# 53<sup>rd</sup> Society of Toxicology Annual Meeting & ToxExpo Phoenix, Arizona

March 23–27, 2014  
Phoenix Convention Center

**Deadline for Proposals  
for SOT 2014  
Annual Meeting  
Sessions: April 30, 2013**

## Why Submit a Proposal?

1. To present new developments in toxicology.
2. To provide attendees an opportunity to learn about state-of-the-art technology and how it applies to toxicological research.
3. To provide attendees an opportunity to learn about the emerging fields and how they apply to toxicology.

## Session Types

**Continuing Education**—Emphasis on quality presentations of generally accepted, established knowledge in toxicology  
*Note: CE courses will be held on Sunday.*

**Symposia**—Cutting-edge science; new areas, concepts, or data

**Workshops**—State-of-the-art knowledge in toxicology

**Roundtables**—Controversial subjects

**Historical Highlights**—Review of an historical body of science that has impacted toxicology

**Informational Sessions**—Scientific planning or membership development

**Education-Career Development Sessions**—Sessions that provide the tools and resources to toxicologists that will enhance their professional and scientific development

**Regional Interest**—Central topics of relevance that describe public health and/or ecological problems of a particular region

Submit your proposal online at [www.toxicology.org](http://www.toxicology.org)

# Preface

**This issue is devoted to the abstracts of the presentations for the Continuing Education courses and scientific sessions of the 52nd Annual Meeting of the Society of Toxicology, held at the Henry B. Gonzalez Convention Center, March 10-14, 2013.**

**An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 536.**

**The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 561.**

**The abstracts are reproduced as accepted by the Scientific Program Committee of the Society of Toxicology and appear in numerical sequence.**

## **The New Mobile Event App**

Use these new planning and networking tools to access the latest meeting information, connect with fellow attendees, build your own schedule, view presentation details and abstracts, request meetings with attendees and exhibitors, and navigate ToxExpo with an interactive floor plan. In addition to these networking and meeting planning tools, use the app and website to access a complete San Antonio city guide including hotels, restaurants, attractions, nightlife, and shopping. One-on-one technology training and support is available during the meeting; visit the @SOT Center—Internet Access and Technology Training just across from Registration at the convention center or the SOT Pavilion in ToxExpo.

**Copies of *The Toxicologist* are available at \$50 each plus \$5 postage and handling (US funds) from:**

**Society of Toxicology  
1821 Michael Faraday Drive, Suite 300 • Reston, VA 20190**

**[www.toxicology.org](http://www.toxicology.org)**

---

This abstract book has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each abstract appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.

## **CE 1 A Refresher of Immunoglobulin and Fc-Receptor Biology and Advances Related to Therapeutic Antibody Development.**

T. W. Salcedo. *Bristol-Myers Squibb Company, New Brunswick, NJ.*

The presentation will review the immunobiology of antibodies and Fc receptors and explore the field of therapeutic antibody development and advances in "antibody engineering" leading to the development of improved therapeutics. A basic overview will be provided on the structure and function of antibodies, as well as the various types and formats of antibody therapeutics and technological methods of production. In addition, the immunobiology of human leukocyte Fc receptors will be discussed. These receptors serve to link humoral immune responses to cellular activities within the immune system, and generally function as either antibody-binding receptors that trigger immune cell effector functions, or as transport receptors (FcRn). Highlights will include how immunoglobulin Fc sequences are now being tailored to trigger specific Fc receptors to improve therapeutic outcomes by introducing amino acid mutations, glycoengineering, or other approaches leading to next generation formats. Known species differences in immunoglobulins and Fc receptors that may be important for pharmacologic and toxicologic evaluations will be explored, as well as other challenges in assessing the nonclinical toxicities of new antibody formats. Building upon these basic themes, the presentation will explore the current landscape of approved therapeutics and forecasts for future developments in the field. The course will provide something for those seeking basic knowledge in the field of immunology and therapeutic antibody development, as well as those seeking to refresh and enhance their knowledge of recent advances.

## **CE 2 Basic Principles of Human Risk Assessment.**

Q. Zhao<sup>1</sup> and M. Meek<sup>2</sup>. <sup>1</sup>US EPA, Cincinnati, OH; <sup>2</sup>University of Ottawa, Ottawa, ON, Canada.

An overview of the fundamental, evolving guiding principles, and general methods used in chemical risk assessment will be provided. These principles and methods are addressed in presentations and discussions organized by the four components identified by the National Research Council in the Risk Assessment Paradigm: Hazard Identification and Characterization; Dose-Response Assessment; Exposure Assessment; and Risk Characterization. Guiding principles and key concepts in risk assessment will be illustrated by examples from the literature and sample calculations for dose-response assessment, exposure assessment, and risk characterization will be presented.

## **CE 3 Recent Developments in Cardiovascular Physiology-Based Toxicology.**

T. L. Knuckles<sup>1</sup> and W. McGuinn<sup>2</sup>. <sup>1</sup>West Virginia University, Morgantown, WV; <sup>2</sup>US FDA-CDER, Columbia, MD.

Contemporary drug development and toxicity assessments are focused on exploiting specific molecular targets that can improve disease outcomes with minimal untoward effects. Unfortunately, modern training in toxicology and pharmacology is directed primarily at specific ligand-receptor interactions at the expense of systems physiology. An overview of cardiovascular physiology, with a thematic focus on toxicology, will be provided. The presentations will include: overall physiological changes that manifest at the whole-animal level following toxicant exposure; in vivo, in vitro and ex vivo cardiac testing protocols in the regulatory environment, and how current testing strategies may potentially miss cardiac effects that manifest chronically; vascular and microvascular effects that result from toxicity initiated in other tissues; and microvascular physiology and toxicology in the context of model development, application, and underlying pathology. The course will be of interest to a broad scope of scientists that are increasingly being requested to consider the impact of novel compounds and toxicants on the physiology of the entire cardiovascular system.

## **CE 4 Approval of Biosimilar Monoclonal Antibodies: Scientific, Regulatory, and Legal Challenges.**

L. LeSauter<sup>2</sup> and J. D. Urban<sup>1</sup>. <sup>1</sup>ToxStrategies, Inc., Austin, TX; <sup>2</sup>Charles River Laboratories, Senneville, QC, Canada.

Technological advances have resulted in the development of a wide range of innovative monoclonal antibodies (mAb). As the patents for these monoclonal antibodies expire, there has been a growing interest in the market of "generic" follow-on

products, or biosimilars. These biosimilar drugs, however, are not generic in the same sense as small molecule drugs since they do not have identical active component(s) as the innovative drug product due to the differences in production. While established standard analytical methodologies enable manufacturers of generic small molecule drugs to demonstrate pharmaceutical equivalence, the complex and sensitive nature of even the most similar biological manufacturing systems (e.g., commercial cell lines) makes producing identical copies of the innovative monoclonal antibody products impossible. Therefore, the scientific and regulatory paradigm for demonstrating that the products are highly similar and that there are no clinically meaningful differences between a biosimilar product and an innovative therapeutic in order to obtain drug approval is necessarily much more complex. Adding to this complexity is the regulatory environment that impacts on the biosimilar approval process. Case studies will compare and contrast the scientific and regulatory approaches used for mAb biosimilar drug development. These examples will cover the GMP to clinical strategies in broad scope but focus on the preclinical breadth of studies conducted based on the extent of GMP and clinical similarity data available. Within these presentations the scientific rationale for similarity with the innovator drug will be highlighted. The basic concepts of the legal challenges and recent Biologics Price Competition and Innovation Act (BPCIA), which creates an abbreviated approval framework for biological products that are demonstrated to be "biosimilar" to or "interchangeable" with a US FDA-licensed biological product, along with the role the patent and data exclusivity provisions will play in biosimilar drug development, will also be discussed.

## **CE 5 The What, When, and How of Nonclinical Support for an IND Submission.**

P. Nugent<sup>1</sup> and D. Colagiovanni<sup>2</sup>. <sup>1</sup>Pfizer Worldwide Research and Development, Groton, CT; <sup>2</sup>N30 Pharmaceuticals, LLC, Boulder, CO.

The initiation of dosing of human subjects in a Phase 1 clinical trial represents the culmination of years of drug development, and immediately preceding the start of dosing, months of work to prepare and submit the Investigational New Drug (IND) application (or Clinical Trial Application (CTA)). A critical part of the submission dossier is the sections that describe the nonclinical data and interpretation that underwrite the clinical plan; specifically, the results of studies in pharmacology, pharmacokinetics, and toxicology, and their integration into a coherent argument that justifies the clinical starting dose, escalation of dose, and "stopping criteria" to be used in the clinical trial. The objective of the course is to elucidate the path to a successful IND/CTA submission by outlining what needs to be done (concentrating principally on the toxicology and safety pharmacology studies), the timeline and order of activities, and the presentation of the data and its integration into a coherent risk assessment to support introduction of the investigational compound into the clinic. The focus will be the content of the Nonclinical Overview (NCO), which represents an integrated detailed summary of the nonclinical studies conducted to support the clinical plan for first-in-human (FIH) dosing. The course will address the expectations of the two main "customers" for the NCO: the FDA pharmacology/toxicology reviewer evaluating the data to determine if it supports the safety considerations of the clinical plan, and the clinician designing the clinical protocol and conducting the FIH trial.

## **CE 6 The Practice and Implementation of Neural Stem Cell-Based Approaches to Neurotoxicology.**

T. J. Shafer<sup>1</sup> and A. B. Bowman<sup>2</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>Vanderbilt University Medical Center, Nashville, TN.

The availability and use of human pluripotent stem cells (hPSC) and human neural stem cells (hNSC) for toxicology has dramatically increased in the past decade. hNSC are powerful tools for toxicologists and can provide tissue that would otherwise be unobtainable. This includes a renewable source of neural tissue from the same genetic stock that is not transformed or derived from a tumor, a source of normal human nervous system tissue, and sources of nervous system tissue from patients with clinical disease. However, culture and differentiation of hNSC are unique from culture of primary or transformed neural tissue. The course will bring together experts in the culture of various types of neural stem cells, including embryonic human derived neural stem cells, neurospheres, and neural cells derived from hPSC. Each expert will discuss the basic approaches to culturing different types of hNSC, including propagation of the cells in a progenitor status, as well as protocols for differentiation of the cells into different types of neurons. Pitfalls that are both common to the different models as well as unique ones will be described. The goal of the course is to provide the student with knowledge regarding different types of neural stem cell cultures, the techniques to successfully culture and differentiate these models, and application of these model systems to neurotoxicology. The course will conclude with an examination of appropriate outcome measures and discuss the possibility of personalized neurotoxicological assessment.

## CE 7 Toxic Effects of Metals.

M. F. Hughes<sup>2</sup> and M. P. Waalkes<sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC; <sup>2</sup>US EPA, Research Triangle Park, NC.

Human exposures to metals are a daily occurrence because of their natural presence in the environment—their uses in production of many commercial products—are byproducts of energy production and are found in many hazardous waste sites. The objective of the course is to highlight the fundamentals of metals toxicology. Metals have unique chemical and physical properties that distinguish them from organic-based chemicals. Even though some metals are essential to life, overexposure to these and other metals may result in a toxic effect in one or more organ systems. Upon exposure, metals may be absorbed, distributed throughout the systemic circulation, metabolized, and eliminated. The response of an organism following exposure to metals may be protective (e.g., induction of the metal-binding protein metallothionein), or toxicological by several mechanisms including oxidative stress. Key organ systems such as the central nervous system, the vascular system, as well as the skeleton system are affected by metals including manganese, lead, aluminum, and others. Accumulation of metals in bone has recently gained renewed interest as an eventual source of internal exposure. Noninvasive methods such as neutron activation are now being used to quantitate bone metal levels. Metals can influence gene expression, signal transduction, and epigenetics. Various toxic and carcinogenic metals such as arsenic and chromium alter the epigenetic program in cells; these effects on DNA methylation, histone tail modifications, and microRNA may be involved in metal-induced toxicity. Metals are known to cause cancer by several proposed mechanisms, including oxidative stress and the cancer stem cell hypothesis. Recent evidence suggests that developmental exposure to metals may affect stem cell population dynamics, which could result in adult onset of cancer. Overall, this is intended to be a basic course on metals toxicology, and is ideal to those who desire knowledge on the health effects of metals and useful tools used in metals toxicology research.

## CE 8 Advances in Nanotoxicology—Challenges.

S. M. Hussain<sup>1</sup> and S. F. Ali<sup>2</sup>. <sup>1</sup>US Air Force, Wright-Patterson AFB, OH; <sup>2</sup>US FDA-NCTR, Jefferson, AR.

Recent developments in nanotechnology have generated a degree of apprehension concerning the potential risk to human health and the environment from manufactured nanomaterials (MN). The unique chemical and physical properties of MN, coupled with their high surface area per unit mass, require an extensive suite of characterization tools to effectively assess the toxicity of MN. Not only must the size and surface area of the MN be characterized prior to cellular exposure, but also a number of other specific features must be additionally evaluated, such as the size distribution, chemical composition, crystallinity, surface structure, shape, and solubility. The ionic strength of biological fluids may produce MN instability, resulting in environmental-specific aggregation tendencies that may impact toxicological results. Since aggregation of MN can modify uptake rates, transport properties, and clearance by the cell model or organ system, it is critical to interpret the data from MN toxicity experiments with a detailed knowledge of the physicochemical properties of the MN at all experimental time points. Due to the lack of standardized methods to determine the physicochemical behavior of MN in biological systems, the mechanisms and nature of acute or chronic toxicity of engineered MN cannot be fully understood at this time. An understanding of a proper manner by which MN should be introduced to a biological environment has yet to be established, and consistency between cellular assay techniques has not been verified—both situations presenting clear challenges that must be addressed. This course raises issues to consider for the toxicity assessment of MN, and addresses recent advances and technical obstructions associated with conducting or interpreting *in vitro* or *in vivo* toxicity studies. The goal is to provide a comprehensive understanding of MN characterization, as well as facilitate valuable discussions of key challenges and advancements in the newly emerging field of nanotoxicology.

## CE 9 Gonadal Development, Function, and Toxicology.

B. McIntyre<sup>1</sup> and J. A. Flaws<sup>2</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC; <sup>2</sup>University of Illinois Urbana-Champaign, Urbana, IL.

The course objectives are to provide the basic tools for toxicologists who desire a better understanding of how to assess the effects of toxicants on the male and female gonads from development through adulthood. A focus on reproductive biology, study design considerations, reproductive endpoints, data interpretation, and

use of data in risk assessment will be highlighted. Reproductive toxicity studies are among the most complex and challenging studies in the field of toxicology. The studies assess multiple interrelated endpoints of male and female reproductive development and function. To properly design, conduct, and interpret these studies, a fundamental knowledge of male and female gonadal development, anatomy, physiology, and endocrinology are required. Individual lectures will discuss the anatomy and physiology of the male and female gonads, as well as endocrine regulation of these systems. Evaluation of toxicity endpoints to assess male and female reproductive function will also be discussed, including folliculogenesis, spermatogenesis, hormone analysis, cyclicity, fertility, histopathology, and proper use of statistical analysis. The regulatory expectations related to reproductive toxicity testing, interpretation of results, and how these results are ultimately used to assess potential risks to human reproduction, will be presented. The course will conclude with methodologies for *in vitro* reproductive toxicity assessments for screening and investigation of mode of action. In summary, key information required for the design of reproductive toxicity studies and interpretation of reproductive toxicity data, and provide guidance for use of the data for risk assessment of reproduction, will be presented.

## CE 10 The Reach Regulation and Safety Assessment Approaches for Chemicals That Come in Contact with the Skin.

J. Mortensen<sup>1</sup> and J. Heylings<sup>2</sup>. <sup>1</sup>CiToxLAB Scantox, Lille Skensved, Denmark; <sup>2</sup>Dermal Technology Laboratory Ltd., Keele University Science Park, United Kingdom.

REACH (Registration, Evaluation, Authorization, and Restriction of Chemical substances) is the European Union regulation on chemicals and their safe use, which came into force on June 1, 2007. The aim of REACH is to improve the protection of human health and the environment through better and earlier identification of the intrinsic properties of chemical substances. REACH places greater responsibility on the industry to manage the risks from chemicals, and to provide safety information on their substances. The regulation will come gradually into force in the period up to 2018. Under REACH, 30-40,000 new and existing chemicals will have to be (re)classified and registered. The regulation requires companies to conduct risk assessment and safety classification, with a minimal use of experimental animals, and to share information via databases managed by the European Chemicals Agency (ECHA). The skin (together with the respiratory system) is important as a route of chemical exposure, and as a target organ for toxicity induced by chemicals. Since under REACH so many chemicals need to be evaluated, it is important to use and develop testing methods that reliably predict human exposure and safety, while minimizing the use of experimental animals. An overview of the REACH regulation, and its practical implications for toxicological safety evaluation of chemicals marketed in Europe, will be given. Efforts to develop new methods and validation status of alternative methods that will limit the number of experimental animals to be used will be highlighted. Specifically, state-of-the-art investigational methods within dermal toxicology will be discussed since the skin is very important, both as a barrier to exposure and as a target organ. Practical examples of the use of the collected dermal safety data in the risk assessment of chemicals under REACH will be presented.

## CE 11 T4: Tools and Technologies in Translational Toxicology.

D. L. Mendrick<sup>2</sup> and V. S. Vaidya<sup>1</sup>. <sup>1</sup>Harvard Medical School, Boston, MA; <sup>2</sup>US FDA-NCTR, Jefferson, AR.

The last decade has seen revolutionary advances in the tools and technologies available for biomedical scientists such that researchers can now conduct transformative experiments to solve unmet medical needs moving from a single cell to whole organism, and vice versa. Novel tools and innovative technologies have facilitated the development of sophisticated molecular diagnostics, enabled the use of new approaches in safety evaluation and risk assessment, and led to the development of targeted therapeutics. The development and utilization of novel technologies and tools requires interaction between scientists of differing backgrounds and talents (e.g., biologists, chemists and programmers). Only with this shared effort can medicine transform itself to meet the needs of the 21st century. The panel of experts will decode and demystify the potential of these translational and transformative technologies over a wide variety of applications, including safety/efficacy screening of compounds, imaging, 'omics, and *in silico* modeling. The key goals are to enable you to understand how recent advances in "T4": 1) help in solving important problems that have been critical barriers to progress in the field and, 2) transform the field by generating foundational resources that will be widely used throughout biomedical science for safety evaluation and risk assessment.

## **CE** 12 Understanding Toxic Neuropathy in Drug Development: Both Clinical and Nonclinical Perspectives.

M. Kallman<sup>1</sup> and J. Benitez<sup>2</sup>. <sup>1</sup>Covance Research Laboratories, Greenfield, IN; <sup>2</sup>Vanderbilt University, Nashville, TN.

