage inhibitory cytokine 1 (MIC-1), are particularly

turned on. Functionally, MIC-1 played pivotal roles in ER stress-linked apoptotic death, which was also influenced by C/EBP homologous protein, a well known apoptotic mediator of ER stress. ER stress enhanced MIC-1 mRNA stability instead of transcriptional activation, and there were two mechanistic translocations critical for mRNA stabilization. First, C/EBP homologous protein triggered protein kinase C-linked cytosolic translocation of the HuR/ELAVL1 (Elav-like RNA-binding protein 1) RNA-binding protein, which bound to and stabilized MIC-1 transcript. As the second critical compartment-regulated modulation, ER stress-activated ERK1/2 signals contributed to enhanced stabilization of MIC-1 transcript by controlling the extended holding of the nucleated mRNA in the stress granules fusing with the mRNA-decaying processing body. Taken together, these two sequential compartment-associate modulation can account for stabilized transcription and subsequent re-initiation of translation of pro-apoptotic MIC-1 gene under mucosal ER stress (This study was carried out with the support of National Joint Agricultural Research Project of RDA (project number PJ008405032012) RDA, Republic of Korea).

**PS 2352 Azathioprine-Induced Hepatotoxicity in an In Vitro Inflammation-Immune Model.**

A. Maruf<sup>1</sup> and P. J. O'Brien<sup>1,2</sup>. <sup>1</sup>Pharmacology & Toxicology, University of Toronto, Toronto, ON, Canada; <sup>2</sup>Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.

Azathioprine (AZP) is widely used in clinical practice for preventing graft rejection in organ transplantations, various autoimmune and dermatological diseases with documented unpredictable hepatotoxicity. Several experimental models suggested that an episode of inflammation during drug treatment predisposes animals to tissue injury. Inflammation caused by infections or endotoxins markedly activates NADPH oxidase. In the phagosome, superoxide radicals spontaneously form hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and other reactive oxygen species. The effect of inflammation on AZP using "Accelerated Cytotoxicity Mechanism Screening" technique was investigated in this study. The concentration of AZP required to cause 50% cytotoxicity in 2 hr towards isolated rat hepatocytes was found to be 400 µM. AZP (400 µM) significantly increased cytotoxicity compared to control hepatocytes. When a non-toxic H<sub>2</sub>O<sub>2</sub> generating system (glucose/glucose oxidase) was added to the hepatocytes prior to the addition of AZP, an increase in AZP cytotoxicity was observed. Because neutrophils or Kupffer cells release myeloperoxidase on activation, the effect of adding peroxidase to the hepatocytes exposed to H<sub>2</sub>O<sub>2</sub> on AZP was also investigated. AZP showed a significant increase in cytotoxicity compared to drug-control in presence of glucose/glucose oxidase with or without horseradish peroxidase. A significant increase was also observed with glutathione depleted and catalase inhibited hepatocytes. Furthermore, AZP increased reactive oxygen species (ROS) formation, lipid peroxidation and decreased %mitochondrial membrane potential with our inflammation-immune model indicating the involvement of oxidative stress by glutathione oxidation, lipid peroxidation and mitochondrial toxicity. Protection was achieved by a ROS scavenger, 4-hydroxy-2,2,6,6-tetramethylpiperidine-1-oxyl (200 µM) and an antioxidant N,N'-diphenyl-p-phenylenediamine (2 µM). These results raise the possibility that the presence or absence of inflammation may be another susceptibility factor for azathioprine-induced hepatotoxicity.

**PS 2353 Indole-3-Carbinol and 3, 3'-Diindolylmethane Decrease Histone Deacetylase 3 Which Plays an Important Role in the Promotion of Staphylococcal Enterotoxin B-Induced Immune Cell Activation.**

P. B. Busbee, M. Nagarkatti and P. Nagarkatti. *USC School of Medicine, Columbia, SC.*

Staphylococcal enterotoxin B (SEB) is an exotoxin produced by the *Staphylococcus aureus* bacterium. This toxin is classified as a "superantigen" because of its ability to directly bind T cell receptors with MHC II class receptors of antigen presenting cells, which activates a large proportion of T cells. SEB is commonly associated with classic food poisoning, and more recently gained attention as a potential biological warfare agent since it is easily aerosolized. We have shown that indole-3-carbinol (I3C) and one of its byproducts, 3,3'-diindolylmethane (DIM), which are found in cruciferous vegetables, is able to reduce the number of SEB-activated T cells both in vitro and in vivo. These compounds were also able to reduce immune cell activation, induce apoptosis, and decrease proinflammatory cytokine release. In the current study, we assessed the role histone deacetylases (HDACs) played in SEB-treated cells, as well as what effect I3C/DIM had on them. Using inhibitors specific for Class I or Class II HDACs, we showed that inhibition of Class I HDACs leads to decreased immune cell activation, increased apoptosis, and reduction in proinflammatory cytokine release in SEB-activated cells. However, inhibition of Class II

HDACs had opposite effects, suggesting a dual role of these HDAC classes in SEB stimulation, where Class I HDACs were important in SEB-mediated immune cell activation. Screening HDAC expression with western blots, we were able to determine that HDAC3 was the main HDAC upregulated after SEB stimulation, and I3C and DIM treatment was able to decrease this expression level. This research establishes for the first time the important role Class I HDACs, particularly HDAC3, play in SEB-induced stimulation. We were also able to provide more evidence for the effectiveness of I3C/DIM treatment in SEB through the downregulation of HDAC3. (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

**PS 2354 Quantification of Cytokines: Enzyme-Linked Immunosorbent Assay versus Cytometric Bead Array.**

M. van Tuyl, M. Stitzinger, M. Vloet, Y. Klijn-Pijnenborg and H. Emmen. *Toxicology, WIL Research Europe B.V., s-Hertogenbosch, Netherlands.*

Cytokines are important inflammatory mediators. Disturbance of the balance of pro- and anti-inflammatory cytokines may result in multiple organ toxicity. In this study, we compared two commonly used immunoassays for the detection of cytokines, i.e. Enzyme-Linked ImmunoSorbent Assay (ELISA) and Cytometric Bead Array (CBA).

BD OptEIA ELISA kits and BD CBA Flex Sets were used to determine interleukin 4 (IL-4), interleukin 10 (IL-10) and interferon gamma (IFN- $\gamma$ ) levels in serum of untreated rats and in assay diluent. The intra-assay variation was determined after spiking with the individual recombinant standard of an ELISA kit at concentrations within the ELISA standard range or spiking with the combined recombinant standards of the CBA sets at concentrations within the CBA standard range. In addition, inter-assay variation was determined by spiking at two concentrations within the range of both ELISA and CBA standards and by analyzing these spiked samples using both methods on the same day.

Both ELISA and CBA methods showed similar coefficients of variation for all cytokines, i.e. less than 15% for the majority of measurements. The accuracy of assay diluent spiked with one or more cytokines was within 75-125% for most measurements using both methods. Spiking of serum samples showed clearly that serum contains factors that interfered with the quantification of IL-4, IL-10 and IFN- $\gamma$  using the selected ELISA kits and CBA sets. For example, quantification of IL-10 in spiked serum showed an accuracy of approximately 30% using both methods and IFN- $\gamma$  analysis resulted in an accuracy of <30% using ELISA and an accuracy of 70-80% using CBA. The absolute values of cytokines in spiked serum samples may differ between both methods, like for IFN- $\gamma$ , but relative levels of cytokines always correlated with the spiked concentrations using either one of these methods.

In conclusion, both ELISA and CBA showed similar precision and consistency in relative cytokine levels.

**PS 2355 Aryl Hydrocarbon Receptor-Dependent Retention of Nuclear HuR Suppresses Cyclooxygenase-2 Expression Independent of DNA-Binding.**

M. Zago<sup>1</sup>, J. Sheridan<sup>1</sup>, P. Nair<sup>2</sup>, A. Rico de Souza<sup>1</sup>, I. E. Gallouzi<sup>1</sup>, S. Rousseau<sup>1</sup>, S. Di Marco<sup>1</sup>, Q. Hamid<sup>1</sup>, D. H. Eidelman<sup>1</sup> and C. J. Baglioni<sup>1</sup>. <sup>1</sup>McGill University, Montréal, QC, Canada; <sup>2</sup>McMaster University, Hamilton, ON, Canada.

**Rationale:** The aryl hydrocarbon receptor (AhR) has emerged an endogenous suppressor of cyclooxygenase-2 (Cox-2). Cox-2 is an immediate-early gene that is robustly increased by cigarette smoke exposure. We have published that the AhR suppresses cigarette smoke-induced Cox-2 protein but not mRNA, suggesting post-transcriptional regulation as a mechanism. The AhR may destabilize Cox-2 mRNA by retaining the RNA-binding protein (RBP) HuR in the nucleus. There is no known association between the AhR and HuR. Therefore, we investigated whether AhR-dependent retention of nuclear HuR is responsible for Cox-2 mRNA destabilization.

**Methods:** AhR<sup>-/-</sup>, AhR<sup>+/+</sup>, AhRDBD/DBD (harboring a mutant AhR unable to bind DNA) and AhRDBD/B6 mouse lung fibroblasts were exposed to cigarette smoke extract (CSE) for 3 h followed by Actinomycin D (ActD) for 30 minutes, 1 or 3 h. Cox-2 protein and mRNA were analyzed by western blot and qRT-PCR, respectively. HuR expression was assessed by western blot and immunofluorescence. AhR<sup>-/-</sup> cells were transfected with HuR siRNA and exposed to 1% CSE for 3 h with or without ActD for an additional 3 h. Cox-2 mRNA was then assessed by qPCR.

**Results:** Steady-state Cox-2 mRNA levels significantly declined upon ActD treatment in AhR<sup>+/+</sup> cells, AhRDBD/DBD and AhRDBD/B6 cells, suggesting that the AhR destabilizes Cox-2 mRNA by a DRE-independent mechanism. Cox-2 mRNA

instability was due to the nuclear retention of HuR. CSE did not alter HuR expression, but induced cytoplasmic HuR shuttling only in AhR<sup>-/-</sup> cells. Knockdown HuR in AhR<sup>-/-</sup> cells significantly decreased Cox-2 mRNA expression after exposure to ActD.

**Conclusions:** AhR-dependent retention of nuclear HuR suppresses cigarette smoke-induced Cox-2 protein by a mechanism that is independent of DNA-binding activity. These important findings open the possibility that a DRE-independent AhR pathway may be exploited therapeutically as an anti-inflammatory target.

**PS 2356 Ultraviolet Radiation (UVB)-Induced Migration of Skin Dendritic Cell Subsets Is Mediated through Transforming Growth Factor Beta Signaling.**

A. Ravindran<sup>1</sup>, J. Mohammed<sup>1</sup>, A. J. Gunderson<sup>1</sup>, M. C. Udey<sup>2</sup> and A. B. Glick<sup>1</sup>. <sup>1</sup>Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, State College, PA; <sup>2</sup>Dermatology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD.

Ultraviolet radiation (UVB) is the leading cause of skin cancer worldwide. UVB also modulates certain inflammation driven cutaneous pathologies such as contact hypersensitivity through actions on skin resident dendritic cell (DC) subsets. Transforming Growth Factor- $\beta$ 1 (TGF- $\beta$ 1) is a potent immunoregulatory cytokine in the skin microenvironment. Here, we show that TGF- $\beta$ 1 is required for UVB induced activation and migration of dendritic cells to the skin draining lymph nodes. We irradiated skin of Skin Hairless (SKH1) mice with UVB in the presence or absence of SB431542, a small molecule inhibitor of the TGF- $\beta$  type I receptor and measured lymph node migration of skin dendritic cell subsets at acute time points. Topical inhibition of TGF- $\beta$ 1 pathway with SB431542 suppressed the migration of skin dendritic cell subsets, primarily CD103<sup>+</sup> CD207<sup>+</sup> and CD207<sup>-</sup> DC populations to the lymph nodes in response to UVB irradiation. In addition, in an ex vivo, skin explant assay for the migration of dendritic cells, UVB induced DC migration into culture media was suppressed with topical inhibition with SB431542. In mice expressing a dominant negative receptor for TGF- $\beta$  in CD11c<sup>+</sup> dendritic cells (CD11c-T $\beta$ R1 DNR), UVB induced migration of the DC subsets was suppressed directly linking TGF- $\beta$  signaling in DCs to UVB induced migration of DCs. Treatment with SB431542 also suppressed UVB-induced Interferon  $\gamma$  (IFN $\gamma$ ) secretion as well as the effector differentiation of T lymphocytes within the lymph nodes. Consistent with decreased activation within the lymph nodes, SB431542 decreased UVB activation of the skin infiltrating CD4 and CD8 lymphocytes after acute treatments and in UVB-induced skin tumors. Together, these data show that the TGF- $\beta$ 1 signaling pathway is important for the initiation of the inflammatory response to UVB irradiation of the skin, mediated primarily through the dendritic cells.

**PS 2357 Alterations in the Hepatic Transcriptome during Live *Citrobacter Rodentium* Infection.**

M. D. Merrell and E. T. Morgan. *Pharmacology, Emory University, Atlanta, GA.*

Infection and inflammatory signaling can significantly alter drug metabolism enzyme expression (DME), thereby impacting the capacity of the liver to clear toxicants from the body. Previous work in our laboratory has detailed the modulation of gene expression of several hepatic DMEs during colonic infection with live *Citrobacter rodentium* (*C. rodentium*). These alterations included particularly strong downregulation of Fmo3 and Cyp4a family members, and appear to be largely independent of LPS-TLR4 signaling. In order to elucidate potential signaling networks and pathways involved in this downregulation, we examined the impact of *C. rodentium* infection on the hepatic transcriptome using the Illumina MouseRef-8 v2 expression BeadChip. HeJ mice (n=4) lacking toll-like receptor 4 (TLR4), along with appropriate wild type animals (HeOUJ), were orally inoculated with live *C. rodentium* in a sucrose solution or received sterile sucrose. After 7 days, animals were sacrificed, livers were harvested, and RNA was prepared and submitted for analysis. Genes showing differential expression during infection were identified and pathway analysis using gene-set enrichment was performed. Increased numbers of genes with altered expression were found in HeJ mice as compared to HeOUJ controls. Several DME genes not previously reported as being altered in *C. rodentium* infection were identified, comprising P450s, UGTs and GSTs. Ontology terms/pathways with high enrichment included *Drug Metabolism*, *Mitochondrion*, *Oxidation Reduction*, and *Inflammatory Response*. Other terms/pathways of interest include *Apoptosis*, *Glutathione Transferase Activity*, and *Lipid Metabolism*. An analysis of the potential transcription control pathways upstream of these observed gene expression changes was also performed. Potential upstream factors include Ahr-ARNT, Ekl-1, and Hnf3beta, among others. Taken together, these results demonstrate that drug metabolizing enzymes as a gene class are particularly sensitive to infection, and indicate several potential pathways that may be responsible for these effects. Supported by grant R01072372 from the NIH.

**PS 2358 Silencing of Keap1 in Macrophages Boosts Lipopolysaccharide-Induced Transcription of Interleukin 6 via IKK $\beta$  Activation.**

P. Lu, P. Xue, J. Dong, C. G. Woods, Q. Zhang, M. E. Andersen and J. Pi. *The Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

Interleukin-6 (IL6) is a multifunctional cytokine that regulates immune and inflammatory responses. Multiple transcription factors, including NF- $\kappa$ B and nuclear factor E2-related factor 2 (Nrf2), are implicated in the transcriptional regulation of IL6. Kelch-like ECH-associated protein 1 (Keap1) is a substrate adaptor protein for a Cullin 3-dependent E3 ubiquitin ligase complex, which regulates the degradation of various vital proteins, including Nrf2 and Ikk $\beta$ . In agreement with previous studies, stable knockdown of Nrf2 in RAW 264.7 mouse macrophages led to significantly attenuated antioxidant response and decreased expression of IL6 under basal and lipopolysaccharides (LPS)-treated conditions. However, Nrf2 activation alone (e.g. under tert-butylhydroquinone exposure) did not increase the expression of IL6, suggesting that Nrf2 is a necessary, but not sufficient, factor in regulating LPS-induced transactivation of IL6. In contrast, silencing of Keap1 in RAW cells and human monocyte THP1 cells markedly augmented the expression of IL6 under non-stressed and LPS-challenged conditions. The enhanced expression of IL6 in Keap1-knockdown (Keap1-KD) cells was significantly attenuated by silencing of Ikk $\beta$ , but not Nrf2, suggesting that stabilized Ikk $\beta$  resulting from Keap1 silencing is the major downstream event responsible for the transactivation of IL6. This finding was further confirmed by the enhanced protein levels of Ikk $\beta$  and subsequent increased expression and phosphorylation of NF- $\kappa$ B p65 in the Keap1-KD cells. Together, the present studies demonstrated that silencing of Keap1 in macrophages boosts LPS-induced transcription of IL6 via IKK $\beta$  activation. Given the importance of IL6 in inflammatory response, targeting Keap1 could be a novel approach in the treatment and prevention of inflammation and associated disorders.

**PS 2359 Potent Protection against PM2.5 Diesel Exhaust Particle-Caused ROS Generation and Vasculature Permeable through Regulation of Nrf2-Induced Pathways by Triterpenoids.**

C. Tseng<sup>1,2</sup>, C. Lin<sup>1</sup>, M. K. Gordon<sup>3</sup> and M. Chao<sup>1</sup>. <sup>1</sup>Bioscience Technology, Chung Yuan Christian University, Chung-Li, Taiwan; <sup>2</sup>Biomedical Engineering, Chung Yuan Christian University, Chung-Li, Taiwan; <sup>3</sup>Joint Program of Toxicology, Rutgers University, Piscataway, NJ.

Epidemiologies suggest that an increase of PM2.5 diesel exhaust particles (DEP) in ambient air corresponds to an increase in myocardial infarctions within 48 hours. To cause such disorder, the close association of capillaries and alveoli should allow inhaled DEP to get in close proximity to capillary endothelial tubes. However, the mechanism of how DEP travel from the alveolar space into bloodstream remains unclear. Our group has suggested that DEP might upregulate Nrf2 pathway and induce vascular permeability factor VEGF-A secretion. Once VEGF-A goes up, DEP may cause cell-cell adherent junction disruption and transmigrate into the circulation. In order to minimize the level that DEP traveling in the bloodstream, two triterpenoids (oleanic acid, ursolic acid) were used as antioxidant. After DEP  $\pm$  triterpenoids treatment, MTT was used to examine cell viability of 3D capillary-like endothelial cultures, Cm-H2DCFDA assays were used to determine the extent of ROS production in the model, and confocal microscopy was used to evaluate the endothelial junctional proteins in the cell-cell borders and localization of Nrf2 as well. At high dose DEP, 80% of the tube cells die within 24 hours. Cells treated with 25  $\mu$ g/ml DEP plus triterpenoids not only the translocation of Nrf2 and downstream HO-1 mRNA expression was reduced, but also ROS generation was inhibited. Additionally, Z-stacks images revealed that DEP not only accumulated on the surface of capillary tubes, but also penetrated into the lumen. VE-cadherin was observed to redistribute in response to DEP. Once combine with triterpenoids, endothelial tube cells were slightly affected only at high dose DEP, injuries caused by DEP-induced ROS were blocked. Our results suggest that triterpenoids might prevent DEP transmigration into bloodstream by inhibiting oxidative stress production and endothelial adherent junctions alternation.

**PS 2360 Differential Responses upon Inhalation Exposure to Biodiesel versus Diesel Exhaust on Oxidative Stress, Inflammatory, and Immune Outcomes.**

A. A. Shvedova<sup>1,2</sup>, N. V. Yanamala<sup>1</sup>, A. V. Tkach<sup>1</sup>, E. R. Kisin<sup>1</sup>, A. R. Murray<sup>1</sup>, T. Khaliullin<sup>1</sup>, M. Hatfield<sup>1</sup>, S. H. Gavett<sup>3</sup> and I. Gilmour<sup>3</sup>. <sup>1</sup>PPRB, HELD, NIOSH, Morgantown, WV; <sup>2</sup>Department of Physiology and Pharmacology, School of Medicine, WVU, Morgantown, WV; <sup>3</sup>Cardiopulmonary and Immunotoxicology Branch, US EPA, Research Triangle Park, NC.

Biodiesel (BD) exhaust may have reduced adverse health effects due to lower mass emissions and reduced production of hazardous compounds compared to diesel exhaust. To investigate this possibility, we compared adverse effects in lungs and liver of BALB/c mice after inhalation exposure (0, 50, 150 and 500  $\mu$ g/m<sup>3</sup>; 4 hr/day, 5 d/wk, for 4 wk) to combustion exhaust from 100% biodiesel (B100) and diesel (D100). Compared to D100, B100 exhaust caused a significant accumulation of oxidatively modified proteins (carbonyls), increase in 4-hydroxynonenal (4-HNE), reduction of protein thiols, depletion of antioxidant - glutathione (GSH), a dose-dependent increase in the levels of biomarkers of tissue damage (LDH) in lungs, and inflammation (myeloperoxidase, MPO) in both lungs and liver. B100 exposure also significantly enhanced expression of cytokines IL-6, and IL-12p70 (in a dose-dependent manner), along with IL-10, TNF- $\alpha$  and MCP-1 (increased compared to control) in both lung and liver tissues. Overall, the cytokine profiles in the lung and liver suggest that B100 and D100 exhaust elicit similar innate immune responses, predominantly involving T-cell independent pathways; however, the magnitude of inflammation was greater following B100 exhaust exposure. Interestingly, exposure to D100, but not B100 exhaust, induced a significant increase in the levels of IFN- $\gamma$  in the lungs, suggesting a broader engagement of Th1 component by D100 exhaust. Based on this, we hypothesize that the distinctive organic compounds and/or oxidative products formed as a result of increased oxidative stress upon B100 exposure, are capable of targeting biological/molecular pathways that are distinct from D100 exposure. (This abstract does not represent US EPA policy).

**PS 2361 THP-1 and HMC-1 Cell Interaction with Epithelial Cells in a 3D Tetraculture System of the Alveolar Barrier Modulates the Response to Oxidative Stress.**

S. G. Klein<sup>1,2</sup>, S. Tommaso<sup>1</sup>, L. Hoffmann<sup>1</sup>, B. Blömeke<sup>2</sup> and A. Gutleb<sup>1</sup>. <sup>1</sup>EVA, CRP - Gabriel Lippmann, Belvaux, Luxembourg; <sup>2</sup>Department of Environmental Toxicology, University of Trier, Trier, Germany.

Exposure to fine and ultra-fine ambient particles is still a problem of concern in many industrialised parts of the world and the intensified use of nanotechnology may further increase exposure to small particles. Among the various mechanisms, the production of oxidative stress is considered to be one of the key mechanisms how particles affect tissues. Complex in vitro coculture systems may be valuable tools to study related processes and to further evaluate the effects of particles on the lung (Klein et al., 2011). Therefore, a system consisting of four different human cell lines that should mimic the cell response of the alveolar surface in vitro was developed in order to be used with a native aerosol exposure system (Vitrocell<sup>TM</sup> chamber). It is composed of an alveolar type-II cell line (A549), differentiated macrophage-like cells (THP-1), mast cells (HMC-1) and endothelial cells (EA.hy 926), seeded in a 3D orientation on microporous membranes.

Oxidative stress was induced by incubating the cells with 2,2'-azobis-2-methylpropanimidamide, dihydrochloride (AAPH; 20 mM), and quantified as the oxidation of dichlorofluorescein diacetate (DCFH-DA) by measuring fluorescence. Results are reported as fold increase in ROS production relatively compared to untreated cells.

Single cell cultures of EA.hy 926 (11.8  $\pm$  1.4), THP-1 (11.5  $\pm$  1.3) and HMC-1 (14.7  $\pm$  2.9) showed significantly higher oxidative stress than the tetraculture (6.6  $\pm$  0.75). A549 cells alone show the lowest amount of oxidative stress (3.4  $\pm$  0.18) compared to other cultures. The interplay of model cell for the immune system (THP-1 and HMC-1) with A549 epithelial cells strongly influences the behaviour of our system, resulting in an alleviative effect for oxidative stress compared to the monocultures. The use of the tetraculture system may lead to a more realistic judgement about the hazard of new compounds in the future.

**PS 2362 ADME Studies on Nanoparticles Are So Far of Limited Use for PBPK Modeling.**

U. Carlander and G. Johanson. *Institute of Environmental Medicine, Work Environment Toxicology, Karolinska Institutet, Solna, Sweden.*

The health hazards with nanoparticles (NP) are largely unknown, and human data are unlikely to be generated to any great extent. Previous experience with xenobiotics shows that combined use of animal ADME studies and PBPK modeling is

useful in human health risk assessment and this approach should be useful also for NP. However, it requires that animal experiments are carried out and reported in an appropriate way. The aim of this study was to review published data on the biodistribution of intravenously injected NP. By this approach the additional complexity of absorption is avoided. Data were mainly retrieved for gold, silver, titanium dioxide, silica and polymeric NP. Very few of the 66 reviewed articles, covering 244 NP varieties, seem useful for PBPK modeling. The following major limitations were identified: (1) incomplete NP and dose characterization, (2) short follow-up post-dosing, (3) few samples per tissue, (4) few tissues/organs studied, and (5) failure to account for the mass balance, and (6) lack of confirmation of NP integrity in the tissues. These shortcomings make time course descriptions, half time calculations, estimates of bioaccumulation uncertain. Most studies present data for blood, liver and spleen, many also for lungs and kidneys. A few studies suggest that NP deposits in muscle, bone and carcass should not be neglected. Overall, our review indicates that it is difficult to draw general conclusions about NP biodistribution. With the limited data at hand, it seems that no individual factor such as size, coating, shape, charge, chemical composition or agglomerations status can explain the biodistribution. In conclusion, the ADME of NP is complex and additional studies are needed. To be useful in PBPK modeling, these studies should include more complete NP characterization, cover more organs and time points, have longer follow-ups, and account for the mass balance. It would be valuable to develop a standard protocol for ADME studies of NP. This study was financed by a grant from the Swedish Council for Working Life and Social Research.

### PS 2363 Copper Oxide Nanoparticle-Induced Acute Pulmonary Inflammation: Role of Dose Rate and Dissolution Rate.

B. L. Baisch, N. Corson, R. Gelein, P. Wade-Mercer, A. Walker, G. Oberdorster and A. Elder. *Environmental Medicine, University of Rochester Medical Center, Rochester, NY.*

Numerous studies in rodents use high doses and bolus delivery of nanoparticles (NPs) to the respiratory tract (RT) in order to identify potential hazards. Past data suggests differences in inflammatory responses following intratracheal instillation as compared to whole body inhalation exposure, indicating that bolus delivery may overestimate NP hazard. However, deposited doses to the lower RT are not always consistent in these studies and the impact of ions from soluble metal oxide NPs interacting with extracellular fluids and within cells is uncertain. We hypothesize that the delivered dose rate and dissolution rate are key determinants of the inflammatory response in the RT when the deposited dose is constant. F-344 rats (175-270g) were exposed to the same deposited dose (3µg) of CuO NPs (30-50nm; 13m<sup>2</sup>/g) by high dose rate (bolus) intratracheal instillation and low dose rate (aerosol) whole body inhalation (1mg/m<sup>3</sup> for 4h). Particle size distributions showed agglomerated structures for both intratracheal instillation (280-420nm, hydrodynamic diameter) and whole body inhalation (990nm, aerodynamic diameter) exposures. Dynamic dissolution of the NPs in simulated lung lining fluid (pH 7.4) showed substantial Cu<sup>2+</sup> release over 30h (67%). There were statistically significant increases in bronchoalveolar lavage fluid (BALF) neutrophils 8 and 24h after bolus delivery of CuO (4.43 ± 1.25 × 10<sup>5</sup>; 84.18 ± 18.53 × 10<sup>5</sup>) compared to saline controls (1.44 ± 0.41 × 10<sup>5</sup>) and 24h after aerosol exposure (48.34 ± 5.45 × 10<sup>5</sup>) compared to air controls (0.62 ± 0.14 × 10<sup>5</sup>). Within 7 days BALF neutrophils returned to control levels. The similar clearance pattern from the lower RT by both methods indicates that clearance was not affected by delivered dose rate. We conclude that both dose rate and dissolution rate should be considered when identifying NP hazard. This research was funded by NIH R01CA134218, P30ES01247, RC2ES018741, T32ES07026 and T32HL066988.

### PS 2364 Association between Neutrophilia and Inflammatory Responses for Ensuring Safety of Nanomaterials.

K. Higashisaka<sup>1</sup>, Y. Yoshioka<sup>1</sup>, T. Nagano<sup>1</sup>, A. Kunieda<sup>1</sup>, Y. Iwahara<sup>1</sup>, K. Tanaka<sup>1</sup>, K. Hata<sup>1</sup>, S. Tsunoda<sup>2,3</sup>, H. Nabeshi<sup>4</sup>, T. Yoshikawa<sup>1</sup> and Y. Tsutsumi<sup>1,2,3</sup>. <sup>1</sup>Laboratory of Toxicology and Safety Science, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan; <sup>2</sup>Laboratory of Biopharmaceutical Research, National Institute of Biomedical Innovation, Osaka, Japan; <sup>3</sup>MEI center, Osaka University, Osaka, Japan; <sup>4</sup>National Institute of Health Science, Tokyo, Japan.

Recently, the development of nanomaterials is promoted extensively. These nanomaterials have been already used in various applications. Under this circumstance, the debate on safety of nanomaterials has expanded worldwide, because they have unique physicochemical properties and exert innovative functions. Therefore, it is urgent need to obtain more information to ensure the safety of nanomaterials. Previously, we demonstrated that some silica nanoparticles (nSP) might induce systemic inflammatory effects, whereas appropriate surface modification suppressed

these effects. However, association with neutrophil that are known to play an important role in inflammatory responses is hardly understood. Here, for clarifying the mechanism of inflammatory effects of nSP, we analyzed the changes of neutrophil proportion in mice. Initially, to evaluate systemic inflammation induced by nSP, we analyzed the changes of neutrophil proportion in mice after intravenous injection of nSP with diameters of 70 nm (nSP70) via tail vein. Flow cytometry analysis showed that the neutrophil proportion was elevated in peripheral blood of nSP70-treated mice. Furthermore, the plasma level of G-CSF was significantly elevated in nSP70-treated mice compared to that of control mice and anti-G-CSF antibody-treated mice exhibited a decrease in neutrophil proportion. These results suggested that the nSP70-induced increasing neutrophil proportion was dependent on G-CSF production. We are now trying to examine the association between neutrophilia and inflammatory responses. We believe that our findings provide useful information for ensuring the safety of nanomaterials.

### PS 2365 Differential Response of Brain and Liver Free Fatty Acids following Administration of Iron Nanoparticles in Rats.

Z. K. Binienda<sup>1</sup>, I. A. Ross<sup>2</sup>, B. Gough<sup>1</sup>, S. F. Ali<sup>1</sup>, S. Z. Imam<sup>1</sup> and C. S. Kim<sup>2</sup>. <sup>1</sup>Neurotoxicology, NCTR/FDA, Jefferson, AR; <sup>2</sup>Toxicology, CFSAN/FDA, Laurel, MD.

Intranasal treatment with ferric oxide nanoparticles (α-Fe<sub>2</sub>O<sub>3</sub> and γ-Fe<sub>2</sub>O<sub>3</sub> NPs), in rats caused microglial proliferation and activation in olfactory bulbs, hippocampus and striatum. Our in vitro studies with SHSY-5Y neuroblastoma cells exposed to 10 and 30 nm ferric oxide NPs showed over expression of alpha-synuclein protein, depletion of dopamine, and conditions for oxidative stress. Here, we examined the response of brain and liver free fatty acids (FFAs) in adult male Sprague-Dawley rats treated intraperitoneally (i.p.) either with saline (control) or ferric oxide (Fe<sub>2</sub>O<sub>3</sub>) – NPs at 25, 50 and 100 mg/kg. Rats were sacrificed 72 hrs after injection to harvest caudate nucleus and liver. Long chain FFAs were extracted with chloroform and methanol (4, 8 v/w) from tissue homogenates and the extracts were shaken, followed by centrifugation. The supernatants were reconstituted with Hepes, chloroform and methanol (3.2, 4, 8 v/w). The chloroform was then evaporated under nitrogen. The residue was reconstituted with ether-hexane (50:50, v/v) and eluted by column chromatography on acid-washed Florisil. FFAs were derivatized with BF<sub>3</sub>/methanol and fatty acid methyl esters were quantitated using gas chromatography. Concentrations of saturated FFAs (palmitic, stearic) in the liver and brain did not change following injection of the iron NPs. However, unsaturated brain FFAs (oleic, linoleic) were decreasing in a dose-related fashion in the CN (p<0.05). In the liver, the concentration of the unsaturated FFAs increased significantly at 25 and 50 mg/kg (p<0.05) but was no different from control at 100 mg/kg. These data indicate a differential response of liver and brain unsaturated fatty acids to iron nanoparticle exposure, suggesting different mechanisms in the liver and brain in response to oxidative stress.

### PS 2366 Effects of Cerium Oxide Nanoparticles on Fibroblast Function in Relation to Lung Fibrosis.

J. Y. Ma, B. Hines, M. Barger, R. R. Mercer and V. Castranova. *PPRB/HELD, NIOSH, Morgantown, WV.*

The emission of cerium oxide nanoparticles (CeO<sub>2</sub>) in the diesel exhaust, when cerium compounds were used as a diesel engine catalyst to lower the diesel exhaust particles, is a health concern. Our previous studies have shown that CeO<sub>2</sub> induced pulmonary inflammation and lung fibrosis. The objective of the present study is to investigate the modification of fibroblast function by CeO<sub>2</sub> in relation to fibrosis. Male Sprague Dawley rats were exposed to CeO<sub>2</sub> (0.15 to 7 mg/kg) by a single intratracheal instillation and sacrificed at various times post exposure. Alveolar macrophages (AM) were isolated by bronchoalveolar lavage (BAL), and lung fibroblasts were isolated from the lung tissues. The first BAL fluid and AM culture medium obtained after a 24 h incubation time were saved for further analysis. The results show that at 28 days after CeO<sub>2</sub> (3.5 mg/kg) exposure, lung fibrosis was evident by increased hydroxyproline content in lung tissues and enhanced Sirius Red staining collagen fibers in the lung. In addition, the presence of stress actin, expressed as α-smooth muscle actin (SMA), in fibroblasts was also significantly increased when compared to the control. Lung fibroblasts isolated from CeO<sub>2</sub>-exposed rats at 28 days post-exposure showed a dose-dependent decrease in proliferation rate using the MTT assay. Treating primary fibroblasts with CeO<sub>2</sub> in vitro, did not significantly affect cell proliferation rate; however, when treated with the first BAL fluid collected at 3- or 10-days after CeO<sub>2</sub> exposure, significantly increased cell proliferation when compared to the control. In vitro treatment of fibroblasts with TGF-β1 significantly increased α-SMA expression. These results

demonstrate that CeO<sub>2</sub> induces a diverse network of mediators that affects fibroblast proliferation and functional changes that may play a role in lung fibrosis. These findings suggest potential health effects of CeO<sub>2</sub> exposure.

## PS 2367 Toxicity of Nanoparticles Embedded in Paints Compared to Pristine Nanoparticles.

S. Smulders, K. Luyts, J. Vanoirbeek and P. Hoet. *Experimental Unit for Toxicology, KU Leuven, Leuven, Belgium.*

Nanomaterials are increasingly being used in the paint industry due to their unique physical and chemical properties. Nanoparticles often used in paints and coatings are TiO<sub>2</sub> (anti-UV, self-cleaning, air purification), Ag (anti-microbial) and SiO<sub>2</sub> (fire retardant, anti-scratch).

In this study, the toxic effects of 3 pristine nanoparticles (TiO<sub>2</sub>, Ag and SiO<sub>2</sub>), 3 aged paints containing nanoparticles (TiO<sub>2</sub>, Ag and SiO<sub>2</sub>) and control paints without nanoparticles were compared.

BALB/c mice were weekly oropharyngeally aspirated with nanoparticles or paint particles (20 µg/aspiration) for 5 weeks. Mice were sacrificed 2 or 28 days after the last aspiration. The local (lung/bronchoalveolar lavage fluid) and systemic (blood) toxicity was evaluated (cell counts, inflammatory cytokines, blood clotting parameters).

The pristine nanoparticles showed no effects in the blood and a subtle toxic effect in the lungs, which was most pronounced in the case of Ag nanoparticles (increase in neutrophils (7.8x10<sup>3</sup>), 2-fold increase in pro-inflammatory cytokines KC and IL-1β). The paints containing nanoparticles did not show significant toxicity.

In conclusion, we demonstrated that although pristine particles show some toxic effects, no significant toxicological changes were observed when they were embedded in a complex paint matrix.

## PS 2368 A 15-Day Oral Exposure to Dispersed TiO<sub>2</sub> P25 Particles Induces Epithelial Barrier Dysfunction and Bacterial Translocation in the Rat Intestine.

E. Houdeau<sup>1</sup>, E. Gaultier<sup>1</sup>, M. Nabila<sup>1</sup>, N. Naud<sup>1</sup>, A. Ait-Belgnaoui<sup>1</sup>, N. Thieriet<sup>2</sup>, M. Carrière<sup>3</sup>, J. Cravedi<sup>1</sup>, V. Theodorou<sup>1</sup> and F. Pierre<sup>1</sup>. <sup>1</sup>INRA Tolaim, Toulouse, France; <sup>2</sup>ANSES, Maisons-Alfort, France; <sup>3</sup>CEA-LAN, Grenoble, France. Sponsor: D. ZALCO.