The topic of risk assessment of peripheral neuropathies is timely due to the increased clinical incidence of challenges related to multiple antecedents for the clinical presentation of neuropathies. The integration of both nonclinical and clinical dialogue on peripheral neuropathies will provide greater possibilities for successful drug development and improved patient outcomes. Peripheral nervous system toxicity is a common complication of exposure to industrial chemicals and drugs such as chemotherapeutics. Neuropathy can be caused by either limited or long-term exposure to drugs or chemicals, and toxic neuropathies can be classified by their presentation (e.g. motor vs. sensory), their electrodiagnostic features or their neuroanatomical location within the peripheral nerve. Identification of toxic neuropathology prior to human exposure in the drug development process requires a multidisciplinary approach. Presentations will include information on the preclinical and clinical syndromes that have been characterized and the specific techniques for assessment. The preclinical presenters will focus on the application of preclinical data to provide risk assessment and to direct clinical assessment possibilities. The clinical presenters will emphasize the clinical situation and current treatment approaches. The course will conclude with open discussion between the presenters and the audience about opportunities for future risk assessment and the application to clinical management.

## **CE** 13 Weighing in on Nutrition—Essential Concepts for Toxicologists.

D. M. Wilson<sup>1</sup> and A. L. Slitt<sup>2</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>University of Rhode Island, Kingston, RI.

There has been an exponential increase in the attention focused on the potential role of nutrition in reducing the risk for numerous health complications, ranging from birth defects to age-associated vascular disease. Underscoring the above is the increasing number of presentations and publications related to this subject, and hallmarks such as the recently revamped Food Pyramid into a Plate Icon. Chronic nutritional diseases are accepted to be a current crisis in our society; three nutrition-related diseases alone, obesity, Metabolic Syndrome, and Type 2 Diabetes, afflict over one-third of the American population. To better understand the components and etiology of nutritional diseases, it's essential for toxicologists to be well versed in the science of nutrition. A comprehensive understanding of nutrition has broad applications in toxicology, especially considering that many of us have roles in investigating the safety of nutrients, food additives or food ingredients, studying nutritional disease, or designing and interpreting preclinical or clinical studies wherein the need to consider and understand nutritional homeostasis is essential. The potential for intersection of normal nutritional metabolic pathways with adverse outcome pathways is becoming even more important to delineate. This course on general nutrition, the biochemistry of nutritional pathways, the essential role of vitamins, the channeling of nutrients such as carbohydrates, proteins and fats, cellular and molecular details of nutrition, and nutritional aspects of development and reproduction, will heighten awareness of their importance in human and animal health at multiple levels. The focus will be on relevant information, starting with an introduction to nutrition, followed by a review of biochemical and metabolic reactions in nutrition, with an emphasis on their relation to toxicology. How the nutritional status of a woman can modulate the developmental toxicity of a number of diverse toxicants, including alcohol, will be presented.

## **S** 14 Genetic and Epigenetic Determinants of Susceptibility to Environmental and Occupational Toxicants.

V. J. Johnson<sup>1</sup> and B. Yucesoy<sup>2</sup>. <sup>1</sup>BRT-Burleson Research Technologies, Morrisville, NC; <sup>2</sup>Toxicology and Molecular Biology Branch, NIOSH/CDC, Morgantown, WV.

The most common chronic disorders are multifactorial in nature, influenced by complex sequences of gene-gene and gene-environment interactions. While gene expression is a dynamic process that varies in response to a myriad of internal and external triggers and the surrounding microenvironment, the epigenetic mechanisms play a key role in mediating environmental influences on gene expression and epistatic interactions. In this respect, the expression of complex phenotypes should be assessed in a functional context that would look at the interplay between environmental, genetic, and epigenetic factors. Recent advances in genetic and epigenetic research offer new opportunities to integrate experimental approaches, including animal models and *in vitro/in vivo* translational research, with

computational strategies to predict such interactions at multiple levels of complexity. The focus of this session will be on current research investigating the role of genetic factors, epigenetic factors, and gene-environment interactions in the development and outcomes of complex diseases caused by environmental and occupational toxicants.

## **S** 15 Genetic Susceptibility to Occupational and Environmental Exposures.

D. C. Christiani. School of Public Health, Harvard Medical School, Boston, MA.

Due to their high prevalence in the general population, genetic polymorphisms in the susceptibility genes may predispose community members exposed to toxicants. Studies in genetic susceptibilities can eventually provide the following benefits: (1) to provide mechanistic insight of the etiology of disease; (2) to identify the more susceptible subpopulations with respect to exposure; (3) to provide valuable input in setting exposure limits by taking into account individual susceptibility. Research in this area has provided promising insights to occupational medicine, such as those illustrated by the NAT2 polymorphisms-aniline dyes and bladder cancer, and the HLA-DPB1Glu69 in chronic beryllium disease, a hypersensitivity-mediated inflammatory disorder. Nonetheless, even for the genetic susceptibility markers that have been shown scientifically to have a clear role in disease risk, the value of wide-scale genetic screening in occupational settings remains limited. In the general environmental setting, there are limited, but growing data on the role of common gene polymorphisms in predisposing children and adults to inflammation-related respiratory disorders induced by air pollution, and to heavy metal toxicity. The purpose of this presentation is to discuss state of knowledge with regard to gene variants interacting with environmental exposures in causing cancer and inflammatory disorders.

## **S** 16 Toxicogenomic and Systems Biology Approaches in the Understanding of Toxicity and Leukemogenesis Induced by Benzene.

C. McHale<sup>1</sup>, L. Zhang<sup>1</sup>, Q. Lan<sup>2</sup>, R. Thomas<sup>1</sup>, A. E. Hubbard<sup>1</sup>, R. Vermeulen<sup>3</sup>, G. Li<sup>4</sup>, S. M. Rappaport<sup>1</sup>, S. Yin<sup>4</sup>, M. T. Smith<sup>1</sup> and N. Rothman<sup>2</sup>. <sup>1</sup>School of Public Health, University of California Berkeley, Berkeley, CA; <sup>2</sup>Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; <sup>3</sup>Institute of Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands; <sup>4</sup>Institute of Occupational Health and Poison Control, Chinese Center for Disease Control and Prevention, Beijing, China.

Benzene is an established cause of acute myeloid leukemia (AML) and may cause one or more lymphoid malignancies in humans. Occupational exposure to benzene, even at levels below the current U.S. occupational standard of 1 ppm, causes hematotoxicity. Toxicogenomics (e.g. genomics, transcriptomics and epigenomics) and systems biology (study of the interactions among toxicogenomic endpoints using bioinformatics) approaches in human populations, animals, and *in vitro* models, exposed to a range of benzene levels, are key to understanding gene-environment interactions in benzene toxicity and can identify biomarkers of exposure, early effect and susceptibility. Through analysis of the peripheral blood mononuclear cell (PBMC) transcriptomes of 125 workers exposed to a wide range of benzene levels, we recently reported highly significant widespread perturbation of gene expression at all exposure levels, as well as alterations in AML and immune response pathways. Sequencing of the PBMC transcriptomes from a subset of the study subjects revealed additional alterations in gene expression. From preliminary epigenomic data in the human subjects, we have identified benzene-induced alterations in the DNA methylome and miRNome. Using genomic screens in yeast, with subsequent confirmation in human cells, we have identified potential biomarkers of susceptibility. We are developing bioinformatic methods to integrate these and future toxicogenomic datasets, in a systems biology approach, to further understand pathways of benzene toxicity and to reveal potential biomarkers associated with a range of exposures.

Supported by NIH grant P42ES04705.

## **S** 17 Integrated Genetic and Genomic Approaches to Understand Susceptibility to Toxicant-Induced Lung Disease.

S. R. Kleeberger. Laboratory of Respiratory Biology, NIEHS, Research Triangle Park, NC. Sponsor: V. Johnson.

Genetic background has an important role in susceptibility to complex lung diseases, and the genetic contribution to disease phenotypes varies between populations. Understanding the mechanisms of interactions between genetic background

and exposures to environmental stimuli are critical to disease prevention. Animal models, particularly inbred mice, provide important insight to understand human disease etiologies because genetic background and environmental exposures can be controlled. Tools including *in silico* haplotyping, collaborative cross and diversity outcross mouse panels, bioinformatic applications, and -omics technologies have enhanced our ability to identify disease genes and pathways to guide translational investigations that apply these discoveries to human populations. Combined genetic and genomic approaches have yielded important insight to mechanisms of susceptibility to many complex traits and diseases. We have integrated inbred mouse and cell-based models with haplotype association mapping (genetic), global gene expression analyses (genomic), and expression quantitative trait locus mapping (eQTL or genetical genomics) to identify candidate susceptibility genes and associated gene networks important in toxicant-induced lung injury. The overarching goal of these investigations is to determine whether human homologues of these susceptibility genes associate with disease risk in human populations. Efforts to identify and validate susceptibility genes in mouse models of environmental disease with a goal towards translational application have enabled identification of individuals who are susceptible to disease. For example, epidemiological and clinical investigations have associated functional polymorphisms in human *NRF2* (NF-E2 related factor 2) and *TNF* (tumor necrosis factor alpha) with susceptibility to acute lung injury and ozone-induced changes in lung function, respectively. Importantly, these discoveries may also lead to novel intervention or therapeutic strategies to prevent disease.

## **S 18 Developmental Exposure to Bisphenol A and Lead: Effects on Metabolic Homeostasis and the Epigenome.**

D. Dolinoy. *University of Michigan, Ann Arbor, MI.*

Environmental exposures during early development and other critical life stages may induce changes to the epigenome resulting in potentially deleterious phenotypic effects including metabolic disease, cancer, and neurological disorders. The field of epigenetics is experiencing a rapid advancement in technology, methodology, and data acquisition that now allows for the identification of the constellation of genomic loci with altered epigenetic status following dose-dependent exposures. Thus, epigenomic profiling facilitates the identification of biomarkers of exposure, enabling clinicians to identify at-risk individuals prior to disease onset. Utilizing a multi-pronged approach with an *in vivo* mouse model, human clinical samples, and an ongoing 15-year longitudinal epidemiological study, the overall goal of this presentation is to elucidate the impact of perinatal bisphenol A (BPA) and lead (Pb) exposure on metabolic homeostasis and DNA methylation, and the interplay between the two. Developmental exposure to environmentally relevant levels of BPA has been shown to affect both global and gene-specific DNA methylation patterns in rodents. We now draw upon data from multiple whole-genome platforms to show that multiple dose levels of BPA affect DNA methylation in mice and humans and that these epigenetic effects are non-monotonic in dose response. Preliminary studies also indicate that Pb exhibits epigenetic effects that may contribute to its known neurotoxic and obesogenic activities.

## **S 19 Predictive Toxicology Paradigms for Understanding Carbon Nanotube Toxicity in the Lung.**

J. C. Bonner<sup>1</sup>, A. Nel<sup>2</sup>, D. W. Porter<sup>3</sup>, V. Castranova<sup>3</sup> and K. E. Pinkerton<sup>4</sup>.  
<sup>1</sup>NCSU, Raleigh, NC; <sup>2</sup>UCLA, Los Angeles, CA; <sup>3</sup>NIOSH, Morgantown, WV; <sup>4</sup>UC Davis, Davis, CA.

Nanotechnology is rapidly developing, resulting in the production of a variety of engineered nanoparticles. Carbon nanotubes (CNTs) represent an important family of nanoparticles because they have many potential uses in engineering, electronics, and medicine due to their ease of functionalization, unusual strength, and electrical conductivity. However, these novel nanostructures also represent a potential human health risk, due to the possibility of inhalation exposure and evidence that the lung and cardiovascular systems are targets for hazardous effects. Inhalation studies in rodents show that CNTs deposit within the distal regions in the lungs and migrate to the pleura to cause inflammatory and/or fibrotic effects. Presentations in this session are aimed at elucidating the pulmonary and cardiovascular effects of CNTs, and how an increasing variety of functionalized CNTs can be evaluated via high-content screening. Because functionalized CNTs vary in toxicological activity, we will address high-content screening for the development of structure-activity relationships relevant to inhalation toxicity and safer design of nanoparticles. This will include exploration of factors that mediate toxic effects such as high aspect ratio, durability, and residual metal content and discuss how removing metal catalysts or changing surface properties alters the pattern and timing of toxicity. While the lung is a major target organ, another goal is to determine the potential for inhaled CNTs to have toxic effects that reach beyond the lung to influence the cardiovascular system. Finally, we will discuss how susceptibility factors,

both genetic and environmental, determine pulmonary and cardiovascular toxicity to CNTs. The outcome of this session is to gain a better understanding of the structure-activity relationships, target organs, and susceptibility factors that will aid the development of predictive toxicology paradigms for understanding CNT toxicity.

## **S 20 Time Course of Pulmonary Responses to Inhaled Multiwalled Carbon Nanotubes.**

D. W. Porter<sup>1</sup>, A. F. Hubbs<sup>1</sup>, R. R. Mercer<sup>1</sup>, N. Wu<sup>2</sup>, W. McKinney<sup>1</sup>, B. T. Chen<sup>1</sup>, M. G. Wolfarth<sup>1</sup>, L. A. Battelli<sup>1</sup>, J. F. Scabilloni<sup>1</sup>, D. Schwegler-Berry<sup>1</sup>, S. Friend<sup>1</sup>, S. Tsuruoka<sup>3</sup>, M. Endo<sup>3</sup>, D. Frazer<sup>1</sup> and V. Castranova<sup>1</sup>.  
<sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>Department of Mechanical & Aerospace Engineering, West Virginia University, Morgantown, WV; <sup>3</sup>Research Center for Exotic Nanocarbons, Shinshu University, Nagano, Japan.

In the present study, an aerosol of multi-walled carbon nanotubes (MWCNT) was produced with an acoustical generator, and airborne concentration and size distribution was determined. Mice were exposed by whole body inhalation to MWCNT (5 mg/m<sup>3</sup>, 5 hours/day, 12 days) and pulmonary responses were monitored at 1 day, 2, 4, 12, 24 and 48 weeks post-exposure. Pulmonary responses were investigated using whole lung lavage, histopathology, morphometry, and enhanced darkfield light microscopy studies. MWCNT lung burden was also measured to assess MWCNT clearance. Data indicate that the lung burdens of MWCNT in this study represent lung burdens relevant to estimated human occupational exposures and caused time-dependent pulmonary inflammation, damage and pulmonary fibrosis. Using enhanced darkfield microscopy, MWCNT fibers were found in lavage of the pleural space, parietal pleura, and respiratory muscles of the diaphragm and chest wall. The time course of pulmonary responses and their relationship to MWCNT lung burden and clearance will be discussed.

## **S 21 Establishment of Carbon Nanotube Structure-Activity Relationships (SARs) That Can Be Used to Understand Pulmonary Toxicity and Safer Design.**

A. Nel. *UCLA, Los Angeles, CA.*

There is a fundamental gap in understanding how the physicochemical properties of carbon nanotubes (CNTs) contribute to hazard generation in the lung. Without this knowledge, it is difficult to evaluate CNT safety in a predictive manner. Our goal is to develop a predictive toxicological paradigm for CNT safety assessment in which we define the structure-activity relationships (SARs) leading to hazard generation at the nano/bio interface, including ways to design safer materials that do not induce chronic inflammation and fibrosis. To achieve this goal, we are developing a series of single-wall and multi-wall CNT test materials that can be screened by robust cellular assays to perform hazard ranking and SAR analysis. We are looking at the role of CNT dimensions (including length, diameter and aspect ratio), dispersability, catalytic surface chemistry, electronic properties and purity in initiating cooperative cellular interactions in macrophages and cells of the epithelial-mesenchymal trophic (EMT), which are involved in the pathogenesis of pulmonary inflammation and fibrosis. The above physicochemical characteristics impact the lysosomal stability in macrophages in a hierarchical fashion, leading to cathepsin B release and assembly of the subunits of the NALP3 inflammasome. This leads to IL-1 beta release, which primes the EMT unit and initiates a march of events leading to TGF-beta and PDGF production and subsequent induction of chronic inflammation and fibrosis in the lung. Utilizing myeloid and epithelial cell lines, it is possible to study the induction of these biomarkers in relation to the property variations of the CNT materials, predicting the SARs that are associated with pulmonary inflammation and fibrosis. Moreover, we have also implemented surface coating and functionalization approaches that can change the hazardous characteristics, leading to the design of safer CNTs. The overall utility of this research exploration is to establish a predictive and quantitative toxicological paradigm for the safety assessment of CNTs and their safe implementation in the marketplace.

## **S 22 Surface and Chemical Modification of Single-Walled Carbon Nanotubes Does Not Necessarily Create a Safer Nanomaterial.**

K. E. Pinkerton. *University of California Davis, Davis, CA.*

We hypothesized iron (Fe) content and morphology of inhaled single-walled carbon nanotubes (SWCNTs) would influence the extent of cellular injury and alters homeostasis in the lung. Rats (SD) were exposed (1 mg/m<sup>3</sup>) to either aerosolized

SWCNTs (raw FeSWCNT or purified cSWCNT), carbon black (CB), crocidolite asbestos, or fresh air via nose-only inhalation for 6 hr/d for 10 d. SWCNTs containing varied amounts of iron. Depending on the endpoint of interest, pulmonary responses of SWCNTs sometimes followed that of CB while in other circumstances matched that of crocidolite. Notably, animals exposed to FeSWCNTs were unable to respond to an additional oxidant challenge and cSWCNTs exposed animals had a latent and persistent development of mucous cells in the distal airways. In summary, while some toxicity endpoints follow patterns comparable to CB or crocidolite, the respiratory effects of inhaled FeSWCNTs and cSWCNTs appear to be unique. These changes could be suggestive of precursor events to pathologic changes that could develop under more prolonged exposure conditions.

## **S 23 Cardiovascular Responses to Pulmonary Inhalation of Nanoparticles.**

*V. Castranova. Pathology & Physiology Research Branch, NIOSH, Morgantown, WV.*

Pulmonary exposure to various nanoparticles has been reported to cause lung inflammation and in some cases fibrosis. This presentation describes cardiovascular responses which occur following inhalation of titanium dioxide nanospheres or multi-walled carbon nanotubes in rats. Pulmonary exposure to nano titanium dioxide inhibits the ability of systemic and coronary arterioles to respond normally to dilators and affects heart rate and blood pressure in response to adrenergic agonists 24 hours post-exposure. This microvascular dysfunction is associated with adherence of polymorphonuclear leukocytes and generation of reactive species at the vessel walls, and resultant scavenging of nitric oxide secreted from dilator-stimulated endothelial cells. Neutrophil depletion or antioxidants partially reverse this vascular dysfunction. There also appears to be a neurogenic component to these cardiovascular changes, since inhibition of pulmonary sensory neurons or neuronal input to the arteriolar smooth muscle partially reverses these effects. Inhalation of multi-walled carbon nanotubes also inhibits coronary arterial responsiveness to dilators. This dysfunction occurs 24 hours after exposure and declines over several days thereafter. Human relevance of these rat data will be discussed.

## **S 24 Genetic and Environmental Factors That Determine Susceptibility to Inhaled Carbon Nanotubes.**

*J. C. Bonner. Toxicology, NC State University, Raleigh, NC.*

While studies with rodents suggest that inhaled carbon nanotubes could represent a human health risk for the development of pulmonary diseases, it is likely that individuals with pre-existing disease or those with specific genetic deficiency would be most susceptible to exposure and lung injury. The goal of this presentation is to emphasize genetic and environmental factors that determine susceptibility to inflammatory, immune, and fibroproliferative responses in the lungs of mice exposed to carbon nanotubes. Evidence will be presented showing that pre-existing non-allergic lung inflammation induced by bacterial lipopolysaccharide (LPS) or allergic airway disease induced by ovalbumin sensitization alters the immune response and fibroproliferative effects of carbon nanotubes as well as modulates other aspects of airway remodeling such as inflammatory cell infiltration and mucus hypersecretion. In addition, transgenic mouse studies show that susceptibility or resistance to carbon nanotubes is determined by the relative abundance or expression of specific genes that encode transcription factors involved in the innate immune response. Finally, the consequence of enhancing the physical or chemical properties of carbon nanotubes by atomic layer deposition will be addressed to better understand how post-synthesis engineering affects toxicity and disease pathogenesis.

## **S 25 Translatable Indicators of Testicular Toxicity: Inhibin B, microRNAs, and Sperm Signatures.**

*K. Boekelheide<sup>1</sup>, B. McIntyre<sup>3</sup>, M. Coulson<sup>4</sup> and R. E. Chapin<sup>2</sup>. <sup>1</sup>Brown University, Providence, RI; <sup>2</sup>Pfizer Drug Safety, DART Group, Groton, CT; <sup>3</sup>National Toxicology Program, NIEHS, NIH, Research Triangle Park, NC; <sup>4</sup>AstraZeneca R&D, Alderley Park, United Kingdom.*

The typical endpoints used in preclinical animal models for reproductive toxicity testing, such as histopathology, are not translatable for human clinical assessment, which typically focuses on the analyses of semen and serum hormones. Therefore, when testicular toxicity arises in preclinical toxicity testing, the methods currently

available to monitor this liability in clinical trials are limited. Because of these limitations, there is a need to develop sensitive and translatable indicators that reliably reflect testicular function. In this symposium, an introductory talk will set the stage by describing testicular physiology, preclinical tests of male reproductive toxicity, and current methods for assessing testicular function in men in clinical trials. The following three talks will discuss currently active efforts to develop improved translatable indicators of testicular toxicity in men. Serum inhibin B is a product of the testicular Sertoli cell and levels fall in response to testicular injury. Testis-specific miRNAs may be released upon testicular injury, and their measurement in serum may be a measure of effect. Sperm mRNA transcripts and DNA methylation may be indicators of testicular toxicity because they are easily measured and persistently altered after testicular injury. Developing reliable and predictive translatable indicators of testicular toxicity would be valuable for drug development in the pharmaceutical industry, and for monitoring men in occupational settings where exposure to potential testicular toxicants is a concern.

## **S 26 Biomarkers of Testicular Injury: Where Have We Been.**

*B. McIntyre. NIEHS/NIH, Research Triangle Park, NC.*

Toxicological findings in the male reproductive system are one of the most challenging events to put into perspective during nonclinical drug toxicity testing. These findings in animal models often consist of adverse changes in testicular histopathology and decreases in male fertility. Understanding the toxicological relevance of these findings to men enrolled in clinical trials is necessary for patient safety and is often paramount for continued development of the drug candidate. The mammalian testis is a complex tissue consisting specialized cell types that support spermatogenesis and reproduction. Although rodents, canines and non-human primates exhibit anatomical and physiological similarities, there are distinct differences that make extrapolation to human males challenging. Historically, alterations in non-invasive biomarkers such as hormone levels (e.g. testosterone and follicle stimulating hormone) and semen parameters (motility, morphology, count) have been used as indicators of altered testicular function. However, these changes are often insensitive and may require significant and potentially irreversible damage to the testes before biologically significant alterations in levels are evident in either animal models or humans. This has led to pragmatic nonclinical approaches where the pathogenesis of testicular toxicity is characterized with respect to both the potential for recovery/reversibility, and the margin of safety between the preclinical toxic exposure and the expected clinical exposure. Noninvasive (and often insensitive) biomarkers are often benchmarked against these exposures. This presentation with review the benefits of this sometimes challenging and inferential paradigm, but will also underscore that new tools and methodologies would be of value in understanding the human relevance of drug-induced testicular findings observed in animals.

## **S 27 Industry Efforts to Evaluate Inhibin B As Potential Biomarker for Testicular Toxicity.**

*M. Coulson. Safety Assessment, AstraZeneca, Macclesfield, United Kingdom. Sponsor: K. Boekelheide.*

Serum inhibin B is a hormone product of the seminiferous epithelium that has long been considered as The Next Great Biomarker. A HESI-sponsored effort in the early 2000's failed due to poor antibody behavior. A new antibody and a new assay kit have revived interest in this protein, and HESI has again sponsored a multi-company analysis of the analytic method and the protein's response to toxicity. This talk will introduce the biology, and the results of the consortium in evaluating the robustness of the analytic method, and the correlation between changes in inhibin B blood levels and the histologic state of the testis.

## **S 28 Circulating microRNAs As Biomarkers of Testicular Damage?**

*R. E. Chapin. DART, Drug Safety R&D, Pfizer, Inc, Groton, CT.*

MicroRNAs released into the blood following injury of specific tissues are emerging as promising biomarkers of toxicity, and the testis is no exception. A large multi-company effort under the auspices of the Predictive Safety Testing Consortium has

been working to define which miRNAs are testis-specific or -enriched, and to define their changes in the blood during testicular toxicant-induced injury. This presentation will briefly review the underlying biology and present an update of the work in this fast-moving area.

## **S** 29 **Sperm mRNA Transcripts and DNA Methylation Marks As Indicators of Testicular Injury.**

K. Boekelheide. *Brown University, Providence, RI.*

As a pure population of cells that have matured and differentiated within the seminiferous epithelium, sperm carry all of the information needed to fertilize an oocyte and initiate embryogenesis. Sperm deliver small and large RNAs and DNA to the oocyte. Using high throughput array technology, a panel of altered sperm mRNAs has been identified after exposure of rats to testicular toxicants. In men, the extent of sperm DNA methylation is related to sperm motility. The ultimate goal is to identify translatable sperm molecular signatures that will allow the rapid assessment of sperm effects in preclinical test species and exposed men.

## **W** 30 **Biology of Low-Dose Response for DNA-Reactive Chemicals.**

J. Klapacz<sup>1</sup> and B. P. Engelward<sup>2</sup>. <sup>1</sup>*TERC, The Dow Chemical Company, Midland, MI;* <sup>2</sup>*Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA.*

In the risk assessment process, DNA-reactive agents are generally considered to have no thresholds for their biological effects and this assumption formed the basis for linear low-dose extrapolation of any carcinogenic effects induced by these agents. On the other hand, cells have evolved to handle DNA lesions from endogenous and many exogenous DNA-reactive agents. In fact, DNA-repair processes are strictly conserved from bacteria to humans underlying their importance in protection against the effects of these agents, such as disease and aging. In recent years, low-dose response for DNA-reactive agents has been an active domain for research in toxicology, with publication of several datasets with large numbers of doses focused on the determination of no-observed-genotoxic-effect-level (NOGEL) values. This effort has included dose-response modelling to identify the best fit between linear and nonlinear models, such as bilinear (hockey-stick) and the benchmark dose (BMD) suite of models, and most datasets have supported a bilinear or nonlinear/threshold dose response as providing best fit based on statistical criteria. However, empirical demonstration of statistically-supported nonlinear/threshold dose response alone is not sufficient to achieve a paradigm shift in risk assessment. A clear understanding of the biological processes behind the shape of the low-dose response curve is similarly a critical piece of this journey, and one where less effort has been focused to date within toxicology. This workshop will explore some of the questions that need to be addressed to understand and bridge DNA-repair processes and cellular responses with the mode-of-action driving these nonlinear/threshold dose responses for genotoxic effects. The workshop will examine existing knowledge from the field of DNA repair and link it with response to low doses of DNA-reactive agents, in order to draw specific recommendations on a path forward.

## **W** 31 **Genotoxic Effects and Dose Response: What Do We Know So Far?**

L. H. Pottenger. *TERC, The Dow Chemical Company, Midland, MI.*

Low-dose genotoxic response for DNA-reactive alkylating agents has been actively investigated recently, with large datasets focused on low-dose response and determination of no-observed-genotoxic-effect-level (NOGEL) values. Most of these recent datasets include dose-response modelling analyses and have demonstrated a bilinear or non-linear/threshold dose-response as the statistically supported best fit, including datasets for directly DNA-reactive chemicals such as MMS, MNU, EMS, and ENU. Recent data have demonstrated the ubiquitous presence of endogenously-derived DNA adducts, some of which are identical to ones induced by exogenous exposure to DNA-reactive chemicals. Use of stable isotopes has permitted differentiation between the identical endogenously- and exogenously-induced DNA adducts, demonstrating that the exogenously-induced DNA adducts can have non-linear dose-responses at low doses; examples include formaldehyde and EO, both of which show that endogenous adduct levels can swamp the exogenously-induced ones at low exposures. Thus the available empirical evidence supporting the existence of non-linear/threshold dose-response for mutagenic effects from DNA-reactive agents is already compelling, while a growing body of evidence

is demonstrating similar non-linear/threshold dose-responses for exogenously-induced DNA adducts. However, statistically supported demonstration of non-linear/threshold dose-response alone is inadequate to achieve a paradigm shift in risk assessment. A clear understanding of the biology behind the shape of the dose-response is a critical piece for this journey, especially at low doses, although considerably less effort has transpired on this aspect to date. Addressing the biology and biologically plausible modes-of-action driving these non-linear/threshold dose-responses for genotoxic effects is the next task, one in which DNA repair mechanisms are likely to play a key role, both for adducts and for impact on dose-response for any resulting mutagenic effects.

## **W** 32 **CometChip and Recombomice Shed Light on Gene-Exposure Interactions That Impact Genomic Stability.**

B. P. Engelward. *Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA.*

We are interested in homologous recombination (HR) and base excision repair (BER) and the interaction between these DNA repair pathways. To explore HR in mammals, we created mice with recombination reporter systems (Recombomice) in which cells that have undergone an HR event fluoresce by combining tandem repeat of truncated copies of EYFP or EGFP gene. Here, we explore genetic and environmental factors that modulate susceptibility to HR in vivo. In particular, the impact of inflammation, producing endogenous oxidative and alkylating DNA damage, as both a modulator and an inducer of HR is presented. Exposure to low dose and high dose radiation causes many of the same changes to DNA as exposure to inflammation and can lead to severe inflammatory responses. Consequently, our inflammation studies have broad relevance. In addition, we have developed Comet assay called 'CometChip' for DNA damage analysis in single cells in an automated fashion. The approach increases throughput and improves reproducibility. Here, we show proof of principle of the technology as well as several applications of the CometChip for studies of gene-environment interactions. Together, this work and the technologies generated new biological insights.

HR has emerged as an important driver of carcinogenic sequence rearrangements. HR repairs double strand breaks in the S/G2 phases of the cell cycle resulting from endogenous and exogenous processes. While usually error free, errors in homologous recombination may result in sequence rearrangements and loss of heterozygosity, both of which are prominent features of cancer cells. BER is also a key DNA repair pathway. In this case, damaged bases are removed, the DNA backbone is cleaved, the ends are processed and the resulting gap is filled from the opposite strand. Both pathways are usually error-free, but there are still rare events where there are misalignments during HR, and misinsertions during BER. Also, both pathways are active in response to spontaneous DNA damage, and thus would be expected to be active in response to low dose radiation.

## **W** 33 **Role of Mismatch Repair in Mutagenesis, Cancer, and DNA-Damage Signaling.**

W. Edelmann. *Department of Cell Biology, Albert Einstein College of Medicine, Bronx, NY.* Sponsor: J. Klapacz.

The DNA mismatch repair (MMR) system is essential for maintaining the integrity of mammalian genomes by removing misincorporated nucleotides that result from erroneous replication. In addition, MMR participates in the early steps of checkpoint activation and apoptosis during the cellular response to alkylation induced O<sup>6</sup>MeG:T mismatches and many other DNA lesions, particularly relevant at low-dose, clinically-relevant exposures. Mutations in mammalian MMR genes result in increased spontaneous mutation rates and strong predisposition to colorectal cancers and other cancers. Eukaryotic MMR is a complex system that requires the interaction of several MutS and MutL proteins for the initiation of the repair reaction. Subsequent to mismatch recognition, downstream events are activated that lead to the excision of misincorporated or damaged nucleotides and the signaling of DNA damage-induced cell cycle arrest and apoptosis. The loss of the MMR-dependent DNA damage response is of significant clinical relevance as it results in increased resistance to many alkylating and chemotherapeutic agents. Our research program focuses on elucidating the functions of the individual MutS and MutL homologs in mammalian MMR and on assessing their importance for tumor suppression and the DNA damage response. Our results show that the DNA damage signaling by MMR is important for the suppression of tumorigenesis in the initial stages of the process. In addition, we found that MMR missense mutations can effectively separate the DNA repair and damage response functions and result in more heterogeneous cancer phenotypes than those caused by complete loss of function mutations.

## W 34 Computational Systems Biology Modeling of DNA-Damage Stress Pathways for Assessing Mutation Rates at Low Doses.

M. E. Andersen. *The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

Homeostasis with cellular stress response pathways involves negative feedback acting through a series of steps to reduce stressor concentrations. Many stress response pathways have rapid response, post-translational signaling and slower signaling through transcriptional upregulation of gene families. Our laboratory, in close collaboration with scientists from Unilever Safety and Environment Assurance Centre (SEAC), UK, has examined multiple biological read-outs in cells treated with several DNA-damaging compounds in order to create mechanistic computational models for micronuclei (MN) formation across wide dose ranges. The readouts in several cell types – AHH-1, HT-1080 and TK6 - included dose and time-dependent examination of whole genome gene expression, high content imaging of DNA-damage markers ( $\gamma$ H2AX and p53), semi-quantitative measures of key phosphoproteins (ATM, ATR, p38, Chk2, and p53), and MN as a measure of DNA-damage. Transcriptional upregulation only occurred in the regions of dose-response with clear increases in MN formation. Post-translational activation of rate constants for DNA-repair processes acting through activation of specific kinases appears to be the main contributor to regulation of DNA-damage at lower doses of these compounds. This talk describes stress pathway homeostatic feedback loops, shows our steps to populate high- and low-dose models for DNA-damage response pathways with etoposide, quercetin and methylmethanesulfonate, notes our progress in creating mechanistically-based low dose threshold models and discusses the value of these computational models in guiding new experimental approaches for assessing thresholds.

## W 35 Do Alkylating Agents Cause Genotoxic Thresholds through a DNA Repair Mode of Action?

G. E. Johnson, S. H. Doak, B. J. Rees, A. D. Thomas, J. R. Verma, Z. M. Zair and G. J. Jenkins. *College of Medicine, Swansea University, Swansea, United Kingdom.*

The long standing theory that linear dose responses exist for all DNA reactive genotoxic agents has recently been challenged. This paradigm shift towards accepting thresholds has been initiated by the scientific and regulatory community. High power non-linear dose responses are being produced in robust test systems. However, for the scientific community to accept a range of low doses as biologically irrelevant, a plausible mechanism of action must be shown experimentally. Many different research groups are tackling this issue for methyl- and ethyl-methane sulphonate (EMS and MMS) and methyl- and ethyl- nitrosourea (MNU and ENU) which have all been shown to exhibit non-linear dose responses for both mutagenicity and clastogenicity in vitro and in vivo. These alkylating agents induce specific DNA adducts (O6-alkylG, N7-alkyl-G and N3-alkyl-A), and recent work has been to investigate the roles of DNA repair in relation to their genotoxic thresholds. Specific DNA repair enzymes (N-methyl DNA purine glycosylase [MPG] and O6- alkyl guanine transferase [AGT]) have been shown to be up-regulated by low dose alkylating agents, and knocking down these specific DNA repair enzymes in vitro alters the shape of the dose response e.g. to EMS and MNU. Therefore, mono-functional alkylating agents have threshold dose responses through a DNA repair mode of action.

## W 36 Incorporation of Exposure Data and Chemical Properties into Early In Vitro Screening Studies: Putting Early Hazard Identification into Appropriate Context.

R. T. Dunn<sup>1</sup> and Y. Will<sup>2</sup>. <sup>1</sup>Discovery Toxicology, Amgen Inc, Thousand Oaks, CA; <sup>2</sup>Compound Safety Prediction, Pfizer R&D, Groton, CT.

Over the past several years, a multiplicity of innovative early-screening assays have been adopted to improve our ability to select drug candidates with the maximal opportunity to eventually succeed in later development. Examples of medium and high-throughput assays that can enable early hazard identification include ion channels related to cardiovascular safety (hERG, Nav1.5, and others), assays to understand CNS permeability and hepatobiliary transport (PgR, BSEP, etc.), and receptor and kinase screens, as well as screening ADME assays. These assays are typically employed early in the drug discovery process when little other data are available to help contextualize the early-screening result. Data output from these early screens is often produced, then utilized by project teams to select molecules for advancement, deprioritization, or to accumulate the knowledge base around a compound. In this model, the early-screening data may become a static entity, such as an IC50 value, which is then stored in a database often without further consideration or re-evaluation. There is a possibility that early-screening data in such a

model is underutilized or potentially misleading. An inherent problem with generating early-screening data is that it is often produced in the absence of accompanying data (e.g., *in vivo* exposure), which is information that can be leveraged to place these data into better context and enable more accurate predictions. In this workshop, several use case examples will be presented where *in vivo* exposure information and chemical compound properties have been weaved into early *in vitro* toxicity screening data enabling the discovery toxicologist to conduct a more robust assessment of the hazard identification assay data.

## W 37 Inclusion of Exposure Data to Early Toxicity Screening: Using the Bile Salt Export Pump (BSEP) Screen As an Illustrative Example.

R. T. Dunn, R. E. Morgan and H. K. Hamadeh. *Discovery Toxicology, Amgen Inc, Thousand Oaks, CA.*

Inhibition of the bile salt export pump (BSEP) is a recognized risk factor in the development of drug induced hepatic toxicity. To date there has not been an animal model that can be reliably used to predict toxicity arising from inhibition of bile salt transport. Thus, in order to provide project teams with an early hazard identification tool for BSEP inhibition, a vesicle-based BSEP assay was developed. Guidance for decision making or prioritization was initially based on a series of cutoff values, where potency on BSEP was used as a singular criterion for hazard flagging. As part of an effort to refine how early screening data are used, BSEP inhibition data was obtained from a compendium of approved and withdrawn drugs. The available human exposure data was then applied in a ratio calculation (BSEP IC50/Exposure) in order to provide an estimate of the safety multiple. Using the ratio-based data, a more robust evaluation of the IC50 data is now possible and the decision making power is enhanced. In addition, both false positive and false negative compounds were further analyzed and hypotheses generated to refine judgment around the hazard for individual molecules.