**Aim:** Titanium dioxide (TiO<sub>2</sub>) has a long-standing use as food additive and is promised to broad use in food packaging as antimicrobial in biosourced films. Possible hazards of ingested TiO<sub>2</sub> particles for human digestive tract are under discussion. We addressed consequences for gut barrier function in rats orally exposed to TiO<sub>2</sub> P25 (85% anatase/15% rutile) at human level exposure. **Methods:** Male rats were orally given either vehicle (Ve) or TiO<sub>2</sub> P25 (provided by European Commission-Joint Research Center in the OECD sponsorship program) at 100, 1, 0.01 µg/kg BW/d in aggregated forms or ultrasonicated to obtain a stable dispersed submicron-sized TiO<sub>2</sub> commonly found in food. Particle size was measured by dynamic light scattering. Duodenal to colonic paracellular (4kD dextran) epithelial permeability was studied by Ussing chamber. Lipid peroxidation was assessed by Thiobarbituric Acid Reactive Substances (TBARS) assay, and inflammation through neutrophil myeloperoxidase activity (MPO). Bacterial translocation (BT) was assessed in mesenteric lymph nodes (MLN), liver and spleen. **Results:** Oral treatment with dispersed TiO<sub>2</sub> P25 particles (mean hydrodynamic diameter 630nm) at 100 or 1 µg/kg/d increased epithelial permeability (p<0.01) in the jejunum (+70±16% vs Ve) and colon (+57±19% vs Ve), and only in the jejunum at 10ng/kg/d (85%: 0.19±0.07 vs 0.10±0.03 nmol dextran.cm<sup>2</sup>.h<sup>-1</sup> in Ve; p<0.05). At all doses, dispersed P25 did not affect TBARS and MPO levels across the gut, whereas rats dosed with 100 µg/kg/d showed enhanced BT to MLN (14 rats/16 vs 4/16 in Ve; p=0.001) (10±0.2 vs 9.3±0.3 log10cfu/g of tissue, respectively), but not to liver and spleen. Neither gut permeability nor BT was affected in rats exposed to non-dispersed P25. **Conclusion:** Chronic oral exposure of rats with dispersed TiO<sub>2</sub> at human relevant dietary exposure alters intestinal barrier, with features of bacterial translocation suggesting enhanced risk of pathogen uptake.

## PS 2369 The Effect of Nanoparticles from Secondhand Cigarette Smoke on the Mouse Lung.

Z. Wu<sup>1</sup>, M. McCawley<sup>2</sup>, E. Kimani<sup>2</sup> and R. D. Dey<sup>1</sup>. <sup>1</sup>Neurobiology and Anatomy, West Virginia University, Morgantown, WV; <sup>2</sup>Community Medicine, West Virginia University, Morgantown, WV. Sponsor: T. Nurkiewicz.

Second hand cigarette smoke (also named Environmental tobacco smoke (ETS)) is an environmental trigger factor that leads to airway inflammation and airway hyperresponsiveness (AHR) in susceptible individuals and animals. The constituents

of ETS exist in the gas-phase and the aerosol particles which consist predominantly nanoparticles (two dimensions less than 100 nanometres). The purpose of this study is to characterize the role of nanoparticles on ETS-induced airway responses. The mice were exposed to side-stream tobacco smoke (SS), a surrogate to ETS, or 50 nm nanoparticles, or 80 nm nanoparticles, or gas-phase or filtered air (FA) for 3hrs. Lung function and inflammation in bronchoalveolar lavage (BAL) were measured following exposure. Methacholine (MCh) dose response for lung resistance (RL) was significantly elevated, and dynamic pulmonary compliance (Cdyn), was significantly decreased, in the SS, nanoparticles exposure groups compared with the FA and groups gas-phase exposure. At the same time, the total cells and neutrophils were significantly elevated in both SS and nanoparticles exposed mice. However, MCh dose-response curves for RL and Cdyn, inflammation were not significantly changed in the 50 nm nanoparticles and 80 nm nanoparticles exposure group. These results suggest that nanoparticles from second hand cigarette smoke play an important role in smoking-induced lung injury.

## PS 2370 The Comparative Immunotoxicity of Mesoporous Silica Nanoparticles and Colloidal Silica Nanoparticles in Mice.

S. Lee<sup>1</sup>, H. Yun<sup>2</sup> and S. Kim<sup>1</sup>. <sup>1</sup>Pharmacology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea; <sup>2</sup>Engineering Ceramics, Powder & Ceramics Division, Korea Institute of Materials Science, Changwon, Republic of Korea.

Mesoporous silica (MPS) nanoparticles (NPs), which have unique pore structure, extremely high surface area and pore volume, have attracted attention for their potential biomedical applications, such as carriers for controlled drug delivery and matrix for tissue regeneration. To use MPS NPs for biomedical devices, their biocompatibility both in vitro and in vivo should be confirmed because the surface area of NPs is one of the important determinants of toxicity such as cellular uptake and immune response. We previously first reported that MPS NPs exhibited less cytotoxicity and inflammation potential than general amorphous colloidal silica (Col) NPs on macrophages. However, the low cytotoxicity does not guarantee high biocompatibility in vivo. In this study, we compared in vivo immunotoxicity of MPS and Col NPs in mouse model to define the influence of pore structural conditions of silica NPs. Both MPS and Col NPs (2, 20, 50 mg/kg/day) were intraperitoneally administered in female BALB/c mice for 4 weeks. There was no overt sign of clinical toxicity in both MPS and Col treated mice. Interestingly, the in vivo test showed opposite results from in vitro. MPS NPs significantly increased weight of liver and spleen, and proliferation of splenocytes. MPS NPs treated mice showed the altered lymphocyte population (CD3+, CD45+, CD4+ and CD8+) of spleen, increased serum IgG and IgM levels, and histological changes. In spite of the slight changes in lymphocytes population of spleen, Col NPs did not alter other immunological factors. Our results showed that in vivo exposure of MPS NPs causes more damages in systemic immunity than Col NPs by the immunoenhancement of spleen. The in vivo data showed opposite results from in vitro showing less cytotoxicity of MPS NPs. Our results suggest the importance of confirmation of biocompatibility both in vitro and in vivo during the design of new nanomaterials. These findings may provide useful information for the bioapplication of silica NPs.

## PS 2371 Evaluation of Intestinal Absorption of Amorphous Silica Nanoparticles.

K. Misato<sup>1</sup>, Y. Yoshioka<sup>1</sup>, M. Uji<sup>1</sup>, A. Uda<sup>1</sup>, T. Mori<sup>1</sup>, M. Yamaguchi<sup>1</sup>, T. Hirai<sup>1</sup>, T. Yoshida<sup>1</sup>, H. Nabeshi<sup>2</sup>, T. Yoshikawa<sup>1</sup>, S. Tsunoda<sup>3,4</sup>, K. Higashisaka<sup>1</sup> and Y. Tsutsumi<sup>1,3,4</sup>. <sup>1</sup>Laboratory of Toxicology and Safety Science, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Suita, Japan; <sup>2</sup>National Institute of Health Science, Tokyo, Setagaya, Japan; <sup>3</sup>Laboratory of Biopharmaceutical Research, National Institute of Biomedical Innovation, Osaka, Ibaraki, Japan; <sup>4</sup>MEI center, Osaka University, Osaka, Suita, Japan.

With the recent development of nanotechnology, amorphous silica nanoparticles (nSP) with particle size below 100 nm have already been used in various foods as anticaking agents. Therefore, to ensure the safety of nSP, it is an urgent need to obtain safety information of nSP. However, there is little information about biodistribution of nSP after oral administration. In this study, we examined the biodistribution and absorption of nSP via oral route in vivo and in vitro. BALB/c mice were orally exposed to nSP with diameter of 70 nm (nSP70) or 1000 nm (mSP1000) at 2.5 mg/body for 28 days. After the last administration, we observed the localization of silica particles in tissues by transmission electron microscope. Both silica particles were observed in some tissues such as spleen and liver, although these results were qualitative analysis. Next, we evaluated the absorption of silica particles through intestine quantitatively by everted sac method. Although about 0.3% of mSP1000 in mucosal side was absorbed into serosal side, the level of absorbed nSP70 was about

1.7% in mucosal side. These results indicated that the particle size would be the major factor in permeability of intestine. Currently, we are trying to evaluate the relationship between physicochemical properties of nanomaterials and biodistribution, precisely. We believe that our study will contribute to create safer forms of nanomaterials.

**PS 2372 Indomethacin/Indomethacin Ester-Loaded Nanocapsules Reduce Brain Tumor in C57BL/6 Mice with No Observable Local Toxic Effect.**

S. F. Rodrigues<sup>1</sup>, L. Fiel<sup>2</sup>, N. Pereira<sup>1</sup>, I. Machado<sup>1</sup>, K. Elache<sup>1</sup>, S. S. Guterres<sup>2</sup>, A. R. Pohlmann<sup>2</sup> and S. H. Farsky<sup>1</sup>. <sup>1</sup>Clinical and Toxicological Analysis, University of São Paulo, São Paulo, Brazil; <sup>2</sup>Organic Chemistry, UFRGS, Porto Alegre, Brazil. Sponsor: S. Barros.

**Introduction:** Potentiation of the indomethacin (IndOH) cytotoxicity was demonstrated *in vitro* when IndOH was loaded combined with its ester (IndOEt) in poly( $\epsilon$ -caprolactone) nanocapsules (NC). **Objective:** To determine whether the antitumor activity of IndOH is kept *in vivo* when it is combined with IndOEt in NC and the capacity of those NC to cross the blood brain barrier (BBB). **Methodology:** Intravital microscopy was used in oral-, intraperitoneally- (i.p.) or intravenously- (i.v.) treated female C57BL/6 mice to visualize: 1) The intensity of red fluorescence within and outside cerebral (pial) venules after rhodamine-labeled NC treatment; 2) The interaction of leukocytes-rhodamine-labeled and platelets-FITC-labeled with the endothelial cells of pial venules. The BBB permeability was measured by the Evans blue extravasation assay. Effect of two week-IndOH/IndOEt-NC treatment on the volume of a brain tumor (induced by direct injection of glioblastoma cell line [GL261] into the brain) was measured. **Ethical Committee number:** CEUA/FCF/349. **Results:** The intensity of fluorescence outside the vessels dramatically increased 30 minutes following i.v. NC injection compared to 10 minutes time ( $P < 0.05$ ), and was maintained constant up to 2 hours. Higher intensity of fluorescence in the parenchyma was also observed 20 minutes, 1 and 2 hours ( $P < 0.05$ ) after i.p. injection, and 1, 2 and 4 hours after oral intake ( $P < 0.05$ ). No increase in leukocyte or platelet adhesion to endothelial cells, and Evans blue extravasation were noticed. IndOH/IndOEt-NC profoundly reduced the brain tumor. **Conclusion:** Antitumor activity of IndOH in brain is kept when it is combined to its ester into NC and may be due to a local effect once they cross the BBB. **Supported by:** FAPESP, CNPq.

**PS 2373 Isoprostanes As a Biomarker of Nanoparticle-Induced Toxicity In Vivo.**

L. Manzo<sup>1,2</sup>, T. Coccini<sup>1,2</sup>, E. Roda<sup>1</sup> and C. Signorini<sup>3</sup>. <sup>1</sup>University of Pavia, Pavia, Italy; <sup>2</sup>Maugeri Foundation IRCCS, Pavia, Italy; <sup>3</sup>University of Siena, Siena, Italy.

Oxidative stress was indicated as one of the main mechanisms associated with nanoparticle (NP)-induced toxicity. In this study, the validity of plasma F2-isoprostanes (F2-IsoPs), a proposed oxidative stress marker (Halliwell & Lee, Antioxid Redox Signal, 2010), was examined in rats treated intratracheally with a single dose of cadmium-doped silica nanoparticle (SiNP-Cd), a model nanoparticle previously shown to induce oxidative stress *in vivo* (Coccini et al, J Nanopart Res, 2012). The response to SiNP-Cd (1 mg/rat) was evaluated 24 hr, 7 and 30 days post-instillation by immunocytochemistry analysis of superoxide dismutase (SOD1), inducible nitric oxide synthase (iNOS) and cyclooxygenase type 2 (COX-2) expression in pulmonary tissue. Lung and plasma levels of F2-IsoPs were measured in parallel by GC/MS/MS analysis. Furthermore, the effects of SiNP-Cd were evaluated in comparison with those caused by equivalent amounts of CdCl<sub>2</sub> or SiNP. In the animals exposed to SiNP-Cd, pulmonary SOD1, iNOS, and COX-2 immunoreactivity was enhanced in a time-dependent manner (7 < 30 days). Pulmonary total F2-IsoPs were also increased significantly on thirty days post-exposure (46.7 ± 11 ng/g in SiNP-Cd vs 32.8 ± 7.8 ng/g in control). Pronounced elevation of free F2-IsoPs similarly occurred in plasma (54.6 ± 2 pg/ml in the SiNP-Cd group compared to 28 ± 8 pg/ml in controls). The increase in plasma F2-IsoPs was already detectable at day 7 and lasted until day 30 post-exposure. In the animals treated with silica nanoparticles no changes were observed regarding the immunological and biochemical parameters tested. The pulmonary response to CdCl<sub>2</sub> was less pronounced than that found with SiNP-Cd. These results indicate (i) the potential of SiNP-Cd to cause long-lasting oxidative tissue injury following pulmonary exposure in rat and (ii) a promising role for plasma F2-IsoPs as indicator of nanoparticle-induced oxidative insult (Grants: Italian Ministries of Health & University, and CARIPLO Foundation Rif. 2011 – 2096).

**PS 2374 Biokinetics of Nanoscaled Europium Oxide Particles following an Acute Inhalation in Rats.**

O. H. Creutzenberg, H. Kock and D. Schaudien. *Inhalation Toxicology, Fraunhofer Institute of Toxicology and Experimental Medicine, Hannover, Germany.* Sponsor: C. Dasenbrock.

Nanoscaled europium oxide (Eu<sub>2</sub>O<sub>3</sub>) particles were selected to investigate the biokinetics following inhalation. The rare earth Eu allowed a very high accuracy in analysis of potential translocation from lungs to remote organs. An aqueous dispersion of commercially available Eu<sub>2</sub>O<sub>3</sub> particles (0.1 w-%) was prepared in phosphate buffer (0.15 w-%) incl. bovine serum albumin (0.25 w-%). A suspension partially consisting of nanoscaled particles could be realized by mechanical homogenization and ultrasonic treatment and was aerosolized with pressurized air. Rats inhaled the dry aerosol for 6 hours in a single inhalation. Phosphate facilitated the disintegration of the Eu<sub>2</sub>O<sub>3</sub> particles in lung ambience after deposition. The potential translocation of Eu<sub>2</sub>O<sub>3</sub> particles was followed by chemical Eu analysis and transmission electron microscopy (TEM). Using chemical analysis, 36.8 µg/lung Eu<sub>2</sub>O<sub>3</sub> were detected 1 hour after inhalation in lungs. The amount declined slightly to 34.5 µg after 1 day and 35.0 µg after 5 days. The liver showed an increase of Eu<sub>2</sub>O<sub>3</sub> from 32.3 ng 1 hour up to 294 ng 5 days after inhalation. Additionally, lung-associated lymph nodes, thymus, kidneys, heart, and testes exhibited an increase of Eu<sub>2</sub>O<sub>3</sub> over the time period investigated. In the blood, the highest amount of Eu<sub>2</sub>O<sub>3</sub> was found after 1 hour whereas feces, urine and mesenteric lymph nodes revealed the highest amount after 1 day. In the other organs such as brain, spleen, adrenals and epididymides no changes of the Eu amount were detected. By TEM analysis, Eu<sub>2</sub>O<sub>3</sub> particles could be detected only in lungs, in liver, however, with one of the highest chemical Eu concentrations, no particles were detectable. In conclusion, mixed type metal oxide/phosphate particles are a suitable tool for biokinetic investigations after inhalative uptake. The use of Eu<sub>2</sub>O<sub>3</sub> combined with chemical and TEM analysis was a very suitable model to examine the translocation potential. Bioavailability was limited to soluble Eu<sub>2</sub>O<sub>3</sub>, a translocation of Eu<sub>2</sub>O<sub>3</sub> particles was not evident.

**PS 2375 NanoMiner—Resource for Human Transcriptomics Data in Nanoparticle Research.**

B. Fadeel<sup>1</sup>, L. Kong<sup>2,3</sup>, S. Tuomela<sup>3</sup>, L. Hahne<sup>2,3</sup>, H. Ahlfors<sup>3</sup>, O. Yli-Harja<sup>2</sup>, R. Lahesmaa<sup>3</sup> and R. Autio<sup>2,3</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Department of Signal Processing, Tampere University of Technology, Tampere, Finland; <sup>3</sup>Turku Centre for Biotechnology, University of Turku and Åbo Akademi University, Turku, Finland.

The potential impact of nanoparticles on the environment and on human health has attracted considerable attention in recent years. Transcriptomics data generated from tissues or cells exposed to nanoparticles are being gathered at ever-increasing rates. In addition to the importance of the original findings, such data can have value if interpreted in a broader context and combined with other published results. To encourage the efficient use of the data, we have developed NanoMiner (<http://nanominer.cs.tut.fi/>), an integrative transcriptomics data resource for nanoparticle research. The data in NanoMiner is collected from public repositories, and the database currently contains 404 human transcriptomics samples of cells exposed to various types of nanoparticles. All samples in NanoMiner have been annotated, preprocessed and normalized using standard methods to ensure the quality of the data analyses and to enable systematic use of the database across different experimental setups and platforms. With NanoMiner, it is possible to: 1) search and plot the expression profiles of one or several genes of interest, 2) cluster the samples within the datasets, 3) find differentially expressed genes in various nanoparticle studies, 4) detect the nanoparticles causing differential expression of selected genes, 5) analyze enriched Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways and Gene Ontology (GO) terms for the detected genes, and 6) search the expression values and differential expressions of the genes belonging to a specific KEGG pathway or Gene Ontology. The NanoMiner database is thus a valuable collection of microarray data and can also be used as a data repository for future analyses.

**PS 2376 Nano-Silica Aspiration Exposure Induces Endothelial Dysfunction in Diabetic Mice.**

S. A. Brenner<sup>3</sup>, M. Frame<sup>1</sup>, A. M. Dewar<sup>1</sup> and J. E. Vigilante<sup>2</sup>. <sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY; <sup>2</sup>Faculty of Medical Sciences, The University of The West Indies, Cave Hill, Barbados; <sup>3</sup>Nanobioscience, University of Albany College of Nanoscale Science and Engineering, Albany, NY. Sponsor: T. Nurkiewicz.

Silica (SiO<sub>2</sub>) nanoparticles are widely used in many diverse industries, such as polishing agents in semiconductor fabrication, as potential biomedical drug delivery agents, and in fabrics to make them wrinkle free. Our goal was to evaluate the ef-

fects of nano-silica (SiO<sub>2</sub>, longest dimension  $51.9 \pm 16.2$  nm, aspect ratio  $1.1 \pm 0.1$ ) on small arterioles in situ. First, a suspension of SiO<sub>2</sub> (in 1gm/ml albumin, saline) was directly applied to arterioles (micropipette, 137 pg total dose), using a hamster cheek pouch intravital microscopy model (isoflurane, N=6). Endothelial dysfunction (loss of dilation to acetylcholine, ACH 10-4M) was evident within minutes (dilation of  $78 \pm 14\%$  to constriction  $-3 \pm 5\%$ ,  $p < 0.05$ ), while dilation to adenosine was unaffected. Constrictor responses to phenylephrine were diminished by SiO<sub>2</sub> exposure (from  $-61 \pm 4\%$  to  $-1 \pm 2\%$ ); importantly, the baseline diameters were not altered by direct exposure to SiO<sub>2</sub>, and the vessels retained some responses. Next, mice were exposed to 20ug of SiO<sub>2</sub> via aspiration, and 24 hours later the cremaster m. model was examined (isoflurane). Db/db controls (N=6) have mild endothelial dysfunction seen as a diminished dilation to ACH (10-4M, dilation of  $43 \pm 14\%$  to  $10 \pm 6\%$ ). Exposure to SiO<sub>2</sub> (40gm wt, N=4) induced a profound endothelial dysfunction seen as constriction to ACH ( $-13 \pm 2\%$ ). Dilation to adenosine was unaffected. In C57BL/6, exposure to SiO<sub>2</sub> (25gm wt, N=2) did not significantly alter dilation to ACH or adenosine compared to controls (N=6). Further, in the aspiration model, constrictor responses to phenylephrine were not affected in either strain. Thus, direct exposure to 137 pg SiO<sub>2</sub> induced endothelial dysfunction immediately in healthy hamsters. Aspiration of 20ug induced a profound endothelial dysfunction in diabetics but not in the genetic background controls. (NIH DK68401, HL55492)

### PS 2377 Copper Nanoparticles or Ionic Copper (II) Causes Neurotoxicity and Cardiotoxicity in Zebrafish Embryos.

W. Trickler<sup>1,2</sup>, S. F. Ali<sup>1</sup>, M. G. Paule<sup>1</sup> and J. Kanungo<sup>1</sup>. <sup>1</sup>Division of Neurotoxicology, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>Toxicologic Pathology Associates Inc., Jefferson, AR.

Copper oxide nanoparticles (Cu-NPs) are frequently used in medical devices, paints, fabrics or as antimicrobials. Their industrial applications may lead to the contamination of aquatic ecosystems. The toxicological and human health risks of NPs in the environment are hard to evaluate due to a lack of knowledge about the mechanisms by which NPs interact with biological systems. In this study, we investigated the toxicity of Cu-NPs and the ionic copper(II) form in wild-type (WT) zebrafish (Danio rerio, AB-strain) embryos and hb9-GFP transgenic zebrafish (Danio rerio, AB-strain) embryos by comparing bare Cu-NPs to the mass equivalent ionic form of copper(II) (CuCl<sub>2</sub>) at various concentrations (1.25-to-20 ug/ml). The toxicity was determined by phenotypic changes in the zebrafish embryos including survival, heart rate, motor neuron development and absorptive permeability. Both Cu-NPs and CuCl<sub>2</sub> were lethal to zebrafish embryos at 20 ug/ml (within 24-hrs) and 10 ug/ml (within 48-hrs), with CuCl<sub>2</sub> being more toxic at equivalent mass concentrations. Similarly, the heart rate was significantly reduced following exposure to either Cu-NPs or CuCl<sub>2</sub> in a concentration-time dependent manner. Additionally, the embryo permeability studies showed that exposure to either Cu-NPs or CuCl<sub>2</sub> (5 ug/ml) for 24-hrs significantly increased the topical absorption of the fluorescent tracer 6-coumarin (6CM). Furthermore, embryos treated with either Cu-NPs or CuCl<sub>2</sub> (2.5 ug/ml for 48-hrs) showed a significant reduction (nearly 2-fold) of spinal motor neurons. These results indicate that both CuCl<sub>2</sub> and Cu-NPs can be toxic to zebrafish embryos causing significant neurotoxicity and cardiotoxicity at exposure levels that do not cause lethality.

### PS 2378 Nickel Oxide Nanoparticles Provoke Intrinsic Apoptotic Pathway in HepG2 Cells, Male Wistar Rats and Tomato Seedling Roots.

Q. Saquib<sup>1</sup>, J. Musarrat<sup>1</sup>, A. A. Al-Khedhairi<sup>1</sup>, M. A. Siddiqui<sup>1</sup>, S. M. Attia<sup>3</sup>, M. Faisal<sup>2</sup>, J. A. Siddiqui<sup>1</sup>, S. Dwivedi<sup>1</sup> and S. T. Khan<sup>1</sup>. <sup>1</sup>Department of Zoology, King Saud University, Riyadh, Saudi Arabia; <sup>2</sup>Department of Botany, King Saud University, Riyadh, Saudi Arabia; <sup>3</sup>Department of Pharmacology, King Saud University, Riyadh, Saudi Arabia. Sponsor: M. Verma.

Many features of programmed cell death in plants resemble with those observed in human and animals. Therefore, this study has been done with a rationale to provide first evidence on the molecular toxicity of nickel oxide nanoparticles (NiO-NPs, <50 nm) in human hepatocellular carcinoma (HepG2) cells, male Wistar rats and tomato seedling roots. The cytotoxicity studies with NRU and MTT assays in HepG2 cells revealed 20.6 % and 18.4 % decline in the cell survival at the highest concentration of 100 µg/ml. Treated cells showed an increase in intracellular ROS generation and 30.5 % increase in flow cytometric sub-G1 apoptotic peak at 100 µg/ml NiO-NPs. Quantitative real-time PCR analysis of apoptotic pathway genes (P53, caspases 3 and 9) showed 2.0, 1.2 and 1.1-fold higher expression in HepG2 cells. Furthermore, western blot experiments also showed the greater activity of P53 and caspase 3 genes in cells exposed to 100 µg/ml NiO-NPs. Oral exposure of male

Wistar rats with 1, 2 and 4 mg/kg b.w of NiO-NPs for 48h and 14 days showed increased intracellular ROS generation, DNA damage, micronuclei formation and apoptosis in bone marrow cells. Tomato seeds exposed to NiO-NPs for 4 h, exhibited repression of root length, higher activities of antioxidant enzymes, and increased frequency of apoptotic and necrotic cells in comet assay. Flow cytometric analysis of 2 mg/ml treatment group revealed 122% higher ROS generation with alteration of mitochondrial membrane. Cell cycle data showed a shift of 65.5% cells towards apoptotic subG1 phase vis-à-vis control showed 16.5% cell in subG1. An increase in caspase-3 like protease activity validates the involvement of mitochondrial dependent intrinsic apoptotic pathway. Thus, this study has provided a new insight into the fundamental mechanism of NiO-NPs induced toxicity and signify its potential to induce cell death in animal and plant cells.

### PS 2379 Quantifying Quantum Dots in Frozen Tissue Sections Using Autometallography.

C. White<sup>1</sup>, C. M. Schaupp<sup>1</sup>, J. Herron<sup>1</sup>, D. K. Scoville<sup>1</sup>, L. A. McConnachie<sup>1</sup>, D. Botta<sup>1</sup>, J. Yu<sup>1</sup>, X. Yu<sup>1</sup>, X. Hu<sup>2</sup>, X. Gao<sup>2</sup>, J. Wilkerson<sup>1</sup> and T. J. Kavanagh<sup>1</sup>. <sup>1</sup>Environmental & Occupational Health Sciences, University of Washington, Seattle, WA; <sup>2</sup>Bioengineering, University of Washington, Seattle, WA.

Quantum dots (QDs) are engineered nanoparticles frequently composed of a CdSe core, ZnS shell, and an assortment of polymer coatings specific to their application. QDs are used in electronic systems because of their semiconductor properties and in biomedical research and medicine as imaging tools because of their unique fluorescent properties. Their widespread use and heavy metal core composition have raised concerns about their safety. An important consideration in evaluating QD toxicity is the accurate quantification of these nanoparticles within tissues. The current measurement methods favored include inductively coupled plasma mass spectrometry (ICP-MS) for the metal components of QDs, and QD fluorescence directly in tissue sections using microscopy. However, ICP-MS is expensive and cannot distinguish between metals present in QDs or free ions, and fluorescence microscopy is often difficult because of interfering tissue autofluorescence. We adapted a silver-enhanced autometallography technique for detecting QDs in frozen tissue sections. This technique is efficient and inexpensive, and quantification using digital imaging and densitometry correlates well with direct QD fluorescence measurements. The ability to efficiently measure QDs in tissues will provide important dose information that can be useful for evaluating the adverse health effects of QD exposures.

### PS 2380 Influence of Primary Particle Size and Agglomeration State of Inhaled Nano-TiO<sub>2</sub> on Rat's Pulmonary Response.

A. Noel<sup>1</sup>, M. Charbonneau<sup>2</sup>, Y. Cloutier<sup>3</sup>, R. Tardif<sup>1</sup> and G. Truchon<sup>3</sup>. <sup>1</sup>Environmental and Occupational Health, University of Montréal, Montréal, QC, Canada; <sup>2</sup>INRS-Institut Armand-Frappier, Université du Québec, Laval, QC, Canada; <sup>3</sup>Institut de Recherche Robert-Sauvé en Santé et en Sécurité du Travail, Montréal, QC, Canada.

The physico-chemical properties of nanoparticles (NP) and their agglomeration state influence their toxicokinetics, reinforcing the importance of the characterization of the exposure dose. The objective of this study was to evaluate the influence of initial particle size and agglomeration state of inhaled 20 mg/m<sup>3</sup> TiO<sub>2</sub> aerosols on rat's pulmonary response. Groups of rats (n=6) were exposed for 6 hr to aerosols composed of either 5; 10-30 or 50 nm TiO<sub>2</sub>. Two distinct agglomeration states were obtained. Aerosols were composed majorly of either large (LA) (>100 nm) or small agglomerates (SA) (<100 nm). A control group was exposed to compressed air. Exposures were characterized using weight measurement for mass concentration, an electrical low pressure impactor (Dekati) for size distribution and electron microscopy for agglomerates observation. Pulmonary response was analyzed 16 hr after the end of exposure through bronchoalveolar lavage fluids and lung histology. Total cell count, number of macrophages and neutrophils were increased statistically ( $p < 0.05$ ) compared to control for the 10-30 and 50 nm LA aerosols, while increases were significant only for total cell count and number of macrophages for the 5 and 10-30 nm SA aerosols. For each initial particle size, percentages of particle laden macrophages in LA aerosols were higher and statistically different from the SA ones. Morphological assessments of lung tissue showed that cellular infiltrates were more important in exposed groups compared to controls, with exemption of the 50 nm SA group. Our results indicate that higher increases in neutrophils number are related to LA aerosols, as for initial particle size, 10-30 nm TiO<sub>2</sub> NP seemed to induce more pronounced effects. Overall, this suggests that initial particle size and agglomeration state play a key role in the toxicity of TiO<sub>2</sub> aerosols.

**PS 2381 Silica Nanoparticles Induce Acute Pulmonary Toxicity in Mice.**

T. Lu<sup>1</sup>, D. Hung<sup>2</sup>, C. Su<sup>3</sup>, T. Tseng<sup>4</sup>, K. Chen<sup>5</sup>, C. Huang<sup>6</sup>, S. Liu<sup>7</sup> and Y. Chen<sup>1</sup>. <sup>1</sup>Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan; <sup>2</sup>Division of Toxicology, Trauma & Emergency Center, China Medical University Hospital, Taichung, Taiwan; <sup>3</sup>Department of Otorhinolaryngology, Head and Neck Surgery, Changhua Christian Hospital, Changhua, Taiwan; <sup>4</sup>Department of Anatomy, China Medical University, Taichung, Taiwan; <sup>5</sup>Department of Urology, China Medical University Hospital and China Medical University, Taichung, Taiwan; <sup>6</sup>School of Chinese Medicine, China Medical University, Taichung, Taiwan; <sup>7</sup>Institute of Toxicology, National Taiwan University, Taipei, Taiwan.

Silica nanoparticles (SiO<sub>2</sub>-NPs) are the one of most widely used and important nanomaterials in nanotechnology. Lung tissue is one of the main routes of entry nanoparticles, which may cause severe pulmonary toxicity. However, the toxicological effects and the precise mechanisms of SiO<sub>2</sub>-NPs on lung are still unclear. Here, we attempted to investigate the toxic injuries and the definite mechanism of SiO<sub>2</sub>-NPs on the acute pulmonary toxicity. The adult male ICR mice were exposed to intratracheal signal dose of 50 mg/kg SiO<sub>2</sub>-NPs and lung tissue were collected after 7 days. Our results found that SiO<sub>2</sub>-NPs increased 40% mortality rate and significantly induced pulmonary morphological and histological changes with neutrophils, macrophage and fibroblast cells from the terminal bronchial. The lung tissue weight/body weight ratio (LW/BW) increased 2-fold suggested that SiO<sub>2</sub>-NPs may trigger pulmonary edema. Meanwhile, the malondialdehyde (MDA) levels in the treated lung tissue were increased. Moreover, SiO<sub>2</sub>-NPs caused apoptosis-related signals, including up-regulation of Bax and down-regulation of Bcl-2 and activations of caspase cascades mRNA expression, which accompanied with triggered the endoplasmic reticulum (ER) stress identified through several key molecules, such as activating the CHOP, XBP-1, caspase-12, and increasing the GRP-78/-94 mRNA expression. These results suggest that SiO<sub>2</sub>-NPs induced an oxidative stress, and cause acute pulmonary toxicity through mitochondria and endoplasmic reticulum pathways.

**PS 2382 Biodistribution and Toxicity Profiling of Nanosilica in Rats after Subchronic Oral Exposure.**

M. van der Zande<sup>1</sup>, R. J. Vandebriel<sup>2</sup>, M. Groot<sup>1</sup>, E. Kramer<sup>1</sup>, K. Rasmussen<sup>3</sup>, P. Hendriksen<sup>1</sup> and H. Bouwmeester<sup>1</sup>. <sup>1</sup>RIKILT - Wageningen University & Research Centre, Wageningen, Netherlands; <sup>2</sup>The National Institute for Public Health and the Environment, Bilthoven, Netherlands; <sup>3</sup>Joint Research Centre, Ispra, Italy. Sponsor: S. Rangarajan.

Synthetic amorphous silica (SAS) is a conventional food additive. In earlier publications, we have shown that up to 43% of SAS in food products can be nanosized. Yet, the behavior and biological effects of ingested nanosized silicas are still largely unknown. We evaluated the biodistribution, accumulation, and toxicity of two nanostructured silicas: NM-202 from the OECD testing program, and a food grade SAS.

To this end, rats (n=5) were fed daily 0, 100, 500 or 1000 mg/kg bw NM-202, or 100, 1000 or 2500 mg/kg bw SAS during 28 days. Additional rats received 0 or 1000 mg/kg bw NM-202, or 2500 mg/kg bw SAS during 84 days. Using hydrodynamic chromatography ICP-MS, high fractions of nanosized silica (up to 100% of the total silica content) were detected in the gut contents of silica exposed rats. Nevertheless, ICP-MS data at day 29/85 show low, dose-independent distribution of both materials to the liver, kidney, spleen, brain, and testis, without organ specificity or accumulation. Analysis of blood biochemical markers and antibodies, NK-cell activity, and lymphocyte proliferation, did not indicate (immuno)toxicity. Contrarily, histopathology showed a significantly increased number of mononuclear cells per mm<sup>2</sup> up to 500% at day 29, and 200% at day 85, and an increase in apoptosis (cells/mm<sup>2</sup>) up to 200% at day 29 in livers of silica exposed rats vs. the controls. Also, the jejunal villus:crypt ratio of NM-202 exposed rats decreased significantly to ~90% vs. the controls after 29 days. However, whole genome liver and jejunal mRNA expression analysis did not indicate toxicity due to silica exposure. In conclusion, both silicas are non-accumulating and absorption is low. They appear to be generally non-toxic, but histopathological data suggest adverse effects on liver and gut tissue, which should be addressed in future research and considered in risk assessment of nanosilica.

**PS 2383 Oral Prenatal Developmental Toxicity Study with Synthetic Amorphous Silica NM-200 in Wistar Rats.**

S. Schneider<sup>1</sup>, W. Wohlleben<sup>2,1</sup>, R. Landsiedel<sup>1</sup>, A. Wolterbeek<sup>3</sup>, I. Waalkens-Berendsen<sup>3</sup> and H. van de Sandt<sup>4</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Polymer Physics, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>Triskelion, Zeist, Netherlands; <sup>4</sup>Quality of Life, TNO, Zeist, Netherlands.

The engineering of new nanomaterials offers extraordinary opportunities in various technological fields, but safety assessments must complement the technological progress. Specifically, application of current developmental and reproductive toxicity test guidelines for hazard testing of nanomaterials must be evaluated. The results of the prenatal developmental toxicity study (OECD 414) are presented here.

Female Wistar rats received synthetic amorphous silica (NM-200, European Joint Research Centre, Ispra, Italy) by oral gavage at dose levels of 0, 100, 300 and 1000 mg/kg body weight/day from gestation day (GD) 6 through GD 19. The NM was dispersed in 10% fetal bovine serum in water and the particle size distribution was characterized. On GD 20, all females were assessed by gross pathology, including weight determinations of the uterus and the placentas. The corpora lutea were counted and the number and distribution of implants (resorptions, live and dead fetuses) were determined. The fetuses were removed from the uterus, sexed, weighed and investigated for external findings. Half of the fetuses of each litter were examined for soft tissue findings and the remaining fetuses for skeletal (and cartilage) findings.

No differences between the treatment groups and controls for clinical observations, body weights and food consumption of the dams were observed. No effects were observed on number of corpora lutea, implants, pre- and post-implantation losses as well as number and viability of offsprings. External, soft tissue and skeletal examination revealed no test-substance-related abnormalities.

This study was sponsored by CEFIC (LRI-N3 project) and is monitored by Monika Maier, Evonik Degussa GmbH, Hanau, Germany on behalf of CEFIC Sector group on Synthetic Amorphous Silica (ASASP).