## W 38 High-Content Mechanistic Screening (HCMS) Technology to Impact Safety in the Context of Efficacy, Exposure, and Toxicity.

K. Tsaion. *Apredica, Watertown, MA.*

High content mechanism screening (HCMS) is a powerful platform that images numerous mechanistic toxicity endpoints in full dose response at various time points in cells of choice to generate IC50 based toxicity profiles presented as heatmaps. This allows to compare toxicity profiles of compounds across chemical series or within a series, with the goal to only take compounds forward that meet an acceptable safety profile and minimize the probability of attrition in later stages of development. We have successfully applied this approach to retrospective analysis for organ toxicity prediction as well as within our own portfolio. This work demonstrated that accurate prediction of clinical safety outcome depended on the availability of accurate information on clinical exposure levels. Rank ordering of compounds should be done in the context of exposure to most accurately define the safety window. When adjusted for clinical Cmax, retrospectively, the rank ordering of compounds fell in line with the FDA status and known clinical adverse events observations. This information was available to us for retrospective validation of the HCMS technology, but is not available for discovery compounds. To address this problem, as part of retrospective validation, we used industry-standard approach of using pharmacologically-based pharmacokinetic (PBPK) model and predicted human Cmax to normalize HCMS toxicity data. We demonstrated that when HCMS data were adjusted for predicted Cmax, that was calculated using PBPK model CloePK, rank order of the compounds fell in the same range as when we used clinical Cmax. In order to generate PBPK predictions a set of standard ADME data is used as an input.

## W 39 Lead Optimization Against Toxicological End Points in Drug Discovery: Recognition of Structural Determinants of Small Molecule Target Organ Exposure and Toxicity.

D. P. Hartley. *Array Biopharma, Boulder, CO.*

Target organ toxicity is a leading cause of attrition for novel small molecules in non-clinical drug discovery and early clinical development. Given the demands on drug discovery teams to produce molecules devoid of toxicity concerns, a paradigm shift has occurred such that toxicologists are now integral members of these teams with new responsibilities geared toward lead optimization. As such, it is no longer sufficient for the toxicologist to simply describe the observed organ toxicities of a new

compound, it is expected that we assess risk for toxicity in a predictive manner, or ascribe a mechanism to early toxicity findings, link the findings to an offending moiety within the structure, and assist in defining the chemical lead optimization path. In many instances, simple modifications to structural or physical chemical properties to molecules with insufficient safety profiles can quickly lead to new candidates with improved exposure and target organ toxicity profiles. Examples will be presented where recognition and subsequent modification of structural and physical chemical features were employed to reduce attrition of small molecules due to undesirable safety pharmacology or target-organ toxicity.

#### **W** 40 **The Challenges of Putting *In Vitro* Safety Assays into Context with *In Vivo* Data.**

N. Greene. *Compound Safety Prediction, Pfizer, Inc., Groton, CT.*

In the quest for higher-throughput, lower cost assays for safety assessment, many efforts have focused on cell based *in vitro* assays that generate a effect at a certain concentration level readout such as an LC50 etc. However, most of the efforts on correlating these *in vitro* concentration responses to *in vivo* effects have looked at the simple presence or absence of a phenotypic response in the *in vivo* study resulting in the potential misinterpretation of a result. In this presentation, we will describe efforts to more fully describe the *in vivo* responses in the context of compound exposure to enhance the interpretation and correlation of *in vitro* assays. We will highlight some of the issues in working with *in vivo* data such as the loosely controlled vocabularies used in describing the findings observed in a study and approaches we have taken to overcome these. Finally, we will show how this may then enhance the predictive value of an *in vitro* assay such as a simple ATP depletion assay.

#### **W** 41 **Relating Molecular Properties and *In Vitro* ADME/Tox Surrogate Assay Results to *In Vivo* Outcomes.**

D. E. Watson. *Lilly Research Laboratories, Indianapolis, IN.*

A primary goal of lead generation and lead optimization is to identify compounds with good pharmacological properties and optimal absorption, distribution, metabolism, excretion and toxicological (ADMET) characteristics. Chemists routinely consider molecular properties in designing compounds and utilize *in vitro* ADMET surrogate assays to select promising compounds for *in vivo* studies. A number of recent reports have investigated the relationship between computed molecular properties and *in vivo* ADMET outcomes. Although there is consensus that compound properties are important, one limitation of these analyses is a lack of controls for possible covariates (i.e. correlation vs. causation). We have examined the relationship between molecular properties and *in vitro* ADMET surrogate assays vs. *in vivo* properties within 175 chemical series identified from a database of 3792 compounds for which short term rodent pharmacokinetic and toxicology data are available. The role of confounding covariates was minimized by focusing on those variable associated with large differences in outcomes between compound pairs within chemically similar series of molecules. The analysis identified the following pairs of surrogates as most predictive among those examined: rat primary hepatocyte (RPH) cytolethality / volume of distribution (Vd) for *in vivo* toxicology outcomes, scaled microsome metabolism / calculated logP for *in vivo* unbound clearance, and calculated logD / kinetic aqueous solubility for thermodynamic solubility. An important practical outcome of the analysis is a set of guidelines defining the utility of specific surrogates for several *in vivo* ADMET endpoint and the magnitude of change required in a surrogate endpoint to achieve a desired *in vivo* result for novel drug candidates.

#### **W** 42 **Inhaled Mixtures: A Mode-of-Action Framework Applied to the Criteria Air Pollutants.**

E. O. Owens and C. C. Bowman. *National Center for Environmental Assessment, US EPA, Durham, NC.*

Although regulated individually, the criteria air pollutants, NO<sub>x</sub>, SO<sub>x</sub>, CO, PM, Pb, and O<sub>3</sub>, exist as a complex mixture in the atmosphere. Thus, the interactions and cumulative effects of multiple pollutants are important to consider when assessing the impact of ambient air exposures on health. The criteria air pollutants act through complex biological pathways to elicit health effects, but many share common modes of action, including oxidative stress and inflammation. Mode of action for a given toxic agent is defined as the set of key events involved in a given toxic effect. Key events are measurable endpoints along a continuum from exposure to effect, and are consistent with emerging concepts of how to use biomarkers, surrogate

endpoints, and toxicity pathways to characterize health risks. Recent discussions have proposed the use of mode of action to develop a unifying framework for the evaluation of mixtures containing multiple pollutants. This session convenes experts in the modes of action of criteria air pollutants to examine how this information can be organized, beginning with a description of an emerging framework for integrating mechanistic and biological plausibility information regarding the criteria air pollutants and a subset of ambient air toxics. Attendees will gain knowledge of how a mode-of-action framework can be used to consider mixtures, as well as emerging and established mechanisms of toxicity of air pollutants, focusing on potential interactions between pollutants encountered in a multipollutant context.

#### **W** 43 **Assessing Health Effects of Air Pollution Mixtures: Mode-of-Action Framework.**

B. Buckley. *National Center for Environmental Assessment, US EPA, Durham, NC.*  
Sponsor: C. Bowman.

To better understand the health effects resulting from exposures to mixtures of criteria pollutants (PM, particulate matter; sulfur oxides, SO<sub>x</sub>; nitrogen oxides, NO<sub>x</sub>; ozone, O<sub>3</sub>; lead, Pb and carbon monoxide, CO) that actually occur in ambient air, we are developing a framework for integrating information provided by toxicological, epidemiologic, and controlled human exposure studies based on mode of action. Mode of action for a given agent is defined as the set of key events which result in a toxic effect. Key events are measurable endpoints along the continuum from exposure to effect, and are consistent with emerging concepts of how to use biomarkers, surrogate endpoints, and toxicity pathways to characterize health risks. The approach elucidates commonalities in key events and pathways triggered by exposure to multiple pollutants. Available literature regarding the respiratory health effects of PM, SO<sub>x</sub>, NO<sub>x</sub> and O<sub>3</sub> indicates that all four pollutants activate neural reflexes, increase bronchial reactivity, initiate inflammation and modulate immune responses which may lead to the exacerbation of allergic responses, asthma and altered host defenses. Emerging evidence also demonstrates that exposure to either PM or O<sub>3</sub> may result in systemic inflammation, oxidative stress and impaired vasomotor function while exposure to NO<sub>x</sub> may result in pro-inflammatory circulating factors; all of which may lead to cardiovascular health effects. Exposure to CO may impair vasomotor function or lead to myocardial ischemia, while exposure to Pb may result in hypertension. Incorporation of important considerations for extrapolation in risk assessment such as adaptive responses, susceptibility factors, dose and duration of exposure, toxicokinetics, toxicodynamics and endogenous species into this framework is explored.

#### **W** 44 **The Effects of Criteria Pollutants in the Brain.**

M. L. Block. *Anatomy and Neurobiology, Medical College of Virginia, Richmond, VA.*

Increasing evidence links air pollution to central nervous system (CNS) disease, but the mechanisms remain poorly understood. Experimental studies and human case reports reveal that neuroinflammation and oxidative stress have emerged as a common deleterious pathway triggered by exposures to diverse criteria pollutants, including ozone and particulate matter. Thus, evidence indicates that not only does the brain's innate immune system respond to criteria pollutants, but that this has been linked to neurodegenerative-disease-like pathology in cell culture, rodent models, and humans. This presentation will focus on the cellular and peripheral mechanisms that may be driving the CNS effects of air pollution, as our work with diesel exhaust shows that both the peripheral immune system and microglia, the brain's resident innate immune cell, may be key to this process. In addition to providing new information on specific mechanisms of CNS disease development related to criteria air pollutant exposure, a mode of action framework will be used to describe the pathways leading to emerging health effects with uncertain mechanisms.

#### **W** 45 **Air Pollution and Pattern Recognition Receptors: Like a Wee LCMS in Every Mouse.**

M. J. Campen. *College of Pharmacy, University of New Mexico, Albuquerque, NC.*

Distinguishing among the toxicities of the numerous criteria pollutants and other unregulated air hazards that exist in the multipollutant environment challenges the most sophisticated human and animal studies. To adopt a more refined approach to assessing the effects of multipollutant exposures, it will be essential to better understand the shared mechanisms driving toxicity. One common pathway that several labs have recently elucidated relates to a class of receptors known as pattern recognition receptors (PRR). Research will be presented looking at the role of PRR in

driving allergic airway response, cardio-metabolic response, and the systemic vascular inflammatory response to combustion-source mixtures, such as gasoline and diesel emissions. These findings, combined with results from other laboratories, indicate a role for PRRs that may help refine our understanding of the link between the chemistry of pollutant interactions at the lung surface and the ultimate pathophysiological outcome.

**W 46 Differential Effects of PM Components: Toward a Better Understanding of Underlying Mechanisms.**

A. Rohr. *Air Quality, Electric Power Research Institute, Palo Alto, CA.*

Multiple epidemiological and toxicological studies have reported differential responses to fine particulate matter components, such as elemental carbon, organic carbon, sulfate, nitrate, and individual elements. While different PM components likely invoke unique pathophysiological pathways, it is also likely that there is overlap between mechanisms of action. For example, oxidative stress is a likely pathway for both organic PM components as well as trace elements. In a multipollutant setting, it is critical to understand the underlying mechanisms of adverse biological responses to these materials. This presentation will review what is currently known about pathophysiological pathways of response to PM components, with an emphasis on shared pathways.

**RI 47 Toxicological Challenges in Food Production in Texas and the Gulf Coast.**

L. M. Plunkett. *Integrative Biostrategies LLC, Houston, TX.*

With recent media attention on episodes of food contamination and the impact of chemicals in the environment on the food supply (i.e., bacterial contamination of food, as well as the 2010 BP oil spill), public awareness of food safety issues has grown. This symposium will explore the topic of food safety as it relates to unique features of food production in Texas and the Gulf Coast. Texas is a major source of fresh fruit and vegetable production for both regional and countrywide consumption, while the Gulf Coast is a major source of fresh fish and seafood for many parts of the United States. Topics covered in the symposium will include recent legislative initiatives such as the Food Safety and Modernization Act of 2010, current regulatory oversight of food safety in the Gulf Coast region, and key public and/or worker health issues associated with food production in the region. The goal of the symposium is to describe the strengths and weaknesses of current regulations and practices to ensure a safe food supply as well as worker safety, and provide dialog for ways to address unique concerns related to food production in Texas and the Gulf Coast. Symposium speakers work in academia, for the United States government (US FDA), and an organization representing the interests of the public (Center for Science in the Public Interest), which will allow for discussion of the topics from a variety of perspectives.

**RI 48 Multiagency Response to Seafood Safety Concerns following the 2010 Deepwater Horizon Oil Spill.**

R. W. Dickey. *US FDA, Dauphine Island, AL.* Sponsor: L. Plunkett.

The April 20, 2010 explosion and sinking of the Deepwater Horizon oil drilling platform (DWH) resulted in the largest oil spill in U.S. history. For a period of 87 days roughly 53 thousand barrels of oil per day flowed into the Gulf of Mexico (GOM). The U.S. Coast Guard estimated 4.9 million barrels of crude oil escaped before the damaged wellhead was sealed on July 15. The DWH spill threatened all States bordering the GOM, and crossed Federal and State jurisdictional boundaries. Agencies responded to the spill in a coordinated manner to execute a unified seafood safety risk assessment and protocol for testing and re-opening GOM fisheries.

Polycyclic aromatic hydrocarbons (PAH) are internationally recognized as the most appropriate indicators of potential human health risk from crude oil residues in seafood. A representative subset of 13 PAH and their alkylated homologues was selected for critical analysis of oil-impacted seafood. A standard set of calculations was used to determine seafood PAH tissue concentrations above which a 10-5 upper-bound risk for low dose, life-time cancer is exceeded. Levels of concern for non-cancer risks were also adopted from EPA IRIS reference dose values. Values for other event-specific variables were selected from the most recent and reliable information available.

FDA and NOAA tested more than 10,000 seafood specimens from state territorial and federal waters that were impacted by the oil spill. Waters were not reopened for fisheries harvest until oil had dissipated and testing showed that seafood was safe for consumption. The duration of fishery closures in the oil-impacted region ranged from 16 days for areas receiving little to no impact to greater than 24 months for areas more heavily oiled.

Most seafood samples that were tested after the oil spill had dissipated, and before waters were reopened for fishing, did not contain measurable levels of oil or dispersant residues. The samples that did contain measurable residues were consistently 100 to 1000-fold below levels of concern established in the unified seafood safety protocol.

**RI 49 Seafood Safety Challenges for the Texas Gulf Coast.**

D. W. Plunkett. *Center for Science in the Public Interest, Washington DC.* Sponsor: L. Plunkett.

Potentially toxic chemistry from the 2010 BP oil spill and clean-up efforts generated widespread public concern over the safety of seafood harvested from the Gulf of Mexico. Government agencies moved swiftly to contain the threat and reassure consumers. The effort, though, masked a larger truth. While contamination events caused by human activities draw public attention, naturally occurring toxins and deadly bacteria in Gulf waters sicken, maim and kill far more people than oil and chemical dispersants. Rare cases of neurotoxic shellfish poisoning occur in Texas. Much more common are illnesses and deaths from naturally occurring vibrios. Oysters harvested from Texas coastal waters have killed 53 people since 1995 and resulted in 45 serious illnesses from *Vibrio vulnificus* contamination. The presentation will cover the risks to human health from human and naturally occurring contaminants, focusing on shellfish. It will also cover responses, adequate and inadequate, by governmental food safety agencies and the fishing industry.

**RI 50 Occupational Hazards in Texas Food Production.**

E. Shipp. *Epidemiology and Biostatistics, Texas A&M School of Rural Public Health, College Station, TX.* Sponsor: E. Bruce.

A substantial number of hired farmworkers help Americans to put food on their tables. This largely foreign-born (>75%) workforce makes a huge contribution to the agricultural economy, yet the average family income ranges from \$15,000 to \$17,499 and less than a quarter are covered by health insurance. The agricultural industry also is among the most hazardous in the United States in terms of fatal and nonfatal injury. Common occupational hazards include: prolonged time in awkward postures, sun and heat stress, sharp implements, motorized farm equipment, inadequate safety training and field sanitation, and pesticides. Pesticides are especially a concern for farmworkers given the potential for long-term consequences such as skin problems, neurologic and motor problems, birth defects, and cancer. There are an estimated 10,000-20,000 cases of physician diagnosed pesticide poisoning among agricultural workers each year in the U.S. Many more cases likely go undiagnosed because symptoms can be flu-like and non-specific or the farmworkers lack access to healthcare. Worker training can reduce this exposure, but employers often do not provide training even when required to do so by law. In a study of adolescent farmworkers from Texas, only 21% had ever received any training in pesticide safety. This is troubling because adolescents are still developing both physically and mentally and may be especially vulnerable to chemical exposures. A recent pilot study showed that adolescent farmworkers who reported 5+ symptoms of neurotoxicity were nearly nine times as likely to report an acute injury compared to those reporting a lower number of symptoms (Whitworth et al., 2010). This presentation provides an overview of the occupational health and safety issues impacting farmworkers with a focus on pesticides and a current research study designed to examine this issue further in adolescents.

**RI 51 Occupational Heat Stress in Agricultural Settings.**

J. L. Levin. *Occupational Health Sciences, The University of Texas Health Science Center at Tyler, Tyler, TX.* Sponsor: E. Bruce.

Occupational heat stress and heat illness disproportionately affect agricultural workers compared with other occupations, including migrant and seasonal farmworkers. From 1992 to 2006, there were 423 occupational heat-related deaths in the United States. The mortality rate from occupational heat-related illness among crop workers was nearly twenty times as high as for all industries during that time frame. This presentation will review underlying causes and risk factors for occupational heat stress, recognition of the continuum of heat illness, and recommendations for monitoring and prevention. Presently, there is no federal occupational regulatory standard specifically regarding heat exposure. This presentation will also review fundamental differences between OSHA and NIOSH and emphasize the complexities of understanding recommended exposure limits. Case examples from outdoor work environments will be presented including one which culminated in adjudication before the Occupational Safety and Health Review Commission.