**PS 2384 The T-Box Transcription Factor TBX21 (T-BET) Inhibits Airway Goblet Cell Hyperplasia Induced by Nickel Nanoparticles in Mice.**

E. E. Glista-Baker, B. C. Sayers, A. J. Taylor, E. A. Thompson and J. C. Bonner. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Engineered nanomaterials (ENMs), including metal nanoparticles, are increasingly used in many industrial applications, including electronics and engineering. Additionally, the human health risks that ENMs pose are of growing concern, especially in susceptible populations such as asthmatics. The T-box transcription factor TBX21 (T-bet) maintains Th1 cell development in the lung and loss of T-bet has been associated with the development of allergic airway inflammation characterized by Th2 cells. The purpose of this study was to determine if mice deficient in T-bet are susceptible to goblet cell hyperplasia caused by nickel nanoparticles (NiNP). Wild type (WT) and T-bet<sup>-/-</sup> mice were exposed to a NiNP (4 mg/kg) and lung tissues were collected at 1 or 21 days. The mucin-positive staining area (goblet cell hyperplasia) was quantified by morphometry using Alcian blue/PAS-stained lung sections. Whole lung mRNA levels for mucin genes (MUC5AC and MUC5B) were measured by Taqman real-time RT-PCR. Bronchoalveolar lavage fluid (BALF) was collected for differential cell counts and for measuring levels of secreted cytokines known to regulate goblet cell hyperplasia, namely IL-13 and CCL2. NiNP exposure caused a marginal increase in goblet cell hyperplasia in WT mice at 1 or 21 day post-exposure. However, NiNP caused a significant (p<0.001) increase in goblet cell hyperplasia in T-bet<sup>-/-</sup> mice and a significant (p<0.05) increase in MUC5AC and MUC5B mRNA levels at 21 days. Furthermore, IL-13 protein levels and eosinophilic infiltration were elevated (p<0.001) after 1 day in the BALF while CCL2 mRNA and protein levels were significantly increased at 1 and 21 days. These findings identify T-bet as a potentially important genetic susceptibility factor for NiNP exposure and suggest that individuals with pre-existing allergic airway disease are at a higher risk for environmental and occupational exposures to nanomaterials. (Funded by NIEHS RC2 ES018772 and R01 ES020897)

**PS 2385 Acute Toxicity Study of Nanoparticles of Bismuth Trioxide by Inhalation Exposure in Male Rats.**

O. C. Barbier<sup>1</sup>, B. Quintanilla-Vega<sup>1</sup>, L. M. Del Razo<sup>1</sup>, M. Cortés-Torres<sup>1</sup>, R. Angulo-Olais<sup>1</sup>, M. Uribe-Ramírez<sup>1</sup>, M. J. Solís-Heredia<sup>1</sup>, G. Martínez-Aguilar<sup>1</sup>, A. Barrera-Hernández<sup>1</sup>, L. C. Sanchez-Peña<sup>1</sup>, E. Berea<sup>2</sup> and A. De Vizcaya-Ruiz<sup>1</sup>. <sup>1</sup>Toxicology Department, CINVESTAV-IPN, Mexico City, Mexico; <sup>2</sup>Farmaquímica, Mexico City, Mexico.

Bismuth (Bi) compounds are widely used in several products, including metallurgical alloys and medical devices; Mexico is among the largest Bi producers. Bi toxicity is poorly studied, at micro scale it alters the kidney, nervous and reproductive systems, but little is known about the cytotoxicity of Bi nanoparticles (Bi-NP). Nanotoxicology has gained attention in the last decade due to the dramatically increase of nanomaterials in new appliances and their release to the environment. We conducted an in vivo study to evaluate the toxicity of Bi-NP by inhalation exposure. We exposed adult male Wistar rats (n=7) to an acute inhalatory dose (140 mg/kg, b.w, dispersed in 10 mg/ml BSA) of Bi<sub>2</sub>O<sub>3</sub> nanoparticles during 5 h using the InExpose SCIREQ® inhalation system by nebulization of 1.05 mL Bi<sub>2</sub>O<sub>3</sub> suspension/min. The control group (n=7) received nebulized phosphate buffer in BSA. Physiological parameters such as body weight and relative organ weights, and histopathology were determined. In addition, complete blood count (CBC) and blood chemistry were evaluated. Bronchoalveolar lavage (BAL) was performed to evaluate pulmonary inflammation by differential cell count. Relative weights of spleen, liver, kidney and testes were significantly higher (12-23% increase) in the exposed group, while the histopathology revealed alterations in lungs, liver, brain and spleen, and damage in the epithelium seminiferous. CBC, blood chemistry and BAL parameters were not affected by the acute inhalation exposure to Bi-NP. In our experimental conditions, Bi<sub>2</sub>O<sub>3</sub> nanoparticles showed moderate toxicity by inhalation exposure. Further studies are needed to evidence adverse effects due to the exposure to these NP; a subchronic study is underway to reach this objective. Funding from the European Community Seven Framework Program and CONACYT (Grant agreements #263878 and 12514).

**PS 2386 Pharmacokinetics and Biodistribution of Iron Oxide Nanoparticles Using Accelerator Mass Spectrometry.**

H. Enright<sup>1,3</sup>, P. D. Nallathambi<sup>2,3</sup>, V. Mikheev<sup>3</sup>, B. Forsythe<sup>3</sup>, W. Wang<sup>2,3</sup>, E. Kuhn<sup>1,3</sup>, S. T. Retterer<sup>2,3</sup>, K. W. Turteltaub<sup>1,3</sup> and M. Malfatti<sup>1,3</sup>. <sup>1</sup>Lawrence Livermore National Laboratory, Livermore, CA; <sup>2</sup>Oak Ridge National Laboratory, Oak Ridge, TN; <sup>3</sup>Battelle Center for Fundamental and Applied Systems Toxicology (B-FAST), Battelle Memorial Institute, Columbus, OH.

Nanoparticles (NP) and their use as diagnostic and therapeutic agents in the biomedical field are becoming increasingly more popular. However, to date, the toxicity and biological fate have not been thoroughly investigated. Iron oxide nanoparticles are utilized for many bio-applications, which include: imaging, as drug delivery vehicles and for cell tracking. In this work, Accelerator Mass Spectrometry (AMS), an ultrasensitive technique for quantifying rare isotopes, is used to quantify the biodistribution and pharmacokinetic properties of <sup>14</sup>C-labeled iron oxide NP in vivo.

<sup>14</sup>C-labeled carboxylated iron oxide NP (~10nm core size) were administered by nose only inhalation (0.175mg) or by a bolus intravenously (IV) (0.15mg) to male mice. For inhalation delivery, over 7 d, NP were observed to clear primarily from the lungs through the gastrointestinal system for excretion in the feces (t<sub>1/2</sub> = 1.42 d). Detectable levels were also observed in plasma and phagocytic organs such as the liver and spleen. Furthermore, accumulation in the olfactory bulb was also observed (1.05 ng/mg at 7d). After intravenous delivery, NP were observed to accumulate primarily in the liver, spleen and lungs over a 24 h period; the half-life in plasma was t<sub>1/2</sub> = 6.4 h. Taken together, these data indicate that once administered, carboxylated iron oxide NP are absorbed and distributed to major organs and are retained in tissue through 24 h for IV and through 7 d for inhalation. These observations may provide insight for assessment of potential toxicity upon exposure to iron oxide nanoparticles.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 and supported by LLNL CRADA No. PNNL/284. LLNL-ABS-586092

**PS 2387 Zebrafish Xenograft Model of Glioblastoma to Identify Metal Oxide Nanoparticles with Anticancer Properties.**

L. Wehmas<sup>1,2</sup>, L. Truong<sup>1,2</sup>, J. A. Greenwood<sup>3</sup>, A. Punnoose<sup>4</sup> and R. L. Tanguay<sup>1,2</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Sinnhuber Aquatic Research Laboratory and Environmental Health Sciences Center, Oregon State University, Corvallis, OR; <sup>2</sup>Safer Nanomaterials and Nanomanufacturing Initiative and Oregon Nanoscience and Microtechnologies Institute, Corvallis, OR; <sup>3</sup>Biochemistry and Biophysics, Oregon State University, Corvallis, OR; <sup>4</sup>Physics, Boise State University, Boise, ID.

Zinc oxide nanoparticles (ZnO-NPs) demonstrate selective cytotoxicity toward cancer cells in culture, and this effect may extend to other metal oxide nanoparticles (MO-NPs). Therefore, MO-NPs may possess unique qualities applicable to nanomedicine. To realize their potential as anticancer agents, we must identify safe and effective MO-NPs. We developed a screening approach that first utilizes cell culture assays to identify MO-NPs that preferentially inhibit cancer proliferation and determine the mechanism of selective toxicity. Then we assess the toxicity of the MO-NPs utilizing the embryonic zebrafish assay, an efficacious model for nano-safety assessment because of its high homology with humans and use of minimal test material. We prioritize MO-NPs that demonstrate relatively low toxicity to the zebrafish yet maintain preferential toxicity toward cancer cells in culture for assessment in a zebrafish xenograft model of glioblastoma. By xenotransplanting human glioblastoma cells into the cranium of zebrafish, we have developed an assay to identify MO-NPs that selectively inhibit cancer cell proliferation in vivo. We are testing four MO-NPs: zinc oxide, titanium dioxide, cerium dioxide, and tin dioxide. Preliminary results demonstrate that ZnO-NPs inhibit glioblastoma cell proliferation at 0.1 mM. Our screening paradigm holds promise for identifying physico-chemical traits which enhance the anti-cancer properties of MO-NPs while supporting safe NP design. Research support: NSF 134468, NIEHS P30 ES000210, ES 016896, T32 ES07060, and Air Force Research Laboratory #FA8650-05-1-5041.

**PS 2388 Toxicity of Zinc Oxide Nanoparticles: Role of Particle Dissolution and Photocatalytic ROS Production.**

H. Ma, L. Wallis, S. Li and S. Diamond. Mid-Continent Ecology Division, United States EPA, Duluth, MN.

Dissolution of zinc oxide nanoparticles (ZnO NPs) to ionic zinc has been recognized as an important mode of toxic action (MOA) due to their high solubility and high potency of ionic zinc to aquatic organisms. However, toxicity of ZnO NPs associated with their photocatalytic properties (generation of ROS under UV radiation) has been rarely reported. To understand the relative importance of these two MOAs, the current study investigated ZnO NP (30-50 nm) toxicity to *Daphnia magna* under simulated solar radiation (SSR) versus ambient laboratory light. *D. magna* immobilization, intracellular ROS production, and oxidative stress (lipid peroxidation) were used as toxicity endpoints. Particle dissolution was measured in a time-course manner using ICP-MS. Photocatalytic ROS production was measured by a fluorescent-based ROS assay and methylene blue photodegradation. Bulk ZnO (> 1µm) and ZnCl<sub>2</sub> were tested as reference toxicants. Concentration-dependent ROS production was detected for ZnO NPs under SSR, but not under laboratory light. Particle dissolution showed no significant differences between irradiation conditions, and both had a maximum dissolution rate of 20% within 24-h period. 48-h EC50s for *D. magna* immobilization under SSR and laboratory light were 0.069 mg/l (95% CI: 0.043, 0.109) and 0.109 mg/l (0.072, 0.171), respectively. Intracellular ROS production and lipid peroxidation in daphnids exposed under SSR were significantly greater than those under laboratory light, suggesting photo-induced toxicity associated with photocatalytic ROS production might have occurred. ZnCl<sub>2</sub> had EC50s of 1.2 mg/l under SSR and 1.1 mg/l under laboratory light. Bulk ZnO showed slightly lower toxicity than ZnO NPs. Our results suggest that photo-induced toxicity of ZnO NPs related to their photocatalytic properties should not be neglected when evaluating potential environmental hazards of these nanomaterials, and the relative importance of this MOA under different exposure scenarios and towards different environmental species warrants further investigation.

**PS 2389 Luminescent Lanthanide-Doped Metal Oxide Nanoparticles for Study of Deposition and Clearance in the Respiratory Tract.**

G. K. Das, D. S. Anderson, C. D. Wallis, A. D. Abid, L. S. Van Winkle and I. M. Kennedy. University of California Davis, Davis, CA.

Epidemiological studies have reported increased morbidity and mortality from respiratory and cardiovascular diseases which have close associations with exposure to airborne particulate matter (PM). Of the PM in the ambient air, ultrafine particles

have been well-demonstrated to be one of the key pathogenic factors for cardiorespiratory disorders. Previous studies investigating deposition and clearance have used mostly radiolabeled-PM, fluorescent labeling or specially engineered nanoparticles (NPs) with physical and chemical properties that are atypical of ambient PM. A low cost and high throughput alternative is needed that will permit direct measurement of PM deposition and clearance. Here, we have used luminescent trivalent europium ion-doped gadolinium oxide ( $Gd_2O_3:Eu^{3+}$ ) PM synthesized by a low cost spray flame synthesis to study the deposition and clearance of PM in rats. As rare earth elements, the lanthanides (i.e. Gd and Eu) exhibit very low natural abundance, and provide extremely good detection sensitivity in different organs with the use of inductively coupled plasma mass spectroscopy (ICP-MS). Moreover, the strong optical emission that arises from the intra-4f transition of the europium ions adds a powerful tool to detect the deposition site via fluorescence microscopy. ICP-MS data from the instillation study showed that 59% of the particles remained in the lung while a significant amount was detected in the feces (20.4%) after 24 hrs, suggesting a fast clearance mechanism. Dissolution of the NPs was investigated *in vitro* by monitoring the photoluminescence at physiological pH (7.0) and at a lysosomal pH (5.0) at 37°C up to 30 days; results confirmed that the lanthanides were transported as particles and not as soluble ions. The result with the instillation studies demonstrated the excellent sensitivity of this method. We have adapted our PM generator to a nose-only inhalation system for exposures of rodents. This work supported by NIEHS P42ES004699. We acknowledge the W. M. Keck Foundation for a research grant.

### PS 2390 Angiogenesis Alterations Caused by TiO<sub>2</sub> Nanoparticles.

V. Freyre-Fonseca<sup>1,2</sup>, A. Délica-Alcaraz<sup>1</sup>, E. M. Flores-Jiménez<sup>1</sup>, N. L. Delgado Buenrostro<sup>1</sup>, G. F. Gutiérrez-López<sup>1</sup> and Y. I. Chirino<sup>1</sup>. <sup>1</sup>Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México, Mexico City, Mexico; <sup>2</sup>Departamento de Graduados e Investigación en Alimentos, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Mexico City, Mexico.

Angiogenesis is a process by which the preexisting vascular tree of a tissue causes growing of new blood vessels. It plays a key role in tumor development and it has been demonstrated that titanium dioxide nanoparticles (TiO<sub>2</sub> NPs) exposure increases hypoxia and growth factors levels and these events are related to angiogenesis. However, the TiO<sub>2</sub> NPs effect in this process has been poorly explored. In this regard, chronic exposure to TiO<sub>2</sub> NPs could develop disorders in angiogenesis. The aim of this work was to study angiogenesis alterations caused by TiO<sub>2</sub> NPs exposure. Characterization of TiO<sub>2</sub> NPs was done using dynamic light scattering to measure nanoparticles size distribution and zeta potential. Chicken chorioallantoic membrane (CAM) model was used as following: fertilized eggs were incubated during 7 days at 37°C and 80% humidity and then exposed to 0, 5 and 10 µg of TiO<sub>2</sub> NPs previously suspended in MCDB-131 cell culture media and injected in blood vessels incubating for 7 days more. On 14th day, eggs were opened and digital analysis of images was done. Umbilical vein endothelial cells were obtained from embryos to measure VEGF expression by flow cytometry. Results showed that suspension of 5 and 10 µg of TiO<sub>2</sub> NPs had an agglomerated size of 535.2±9.35 nm and 503.1±1.069 nm, respectively. Zeta potential of agglomerates suspended in MCDB-131 was -17.36 ±1.18. Images of CAM showed structural differences between vessels of treated and untreated TiO<sub>2</sub> NPs eggs. An increase of 0.5 cm and of 1 cm between blood vessels was found in CAM of 5 µg and 10 µg TiO<sub>2</sub> NPs treated eggs, respectively. In addition, an increase in VEGF expression was observed in endothelial cells from TiO<sub>2</sub> NPs treated eggs. In conclusion, TiO<sub>2</sub> NPs exposure in CAM model induced and increase in the distance between blood vessels and in the VEGF expression in endothelial cells.

### PS 2391 Radiolabeled, Superparamagnetic, Nanoparticles for Bio-Distribution Studies in Life Sciences.

P. D. Nallathambay<sup>1,2</sup>, H. Enright<sup>1,3</sup>, M. Malfatti<sup>3</sup>, S. T. Retterer<sup>2</sup> and W. Wang<sup>2</sup>. <sup>1</sup>Health & Life Sciences, B-FAST, Battelle Memorial Institute, Columbus, OH; <sup>2</sup>BESD, Oak Ridge National Lab, Oak Ridge, TN; <sup>3</sup>Biosciences and Biotechnology Division, Lawrence Livermore National Lab, Livermore, CA.

Nanoscale drug delivery systems have generated considerable interest because they allow for the addition of cell specific targeting molecules and/or multiple therapeutic agents, while their bio-distribution in vivo displays molecular level kinetics. Iron based nanomaterials, with their inherent magnetic properties and an easily tailored surface chemistry, are of particular interest because of their simultaneous diagnostic and therapeutic potential. To determine how bio-distribution affects the biological efficacy of an iron based nano-carrier system, hydrophilic iron oxide nanoparticles (~10 nm) were synthesized, with either a carboxylic acid (-COOH) or an amine (-NH<sub>2</sub>) functional group. <sup>14</sup>C labels ( $t_{1/2}$ =5730 years) were incorporated into the organic functional groups on the surface of the nanoparticles. The radiolabeled, superparamagnetic, nanoparticles were then delivered intra-venously to mice and the

pharmacokinetic distribution in vivo was determined by Accelerator Mass Spectrometry (AMS); an ultrasensitive (10<sup>-18</sup> moles) quantitative spectrometric technique with small sample requirements. The radiolabeled nanoparticles were well distributed in plasma and also detected in different organs like the lungs, liver and spleen. The radiolabeling approach used in this study provides comparable bio-distribution data as the radio-labeled probes have the same chemical properties as the non-labeled probes. The synthesis approach described here is broadly applicable to the synthesis of nanoscale materials with multiple core and surface functionalities. The pharmacokinetic data, suggest that functionalized iron nanoparticles may have broad use as therapeutic, diagnostic or even theranostic agents in biological systems.

### PS 2392 Susceptibility to Quantum Dot-Induced Lung Inflammation Is Mouse Strain Dependent.

D. K. Scoville<sup>1</sup>, C. C. White<sup>1</sup>, D. Botta<sup>1</sup>, L. A. McConnachie<sup>1</sup>, M. E. Zadworny<sup>1</sup>, X. Hu<sup>2</sup>, X. Gao<sup>2</sup>, J. Yu<sup>1</sup>, R. Dills<sup>1</sup>, R. C. Zanger<sup>3</sup>, J. G. Pounds<sup>3</sup> and T. J. Kavanagh<sup>1</sup>. <sup>1</sup>Environmental and Occupational Health Sciences, University of Washington, Seattle, WA; <sup>2</sup>Bioengineering, University of Washington, Seattle, WA; <sup>3</sup>Systems Toxicology Group - Division of Biological Sciences, Pacific Northwest National Laboratory, Richland, WA.

Quantum dots (QDs) are nanoparticles typically composed of a CdSe core, a ZnS shell, and an assortment of polymer coatings specific to the application. Unique fluorescent and excellent semiconductor properties make QDs useful in biomedical imaging and electronics. However, due to their small size, large surface area, and heavy metal composition, there is concern over the safety of QDs. Using 8 genetically inbred mouse strains we have investigated susceptibility to QD induced lung inflammation using % neutrophils, total protein, and levels of inflammatory cytokines in bronchoalveolar lavage fluid (BALF) as biomarkers. Cadmium was measured as a marker of exposure and total glutathione (GSH) levels in frozen lung tissue were also measured. Significant treatment group and strain specific differences in the % neutrophils in BALF indicate that susceptibility to QD induced lung inflammation is mouse strain dependent. We also observed that the % neutrophils in BALF is correlated with lung Cd and GSH levels, as well as BALF cytokines. It is clear that strong relationships exist in some mouse strains and not in others. For example, the % neutrophils in BALF is highly correlated with macrophage inflammatory protein 1a (MIP1a) in A/J, C57BL/6J, WSB/Eij, NZO/HLtJ mice. However, CAST/Eij, NOD/ShiLtJ, PWK/PhJ, and 129S1/SvImJ mice do not show as strong a relationship. In future studies, recombinant inbred mouse strains will be used to map expression quantitative trait loci (eQTLs) associated with QD-induced lung inflammation. Analysis of such eQTLs could lead to insights regarding the molecular mechanisms responsible for QD toxicity and ultimately provide guidance on how to produce safer QDs. Supported by NIH grants R01ES016189, U19ES019545 and P30ES07033.

### PS 2393 Nrf2 Is a Positive Regulator of Cytokine Expression in Lung of Titanium Dioxide Nanoparticles Exposed Mice.

N. L. Delgado Buenrostro<sup>1</sup>, E. I. Medina-Reyes<sup>1</sup>, A. Cuadrado Pastor<sup>2</sup>, I. Lastres<sup>2</sup>, J. Pedraza<sup>3</sup>, R. Hernández<sup>4</sup> and Y. I. Chirino<sup>1</sup>. <sup>1</sup>Investigación y Posgrado UBIMED, Fesiztacala, UNAM, Mexico City, Mexico; <sup>2</sup>Investigación y Posgrado, Instituto Alberto Sols, Madrid, Spain; <sup>3</sup>Posgrado, Facultad de Ciencias UNAM, Mexico City, Mexico; <sup>4</sup>Investigación, Instituto de Nutrición, Mexico City, Mexico.

Background. Titanium dioxide nanoparticles (TiO<sub>2</sub> NPs) increase the generation of reactive oxygen species and the inflammatory response in lung tissue of exposed animals. As a result, the expression of Nrf2 acts a defense mechanism against ROS generation; however its role in inflammation remains unclear.

Aim. The goal of this work was to evaluate role of Nrf2 in inflammatory process induced by TiO<sub>2</sub> NPs in lung from exposed mice.

Methods. Male wild type mice (WT) and Nrf2 knockout mice (KO) were divided in the following groups: a) control-WT, b) TiO<sub>2</sub>-WT, c) control-KO and d) TiO<sub>2</sub>-KO. TiO<sub>2</sub> NPs were suspended in 50µl of SSI and received 5 mg/kg by oropharyngeal via twice a week/4 weeks. Then, mice were perfused with p-formaldehyde and lung tissue was obtained for histological and immunohistochemical analysis.

Results. Bronchioles, venules and interstitial space of TiO<sub>2</sub>-KO group showed higher inflammation and oxidative stress damage, than TiO<sub>2</sub>-WT group. On the other hand, Nrf2 was a positive mediator in the expression of IL-10, Interferon-gamma, TNF-alpha, and TGF-beta, and acts as a negative mediator of IL-4 expression in bronchial epithelium and alveolar space.

Conclusion. This work suggests that Nrf2 has a central role in up-regulation of cytokines released during inflammation induced by TiO<sub>2</sub> NPs in lung tissue.

**PS 2394 Distinct Expression Profiles of Stress Defense and DNA Repair Genes in *Daphnia pulex* Exposed to Cadmium, Zinc and Quantum Dots.**

S. Tang<sup>1</sup>, Y. Wu<sup>2</sup>, C. N. Ryan<sup>1</sup>, S. Yu<sup>1</sup>, D. Edwards<sup>1</sup> and G. D. Mayer<sup>1</sup>.  
<sup>1</sup>Environmental Toxicology, Texas Tech University, Lubbock, TX; <sup>2</sup>Biological Sciences, Texas Tech University, Lubbock, TX.

Use of nanocrystalline semiconductors (Quantum dots; QDs) is growing as new applications, especially in biomedical research, adopt this technology. More importantly, industrial and other mainstream uses of QDs seem likely to increase since QDs can theoretically more than double the efficiency of semiconductors in current photovoltaics. Often, with increased use comes increased appearance in the environment and, given the heavy metal composition of QDs, there exists a concern regarding the potential toxicity of these nanoparticulates on aquatic organisms. The freshwater invertebrate *Daphnia* is a ubiquitous dweller of ponds and lakes throughout North America, a keystone species in aquatic food chains, and an indicator species for environmental contaminants. In this study, we aimed to compare transcriptional responses of several key stress-mediated and DNA repair genes in *D. pulex* following exposure to QDs and the individual metallic components of which they are comprised. Exposure to both Cd and QDs led to induction of mortality and Cd accumulation, which was biologically supported by the increased expression of the heavy metal responsive gene, metallothionein (MT). Our study also revealed that Cd, Zn and CdSe/ZnS QDs induced a different pattern of gene expressions regarding stress defense and DNA repair, which furthered our knowledge regarding the different mechanisms of toxicity that are elicited by the nanoparticulate form of metals versus the ionic form.

**PS 2395 A Delphi Pilot Study in Brazilian Stakeholders About Nanotechnology, Nanomaterial, and Their Toxicological and Regulatory Implications.**

W. Waissmann<sup>1</sup>, R. S. Barros<sup>1</sup>, M. Moura<sup>1</sup>, E. Wilson<sup>2</sup>, A. S. Arcuri<sup>3</sup>, V. S. Pinto<sup>3</sup>, A. B. Veggi<sup>4</sup>, T. P. Silva<sup>4</sup> and L. Brickus<sup>1</sup>. <sup>1</sup>School of Public Health, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil; <sup>2</sup>Law, Unisinos, Sao Leopoldo, Brazil; <sup>3</sup>Centro Nacional, Fundacao Jorge Duprat de Figueiredo, São Paulo, Brazil; <sup>4</sup>Nutricao, Universidade Gama Filho, Rio de Janeiro, Brazil.

**Abstract:**

We conducted an email study using Delphi method. In the first phase, 108 questionnaires (5 questions) were sent, 12 for each of the following groups: Researchers; Regulators, Personal from Funding Institutions (PFI), Public Health/Environmentalists, Producers, Workers/Unions Representatives, Consumers, Legislators, NGOs. Only two rounds were need. At the first, 43 (40%) questionnaires were completed. From the 43 sent, 33 (77%) were completed at the second round. We have no answers from legislators and NGOs. Only two answers have been changed, and this not modified the general results, which show: 60% of respondents considered the benefits equal or outweigh the risks, but recognize that population must better understand risks. More than 20% believe all research and production in nanotech should be suspended until the increase of nanorisk knowledge. Around 60% of the respondents believed Brazil is in a disadvantageous position in nanotech market products comparing to other developing countries, even though who agree that research is at a good level in the country. 80% consider inadequate and insufficient the legislation that deal with risks of nanotech, almost 100% understand consumers have insufficient information and more than 80% understand that even workers who deal with nanotechnology have little information on legislation and potential risks. It was used regular ways to send emails, similar for all categories. For next researches, the approach to NGOs and legislators should be modified.

**PS 2396 In Vitro/In Vivo Assessment of Engineered Nanomaterials Using a High-Content Analysis Platform.**

S. Anguissola<sup>1</sup>, L. Cooke<sup>1</sup>, D. Garry<sup>1</sup>, M. Esquivel-Gaón<sup>2</sup>, A. De Vyzcaia Ruiz<sup>2</sup>, M. Monopoli<sup>1</sup> and K. A. Dawson<sup>1</sup>. <sup>1</sup>Centre for Bionano Interactions, School of Chemistry and Chemical Biology, University College Dublin, Dublin, Ireland; <sup>2</sup>Department of Toxicology, Cinvestav, Mexico City, Mexico.

With increasing numbers of nanomaterials introduced on the market in consumer products, bio-medical and environmental applications it is of primary importance to assess, understand and manage their potential toxicity. To effectively assess and understand the mechanisms of toxicity induced by nanoparticles (NPs) we implemented a platform that correlates physico-chemical properties of nanomaterials with their biological effects in vitro on human cell lines and in vivo on zebrafish as a model of toxicity to aquatic species. Nanomaterials' physico-chemical characteristics were evaluated in the relevant exposure media for in vitro and in vivo exposure

and High Content Analysis (HCA) was employed to quantify several parameters of toxicity on exposed human cell lines and anatomical defects observed on exposed zebrafish larvae. To demonstrate the power of the platform the toxicological outcomes of surface-functionalized model nanoparticles (i.e. polystyrene Nanoparticles with carboxyl and amine surface modifications) are described along with Bismuth (Bi)-derived Nanoparticles designed for industrial applications developed within the EU/Mexico collaborative project Bisnano. The model NPs were well dispersed in either complete cell culture medium or zebrafish embryo medium; for Bi-derived NPs it was necessary to develop a dispersion protocol in order to isolate particles in the nanometer range from a heterogeneous powder which were subsequently stabilized with bovine serum albumin. The HCA approach was able to differentiate between apoptosis and necrosis induced in different cell models by amine-modified polystyrene (PS-NH<sub>2</sub>) NPs and highlighted lysosomal damage as the triggering mechanism of toxicity for both the PS-NH<sub>2</sub> NPs and the Bi-derived NPs. HCA analysis of zebrafish larvae quantified changes of anatomical features such as head/torso ratio, spine length and body curvature. The project was funded by QNano and Bisnano.

**S 2397 Biomarkers of Disease and Toxicity: Exploiting the Interconnections.**

D. L. Mendrick<sup>1</sup> and W. B. Mattes<sup>2</sup>. <sup>1</sup>Division of Systems Biology, NCTR, US FDA, Jefferson, AR; <sup>2</sup>Toxicology, PharmPoint Consulting, Poolesville, MD.

With the recent focus on (a) cellular pathways involved in toxicity sequelae and (b) translational biomarkers that may link animal and *in vitro* model observations with clinical reality, there is a need to broaden the understanding of how experimental models may replicate human toxicity and disease processes. Multicellular organisms may have large numbers of genes and proteins, but a relatively limited repertoire in terms of pathophysiology in response to disease or toxicant exposure. This fact allows research to improve and protect human health to be founded on the use of model systems that allow for tractable experimentation. Animal models and, more recently, *in vitro* systems have served as a means of both exploring mechanisms and identifying hazards in terms of disease and adverse events. However, the interconnections between disease and toxicity are rarely explored leaving the information in silos. This symposium will examine organ-based toxicity and disease processes, and compare lessons learned in biomarker identification and use across toxicity, disease, and species.

**S 2398 Introduction.**

D. L. Mendrick. US FDA, Jefferson, AR.

Biomarkers are needed that increase translation between *in vitro/in vivo* environments and across species. For clinical situations particularly, biomarkers that could distinguish a reaction to a toxin from a disease process would be valuable. However, since biomarkers arise due to perturbations of normal metabolic pathways, toxicity-specific biomarkers are scarce. The good news is that it means that research into toxicity or disease can yield biomarkers of interest in both fields. It is important that toxicologists and clinicians work together to select appropriate models to advance our understanding of biological processes.

**S 2399 Use of Biomarkers in Hepatology, Liver Disease, and Liver Toxicity.**

A. Regev. Global Patient Safety, Eli Lilly & Company, Indianapolis, IN. Sponsor: D. Mendrick.

Biomarkers in use today do not distinguish drug-induced liver injury (DILI) from other causes of hepatic damage such as viral hepatitis, alcoholic liver disease, and metabolic liver injury. Such specific biomarkers would be valuable to better manage patients. Currently available biomarkers fail to differentiate, during the early stages of live injury, between mild self-limiting hepatic abnormality and one that will progress to severe liver injury, liver failure and death. There is a clear need for new translational biomarkers to detect liver injury in animals and humans and to identify significant injury with more specificity than ALT. To enable the identification and qualification of translational biomarkers, better communication is needed between those that focus on preclinical safety testing and clinicians.

**S 2400 Fibrinogen: A New Kid on the Block of Translational Biomarkers for Kidney Damage.**

V. S. Vaidya. *Harvard Medical School, Boston, MA.*

Environmental contaminants and therapeutic substances contribute significantly to the high incidence and prevalence of acute kidney injury (AKI). Preclinical observations of kidney toxicity stops many compounds from entering later development due to the lack of early biomarkers of injury. In the clinic, morbidity and mortality with AKI remains unacceptably high. Our recent work has shown urinary as well as tissue fibrinogen levels increase significantly in mice, rats and humans following kidney injury/toxicity. We provide evidence that fibrinogen may function as a key molecular link between tubulo-vascular damage and regeneration in the kidney and provides new opportunities for its use in the diagnosis and prevention of kidney disease and enablement of the clinician to institute therapeutic interventions.

**S 2401 Cardiac Disease, Cardiotoxicity, and Translational Biomarkers.**

J. R. Turk. *CBSS, Amgen Inc, Thousand Oaks, CA.*

Heart disease is the leading cause of death in the United States. Cardiovascular health is a prime concern for both toxicologists and physicians. Interactions among genes and environmental factors including lifestyle and drugs, may negatively affect the cardiovascular system. Myocardial damage from ischemia, infectious and metabolic diseases, or cardiotoxic drugs may be followed with biomarkers such as the troponins, natriuretic peptides, and their combination in panels with multiple evolving biomarkers. These tools facilitate an understanding of the parallels between toxicity and background disease in animal models and human heart disease.

**S 2402 Links between Neurological Disease and Toxicity.**

D. L. Gerhold and C. P. Austin. *Division of Preclinical Innovation, National Center for Advancing Translational Sciences, NIH, Rockville, MD.* Sponsor: D. Mendrick.

It is well known that environmental agents, including self-administered drugs, are capable of causing neurological damage. Such agents may be used to create animal models of human disease, which may be useful in identifying drug targets, therapeutic strategies, and biomarkers. A well-known example is MPTP, a chemical contaminant in the illicit manufacture of a synthetic opioid which produced an acute Parkinsonian syndrome in users. MPTP has been extensively used in Parkinson's disease research as an investigative agent in both cultured cells and animals. A challenge remains that few good biomarkers exist for early neurological damage and thus there is an intensive focus on better predictive and diagnostic biomarkers. The combined use of models of neurological damage caused by drugs, toxicants, and disease may move the field forward faster in the identification and use of translational biomarkers.

**S 2403 Mechanistic Role(s) of Cytochrome(s) P450 in Oxidative Stress and Inflammation: New Opportunities for Drug Discovery.**

J. E. Manautou<sup>2</sup> and B. Moorthy<sup>1</sup>. <sup>1</sup>*Pediatrics, Baylor College of Medicine, Houston, TX;* <sup>2</sup>*Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

The major goal of this symposium is to discuss the molecular and cellular mechanisms by which cytochromes P450 (CYP) contribute to oxidative stress, which could in turn lead to inflammatory processes, ultimately leading to many human diseases including cancer, neurodegenerative diseases, bronchopulmonary dysplasia (BPD), acute respiratory distress syndrome (ARDS), and drug-induced hepatotoxicity. Although much is known about the functional role of CYPs in drug metabolism, their role in endobiotic metabolism, in relation to oxidative stress and inflammation, is understudied. The recent findings of the novel role of CYPs in oxidative stress and inflammation in the manifestation of multiple human diseases warrant the need for a symposium to discuss the latest mechanistic research in this area and its impact on human health. Specifically, the symposium will discuss: i) the role of CYP4f in neuroinflammation, which in turn contributes to neurodegenerative diseases such as Parkinson's and Alzheimer's diseases; ii) the role of the Ah receptor, oxidative stress, and inflammation in 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-induced hepatotoxicity; iii) the functions of CYP1A1, 1A2, and 1B1 in the metabolism of eicosanoids, which in turn play mechanistic roles in TCDD toxicity; iv) the contribution of CYP4As in eicosanoid metabolism and the mechanism of down-regulation of CYPs during infection; and v) the novel protective role of

CYP1A1 and 1A2, and the pro-oxidant role of CYP1B1 in hyperoxic lung injury, in relation to BPD and ARDS. The symposium will also discuss new opportunities for drug discovery and their potential translatability in clinical settings.

**S 2404 Cytochromes P4504f, a Potential Therapeutic Target for Neuroinflammation.**

V. Ravindranath. *Center for Neuroscience, Indian Institute of Science, Bangalore, India.* Sponsor: B. Moorthy.

Inflammatory processes are involved in pathogenesis and progression of CNS disorders, such as infection, traumatic brain injury, and neurodegenerative diseases. Eicosanoids including leukotrienes, particularly leukotriene B4 (LTB4) mediate inflammatory response by initiating and amplifying generation of cytokines and chemokines. Cytochrome P450 (Cyp), a family of heme proteins mediate metabolism of xenobiotics and endogenous compounds, such as eicosanoids. We demonstrate that mouse brain Cyp4fs are expressed ubiquitously in several cell types in the brain including neurons and microglia, and modulate inflammatory response triggered by lipopolysaccharide (LPS), *in vivo* and in microglial cells, *in vitro* through metabolism of LTB4 to the inactive 20-hydroxy LTB4. Chemical inhibitor or shRNA to Cyp4fs enhance the inflammatory response, while the PPAR $\alpha$  agonist, fenofibrate induces Cyp4fs and attenuates it. Fenofibrate also confers neuroprotection against Japanese encephalitis (JE), *in vivo*, in a mouse model of JE viral infection through up-regulation of Cyp4fs, and could potentially be used for prophylaxis during JE epidemics to reduce mortality and morbidity. Thus, catalytic activity of Cyp4fs is a novel target for modulating neuroinflammation.

**S 2405 Metabolomics Identifies an Oxidative Stress-Mediated Signal Transduction Cascade Involved in Dioxin-Induced Hepatotoxicity.**

E. J. Gonzalez, T. Matsubara, N. Tanaka, K. W. Krausz, A. D. Patterson and Y. M. Shah. *Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.*

A number of chemical contaminants that are highly prevalent in the environment, elicit some or all of their toxicity through the arylhydrocarbon receptor (AhR), a ligand-activated transcription factor. Activated AhR forms a heterodimer together with the AhR nuclear translocator (ARNT), and binds to xenobiotic response elements in the promoter regions of target genes resulting in induction or inhibition of expression. Among the AhR target genes are the cytochromes P450 CYP1A1, CYP1A2 and CYP1B1. 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is among the most potent environmentally toxic compounds. TCDD exposure alters serum metabolite profiles as a result of attenuating hepatic carboxylesterase 3, CES3 (also known as triglyceride hydrolase), expression in an AhR-dependent manner. Serum metabolomics identified azelaic acid-mono esters as significantly increased metabolites after TCDD exposure. The decreased CES3 expression was accomplished by TCDD-stimulated TGF $\beta$ -SMAD3 and IL6-STAT3 signaling, but not by direct TCDD-activated AhR induction of target genes. Proinflammatory cytokine activation was achieved by TCDD-mediated oxidative stress in the liver through TCDD-induction of xanthine dehydrogenase and NADPH oxidase expression in an AhR-dependent manner. Methionine- and choline-deficient diet-treated mice also showed enhanced serum azelaic acid ester levels following attenuation of hepatic CES3 expression, while genetically obese db/db mice did not, suggesting an association with steatohepatitis. These results support the view that azelaic acid-mono ester is an indicator of dioxin exposure and a possible diagnostic biomarker of steatohepatitis and indicate oxidative stress in the mechanisms of hepatotoxicity by TCDD.

**S 2406 Lipidomic Analysis Demonstrates That 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin Increases the Levels of Multiple Pro- and Anti-Inflammatory Cytochrome P450 Metabolites of Polyunsaturated Fatty Acids in Several Organs of the Mouse.**

O. Hankinson<sup>1,2</sup>. <sup>1</sup>*Pathology, UCLA, Los Angeles, CA;* <sup>2</sup>*Molecular Toxicology Program, UCLA, Los Angeles, CA.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) adversely affects the immune system and many organs and tissues. These effects are mediated by the aryl hydrocarbon receptor (AHR). CYP1A1, CYP1A2 and CYP1B1 are upregulated by the liganded AHR. These cytochromes P450 are known to metabolize arachidonic acid and certain  $\omega$ -3 polyunsaturated fatty acids *in vitro*. Towards investigating a potential role of metabolism of these fatty acids in TCDD toxicity *in vivo*, we determined

the levels of 81 metabolites in several mouse organs/tissues of mice treated with TCDD. TCDD increased the levels of many hydroxides, epoxides and diols of arachidonic acid in the liver, lung, spleen and serum, but not the heart. That such increases occurred in serum, suggests that increases in these metabolites may be transferred from one organ to another via the blood. The changes in the levels of the metabolites correlated with changes in levels of CYP1A1, CYP1A2 and CYP1B1 in some organs but not others, suggesting that other enzymes may also be involved. TCDD increased the levels of the esterified forms of the eicosanoids in the liver in parallel with the corresponding free forms. The phospholipids so formed therefore represent a reservoir for these metabolites. Analysis of Ahr<sup>-/-</sup> null mice demonstrated that the changes in eicosanoid levels elicited by TCDD depend upon AHR. Many epoxides and diols of three  $\omega$ -3 unsaturated fatty acids, eicosapentaenoic acid {20:5(n-3)}, docosahexaenoic acid {22:6(n-3)}, and  $\alpha$ -linolenic acid {18:3(n-3)}, were also markedly increased in the liver, lung, but not the heart of mice treated with TCDD. Since many of the oxlipin metabolites that were increased by TCDD treatment exhibit potent biological activities, including both pro- and anti-inflammatory effects, these studies lay the foundation for future experiments addressing their potential role in mediating the toxic and other effects of TCDD and other ligands of the AHR.

## **S 2407 Regulation and Functions of Cytochromes P450 during Infection.**

E. T. Morgan and B. A. Nyagode. *Pharmacology, Emory University, Atlanta, GA.*  
Sponsor: B. Moorthy.

Activation of the innate immune system, whether by infection or aseptic stimuli, causes significant changes in hepatic cytochrome P450 (P450) enzyme expression, drug metabolism and clearance. This regulation has important consequences for drug administration and responses in disease states. Its reversal by therapeutic proteins targeting proinflammatory cytokines gives rise to a newly recognized drug-drug interaction mechanism. Understanding the regulatory pathways for the different enzymes is pivotal to predicting the clinical consequences of such regulation during disease and therapy. We have studied the regulation of hepatic P450 expression in various disease models in mice, including injection of bacterial lipopolysaccharide and infection with the colonic pathogen *Citrobacter rodentium*. The enzymes affected are dependent on the disease model, so that different drugs are likely to be affected in different human disease states. In the *C. rodentium* model, studies in cytokine or cytokine receptor-null mice indicate roles for interleukin-6 and tumor necrosis factor- $\alpha$  in the regulation of a small subset of P450 transcripts, including some members of the *Cyp3a* subfamily. Studies in SCID mice suggest that T cells or T-cell-derived cytokines might also be important in this model. However, the absence of cytokine signals fails to alter the down-regulation of the most profoundly suppressed liver enzymes i.e. *Cyp4a10*, *Cyp4a14* and flavin monooxygenase 3 (*Fmo3*), suggesting a different mechanism of regulation for these genes. To address whether or not *Cyp4a* enzymes play a role in the host-pathogen interaction, we infected *Cyp4a14*<sup>-/-</sup> and *Cyp4a10*<sup>-/-</sup> mice with *C. rodentium*, and compared their responses to those of wild-type mice. Results from these ongoing studies will be presented. Supported by National Institutes of Health grant R01DK072372.

## **S 2408 Mechanistic Role(s) of Cytochrome P4501A and 1B1 Enzymes in Hyperoxic Lung Injury: Implications for Bronchopulmonary Dysplasia (BPD) in Premature Infants and ARDS in Adults.**

B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Hyperoxia is routinely used in the treatment of pulmonary insufficiency and respiratory distress in preterm and term infants and in adults with acute respiratory disease (ARDS). However, in premature infants, hyperoxia contributes to the development of chronic lung disease (CLD), which is termed bronchopulmonary dysplasia (BPD). The molecular mechanisms of oxygen-mediated lung injury are not understood, but reactive oxygen species (ROS) are the most likely candidates. ROS-mediated reactions with biological macromolecules such as DNA, proteins, and lipids are also responsible for many other lung diseases such as acute respiratory distress syndrome (ARDS), asthma, emphysema, chronic obstructive pulmonary disease (COPD), and lung cancer induced by environmental pollutants. Results from our laboratory demonstrate a novel role for cytochrome P450 (CYP)1A enzymes in the detoxification of ROS-mediated lipid peroxidation products, e.g., F<sub>2</sub>-isoprostanes. Our major observations are that mice lacking the genes for CYP1A1 or 1A2 are more susceptible to hyperoxic lung injury than wild type mice, with *Cyp1a2*-null mice being the most sensitive. On the other hand, mice lacking the gene for CYP1B1, are less susceptible to lung injury, suggesting a pro-oxidant role for CYP1B1. Mice pre-treated with the CYP1A inducer  $\beta$ -naphthoflavone (BNF), followed by exposure to hyperoxia leads to protection against lung injury. We also found formation of bulky oxidative lesions (oxidative DNA adducts) in tracheal aspirates of premature infants and adults who received supplemental oxygen, and this

was associated with BPD and ARDS, thereby suggesting that these adducts could serve as novel biomarkers of these diseases. Future studies could lead to the development of rational strategies for the prevention/treatment of lung diseases associated with hyperoxia.

## **S 2409 Molecular Basis of Age-Related Susceptibility to Chemicals and Environmental Hazards: From Model Systems to Humans.**

J. S. Lee<sup>1</sup> and J. C. Fuscoe<sup>2</sup>. <sup>1</sup>US EPA, Durham, NC; <sup>2</sup>US FDA, Jefferson, AR.

The susceptibility of individuals to chemicals and environmental hazards at the extremes of the population age-distribution (the very young and the very old) is often not adequately assessed. By understanding genes expressed at the various life stages, the assessment of health risk versus benefit can be more rationally determined. Children are more susceptible to exposures to environmental toxicants compared to adults because intakes are increased, biologically-effective doses may differ, and early life stage exposure may lead to adverse health effects that are chronic in nature. Older adults are more susceptible to environmental toxicants because of pharmacokinetic and pharmacodynamic changes associated with aging. Altered absorption, distribution, metabolism, and excretion (ADME), along with decreased blood flow to the liver, decreased liver mass, and decreased content of specific cytochrome P450s (CYPs) could result in decreased clearance of chemicals in older adults. In addition to these factors, genetic and epigenetic changes that occur with age and chemical exposure may also increase susceptibility to environmental hazards. Our panel will examine genomic and epigenomic changes that occur with age using animal and human data. Rat liver and kidney data will be used to discuss age-related target organ vulnerabilities. Human relevance will be addressed using a longitudinal birth cohort study in Mexican-American children, two mother-child cohort studies in Mexico and the United States, and a cohort study of older men from the Normative Aging Study. Ultimately, understanding the implications of genetic and epigenetic changes related to age on the effects of chemical exposure will help to protect the health of children and older adults. Disclaimer: The views expressed are those of the authors and do not necessarily represent the views or policies of the US EPA or US FDA.

## **S 2410 Functional Genomic and Epigenomic Changes in the Liver and Kidney during the Rat Life Cycle.**

J. C. Fuscoe, T. Han, V. Vijay, V. Desai and J. C. Kwekel. *Division of Systems Biology, NCTR, US FDA, Jefferson, AR.*

The susceptibility of individuals at the extremes of the population age-distribution (the very young and the very old) and differences between sexes are often not adequately assessed. By understanding the genes expressed in each sex at the various life stages, the assessment of health risk versus benefit can be more rationally determined. Comprehensive analysis of the transcriptome, including miRNA, and the epigenome in the liver and kidney of Fisher 344 rats from 2 weeks to 2 years of age reveals substantial differences at various life-stages and between the sexes. In the liver and kidney, the expression of nearly 4000 genes was found to significantly vary with age and/or sex. Many of these genes are involved in xenobiotic metabolism and transport, processes that impact drug efficacy and safety. The expression of genes that code for some of the kidney injury protein biomarkers recently qualified by the FDA were found to vary substantially with age and sex, in some cases up to 100-fold. Such dramatic differences may impact the interpretation of biomarker results. Examination of miRNA expression in the liver showed nearly 200 miRNAs varied with age and/or sex. Notably, a group of 42 miRNAs was expressed at a relatively high level at 2 weeks of age in both sexes followed by low or no detectable expression at older ages. However, this 2 week-specific miRNA expression was not evident in the kidney. Analysis of potential target mRNAs for liver miRNAs suggests roles in disease susceptibility involving fibrosis as well as regulation of xenobiotic metabolism related genes. A similar number of kidney miRNAs also displayed sex and age-related changes which may be linked to gene regulation. These differences may be related to age- and sex-specific susceptibilities to adverse drug reactions or disease states. Understanding these differences should improve personalized medicine both in terms of disease prevention and management, and safer use of drugs.

## **S 2411 A Case-by-Case Approach to Pediatric Drug Safety Involving Multiage Juvenile Rat Models That Target Developmental Issues and Address Regulatory Concerns.**

P. Espandiar, W. Rodriguez and J. P. Hanig. *CDER, US FDA, Silver Spring, MD.*

The toxicity of drugs in pediatric populations may vary considerably from that seen in adults. Capacity to generate or inactivate the toxic moiety, issues of drug half-life, volume of distribution or specific target organ toxicity as well as hypersensitivity are

all critical factors. Vital organ systems mature at different times and present many challenges for selecting an appropriate model that captures the vulnerability necessary to characterize safety issues. One example of a multi-age pediatric model utilizes rats 10, 25, 40 and 80 days old roughly corresponding to human infants, toddlers, teenagers and young adults exposed to either the nephrotoxins gentamicin, or cisplatin or the hepatotoxin valproic acid. The differential effects across the various age groups were assessed by organometrics, histopathology, hematology, clinical chemistry, liver and kidney biomarkers, and metabolomics technologies to establish specific age-related target organ vulnerabilities. Each age group was shown, using principal component analysis, to be a distinctly separate entity in terms of treatment responses. This published model, representing a single possible approach, has potential for significant utility as a tool for pediatric safety evaluation, in comparison to dosing throughout the complete maturation process. The FDA Guidance for Nonclinical Safety Evaluation of Pediatric Drug Products (Feb., 2006) presents a wide variety of parameters involving juvenile/adult differences. These constitute many possible choices that may be incorporated into a pediatric preclinical model appropriate to address preclinical safety. The age of intended exposure, route, frequency and length of exposure are critical and will be discussed. In general the preclinical safety evaluation of new and approved drugs for pediatric use is handled on a case by case basis. This is reflected in some of the more recent EMA and ICH documents (2008, 2009) that allow for a multitude of choices based on the ultimate requirements of subsequent clinical trials.

### **S** 2412 Genetic and Epigenetic Mechanisms of Susceptibility to Environmental Exposures in Children.

N. Holland, P. Yousefi, K. Huen, K. Harley, V. Volberg, L. Barcellos, H. Quach, A. Bradman and B. Eskenazi. *SPH, CERCH, University of California Berkeley, Berkeley, CA*. Sponsor: [J. Lee](#).

Children are more susceptible to exposures to environmental toxicants than adults, and in utero exposures may result in developmental problems and chronic diseases. Some children can be particularly vulnerable due to their genetic makeup and age-related differences in protective enzyme levels such as paraoxonase (PON1). Results from the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS) birth cohort study will be presented to illustrate complex relationships of the effects of prenatal exposure to pesticides, PON functional genomics and genome-wide DNA methylation in Mexican-American children. We determined PON1 genotypes and three PON1 enzyme activities in 450 mothers and their children. Although it was previously thought that children's PON1 levels reach adult ones by age 2, we found that PON1 levels and activities were the lowest in newborns and steadily increased with age. However, they remained below adult levels up to 7 years. Infants and young children, particularly those with PON1 genotypes encoding for lower PON1 levels and activities, have up to 65-fold lower levels of the protective PON1 enzyme than adults and may be especially susceptible to OP exposures. To assess DNA methylation in cord blood and peripheral blood (clots) of 9 year old CHAMACOS children we interrogated 485,577 CpG sites from >24,000 genes using the Illumina BeadChip platform. We found that ~15.5% of all CpG sites were differentially methylated between children at birth and 9 years of age. More than 2% of CpG sites investigated, in >1,900 genes, showed significant differences in methylation by sex, including 731 CpG sites located in autosomes. Candidate genes and pathways involved in response to environmental exposures during pregnancy have been identified. Unlike genetics, epigenetic mechanisms could be reversible and an enhanced understanding of their role may lead to better protection of pregnant women and children, and improved public health.

### **S** 2413 Prenatal Metal Exposure and Health Effects.

R. C. Fry. *Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC*.

We will present data that we are collecting from two mother-child cohorts, one in Gómez Palacio, Mexico and one in North Carolina, USA. Both of the newborn cohorts are at risk for metal exposure. The research focuses on an arsenic endemic area of Mexico, Gómez Palacio, the study site for our newly established birth cohort. In this region we are assessing exposure to inorganic arsenic in pregnant women. Our results suggest that pregnant women in this region are at risk for high level exposure to arsenic, a finding that has implications both for the health of the women and also their children. In related research we show that exposure to inorganic arsenic is associated with changes in DNA methylation patterns. We are also examining changes in DNA methylation patterns in fetal DNA collected from the NC cohort which is at risk for prenatal exposure to cadmium. We demonstrate using genome-wide gene-specific DNA methylation analysis that there are significant differences in levels of promoter methylation in fetal or maternal samples. In addition, we

highlight that prenatal exposure to cadmium is associated with altered patterns of methylation of genes that play varied roles in the cell. Results from these cohort studies underscore the potential health effects of early life exposure to inorganic arsenic and cadmium, the potential for epigenetic alterations, short term health consequences, and potential relationships to detrimental health outcomes later in life.

### **S** 2414 Particulate Pollution, Susceptibility, and Epigenetic Pathways in an Elderly Cohort.

J. Madrigano<sup>1,2</sup>, A. Baccarelli<sup>2</sup>, M. A. Mittleman<sup>2,3</sup>, R. O. Wright<sup>2</sup>, D. Sparrow<sup>4</sup>, P. S. Vokonas<sup>4</sup>, L. Tarantini<sup>5</sup> and J. Schwartz<sup>2</sup>. <sup>1</sup>*Mailman School of Public Health, Columbia University, New York, NY*; <sup>2</sup>*Harvard School of Public Health, Boston, MA*; <sup>3</sup>*Beth Israel Deaconess Medical Center, Boston, MA*; <sup>4</sup>*Veterans Administration Boston Healthcare System and Department of Medicine, Boston University, Boston, MA*; <sup>5</sup>*Environmental and Occupational Health, University of Milan, Milan, Italy*. Sponsor: [J. Lee](#).

DNA methylation is a potential pathway linking environmental exposures to disease, and lower blood DNA methylation has been found in processes related to cardiovascular morbidity. Genetic and other host characteristics, such as psychological functioning, have been found to modify the association between air pollution and morbidity. In our study, DNA methylation of repetitive elements, as well as specific genes, was measured in 1406 blood samples from 706 elderly participants in the Normative Aging Study (NAS). We will discuss the changes in repetitive element DNA methylation, as well as two specific genes (the inducible nitric oxide synthase gene, iNOS, and the glucocorticoid receptor gene, GCR) associated with ambient particles (PM<sub>2.5</sub>) and black carbon (BC), estimated with mixed models. We will also discuss genotype and phenotype characteristic that may modify this association.

### **W** 2415 Challenging the Limits of Nonclinical Safety Assessment of Pediatric Medicines.

J. S. Moffit<sup>1</sup>, T. Ernest<sup>2</sup>, A. Mauz<sup>3</sup>, M. G. Paule<sup>4</sup>, J. Stewart<sup>5</sup> and P. Ji<sup>6</sup>. <sup>1</sup>*Nonclinical Drug Safety US, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT*; <sup>2</sup>*Product Development, GlaxoSmithKline, Harlow, United Kingdom*; <sup>3</sup>*Nonclinical Drug Safety GER, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riß, Germany*; <sup>4</sup>*Division of Neurotoxicology, US FDA-National Center for Toxicological Research, Little Rock, AR*; <sup>5</sup>*Reproductive Toxicology Safety Assessment, AstraZeneca, Macclesfield, United Kingdom*; <sup>6</sup>*Division of Clinical Pharmacology II, US FDA-Office of Clinical Pharmacology, Silver Spring, MD*.

Pediatric safety assessments are a fundamental and integral part of drug development programs. Introduction of regulatory guidance in the last decade has formalized the inclusion of safety evaluations in juvenile animals, leading to a better understanding of potential drug effects on developmental processes and risks specific to pediatric age groups. Toxicology studies in juvenile animals have evolved to address inherent differences in susceptibility between mature and immature systems. Pediatric safety assessments are challenged by practical and interpretive complexities of conducting toxicity studies in immature animals against a background of increasingly diverse disease indications. This symposium will review a number of innovative approaches that challenge the current limits of the nonclinical safety assessment of new pharmaceuticals. Our panel of experts will discuss unique approaches and case studies dealing with the challenges of supporting pediatric formulations, nontraditional routes of administration, and the complexities of developmental neurotoxicity assessments. Furthermore, our experts will discuss how information from various sources such as in vitro experiments using neonatal tissue, pharmacokinetics, and clinical pharmacology work may be brought together to build a risk assessment specific for a young infant and pediatric dosing. These innovative approaches from industry and government challenge the limits of nonclinical safety assessment and provide reassurances of safety for pediatric medicines.

### **W** 2416 Safe and Effective Use of Established and Novel Excipients in the Development of Children's Medicines.

S. R. Maguire. *Product Development, GlaxoSmithKline R&D, Harlow, United Kingdom*. Sponsor: [J. Moffit](#).

Developing medicines for children is in some respects even more challenging than developing medicines for adults yet the range of excipients available for use in the development of children's medicines is likely to be significantly reduced without appropriate evidence of safe, tolerated excipient limits across the whole paediatric age range. Industry, with the support of academia, have the opportunity to work with

national regulatory agencies to raise awareness of the need to build a risk/benefit approach focused on the use of excipients in paediatric drug products; in particular the use of novel excipients in this population. Identification of key data should be determined together with an appropriate mechanism for this data to be shared to enhance access to medicines for children.

#### **W 2417 Technical Challenges and Data Interpretation Evaluating an Inhaled Long Acting $\beta$ 2-Agonist in Juvenile Dogs.**

A. Mauz. *Nonclinical Drug Safety Germany, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riß, Germany.*

Numerous inhaled medications are marketed to pediatric populations, but most of these products were registered prior to the regulated integration of juvenile toxicity studies in nonclinical safety programs. In order to initiate clinical trials in pediatric populations, safety assessments are conducted in juvenile animals to assess any potential toxicity effects during postnatal development, particularly with regard to lung development. This presentation will detail a case study for an inhaled, long acting  $\beta$ 2-agonist in juvenile dogs. Discussion will include insight into the pediatric safety strategy, technical challenges involved in dosing an inhaled medication to juvenile dogs, and data interpretation.

#### **W 2418 Modeling Pediatric Exposures to Neuroactive Agents: Developmental Neurotoxicology.**

M. G. Paule. *Division of Neurotoxicology, National Center for Toxicological Research, US FDA, Jefferson, AR.*

Given the obvious limitations, it is difficult to thoroughly explore the effects of pediatric neuroactive agents on neurons in human infants or children. Due to the complexity of the primate brain, the monkey is often the animal model of choice for developmental neurotoxicology experiments. Case studies will be presented on nonhuman primate models of pediatric exposures to general anesthetics and other neuroactive compounds. These examples will focus on translational endpoints involving cognitive functions such as learning and memory and in vivo imaging using PET. Strategies for neuroprotection will also be discussed.

#### **W 2419 Technical and Scientific Challenges in Risk Assessments for Neonates and Infants.**

T. Mitchard and J. Stewart. *Reproductive Toxicology, AstraZeneca, Macclesfield, United Kingdom.* Sponsor: J. Moffit.

Progression into clinical trials in neonates and infants often involves a risk assessment specific for that age group. The risk assessment is likely to include information from technically challenging bespoke studies in very young animals. However, these studies may not be limited to just repeat dose toxicity studies in young animals but may also include in vitro experiments using neonatal tissue (exploring pharmacodynamic endpoints), safety pharmacology and ADME work. This presentation will illustrate with case examples how information from various sources may be brought together to build a risk assessment specific for the young infant.

#### **W 2420 Pediatric Dosing Regimen Determination during Drug Development.**

P. Ji. *Division of Clinical Pharmacology II, US FDA, Office of Clinical Pharmacology, Silver Spring, MD.* Sponsor: J. Moffit.

In the past 10 to 15 years, the medical treatment options for Juvenile Idiopathic Arthritis (JIA) have greatly evolved and expanded due to a better understanding of the disease and the application of biologic agents. Regulations pertinent to pediatric clinical research have also helped provide a legal basis for investigating the effects of drugs and biologics in pediatric populations and facilitate pediatric drug development. The evaluation of clinical pharmacology, efficacy, and safety data has provided valuable labeling information for pediatric use. This presentation will discuss the application of clinical pharmacology, safety, and efficacy assessments in determining JIA pediatric dosing regimens.

#### **W 2421 Nanotoxicology: Computational Strategies, Advances, and Challenges.**

S. M. Hussain and J. J. Schlager. *Air Force Research Laboratory, US Air Force, Wright-Patterson AFB, OH.*

Engineered Nanomaterials (ENM), in the range of 1–100 nm, have been found to exhibit fascinating physicochemical properties making them suitable for numerous applications, extending into numerous military, industrial, medical, and scientific specialties. However, massive quantities of ENM would need to be produced for these applications to be realized, thereby increasing the potential risk of human exposure and raising additional concern about their short and long-term toxicological effects. Nanotoxicology has recently emerged as a new branch of toxicology which deals with toxicological ramifications of these ENMs based on their physicochemical properties, such as size, shape, surface coating, and charge. Conducting toxicological studies considering massive quantities of ENM already in the market would be time consuming and resource intensive. Therefore, there is a great need to develop computational models to predict toxicity and human health effects of ENMs. A recent report (Nature Nanotechnology Vol 6, 2011 P138) has demonstrated a computational model to predict the cytotoxicity of various metal-based nanoparticles. The main objective of this workshop is to discuss modeling techniques based on the electronic and structural complexity of ENMs to predict their biological effects.

#### **W 2422 Quantitative Nanostructure-Activity Relationships Modeling.**

A. Tropsha. *Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC.* Sponsor: S. Hussain.

Evaluation of biological effects of Manufactured NanoParticles (MNP) (including toxicity and environmental fate) is of critical importance for the future of nanotechnology. Our group was among the first to assess the potential of modern cheminformatics methods such as Quantitative Structure – Activity Relationship modeling to develop statistically significant and externally predictive models that can accurately forecast biological effects of MNPs from the knowledge of their physical, chemical, and geometrical properties; we termed this approach Quantitative Nanostructure Activity Relationship (QNAR) modelling. We developed QNAR models for two different categories of MNP datasets: (i) those comprising MNPs with diverse metal cores and organic surface modifiers, in which experimentally measured properties were used as particle's descriptors, and (ii) those involving MNPs possessing the same core, but different surface-modifying organic molecules, for which descriptors can be calculated for a single representative of the surface-modifying molecule. In the former case, binary QNAR models with external predictive accuracy as high as 73% were developed for 44 MNPs tested for cellular bioactivity and characterized by experimental descriptors such as size, relaxivities, and zeta potential. For the latter case, we developed QNAR models for a library of 109 MNPs with CLIO-NH<sub>2</sub> core decorated with different synthetic small molecules that were tested for uptake in PaCa2 pancreatic cancer cells; models' external prediction power was shown to have an R<sup>2</sup> of 0.72 with a mean absolute error of 0.18 under 5-fold external validation procedure. Similar results were obtained for another dataset of 84 surface-modified Carbon Nanotube MNPs tested for protein binding and acute cellular toxicity; these models were used to design novel MNPs that were tested experimentally with the success rate of 80%. Our studies show that QNAR modelling can be used successfully for (i) predicting activity profiles of novel MNPs solely from their representative descriptors and (ii) designing and manufacturing safer nanomaterials with the desired properties.

#### **W 2423 Toxicity of Nanomaterials—Major Challenges for Theoretical Predictions.**

J. Leszczynski. *Department of Chemistry, Jackson State University, Jackson, MS.* Sponsor: S. Hussain.

Nanotechnology is expanding rapidly, but development of novel materials synthesized at the 'nano' scale should be always accompanied by a comprehensive assessment of risk to human health and to environmental ecosystems. It is vital to be able to predict possible environmental impact of new nanomaterials before their mass production and application. Computational Chemistry provides various tools to evaluate interaction of nanomaterials with biomolecules, shed a light on mechanisms of such phenomena, and predict toxicity of nano sized species. We believe that there is a strong need to develop "nano descriptors" i.e. novel and reproducible ways of representing the structures and/or physical properties of nanoparticles that are suitable for distinctive grouping these types of chemicals. This will facilitate development of QSARs that could reliably predict their characteristics and activities. A conceptual framework for grouping NPs should be considered as a first step in

identifying QSARs that are applicable within each group. Due to high variability in the molecular structure and different mechanisms of action, individual groups of nanoparticles should be modeled separately. In each case, according to the general QSAR rules, the applicability domain of the models should be carefully validated. Our recent *ab initio* study revealed details of interactions of gold clusters, carbon nanotubes and fullerenes with DNA bases and base pairs. Direct prediction of toxicity of unknown nanomaterials was done using QSAR models developed for a test set of compounds characterized experimentally. Based on experimental testing, we developed and tested novel interpretative nano-QSAR model describing cytotoxicity of 17 nano-sized metal oxides to bacteria *Escherichia coli*. The proposed model allowed us to formulate a hypothesis that mechanistically explained differences in toxicity between the individual oxides.

#### **W 2424 Biological Surface Adsorption Index (BSAI): A Molecular Signature for Nanomaterial Interactions.**

J. E. Riviere. *Institute of Computational and Comparative Medicine, Kansas State University, Manhattan, KS.*

Most characterization techniques available today for nanomaterials are based on hard physical-chemical properties of size, shape, and surface properties, often determined under very non-biological conditions. However, a major factor that determines biological interactions of nanomaterials *in vivo* are their surface properties related to forming interactions with molecules in the biological environment. We have developed the BSAI metric, which develops a signature of nanomaterial surface properties specifically related to biomolecular interactions. These properties are developed based on how a nanomaterial interacts with a series of probe compounds using a QSAR approach to generate five molecular descriptors that could be described as a multidimensional partition coefficient. This presentation will introduce the index and illustrate how it can be used to improve modeling of biological interactions.

#### **W 2425 Predictive Modeling on Nanoparticle-Biomolecular Interactions.**

R. Pandey. *Department of Physics, Michigan Technological University, Houghton, MI.*  
Sponsor: S. Hussain.

Nano-scale materials, such as semiconductor and metal quantum dots, carbon nanotubes, and graphene, exhibit novel optical, electrical, and magnetic properties that can be exploited for new generations of electronics and sensors. Nanoscale materials also exhibit unique affinity with biological molecules, such as nucleic acids and proteins, which can be utilized for a wide variety of biological diagnostics and sensing applications. In order to develop such application concepts, however, a fundamental understanding of the interactions between various nano and biological systems is critically important. This talk will present a brief overview of recent developments in the assembly and structure-property characterizations of hybrid nano-bio materials with a focus on the physical and chemical properties of their interface. Results obtained from recent theoretical and experimental investigations on optical protein-QD and nucleic acid base-nanotube (C, BN) interactions will be presented.

#### **W 2426 Toxicogenomics in Risk and Safety Assessment: Recent Advances and Continuing Challenges.**

C. Thompson<sup>1</sup> and M. D. Waters<sup>2</sup>. <sup>1</sup>*ToxStrategies, Inc., Katy, TX;* <sup>2</sup>*Integrated Laboratory Systems, Inc., Research Triangle Park, NC.*

Toxicogenomic studies can provide a vast amount of data with regard to the changes a chemical can have on a cell, tissue, or organism, and technological achievements continue to make it easier and cheaper to generate such data. However, the application of toxicogenomic data to environmental risk assessments and pharmaceutical safety assessments has progressed more slowly and, despite recent advances, challenges remain as to how best to harness and interpret these large and complex datasets to facilitate their practical application. This session will describe recent applications of toxicogenomics in environmental risk assessment with focus on assessing and predicting genotoxic modes of action and utilizing transcriptome changes from multidose and multi-endpoint animal bioassays in quantitative risk assessment. In addition, recent advances in the usage of toxicogenomics in pre-clinical pharmaceutical safety, clinical trial placement, and individualized medicine will be described.

#### **W 2427 Characterizing and Predicting Modes of Action of Carcinogenicity Based on Conventional and Toxicogenomics Methods.**

M. D. Waters. *Integrated Laboratory Systems, Inc., Research Triangle Park, NC.*

Predictive toxicogenomics uses global molecular expression data resulting from genomic perturbation (e.g., transcript profiles) to predict a toxicological outcome, such as carcinogenicity. In the context of risk assessment, the classification of carcinogens as genotoxic or nongenotoxic has become an essential and debatable issue because of the default assumption that drives regulatory decision-making regarding the presumed linearity of the dose-response curve for genotoxic carcinogens. In fact, the great majority of known human carcinogens are easily detected in conventional short-term tests for genotoxicity and induce tumors at multiple sites in rodents, thus provoking challenges as to the human relevance of nongenotoxic rodent carcinogens. Toxicogenomics studies appear quite useful in resolving this dichotomy and in pursuing mechanisms of action. In toxicogenomics studies, a strong DNA damage response at the gene expression level suggests direct DNA modification whereas increased expression of genes involved in cell cycle progression is more characteristic of the indirect-acting agents such as those that induce oxidative stress. Gene expression profiles have been demonstrated that discriminate nongenotoxic modes of action (e.g., cytotoxicity and regenerative proliferation, xenobiotic receptor agonists, peroxisome proliferator-activated receptors, or hormonal-mediated processes) and other profiles appear to delineate various paths to the formation of conventional cytogenetic alterations. The evidence accumulated to date suggests that toxicogenomics approaches will be useful in conjunction with conventional test methods in the dose and phenotype anchored assessment of chemical carcinogenicity. Case studies will be used to illustrate these points.

#### **W 2428 Case Studies of Dose-Response Genotoxicity and Toxicogenomic Studies Designed to Replace Default Assumptions Used in Carcinogenic Risk Assessments.**

L. Recio. *Integrated Laboratory Systems, Inc., Research Triangle Park, NC.*

Characterizing dose-response is a fundamental aspect of toxicology and can be used to determine and predict the potential adverse effects of chemicals to humans. Only recent genetic toxicology and toxicogenomic studies have adequately characterized dose-response over a range of exposures and have used these data for point-of-departure (POD) calculations needed in risk assessment, such as benchmark dose 10 (BMD10). Genotoxicity and toxicogenomic endpoints can be considered as biomarkers of 'key events' or adaptive responses that with robust experimental designs can provide the needed qualitative and quantitative dose-response information to establish chemical-specific modes-of-action that can be integrated into weight-of-evidence-based approaches for risk assessments. More recently genomic signatures for mode-of-action (MOA) (e.g., genotoxic vs nongenotoxic MOA) in target organs are emerging as mRNA biomarkers of effects. Low dose studies designed to identify exposure levels that do not cause alterations in basal genotoxicity or gene expression can be used to identify exposure levels (or dose) that represent the transition between the NOEL concentrations and other PODs such as BMD. Recent studies conducted at ILS with collaborators, represent case studies aimed at identifying the NOEL concentrations and other PODs using the *in vitro* micronucleus and mutagenicity studies in human cells for acetaldehyde, dose-response and impact of liver GSH detoxication on naphthalene genotoxicity, expression profiling studies to assess genotoxic vs nongenotoxic MOA in human TK6 cells, and an *in vivo* dose-response study conducted with the mouse liver carcinogen furan examining impact on the mouse genome and epigenome.

#### **W 2429 Application of Transcriptomic Data for Quantitative Chemical Risk Assessment.**

R. S. Thomas. *The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

Current challenges facing chemical risk assessment are the time and resources required to meet the data standards necessary for a published assessment and the incorporation of modern molecular biology information. The integration of transcriptomic data into the risk assessment paradigm may address both challenges by providing an efficient means to quantitatively and comprehensively evaluating the molecular changes resulting from chemical exposure. To assess the value of applying transcriptomics in quantitative chemical risk assessment, a series of studies was performed. In the first study, mice were exposed for 13 weeks to multiple concentrations of five chemicals that were positive in a two-year cancer bioassay. In a second study, rats were exposed in a time course to multiple concentrations of six chemicals with published risk assessments. In both studies, histological changes were evaluated and transcriptional microarray analysis was performed on the target tissues.

The histological and the tumor responses were analyzed using standard benchmark dose (BMD) methods to identify noncancer and cancer points-of-departure. The dose-related changes in gene expression were also analyzed using a BMD approach and grouped based on signaling pathways. The transcriptional BMD values showed a high degree of correlation with apical responses for specific pathways and many of the correlated pathways have been implicated in relevant disease pathogenesis. Importantly, transcriptional points-of-departure for even the most sensitive pathway were on average less than three-fold different than traditional apical points-of-departure for both cancer and non-cancer endpoints suggesting that transcriptomic changes in signaling pathways can be used to estimate noncancer and cancer points-of-departure for use in quantitative risk assessments.

## **W** 2430 **Challenges and Opportunities of Toxicogenomics Analyses in Safety Assessment during Preclinical Safety Studies.**

C. Karbowski. *Discovery Toxicology, Amgen, Thousand Oaks, CA.*

Microarray analysis is a key tool utilized in the biotechnology/pharmaceutical industry as part of a holistic approach to predicting and understanding mechanisms of toxicity of molecules in development. Historically, researchers have faced significant challenges in analyzing and interpreting these large datasets such as understanding the translation of molecular changes to phenotypic changes in an organism and the relevance of observed alterations to other species. However, progress in overcoming these challenges continues to be made. For example, contextualization of gene expression changes utilizing historical and publically available reference toxicant datasets coupled with recent advances in Systems Biology such as more comprehensive and toxicologically relevant content along with the incorporation of transcription factor analyses and gene directionality provides opportunities to understand the genesis and cross-species relevance of pre-clinical phenotypic changes. This presentation will provide an historical view of the utility of microarray analysis in preclinical safety assessment and then illustrate, through case examples, the added value provided when current state of the art tools are applied to help dissect molecular changes underlying phenotypic alterations.

## **W** 2431 **Role of Causal Reasoning in Patient Stratification from Efficacy and Safety Perspectives.**

A. Enayattallah. *Drug Safety Research & Development, Pfizer, Inc., Groton, CT.*

Advances in genomic technologies have led to the ability to rapidly generate extraordinary amounts of data. However, a lack of efficient tools to manage and interrogate such large amounts of data has limited the application of genomics in the pharmaceutical industry. Recently, we developed a computational platform we call the Causal Reasoning Engine (CRE) that is a powerful tool for transcriptomic data analysis. The CRE provides explanation of the observed transcriptomic changes in the context of prior biological knowledge, captured in a knowledge base of computable biological assertions. The platform was initially applied to investigative toxicology to provide mechanistic understanding of organ toxicities, including drug-induced liver injury (DILI) and drug-induced cardiac injury. More recent developments of the CRE platform indicate potential predictive power for evaluating compound responses and safety liabilities at the individual patient level, which would enable the stratification of patients in clinical trials. In the context of efficacy we will show a use case for patients with diseases known for their heterogeneity, such as systemic lupus erythematosus and inflammatory bowel disease. In this case individualized analysis using CRE clearly classifies patients based on their underlying disease mechanisms, and we will discuss the potential impact on patient and treatment selection in clinical trials. Finally, the results from the individualized analysis approach in patients with immune-mediated DILI will also be presented. Based on the examples presented here, we believe that the CRE approach shows great promise in being able to stratify patients to support the development of more effective and safer medicines.

## **RI** 2432 **Assessment of Environmental, Dietary, and Biological Risk Factors Impacting Liver Cancer Incidence in Texas.**

E. D. Bruce<sup>1,2</sup> and A. Romoser<sup>3</sup>. <sup>1</sup>*Institute of Biomedical Sciences, Baylor University, Waco, TX;* <sup>2</sup>*Institute of Ecological, Earth, and Environmental Science, Baylor University, Waco, TX;* <sup>3</sup>*Toxicology, Texas A&M University, College Station, TX.*

The increasing incidence of primary liver cancer in Texas is a result of multiple risk factors, including environmental and dietary exposures to carcinogens, as well as biological factors, such as hepatitis C infection. Texas has the highest liver cancer mortality rate in the United States, affecting the Hispanic portion of the population

most acutely. It is speculated that the increased incidence of primary liver cancer observed in these Hispanic communities is due to occupational exposures to pesticides, polycyclic aromatic hydrocarbons (PAHs), and dietary risk factors from contaminated maize. Current research and risk assessment in this field is focused on cancer epidemiology within these populations to determine those risk factors that are most hazardous to the community health of south Texas. Many pesticides used in farming and households are labeled as probable carcinogens and can cause many other negative health effects in people chronically exposed. Research and educational programs in Texas are striving to increase awareness of health effects from exposure and pesticide safety. PAHs are also known hepatic carcinogens, forming DNA adducts within the liver. Health effects observed in Texas from chronic PAH exposure through foods and poor air quality are being assessed. Additionally, mycotoxin occurrence is heightened in the southern portion of the state where drought conditions and excessive heat contribute to fungal growth on staple crops (i.e., maize). Specifically, aflatoxin and fumonisin exposures have been observed in various communities in San Antonio and along the Texas-Mexico border. These mycotoxins are known to both initiate and promote hepatocellular carcinoma. Understanding the risk factors for primary liver cancer in Texas is essential to developing future remediation, prevention, and treatment strategies, as well as identifying and establishing necessary changes in state regulations.