**PL 52**    **Developmental Toxicity and Neurobehavioral Effects of Dietary Flavonoids.**

S. M. Bugel and R. L. Tanguay. *Department of Environmental and Molecular Toxicology, Environmental Health Sciences Center, Oregon State University, Corvallis, OR.*

Flavonoids are a structurally diverse group of phytochemicals that are known hormone mimics (phytoestrogens), and are thought to have therapeutic properties. Humans are exposed to flavonoids through consumption of fruits, vegetables, and dietary supplements. These ubiquitous chemicals are found in baby formulas and foods, and are detected in human urine, plasma, and breast milk. Therefore, the potential for developmental effects should be explored. Using zebrafish (*Danio rerio*) as a model vertebrate, we tested the hypothesis that flavonoids exhibit structure-dependent effects on development. Embryos were treated with 5 representative flavonoids (apigenin, biochanin A, S-equol, galangin and kaempferol), 1-50  $\mu$ M, from 6 hours post fertilization (hpf) to 120 hpf. At 120 hpf, effects included yolk-sac and pericardial edemas, axis curvature, fin dysmorphogenesis and craniofacial abnormalities. For all 5 compounds, we also observed spastic pectoral fin and caudal tail movements at 72 hpf, suggestive of neurotoxicity. To test the hypothesis that flavonoids are stimulants, we assessed acute effects on neurobehavior in naïve 120 hpf larvae challenged with 16 flavonoids: apigenin, biochanin A, chrysin, daidzein, S-equol, fisetin, formononetin, galangin, genistein, kaempferol, luteolin, myricetin, naringenin, puerarin, quercetin and resveratrol. With the exception of puerarin, all induced hyperactive swimming behavior suggesting that flavonoids have psychoactive and stimulant properties. This zebrafish larval bioassay is amenable to rapid throughput screening for anxiogenic and anxiolytic properties, which we validate using neurotoxins chosen to represent diverse mechanisms (e.g. nicotine, chlorpyrifos, picROTOXIN, etc.). Using pharmacological intervention with receptor specific chemicals, this screen will be valuable for identifying interaction of dietary flavonoids and other chemicals of interest with neuro-receptors to identify the mechanism of toxicity in vivo. This research is supported by NIEHS grants P30 ES00210, RC4ES019764 and T32 ES07060.

**PL 53**    **Perinatal Toxicity and Carcinogenicity Studies of Styrene Acrylonitrile Trimer, a Ground Water Contaminant.**

M. Behl<sup>1,2</sup>, S. A. Elmore<sup>1</sup>, M. R. Hejtmančík<sup>3</sup>, D. K. Gerken<sup>3</sup> and R. S. Chhabra<sup>1</sup>. <sup>1</sup>Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>Kelly Government Solutions, Research Triangle Park, NC; <sup>3</sup>Battelle Memorial Institute, Columbus, OH.

Styrene Acrylonitrile (SAN) Trimer is a by-product of the production of acrylonitrile styrene plastics. Following the report of a childhood cancer cluster in the Toms River section of Dover Township, New Jersey, SAN Trimer was identified as one of the groundwater contaminants at Reich Farm Superfund site in the township. The contaminants from the Reich Farm site's ground water plume impacted two wells at the Parkway well field. The National Toxicology Program (NTP) studied the toxicity and carcinogenicity of SAN Trimer in F344/N rats exposed during their perinatal developmental period and adulthood. The chronic toxicity and carcinogenicity studies in rats were preceded by 7 and 18-week perinatal toxicity studies to determine exposure concentrations for the 2 year studies. Pregnant dams were exposed to SAN-Trimer in the diet at 400, 800, or 1600 ppm during gestation, nursing and weaning periods of offspring followed by two years of adult exposure to both male and female pups. There was no statistically significant evidence of carcinogenic activity following SAN-Trimer exposure; however, rare neoplasms in the brain and spinal cord were noted in males and to lesser extent in female rats. These incidences were considered within the range of historical control background in the animal model used in the current studies. The major finding was a dose-related peripheral neuropathy associated with the sciatic nerves in females and spinal nerve roots in males and females, thereby suggesting that SAN-Trimer is a potential nervous system toxicant. Other non-neoplastic lesions included increased incidences of some lesions in the bone marrow and liver in males and females, and in the urinary bladder in females.

**PL 54**    **Does Developmental Hypothyroidism Produce Lasting Effects on Adult Neurogenesis?**

J. Nance<sup>1</sup>, R. C. Switzer<sup>2</sup>, A. Tennant<sup>1</sup>, A. F. Johnstone<sup>1</sup> and M. E. Gilbert<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>NeuroScience Associates, Knoxville, TN.

The subgranular zone of the dentate gyrus (DG) of the adult hippocampus generates new neurons throughout life. Thyroid hormones (TH) are essential for brain development, but impaired neurogenesis with adult hypothyroidism has also been reported. We investigated the role of milder degrees of TH disruption on adult neurogenesis following hypothyroidism induced during development, in adulthood, or

both. Pregnant dams were administered the TH synthesis inhibitor, propylthiouracil (PTU, 0 or 3ppm in drinking water) from gestational day 6 and pups were weaned to control water on postnatal day (PN)21. On PN60, offspring from control or PTU dams were either re-exposed to PTU (3ppm) for 1 month or maintained on control. Bromodeoxyuridine (BrdU 50 mg/kg, ip, twice daily) was administered to all animals on the last 5 days of the re-exposure period, and animals sacrificed 28 d later. Animals were perfused intracardially, the brains removed and embedded in a MultiBrain (NSA) array and freeze sectioned. Every 8th section throughout the hippocampus stained with an antibody against BrdU to mark actively dividing cells. The volume of the DG and the number of BrdU-positive cells were assessed from images captured on a Nikon microscope (400X) and Nikon Elements software. Preliminary findings indicate that developmental exposure to PTU produced a persistent reduction in the volume of the adult DG. BrdU cell counts were reduced similarly in all PTU-exposed groups. These data suggest that moderate levels of hypothyroidism decrease cell survival in the adult brain and that transient developmental hypothyroidism leads to persistent decreases in DG volume and cell survival. The degree to which these findings are determined by reductions in cell proliferation is currently under investigation. As neurogenesis in the adult recapitulates developmental processes of proliferation, differentiation, and migration, study of this neurogenic niche in the adult may provide a simpler means to assess the consequences of TH insufficiency on neurodevelopment. (Does not reflect EPA policy).

**PL 55**    **Dietary Administration of Paraquat for 13 Weeks Does Not Result in a Loss of Dopaminergic Neurons from the Substantia Nigra of Mice.**

N. Sturgess<sup>1</sup>, P. Botham<sup>1</sup>, M. Butt<sup>3</sup>, D. Minnema<sup>2</sup>, L. Smith<sup>1</sup> and J. Wolf<sup>4</sup>. <sup>1</sup>Syngenta, Bracknell, United Kingdom; <sup>2</sup>Syngenta, Greensboro, NC; <sup>3</sup>Tox Path Specialists, Frederick, MD; <sup>4</sup>EPL, Sterling, VA.

A number of publications have reported that i.p. administration of paraquat (PQ) to rodents (e.g. C57Bl6J mouse) at high doses results in a loss of dopaminergic neurons from the substantia nigra pars compacta (SNpc), the primary area of neuropathological damage in Parkinson's disease (PD). Such studies have been used to indicate mechanistic plausibility for epidemiological claims of a link between PQ exposure and PD. A major criticism of the i.p. mouse model is that it uses a route of administration and duration of exposure which is not relevant to human exposure. To better understand the relevance of the reported findings from the i.p. mouse model we have conducted a study where male C57Bl6J mice were exposed to PQ in the diet for 13 weeks, and the brains examined for evidence of dopaminergic neuronal cell loss using stereology, changes in striatal neurochemistry and pathological changes using stains to detect neuronal cell damage and inflammatory responses. Dietary concentrations of 10 & 50 ppm paraquat dichloride salt were used which resulted in achieved doses of 2.4 & 14.1 mg/kg/day. A low dose of N-1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP; 10 mg/kg administered i.p. to a separate group of male mice 4 times in a single day at 2 hr intervals, 7 days prior to the end of the dietary study) served as a positive control. PQ at either dose level did not induce a loss of tyrosine hydroxylase positive (TH+) dopaminergic neurons in the SNpc, alter the concentration of striatal dopamine and its metabolites or result in evidence of neuronal cell damage or astrocyte/microglial activation in the SNpc. In the MPTP group the number of TH+ neurons in the SNpc and striatal dopamine was reduced and there were significant pathological changes including neuronal necrosis and astrocyte/microglial activation. This study further brings into question the relevance of the findings from previous i.p. mouse studies as evidence for a link between PQ exposure and PD/parkinsonism.

**PL 56**    **Neurodevelopmental Effects of Inhaled Vapors of Gasoline and Ethanol in Rats.**

P. J. Bushnell<sup>1</sup>, T. E. Beasley<sup>1</sup>, W. M. Oshiro<sup>1</sup>, P. A. Evansky<sup>1</sup>, S. A. Martin<sup>1</sup>, V. C. Moser<sup>1</sup>, K. L. McDaniel<sup>1</sup>, P. M. Phillips<sup>1</sup>, J. Norwood<sup>1</sup>, M. E. Gilbert<sup>1</sup>, M. M. Taylor<sup>2</sup>, C. J. Gordon<sup>1</sup>, C. E. Grace<sup>1</sup> and J. M. Rogers<sup>1</sup>. <sup>1</sup>NHEERL/ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>MMT Inc, Durham, NC.

Gasoline-ethanol blends comprise the major fraction of the fuel used in the US automotive fleet. To address uncertainties regarding the health risks associated with exposure to gasoline with more than 10% ethanol, we are assessing the effects of prenatal exposure to inhaled vapors of gasoline-ethanol blends. Pregnant Long-Evans rats are exposed to fuel vapors, 6.5 hr/day, on days 9–20 of gestation, and their offspring are assessed for a variety of neurodevelopmental effects. This report compares effects of inhaled gasoline vapor lacking ethanol (E0) at concentrations of 0, 3000, 6000, or 9000 ppm with previously-reported effects of inhaled ethanol (E100) at concentrations of 0, 5000, 10000 or 21000 ppm. Maximum concentrations were limited by the lower explosive limits of the vapors. As observed with

E100, E0 vapors caused no overt maternal toxicity, changes in litter size or weight, or weight gain of the pups. In contrast to E100, E0 did not alter locomotor activity of adults. Both E0 and E100 produced a few minor, unsystematic changes in the functional observational battery. In water maze tests, E100 altered search strategies (not dose-related) and impaired memory in females (no-platform probe trials, all doses); in contrast, E0 was essentially ineffective. No treatment affected working memory, as assessed in operant delayed-matching-to-position tests. In an operant reaction-time test, 21000 ppm E100 and 9000 ppm E0 increased hold failures, a measure of impulsivity, and increased decision times at the lower doses. Responses to a conditioned audiovisual cue were reduced in females at all doses of E100, but were not affected by E0; neither agent affected conditioning to context. Telemetered mean blood pressure (BP) was increased in male offspring by 9000 ppm E0 at PND 90 and 180; tail cuff tests corroborated these results at PND 180 only. E100 increased BP (tail cuff) in males at all doses on PND90 only. This abstract does not reflect EPA policy.

**PL 57 Postnatal Trichloroethylene Exposure Is Associated with Abnormal Behavior and Alterations Global DNA Methylation Patterns in Mouse Cerebellum.**

S. Blossom<sup>1</sup>, J. L. Rau<sup>1</sup>, S. B. Melnyk<sup>1</sup>, C. A. Cooney<sup>1</sup>, S. J. James<sup>1</sup> and W. D. Wessinger<sup>2</sup>. <sup>1</sup>*Pediatrics, Arkansas Children's Hospital Research Institute, Little Rock, AR;* <sup>2</sup>*Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Previous studies have shown that continuous exposure throughout gestation until the juvenile period to environmentally-relevant doses of trichloroethylene (TCE) in the drinking water of MRL+/+ mice promoted adverse behavior associated with glutathione (GSH) depletion in the cerebellum indicating increased sensitivity to oxidative stress. Here we extend these findings to further characterize the impact of TCE exposure on redox homeostasis, biomarkers of oxidative stress, transmethylation metabolites and global DNA methylation patterns in mice exposed to water only or two doses of TCE in the drinking water postnatally from birth until 6 weeks of age. The mice were subjected to a variety of open field behavioral tests in order to correlate behaviors with metabolic and methylation patterns observed in our model. Our results show that the cerebellum from male mice exposed to TCE have lower GSH and increased biomarkers of oxidative stress compared with controls. Methionine levels were also significantly reduced in the TCE-exposed mice which suggested compromised cellular methylation. Global DNA methylation, including hydroxymethylation patterns, were significantly lower in the cerebellum of TCE exposed mice, compared to controls. Mice exposed to TCE exhibited increased locomotor and exploratory activity compared to control mice suggesting increased novelty seeking behavior similar to that observed in humans with attention deficit disorder. Understanding the mechanisms of TCE neurotoxicity during sensitive windows of exposure is important in order to enhance mechanistic understanding of environmentally-related neurologic disorders in susceptible populations.

**PL 58 Perfluorohexane Sulfonate (PFHxS) Causes Adult Behavioral Disturbances in Male and Female Mice, after Neonatal Exposure.**

H. Viberg, I. Lee, A. Fredriksson and P. Eriksson. *Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

Perfluorohexane sulfonate (PFHxS) is a perfluorinated compound (PFC) used as an industrial additive. PFC chemical properties make them suitable as surfactants and oil- and water repellents, which are frequently used in products for packaging and as protective coatings. However, the same properties also account for their extreme physico-chemical stability, making them practically non-biodegradable, accumulating in the global environment, causing concern, since little is known about the toxicity of the compound. We recently have seen that other PFCs, like perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA), can induce developmental neurotoxic effects and the purpose of the present study was to explore if neonatal exposure to PFHxS can affect behavior and cognitive function. In the present study we exposed male and female mouse pups to a single dose of PFHxS (0.61-9.2 mg/kg bw) during the defined critical period of brain development, on postnatal day 10. At two months of age male and female mice showed altered spontaneous behavior in a novel home environment, affecting cognitive function. Furthermore, these functional behavioral effects were long-lasting or irreversible since they were once again seen at four month of age. The nicotine-induced behavior test revealed that male and female mice neonatally exposed to PFHxS responded differently compared to control animals, when challenged with a dose of nicotine. The present findings show that PFHxS can cause developmental neurotoxicity, effects similar with effects earlier reported after neonatal exposure to PFOS and PFOA and other persistent pollutants, such as PBDEs and PCBs.

**PL 59 Acute Ozone-Induced Impairment of Glucose Regulation: Age-Related and Temporal Changes.**

V. L. Bass<sup>1</sup>, R. C. MacPhail<sup>1</sup>, D. L. Andrews<sup>1</sup>, B. Vallanat<sup>1</sup>, W. O. Ward<sup>1</sup>, M. C. Schladweiler<sup>1</sup>, A. D. Ledbetter<sup>1</sup>, D. B. Johnson<sup>2</sup>, K. A. Jarema<sup>1</sup>, C. J. Gordon<sup>1</sup> and U. P. Kodavanti<sup>1</sup>. <sup>1</sup>*EPHD/NHEERL/ORD, US EPA, Research Triangle Park, NC;* <sup>2</sup>*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Ozone (O<sub>3</sub>) is associated with adverse cardiopulmonary effects in humans and thought to produce metabolic effects, such as insulin resistance. We showed that episodic O<sub>3</sub> exposure increased insulin levels in aged rats. We hypothesized that O<sub>3</sub> could impair glucose homeostasis by altering insulin signaling and/or causing an unfolded protein response (UPR) in the liver. Brown Norway rats, 1, 4, 12, 21, and 24mo old, (a model of non-obese aging) were exposed to O<sub>3</sub> at 0, 0.25 or 1ppm, 6h/day for 2 consecutive days. As a follow-up study, 4mo old rats were exposed to 0 or 1ppm O<sub>3</sub> over 2 days to examine the time course of response. Glucose tolerance tests (GTT) directly followed exposure in all studies and additionally at 24h post-exposure in the time-course experiment. Liver gene expression was examined using Affymetrix RG-230PM Array strips. Liver and adipose tissues were also analyzed using RT-PCR for metabolic and UPR markers. Phospho-protein analysis to assess insulin signaling was done in the liver, adipose tissue, and muscle. GTT showed a marked impairment of glucose clearance among 1ppm O<sub>3</sub> exposed rats of all ages. The reduction in glucose regulation after O<sub>3</sub> exposure was most apparent in 1mo rats, who exhibited no baseline glucose intolerance. The 24mo rats exhibited glucose intolerance at baseline. Analyses of metabolic and acute phase response (APR) biomarkers show that the insulin signaling pathway is altered by O<sub>3</sub> in all three tissues and serum APR proteins were increased. Selected UPR genes were upregulated in the liver. Serum leptin increased acutely following 1 day (6h) O<sub>3</sub> exposure. Maximum effects of O<sub>3</sub> on insulin signaling and APR were seen directly following the second day of exposure. Our results suggest that glucose intolerance is a result of metabolic changes in response to O<sub>3</sub>. These findings raise concern about ambient O<sub>3</sub>'s potential to cause predisposition towards metabolic impairment. (Does not reflect US EPA policy).

**PL 60 Fine Particulate Matter (PM<sub>2.5</sub>) Exposure Impairs Vascular Insulin Signaling and Exacerbates Diet-Induced Systemic Insulin Resistance in Mice.**

P. Habertzell, J. McCracken, J. Lee, A. Bhatnagar and D. J. Conklin. *University of Louisville, Louisville, KY.*

Recent epidemiological studies suggest that increases in fine particulate matter (PM<sub>2.5</sub>) air pollution contribute to the rapidly evolving epidemics of obesity and diabetes. Because metabolic syndrome, diabetes and air pollution all induce endothelial dysfunction, and because we recently showed that short-term exposure to concentrated ambient PM<sub>2.5</sub> (CAP) impairs endothelial VEGF signaling and decreases circulating endothelial progenitor cells (EPCs), we examined the effects of CAP exposure (9-30 consecutive days, 6h/d) on endothelial and systemic insulin resistance and inflammation, adiposity and vascular function in mice fed normal chow or high fat-diet (HFD). Surprisingly, CAP exposure impaired vascular insulin signaling after only 9 or 30 days, and exacerbated HFD-induced systemic insulin resistance after 30 days without increasing adiposity. Insulin sensitivity and inflammation in adipose and liver were unaltered by CAP or HFD. In contrast, CAP exposure (30 days) impaired endothelial insulin signaling diet-independent in heart and aorta, but HFD-dependent skeletal muscle. Changes in insulin sensitivity were accompanied by organ-specific but not systemic inflammation and a decrease in circulating EPCs. Collectively, our results suggest that short-term CAP exposure provokes HFD-induced systemic insulin resistance by inducing inflammation and endothelial insulin resistance accompanied by decreased circulating EPC levels. Impaired vascular maintenance due to EPC suppression could contribute to vascular insulin resistance (or vice versa) thereby increasing systemic insulin resistance and the risk for the development of T2D and CVD by PM<sub>2.5</sub>.