## **RI** 2433 **Liver Cancer Incidence Trends in Texas 1995–2009.**

J. F. Villanacci, C. Bowcock and A. Hackenwerth. *Texas Department of State Health Services, Austin, TX.* Sponsor: E. Bruce.

Liver cancer is the 12th most commonly diagnosed cancer in the US and the 6th most common cause of cancer deaths. Liver cancer incidence has been increasing in both Texas and the US. Although liver cancer only accounts for 1.3% of new cancer cases, it accounts for 2.6% of cancer deaths. Survival rates are poor with a five-year survival of 13 to 15 percent. In 2012, approximately 2,197 Texans are expected to be diagnosed with liver cancer and 1,768 are expected to die from the disease. Liver cancer incidence trends for Texas and the US were determined using data from the Department of State Health Services, Texas Cancer Registry and National Cancer Institute, Surveillance Epidemiology & End Results. For a 15-year period (1995 to 2009) age-adjusted incidence rates were computed by gender and race/ethnicity.

Texans experience higher liver cancer incidence rates than the US and the rates are increasing faster. From 1995 to 2009 Texas rates increased by an average annual rate of 5.7% compared to 3.9% for the US. The 15-year percent changes in incidence for Texas and the US were 126% and 77%, respectively.

In Texas, liver cancer incidence has been increasing in both men and women but faster in men. From 1995 to 2009 age-adjusted rates for men increased by 130%, while rates for women increased by 96%. In both Texas and the US, men of all race/ethnic groups are diagnosed two to four times as often as women. In Texas, Hispanics (any race) and Asian/Pacific Islanders have the highest rates but Blacks had the highest rate of change from 1995 forward with an annual percent increase of almost 7% and a 15-year increase of 141%. Texas Hispanics and Blacks have significantly higher liver cancer incidence rates than US Hispanics and Blacks. Hispanic men living in the 38 South Texas counties have the highest age-adjusted rate (25.7). Hispanic and Black men living in the remaining Texas counties have the next highest rates (19.4 and 19.1). From 1995 to 2005 there has been a downward shift in the age of diagnosis of liver cancer for both men and women of all race/ethnic groups.

## **RI** 2434 **A Lay Health Worker-Based Intervention for Reducing Families' Environmental Exposures.**

L. Cizmas<sup>1</sup>, J. Ross<sup>1</sup>, R. Rincon<sup>2</sup>, H. Tamez<sup>2</sup>, A. Ginez<sup>2</sup>, R. Perales<sup>2</sup>, C. Miller<sup>2</sup> and T. McDonald<sup>1</sup>. <sup>1</sup>*Texas A&M Health Science Center School of Rural Public Health, Texas A&M University, College Station, TX;* <sup>2</sup>*South Texas Environmental Education and Research Program, University of Texas Health Science Center, San Antonio, San Antonio, TX.*

In economically disadvantaged areas of San Antonio and Laredo, TX, poor living conditions and a hot climate increase the likelihood of pest infestations, leading to increased pesticide use. Promotoras (lay health workers) were employed to deliver a pesticide health education module to families with children between 6 months to 5 years of age. Assessments of attitudes and behaviors relating to pesticide use were given prior to and 6 months after module delivery. In Laredo, participants reported statistically significant changes in behavior and attitudes six months after the module. For example, the percent of participants reporting that they always had emergency numbers by the phone was 35% before the training and 86% six months

after the training, and the percentage reporting that they always used gloves when applying pesticides was 35% before the training and 84% six months after the training. Promotora-driven health education with local collaboration may improve family attitudes and practices relating to pesticide use, and may be explored as an option for addressing other environmental exposures as well.

#### **RI 2435 Early Obesity and Risk of Hepatocellular Carcinoma in USA.**

M. Hassan<sup>1</sup>, D. Li<sup>1</sup>, A. Kaseb<sup>1</sup>, J. L. Abbuzzese<sup>1</sup>, H. M. Hassabo<sup>1</sup>, M. Khalil<sup>1</sup>, I. Sahin<sup>1</sup>, J. Morris<sup>1</sup>, E. Hawk<sup>1</sup> and M. R. Spitz<sup>2</sup>. <sup>1</sup>The University of Texas MD Anderson Cancer Center, Houston, TX; <sup>2</sup>Baylor College of Medicine, Houston, TX. Sponsor: E. Bruce.

Despite the public health problem of obesity and increasing incidence of hepatocellular carcinoma (HCC) in the United States (US), the relationship between obesity and HCC has never been examined extensively in US population. At the University of Texas MD Anderson Cancer Center we conducted a case-control study aimed at examining HCC risk factors in the US. Cases were patients with pathologically confirmed diagnosis of HCC and US residency. The healthy control subjects were spouses of patients at MD Anderson who had cancers other than liver, gastrointestinal, lung, or head/neck cancer. Self-reported weight and body size (Stunkard pictograms) at ages 20, 30, 40, 50, 60, 70 was obtained from participants by personal interview. Between 2005 and 2011 we enrolled 403 cases and 661 controls. Body mass index (BMI) was classified as "underweight" (BMI < 18.5), "normal" (BMI range, 18.5-24.9), "overweight" (BMI range, 25-29.9), and "obese" (BMI ≥ 30.0). We found that individuals who were obese from the ages of 30 to 49 had a significant increased risk of HCC, independent of HCC established risk factors. The estimated odds ratio (OR) and 95% confidence interval (CI) was 4.1(1.6-10.5). The association was observed in men and women; the ORs (95% CIs) were 2.3(1.1-4.9) and 2.9(1.2-8.9) respectively. Moreover, individuals who were overweight or obese from the ages of 30 to 49 years had an earlier onset of HCC by 3 to 6 years (median age of onset was 65 years for patients with normal weight, 62 years for overweight patients [P=.02], and 59 years for obese patients (P <.001). Underlying evidence of cirrhosis was significantly observed in HCC patients with early obesity. We concluded that obesity is a significant risk factor for HCC in US where underlying cirrhosis can be a significant burden in disease management. Integration of obesity with other HCC risk factors into a risk model may lead to the development of a new scoring system to identify high-risk individuals who may benefit from HCC screening and prevention.

#### **RI 2436 Biomarkers of Hepatocellular Cancer Risk and Diagnosis.**

R. M. Santella. NIEHS Center for Environmental Health, Columbia University Mailman School of Public Health, New York, NY.

Hepatocellular carcinoma (HCC) incidence is increasing in the US and HCC has one of the fastest growing death rates of any cancer. There is wide geographic variation in HCC incidence around the world likely due to geographic differences in the prevalence of various etiologic factors. In Asia and Africa hepatitis B virus is the primary etiologic agent while in the US, hepatitis C virus is more common. Identified environmental/lifestyle risk factors include aflatoxin B1 (AFB1), a dietary mold contaminant, alcohol drinking, and cigarette smoking. We have used biomarkers in a prospective study in Taiwan to demonstrate that elevated baseline levels of AFB1 urinary metabolites, AFB1-albumin adducts, polycyclic aromatic hydrocarbon (PAH)-albumin adducts and urinary isoprostanes, a biomarker of oxidative stress, are associated with later development of HCC. We have also found AFB1- and PAH-DNA adducts in liver tissues of US HCC cases. Using a candidate gene approach, studies of liver tumor tissues have identified genes that are hypermethylated in tumors compared to adjacent tissues and found that this methylation was associated with elevated levels of AFB1-DNA adducts in the tissues. DNA isolated from plasma collected at the time of diagnosis contains these same methylated markers. More importantly, methylated DNA released from the tumor can be frequently found in plasma collected many years before clinical diagnosis suggesting their potential utility in screening high populations such as those with viral infection. More recently, we have used Illumina Infinium arrays that interrogate methylation of 27k or 450k CpG sites to more comprehensively identify regions with altered DNA methylation. These studies have found large numbers of hyper or hypomethylated regions in tumors compared to adjacent tissues and identified methylation markers that should enhance early diagnosis. Biomarkers of environmental exposure in combination with viral infection markers can identify populations at increased risk while methylation and microRNA markers may potentially be used for the early diagnosis of HCC.

#### **RI 2437 Mitigation of Aflatoxin Exposures Using a Clay-Based Enterosorbent.**

T. D. Phillips. Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.

Concerns about the quality and safety of foods destined for human and animal consumption have evoked a growing awareness of the significant hazards associated with chemicals known as aflatoxins. The aflatoxin problem in foods is longstanding, unavoidable and seemingly inextricable. Aflatoxin exposure is often considered a risk factor for disease in countries where there is a lack of infrastructure for food safety regulation. However, aflatoxin exposure has been observed and is a cause for concern in underprivileged communities in Texas and the Southwest U.S. as well. Aflatoxin B1 (AFB1) is a direct acting mutagen and has been shown to disrupt genes involved in carcinogenesis and tumor suppression. Recent research with mycotoxin enterosorbent, NovaSil (NS), in an African population has shown the product to be safe and efficacious in reducing biomarkers of exposure to aflatoxin. Blood and urine samples were taken at Baseline, 1 Month, 3 Months and 4 Months. NS clay significantly reduced biomarkers for aflatoxin exposure in urine and blood and the treatment was well tolerated by participants. In a recent San Antonio study focusing on a population with a significantly elevated incidence of liver cancer, it was determined that biomarkers for aflatoxin correlated with ingestion of foods known to contain relatively higher levels of aflatoxin. Phase II of this study is underway to determine NS efficacy in reducing exposures to this toxin in Texas. Mitigating AFB1 exposure using NS represents an innovative, practical, sustainable and environmentally benign approach that will benefit more than 4.5 billion people living in climates conducive to the growth of fungi and production of mycotoxins in staple foods.

#### **RI 2438 Risk Factors Influencing the Incidence of Liver Cancer in San Antonio.**

F. A. Guerra. Department of Pediatrics, University of Texas Health Science Center San Antonio, San Antonio, TX. Sponsor: E. Bruce.

The incidence of hepatocellular carcinoma (HCC) is significantly elevated in Hispanic communities in Bexar County, Texas. Multiple factors including diet, environment, occupation, lifestyle, health status, and gender play a role in the etiology of HCC. Previous research with Texas A&M University has focused on defining the risk factors that may influence the high incidence of liver disease observed in San Antonio. Epidemiological and clinical intervention studies are ongoing in Bexar County, and have been successful in raising awareness in the community regarding environmental, dietary, and biological risk factors for disease. Ongoing studies with The University of Texas Health Science Center-San Antonio and Texas A&M University will investigate the impact of an intervention trial designed to decrease biomarkers of mycotoxin exposure and enhance public health in communities at high risk for HCC.

#### **PL 2439 A Novel Single Cell-Based High-Throughput Toxicity Study of Drugs.**

L. Ma, Y. Qiao and M. Su. NanoScience Technology Center, University of Central Florida, Orlando, FL. Sponsor: T. Lam.

Many anticancer drugs are genotoxic. The ability of tumor cells to repair drug induced DNA damage is indicative of therapeutic outcomes. But, tumors are heterogeneous in their ability to repair damaged DNA, and evaluation population response only gives a statistical average. Thus selection of drugs without knowing tumor response at single cell level can cause side effects due to toxicity of drugs. There is a need to screen drugs reliably and rapidly for individual patients. This paper describes a new single cell based HaloChip assay that can be used to detect and quantify DNA damage and repair capacity after exposing to genotoxic drugs, and examine drug response without population interference. After forming cell array, cells are embedded in agarose that provides an interconnected network for DNA diffusion, followed by exposure to NaOH and stained with ethidium bromide. Dimensions of halo and nucleus are derived from collected fluorescent image. In the case of repair, cells are washed after exposing to drug and incubated for different time before HaloChip assay. The level of DNA damage is quantified using relative nuclear diffusion factor (rNDF) derived from surface areas of halo and nucleus. The rNDFs increase from 0 to 6 as drug concentration increase from 0 to 50 μM, and reach plateau when drug concentration is over 10 μM. At same dosage, VP-16 induces more DNA damage in HeLa cells than that of other two drugs; CPT-11 induces more DNA damage in LNCaP cells than that of other two drugs. The bimodal repair curves are attributed to diversity of DNA lesions induced by drugs. The repair data are regressively fitted using first order exponential

equation. Longer repair time significantly reduces rNDF values. CPT-11 shows a slower reduction than the other two drugs for LNCaP cells. The time required to repair 50% DNA damage ( $t_{50}$ ) is derived within 0-24 hr repair time. In summary, HaloChip assay can be used to measure genotoxic drug induced DNA damage and its repair capacity. It is expected that the method will be useful in clinical, epidemiological, and experimental settings.

**PL 2440 New High-Throughput Version of the DEL Assay Detects Nonmutagenic Carcinogens.**

R. H. Schiestl, L. Parfenova, Y. Rivina, V. Kuteпова and D. Nguen. *Pathology; Environmental Health Sciences, Radiation Oncology, University of California Los Angeles, Los Angeles, CA.*

Genetic instability is a hallmark of carcinogenesis. Furthermore, cells from patients carrying mutations conferring cancer prone phenotypes show a higher level of genetic instability, including DNA deletions. In fact, the original yeast-based DEL (deletion) Assay with 100 chemicals shows an accuracy of 92% to detect carcinogens as compared to 62% detected with the Ames Assay. DEL events in all three formats are inducible by a wide variety of carcinogens including carcinogens that are negative in many other short-term tests. The DEL assay results also highly correlate with the clastogenicity of chemicals. Here we introduce the next generation DEL assay: a novel dual-read out *Saccharomyces cerevisiae* screen DEL-XG. DEL-XG simultaneously assesses the compound's genotoxicity and cytotoxicity properties. During an exposure to a genotoxic event the sequence is excised and the lacZ gene recombines to a functional beta-galactosidase genotype that with an addition of the X-Gal substrate produces a strongly positive indole (blue) product. The most important advance is that we can determine the effect of target gene expression on genotoxicity. Surprisingly and most importantly we found that the Ames negative carcinogens that were weakly positive in our standard His reversion assay, are 10 fold more potent in expressed DNA. This makes the new version of the DEL assay even more useful and makes sure that the Ames negative carcinogens will be positive even in the high throughput version. DEL-XG is a rapid and economical way to screen large chemical libraries for toxicity and potential carcinogenicity properties.

**PL 2441 In Vitro Genotoxicity Assays (Comet and Micronucleus) Using Engineered Skin.**

G. Ouedraogo<sup>1</sup>, F. Nessler<sup>2</sup>, S. Simar<sup>2</sup>, S. Talahari<sup>2</sup>, D. Lagache<sup>2</sup>, E. Vercauteren<sup>2</sup>, L. Nakab<sup>2</sup>, A. Mayoux<sup>2</sup>, N. Flamand<sup>1</sup>, G. Massin<sup>2</sup> and J. Cotovio<sup>1</sup>. <sup>1</sup>Predictive Model and Method Development, L'Oréal R&D, Aulnay sous bois, France; <sup>2</sup>Laboratoire de Toxicologie, Institut Pasteur de Lille, Lille, France. Sponsor: E. Dufour.

An in vitro micronucleus assay using human engineered skin and target cells grown beneath the tissues was developed. The purpose was to bring some information on exposure in in vitro genotoxicity assays for dermally applied compounds. Previous results have shown that this method was reproducible and could be transferred to other laboratories. The system has now evolved to combine both the comet assay and the micronucleus assay.

The approach is based on performing the comet assay in cells dissociated from the tissues, while the micronucleus assay was performed using the cells cultured beneath the reconstructed tissues. Four different time schedules were considered for this project: a 4 h treatment and a 27 h treatment period with or without an extra 27 h recovery period.

A set of 13 chemicals were tested with this approach. The results obtained show that the best prediction model was the long treatment period (27 h) without recovery for both the comet assay and the micronucleus assay.

Most of the "irrelevant positives" yielded negative in vitro results using this system.

**PL 2442 Development and Validation of a Toxicogenomics Signature to Differentiate Genotoxins vs Nongenotoxins.**

S. Beedanagari, S. Nicotra and L. Custer. *Bristol-Myers Squibb, East Brunswick, NJ.*

Genotoxicity testing has long been used to assess a compound's potential to induce genetic damage and hence its carcinogenic potential. The standard genotoxicity testing battery was designed to have high sensitivity but low specificity for detecting carcinogens that act by damaging DNA. As a consequence, positive genotoxicity test results require follow-up *in vitro* and/or *in vivo* testing to determine the biological relevance of the *in vitro* genotoxicity potential. Recent literature suggests that

Toxicogenomic approaches could serve as a useful tool to identify different mechanisms through which compounds/ chemicals exerts their genotoxic effects. Although multiple research groups to date have published papers listing several gene expression based molecular signatures *in vitro* using human and rodent cell lines, and *in vivo* using rodent models, there exists no consensus largely due to species differences and diverse "omics" technologies used. The broad objective of this study is to extend the work conducted by the ILSI-HESI technical committee on differentiating genotoxic and non-genotoxic carcinogens using real-time PCR (qPCR) based toxicogenomic approaches. In this study using a human lymphoblast TK6 cell line, we evaluated the utility of a qPCR technique to identify a molecular signature by studying gene expression profiles of twenty five genes. In our initial screening study we identified six genes that differentiated genotoxins vs non-genotoxins. However, in our validation study using ten model compounds per each group of aneugens, clastogens and non-genotoxins, we succeeded in reducing six gene signature to three gene signature. The proposed three genes that could effectively differentiate clastogens and aneugens from non-genotoxins with high specificity and sensitivity are Cyclin-dependent kinase inhibitor 1A (CDKN1A), Growth differentiation factor 15 (GDF15) and Tumor protein p53 inducible protein 3 (TP53I3).

**PL 2443 Characterization of Threshold Dose Response of Genotoxicity from Chemicals with Diverse Mechanisms of Damage.**

B. Sun<sup>1</sup>, S. M. Ross<sup>1</sup>, A. Scott<sup>2</sup>, Y. Adeleye<sup>2</sup>, M. E. Andersen<sup>1</sup> and R. A. Clewell<sup>1</sup>. <sup>1</sup>The Hamner Institute, Durham, NC; <sup>2</sup>SEAC, Unilever PLC, Bedfordshire, United Kingdom.

There is much debate regarding the existence of threshold dose-response for genotoxicity with DNA reactive chemicals. This study used in vitro high content imaging and flow cytometry assays together with Lutz threshold model (Lutz et al, 2009) to identify the threshold of dose-response for induction of double strand breaks (DSBs) and micronuclei (MN) in human p53-competent fibrosarcoma cells (HT1080). We evaluated 9 prototype chemicals: neocarcinostatin (NCS; direct DSB induction, mimics  $\gamma$ -irradiation), etoposide (ETP; topoisomerase II inhibitor), mitomycin C (MMC; DNA crosslinker), methyl methanesulfonate and ethyl nitrosourea (MMS, ENU; alkylating agents), hydrogen peroxide and *tert*-butylhydroquinone ( $H_2O_2$ , TBHQ; oxidative damage), quercetin and curcumin (QUE, CUR; oxidative polyphenols). All the oxidative agents  $H_2O_2$ , TBHQ, QUE and CUR induced a significant threshold response in both DSBs and MN, while the topo II inhibitor (ETP) and DNA crosslinker (MMC) induced non-threshold DSBs and MN response. The two alkylating agents showed different dose response trends: MMS exhibited threshold behavior of MN and DSBs, while ENU did not at the doses examined. Interestingly, NCS, a direct genotoxin and potent inducer of DSBs, induced a linear-like DSB response, but a threshold increase in MN, indicating that the DNA repair response prevents conversion of DSB to MN at low doses. We also assessed p-p53 (ser15) and total p53 induction by these chemicals. The shapes of the p-p53 curves are generally comparable to p-H2AX, demonstrating that dose-response relationship of p53 activation follows similar pattern as DSBs. Our results indicate that dose-response relationship for DNA damage and MN formation may exhibit threshold or non-threshold depending on the chemical. Whole genome transcriptomics and repair enzyme proteins induction are currently being measured to evaluate the role of chemical specific activation/inhibition of DNA repair in the determination of linear vs. nonlinear dose-dependency of genotoxic response.

**PL 2444 Concurrent Evaluation of General, Immune, and Genetic Toxicity Endpoints As Part of an Integrated Testing Strategy Approach.**

L. Sosinski, L. A. Murphy, M. R. Schisler, N. Visconti, R. Sura, M. J. LeBaron and D. R. Boverhof. *The Dow Chemical Company, Midland, MI.*

Integrated testing strategies involve the assessment of multiple endpoints within a single toxicity study and represent an important approach for reducing animal use and streamlining testing. The present study evaluated the ability to combine general, immune, and genetic toxicity endpoints into a single study. Specifically, this study evaluated the impact of sheep red blood cell (SRBC) immunization, as part of the T-cell dependent antibody response (TDAR) assay, on organ weights, RBC micronuclei formation, Comet response, and spleen T-cell immunophenotyping. Groups of female F344/DuCr1 rats were dosed with cyclophosphamide (CP) by i.p. injection for five consecutive days at 0, 1, 3, and 10 mg/kg bw/day. Six rats from each dose group were injected i.v. with SRBCs on the initial day of dosing, as per the TDAR assay, while an additional 6 rats per group did not receive SRBCs. A

sham control group was included to account for animal handling and an additional group was dosed with ethyl methanesulfonate by oral gavage as a positive control for the comet assay. For the TDAR assay, treatment with CP resulted in a dose-dependent decrease in the antibody response with a suppression of greater than 95% at the high dose. Injection with SRBC had no impact on evaluated organ weights. Analysis of micronuclei formation revealed a dose-dependent increase in response to CP treatment, with an induction of greater than 10-fold at the mid and high doses. Injection with SRBC had no impact on the level of micronuclei in control animals and did not alter the dose response to CP. There was no increase in liver DNA damage in response to CP as measured by the comet assay and injection with SRBCs did not alter this endpoint. Similarly, injection with SRBC did not alter the spleen T-cell profile in response to CP. Overall these data provide strong support for the concurrent assessment of general, immune, and genetic toxicology endpoints within a single study as part of an integrated testing strategy approach.

**PL 2445 Evaluation of Repeated Dose Liver Micronucleus Assay in Rats: Summary of Collaborative Study by CSGMT/JEMS-MMS.**

Takayanagi<sup>16</sup>, Y. Ogiwara<sup>17</sup>, A. Maeda<sup>18</sup>, K. Narumi<sup>19</sup>, Y. Wako<sup>1</sup>, T. Morita<sup>20</sup>, H. Kojima<sup>20</sup>, M. Hayashi<sup>20</sup> and M. Honma<sup>20</sup>. <sup>1</sup>Mitsubishi Chemical Medicine, Ibaraki, Japan; <sup>2</sup>Astellas Pharma, Osaka, Japan; <sup>3</sup>Astellas Research Technologies, Osaka, Japan; <sup>4</sup>Asahi Kasei Pharma, Shizuoka, Japan; <sup>5</sup>Biosafety Research Center, Shizuoka, Japan; <sup>6</sup>Food and Drug Safety Center, Kanagawa, Japan; <sup>7</sup>Hokko Chemical Industry, Kanagawa, Japan; <sup>8</sup>Ina Research, Nagano, Japan; <sup>9</sup>Kao Corporation, Tochigi, Japan; <sup>10</sup>Kaken Pharmaceutical, Shizuoka, Japan; <sup>11</sup>Kissei Pharmaceutical, Nagano, Japan; <sup>12</sup>Maruho, Kyoto, Japan; <sup>13</sup>Mitsubishi Tanabe Pharma, Chiba, Japan; <sup>14</sup>Nissan Chemical Industries, Saitama, Japan; <sup>15</sup>Shin Nippon Biomedical Laboratories, Kagoshima, Japan; <sup>16</sup>Suntory Business Expert, Kyoto, Japan; <sup>17</sup>Taisho Pharmaceutical, Saitama, Japan; <sup>18</sup>Tonay Industries, Kanagawa, Japan; <sup>19</sup>Yakult Honsha, Tokyo, Japan; <sup>20</sup>National Institute of Health Sciences, Tokyo, Japan.

The repeated dose liver micronucleus (RDLMN) assay has a potential to detect genotoxic hepatocarcinogens that can be integrated into a general toxicological study. We have conducted a joint research in the Collaborative Study Group for the Micronucleus Test (CSGMT) to investigate the inter-laboratory variability and stable data acquisition in the RDLMN assay, which is supported by 19 Japanese facilities. In order to evaluate the performance of the assay, 28 chemicals including hepatocarcinogens were tested in 14- or 28-day RDLMN assays. As a result, the RDLMN assay detected the 9 chemicals positive out of 10 hepatocarcinogens, which were positive in the *in vitro* study while negative in the established bone-marrow micronucleus test. Also, the RDLMN assay detected the 2 hepatocarcinogens positive, which were positive in the short-term bone-marrow micronucleus test while negative in the 14- and 28-day repeated dose bone-marrow micronucleus tests. Accordingly, the RDLMN assay is not only useful in detecting genotoxic hepatocarcinogens but also appropriate for evaluation using a repeated low-dose regimen, and thus is considered ideal for integration into the general toxicity study.

**PL 2446 Acquisition of *In Vivo* Mutation and Cytogenetic Damage Information to Support Cancer Risk Assessment.**

S. Dertinger<sup>1</sup>, S. Phonethepswath<sup>1</sup>, J. Mereness<sup>1</sup>, S. Avlasevich<sup>1</sup>, D. Torous<sup>1</sup>, J. Bemis<sup>1</sup> and J. T. MacGregor<sup>2</sup>. <sup>1</sup>Litron Laboratories, Rochester, NY; <sup>2</sup>Toxicology Consulting Services, Arnold, MD.

Assessing the mode of action of carcinogenic chemicals is a critical component of cancer risk assessment. The US EPA's Cancer Risk Assessment Guidelines stress the importance of determining whether or not a chemical causes tumors through a direct DNA-reactive mechanism, particularly in respect to the choice of an appropriate quantitative model for the extrapolation of cancer risk to low doses. Weight of evidence (WoE) approaches that rely heavily on data from *in vitro* hazard identification assays are commonly used to address carcinogenic mode of action. *In vivo* data needed to improve the WoE include both concordance analysis of temporal mutation induction and dose-response concordance of mutation with tumor incidence (e.g., Moore *et al.*, Reg Toxicol Pharmacol 51:151-61, 2008). We used flow cytometric methods to acquire such data and thereby to test and extend this hypothesis. For example, male Sprague Dawley rats were treated for 28-consecutive days with the genotoxic carcinogen melphalan at 0, 0.031, 0.094, 0.28 and 0.75 mg/kg/day, which included dose levels corresponding to 0.33x, 1x, and 3x the tumorigenic dose rate 50 (TD50). We assessed two endpoints of genotoxicity *via* low

volume blood draws in order to efficiently obtain temporal data within the tumorigenic dosage range: MN-RET at days 4 and 29, and *Pig-a* gene mutation at days 15, 29, and 56. The earliest time points evaluated showed dose-related increases for both endpoints, long before tumors or pre-neoplastic lesions would be expected. These data illustrate the potential of these blood-based analyses to provide dose-response and temporality information that relates genetic damage to cancer induction. Continuing studies will include additional genotoxic and non-genotoxic carcinogens and non-carcinogens to provide a deeper understanding of the relationships between genetic damage and cancer induction.

**PL 2447 Axonal Degeneration of Chronic Organophosphate Ester-Induced Delayed Neurotoxicity (OPIDN) Has Different Features in Central and Peripheral Levels of the Nervous System.**

B. S. Jortner. Laboratory for Neurotoxicity Studies, Virginia PolyTech Inst State University, Blacksburg, VA.

OPIDN is considered one of the toxicant-induced central-peripheral distal axonopathies. The latter are characterized by degeneration of distal fibers in both the central and peripheral regions of the nervous systems. This has been noted in a rat model of long-term exposure to tri-ortho-tolyl phosphate (TOTP). In the present report we explore a difference in the nature of the axonopathy in the peripheral and central extensions of somatosensory fibers arising from neurons of dorsal root ganglia as seen in the sural nerve and spinal-medullary levels of the gracile fasciculus. As reported earlier (Jortner *et al.*, Toxicol. Pathol. 33:378) young adult male Long-Evans rats were administered 14 TOTP gavage doses at 75, 150 or 300 mg/kg, over a 63-day period. Sacrifice was on days 63 and 90 (after a 27 day recovery period). OPIDN was manifest by TOTP dose-related diminished activity of brain neurotoxic esterase on day 63, and distal gracile fasciculus and peripheral nerve (including sural nerve) myelinated fiber degeneration. In the present report we draw attention to a qualitative difference between lesions of central somatosensory myelinated fibers in the distal levels of the gracile fasciculus and those in peripherally directed sural nerve fibers. Axonopathy progressing to myelinated fiber degeneration was seen in both regions, and was more florid in the gracile tract. In addition, prominent dystrophic axons (Jellinger, Progr. Neuropathol. 1973) were seen in the central region, and were absent peripherally. Axon dystrophy is considered to reflect terminal degeneration with retrograde progression, possibly due to aberrant regeneration, synaptic dysplasia, failing terminal catabolism or transport. This varying pathological response of myelinated fibers from the same neuronal population is considered an effect of the differing (central vs. peripheral nervous system) environments on the evolution of axonal lesions in this chronic neurotoxic condition. Supported by USAMRMC DAMD17-99-1-9489.

**PL 2448 Maternal Paraoxonase (PON1) Status Modulates Fetal Effects Associated with Gestational Exposure of Mice to Chlorpyrifos Oxon.**

T. B. Cole<sup>1</sup>, W. Li<sup>1</sup>, A. Co<sup>1</sup>, J. Marsillach<sup>1</sup>, A. Hay<sup>1</sup>, R. Richter<sup>1</sup>, M. J. MacCoss<sup>1</sup>, L. G. Costa<sup>1,2</sup> and C. E. Furlong<sup>1</sup>. <sup>1</sup>Departments of Medicine, Environmental and Occupational Health Sciences, Genome Sciences, and Center on Human Development and Disability, University of Washington, Seattle, WA; <sup>2</sup>Department of Neuroscience, University of Parma, Parma, Italy.

Paraoxonase-1 (PON1) status (PON1 level and presence of the Q192R polymorphism) is an important determinant of toxicity for chlorpyrifos (CPF) and its metabolite, CPF-oxon (CPO). We examined whether maternal PON1 status influences fetal toxicity associated with gestational CPO exposure by comparing CPO toxicity among PON1<sup>-/-</sup>, wild type (WT), and humanized transgenic mice expressing tgHuPON1R192 or tgHuPON1Q192. Pregnant mice were exposed dermally to 0, 0.50, 0.75 or 0.85 mg/kg/d CPO from gestational days 6-17, and sacrificed on day 18 to measure enzyme inhibition in maternal and fetal tissues and gene expression in the GD18 fetal brain using Affymetrix microarrays. Fetal body weights from the PON1<sup>-/-</sup> dams exposed to 0.75 mg/kg/d CPO were significantly lower compared to vehicle controls. Pregnancy rate, number of resorptions and presence of fetal abnormalities were not significantly different among treatment groups in all genotypes. In the dams, repeated CPO exposure was associated with inhibition of RBC acylpeptide hydrolase (APH), plasma carboxylesterase (CES), plasma butyrylcholinesterase (BChE), and brain acetylcholinesterase (AChE). Maternal tgHuPON1 had protective effects on inhibition of fetal brain AChE and plasma CES, which were both inhibited only in PON1<sup>-/-</sup> fetuses. In fetal plasma, BChE was inhibited in PON1<sup>-/-</sup> and tgHuPON1Q192, but not WT or

tgHuPON1R192 mice, supporting the hypothesis that the R allele is more protective. The relatively high sensitivity of BChE to CPO inhibition is relevant for human exposures. Using a mass spectrometric (MS)-based approach to identify OP-adducted active-site serines in plasma BChE, we identified a monoethyl phosphoserine aged adduct in the plasma of exposed agricultural workers that is consistent with CPF exposure. Supported by NIEHS ES04696, ES09883, ES07033, ES09601/EPA-R826886.

**PL 2449 Comparative Effects of Parathion and Chlorpyrifos on Extracellular Endocannabinoids: Influence on Cholinergic Toxicity.**

C. Pope<sup>1</sup>, L. Parsons<sup>2</sup> and J. Liu<sup>1</sup>. <sup>1</sup>Physiological Sciences, Oklahoma State University, Stillwater, OK; <sup>2</sup>Committee on the Neurobiology of Addictive Disorders, Scripps Research Institute, La Jolla, CA.

Parathion (PS) and chlorpyrifos (CPF) are organophosphorus insecticides (OPs). Acute subcutaneous exposure to either can elicit extensive acetylcholinesterase inhibition but cholinergic signs are relatively minimal following CPF compared to PS. Endocannabinoids (eCBs, e.g., anandamide [AEA] and 2-arachidonoyl glycerol [2-AG]) inhibit neurotransmitter release via presynaptic cannabinoid CB1 receptors. Paraoxon and chlorpyrifos oxon, active metabolites of PS and CPF, can block CB1 receptor binding and inhibit eCB-degrading enzymes. We hypothesized that differential effects on eCB signaling play a role in selective toxicity. Male rats were treated with vehicle, PS (27 mg/kg, sc) or CPF (280 mg/kg, sc) and toxicity evaluated 2 and 4 d later, just prior to insertion of hippocampal microdialysis probes and dialysate collection. eCBs were evaluated by LC-MS/MS. PS-treated rats showed extensive toxicity while CPF elicited few signs. AEA levels were elevated 2 and 4 d following either CPF ( $\approx$  4-fold) or PS (2-3 fold), while 2-AG levels were unaffected. If eCB-mediated inhibition of neurotransmitter release influences OP toxicity, blockade of CB1 receptors should alter functional responses. The CB1 antagonist AM251 (3 mg/kg, ip, 1 or 3 daily doses) had no effect on CPF toxicity. In contrast, a single dose of AM251 reduced PS-induced signs, and 3 daily doses further reduced toxicity. Although both CPF and PS can increase extracellular AEA levels, eCB signaling only appears to influence the expression of PS toxicity. This interpretation assumes an essential role for the CB1 receptor, whereas a number of recent studies suggest non-classical cannabinoid receptors mediate some eCB actions. CPF may potentially influence eCB signaling through a CB1-independent pathway. Together, these results suggest that targeting the eCB signaling pathway may have selective actions in the treatment of acute poisoning by different organophosphorus toxicants. (Supported by NIEHS R01 ES009119)

**PL 2450 Developmental Exposure to Chlorpyrifos Increases Accumulation of the Endocannabinoid Anandamide in the Brain in the Absence of Cholinesterase Inhibition.**

R. L. Carr, C. A. Nail, L. C. Mangum and M. K. Ross. Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.

Traditionally, chlorpyrifos (CPS) mediates its toxicity through inhibition of cholinesterase (ChE). However, in recent years, the toxicological effects of developmental CPS exposure have been attributed to an unknown non-cholinergic mechanism of action. We hypothesize that the endocannabinoid system may be an important target because of its vital role in nervous system development. We have previously reported that repeated exposure to CPS results in greater inhibition of the fatty acid amide hydrolase (FAAH), the enzyme that metabolizes the endocannabinoid anandamide (AEA), than inhibition of either ChE or monoacylglycerol lipase (MAGL), the enzyme that metabolizes the endocannabinoid 2-arachidonoylglycerol (2-AG). This exposure resulted in the accumulation of AEA in the forebrain of juvenile rats, but even at the lowest dosage level used (1.0 mg/kg) ChE inhibition was still present. Thus, it was not clear if FAAH activity will be inhibited as dosage levels that do not inhibit ChE. To determine this, 10 day old rat pups were exposed daily for 7 days to either corn oil or 0.5 mg/kg CPS by oral gavage. At 12 hrs post-exposure, the activities of ChE, MAGL, and FAAH were determined in the forebrain, as well as the levels of the endocannabinoids AEA and 2-AG. There was no significant inhibition of the activities of ChE or MAGL and no significant change in the amount of 2-AG. In contrast, FAAH activity was significantly inhibited resulting in a marked accumulation of AEA in the forebrain. Although it has not been determined whether this alteration of endocannabinoid signaling can impact brain maturation, it does suggest a potential candidate for the non-cholinergic mechanism of action of CPS.

**PL 2451 Prenatal Dexamethasone Augments Neurobehavioral Teratology of Chlorpyrifos.**

E. D. Levin, M. Cauley, J. E. Johnson, H. Sexton, K. Gordon, F. J. Seidler and T. A. Slotkin. Psychiatry, Duke University Medical Center, Durham, NC.

Interactive effects of environmental toxicants and therapeutic drugs have received little attention despite the fact that there is often simultaneous or sequential exposure to these compounds. We evaluated whether dexamethasone, which is widely used in preterm labor, augments the subsequent developmental neurotoxicity of the organophosphate insecticide, chlorpyrifos. Pregnant rats were administered dexamethasone on gestational days 17-19 at a dose (0.2 mg/kg) mimicking that used in preterm labor; after birth the pups were given 1 mg/kg chlorpyrifos on postnatal days 1-4, a regimen just above the threshold for barely-detectable cholinesterase inhibition. Dexamethasone and chlorpyrifos each caused significant locomotor hyperactivity in the figure-8 apparatus in male but not female offspring, assessed during adolescence at 5 weeks of age. However, the group that received the combined exposure showed greater hyperactivity than with either agent alone. In controls, females showed greater activity than males, and consequently, the elevation in males with the combined exposure abolished the normal sex difference in locomotor activity. Both dexamethasone and the combined treatment reduced habituation to approximately the same degree. The combined exposure also had a greater effect on novelty-suppressed feeding behavior, pointing to a greater level of anxiety. Our results indicate that prenatal exposure to glucocorticoids used in preterm labor could create a subpopulation with enhanced vulnerability to developmental neurotoxins. (Support: USPHS ES010356)

**PL 2452 Oxidative Stress: A Mechanism-Based Biomarker of Organophosphorus Pesticide (OP)-Induced Neurotoxicity?**

S. N. Levoe<sup>1</sup>, D. Bruun<sup>1</sup>, S. Y. Gyu<sup>1</sup>, E. Napoli<sup>1</sup>, D. Milatovic<sup>2</sup>, C. Giulivi<sup>1</sup>, M. Aschner<sup>2</sup>, K. M. Lattal<sup>3</sup> and P. J. Lein<sup>1</sup>. <sup>1</sup>Molecular Biosciences, University of California Davis, Davis, CA; <sup>2</sup>Pediatric Toxicology, Vanderbilt University, Nashville, TN; <sup>3</sup>Behavioral Neuroscience, Oregon Health & Science University, Portland, OR.