**PL 61 Ozone (O<sub>3</sub>): A Potential Contributor to Metabolic Syndrome through Altered Insulin Signaling.**

D. B. Johnson<sup>3</sup>, D. L. Andrews<sup>2</sup>, V. L. Bass<sup>1</sup>, M. C. Schladweiler<sup>1</sup>, A. D. Ledbetter<sup>1</sup> and U. P. Kodavanti<sup>1</sup>. <sup>1</sup>*EPHD/NHEERL/ORD, US EPA, Research Triangle Park, NC;* <sup>2</sup>*RCU/NHEERL/ORD, US EPA, Research Triangle Park, NC;* <sup>3</sup>*Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Air pollutants have been associated with diabetes and metabolic syndrome, but the mechanisms remain to be elucidated. We hypothesized that acute O<sub>3</sub> exposure will produce metabolic impairments through endoplasmic reticular stress (ER) stress

and altered insulin signaling in liver, muscle and adipose tissues in the Wistar Kyoto rats. Rats were exposed to air or 1ppm O<sub>3</sub>, 6hr/day for 1 or 2 days. Glucose tolerance tests were conducted immediately following each day or one day after 2-day exposure. Tissues were analyzed for insulin and ER stress signaling and serum for inflammation and metabolic biomarkers. O<sub>3</sub> produced severe hyperglycemia and glucose intolerance that was reversible following 1 day recovery. Phosphorylation of insulin receptor substrate (pIRS) decreased after 2nd day O<sub>3</sub> in all three organs. Downstream mediators, phospho-serine/threonine kinase and phospho-glycogen synthase kinase also decreased but only in adipose tissue. Serum insulin changes were correlated with tissue levels of pIRS. Serum IL-6, thought to link ozone-induced inflammation and metabolic alterations, did not increase at any time; however lipocalin and acute phase proteins increased after O<sub>3</sub>. Serum leptin was also increased sharply after 1-day O<sub>3</sub> exposure and it was correlated with O<sub>3</sub>-induced hyperglycemia, but not glucose intolerance. Genes downstream of unfolded protein response were changed in the liver indicating ER stress. To examine the role of liver ER stress in O<sub>3</sub> induced impairment of metabolism, we treated rats with ER-stress inhibitor, salubrinal prior to air or 1ppm O<sub>3</sub>. Salubrinal did not diminish O<sub>3</sub> induced hyperglycemia and glucose intolerance, suggesting that hyperglycemia likely did not result from ER stress. In conclusion, acute O<sub>3</sub> exposure alters insulin signaling in metabolic organs causing hyperglycemia and glucose intolerance, which might contribute to increased incidences of diabetes and metabolic syndrome. (Does not reflect USEPA policy).

## PL 62 Inhaled Ozone Induces Metabolic Abnormalities in Mice Fed a High-Fructose Diet.

K. M. Allen<sup>1,2</sup>, P. Brooks<sup>1</sup>, M. Dereski<sup>1</sup>, R. Lewandowski<sup>1,2</sup>, I. Hotchkiss<sup>1</sup>, D. Jackson-Humbles<sup>1</sup>, C. Brandenberger<sup>1</sup>, L. Bramble<sup>1,2</sup>, J. G. Wagner<sup>1,2</sup> and J. Harkema<sup>1,2</sup>. <sup>1</sup>Pathobiology, Michigan State University, East Lansing, MI; <sup>2</sup>Great Lakes Air Center for Integrated Environmental Research, Michigan State University, East Lansing, MI.

Results of recent inhalation toxicology studies have indicated that long-term exposure of mice to concentrated ambient particulate matter induces insulin resistance and potentiates other adverse metabolic effects brought on by consumption of a high fat diet. Similar adverse metabolic effects on insulin signaling and glucose homeostasis caused by gaseous air pollutants, such as ozone (O<sub>3</sub>), have not been investigated. In the present study, we tested the hypothesis that subacute inhalation exposure to O<sub>3</sub> enhances metabolic abnormalities, caused by a high fructose diet (HFrD), in mice. C57/Bl6 male mice were maintained on either a normal chow (NC) or a HFrD (from which 60% of the calories were derived from fructose) for the duration of the study. Mice were exposed to 0 (filtered air controls; FA) or 0.5 ppm O<sub>3</sub>, 4 h/day for 24 consecutive weekdays. No combination of exposure or diet caused changes in glucose metabolism, as measured by oral glucose tolerance testing. In contrast, mice fed the HFrD and exposed to O<sub>3</sub> had an increased fasting insulin (1519±128 pg/mL) as compared to all other groups (NC/FA: 646±62.73, HFrD/FA: 841±87.17, NC/O<sub>3</sub>: 535±48.32). Similarly, plasma leptin levels were markedly increased in the HF/O<sub>3</sub> group. HOMA-IR, an indicator of insulin resistance, was also increased in the HFr/O<sub>3</sub> (16.61±2.23) mice as compared to the NC/FA, HFr/FA or NC/O<sub>3</sub> mice (7.64±0.91, 7.98±0.7 and 5.23±0.44, respectively). In addition, O<sub>3</sub> exposure enhanced the severity of HFrD-induced hepatic steatosis. Overall these data in mice suggest that subacute inhalation exposure to O<sub>3</sub> may induce or enhance some adverse metabolic effects caused by a HFrD. The interaction of diet and air pollution exposure on human health requires further study. Funded by USEPA RD83479701

## PL 63 Suppressed Responses in Heart Rate Variability during Inhalation Exposure to Ozone and Ambient Fine Particles in Rats on a High-Fructose Diet.

J. G. Wagner<sup>1</sup>, H. Yang<sup>2</sup>, K. M. Allen<sup>1</sup>, M. Morishita<sup>2</sup>, B. Nan<sup>2</sup>, B. Mukherjee<sup>2</sup>, G. Fink<sup>1</sup> and J. Harkema<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>University of Michigan, Ann Arbor, MI.

People with diet-induced cardiometabolic disorders (diabetes, hypertension) may be more susceptible to the adverse cardiovascular effects of air pollution. The present study was designed to determine if a high-fructose diet affects cardiovascular responses to inhaled air pollutants. We used a mobile air research laboratory located in an industrial area of Dearborn, MI, to expose male Sprague Dawley rats, to filtered air (FA), ozone (O<sub>3</sub>; 0.5 ppm), concentrated ambient fine particles (CAPs; 400 µg/m<sup>3</sup>) or the combination of O<sub>3</sub> & CAPs. Rats were fed a normal (ND) or high-fructose diet (HFD) for 8 weeks prior to exposure and during exposure. Inhalation exposures were 8h/day for 9 days (4-5 days/week). Heart rate (HR) and ECG waveforms were collected by radiotelemetry every 5 minutes during exposures, and measures of heart rate variability (HRV, indicated as SDNN and

rMSSD) were calculated and analyzed by a linear mixed model. Compared to FA-exposed rats fed ND, rats fed HFD had significantly greater HR (328 ± 27.5 vs 299 ± 35 bpm, respectively) and lower SDNN (44.6 ± 78.8 vs 64.4 ± 86 ms). All exposures caused decreases in HR that were greater in HFD rats (25-40 bpm) than in ND rats (6-15 bpm). However responses in HRV were dependent on the specific exposure and diet. Exposure to O<sub>3</sub>&CAPs induced significant decreases in HRV in ND- but not HFD-fed rats, with a 55% decrease in SDNN over the nine days of exposure. By comparison exposure to O<sub>3</sub> alone had the opposite effect on HRV, with a 48% increase in SDNN, but with no effect in HFD rats. Lastly, ND-fed rats exposed to CAPs alone had a modest decrease in SDNN (23%), while similarly exposed HFD-fed rats again had no change. In summary, while HR was decreased in all experimental groups, the degree and direction in change of HRV depends on the specific exposure and diet. The mechanism(s) underlying altered autonomic responses in HFD rats to single- or multi-pollutant exposures requires further study. US EPA RD83479701

## PL 64 Oxidative Stress and the Acceleration of Atherosclerosis in Susceptible Mice after Exposure to Semivolatile Components of Ultrafine Particulate Matter.

A. J. Keebaugh<sup>1</sup>, P. Pakbin<sup>2</sup>, L. B. Mendez<sup>1</sup>, Z. Ning<sup>2</sup>, G. Gookin<sup>1</sup>, C. Sioutas<sup>2</sup> and M. T. Kleinman<sup>1</sup>. <sup>1</sup>Community and Environmental Medicine, University of California Irvine, Irvine, CA; <sup>2</sup>Environmental Engineering, University of Southern California, Los Angeles, CA.

Exposure to ultrafine particulate matter (UF-PM) has been associated with adverse cardiovascular health effects. UF-PM contains semi-volatile organics (SVOCs) that are bound to particles but can partition to the vapor phase after emission. SVOCs contain species such as polycyclic aromatic hydrocarbons and quinones that can induce oxidative stress and may be responsible for the exacerbation of cardiovascular disease by UF-PM. Therefore, we hypothesized that the removal of SVOCs from an aerosol should decrease the ability of the particle to cause oxidative damage and consequently the acceleration of atherosclerotic plaque formation. ApoE <sup>-/-</sup> mice, which are prone to developing atherosclerosis, were exposed to UF concentrated ambient particles (CAPs), CAPs with the SVOC components removed, or SVOC components without the particle core. A control group was exposed to purified, filtered air. Particles were concentrated using a VACES, and SVOCs were separated from the particle core using a thermal denuder. The exposures took place 5 hours/day, 4 days/week for 8 weeks in downtown Los Angeles, 100m downwind of a major freeway. Plaque formation in the aortic arch and total and LDL cholesterol in the serum were measured to evaluate the progression of atherosclerosis. Serum concentrations of lipid peroxidation, protein carbonyl content, and glutathione were assessed to determine systemic oxidative stress. Aortic plaque formation in mice exposed to unmodified CAPs was higher than in those exposed to CAPs with no SVOCs. Similarly, higher levels of lipid peroxidation were measured in mice exposed to unmodified CAPs and SVOC components of CAPs compared to those exposed to CAPs without SVOCs. The corresponding trends in plaque formation and lipid peroxidation support the notion that exposure to SVOCs may contribute to the acceleration of atherosclerosis via an oxidative stress pathway.

## PL 65 Acrolein-Induced Increases in Blood Pressure and Heart Rate Are Coupled with Decreased Blood Oxygen Levels during Exposure in Hypertensive Rats.

C. M. Perez<sup>1</sup>, A. D. Ledbetter<sup>2</sup>, M. S. Hazari<sup>2</sup>, N. Haykal-Coates<sup>2</sup>, A. P. Carll<sup>1</sup>, D. W. Winsett<sup>2</sup>, D. L. Costa<sup>3</sup> and A. K. Farraj<sup>2</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Public Health Division, US EPA, Research Triangle Park, NC; <sup>3</sup>ORD, US EPA, Research Triangle Park, NC.

Exposure to air pollution increases the risk of cardiovascular morbidity and mortality, especially in individuals with pre-existing cardiovascular disease. Recent studies link exposure to air pollution with reduced blood oxygen saturation suggesting that hypoxia is a potential mechanism that mediates the adverse cardiovascular effects of air pollution. The purpose of this study was to characterize the cardiovascular effects of exposure to acrolein, a potent irritant and component of cigarette smoke and diesel exhaust and determine if acrolein exposure causes decreased blood oxygen levels. We hypothesized that hypertensive rats would be more sensitive to the adverse cardiovascular effects of acrolein and that the cardiovascular effects of acrolein would be coupled with decreased arterial blood oxygen levels during exposure. Spontaneously hypertensive (SH) and Wistar Kyoto (WKY; rats with normal blood pressure) rats implanted with biopotential radiotelemetry transmitters were exposed once for 3 hours to 3 parts per million acrolein gas or filtered air (control) in whole body plethysmograph chambers while cardiovascular and ventilatory parameters were monitored. In a separate cohort of rats, arterial blood samples were drawn before, during, and after exposure to acrolein to monitor blood oxygen saturation. We found that hypertensive, but not normal rats, had significant increases

in heart rate, blood pressure, breathing frequency, and minute volume during acrolein exposure. These effects were coupled with significant decreases in arterial blood pO<sub>2</sub> and K<sup>+</sup> levels and significant increases in pCO<sub>2</sub>. The data suggest that hypertension predisposes to the adverse health effects of air pollution exposure and that hypoxia may have an important role in mediating these physiologic responses (This abstract does not reflect EPA policy).

## PL 66 PM<sub>2.5</sub> Exposure and RAGE: Insight into an Emerging Risk for Diabetes.

J. M. Vaughan, J. T. Zelikoff, B. Narayanan, A. Schmidt and L. Chen. *Environmental Health Science, New York University, Tuxedo, NY.*

Diabetics are a particularly vulnerable population to the adverse cardiopulmonary effects of particulate air pollution (PM)—often attributed to enhanced inflammation and endothelial dysfunction. Recent reports have implicated activated receptors for advanced glycation end-products (RAGE) as an integral factor in the inflammatory processes of cardiovascular dysfunction and diabetes; nonetheless, it is unclear whether ambient PM alone/or in combination w/ other endogenous factors may contribute to RAGE activation. Levels of soluble RAGE (sRAGE) were measured in human serum samples (n=60) from two cities in Gansu, China (Jinchang (JC) and Zhangye (ZH)—albeit similar ambient levels of PM; Ni, Cu, As, and Se in JC were 76, 25, 17, and 7 fold higher than ZH, respectively). In addition, human pulmonary endothelial cells were exposed to PM (collected from the same region) to investigate RAGE-mediated vascular dysfunction. Lastly, to examine the link between PM and overt diabetic endpoints, B6C3F<sub>2</sub> mice were exposed to concentrated ambient PM (CAPS). Results: sRAGE was significantly higher (p=0.04) in residents of JC (538.7±37.5ng/ml) than that measured in ZH (452.6±29.1ng/ml). Multiple regression analyses revealed PM<sub>2.5</sub> concentration as a significant (p=0.03) predictor of RAGE outcome. In the in vitro work, after 48h of PM<sub>2.5</sub> exposure, a dose dependent increase in cell proliferation and small increases in sRAGE activity at higher doses of PM was evident. Immunofluorescence detection showed an elevation in cells positive for membranous RAGE expression; accompanied w/ a 2-fold increase in mRNA for RAGE & NF-κB and >2 fold increase of ATF4 & NF-κB in cells treated w/ PM+BSA. These findings suggest plausible interaction between PM & RAGE resulting in enhanced expression of NF-κB, ATF4 and RAGE. Finally, preliminary mouse exposures have yielded supportive findings: progeny of CAPs exposed pregnant mice have shown significantly decreased glucose tolerance compared to controls (p=0.03). Collectively, these data offer valuable insight into PM-mediated RAGE activation / its influence on diabetes.

## PS 67 Integration of Jacketed Telemetric Hemodynamics in a Toxicology Study Design: Assessment of Sensitivity and Distribution and Impact of Erroneous Values.

H. Holzgrefe, S. Tichenor, R. Kaiser and D. Meyer. *Toxicology, Charles River Laboratories, Reno, NV.*

Integration of telemetered hemodynamics in toxicology studies is an emerging trend which offers detailed information on potential cardiovascular safety issues that are only identified with repeat dosing. Jacketed external telemetry (JET) is an enabling technology for which the intrinsic variability of the associated minimally invasive blood pressure (BP) device (PA-C10, DSI, St. Paul, Minn.) has not been extensively characterized. Accordingly, we evaluated the intrinsic and extrinsic beat-to-beat pressure measurement errors of JET BP in 10 male cynomolgus monkeys (2.7-3.7 yrs, 3.0±0.2 kg). BP catheters were advanced to the descending aorta via the femoral artery. BP (24 h) was continuously digitized (500 Hz) in a quiet radio frequency environment and retrospectively analyzed in beat-to-beat increments (Life Sciences Suite, ver. 5.0, DSI). Data are presented as mean±std. Sham dosing occurred at 2.5 h post acquisition start to mimic a typical toxicology study design. Erroneous values were categorized as beats where either systolic pressure, pulse height, and/or +dP/dt were 60<>240, 20<>80, or 600<>4000 native units, respectively. Transducer stability was assessed as the beat-to-beat change (Δ) in systolic pressure. Over 24 h, systolic pressure was 130.6±8.5 mmHg and Δ was 0.0±2.67 mmHg. During a quiescent nocturnal period (10 h) systolic pressure was 131.9±8.5 mmHg and Δ was 0.0±2.42 mmHg. Erroneous values (8874/2428462 beats, 0.36%) were infrequent and temporally random. These data confirm that the JET BP device conformed to, or exceeded, design sensitivity (± 3 mmHg) at all times. Systolic pressures exhibited stable diurnal variances of ± 8.5 mmHg yielding ~ 80% power to detect a 10 mmHg change (p<0.05) with n=6. The sparse, sporadic incidence of non-physiologic hemodynamic values was insufficient to influence mean BP values aggregated over times ≥ 5 min. Consequently, resources devoted to the beat-to-beat filtering of JET BP values will not improve the accuracy, precision, or power of these data.

## PS 68 Evaluation of an in Line Filter for Reducing Noise in Subcutaneous Telemetered ECGs.

C. M. Kelly<sup>1</sup>, M. Miyamoto<sup>1</sup>, M. Brockway<sup>2</sup> and B. Brockway<sup>2</sup>. <sup>1</sup>Huntingdon Life Sciences, East Millstone, NJ; <sup>2</sup>VivaQuant, St. Paul, MN.

EMG noise and movement artifact are barriers to obtaining accurate interval measurements in ambulatory subjects in preclinical studies. Herein we report the results of testing of a new device, an In Line Filter (ILF) that employs Multi-Domain Signal Processing™ (MDSP) technology, for real-time noise and artifact suppression in telemetered subcutaneous ECG recordings. Prior evaluations of MDSP technology using ECGs already acquired by the Dataquest™ system showed that it reduces the amplitude of in-band noise by > 95% without distorting ECG morphology and provides a corresponding increase in the number of analyzable beats. In this work, studies of ILF performance were conducted using freely moving subjects instrumented with DSI™ D70-PCT telemetry transmitters. An ILF was inserted between the telemetry receiver and the Dataquest system to filter out noise. Raw and filtered ECG signals were collected from multiple species commonly used in safety studies and were analyzed with emka ECGauto using standard methods. Results obtained from filtered and unfiltered recordings were evaluated to assess the impact of filtering on parameter measurement accuracy, the increase in beats available for analysis, and the amount of labor required to perform interval analysis. Results show that, on average in all species tested, filtering the ECGs using the ILF prior to analysis increased the analyzable portion of the data to roughly that reported in the literature for telemetered epicardial and intravenous ECG sensors and significantly reduced the amount of labor required to perform interval analysis. There was no degradation in the accuracy of parameter measurements as a result of filtering the signal. Use of the ILF could make routine beat-to-beat analysis of 24-hour subcutaneous ECG recordings practical and cost-effective without the complications and complexities associated with epicardial, endocardial, and intravenous ECG sensing leads.

## PS 69 The Application of Telemetry EEG and EMG in Conscious Dogs and Monkeys for Safety Assessment and Translational Science.

X. Cheng, C. Cao, N. N. Niu, K. H. Chen, S. L. Sun and A. Hu. *Toxicology and Safety Pharmacology, Pharmaron, Beijing, China.*

The species differences are the common and major concerns in safety assessment and translational science, particular in situations where results from CV and CNS safety studies in the same species are required or the receptor subunits expression are significantly difference cross species etc. In this study, we have used the radio-telemetry technique to record EEG and EMG from conscious, non-sedated dogs and monkeys and validated the model with a proconvulsant, pentylenetetrazole (PTZ).

Beagle dogs and cynomolgus monkeys were implanted with four electrodes epidural over the motor cortex and connected to the radio-transmitter (DSI) placed subcutaneously in the lateral neck region. Two additional electrodes were inserted into the ridge cervical muscle for EMG recording simultaneously. The signals captured by the receiver were routed via a data matrix board to a PC and sampled at a rate of 500Hz.

Subcutaneous (s.c) administration of PTZ dose-dependently (10, 20 and 50 mg/kg s.c) induced paroxysmal activity, clonic convulsion and tonic convulsion in both dogs and monkeys, indicating a remarkable CNS safety issue of PTZ as positive control article. When PTZ administrated i.v at 1.5mg/kg/min and 1.5mL/min, both dogs and monkey showed similar level of paroxysmal spike-and-wave activity associated with clonic convulsions occurred between 17 and 36 min after the start of infusion at 4-5Hz.

The data indicate that the electroencephalogram (EEG) and electromyogram (EMG) are the most sensitive and valuable biomarkers in identifying pathologic CNS activity, in particular for safety pharmacology evaluation and translational application.

## PS 70 Established Method to Assess Cardiorespiratory Parameters in Inhalation Safety Pharmacology Studies in Conscious Beagle Dogs.

T. Ziegelhofer, J. Sheehan, J. Sentz, M. Miyamoto and A. Curran. *Safety Pharmacology, Huntingdon Life Sciences, East Millstone, NJ.*

A critical aspect of cardiorespiratory safety pharmacology studies is the collection of good quality cardiovascular and respiratory data immediately prior to dose, during dose and immediately after dose to be able to recognize any acute effects of the test

article. This is especially challenging when the test article is administered via inhalation. This poster describes the method for achieving a successful outcome in these types of studies, including the factors that must be considered in the design and execution. Effects of proper habituation to equipment and carefully scheduled study activities were assessed based on the overall character of cardiorespiratory response from 3 different studies.

Prior to the first data collection, all animals were surgically implanted with DSI telemetry transmitters and habituated to the exposure/data collection system. Respiratory parameters were collected using respiratory inductance plethysmography (RIP). Telemetry data were collected continuously while animals were in their home cage, after transfer to the exposure suite but prior to either air or the vehicle, during the exposure period, and for 24 hours post dose in 3 different studies. Each study used a different vehicle and an air (sham) control was administered to assess the vehicle effect.

Administration of the vehicle produced no effects on blood pressure, heart rate, body temperature, respiratory rate, tidal volume and minute volume during pre-dose, exposure period and for the 24 hour post dose recording period when compared to air (sham) control in all 3 studies. Very similar patterns in blood pressure and heart rate were noted in all 3 studies; however, each study has a specific pattern for body temperature and respiratory parameters, which was attributed to individual variation in these parameters. This poster presents a consistent and reliable method of collecting cardiorespiratory data from conscious beagle dogs prior to, during and after inhalation exposure in our Testing Facility.

**PS 71 Assessment of QT-Interval Prolongation in Nonclinical Safety Study Using External Telemetric Device in Conscious Beagle Dogs: Application of QT Shift and Probabilistic Methods.**

L. Renaud<sup>1</sup>, P. Champeroux<sup>2</sup>, S. Ruillon<sup>1</sup>, N. Velasquez<sup>1</sup>, P. Desbois<sup>1</sup>, O. Wattrelos<sup>1</sup> and N. Claude<sup>1</sup>. <sup>1</sup>*Drug Safety, Servier, Gidy, France;* <sup>2</sup>*Centre de Recherches Biologiques, CERB, Baugy, France.*

The detection of delayed ventricular repolarization, characterized by a QT interval prolongation, is one of the main issues for the preclinical evaluation of potential risk of pro-arrhythmia for a new drug candidate. This study was designed to compare different methods of QT interval prolongation assessment in conscious beagle dogs using external telemetric device. The same 6 dogs (3/sex) were given vehicle or reference compounds known to induce QT interval prolongation using a sequential design (single oral dosing of Sotalol at 30 mg/kg and Moxifloxacin at 30 then 90 mg/kg or repeated oral dosing for 6 days of Thioridazine at 20 mg/kg/d and Terfenadine at 30 mg/kg/d). Electrocardiograms were recorded during a treatment-free period and on day 1 and/or day 6 for approximately 20 h post dosing. QT intervals were measured from a beat to beat analysis over 10-min periods centred on selected timeslots and corrected according to the Van de Waters formula (QTvdw). QT shift calculations and an analysis based on the principles of the Holzgrefe's probabilistic method (QTh, using a minimum 250 beats/timeslot) were also performed. All methods allowed an accurate evidence of QT effect for Sotalol and Moxifloxacin. The QT shift and QTh methods gave more evidences for Terfenadine effect than QTvdw. As expected, the marked increase in heart rate (HR) induced by Thioridazine resulted in no apparent effect on QT and a statistically significant overcorrection for QTvdw whereas QT shift and QTh gave more accurate and reliable results. The statistical sensitivity threshold detection of QT prolongation was low, i.e. 10 to 15 ms for QT shift and QTh methods. Thus, external telemetry in non-clinical safety dog studies allows new perspectives for a better assessment of QT prolongation when associated to QT shift and Holzgrefe's probabilistic methods, especially in case of slight drug-induced QT effect or marked changes in HR.

**PS 72 Integration of Automated Patch Clamp Systems and Logistic Models in the Cardiochannelgramtm (CCGTM) for Better Prediction of Cardiac Risk.**

J. W. Kramer<sup>1</sup>, G. J. Myatt<sup>2</sup>, C. A. Obejero-Paz<sup>1</sup>, A. Bruening-Wright<sup>1</sup>, Y. A. Kuryshev<sup>1</sup> and A. M. Brown<sup>1</sup>. <sup>1</sup>*ChanTest Corporation, Cleveland, OH;* <sup>2</sup>*Leadscope Inc., Columbus, OH.*

Drug-induced inhibition of the cardiac hERG potassium channel is recommended by ICH and FDA to predict delayed cardiac repolarization (DR) and cardiac risk. The consequent QTc prolongation is a surrogate marker of Torsade de Pointes (TdP), a rare but potentially lethal iatrogenic outcome. Drugs with effective therapeutic plasma concentrations (ETPC) within 30-fold of their hERG IC50s are thought to be dangerous despite the fact that multiple ion channel effects (MICE)

can mitigate DR. Here we demonstrate that logistic regression models, which integrate MICE, predict TdP with much greater certainty than the hERG safety ratio (hERG IC50/ETPC or safety margin (SM)) alone. To this end we measured hERG, Nav1.5, Cav1.2, Kir2.1 and KvLQT1/minK IC50 values of 56 drugs (33 +TdP and 23 -TdP) from multiple classes using automated patch clamp systems including Qpatch and PatchXpress. The sensitivity of the automated patch clamp platforms was evaluated in a comparison to manual patch clamp. ETPC values and the torsadogenic liability of drugs was obtained from the literature, package inserts and Arizona CERT. Eleven logistic regression models were constructed; one using the hERG SM alone, the others integrating hERG SM, Nav1.5 SM and/or Cav1.2 SM data. The predictive power of each model was evaluated using the likelihood ratio test. Leave-one-out cross validations were performed and each model's accuracy was determined by comparing receiver-operating characteristics (ROC, sensitivity vs. 1-specificity). Models that include Nav1.5, Cav1.2 or both variables are statistically significant better predictors of TdP liability than the model that contains only hERG (Model 1). Model 1 had a ROC area under the curve (AUC) of 0.80 and Model 11, that includes hERG, Nav and Cav1.2 SMs, significantly improved accuracy showing a ROC AUC of 0.94. Thus, Model 11 that incorporates the concept of MICE in the CardioChannelGramTM (CCGTM) is a robust nonclinical predictor of cardiac risk.

**PS 73 Characterization of Jacketed External Telemetry with Blood Pressure in Conscious Nonhuman Primates in Pen-Style Housing Administered Etilefrine, Sotalol, or Hydralazine.**

L. Kreckler, J. Kopshinsky, J. Schneider, G. Hanson, D. Morris and C. Foley. *Covance Laboratories, Inc., Madison, WI.*

An important component of nonclinical safety assessment is the evaluation of electrocardiography (ECG) and hemodynamic parameters. Jacketed external telemetry with an implanted telemetry blood pressure transmitter (JET-BP) is a minimally invasive technology being utilized in general toxicology studies to assess ECG and blood pressure measurements in conscious, unrestrained animals. We characterized JET-BP in nonhuman primates (NHPs) housed in pen-style caging with three reference compounds with known effects on blood pressure or ECG parameters. Thirty-six male NHPs were implanted with a telemetry blood pressure device and group-housed in pen-style caging (3 animals/pen). Four animals per group were given reference material or a concurrent control article. Etilefrine, a sympathomimetic, was given at 1 or 10 mg/kg; hydralazine, a vasodilator, at 1 or 10 mg/kg; and sotalol, a non-specific  $\beta$ -blocker, at 3 or 30 mg/kg. JET-BP measurements were recorded for at least 90 minutes prior to dosing and continuously for at least 20 hours postdose. The following ECG and hemodynamic parameters were determined as one (light phase) or two-hour (dark phase) averages: PR, QT and rate-corrected QT; systolic, diastolic, and mean arterial pressures; heart rate; and arterial pulse pressure. In addition, blood was collected at seven postdose timepoints for each test article for pharmacokinetic analysis. Etilefrine significantly increased mean arterial pressure, systolic blood pressure and pulse height, while diastolic blood pressure remained unchanged. Sotalol significantly prolonged QT with no significant change in blood pressure. Administration of hydralazine did not significantly change blood pressure at the dose levels administered. In summary, ECG and blood pressure changes caused by three different reference compounds were detectable using JET-BP technology in group-housed NHPs.

**PS 74 Differential Cardiovascular Physiology and Pathology in Selected Lineages of Miniature Swine.**

A. Stricker-Krongrad<sup>1</sup>, T. J. Madsen<sup>1</sup>, B. C. Hanks<sup>1,2</sup>, D. Brocksmitz<sup>2</sup>, J. Liu<sup>1</sup>, L. D. Brown<sup>1,2</sup> and G. F. Boucard<sup>1,2</sup>. <sup>1</sup>*Sinclair Research Center, LLC, Columbia, MO;* <sup>2</sup>*Sinclair BioResources LLC, Auxvasse, MO.*

The miniature swine has been increasingly recognized as a valid alternative to canine and non-human primates in regulatory toxicity. This poster presents the results of cardiovascular assessments in the Yucatan, Hanford, and Sinclair miniature swine conducted during clinical investigations and control toxicity testing. Anatomic parameters were obtained at necropsy. Blood vessels diameter, velocity, and flow were obtained by Doppler ultrasonography. Cardiac electrophysiology was obtained using clinical ECG and surgical monitor units. Macroscopic lesions and histopathology assessments were conducted on heart and kidneys. Data were compared to published measurements of adult human illustrating similarities or differences (for practicality, male data are reported here). Across the three lineages, heart-to-body weights ratio ranged from 0.41 to 0.50 and were higher than human (0.42). The geometric corrections for heart rate adjustment to body size ranged from 215 to 297 and were comparable to human (241), indicating that heart volume and function were well adjusted to the reduction in body size. The miniswine

hearts showed a coronary artery distribution comparable to human. The right coronary internal diameters ranged from 1.44 to 1.79 mm and were comparable to human (3.9 mm) when adjusted to body surface area (weight range: 10-30 kg). External femoral blood flows at rest averaged 93 mL/min and were slightly lower than human (260 mL/min) when adjusted to body size. Electrophysiological heart segments duration (e.g. RR ranged from 360 to 662 msec) and their ratio (QT/RR) were proportional to human and well-adjusted to body size. Macroscopic lesions were nonexistent. Histopathology findings were rare and limited to sub-level myocardial inflammation with low incidence in the Hanford lineage. In conclusion, the similarities between the cardiovascular systems make these three lineages of miniature swine suitable animals to model the human counterpart.

## PS 75 Whole Heart Energetics and Stress Test As an Indicator of Drug-Induced Cardiac Toxicity.

K. A. Henderson<sup>1</sup>, R. Borders<sup>1</sup>, J. Ross<sup>1</sup>, A. Jalil<sup>2</sup>, W. Brandon<sup>1</sup>, J. Ma<sup>1</sup> and R. M. Brian<sup>1</sup>. <sup>1</sup>Battelle Memorial Institute, Columbus, OH; <sup>2</sup>Ohio State University, Columbus, OH.

Cardiac toxicity, manifested as compromised contractility or ischemic heart disease, comprises 26.9% of post-approval drug failures. The heart has a high demand for a constant energy supply which can be affected by many sources of stress and thus may be a good indicator of potential toxicity. The purpose of this research was to utilize the ex vivo heart model to assess contractility and whole heart energetics in response to drugs with known/unknown mechanisms of toxicity. We used FCCP and verapamil as positive and negative controls and doxorubicin (dox), doxorubicin-ol, sunitinib, and sorafenib as the chemotherapies associated with latent toxicity. Rat hearts were removed, perfused with Modified Henselet Krebs, and LVP was monitored via insertion of a fluid-filled balloon. The perfused heart was inserted into an 11.7 NMR magnet. Whole heart phosphogen content was assessed before and during 60 min of drug exposure and then during 20 min of 0.1 μM isoproterenol (iso) with drug to assess energy reserve. Control heart contractility and energetics were stable throughout the experiment until the iso challenge, where contractility increased as expected and PCr and ATP decreased and Pi increased. FCCP treated hearts showed a decline in contractility and PCr and reduced reserve during the iso challenge. Verapamil treated hearts did not change in energetics during treatment or during the iso challenge. Dox increased contractility, while the other chemotherapies showed very little change in contractility during drug treatment. Dox treated hearts demonstrated a drop in Pi, PCr, and ATP. In addition, during the iso challenge contractility increased compared to control and PCr decreased. Dox and sorafenib may be enhancing part of the beta-agonist pathway, causing a more pronounced response to iso and thus resulting in an increased work load for the heart. This may be a possible pathway to investigate as a mechanism for latent toxicity, as well as an early indicator of potential drug induced cardiac issues after treatment.

## PS 76 Simultaneous Recording of Action Potentials and Calcium Transients from Stem-Cell Derived Cardiomyocytes: Applications for Cardiotoxicity Testing.

R. Whittaker<sup>1</sup>, F. Cerignoli<sup>1</sup>, R. Vega<sup>1</sup>, R. Ingermans<sup>1</sup>, R. Towart<sup>2</sup>, D. Gallacher<sup>2</sup>, M. Mercola<sup>3</sup> and J. Price<sup>1,3</sup>. <sup>1</sup>Vala Sciences Inc, San Diego, CA; <sup>2</sup>Center of Excellence for Cardiovascular Safety Research, Janssen Pharmaceuticals, Beerse, Belgium; <sup>3</sup>Sanford-Burnham Medical Research Institute, La Jolla, CA.

Current methods for preclinical cardiotoxicity testing generally examine the effects of candidate compounds on the activity of single ion channels using manual or planar patch clamp methods. Limitations in these assays require that the tests be performed with cell lines which stably express the ion channel of interest. This reductionist approach grossly underestimates the complexity of cardiomyocyte excitability and physiology. We have developed a new automated image cytometer and associated software which facilitates a more physiologically relevant test of compound effects on cardiomyocyte excitation-contraction coupling. This new approach utilizes a dual channel automated Image cytometer that allows for simultaneous measurement of the cardiomyocyte action potential and calcium transient using voltage and calcium sensitive dyes. By using these advanced imaging techniques this system frees the need for the assay apparatus to interact physically with the cells, allowing the use of a wide array of cell types including more clinically relevant models such as cardiomyocytes derived from human induced pluripotent stem cells (hiPSC). Here we demonstrate the application of this system to a small scale screen of known cardioactive compounds in hiPSC derived cardiomyocytes. Our results suggest that the ability to identify perturbations in the cardiomyocyte action potential and/or calcium transient due to exposure to cardioactive compounds is on par with existing technologies. However, this system demonstrates a

much higher throughput than existing systems and provides a more complete analysis of compound effects on excitation-contraction coupling in the cardiomyocyte.

## PS 77 Effect of Cell Culture Media on the Growth and Viability of Neonatal Rat Cardiomyocytes.

L. Baeva, D. Chan, H. Dinesdurge, M. W. Betz and R. P. Brown. *CDRH, US FDA, Silver Spring, MD.*

We studied the suitability of serum-free medium, reduced serum medium, and chemically defined medium with serum replacement for growing rat neonatal cardiomyocytes. The cardiac cells were grown for up to 48 hours under six different culture conditions: the base make up (Dulbecco's Modified Eagle Medium (DMEM) containing 100 μM BrdU, 10 mM HEPES, 50 U/mL penicillin and 50 μg/mL streptomycin) with 10% Fetal Bovine Serum (FBS)-(A), or 10% Goat Serum-(C), or 10% Knockout Serum Replacement (KRS)-(D) or no serum -(B); Knockout DMEM(Gibco) (E) and Advanced DMEM(Gibco) (F) were supplemented by 15% KSR and 2% FBS, respectively. The beating rates and viabilities of the cells were evaluated by counting the beats of cells under a phase contrast microscope and Neutral Red Assay method, respectively. The cell damage and cytotoxicity were determined by measuring lactate dehydrogenase (LDH) activity and the troponin I release from the cardiomyocytes were examined by rat cardiac Troponin ELISA. The results indicate poor cell beating and viability for medium C without serum. The media D, E, and F had relatively low background troponin level, provided good viability and morphology and low cytotoxicity, and may be used for the cardiotoxicity study.

## PS 78 Understanding the Relationship of PI3K Inhibition to HERG Liabilities and QT Prolongation.

D. Puppala<sup>1</sup>, H. Cheng<sup>3</sup>, A. Rosado<sup>2</sup>, K. McKiernan<sup>2</sup>, S. Sun<sup>2</sup>, B. Fermini<sup>2</sup> and K. Leach<sup>1</sup>. <sup>1</sup>Compound Safety Prediction, Pfizer Inc, Groton, CT; <sup>2</sup>Global Safety Pharmacology, Pfizer Inc, Groton, CT; <sup>3</sup>Oncology Medicinal Chemistry, Pfizer Inc, Groton, CT.