OPs are widely used in agriculture and industry, and their prevalence has prompted concern for public and worker safety. However, predicting individuals at risk is challenging because standard biomarkers of exposure (cholinesterase inhibition and urinary metabolites) do not correlate well with neurotoxicity following chronic low-level OP exposures. This may reflect the fact that mechanisms by which such exposures cause neurotoxicity are independent of or in addition to cholinesterase inhibition. We are testing the hypothesis that oxidative stress contributes to learning and memory deficits reported in individuals exposed occupationally to OPs. To test this hypothesis, we are determining whether biomarkers of oxidative stress correlate with learning and memory deficits caused by chronic exposure to the OP chlorpyrifos (CPF) and whether treatment with antioxidants protects against chronic CPF neurotoxicity. We are using a rat model based on exposure data collected from 255 Egyptian agricultural workers responsible for applying CPF to cotton fields. Our preliminary data indicate that exposure to CPF (10 mg/kg/d, s.c.) for 21 d causes deficits in performance in contextual fear conditioning. This exposure paradigm also causes decreased mitochondrial ATPase activity and increased expression of PGE2 in the brain of CPF animals that precede the onset of behavioral deficits. Preliminary studies also suggest that administration of the antioxidant 2-acetylcylopentanone (2-ACP) attenuated oxidative stress; ongoing studies are investigating whether 2-ACP protects against the behavioral deficits caused by chronic CPF exposure. If successful, these studies will not only identify a novel biomarker of effect for chronic OP neurotoxicity but also suggest novel approaches for protecting workers occupationally exposed to OPs. Supported by NIH R01 ES016308.

**PL 2453 Interactions between Paraoxon and Polyhydroxyfullerenes Chemically Defined.**

G. Magnin-Bissel<sup>1</sup>, Z. Zhou<sup>2</sup> and M. Ehrlich<sup>1</sup>. <sup>1</sup>Virginia Tech, Blacksburg, VA; <sup>2</sup>Luna Nano Works, Danville, VA.

Polyhydroxyfullerenes decrease organophosphate (OP)-induced inhibition of acetylcholinesterase (AChE) in vitro and moderate OP toxicity in vivo (Toxicol in Vitro 25, 301, 2011; SOT abstract 2576, 2011; SOT abstract 942, 2012). Mechanisms contributing to the interaction of OP compounds such as paraoxon (PON) and fullerenes were evaluated. Formation of a covalent bond was ruled out by monitoring the release of p-nitrophenol and the decrease in concentration of PON by HPLC. Nuclear Magnetic Resonance (NMR) was used because hydroxylated fullerenes are known to make aggregates in aqueous media and PON could be trapped in these aggregates by non-covalent bonding resulting in host-guest interactions. Complexation of PON with two hydroxylated fullerenes was examined

after 15 min incubation with the C80 derivative containing gadolinium (GdTMSOH) and a C70 derivative (C70-OH) without any metal. Proton-decoupled phosphorus (31P) NMR spectra were recorded on a Bruker Advance III 600 NMR instrument. The experiments with PON and the fullerenes were run in deuterium oxide with phosphoric acid 0.04% as an internal reference. Results for GdTMSOH demonstrated a small upfield change in the chemical shift as the concentration of fullerene increased. However, due to strong interferences from the metal, further studies were done with the C70-OH fullerene. Plotting the variation its chemical shift versus the concentration of fullerene resulted in a binding isotherm curve that reached a plateau at 0.03 mole/l. The binding constant (Kb) calculated by dividing the intercept by the slope from the double reciprocal plot was determined to be 19 (mole/l)<sup>-1</sup>. The results suggest that the fullerenes act in a manner much like cyclodextrins, which have previously been shown to chemically interact with OP compounds, decreasing their capability to inhibit AChE (Carbohydrate Res. 345, 141, 2010; Euro J Med Chem. 40, 615, 2005; Toxicology 265, 96, 2010). Supported by the CounterACT Program, NIH OD and NINDS, grant NS063723.

## PL 2454 Conditional Toxicity Value (CTV) Predictor for Generating Toxicity Values for Data Sparse Chemicals.

J. Wignall<sup>1</sup>, E. Muratov<sup>1</sup>, D. Fourches<sup>1</sup>, A. Tropsha<sup>1</sup>, T. J. Woodruff<sup>2</sup>, L. Zeise<sup>3</sup>, N. Wang<sup>4</sup>, D. Reif<sup>5</sup>, V. Coglian<sup>4</sup>, W. A. Chiu<sup>4</sup>, K. Guyton<sup>4</sup> and I. Rusyn<sup>1</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>University of California San Francisco, San Francisco, CA; <sup>3</sup>California EPA, Oakland, CA; <sup>4</sup>National Center for Environmental Assessment, US EPA, Washington DC; <sup>5</sup>National Center for Computational Toxicology, US EPA, Durham, NC.

Chemical hazard assessments necessarily vary based on data availability and the type of risk management decision they support. While much recent attention has been on use of high-throughput toxicological data for screening and prioritization, assessments that support toxicity guidance values or standards still rely on epidemiological and in vivo experimental data. Such assessments, including Integrated Science Assessments and Integrated Risk Information System Toxicological Reviews, are highly data-, time-, and resource-intensive, and cannot be realistically expected for most environmental chemicals. Thus various stakeholders and expert groups, including the National Research Council in Science and Decisions, call for "default approaches to support risk estimation for chemicals lacking chemical-specific information." This project aims to address this challenge through the Conditional Toxicity Value (CTV) Predictor. This tool uses chemical properties and limited experimental data to predict toxicity values, such as the reference dose (RfD) and concentration (RfC), oral slope factor (OSF), inhalation unit risk (IUR), or cancer potency value (CPV). CTV predictions combine QSAR, regression, and hybrid modeling, rely on a new comprehensive database of existing guidance values and experimental data, and incorporate OECD principles for model building and external cross-validation. QSAR models for predicting existing RfD values (which span 7 orders of magnitude) had an R<sup>2</sup> up to 0.46±0.07 and Mean Absolute Error of 0.67±0.03 (Log10 mg/kg/day). A tool that can predict a toxicity value within an order of magnitude fills a critical gap in the current risk assessment /risk management paradigm.

## PL 2455 Application of the Threshold of Toxicological Concern (TTC) Decision Support Approach to Antimicrobial Pesticides.

R. Canady<sup>2</sup>, T. McMahon<sup>1</sup>, M. Cheeseman<sup>7</sup>, C. Yang<sup>5</sup>, S. Felter<sup>6</sup>, A. Boobis<sup>4</sup>, M. Martin<sup>3</sup>, V. Dellarco<sup>1</sup>, P. Price<sup>8</sup>, M. Lauferweiler<sup>6</sup> and K. Jacobs<sup>9</sup>. <sup>1</sup>US EPA, Washington DC; <sup>2</sup>ILSI RF, Washington DC; <sup>3</sup>US EPA, Research Triangle Park, NC; <sup>4</sup>Imperial College London, London, United Kingdom; <sup>5</sup>Altamira llc, Columbus, OH; <sup>6</sup>Procter & Gamble Company, Cincinnati, OH; <sup>7</sup>Stephoe and Johnson, Washington DC; <sup>8</sup>Dow Chemical Company, Midland, MI; <sup>9</sup>CFSAN, US FDA, College Park, MD.

A tiered decision support approach has been developed to apply existing knowledge of antimicrobial pesticides (AMs) to new AMs being considered for use. The approach is intended to inform product development and regulatory review processes so that antimicrobial pesticides and pesticide products can be targeted early in development and so that animal testing can be focused on those chemicals that need the most attention. Expert groups were convened comprised of scientists from non-government organizations, industry, academia, and government. The experts have 1) collected high quality data from studies submitted to EPA's Office of Chemical Safety and Pollution Prevention and the U.S. Food and Drug

Administration's regulatory review files and entered the data into a publicly accessible data set using the structure and approach of EPA's ToxRef Database; 2) developed a tiered decision framework for estimating systemic dose from dermal exposures so that comparisons could be made to the oral toxicity data available; 3) applied chemoinformatics techniques to evaluate whether and how to bridge the AM data set to the 3 non-cancer TTC values of Munro et al (1996); 4) also used chemoinformatics techniques to define classes of AMs within a TTC decision framework, and 5) developed a decision tree to guide consideration of new AMs with respect to likely toxicity for anticipated systemic dose of a given formulation and the chemoinformatics class into which it falls. We will present the method for data curation, chemoinformatics, rationale for the decision approach, and case examples of the use of the approach. This work will advance the science and practical use of computational toxicology in support of risk management decision making.

## PL 2456 The Navigation Guide As an Evidence-Based Medicine Methodology to Evaluate Human Health Effects of Environmental Chemicals: Perfluorooctanoic Acid (PFOA) and Fetal Growth.

E. Koustas<sup>1</sup>, J. Lam<sup>1</sup>, P. Sutton<sup>2</sup>, P. Johnson<sup>2</sup>, D. Atchley<sup>2</sup>, S. Sen<sup>3</sup>, K. Robinson<sup>4</sup>, D. Axelrad<sup>1</sup> and T. J. Woodruff<sup>2</sup>. <sup>1</sup>Office of Policy, US EPA, Washington DC; <sup>2</sup>Program on Reproductive Health and the Environment, University of California San Francisco, Oakland, CA; <sup>3</sup>Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA; <sup>4</sup>Medicine, Epidemiology, and Health Policy & Management, Johns Hopkins University, Baltimore, MD.

Rationale: Evaluating environmental health literature and determining the weight of evidence are critical for informing policy and health recommendations. The National Academy of Sciences has called for an enhanced systematic and transparent approach to risk assessment and scientific decision-making. The Navigation Guide was developed through a collaboration of 22 scientists to improve methods of research synthesis in environmental health. The methodology is based on best practices in evidence-based medicine and environmental health sciences and aims to systematically and transparently synthesize the evidence from toxicology and observational epidemiology studies.

Approach: To establish proof of concept, we applied the Navigation Guide to the question of the impact of exposure to perfluorooctanoic acid (PFOA) on fetal growth. Steps include: (1) Specify the study question; (2) Select the evidence; (3) Rate the quality and strength of the evidence.

Findings: We identified 24 human observational and 21 animal toxicological studies relevant to the study question. Study quality was assessed using a modified version of the Cochrane Collaboration's Risk of Bias tool. Preliminary meta-analysis of combinable studies suggests there may be small reductions in birth weight with increased PFOA exposure in animals and humans.

Implication: The case study illustrates that the Navigation Guide can be used to apply the rigor of systematic review methodology to questions in environmental health. As has been demonstrated in the clinical field, the adoption of a systematic and transparent method to synthesize the scientific evidence in the environmental health field would speed incorporation of research into decision-making.

## PL 2457 Incorporating Population Variability and Susceptible Subpopulations into Dosimetry for High-Throughput Toxicity Testing.

B. A. Wetmore<sup>1</sup>, J. F. Wambaugh<sup>2</sup>, H. J. Clewell<sup>1</sup> and R. S. Thomas<sup>1</sup>. <sup>1</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

Xenobiotic clearance can vary widely across age-based or ethnic subpopulations due to differences in metabolic enzyme abundances and activities. A strategy to measure population-specific hepatic clearance values across a wide range of chemicals would allow pharmacokinetic variability due to age, ethnicity, and other factors to be incorporated into in vitro toxicity screening data. Metabolic clearance of ToxCast chemicals selected based on LC-MS method compatibility and exposure estimate availability were measured in vitro using 13 cytochrome P450 (CYP) and 5 UDP-glucuronosyltransferase (UGT) recombinantly expressed isoforms. Together with plasma protein binding, these isoform-specific clearance rates were then incorporated into an in vitro-to-in vivo extrapolation (IVIVE) modeling tool, Simcyp. The modeling tool accounts for known differences in isoform abundances among various age- or ethnic-based subpopulations to estimate the daily oral dose for each subpopulation, called the oral equivalent dose, necessary to produce steady-state in vivo blood concentrations equivalent to in vitro AC50 values across the ~600

ToxCast endpoints. CYPs 3A4, 3A5, 2C9, and 2C19 were the most active enzymes, contributing to the clearance of all of the chemicals tested. The subpopulation-specific oral equivalent dose values spanned ranges of 1.2 to 6.7-fold for the chemicals assessed. For most chemicals, the oral equivalent dose values for pediatric subpopulations fell closer to the estimated exposures than those derived for an adult population. Generation of these age-specific oral equivalents also affords direct comparison to age-specific exposure estimates in USEPA regulatory documents. This study demonstrates the feasibility and value of using isozyme-specific clearance data to tailor dosimetric values for a wide range of subpopulations. This abstract does not necessarily reflect EPA policy.

**PL 2458 Extrapolating *In Vitro* Embryotoxicity Data Toward *In Vivo* Exposure Levels Using a Combined *In Vitro*-Physiologically-Based Kinetic Modeling Approach.**

M. Strikwold<sup>1,2</sup>, R. Woutersen<sup>1,3</sup>, B. Spenkelink<sup>1</sup>, I. Rietjens<sup>1</sup> and A. Punt<sup>1</sup>.  
<sup>1</sup>Division of Toxicology, Wageningen University, Wageningen, Netherlands; <sup>2</sup>Van Hall Larenstein, University of Applied Sciences, Leeuwarden, Netherlands; <sup>3</sup>TNO Innovation for Life, Zeist, Netherlands.

*In vitro* assays play an important role in screening chemicals for their toxic potency and prioritizing them for further toxicity testing. Most of these *in vitro* assays are not suitable for a quantitative risk characterization as they lack *in vivo* kinetic processes. To overcome this limitation, the present research aimed at combining *in vitro* toxicity data with physiological based kinetic (PBK) modeling to predict *in vivo* exposure levels. In order to contribute to the 3Rs principle for the replacement, reduction and refinement of animal testing in the most optimal way the required PBK models were developed on the basis of only *in vitro* and *in silico* data and data available from literature. Phenol was selected as the model compound and the endpoint of interest concerns embryotoxicity. At first, the embryotoxicity of phenol was evaluated *in vitro* using the embryonic stem cell test (EST), revealing a concentration dependent inhibition of differentiation into beating cardiomyocytes. In a second step, PBK models were developed for rat and human using *in vitro* derived kinetic constants, *in silico* derived physico-chemical parameters and literature derived physiological data. After evaluating the performance of the PBK models, the *in vitro* concentration-response information from the EST served as an input in the PBK model, thereby generating an *in vivo* dose-response curve from which a Point of Departure for risk assessment could be derived. Finally, *in vivo* embryotoxic effect levels available from literature were used to evaluate this combined *in vitro*-PBK approach. In summary, this study shows how combining different alternatives to animal testing like *in vitro* toxicity testing and PBK modeling will enlarge their application from screening and prioritizing of chemicals toward deriving safe exposure levels for the risk assessment of chemicals.

**PL 2459 A Genomics-Based Determination of Relative Potencies of Dioxin-Like Compounds in Primary Human Hepatocytes.**

J. Rowlands<sup>1</sup>, R. Budinsky<sup>1</sup>, M. B. Black<sup>2</sup>, R. D. Wolfinger<sup>3</sup>, D. Cukovic<sup>4</sup>, S. Salagrama<sup>4</sup>, A. Dombkowski<sup>4</sup> and R. S. Thomas<sup>2</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>SAS Institute Inc., Cary, NC; <sup>4</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.

Toxic equivalency factors (TEFs) for dioxin-like compounds are predominantly derived from relative potency (REP) determinations of endpoints such as enzyme activity from animal studies and *in vitro* studies in immortalized animal cells. Currently, REPs based on gene expression changes have not been considered when deriving TEF values. Moreover, data from humans and human cells are not included in the REP database for deriving TEF values. In this study, primary human hepatocytes were treated for 24 hours with 11 concentrations of 2,3,7,8-tetrachlorodibenzo-p-dioxin, 2,3,4,7,8-pentachlorodibenzofuran, or 2,3,7,8-tetrachlorodibenzofuran ranging from 0.00001-100 nM. Gene expression changes were analyzed using ANOVA to assess the relative contributions of concentration, congener, and the interaction between concentration and congener. A total of 1,443 genes showed significant changes with concentration (FDR < 0.05 and fold-change + 1.5 in at least one concentration for one congener). Of these, 399 were significant for both concentration and congener effects indicating parallel concentration response curves with differences in potency. Pathway enrichment analysis was performed on the 1,443 genes differentially expressed by concentration. The top 10 most enriched pathways included several nuclear receptors, immune response, and cell adhesion pathways. A focused assessment of the benchmark dose values for signaling pathways in the modes of action for DLC-induced effects can be used to determine more relevant REPs used by the World Health Organization (WHO) to

derive TEF values. The addition of human cells to the WHO database could provide meaningful measures of relative potency and provide quantitative data to reduce TEF uncertainty in human health risk assessments.

**PL 2460 Aryl Hydrocarbon Receptor Mode-of-Action and Human Relevance Framework for XDE-729 Methyl-Induced Rodent Liver Effects.**

D. L. Eisenbrandt<sup>2</sup>, L. A. Murphy<sup>1</sup>, N. J. Stagg<sup>2</sup>, M. J. LeBaron<sup>1</sup>, V. A. Marshall<sup>1</sup>, A. T. McCoy<sup>1</sup>, L. Kan<sup>1</sup>, D. R. Boverhof<sup>1</sup>, M. Bartels<sup>1</sup>, R. Billington<sup>2</sup> and R. J. Rasoulpour<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences LLC, Indianapolis, IN.

XDE-729 methyl, a novel herbicide in development, induces rodent liver enlargement, hypertrophy, and hyperplasia via an aryl hydrocarbon receptor (AhR) mediated mode-of-action (MoA) with the following key events: 1) presystemic liver exposure to XDE-729 methyl, 2) AhR activation with associated liver hypertrophy, leading to 3) hepatocellular proliferation. For key event 1, low levels of XDE-729 methyl are present in the liver after dietary exposure; however, XDE-729 methyl is rapidly metabolized in the liver to primarily XDE-729 acid, which is not an AhR activator, and excreted in the urine. For key event 2, AhR activation, measured by Cyp1a1 transcript induction occurred at dose levels of  $\geq 50$  mg/kg/day XDE-729 methyl and correlated with liver hypertrophy. For key event 3, hepatocellular proliferation was observed with exposure to 261 mg/kg/day XDE-729 methyl. A threshold for AhR activation and liver effects occurs at 10 mg/kg/day XDE-729 methyl, the no-observed-adverse-effect level (NOAEL) from the rat 90-day toxicity study. Collectively, the data provides a high level of confidence that XDE-729 methyl induces rodent liver effects through an AhR-mediated MoA at doses  $\geq 10$  mg/kg/day XDE-729 methyl. The AhR pathway is conserved across species and prototypical AhR ligands are activators of both human and rodent AhR; however, human AhR binding affinity for prototypical AhR ligands is quantitatively lower than rodent AhR. XDE-729 methyl is rapidly metabolized to XDE-729 acid, which does not activate AhR, and does not bioaccumulate in the rat liver. XDE-729 methyl exposure does not result in sustained activation of the AhR pathway and hepatic effects are transient and reversible. Based on the above, a margin of exposure risk assessment using the 10 mg/kg/day NOAEL from the rat 90-day toxicity study to derive the chronic reference dose/acceptable daily intake (cRfD/ADI) for XDE-729 methyl is protective of human health.

**PL 2461 Estimation of Cumulative Risk from Exposure to Phthalates Using NHANES Exposure Data and an *In Vitro* Potency Assay.**

P. Balbuena, J. Campbell, H. J. Clewell and R. A. Clewell. The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Endocrine active phthalates reduce testosterone synthesis in fetal rat testes, interfering with male sexual development at high doses. As they share the same mode of action, it is logical that a phthalate risk assessment should account for cumulative exposure. Lack of potency data *in vivo* limits the derivation of a cumulative risk estimate. We illustrate an approach using *in vitro* pharmacodynamic data together with NHANES exposure estimates to predict human risk from multiple phthalates. First, we developed a rat Leydig tumor cell line (R2C) *in vitro* assay to assess testosterone inhibition with several environmentally relevant phthalate metabolites: monobutyl (MBP), monoethylhexyl (MEHP), monoethyl (MEP), monomethyl (MMP), monoethyl (MOP), monobenzyl phthalate (MBzP) and two oxidative metabolites of MEHP (5-Ox-MEHP, 5-OH-MEHP). Effects of these chemicals on steroidogenesis *in vitro* were highly consistent with *in vivo* studies. *In vitro* IC50 values were used to derive relative potency factors (RPFs) in relation to MBP. These RPFs were used with the 2005 NHANES urine data to calculate relative risk estimates for each phthalate at the 50th or 95th percentile (exposure). Estimates for individual phthalates were then combined to obtain a dibutyl phthalate (DBP) equivalent risk estimate (mg DBP/kg/day). This *in vitro* predicted cumulative risk estimate was then compared to the USEPA *in vivo* derived reference dose (RfD) for DBP. At the 50th percentile DBP accounted for 8% of total exposure but represented 70% of the total risk of all phthalates. At the 95th percentile, the other phthalates contributed more to the cumulative risk. Cumulative potency weighted exposure for all phthalates was markedly lower than the USEPA RfD for DBP (0.1 mg/Kg BW/day), whether calculated for exposure at the 50th (0.0007 mg/kg/day) or 95th (0.004 mg/kg/day). Margin of exposure was 148.5 and 27.4 for the 50th and 95th percentile respectively. The analyses indicate the risk from exposure to phthalates is below current RfDs, even considering multiple phthalates.

## **R** 2462 Nonhuman Primate Sexual Maturity: What Is the Capacity to Endure Uncertainty?

D. Blanset<sup>1</sup>, D. M. Creasy<sup>2</sup>, G. F. Weinbauer<sup>3</sup>, J. L. Bussiere<sup>4</sup>, K. P. Hatfield<sup>5</sup> and J. S. Moffitt<sup>1</sup>. <sup>1</sup>Nonclinical Drug Safety US, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; <sup>2</sup>Huntingdon Life Sciences, East Millstone, NJ; <sup>3</sup>Covance Inc, Muenster, Germany; <sup>4</sup>Amgen Inc, Thousand Oaks, CA; <sup>5</sup>US FDA-CDER, Silver Spring, MD.

Evaluation of reproductive toxicity in regulatory studies relies on the use of sexually mature animals. This often involves the use of nonhuman primates (NHP) when lower order species are pharmacologically irrelevant. However, the decision on whether to utilize mature NHP and the criteria used to establish sexual maturity is anything but standardized. Several factors contribute to these differing opinions. Sexual maturity can occur over a wide range of ages and body weights and historical methods of predicting sexual maturity have not always correlated with the histopathological appearance of the gonads at necropsy. Evaluation of toxicity in the reproductive organs of pre/peripubertal animals is often difficult, given that the histology of the maturing reproductive organs may resemble the degenerative changes induced by reproductive toxicants in the sexually mature adult. Finally, there is a lack of consensus on the toxicological relevance and interpretation of the various possible reproductive endpoints. All of these factors result in a complicated balancing act: Ethically weighing the limited availability, high costs, and relevance of incorporating sexually mature NHP in toxicology studies against effective and meaningful evaluation of reproductive risks. This roundtable will discuss the challenges of assessing toxicity in immature vs. peripubertal vs. mature NHP, screening methods for identifying sexually mature NHP, factors that influence sexual maturity, and case studies where sexual maturity impacted the study interpretation. Overall, this session seeks to provide an opportunity for stakeholders to review the current state of the art and exchange views on appropriate paths forward to encourage ethical use of animals, while preserving appropriate risk assessments.

## **IS** 2463 Exposure Science in the 21st Century: Perspectives from the NAS and What It Means for Toxicology.

L. S. Birnbaum<sup>1</sup> and J. Orme-Zavaleta<sup>2</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC; <sup>2</sup>US EPA, Research Triangle Park, NC.

In 2010, US EPA with additional support from NIEHS, requested the National Academy of Sciences (NAS) to develop a long-range vision for exposure science in the 21st century and a strategy for implementing this vision over the next twenty years. Exposure science is the bridge between the sources of chemical, physical and biological agents and ecological and human health. Exposure science is critical for predicting, preventing, and reducing human health and ecosystem risks. The report, *Exposure Science in the 21st Century: A Vision and a Strategy*, was released September 7 by the NAS National Research Council. This report along with three other NAS reports, *Toxicity Testing in the 21st Century*, *Science and Decisions: Advancing Risk Assessment* and *Sustainability and the US EPA*, chart the future directions for using innovative technology and scientific advances to better understand environmental impacts on human and ecological health. The report outlines a framework for advancing exposure science to study how humans and ecosystems interact with chemical, biological, and physical agents in their environments. Key visions in the report in are to develop a universal exposure-tracking framework with a focus on preventing and mitigating adverse exposures. This will include the application of systems science to understand and characterize exposures across time, space, and biological scale.

## **IS** 2464 Regulatory-Based Nanotoxicology: Evolving National Strategies, and Research to Address Engineered Nanomaterial Health Risk Assessments.

W. K. Boyes<sup>1</sup>, S. Nadadur<sup>2</sup>, P. Sayre<sup>3</sup>, V. Castranova<sup>4</sup>, K. Dreher<sup>1</sup>, P. C. Howard<sup>5</sup> and D. B. Warheit<sup>6</sup>. <sup>1</sup>ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>NIEHS, NIH, Research Triangle Park, NC; <sup>3</sup>ORD, US EPA, Washington DC; <sup>4</sup>NIOSH, CDC, Morgantown, WV; <sup>5</sup>NCTR, US FDA, Jefferson, AR; <sup>6</sup>Haskell Global Centers, DuPont, Wilmington, DE.

Engineered nanomaterials are increasingly being developed and incorporated into a variety of products and applications. However, the full development of nanotechnology is hampered by an uncertainty regarding their environmental, health and safety implications, and how these issues will be addressed by responsible regulatory agencies at the federal and state levels. Novel nanoscale materials present a number of scientific and technical challenges for assessing their potential health implications including: exposure and material characterization; adequacy of conventional toxicity testing methods/guidelines; dose metric(s) across the exposure-dose-effects

paradigm; and the role of alternative testing approaches to assess their toxicity. This session will bring together scientists from scientific advisory bodies, regulatory agencies and the private sector to present/discuss research needs, strategies, approaches and findings regarding the health effects testing of engineered nanomaterials and nano-enabled products as it relates to regulatory mission(s). Key topics include: assessing nanomaterial toxicity for regulatory and risk assessment applications; the status or role of alternative test methods to screen or prioritize nanomaterials for in vivo toxicity testing, and the extent to which harmonized testing can be achieved for these novel materials. Each speaker will have 10-12 minutes to highlight agency/institutional approaches and regulatory actions regarding the potential for health effects from engineered nanomaterials. The session will conclude with a 15 minute general discussion period. The overall goal is to provide participants with a view of the status of the development of nanomaterial toxicological assessments that would be sufficient to evaluate health and safety for regulatory agencies.

## **EC** 2465 Toxicological Writing for Industrial and Regulatory Audiences.

C. J. Amuzie<sup>1,2</sup> and M. La Merrill<sup>3</sup>. <sup>1</sup>Department of Pathology, MPI Research, Mattawan, MI; <sup>2</sup>Department of Pathobiology and Diagnostic Investigations, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Preventive Medicine, Mount Sinai School of Medicine, New York, NY.

Excellence in scientific and technical writing leading to high-quality publications, a skill set developed and refined from graduate training through early career in toxicology, is one key trait that can lead to a successful career as a toxicologist. Some academic institutions have programs that support scientific and technical writing for their staff. However, the majority of toxicologists (80%) are employed outside academia, predominately within biopharmaceutical and chemical industries, government, and contract research organizations. Graduates from academic programs that train in writing might acquire skills related to preparation of dissertations, grant proposals, and manuscripts for scientific peer-reviewed journals. The skills acquired from this training, when existent, does not necessitate a smooth transition to a successful career outside academia. Thus early-career toxicologists are sometimes unaware of, or otherwise unprepared for, technical writing assignments that occur in industrial and regulatory toxicology. In addition, different writing skills are required for clear and concise communication of toxicological results to nontoxicologist stakeholders. Therefore, an interactive workshop that evaluates the challenges presented by, and the skills required for, toxicological writing outside academia will be of great use to the majority of graduate students, postdoctoral trainees, and early-career toxicologists. Four speakers from the pharmaceutical industry, the chemical industry, a government regulatory agency, and a contract research organization will review the type(s) of technical writing required within their setting. Notably, they will extensively highlight common mistakes and discuss valuable strategies and tools to avoid these mistakes through interactive exercises using provided writing examples.

## **S** 2466 From Immunotoxicity to Nanotherapy: The Effects of Nanomaterials on the Immune System.

M. J. Smith<sup>1,2</sup>, D. R. Germolec<sup>3</sup> and N. J. Walker<sup>3</sup>. <sup>1</sup>Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA; <sup>2</sup>ImmunoTox, Inc, Richmond, VA; <sup>3</sup>National Toxicology Program, Research Triangle Park, NC.

The potential for human exposure to the diverse and ever-changing world of nanomaterials has raised concerns about the ability of these materials to influence health and disease. The small size of nanomaterials makes them a prime target for interaction with the cells of the immune system. Exposure to nanomaterials (inhalation, dermal, oral, parenteral) can affect multiple components of the immune system. For example, a single respiratory exposure to titanium dioxide nanoparticles can significantly increase the antibody-forming cell response to sheep erythrocytes, suggesting the possibility of nanomaterial interactions with lymphocytes and/or antigen-presenting cells. Furthermore, the cells of the innate immune system, including mast cells and the cells of the mononuclear phagocytic system, are also potential targets following nanomaterial exposure. A varied spectrum of effects, including inflammation, hypersensitivity, and immunomodulation, may then occur, via mechanisms which have yet to be elucidated. While incidental exposure may be undesirable, nanomaterials and nanomedicines engineered for various clinical applications provide opportunities to develop therapies that may or may not intentionally target the immune system. The interplay between nanomaterials and the immune system and the pharmacokinetic and phenotypic responses that result from these interactions are therefore critical factors that dictate the balance between toxicity and clinical efficacy of nanomedicines.

## **S** 2467 Overview of Concepts and Strategies Needed for Assessing the Safety of Nanoscale Materials.

N. J. Walker. *National Toxicology Program, NIEHS/NIH, Research Triangle Park, NC.*

In recent years there has been considerable research examining the potential utility of nanoscale materials and nanostructures in commercial and biomedical applications. Nanoscale materials (nanomaterials, nanoparticles), are a broadly defined set of substances that have at least one critical dimension less than 100 nanometers. The same novel chemical and physical properties that make nanomaterials useful also make their interactions with biological systems difficult to predict and evaluate in traditional toxicity models. The diversity in composition, size, surface coatings, and physico-chemical properties even within classes of "similar" nanomaterials can make translation of findings from one nanomaterial to another problematic. On the other hand though, testing of each nanomaterial individually and what change in a physicochemical property constitutes creation of a "new" material, remains uncertain. Over the past years there has been considerable effort looking at developing guidance for assessing safety of nanomaterials. Some of the key considerations include; effective characterization of physicochemical properties of nanomaterials not only in the bulk phase but also within the toxicological test system; use of in vitro biological responses and shorter term in vivo studies of panels of nanomaterials to develop structure activity relationships for predicting hazard and guide prioritizing further targeted in depth testing; development of best practices to reduce potential interference of a nanomaterial with the test systems.

## **S** 2468 Molecular Dynamics Simulations with Advanced Sampling Techniques to Study Nanoparticle-Membrane Interactions.

M. A. Philbert<sup>2</sup>, P. Elvati<sup>1</sup>, K. A. Russ<sup>2</sup> and A. Violi<sup>1</sup>. <sup>1</sup>Mechanical Engineering, University of Michigan, Ann Arbor, MI; <sup>2</sup>Toxicology Program, University of Michigan, Ann Arbor, MI.

Classical toxicology assessments consider bulk transport of particulate matter into discrete organelles of living cells as the primary means of nanoparticle (NP) toxicity. However, little is known about the potential of low-level exposure to alter biophysical functions (membrane form/function). Atomistic simulations, such as molecular dynamics (MD), can provide mechanistic information that is hard to measure experimentally. They may be used to validate theories derived from indirect experimental analysis, but the results of MD simulations are meaningful only if the run is long enough to visit all energetically relevant configurations. Well-tempered metadynamics can accelerate system dynamics allowing the analysis of processes that can take several seconds or hours to occur in real systems. Classically biased MD simulations were used to reconstruct the free energy landscapes of the mechanisms of NP entry into biological cells, thus accelerating the sampling of rare events and allowing exploration of potentially new biologically relevant reaction pathways. Results show that pristine C<sub>60</sub> resides preferentially in the aliphatic region of the lipid bilayers composed of POPC and cholesterol. With increasing cholesterol concentration, the minimum of the free energy profile moves towards the interface with water, showing a tendency of C<sub>60</sub> to move away from the membrane center. C<sub>60</sub> motility inside the hydrophobic region is not limited by any relevant thermodynamic barriers at body temperature, but the energetic cost to leave the membrane is system-dependent and varies from 10 to 20 k<sub>B</sub>T. Charges (C<sub>60</sub><sup>2-</sup>) or hydroxyl groups (C<sub>60</sub>(OH)<sub>24</sub>) make the region where the lipid heads are solvated by water the most favorable position for these species. These studies make plausible the potential for intramembranous mechanisms of NP toxicity in immune and other mammalian cells. Supported by ES08846, NIEHS NCNHR U01 (MAP), CBET 0644639 (AV), 1 U02 ES020128-01 (KR), T32-ES007062-26 (KR).

## **S** 2469 Evaluating the Local and Systemic Immunomodulatory Effects of Nanomaterials.

M. J. Smith<sup>1,2</sup>, D. R. Germolec<sup>3</sup>, C. E. McLoughlin<sup>1,4</sup>, W. Auttachoat<sup>1</sup> and K. L. White<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA; <sup>2</sup>ImmunoTox, Inc, Richmond, VA; <sup>3</sup>National Toxicology Program, Research Triangle Park, NC; <sup>4</sup>Biomedical Engineering, Virginia Commonwealth University, Richmond, VA.

The small size of nanomaterials (NM) makes them a prime target for interaction with the immune system following their uptake, processing, and presentation to lymphocytes by antigen-presenting cells. Traditional in vivo testing strategies have been used to evaluate NM-mediated immunotoxicity. The varied routes of exposure to NM (dermal, oral, inhalation, parenteral), as well as particle size, can produce differing immune effects, including contact hypersensitivity as well as local or systemic effects. For example, a single pharyngeal aspiration of anatase TiO<sub>2</sub> nanoparticles (< 25 nm) produced an enhanced antibody-forming cell response to

sheep erythrocytes, while TiO<sub>2</sub> microparticles (< 45 µm) produced no such effect. Subcutaneous, but not dermal, exposure to anatase nano-TiO<sub>2</sub> for 3 days increased cell proliferation in the draining lymph nodes, while oral exposure for 28 days was non-immunotoxic. Inhalation of 1.0 and 0.05 µm C60 fullerene for 13 weeks did not affect the systemic immune response, although inflammatory cytokines (MCP-1, MIP-1α) in the bronchoalveolar lavage fluid were increased for the 1.0 µm C60 only. Subcutaneous implantation of sub-micron electrospun biodegradable polycaprolactone materials in the ventral quadrant for 28 days had minimal effects on the immune system, suggesting that this material may have the potential for use in a variety of clinical applications. Nanomedicines intended for clinical applications unrelated to the immune system must be examined for the possibility that they might produce unintentional or unanticipated immune effects. However, depending upon the application (e.g. local anti-inflammatory drug delivery), effects on the immune system may be desirable.

## **S** 2470 Mast Cell Directed Nanomaterial Toxicity.

J. M. Brown<sup>1</sup>, X. Wang<sup>1</sup>, R. Urankar<sup>2</sup>, C. J. Wingard<sup>2</sup> and P. Karwa<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, East Carolina University, Greenville, NC; <sup>2</sup>Physiology, East Carolina University, Greenville, NC.

Concern about the use of engineered nanomaterials (ENMs) has increased significantly in recent years due to potentially hazardous impacts on human health. Mast cells are critical for innate and adaptive immune responses, often modulating allergic and pathogenic conditions. Mast cells are well known to act in response to danger signals through a variety of receptors and pathways including IL-33 and the IL-1 like receptor ST2. We have examined the involvement of mast cells and the IL-33/ST2 axis in pulmonary and cardiovascular responses to ENMs including multi-walled carbon nanotubes (MWCNT) and silver nanoparticles (AgNP). We have utilized C57BL/6 mice, mast cell deficient mice (KitW-sh), KitW-sh mice reconstituted with wild-type or ST2-/- mast cells and ST2-/- mice to assess systemic and pulmonary inflammatory responses as well as cardiac ischemia-reperfusion (IR) injury responses following ENM exposure. In addition, we have used an in vitro mast cell model to screen for the ability of ENMs to directly induce mast cell degranulation. We have found that mice with normal mast cell populations (C57BL/6 and mast cell reconstituted KitW-sh), exhibit significant ENM directed systemic and pulmonary inflammation, fibrosis, altered lung function and exacerbated IR injury. In contrast, these toxicological effects of ENMs were not observed in mice deficient in mast cells (KitW-sh) or mice with mast cells unable to respond to IL-33 (ST2-/- mast cell reconstituted KitW-sh mice). Lastly, we have established that certain ENMs are capable of inducing mast cell activation in vitro. Our findings establish for the first time that mast cells and the IL-33/ST2 axis orchestrate adverse immune effects to ENMs giving insight into a previously unknown mechanism of toxicity and providing a realistic therapeutic target. The use of mast cells and the IL-33/ST2 axis as a screening tool for ENM toxicity and in the preclinical development of nanomedicines will be discussed.

## **S** 2471 Phenotypically Profiling the Factors Affecting the Pharmacokinetics and Pharmacodynamics of Nanoparticle Agents in Preclinical Models and in Patients.

W. Zamboni, W. Caron, G. Song, P. Kumar, J. Lay and P. Gehrig. *Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC.* Sponsor: M. Smith.

Carrier-mediated agents consist of nanoparticles, nanosomes (nanoparticle sized liposomes) and conjugates. The theoretical advantages for using carrier-mediated drugs, including increased drug solubility, prolonged duration of exposure, selective delivery of entrapped drug to the site of action, and improved therapeutic index. Pegylated nanosomal formulations contain lipid conjugated to polyethylene glycol. The disposition of encapsulated drug is dictated by the composition of the carrier, thus altering the pharmacokinetic (PK) profile of the drug. A proposed clearance pathway of carrier agents is the monocytes and macrophages of the mononuclear phagocyte system (MPS). Our studies suggest there is a bi-directional interaction between nanosomal agents and the MPS. However, potential factors associated with clearance of carrier agents in patients and preclinical animal models have not been extensively evaluated. Standard allometric scaling approaches for nanosomal agents did not scale across all species. In addition, preliminary studies suggest that there is high variability in the function of the MPS in animal models and in patients. Thus, new methods for allometric scaling and measures of MPS function need to be developed for carrier-mediated agents. In addition, the most appropriate animal models for toxicology and pharmacology of carrier agents needs to be identified. Novel methods for phenotypically profiling the factors affecting the pharmacokinetics and pharmacodynamics of nanoparticle agents in preclinical models and in patients will be presented.

**S 2472 Modeling Human Genetic Variability and Susceptibility in the Laboratory.**

R. Woychik<sup>1</sup> and D. Threadgill<sup>2</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC; <sup>2</sup>North Carolina State University, Raleigh, NC.

Within a population of genetically heterogeneous individuals, a range of responses is observed for environmental exposures. The observed variability in response is attributable to extrinsic and intrinsic factors, including individual differences in exposure to environmental stressors and genetic/epigenetic heterogeneity, respectively. Current risk assessment practice is to account for interindividual variability with default uncertainty factors (e.g., a ten-fold decrease in allowable exposure to protect the most sensitive subpopulations), even though these defaults are seldom supported by scientific evidence. Advances in exposure science and molecular genetics are greatly increasing our ability to characterize intrinsic differences among individuals in their exposure and response to toxicants. This symposium highlights several novel and exciting approaches in safety evaluation that utilize recent advances in genetics. First, recent collaborative efforts in the complex traits community have led to the development of several new, powerful mouse resources that greatly facilitate the identification of allelic variants of genes associated with differential response to toxic exposure through genotype-phenotype associations. Second, several laboratories, including the National Toxicology Program, have begun applying these new mouse models of human population diversity to studies on the molecular mechanisms of interindividual variability in chemical metabolism and toxicity. Third, the ability to generate induced pluripotent stem (iPS) cells from population-derived human cell resources, as well as the availability of embryonic stem (ES) and iPS cells from mouse strains, makes it possible to conduct *in vitro* studies to investigate interindividual differences in resistance and susceptibility to xenobiotic exposures. Ultimately, these new approaches should greatly enhance our ability to characterize variability in response to toxicants and to identify those genes and pathways that contribute significantly to the observed differential responses to environmental exposures in humans.

**S 2473 Modeling Genetic Heterogeneity to Understand Susceptibility to Chemical Combinations: A Mouse Population-Based Study Using Trichloroethylene (TCE) and Inorganic Arsenic (iAs).**

D. Threadgill. North Carolina State University, Raleigh, NC.

Using the results of a recent mouse population-based study that investigated via dose response curves the differential toxicity to TCE and iAs singly and in combination, this presentation illustrates how genetic heterogeneity can be modeled to understand individual susceptibility to combinations of chemicals. The results demonstrate that these chemicals can elicit additive and synergistic toxicities in susceptible individuals. Furthermore, the target organs in the genetically heterogeneous mouse populations are similar to those in humans, indicating that susceptibility alleles in the mouse population model will inform on human susceptibility.

**S 2474 The Use of Population-Based Inbred Panels and Diversity Outbred Mouse Models to Explore Individual Variability and Toxicity to Benzene.**

J. E. French. Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC.

Benzene is hematotoxic, genotoxic, and tumorigenic to the lymphohematopoietic systems in both laboratory animals and humans. Results from NTP population-based mouse model studies show significant individual variability in benzene ADME/TK and levels of DNA damage at human relevant exposures. The results of these studies illustrate how individual variability in genetically defined populations may be used to identify genetic variants associated with differences in toxicokinetics, resistance or susceptibility to a toxicant, and to identify causally related mechanisms of toxicity. Benchmark dose models can be used on quantitative data to determine a reference dose that will aid in the quantification of uncertainty factors and, possibly, eliminate default assumptions in risk assessment. In addition, by identifying multiple genetic variants through genotype-phenotype associations with significant size effects, networks and pathways may be predicted that are statistically anchored to toxicity phenotypes and functionally-validated through the use of recombinant inbred mice (Collaborative Cross) cell-based assays, *in vivo* targeted testing, and molecular biology using reverse genetics. Across species extrapolation is enhanced by identifying variants that are orthologous between mouse and human and if there are associated in orthologous networks or pathways. In combination with high-throughput and high content assays validated by *in vivo* targeted testing, these new tools will provide a new paradigm for toxicology and exposure related diseases.

**S 2475 Modeling Genetic Variability in Response to Environmental Toxicants Using Mouse ES Cells *In Vitro*.**

T. Choi. Predictive Biology, Inc., Carlsbad, CA.

A genetically diverse panel of ES cell lines have been produced from inbred, F1, and outbred mice, and this panel has been used to investigate the role of strain background on variable response to environmental toxicants. An example of such a study is an investigation of how genetic background and environmental factors interact in the onset or severity of arrhythmia, and how these interactions may be involved in the cardiotoxicity of environmental toxicants. The ultimate goal is to discover novel mechanisms, targets, and chemical structures underlying variability in cardiotoxic response. The approach is to conduct large scale, high throughput *in vitro* screens using cardiomyocytes derived from genetically diverse ES or iPS cells to interrogate gene x toxicant interactions *in vitro*. Toward this end, a large panel of genetically diverse mouse ES lines as well as an automated beating assay performed in 384 well plate format for time domain analysis of arrhythmia have been developed. Data based on testing reference compounds of known arrhythmogenic potential in ES derived cardiomyocytes support the validity of this approach.

**S 2476 The 1,000 Genomes *In Vitro* Toxicology Project: Quantitative High-Throughput Screening for Chemical Toxicity in a Population-Based *In Vitro* Model.**

I. Rusyn. University of North Carolina at Chapel Hill, Chapel Hill, NC.

A series of collaborative studies between the Tox21 consortium and the University of North Carolina have been conducted in which inter-individual variability in exposure response is being assessed in a population-wide human *in vitro* model. These experiments have generated quantitative high-throughput cytotoxicity data on about 200 chemicals in over 1000 cell lines representing 9 populations from 5 continents and all major racial groups. This rather simple toxicity phenotype of cytotoxicity can be leveraged with other molecular data (genotyping and transcript profiling) available on the same cell lines through the HapMap and 1000 Genomes consortia and applied to human health assessments.

**S 2477 Opportunities and Challenges to Incorporating Genetic Variability Data in Risk Assessment.**

W. A. Chiu. US EPA, Washington DC. Sponsor: R. Tice.

This presentation discusses how the new approaches and data sources on genetic variability described by the previous speakers will fit into a changing risk assessment landscape in the 21st Century. Key opportunities include the direct estimation how genetic variability contributes to susceptibility to toxicants and the identification of key biological pathways that confer differential susceptibility. However, some important challenges remain, such as inter-species and *in vivo-in vitro* extrapolation and, especially, the integration of genetic variability with other sources of human variability. [Disclaimer: The views in this presentation are those of the author, and do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency.]

**S 2478 Role of Air Pollution As a Risk Factor for Central Nervous System Diseases and Disorders.**

D. A. Cory-Slechta. Environmental Medicine, University of Rochester Medical School, Rochester, NY.

Increasing evidence suggests that many of the adverse consequences of air pollutants extend beyond the lungs and indeed can target the brain where they produce many of the same types of inflammatory and other adverse consequences as documented in the lungs. Such findings have been variously described in experimental models for exposures such as the metal constituents of the ultrafine particulate matter of air pollution, for diesel exhaust and for ozone. Both direct effects via constituents of air contaminants translocated to the CNS and indirect effects via induction of systemic acute phase responses have to be considered. In addition, epidemiological studies have now begun to report associations of traffic- and combustion-related air pollutants with cognitive deficits in children. While our understanding of the extent of such impacts is still quite limited, these highly provocative findings could suggest that air pollution has been a greatly underappreciated risk factor for neurodevelopmental or neurodegenerative diseases. This symposium will present findings from experimental models describing the CNS toxicity of concentrated ultrafine particles in adults and in postnatally-exposed rodent models in relation to neurodevelopmental and neurodegenerative consequences, and of ozone in

the context of Parkinson's disease. In addition, recent epidemiological findings linking residential proximity to freeway with autism will be presented. The intent of the symposium is to stimulate discussion especially in the context of future research needs in this rapidly emerging area of neurotoxicology which requires a multidisciplinary approach involving expertise in the toxicology of the CNS, air pollution, mixtures, and nanoparticles in order to conduct appropriate risk assessment.

## **S** 2479 CNS Consequences of Postnatal Exposure to UFP.

D. A. Cory-Slechta and J. L. Allen. *Environmental Medicine, University of Rochester Medical School, Rochester, NY.*

Accumulating evidence suggests that air pollutants can induce inflammation and oxidative stress in the brain and that early development may be a period of particular vulnerability to such exposures. Epidemiological studies report associations between air pollutant exposure and impaired cognitive function in children and adults and attention deficit in children. Our studies seek to determine the effects of developmental and/or adult concentrated ambient particulate matter (CAPS) exposure on cognitive behaviors and their potential CNS mechanisms. C57Bl6 mice were exposed to AIR or CAPS during early postnatal life with or without adult challenge, yielding 4 groups: Air/Air, Air/CAPS, CAPS/Air and CAPS/CAPS. Behavioral measures included repeated learning, a fixed ratio wait for reward paradigm related to impulsivity (males only), Fixed Interval schedule-controlled behavior and locomotor behavior. Learning accuracy was significantly impaired after CAPS/Air and CAPS/CAPS exposures, particularly in females, even though ability to perform already-learned responses remained intact. In the fixed ratio wait for reward paradigm, CAPS/AIR and CAPS/CAPS decreased the time animals would wait for free reward deliveries, and thereby resulted in emission of a greater number of responses for reach reward earned. Response rates on the fixed interval schedule were reduced in CAPS/AIR males but increased in Air/CAPS females. Notably, as measured at the termination of behavioral testing, i.e., almost a full year after the adult exposures, histopathological hallmarks of CNS perturbation, namely astrogliosis and increased microglial presence, were seen in multiple brain regions, including dentate gyrus and ventral midbrain and increased glutamate and GABA was prevalent in frontal cortex of both sexes. Current efforts focus on understanding the relationships between inflammatory and neurotransmitter changes and behavioral outcomes. Exposure to CAPS appears to have long-term consequences for the CNS. As such, air pollutants may represent an underappreciated contribution to CNS disease and disorders.

## **S** 2480 Microglia and the Peripheral Immune Response in Diesel Exhaust-Induced Neuropathology.

M. L. Block. *Anatomy & Neurobiology, VCU, Richmond, VA.*

Air pollution has been linked to central nervous system (CNS) disease, but the mechanisms driving this response and the type of exposures responsible are largely unknown. To discern the early CNS response to diesel exhaust (DE), adult male rats were exposed to DE (2.0, 0.5, and 0 mg PM/m<sup>3</sup>) for one month by inhalation. DE exposure elevated markers of neuroinflammation (nitrotyrosine, IL-6, TNF $\alpha$ , and MIP-1 $\alpha$ ) in the midbrain, cortex, and olfactory bulbs, in addition to activation of microglia, as determined by morphology. The highest levels of neuroinflammation occurred in the midbrain, which also contained the highest level of the IBA-1 microglial marker. Neurotoxicity and early markers of neurodegenerative disease were unaffected. One month exposure to biodiesel exhaust revealed only changes in microglia morphology without any elevation of pro-inflammatory factors, demonstrating that neuroinflammation may be exposure specific. To reveal how DE might be causing neuroinflammation, rats were administered an IT bolus of DE particles (DEP, 20 mg/kg) where DEP exposure elevated serum and brain TNF $\alpha$ , suggesting a potential role for the particles in initiating peripheral inflammation capable of transferring to the brain. Microglia cultures treated with DEP (50 $\mu$ g/ml) failed to produce TNF $\alpha$ , indicating that brain TNF $\alpha$  production may not be due to the direct interaction of microglia with the particles. To explore the role of long-term exposure, we tested the effect of subchronic (6 month) DE (992, 311, 100, 35 and 0  $\mu$ g PM/m<sup>3</sup>) inhalation in rats and found elevated levels of the neurotoxic cytokine TNF $\alpha$  at lower exposures (DE, 100  $\mu$ g PM/m<sup>3</sup>) and early protein markers of neurodegenerative diseases (A $\beta$ 42,  $\alpha$  synuclein and phosphorylated tau) at higher levels (DE 992  $\mu$ g PM/m<sup>3</sup>), suggesting that subchronic DE exposure may impinge on common neurodegenerative disease pathways. Together, these findings demonstrate that the brain's immune system can detect and respond to DE and support that circulating cytokines (or another peripheral signal) may play a role in how neuroinflammation transfers to the brain.

## **S** 2481 Particle Translocation As an Explanation for the Adverse Effects of Inhaled Particulates in the CNS.

A. Elder. *Environmental Medicine, University of Rochester, Rochester, NY.*

The hypothesis that air pollution can adversely impact the central nervous system (CNS) is supported by the demonstration of gene-environment interactions for neurodegenerative disorders, such as Alzheimer's and Parkinson's diseases. The mechanisms by which this might occur are not fully understood, but may include transport of particulates into the brain, thus resulting in direct delivery of toxicants to the target tissue. Transport via the olfactory route, for example, has been demonstrated for poorly-soluble ultrafine or nanosized particles (<100 nm in diameter in at least one dimension) and for some soluble compounds following inhalation exposures. However, other pathways have been identified and the contribution of these to the overall accumulation in the CNS is unclear. Likewise, the contributions of particle physicochemistry and blood-brain barrier integrity are important to address in order to understand the long-term consequences to CNS health. Such consequences have been explored in recent research. Using a mouse model of Alzheimer's disease, we found that a 12-day inhalation exposure to poorly-soluble manganese oxide nanoparticle aerosols resulted in the activation of hippocampal microglia and astrocytes, suggesting activation of an innate immune response in the brain. Interestingly, this activation persisted for two months post-exposure. Increased immunostaining for amyloid beta and a loss of synaptophysin staining were also found. These data contribute to the growing evidence for an association between environmental exposures and neurodegenerative disease progression.

## **S** 2482 Does Air Pollution Exposure Increase Risk for Autism?

I. Hertz-Picciotto<sup>1</sup>, H. E. Volk<sup>2</sup> and R. S. McConnell<sup>2</sup>. <sup>1</sup>MIND Institute & Center for Children's Environmental Health, University of California Davis, Davis, CA; <sup>2</sup>Center for Children's Environmental Health, University of Southern California, Los Angeles, CA. Sponsor: D. Cory-Slechta.

Windham et al. (2006) reported that children with autism were more likely to live in census tracts with higher ambient levels of diesel, certain metals, and solvents. Traffic is a major source of air pollution, including particulates, polycyclic aromatic hydrocarbons, metals, sulfur dioxide and nitrogen oxides. Proximity to freeways and major roadways is highly correlated with ambient levels of such traffic-related air pollution. Using data from the CHARGE (CHildhood Autism Risk from Genes and Environment) Study, we examined the association between autism and proximity of residence to freeways and major roadways during pregnancy and near the time of delivery (Volk et al 2011). Using data from 304 autism cases and 259 typically developing controls, the mother's address recorded on the birth certificate and trimester-specific addresses obtained by questionnaire were geocoded, and measures of distance to freeways and major roads calculated with ArcGIS software. After adjustment for sociodemographic factors and maternal smoking, mothers of cases were more likely, at the time of delivery, to live within a quarter mile of a freeway as compared with mothers of controls: odds ratio (OR) = 1.86. At greater distances, risk was not elevated. Autism was also associated with residential proximity to a freeway during the third trimester (OR = 2.22). For each address, exposures to specific air pollutants from traffic and stationary sources were estimated with U.S. EPA's Air Quality System (Volk et al, in press). Exposures to nitrogen dioxide (NO<sub>2</sub>) and particulate matter less than 2.5 and 10  $\mu$  in diameter (PM<sub>2.5</sub> and PM<sub>10</sub>) in the first year of life were associated with about a two-fold increased risk for autism (NO<sub>2</sub> OR=2.06; PM<sub>2.5</sub> OR=2.12; PM<sub>10</sub> OR=2.14), with similar findings for gestational exposures. Given that many constituents in air pollution induce neurodevelopmental deficits in experimental rodent studies, a contribution from air pollution to autism susceptibility is plausible.

## **S** 2483 Ozone Pollution, Oxidative Stress, and Dysregulation of Inflammatory Responses in Rat Hippocampus.

S. Rivas-Arancibia. *Fisiología, Facultad de Medicina, Universidad Nacional Autónoma de México, México City, Mexico.* Sponsor: D. Cory-Slechta.

The oxidizing compounds contained in the air that we breathe in the large cities, is related to a large number of chronic degenerative diseases. To study the effects of ozone pollution on the brain, we developed a model consisting in a chronic exposure of rat to ozone doses, similar to total levels that occur in a day of high pollution in Mexico City. For this purpose, 84 male Wistar rats (250 to 300 gr) were randomly divided into 7 groups, each group received one of the following treatments: 1) control, 2) exposed to ozone free air for 30 days, 3) exposed to ozone for 7 days, 4) exposed to ozone for 15 days, 5) exposed to ozone for 30 days, 6) exposed to ozone for 60 days, and 7) exposed to ozone for 90 days. (0.25 ppm /4 hours daily). Two hours after the last exposure to ozone, each group was randomly divided into

two subgroups, hippocampus were dissected and afterward processed for immunohistochemistry. The second subgroup was used for western blot and spectrophotometric techniques (to determine lipid peroxidation, oxidized proteins, superoxide dismutase and glutathione). The results indicate that ozone, causes an increase in lipids and proteins oxidation after 15 days of exposure. After 30 days we found in the hippocampus damage and decrease of the neuroblasts, and neurons number, glial activation, increased of proinflammatory markers, together with changes in levels of antioxidant defenses and loss of its enzymatic activity. Results also showed accumulation of deposits of amyloid beta (A $\beta$ ) 1-42 at 90 days exposure. In conclusions: ozone lead to oxidative stress causing a neurodegenerative process in hippocampus, together with, dysregulation of immune responses, and loss of brain to capacity repair, and A $\beta$  1-42 plaques formation at 90day of ozone exposure. These experiments showed that chronic exposure to ozone at low doses, per se, is able to cause an oxidative stress state, which produces progressive cellular damage and cell death that resembling the damage described in the physiopathology of neurodegenerative diseases.

Grant DGAPA IN 219511

## **S** 2484 **Translational Methods to Assess the Safety of Natural Health Products, Including Traditional Medicines and Dietary Supplements.**

J. C. Griffiths<sup>1</sup> and S. A. Jordan<sup>2</sup>. <sup>1</sup>*Doc Standards, US Pharmacopeia, Rockville, MD;* <sup>2</sup>*Marketed Health Products, Health Canada, Ottawa, ON, Canada.*

Globally, ~80% of the world's population relies upon traditional medicines as part of standard healthcare; ~100 million Americans spend ~\$28 billion annually to consume herbals, vitamins, minerals, amino acids, and other naturally occurring products in the form of dietary supplements, botanical drugs, and natural health products. The complexity of mixtures with variance in composition and quality presents a challenge for risk practitioners. To address these issues, new methodologies and predictive technologies are being developed, tested and validated to mitigate risk of human toxicity and effectively increase the quality of information useful for application in safety assessments. Many of these methods are already reflected in multiagency government initiatives. Such methods are referred to as "translational" for making use of and extrapolating data from scientifically defensible approaches towards establishing human safety and use of viable products. In this symposium, various *in vitro*, *in vivo*, state-of-the-art *in silico* (computational), and 'omic methodologies will be presented. Discussion will cover case studies and regulatory science activities at US FDA/CDER and NCTR including conventional toxicological and computational assessments of individual chemical constituents and mixtures. Computational tools to deconvolute complexities and predict molecular targets for constituent phytochemicals will also be highlighted. Speakers will also address how the United States Pharmacopeia (USP) conducts evidence-based reviews on the safety of dietary supplements and how to couple data from *in silico* structure-based methods to complement and strengthen evidence and support committee-based human expert decision making regarding the suitability of dietary supplements for monograph development on product quality. Collectively, these presentations will provide a global picture of the state and utility of modern methods for assessing toxicity and safety of these products.

## **S** 2485 **Session Overview: The Promise of Translational and Integrative Safety Assessments of Dietary Supplements, Traditional Medicines, and Herbal Drugs.**

S. A. Jordan. *Marketed Health Products, Health Canada, Ottawa, ON, Canada.*

For thousands of years, herbs and other natural substances have been used in health care. Some traditional healing paradigms include knowledge of potential toxicity, and ways of preventing adverse effects. However, with modern use, a much larger and varied population now uses these products. In addition, commercial products may not be true to traditional use, indication, or form. A rise in use of these products with pharmaceutical drugs, resulting in possible herb-drug interactions, also has become an issue of concern. Potential safety concerns may also arise from quality issues. Regulators are often faced with a lack of quality information when making risk-based decisions on the safety of dietary supplements or traditional medicines, and an increase in these data allows for improved decision making. The development of translational methods, including omics, and computational models, has presented an opportunity to increase the amount of information, and to integrate novel data with traditional methods of assessing toxicity. The integration of all available data, including those derived from translational studies, can reduce uncertainty in decision making related to the potential hazard and risk associated with the use of these product types. Overall, this will benefit the public, the industry, and the regulatory community which is charged with licensing and monitoring the safety of dietary supplements and traditional medicines.

## **S** 2486 ***In Silico* Methods As Translational Tools for Supporting the Safety Assessment of Natural Health Products.**

L. G. Valerio. *CDER/Office of Pharmaceutical Science, US Food & Drug Administration, White Oak, MD.* Sponsor: J. Griffiths.

*In silico* methods including computational toxicology can serve to help address data gaps during safety evaluations for regulatory and industrial product safety. Natural health products including dietary supplements, botanicals, herbals, and related substances can benefit from the wide spectrum of scientific evidence produced by *in silico* toxicology analyses. Discussion will cover case studies and regulatory science activities in the application of structure-based computational assessments of individual chemical constituents derived from natural products and mixtures modeling. Translation of these data to support human safety and risk assessment processes will be presented. The *in silico* approach as a translational tool with emerging evidence-based predictive technologies and the use of these methods in applied safety science is of extraordinary heightened interest with the goal of meeting today's needs for protecting public health.

## **S** 2487 ***In Vitro* and *In Vivo* Approaches for Assessing the Safety of Natural Health Products.**

W. F. Salminen. *NCTR-Center for Hepatotoxicology, US Food & Drug Administration, Benton, AR.*

Dietary supplement use continues to increase as many people see these "natural" products as inherently safe alternatives to drugs. However, in the US and many other parts of the world, dietary supplements require none to minimal safety data before they are marketed. Many dietary supplements are complex mixtures of a wide variety of chemical compounds and the composition can vary greatly from manufacturer to manufacturer and even batch to batch making safety assessments very difficult. Various *in vitro* and *in vivo* approaches for assessing the safety of dietary supplements from classical toxicology studies to state-of-the-art toxicogenomics assessments will be reviewed. An overview of the US National Toxicology Program's (NTP) testing of dietary supplements will be presented and examples of potential drug-dietary supplement interactions will be discussed since these are likely to increase as people use dietary supplements in combination with approved drugs.

## **S** 2488 **Computational Methods Linking Traditional Chinese Medicine (TCM) and Western Therapeutics.**

D. E. Johnson. *Molecular Toxicology, University of California Berkeley, Berkeley, CA.*

Herbal remedies are widely used throughout the world with approximately 80% of the global population relying on traditional medicines as part of standard healthcare. In the US, an estimated 1 in 5 adults regularly consume herbal products and most of these are not included in patient records as "other medications", thereby limiting the understanding of potential herb-drug interactions to both the patient and health care professional. We have been using computational tools to deconvolute complex recipes and predict molecular targets for constituent phytochemicals with the goal of forming a comprehensive tool to help predict herb-drug interactions. This work will be illustrated using both open-source tools and commercial biological pathway mapping and predictive algorithms. Translational methodology will be introduced that proposes a chemical-disease category linkage between TCM and Western medicine for a rational integrative medicine approach.

## **S** 2489 **Herbogenomics As a Translational Method for the Safety Assessment of the Complex Mixtures in Traditional Chinese Medicines.**

Y. Kang. *Department of Pharmacology and Toxicology, University of Louisville School of Medicine, Louisville, KY.*

Natural health products, including traditional Chinese medicines (TCMs) are often complex mixtures. Assessing the safety of individual components of such products is problematic. The use of TCM has raised concerns of heavy metal contamination and toxicity. However, it has been known that metals and metalloids are essential components in some TCM preparations. For instance, mercury in cinnabar is irreplaceable for its therapeutic effect. Another scenario is that the TCM formulation is toxic to healthy population, but becomes remedy to seriously sick people. In this context, the dose regiment of arsenic trioxide used to treat acute promyelocytic leukemia (APL) is extremely toxic to general population, but is of high therapeutic efficacy for APL patients. It is difficult, if not impossible, to distinguish metal composition from metal contamination in TCM and their associated therapeutic or toxic effects. A novel approach of herbogenomics can provide

alternate perspectives on the active ingredients and toxic contaminations of TCM. The overall effects of TCM on target organs can be elucidated by functional genomics and proteomics, thus the addition or subtraction of heavy metals from TCM preparations would affect the outcome, which can be reflected by the genomic profile alterations. The information about metal composition and contamination is critical for general population considering the use of TCM as an alternative remedy.

**S 2490 Evidence-Based Reviews As a Method for Assessing the Safety of Dietary Supplements.**

M. L. Hardy. *Center for Integrative Medicine, University of California Los Angeles, Los Angeles, CA.* Sponsor: J. Griffiths.

Dietary supplement safety is one of the main regulatory concerns in the United States. Adverse events occur for a variety of reasons including contamination, misidentification or adulteration of plant based dietary supplements. However, even when a product is correctly made, adverse events in human subjects have been reported. Systematic review and meta-analysis of published clinical trials and adverse event case reports allow aggregation of disparate reports in order to improve the analytic strength of evaluations of potential harms. When adverse events are reported in properly randomized clinical trials, causality of the reported adverse event can be assumed. Clinical trials are almost always of insufficient power to detect any but the most common adverse events. Rare or serious adverse events are usually reported in as case reports or small case series. Attribution of risk in this case is limited by a number of factors including timing and duration of exposure to suspected offending substance as well as the clinical circumstances of the user. Although causality can rarely be attributed based on case reports, systematic review of aggregated cases can identify a suspicious signal. Additional limitations of all sources of adverse event reports are the result of incomplete information including very often poor characterization of the potential offending material. The application of these principles will be illustrated using an analysis of adverse events related to ephedra.

**W 2491 Are We Like Rodents, Rabbits, or Something Else? Mechanisms of Developmental and Reproductive Toxicity across Species.**

R. J. Rasoulpour<sup>1</sup>, K. Johnson<sup>3</sup>, S. N. Campion<sup>2</sup>, C. Timchalk<sup>4</sup> and J. E. Goodman<sup>5</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Pfizer Global, Groton, CT; <sup>3</sup>Alfred I duPont Hospital for Children, Wilmington, DE; <sup>4</sup>Pacific Northwest National Laboratory, Richland, WA; <sup>5</sup>Gradient, Cambridge, MA.

Given the inherent complexity of embryo/fetal development and reproductive biology, developmental and reproductive toxicity (DART) hazard identification and research still heavily relies on animal models. Typically, this type of research is conducted in rodents (e.g., mouse and rat) as well as nonrodent species (e.g., rabbit and nonhuman primate), which, in the face of toxicity findings, raises the question of relevance to humans. Are we more like mice, rats, or other model organisms? Not surprisingly, answering this question is a challenge, and the scientific approach may be quite different depending upon the biological system and the level of mechanistic information available. However, within this challenge is an opportunity to understand the toxicokinetic and toxicodynamic differences between the species and provide the appropriate context for developmental and reproductive findings. Providing this context can directly impact the risk assessment and regulatory decision-making process. This workshop will highlight several different approaches to relate animal reproductive and developmental toxicity findings to human health. Speakers in fields of basic research, product safety testing, epidemiology, and physiologically-based pharmacokinetic modeling will address the central theme of the workshop, which is applying different experimental strategies to analyze cross-species toxicity. Within each presentation, potential regulatory implications and feedback from agencies, when available, will be addressed. The expected outcomes of the workshop are an increased understanding of the different approaches to dissect complex toxicity mechanisms and to take the next step towards cross-species comparisons that impact human relevance and regulatory decisions.

**W 2492 Challenges in Elucidating Developmental Toxicity Mechanisms in the Context of Guideline Safety Assessment Studies.**

R. J. Rasoulpour. *Developmental and Reproductive Toxicology, The Dow Chemical Company, Midland, MI.*

This presentation will provide a case study on unique challenges often posed by elucidating developmental toxicity mechanisms identified within guideline toxicity studies. The case study will focus on a recently identified novel mechanism of rat-

specific developmental toxicity induced by a developmental molecule, sulfoxaflo. At high doses, neonatal death and limb flexure effects occurred in rats, but not rabbits. The proposed mode-of-action was that these effects had a single mechanism mediated via the rat fetal isoform of the muscle nicotinic acetylcholine receptor. The studies included a combination of novel in vivo and in vitro mechanistic studies, which were integrated to identify agonism on this receptor as a critical event. Moreover, species comparison studies revealed that this initial event was isolated to sustained agonism on the rat fetal isoform of the nicotinic acetylcholine muscle receptor and did not occur in humans. Feedback on this project from global regulatory agencies will be presented and discussed. This stage-setting talk provides a clear example of how human relevance can be understood if the toxicity is mediated by a relatively simple mechanism (e.g., agonism at a single receptor).

**W 2493 Endocrine Disruption Mediated Developmental Toxicity in Mice versus Rats: Implications for Humans.**

K. Johnson. *Alfred I duPont Hospital for Children, Wilmington, DE.*

This presentation will examine the mechanisms behind phthalate-induced fetal testis endocrine disruption in mouse and rats and extrapolation of these rodent data to humans. It will analyze the species-sensitivity of phthalate endocrine disruption and compare these responses to those observed after phthalate exposure of human biological samples. In rats, gestational phthalate exposure produces male reproductive tract malformations (including hypospadias and cryptorchidism) via a phthalate-induced reduction of fetal testis insulin-like 3 and testosterone production. Although the phthalate molecular target is unknown, extensive molecular mechanistic studies in the rat have established reduced Leydig cell steroidogenic gene expression as causal for the inhibition of testosterone production. In contrast to the rat, available data for mouse gestational phthalate exposure indicate this species is resistant to inhibition of fetal testis hormone production. Despite mouse gestational phthalate exposure extensively altering the fetal testis gene expression profile and inducing fetal testis histopathology, no reductions in mouse fetal Leydig cell steroidogenic gene expression are evident. Because in vitro models do not recapitulate the fetal testis/Leydig cell endocrine disruption phenotype, the question of human susceptibility has been addressed with experiments using human fetal testis explants xenografted into rodent hosts. In these experiments, phthalate exposure of host animals harboring rodent fetal testis explants recapitulates the rodent in vivo phenotypes, and human fetal testis xenografts respond similarly to mouse fetal testis xenografts. While histopathology is observed in the human fetal testis xenografts, reductions in fetal testis testosterone production or steroidogenic gene expression are not seen. These xenografts data have important implications for current and future regulatory decisions but are not without caveats. The potential regulatory impact and caveats of these experiments will be presented.

**W 2494 Case Studies on Testis Toxicity in Rodent Models and Risk Management Strategies.**

S. N. Campion. *Pfizer Global, Groton, CT.*

This presentation will provide case examples of testis toxicity findings in regulatory studies for pharmaceutical development. For some of these examples, strategies used to elucidate the mechanisms of toxicity in order to put these findings into perspective for human risk assessment will be described. One of these case studies will focus on mechanistic work performed to determine that the adverse findings noted in rats were the result of a species specific mechanism that is not relevant in humans. A second case study will discuss work performed to elucidate the binding targets of a compound that elicits testis toxicity in rodents. While there are some examples of mechanistic work to de-risk testis issues with pharmaceuticals, mechanistic work is not commonly performed since the toxicity is often due to off-target effects of small molecules. In addition, the impact of the time required to perform mechanistic work to a program's timeline often makes this work unfeasible. Alternative approaches to understanding the impact of the toxicity in order to develop human health risk management strategies will be discussed, including evaluating the safety margin as well as the intended use of the drug (e.g., indication, patient population, duration of treatment). Marketed drugs with testicular toxicity findings in nonclinical studies will be discussed to provide a perspective of the tolerance of regulatory agencies to such findings. In general, there is a higher tolerance for male reproductive toxicity findings with pharmaceuticals relative to environmental chemicals because the benefit of the pharmaceutical exposure is considered relative to the risk when determining the impact of findings in preclinical studies.

**W 2495 Physiologically-Based Pharmacokinetic/Pharmacodynamic Modeling of Developmental Toxicity.**

C. Timchalk. *Pacific Northwest National Laboratory, Richland, WA.*

The developing brain is vulnerable to insults and evidence implicates low-level chemical exposures as potential developmental neurotoxins. Organophosphorus (OP) insecticides, like chlorpyrifos (CPF), inhibit cholinesterase (ChE) and are neurotoxic. PBPK/PD models have been exploited to enable cross-species extrapolation of CPF brain dosimetry and ChE inhibition and when linked with a dietary exposure model can predict response across populations. However, recent epidemiology studies suggest that OP neurotoxicity occurs at low-doses, even in the absence of significant brain ChE inhibition. The lack of quantitative cross-species brain dosimetry data associated with epidemiology results hampers any mechanistic based risk assessments. The implication of localized heterogeneous CYP450 brain metabolism has historically not been extensively investigated, but recent research suggests it is of key importance. To address these limitations, we are testing the hypothesis that low-dose exposures of preweanling rats to OP insecticides will result in differential brain region dosimetry, enhanced by localized brain bioactivation, potentially resulting in subtle changes in brain chemistry. Comparative in vitro metabolism studies in rats indicate that the overall brain microsomal metabolism was a fraction (~3%) of the liver. Following in vivo oral administration (1 and 5 mg/kg/day) of CPF to post-natal day-10 pups, CPF and its major metabolite were quantified in the brain with evidence of regional deposition and localized metabolism. The importance of localized brain metabolism is highly relevant for lipophilic pesticides that sequester in the lipid rich regions of the brain and can undergo localized metabolic activation to produce neurotoxic effects. This is particularly important in juvenile animals, and children, where there may be a disproportionate deposition of the parent pesticide in the brain. In this regard, these PBPK/PD modeling strategy have significant regulatory implications for assessing developmental neurotoxicity.

**W 2496 Using Epidemiology to Analyze Neurodevelopmental Toxicity across Species.**

J. E. Goodman. *Gradient, Cambridge, MA.*

The final presentation of the session will tackle cross-species analysis from a different angle by utilizing epidemiology data. This presentation will explore how epidemiology studies can address toxicity across species by estimating human exposures and/or outcomes with biomarkers and putting these into context with the animal model results. It will focus on how the effect of timing, selection choice, and measurement of biomarkers, as well as the results of toxicology studies, can influence the interpretation of results. Chlorpyrifos and neurodevelopmental effects will be used as a case study. US EPA assessed whether epidemiology data suggest that fetal or early-life chlorpyrifos exposure causes neurodevelopmental effects and, if so, whether they occur at exposures below those causing 10% inhibition of blood acetylcholinesterase (AChE), which is currently considered the most sensitive endpoint. We conducted a hypothesis-based weight-of-evidence analysis and found that a proposed causal association between chlorpyrifos exposure and neurodevelopmental effects in the absence of AChE inhibition does not have a substantial basis in existing animal or in vitro studies, and there is no plausible basis for invoking such effects in humans at their far lower exposure level. The epidemiology studies fail to show consistent patterns; the few associations are likely attributable to alternative explanations. The human data are inappropriate for a dose-response assessment because biomarkers were only measured at one time point, may reflect exposure to other pesticides, and many values are at or below limits of quantification. When considered with pharmacokinetic data, however, these biomarkers provide information on exposure levels relative to those in experimental studies and indicate a margin of exposure of at least 1,000. Because animal data take into account the most sensitive lifestages, the use of AChE inhibition as a regulatory endpoint is protective of adverse effects in sensitive populations.

**W 2497 Cumulative Risk: Toxicity and Interactions of Physical and Chemical Stressors.**

J. Simmons<sup>1</sup> and C. Rider<sup>2</sup>. <sup>1</sup>NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>NTP, NIEHS, Research Triangle Park, NC.

Recent efforts to update cumulative risk assessment procedures and develop community-based risk assessment methods reflect increased interest in incorporating the totality of variables affecting human health into the risk assessment process. One key roadblock in advancement is uncertainty as to how nonchemical stressors behave in relationship to chemical stressors. An assumption that simplifies incorporation of nonchemical stressors into current risk assessment paradigms is that nonchemical stressors act in the same manner as chemicals. However, evidence is required to support this assumption. The term nonchemical stressors encompasses a

diverse set of variables including physical stressors, such as noise, temperature, disease, and radiation, as well as psychosocial stressors, which involve perception of circumstances. Physical stressors offer a reasonable starting place for measuring the effects of nonchemical stressors and their modulation of chemical effects (and vice versa), as they clearly differ from chemical stressors, present many diverse and highly-relevant stressors, and "doses" of many physical stressors are easily quantifiable. There is a commonly held belief that virtually nothing is known about the impact of nonchemical stressors on chemical-mediated toxicity or the joint impact of coexposure to chemical and nonchemical stressors. While generally true, there are several instances where a substantial body of evidence exists. The objective is to provide expert overviews, for those chemical and physical stressors that have been sufficiently studied to gain at least a limited understanding of their joint impact. In addition to providing the current state of knowledge, data gaps will be identified that should be addressed to facilitate inclusion of nonchemical stressors in risk assessment. (This abstract does not reflect US EPA or NIEHS policy.)

**W 2498 Cumulative Risk: Chemicals and Infectious Disease.**

M. Selgrade. *ICF International, Durham, NC.*

At least 4 types of mechanisms underlie potential interactions between toxic chemicals and infectious disease. 1) The best understood is suppression of immune responses, resulting in increased incidence/severity of infectious disease. For example, decreased alveolar macrophage function following exposure to several air pollutants enhances the risk of certain bacterial infections. Research on this model provides both qualitative and quantitative approaches to describe this risk. 2) Certain immune/inflammatory mediators that are activated during infection affect metabolic enzymes and transporters and have the potential to alter chemical toxicity as illustrated by the effects of murine cytomegalovirus on parathion poisoning, sodium pentobarbital induced sleeping time, and cyt P450. Infection and inflammation have also been shown clinically to affect the metabolism, distribution, and elimination of certain drugs. 3) Chemical exposure may enhance inflammation and immune pathology associated with an infection. This is best illustrated by effects of ozone, ultraviolet radiation, and TCDD on influenza infection. In all cases mortality is enhanced in the absence of increased virus titers in the lung or viral dissemination. Deaths appear to be due to increased inflammatory responses. Similarities exist between receptors and subsequently triggered signaling pathways for pathogen associated molecular patterns (PAMPs) and damage associated molecular patterns (DAMPs), which trigger inflammatory responses. A systems approach that examines the integration of these pathways is needed to better describe this phenomenon. 4) Infection enhances chemical induced lesions, e.g., p53 mutations, inflammation, cell proliferation. Such mechanisms might explain the interaction between hepatitis B virus infection and aflatoxin in the induction of liver cancer. These mechanisms are not necessarily comprehensive, distinct, or mutually exclusive and are imperfectly understood. However, they provide a useful framework to further explore the interactions between infectious disease and exposure to toxic chemicals with the ultimate goal of improving our understanding of cumulative risk.

**W 2499 Enhancement of Noise-Induced Hearing Loss by Chemicals.**

T. C. Morata. *Division of Applied Research & Technology, NIOSH, Cincinnati, OH.* Sponsor: J. Simmons.

The auditory effects of chemical toxicants have been investigated in the past two decades, in animal and human field and clinical studies. A number of studies demonstrated that some solvents, metals, asphyxiants, pesticides not only affect the sensory organ of the auditory system, as noise does, but also affect central auditory structures. Ototoxicity induces outer hair cell dysfunction in the cochlea (similar to the effects of noise), whereas neurotoxicity induces central auditory dysfunction. Audiological signs of neurotoxicity may or may not include poorer hearing thresholds, in addition to difficulties discriminating sounds such as speech, particularly in adverse listening conditions. The existing evidence prompted the proposal of new guidelines and standards on hearing loss prevention. In the U.S., the National Institute for Occupational Safety and Health has discussed specific research needs regarding the ototoxicity of chemicals used at work. The American Conference of Governmental Industrial Hygienists and the U.S. Army have proposed preliminary practical steps that employers and occupational health professionals can take to improve hearing loss prevention. Australia and New Zealand have developed standards recommending hearing tests for workers exposed to ototoxic agents. In the legislative arena, the European Parliament published a new noise directive (2003/10/EC), that requires employers to give attention to any effects on workers' health and safety resulting from interactions between noise and work-related ototoxic substances, when performing risk assessment of workplaces. Legislation regarding compensation has also changed in Australia and Brazil. In this presentation

the auditory effects of chemical alone or in combination with noise will be reviewed, and the recent guidelines, legislative developments and alternative strategies for the prevention of auditory effects resulting from exposure to chemicals in the workplace will be presented.

## **W** 2500 Exacerbation of Toxicity of Air Pollutants and Pesticides by Thermal Stress.

C. J. Gordon, C. Aydin and A. F. Johnstone. *Toxicity Assessment Division, US EPA, Research Triangle Park, NC.*

Considering the likelihood of global warming in the near future, it is important to understand how heat stress will alter the health effects of toxicants. The toxicity of pesticides and airborne toxicants is generally exacerbated in a warm environment. As air temperature increases, the pulmonary intake of air pollutants and absorption of pesticides applied to the skin is generally accelerated. Cellular toxicity is typically exacerbated when body temperature is elevated. This is primarily a result of a Q10 effect, meaning that the rate of a biochemical reaction doubles with a 10 °C increase in tissue temperature. The generation of reactive oxygen species is also exacerbated with warmer temperatures.

Since warmer temperatures worsen chemical toxicity, a thermoregulatory response to lower body temperature can be protective. Hyperthermia is most likely going to be detrimental in the recovery from toxicant exposure. Rodents and other small mammals have relatively large surface area:volume ratio. Following exposure to pesticides and air pollutants, metabolism is reduced and a rapid reduction in body temperature ensues. If given the opportunity to thermoregulate behaviorally, rodents seek colder temperatures, allowing body temperature to decrease quickly. Thus, the hypothermic response is a regulated response. This is thought to be an adaptive response because the hypothermic response is protective. Large mammals, including humans, have a greater thermal inertia and are unable to mount a hypothermic response as is seen in rodents. A warmer environmental temperature will thus impede the hypothermic response to toxicant exposure in rodents and will also be stressful to large mammals that are unable to undergo a significant cooling response. With the potential impact of global climate change on increased incident of heat stress in urban areas that are also rife with pollution, the topic of the thermoregulatory responses to environmental toxicants is timely. This is an abstract of a proposed presentation and does not reflect US EPA policy.

## **W** 2501 Modulation of X-Ray Mediated Testicular Toxicity by Chemical Exposure.

K. Boekelheide. *Brown University, Providence, RI.*

High density microarrays and a detailed bioinformatics analytical approach were used to demonstrate that an initial chemical exposure to 2,5-hexanedione (HD) altered the rat testis to ameliorate the response to a subsequent exposure to x-irradiation. Adult male rats were exposed to HD (0.33% or 1%) in the drinking water for 18 days followed by x-ray (2Gy or 5Gy), resulting in a total of 9 treatment groups. Testis samples were collected after 3 hr and gene array analysis was performed. Using a novel bioinformatic approach to summarize the effect of HD across all treatment groups, we focused on the modification of x-ray-induced gene alterations by HD co-exposure. Enrichment analysis was used to identify biological pathways where HD modification of gene expression was the greatest. HD exerted a significant influence on genes involved in Cell Cycle and DNA Replication, Recombination, and Repair. HD also had an antagonistic effect on x-ray-induced alterations of several apoptotic genes (Fas, BBC3, AEN). To further investigate the specific cell populations and stages in which these critical gene alterations occur, laser capture microdissection (LCM) samples were collected from the basal compartment of the seminiferous epithelium, enriching for those germ cells most susceptible to x-ray-induced apoptosis. Quantitative RT-PCR of the LCM samples confirmed the suppression of apoptotic genes by HD co-exposure. The co-exposure attenuation of germ cell apoptosis is the result of an adaptive response to the chemical exposure, causing altered paracrine signalling of the supportive cells in the seminiferous epithelium. These results suggest that toxicity pathway responses determine the outcome of co-exposures, whether chemical or physical in nature, and that complex paracrine interactions between cells modulate the extent of injury.

## **W** 2502 Sunlight Enhancement of the Toxicity of Air Pollutant Mixtures.

K. G. Sexton<sup>1</sup>, J. Zavala<sup>1</sup>, B. O'Brien<sup>1</sup>, W. Vizuete<sup>1</sup>, R. C. Fry<sup>1</sup>, I. Jaspers<sup>1,2</sup> and I. Rusyn<sup>1</sup>. <sup>1</sup>*Environmental Sciences & Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Center for Environmental Medicine and Lung Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Sunlight can significantly drive photochemical reactions of mixtures of air pollutants commonly observed in the atmosphere, producing many well known toxic compounds such as formaldehyde and other carbonyl containing products. These reactions also contribute to the formation of secondary organic aerosols as well as modifying the composition of existing aerosols or particulate matter (PM). Smog chambers can be used to prepare repeatable, controlled mixtures of simple to increasing complexity and be used to study photochemical atmospheric transformation with natural sunlight or simulated sunlight. Smog chambers can be interfaced with direct exposure to *in vitro* or *in vivo* models for toxicity studies including direct air-liquid-interface *in vitro* or *in vivo* inhalation exposures. Photochemical experiments have been conducted in smog chambers with industrial mixtures and complex mixtures of motor vehicle exhaust in urban atmospheres, often demonstrating enhanced toxicity as measured by markers of inflammation and other biological endpoints such as cytotoxicity. Modifications of experiments, exposure conditions and additional toxicological analyses can provide mechanistic and mode of action understanding. Novel genomic analyses of cells exposed to an urban-like mixtures showed transcriptional changes on a subset of genes, increasing the number of genes with altered expressions from 19 for the un-irradiated mixture, to 709 genes after a one-day sunlight irradiation. The implication is that toxicologists and those dependent on their findings, should consider studies that include mixtures resulting from natural atmospheric photochemical reactivity, transformation of air components, and the resulting enhancement of toxic effects of air pollutants and their products. Not considering such effects, could result in misinterpreting the mode of action and underestimating the potential risk of exposure to air pollution mixtures or its sources.

## **W** 2503 Mechanistic, Occupational, and Clinical Aspects of Lead Exposure.

A. Vale. *School of Biosciences, University of Birmingham, Birmingham, United Kingdom.*

The mechanisms of lead toxicity are increasingly being explained by the ubiquitous reactivity of the bivalent lead cation and its ability to substitute for essential cations, notably calcium and zinc. By these means, lead complexes with important functional groups including thiol and carboxyl groups, and damages many fundamental cell processes and structures including enzyme pathways, phospholipid integrity, ion channel specificity and control, and intrinsic protective systems including free radical scavengers and cellular repair mechanisms. Owing to the large sample sizes involved and its nationally-representative nature, NHANES has been the subject of a number of epidemiological analyses relating blood lead concentrations to a range of adverse outcomes such as blood pressure, renal function, auditory thresholds, and a host of other cardiovascular, neurobehavioral, and other developmental or adult outcomes. Some practitioners are now proposing that, as the NHANES data suggest that lead concentrations even less than 5 µg/dL (0.24 µmol/L) can have some health consequences, chelation should be performed at even very low lead concentrations. Is this an appropriate interpretation of these data? There is concern that the occupational intervention concentrations worldwide are not only unsupported scientifically and clinically but also have been set at concentrations that permit unsafe practices to continue. A group of experts has proposed that workers should be removed from occupational exposure if a single blood lead concentration exceeds 30 µg/dL (1.45 µmol/L), or if two successive blood lead concentrations measured over a four-week interval equal or exceed 20 µg/dL (0.97 µmol/L). Will these recommendations prevent clinically significant occupational lead exposure? Due to the paucity of clinical data, there is controversy about the lead concentration at which chelation therapy should be instituted in adults when exposure prevention has failed, the antidote to be used, and the most effective regimen to be employed.

## **W** 2504 Novel Mechanisms of Toxicity.

R. Lantz. *Cellular and Molecular Medicine, University of Arizona, Tucson, AZ.*

The broad spectrum of lead toxicity with adverse manifestations in developmental and functional aspects of many if not all organ systems are increasingly being explained by the ubiquitous reactivity of the bivalent lead cation and its ability to substitute for essential cations, notably calcium and zinc. By these means lead com-

plexes with important functional groups including thiol and carboxyl groups and damages many fundamental cell processes and structures including enzyme pathways, phospholipid integrity, ion channel specificity and control and intrinsic protective systems including free radical scavengers and cellular repair mechanisms. The ability for lead to substitute for calcium causes erroneous activation of calcium-dependent proteins and modulation of calcium-sensitive receptors. At its extreme, impaired regulation of calcium transport results in intracellular calcium accumulation which triggers apoptosis. Lead can activate protein kinase C to disrupt intracellular regulatory processes causing incorrect gene expression resulting in disordered cell proliferation and differentiation. Lead-mediated malfunction of the calcium sensitive N-methyl-D-aspartate (NMDA) receptor is recognized as one of, if not the most, important mechanism of lead-induced damage to neuronal development, learning and memory.

As the details of the molecular mechanisms of lead toxicity are unravelled, it is becoming clear that their complexity is increased by the fact that lead, like many toxins, acts not in isolation but as part of a multifactorial armoury of adverse influences including environmental factors, which together dictate the development, manifestations and progress of disease.

## **W** 2505 Threshold Toxic Dose: What Can We Learn from the NHANES Studies?

H. Hu. *Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.*

The National Health and Nutrition Examination Survey (NHANES) are cross-sectional surveys of the civilian noninstitutionalized population of the United States that have been administered by the National Center for Health Statistics and ongoing for decades. Subjects are selected based on a stratified multistage probability sampling of counties, blocks, households, and persons within households, with oversampling of some population subgroups (such as Mexican Americans, non-Hispanic blacks, and adults 60 years or older). Evaluations included the administration of extensive questionnaires, physical examination, and collection of urine and venous blood for a wide range of laboratory analyses. Lead levels have been measured in samples of venous blood since the 1970's. Owing to the large sample sizes involved (typically >10,000 individuals) and its nationally-representative nature, NHANES has been the subject of a number of epidemiologic analyses relating blood lead levels to a range of outcomes such as blood pressure, renal function, auditory thresholds, and a host of other cardiovascular, neurobehavioral and other developmental or adult outcomes. This presentation will provide an overview of these studies from the perspective of understanding dose-response relationships; it will also compare them with the parallel body of recent epidemiologic studies using other biomarkers of lead exposure (e.g., KXRF-measured bone lead levels as a marker of cumulative exposure) and/or other study designs (e.g., prospective or case-control studies).

## **W** 2506 Occupational Exposure Limits: Do They Protect Workers?

M. Kosnett. *Division of Clinical Pharmacology and Toxicology, University of Colorado Denver, Denver, CO.*

Research findings have heightened public health concerns regarding the hazards of low dose lead exposure to adults and children. In adults, studies have established the potential for hypertension, effects on renal function, cognitive dysfunction and adverse female reproductive outcome in adults with whole blood lead concentrations less than 40 µg/dL (1.93 µmol/L). However, in most nations worldwide, regulatory occupational exposure limits permit workers to maintain blood lead concentrations in excess of 40 µg/dL for a working lifetime. A group of experts has recently recommended that workers undergo removal from occupational lead exposure if a single blood lead concentration exceeds 30 µg/dL (1.45 µmol/L), or if two successive blood lead concentrations measured over a four week interval equal or exceed 20 µg/dL (0.97 µmol/L). Removal from lead exposure should be considered to avoid long-term risk to health if exposure control measures over an extended period do not decrease blood lead concentrations below 10 µg/dL (0.48 µmol/L), or if selected medical conditions exist that would increase the risk of continued exposure. In order to assure reductions in permissible blood lead concentrations, medical surveillance for lead exposed workers is recommended to include quarterly blood lead measurements for individuals with blood lead concentrations between 10 to 19 µg/dL (0.48 – 0.92 µmol/L), and semi-annual blood lead measurements when sustained blood lead concentrations are less than 10 µg/dL (0.48 µmol/L).

## **W** 2507 Chelation Therapy for Lead Poisoning: Unanswered Questions and Controversies.

S. M. Bradberry. *West Midlands Poisons Unit, City Hospital, Birmingham, United Kingdom.*

Intravenous edetate calcium disodium and oral succimer (dimercaptosuccinic acid; DMSA) are potent chelators of lead approved in many countries for the clinical management of lead poisoning. Both agents reduce the body burden of lead by the renal elimination of a lead-chelating agent complex but there remain unanswered questions regarding their precise pharmacokinetic and pharmacodynamic properties. These include the specific effects of each agent on tissue lead distribution and mobilization and how these parameters are affected by dose and duration of both lead poisoning and chelation. Edetate calcium disodium chelates by exchanging its central calcium ion for lead but the exact chemical nature of the succimer-lead chelate in man remains ill-defined. While assessment of efficacy of both agents is hampered by limited data, the inadequacy of blood lead as a marker of toxicity, variations in study design, species differences and, for clinical studies, the subjective nature of reporting changes in symptoms, available data overall suggest both drugs offer similar efficacy with regard to enhancing lead elimination, though this remains controversial. In addition, the indications for chelation in man remain ill-defined. The adequacy of treatment remains contentious both because of the paucity of efficacy data and because of increasing evidence that toxic effects of lead sustained during early development cannot be reversed by chelation. Moreover, even though most clinical toxicologists agree that where exposure prevention has failed, chelation should be considered in adults whose blood lead concentrations  $\geq 50$  µg/dL (2.4 µmol/L), the most effective regimen to employ in these circumstances is still controversial.

## **W** 2508 Ocular Medical Devices and Ocular Drug Delivery Systems: Challenges and Opportunities.

J. A. Render. *Toxicology, NAMS, Northwood, OH.*

The eye is a unique organ composed of many different structures working together to facilitate vision. The maintenance of clear vision during aging is threatened by various physiological changes (e.g., presbyopia) or diseases (e.g., age-related macular degeneration). The need for treatments is of increasing importance as the size of the aging population grows. The National Eye Institute predicts that by 2020, more than 50 million Americans will be impacted by age-related eye disease. Some of these conditions have been overcome through the use of medical devices. Ocular medical devices consist of instruments, apparatuses, appliances, and materials. Some devices are purely structural; whereas, other medical devices are a part of a delivery system that releases a drug. The five presentations in this program are designed to educate the audience on the therapeutic, safety, and regulatory challenges of developing ocular medical devices and drug delivery systems. The first presentation will cover the special requirements for developing contact lenses and contact lens solutions. The second presentation will describe the challenges associated with accommodative intraocular lenses (IOLs). The third presentation will discuss the ocular barriers (e.g., blood-eye-barrier) and how ocular medical devices and sustained release drug formulations have been designed to address these barriers with respect to developing protein therapeutics. Development of and regulatory challenges associated with a unique biodegradable small molecule ocular drug/injection applicator delivery system will be discussed in the fourth presentation. The symposium will conclude with a presentation that discusses the safety and regulatory requirements and complexities pertaining to ocular medical devices and ocular drug delivery systems.

## **W** 2509 Assessment of the Ocular Safety of Contact Lenses and Lens Solutions.

M. E. Richardson. *Nonclinical Safety, Bausch & Lomb, Rochester, NY.*

Contact lenses and lens care solutions are typically categorized as medical devices and therefore require biocompatibility testing per ISO standards and regional regulatory guidance documents. Recently evolving Regulatory Body expectations have significantly impacted the number and design of the biocompatibility studies required to clear an ocular medical device for marketing. The current 10993-1 (4th Edition) ISO guideline requires that medical device manufacturers utilize a risk management process as part of the design and implementation of a biological evaluation program for medical devices. ISO 10993-1 also requires that the choice of biocompatibility tests be based on, among other things, the end-use application, and take into account the chemical composition of the device, the conditions of exposure as well as the nature, degree, frequency and cumulative duration of exposure. These ISO requirements, along with those of the regional regulatory expectations, create a significant amount of complexity when designing the

biocompatibility testing strategies for contact lenses and solutions. For example, depending on the type of assay, the tested material may need to be the formulation itself, a lens extract or a lens/formulation combination. Further, it has been demonstrated that the selection of assays and individual study designs can influence the outcome of the study, which could potentially impact product registration. Testing protocols therefore need to be designed to account for the unique chemical and physical properties of the ocular medical device being tested in order to avoid potentially false positive outcomes. Consequently, a rational science-based approach should be used to develop and justify the biocompatibility testing strategy and study designs to ensure that the biological evaluation conducted is appropriate, robust and Regulatory-acceptable. This presentation will highlight some of the key challenges and case studies when conducting biocompatibility evaluations on contact lenses and solutions.

**W 2510 Accommodative Intraocular Lenses: A New Class of IOLs with a New Class of Challenges.**

A. Glasser. *College of Optometry, University of Houston, Houston, TX.* Sponsor: J. Render.

A new class of intraocular lenses (IOLs) is being developed with the goal of restoring the focusing ability of the eye (accommodation) for treating presbyopia (the age-related loss of near focusing ability). Although cataract surgery may be among the safest and most common of surgical procedures, these so called accommodative IOLs (A-IOLs) present new challenges as well as offer new opportunities. A-IOLs differ considerably from standard IOLs in that they are biomechanical devices designed to move or change shape in response to ciliary muscle contraction. A-IOLs are bulkier, made from different materials, may be implanted in different locations in the eye and have mechanisms of action that differ fundamentally from standard IOLs. The surgical procedures required to implant these devices are also more challenging, as they require new surgical devices. In addition, the safety considerations for A-IOLs are different. Pre-clinical animal testing that can be done is limited, complications that can arise are unique, and regulatory hurdles for demonstrating safety and effectiveness are higher. The ultimate success of A-IOLs will rely on solving significant biological challenges that still remain, such as resolving the post-operative healing response of the eye including prevention of post-operative lens epithelial cell proliferation and fibrosis of the lens capsule. This presentation will describe the challenges associated with the development A-IOLs. It will also introduce some future potential applications such as, the possibility of delivering drugs from A-IOLs to solve these biological challenges, as well as other unique surgical and pharmacological interventions aimed at resolving the problem of presbyopia.

**W 2511 Safety Assessment Strategies and Challenges for Developing Intravitreally Administered Biologics.**

E. A. Thackaberry. *Safety Assessment, Genentech, Inc, San Francisco, CA.*

The development of intraocular drugs to treat posterior segment disease, such as age-related macular degeneration, presents both advantages and challenges due to the unique aspects of ocular anatomy and physiology. While drug administration within the eye affords the promise of direct and local delivery, the reduction of systemic exposure and toxicity, and the availability of non-invasive tools allowing for real-time monitoring of the eye, there is an unmet need to reduce intravitreal injection frequency and treatment burden through sustained delivery formulations and devices. Adding to these complexities, developing antibody-based therapeutics presents additional challenges due to their inherent specificity (often limited to primates), which may limit the animal models available for assessing safety. Case studies on the safety assessment strategies and challenges encountered in developing protein therapeutics to the posterior segment of eye will be presented.

**W 2512 Development and Regulatory Considerations for an Ocular Drug Release System for Ocular Disease.**

A. Wiese. *Nonclinical Safety, Allergan, Irvine, CA.*

Delivering drugs to various compartments of the eye presents unique scientific and regulatory challenges. This presentation describes these challenges in the context of the development of Ozurdex®, a bioerodable drug delivery system containing dexamethasone delivered to the posterior segment of the eye. Key to the development of this drug was understanding the drug distribution and its effects in the eye, drug release characteristics and erosion profile of the implant, and evaluation of the toxicological profile of both drug and implant. Additionally, and in parallel, development and testing of the applicator and consideration of drug interactions was ongoing. Regional differences in regulatory agency expectations will be presented. Finally, general learnings and applicability of those learnings to the development of drug delivery systems to various compartments of the eye will be discussed.

**W 2513 Regulatory Considerations in Ocular Medical Device and Drug Delivery Systems Development.**

C. Ghosh. *Center for Drug Evaluation Research, US FDA, Silver Springs, MD.*

Ocular medical devices and drug delivery systems encompass a wide variety of products including solid devices (such as intraocular lenses, surgical instruments and contact lenses) and devices that are liquid-based (such as viscoelastics and contact lens solutions). This presentation will present the classification and regulatory requirements for major categories of ocular medical devices and drug delivery systems and discuss the regulatory decision making and implications pertaining to preclinical and clinical evaluations.

# Notes

A large rectangular area with horizontal ruling lines, intended for taking notes. The area is framed by a dark border on the top and sides, and a decorative floral pattern on the bottom.

# Abstract Keyword Index (Continued)

The numerals following each keyword refer to the relevant abstract number(s).

ARPE-19 .....	1737	bacterial infection .....	2034	Bioindicator .....	1320, 1395	Body-residue based approach .....	1552
Arrhythmia .....	239	baicalin .....	286, 287	Bioinformatics .....	119, 578, 871, 886	body-weight loading .....	1829
Arsenic .....	168, 268, 385, 386, 473, 526, 541, 659, 1115, 1136, 1193, 1206, 1273, 1640, 1643, 1644, 1645, 1646, 1647, 1835, 2225, 2230, 2234, 2278, 2282, 2283, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2315, 2344	<i>Balanites aegyptiaca</i> .....	1305	Biointeractions .....	1761	bone .....	736, 1158, 1302, 1519, 1586, 1864
arsenic (+3 oxidation state) .....		BaP .....	688	biokinetic .....	1514	Bone endpoints .....	1220
methyltransferase .....	2299	Bariatric .....	1493	biokinetics .....	2374	bone marrow .....	1591
Arsenic (Organic arsenicals) .....	2292	Barnett Shale .....	768, 1568	biologic .....	1800	Bone marrow progenitor cells .....	250
arsenic exposure .....	472, 1249	Basic Red 51 .....	1040	Biologic Therapeutic .....	1003, 1803	Bone marrow toxicity .....	1819
Arsenic species .....	2306	Batracylin .....	1221	Biological limit values .....	622	Bone regulating hormones .....	1896
Arsenic toxicity .....	2279	BAX .....	1726	biological modeling .....	613, 624, 879, 885, 1914	bone resorption .....	1589
arsenical .....	2314	Bayesian .....	142	biological monitoring .....	1887	bone toxicity .....	1587
Arsenite .....	2284	Bayesian Network .....	134, 1627	biologically effective dose .....	805	Bone turnover .....	1896
Arsenobetaine .....	2306	BBDR-HPT axis .....	893	Biologicals .....	1815, 2059	BoNT/A .....	676
artificial skin .....	1040	Bcl-2 .....	1730	Bioluminescence .....	100	borate .....	2228
Artificial sweat .....	1496	BCOP .....	976, 977, 979, 981, 982	biomarker .....	25, 28, 29, 528, 800, 915, 925, 928, 929, 933, 934, 936, 937, 943, 953, 1058, 1089, 1265, 1603, 1613, 1614, 1808, 1864, 1875, 1879, 1880, 1883, 1888, 1889, 1892, 1898, 1899, 1901, 1902, 1903, 1910, 2119, 2120, 2122, 2124, 2126, 2191, 2197, 2401, 2402	Boric Acid .....	1021
aryl hydrocarbon receptor .....	171, 326, 323, 333, 392, 525, 612, 883, 1138, 1190, 1271, 1278, 1279, 1280, 1282, 1283, 1287, 1288, 1291, 1716, 2292, 2459	BCRP .....	524, 662	biomarkers ..	276, 591, 658, 801, 926, 935, 945, 1062, 1126, 1143, 1180, 1234, 1460, 1482, 1579, 1651, 1711, 1878, 1882, 1886, 1894, 1895, 1896, 2130, 2175, 2192, 2199, 2325, 2397, 2398	botanical drugs .....	2486
Aryl hydrocarbon receptor (AHR) .....	175, 666, 673, 811, 1281, 1392, 1929, 1994, 2460	BDE-100 .....	1993	biomarker qualification .....	1912	botanicals .....	957, 1796, 1959, 2336
Aryl hydrocarbon Receptor Repressor .....	1039	BDE-154 .....	1733	biomarker translation .....	26	Bovine Corneal Opacity and Permeability Assay .....	978
As3mt .....	2295	BDE-209 .....	559	Biomarkers ..	276, 591, 658, 801, 926, 935, 945, 1062, 1126, 1143, 1180, 1234, 1460, 1482, 1579, 1651, 1711, 1878, 1882, 1886, 1894, 1895, 1896, 2130, 2175, 2192, 2199, 2325, 2397, 2398	BPA .....	1570, 2096
asarone .....	2333	Beagle dog .....	2069, 2417	biomarkers for exposure .....	2437	BPA TBBPA .....	1930
asbestos .....	230, 231, 380, 381, 382, 383, 607, 1255, 1424, 1495, 1735, 2083	Beagle dogs .....	761	Biomarkers of early effects .....	942	BPA-glucuronide .....	485
<i>Aspergillus flavus</i> .....	2317	BEAS-2B .....	609, 687, 1773	Biomarkers of exposure .....	942	BPD .....	2408
assay development .....	99	BEAS-2B cell line .....	428	biomaterials .....	1326	Bradycardia .....	1148
assay kits .....	1269	behavior .....	57, 58, 322, 674, 835, 1023, 1389	biomonitoring .....	805, 1534, 1649, 1883	Brain .....	916, 1382, 1611, 1915, 2478, 2481
Assessment .....	722	behavioral model .....	1657	Biomonitoring Equivalent .....	804	Brain cancer .....	2372
Assessment factor .....	1947	behavioral toxicology .....	2451	Biomonitoring Equivalents .....	1248	Brain morphometry .....	1393
Assessment factors .....	1965	Behavioural Deficits .....	1022	biopersistence .....	819, 1749	brain stimulation reward .....	1658
Asthma .....	263, 416, 425, 438, 467, 475, 1947, 1974, 2384	behentrimonium chloride .....	972	Biosimilar .....	1800	branched DNA assay .....	2171
asthma models .....	219	benchmark dose .....	711, 718, 876, 1946, 1953, 2215, 2217	Biotechnology .....	1547	Brazil .....	1620
Astrocyte .....	918, 1373	benchmark dose analysis .....	705, 709	Biotherapeutics .....	849, 850, 851, 852, 853, 1620	Brcal .....	999
astrocytes .....	776, 1403	Benchmark Dose Model .....	1944	Biotransformation .....	288, 495, 1082, 1083, 1266	BrdU .....	1441
Ataxia .....	1695	Benchmark Dose Modeling .....	2429	Biotransformation/ Cytochrome P450 .....	311	Breast cancer .....	147, 169, 171, 479, 482, 544, 672, 695, 1176, 1296, 2274
Atherosclerosis .....	64, 83, 124, 770, 829, 2101, 2291	Benchmark Response .....	1955	birds .....	325	Bromate .....	615
ATM .....	685, 1695	Benefin .....	104	Birth Cohort Study .....	1249	bromide .....	2233
Atmospheric aging .....	2502	benzene .....	16, 481, 668, 1265, 1944, 2218, 2238, 2474	birth defects .....	477	Brominated Flame Retardant .....	484
atmospheric systems .....	1605	benzene metabolites .....	165	Bismuth .....	1761, 1769, 2385	brominated flame retardants .....	471, 491, 902, 903
atomic absorption spectroscopy .....	226	Benzidine-azo-dye .....	1496	Bismuth derivatives .....	1748	bronchiolitis obliterans .....	209
Atopic dermatitis .....	1314, 1315, 1789	Benzo(a)pyrene .....	306, 328, 331, 542, 618, 942, 1110, 2110	Bisphenol .....	1921	Brown Norway rat .....	728
atopy .....	402	benzo[a]pyrene (BaP) .....	313, 1966, 2189	Bisphenol A .....	1261, 18, 202, 203, 314, 396, 485, 486, 550, 989, 1551, 1830, 1925, 2093, 2106, 2112, 2115, 2117, 2329, 2330, 2331	BSEP .....	37, 1463, 1881
atrazine .....	324, 490, 583, 584, 682, 988, 1408, 1940, 2088	bile acid .....	1059, 1073, 1082, 1083, 1881	Bisphenol A (BPA) .....	329, 807, 2328	<i>Bufo bufo gargarizans Cantor</i> .....	1794
Aurora kinase .....	2176	Bile acid transport .....	881	Bisphenol AF .....	308, 904, 1934	BUN .....	2190
autism .....	745, 1250, 2482	Bile acid transporter .....	1087	Bivalves .....	2342	butyl paraben .....	1481
Autism Spectrum Disorder .....	1374	bile acids .....	1717	black mold .....	399	butyrylcholinesterase .....	368
autoantibodies .....	835	bile salt .....	1075	Bladder .....	2286, 2288	C x t .....	236
Autoimmune .....	379, 418, 536, 1807	biliary hyperplasia .....	631	Bladder cancer .....	188, 1186, 2234	c-Jun N-terminal kinase .....	628
Autoimmune disease .....	1424	biliary toxicity .....	946	bleomycin sulfate .....	743	<i>C. elegans</i> .....	1153, 1157, 1452, 1525, 1846, 1847, 2143, 2148, 2205

# Abstract Keyword Index (Continued)

The numerals following each keyword refer to the relevant abstract number(s).

- mitochondrial modulator ..... 1224  
Mitochondrial Toxicity ..... 1623,  
2022, 2171, 2261  
MitoPark mouse model ..... 729  
Mixture ..... 570, 581, 1566, 2111  
mixtures ..... 42, 43, 560, 574, 577,  
578, 582, 606, 721, 1383, 2134  
Mixtures, Metals ..... 698  
MMP ..... 1910  
Mn in human bone ..... 1179  
Mn-related differentially  
expressed proteins ..... 1861  
mode of action ..... 1969, 42,  
43, 44, 45, 46, 120, 549, 806, 809, 859,  
868, 1091, 1099, 1101, 1562, 1624, 1696,  
2222, 2236, 2270, 2460  
Mode-of-Action ..... 2492  
model ..... 133, 279, 621, 788, 1046  
model evaluation ..... 480  
modeling ..... 611, 708, 720, 1230  
modelling ..... 131  
models ..... 702  
moist snuff consumer ..... 941  
Molecular Docking ..... 321, 2180  
molecular dynamics ..... 2468  
molecular pharmacology ..... 1593  
Molecular Signature ..... 2424  
mollugin ..... 1790, 1791  
monitoring ..... 1568  
monkey ..... 757, 1130, 1223,  
1817, 1890, 1892  
Monoamine ..... 920  
Monoamine transporter ..... 1872  
monoclonal ..... 4  
monoclonal antibody ..... 1801,  
1802, 1803, 1804, 1805, 2107  
monocyte derived macrophage ..... 1751  
mononuclear phagocyte system ..... 819  
Monte Carlo simulation ..... 480  
*Morinda morindoides* ..... 1307  
mortality patterns ..... 717  
motor activity ..... 922  
motor function ..... 1391  
motor neurons ..... 2145  
mouse ..... 620, 1860, 2061, 2367  
Mouse Diversity Panel ..... 716  
mouse embryonic stem cells ..... 2152  
Mouse Epididymides ..... 2129  
mouse liver ..... 642  
mouse lung tumors ..... 457  
mouse lymphoma assay ..... 1486  
mouse model ..... 55, 1401, 1869, 1919  
mouse model of  
human population ..... 2474  
mouse populations ..... 2473  
mouse stem cells ..... 2475  
MPPD modeling ..... 1349  
MRI ..... 907, 993, 1613  
MRI biomarkers ..... 2056  
mRNA ..... 2139  
MRP ..... 1463  
Mrp2 deficiency ..... 2178  
Mrp4 ..... 660, 697  
MRS ..... 907, 908  
MTBE ..... 1457, 2222  
MTF-1 ..... 1188  
mu opioid receptor ..... 1222  
mucosal tissue ..... 2252  
multi-color flow cytometry ..... 2066  
multi-electrode array system ..... 1475  
multi-mycotoxins urinary  
exposure assessment ..... 1883  
multi-wall carbon nanotubes ..... 463  
Multi-walled carbon  
nanotube ..... 432, 457, 1147  
Multi-walled carbon  
nanotubes ..... 20, 441, 471, 817  
Multicase ..... 860, 874  
multigenerational toxicity ..... 950  
multiple myeloma ..... 481  
Multiple Reaction Monitoring ..... 1614  
Multiple Sclerosis ..... 125  
multiplex ..... 1725, 1877  
multipollutants ..... 2502  
Multiwall carbon nanotubes ..... 434  
Multiwalled Carbon  
Nanotubes ..... 433, 453, 462  
munitions ..... 515, 1295  
Murine local lymph node assay ..... 2071  
murine model ..... 398  
MUSST ..... 970  
mutagenesis ..... 1500, 1687  
Mutagenic activity ..... 1505  
mutagenicity ..... 1484, 1503, 1504,  
1508, 1708  
mutagenicity, genotoxicity ..... 839  
Mutation ..... 2446  
mutation assay ..... 1331  
MWCNT ..... 459  
mycotoxin ..... 2326  
mycotoxins ..... 391  
myeloid-derived suppressor cells ..... 461  
myelosuppression ..... 250, 568  
Myoc-estrogen ..... 1923  
Myocardial infarction ..... 1144  
Mytilus edulis ..... 264  
N-acetyl-B-D-  
glucosaminidase (NAG) ..... 2201  
N-Acetyltransferase 1 (NAT1) ..... 293  
N-acetyltransferases ..... 1054  
NAAQS ..... 1567, 1945  
NAC ..... 2263  
NADPH oxidase ..... 772, 1715  
NAFLD ..... 1064, 1065  
nail ..... 1901

A large rectangular area with horizontal ruling lines, intended for taking notes. The area is framed by a dark border at the top and bottom, and a decorative floral pattern on the sides.

# The Official Journal of the Society of Toxicology

## Toxicological Sciences

- *Premier, hypothesis-driven, original research articles in all areas of toxicology*
- *Advance Access—quick online publication, weeks ahead of print*
- *Optional open access for authors*