Off target promiscuity is one of the biggest issues that kinase targeting drug discovery teams have to overcome in order to achieve efficacy with limited toxicity. In a recent paper, Zhongju Lu et al (Science Translational Medicine 25 April 2012 Vol 4 Issue 131) showed that suppression of Phosphoinositide 3-Kinase(PI3K) signaling directly or indirectly via tyrosine kinase inhibition prolongs the QT interval by affecting multiple ion channels, including HERG. In an effort to understand the role of PI3K inhibitors and HERG channels, we investigated the effects of Pfizer PI3Ka inhibitors both in a Dofetilide binding assay that determines their affinity for HERG channels as well as in a patch clamp assay that assesses their functional activity on these channels. Out of 48 PI3K inhibitors selected from four structurally distinct series and with PI3Ka Ki less than 1 nM, 47 exhibited Dofetilide Ki values > 10 uM, and one demonstrated a Ki value of ≈ 2.0 uM, a concentration > 2000-fold above its kinase activity. 8 compounds, including the one with a Dofetilide Ki of 2.0 uM, were tested in the HERG functional assay and all showed IC50 values > 30 uM.

In addition, 16 marketed drugs, which are known HERG blockers and that have been shown to induce QTc prolongation (14/16) and/or cause Torsades de Pointes in the clinic (8/14), were tested in a PI3Ka enzyme assay. Only Verapamil, a calcium channel blocker that inhibits HERG current (IC50: 0.2 uM) but does not prolong the QTc interval or cause TdP in the clinic exhibited activity on PI3Ka (IC50: 33 uM), while the rest showed IC50 > 100 uM.

In summary, the data obtained from both Pfizer potent PI3Ka inhibitors and marketed drugs demonstrate the absence of the correlation between PI3Ka inhibition and HERG activity.

Furthermore, our results support the notion that HERG inhibition, in the absence of PI3K inhibition, is sufficient to prolong the QT interval.

## PS 79 Characterization of Cell Signaling Events in Human Cardiomyocytes.

S. Eldridge<sup>1</sup>, M. Davis<sup>1</sup>, J. Mussio<sup>2</sup> and R. Parchment<sup>2</sup>. <sup>1</sup>DCTD, NCI, Bethesda, MD; <sup>2</sup>SAIC-Frederick, Frederick National Laboratory for Cancer Research, Frederick, MD.

Cardiotoxicity is a significant concern for anticancer therapeutics. "On-target" toxicity may result when a drug target that regulates cancer growth also serves an important role in normal cardiac function. To explore mechanisms of cardiac toxicity

associated with anti-cancer agents, in vitro approaches are key investigative tools. iCell® cardiomyocytes (Cellular Dynamics International, Madison, WI) are highly purified human cardiomyocytes derived from induced pluripotent stem cells through reprogramming adult cells, and are becoming widely used for the assessment of cardiac toxicity. To begin to inform the utility of these cells to monitor cellular events involved in critical cardiac myocyte signaling, we measured expression and activity of ErbB receptors, Erk1, Erk2, AKT, troponins, and endothelin-1 (ET-1) receptors A and B. Untreated iCell® cardiomyocytes expressed ErbB2 and ErbB4 receptors, Erk1, Erk2, AKT, cardiac troponin I, cardiac troponin T and ET-1 receptors A and B, but not ErbB1 or ErbB3 receptors. Furthermore, treatment with neuregulin-1 (a natural ligand for ErbB4) activated ERK1/2 and AKT as demonstrated by increased levels of phosphorylated proteins measured by western blotting with phospho-specific antibodies. Ligand-activated ErbB2/ErbB4 signaling was both dose and time dependent. We also examined the effect of tyrosine kinase inhibitors (lapatinib, sorafenib and staurosporine) and anthracyclines (doxorubicin) on cell death and mitochondrial membrane potential (MMP) using a high content multiplexed imaging system, and on troponin release into the cell culture media using the Meso Scale Discovery® platform. All of these anticancer agents induced a dose-dependent release of cardiac troponins I and T and caused a reduction in MMP. Based on these results, this model may present an opportunity to explore and “back-translate” mechanisms of cardiotoxicity using human cardiomyocytes in vitro. Funded by NCI Contract No HHSN261200800001E.

## PS 80 Mitochondria and Intrinsic Apoptotic Pathway Mediate Cardiac Toxicity of Environmentally Persistent Free Radicals (EPFR).

G. C. Chuang<sup>1</sup>, B. Dellinger<sup>2</sup> and K. J. Varner<sup>1</sup>. <sup>1</sup>Pharmacology, Louisiana State University Health Sciences Center, New Orleans, LA; <sup>2</sup>Chemistry, Louisiana State University and A&M College, Baton Rouge, LA.

Epidemiology studies have linked combustion-derived particulate matter to increased cardiac morbidity and mortality. To conduct prospective controlled-exposure studies, we synthesized the model EPFR, DCB230, by chemisorption of 1,2-dichlorobenzene to 0.2 µm silica particles containing 5% Cu(II)O at 230°C. Electron paramagnetic resonance showed that DCB230 generates radicals in solution similar to those produced by EPFRs found in environmental samples. We have shown that DCB230 inhalation produces inflammation and oxidative stress in both lung and heart. Since oxidative stress and apoptosis are mechanisms implicated in cardiac injury, we hypothesized that DCB230 exposure exerts cardiotoxicity by activating apoptotic pathways. HL-1 cardiomyocytes were dosed with 0-200 µg/mL DCB230 for 8 h and assessed for cytotoxicity and apoptotic markers. DCB230 dose-dependently increased lactate dehydrogenase (LDH) release, a marker of late cell death. Caspase 3, caspase 9, and poly (ADP-ribose) polymerase 1 cleavage also increased concomitant with DCB230 concentration, indicating apoptotic signaling activation. Next, HL-1 cardiomyocytes were treated with 0-200 µg/mL DCB230 for 2 h to examine early signaling events. While neither LDH release nor caspase 3 cleavage were detected after 2 h, increased caspase 9 cleavage suggests that mitochondrial dysfunction initiated early intrinsic apoptotic signaling. Confocal microscopy showed that mitochondrial membrane potential decreased after 2 h treatment with DCB230. Lastly, fluorescence data was validated as mitochondrial via FRET and co-localization with MitoTracker Green. Taken together, DCB230 exposure depolarized mitochondria in cardiomyocytes, leading to the activation of canonical intrinsic apoptotic signaling and resulting in cell death. Future studies will assess mitochondrial permeability transition and autophagy as contributing mechanisms. Supported by NIH P42-ES013648, sub-award 61365.

## PS 81 Evaluation of Cellular Impedance Assays for Drug Screening in Cardiomyocytes.

M. Peters, C. W. Scott, S. D. Lamore and Y. P. Dragan. *Safety Assessment, AstraZeneca, Waltham, MA.*

Cardiovascular (CV) toxicity is a leading contributor to drug withdrawal and late-stage attrition. Earlier screening is a validated approach to build-in CV safety, as demonstrated for hERG screening to reduce arrhythmia. There is an urgent need for novel in vitro assays to extend this success to contractility, heart rate, hypertrophy, structural damage, and non-HERG arrhythmia. Advances in cellular impedance technology enables label-free tracking of spontaneous synchronized beating of cultured cardiomyocytes (CM). To validate and translate CM impedance assays, we tested a set of drugs with established CV effects in humans- 22 neg. inotropes, 8 pos. inotropes, and 21 inactives (previously tested in canine CM Tox Appl Pharm 260(2):162). The data clearly indicate that beat rate and amplitude are independent variables, capable of providing robust potency data. Consistent with the balance of negative inotropes, the most frequent response was a dose-dependent decrease in

amplitude until beating stopped. The cessation of beating was not linked to cytotoxicity (judged by ATP and cell index) indicating specific changes in CM function. Since rat neonatal (and stem cell-derived) CMs have a negative frequency-force relationship, it is not surprising that the decrease in amplitude was linked to a concomitant increase in rate. However, for another subset of validation compounds, rate initially decreased, whereas amplitude showed no associated change until higher drug concentrations. Moreover, for a test compound not in the validation set (that was selected for inducing myocarditis in 2 days), beat rate increased with no change in amplitude or cytotoxicity. Together this data demonstrates that impedance assays can detect and differentiated functional changes in CMs. The changes are sensitive to electrical and mechanical aspects of contraction, yield robust data, and offer a versatile format with moderate throughput making this platform a candidate for addressing gaps in early phase screening for CV toxicity.

## PS 82 Cellular Impedance Assays for Predictive Preclinical Drug Screening of Kinase Inhibitors in Cardiovascular Toxicity.

S. D. Lamore, C. W. Scott, Y. P. Dragan and M. Peters. *Safety Assessment, AstraZeneca, Waltham, MA.*

Cardiotoxicity is the leading cause for late stage drug attrition and withdrawals from the market. Serious adverse cardiac events have emerged as a prevalent risk for kinase inhibitors (KI). Although current in vivo screens can reduce known risks due to arrhythmia, there is urgent need for novel in vitro assays with sufficient throughput to identify risks and support the development of SAR against other prevalent cardiovascular (CV) toxicities. Recently, cellular impedance technology has been adapted for detecting spontaneous, synchronized beating of cultures of cardiomyocytes (CM) in a real-time, label-free format. Impedance technology is a good candidate for detecting the pleiotropic cellular effects of kinases since it detects morphological changes thereby giving a readout that is downstream of key toxicity targets in the contraction cascade (i.e. cardiac action potential, calcium flux, mechanical elements of contraction). We evaluated the application of impedance-based assays for screening KI effects on rat neonatal CM. We selected compounds from a MAP-microtubule affinity-regulating kinase (MARK) inhibitor program that failed in late-stage preclinical development with dramatically decreased blood pressure in anesthetized dogs as an example for the earlier detection of CV toxicity. Two MARK inhibitors were tested and both dose-dependently influenced CM beat rate and amplitude without causing cell death as judged by cell index, cellular ATP levels, or cardiac troponin release assays. The relative potency of the two compounds on reducing beat amplitude in impedance assays (EC<sub>50</sub>= 4.31 µM and 0.55 µM; 20 min exposure) aligned with the ~10-fold difference in affinity for MARK isoforms 1-4. Knockdown of pan-MARK expression reduced beat amplitude by 40%. These MARK data indicate that impedance assays can specifically detect non-cytotoxic functional effects of KIs on CM. Our data support the validation of cellular impedance-based assays for an early preclinical CV toxicity screening of KIs.

## PS 83 Activation of Human Monocytic NADPH Oxidase by Chlorinated Cyclodiene Insecticides.

L. C. Mangum, J. E. Chambers and M. K. Ross. *CVM Basic Sciences, Mississippi State University, Mississippi State, MS.*

Although the mechanistic relationship between bioaccumulative organochlorine (OC) insecticide exposure and increased atherosclerosis risk is poorly defined, elevated systemic oxidative stress stemming from OC-mediated induction of NADPH oxidase activity may play a significant role in disease development. Activation of phagocytic Nox2-containing NADPH oxidase can result in a rapid intracellular accumulation of superoxide-derived reactive oxygen species (ROS) that may be directly linked to the progression of atherosclerosis. This study measured the ability of two legacy OC compounds to induce Nox2-containing NADPH oxidase activity in vitro, in addition to providing evidence for a possible mechanism of action. Human THP-1 monocytes exposed to micromolar amounts (1-20 µM) of the cyclodiene OC insecticides trans-nonachlor and dieldrin exhibited increased levels of serine phosphorylation of the p47phox regulatory subunit of NADPH oxidase, a necessary process for enzyme assembly and translocation, with trans-nonachlor demonstrating several fold greater potency than dieldrin. OC treatment also induced elevated levels of intracellular ROS, as shown by 2',7'-dichlorofluorescein-diacetate fluorescence assay, suggesting increased superoxide anion production. Pretreatment of monocytes with arachidonyl trifluoromethyl ketone, a specific inhibitor of cytosolic phospholipase A2, prior to cyclodiene treatment abrogated p47phox serine phosphorylation and blocked the induction of arachidonic acid and prostanoid liberation, as determined by UPLC-ESI MS/MS, suggesting that this enzyme may play a crucial role in the induction of NADPH oxidase activity by cyclodienes via the modulation of intracellular arachidonic acid levels. The results suggest that trans-nonachlor and dieldrin are capable of altering intracellular ROS levels via an

inducible NADPH oxidase dependent mechanism that may be significant in the etiology of atherosclerosis associated with exposure to bioaccumulative cyclodiene insecticides. (NIH R15ES015348)

#### PS 84 Mechanistic Studies of Drug-Induced Cardiac Hypertrophy in H9c2 Cell.

Z. Lin and Y. Will. *Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT.*

Drug induced cardiotoxicity can manifest itself through a variety of mechanisms including mitochondrial toxicity, apoptosis, oxidative stress and ion channel disturbance. However, cardiac hypertrophy is the most common safety finding. Here, we aimed at established an in vitro platform which could reliably characterize hypertrophic responses. Fifty drugs reported to cause hypertrophy in vivo were utilized in this study and consistent of a variety of drug classes such as anthracyclines, statins, kinase inhibitors and catecholamines. Compounds were characterized in H9c2 cell assessing the following endpoints: cell size, protein synthesis, fetal gene expression (ANP, BNP, MYH7), cell viability and reactive oxygen species (ROS).

Our results indicate that unlike the traditional cardiac hypertrophy which is driven by ventricular wall stress and hormonal factors including angiotensin II, endothelin-1, and catecholamine, compound-induced cardiac hypertrophy (increase in protein and cell size) may be initiated by the same mechanisms that drive cytotoxicity. In contrast, fetal gene expression is different from the mechanisms that drive cell size and protein increase.

Specifically, our results demonstrate that: 1) all protein synthesis-inducing compounds (23) caused significant cytotoxicity; 2) all compounds causing increase in cell size also induced protein synthesis; 3) both protein and cell size increase were compound-concentration dependent with protein increase occurring always ahead of cell size increase; 4) of the total of 50 drugs known to cause hypertrophy in vivo, 28 compounds induced fetal gene expression; 5) Oxidative stress was associated with the hypertrophic response (25%).

In summary, our data suggest the initial trigger(s) of compound-induced hypertrophic response are multi-factorial; one of which shares the same mechanism that induces cytotoxicity. Not all compounds known to cause hypertrophy in vivo were accurately characterized by our in vitro approach. Whether stem cells and additional mechanistic parameters can improve our assay is subject to future studies.

#### PS 85 Optical Measurements of Electrical Activity from hiPSC-Derived Cardiomyocytes Is a Robust and High-Throughput Method for Measuring NCE-Effects on the Cardiac Action Potential.

G. Smith<sup>2</sup>, B. D. Anson<sup>1</sup>, M. A. Craig<sup>3</sup> and I. Ghouri<sup>2</sup>. <sup>1</sup>*Cellular Dynamics International, Madison, WI*; <sup>2</sup>*University of Glasgow, Glasgow, United Kingdom*; <sup>3</sup>*Clyde Biosciences, Glasgow, United Kingdom*. Sponsor: K. Kolaja.

Pro-arrhythmic assessment of new chemical entities (NCEs) is a vital component of toxicological and safety profiling. Manual patch clamp interrogation of the cardiac action potential (AP) is a gold standard for proarrhythmia assessment; however this technique is laborious, requires highly skilled scientists, and neither the technique nor traditional tissue cells have been readily amenable to higher throughput techniques. Optical measurements of electrical activity with human cardiomyocytes may offer a solution. We present data here characterizing and demonstrating the suitability of a novel optical platform used in conjunction with hiPSC-derived cardiomyocytes to assess NCE-mediated pro-arrhythmogenicity.

Cardiac electrical activity was monitored from spontaneously beating hiPSC-cardiomyocyte syncytia with di-4-ANEPPS at a 10kHz over 60 second time windows from 2-3 areas per well over 3 wells for both experimental and control values. Small molecule effects on Na<sup>+</sup>, hERG, and Ca<sup>2+</sup> channels were assessed and compared with time matched controls. Ion channel block by all agents produced dose-dependent changes in the expected AP parameters relative to controls. Na<sup>+</sup> channel block by 3μM mexiletine produced a 244±86% (n=3) increase in AP rise time, hERG channel block by 30nM E4031 produced a 39±14% (n=3) increase in APD90, and Ca<sup>2+</sup> channel block by 300nM nifedipine produced an approximate 50% shortening in APD90. Experimental measurements for a single compound were completed in less than 3 hours. Similar data was obtained across cellular manufacturing batches and experimental days. This dataset demonstrate that optical measurements of electrical activity on hiPSC-derived cardiomyocytes is a suitable methodology for assessing NCE arrhythmogenic potential with a robustness that approaches that of manual patch clamp and throughput that is an order of magnitude greater.

#### PS 86 Multiparameter In Vitro Assessment of Drug Effects on Cardiomyocyte Physiology Using iPSCs.

O. Sirenko<sup>1</sup>, C. Crittenden<sup>1</sup>, A. Blake<sup>2</sup>, I. Rusyn<sup>3</sup> and E. F. Cromwell<sup>1</sup>.

<sup>1</sup>*Molecular Devices LLC, Sunnyvale, CA*; <sup>2</sup>*Cellular Dynamics International, Madison, WI*; <sup>3</sup>*University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Highly predictive in vitro assays suitable for high throughput screening (HTS) for potential cardiotoxicity are critical to drug safety testing. Adult human stem cell derived cardiomyocytes show promise for screening compounds during early drug development. We developed methods for measuring the impact of drug candidates on the beating rate of human iPSC derived cardiomyocytes using fast kinetic fluorescence imaging. Cardiomyocyte contraction rate and pattern are characterized by monitoring changes in intracellular Ca<sup>2+</sup> measured using calcium sensitive dyes. The assay was optimized for HTS and allows characterization of beating profiles by using multi-parameter analysis outputs such as beating rate, peak frequency and width, or waveform irregularities. The assay is suitable for assessment of short-term (minutes) and delayed (days) effects. Next, we tested known cardiotoxic compounds including alpha and beta blockers, hERG inhibitors, ion channel blockers, etc., as well as control drugs. IC50 values showed a significant rank correlation with published values determined by other cardiotoxicity models as well as good concordance with reported human plasma Cmax values. The assay was further tested using commercially available cardiotoxicity library representing different classes of compounds including receptor antagonists, ion channel blockers, anti-cancer and anti-inflammatory drugs, and kinase inhibitors. The estimated balanced prediction accuracy of the assay was greater than 80%, and multi-parameter characterization of beating profiles allowed identification of specific patterns defining hERG or Na channel blockers. We conclude that this assay shows utility for screening compounds for potential to cause arrhythmic and non-arrhythmic cardiotoxicity.

#### PS 87 Nucleoside Reverse Transcriptase Inhibitors Induced Premature Senescence in Aortic Endothelial Cells.

V. Y. Hebert, K. Slaybaugh, C. N. Robinson, S. Xue, D. Hayes, M. C. Glover and T. R. Dugas. *Pharmacology, LSU Health Sciences Center, Shreveport, LA.*

HIV patients undergoing antiretroviral therapy exhibit an increased incidence of cardiovascular events and their associated diseases. Though HIV therapy generally involves a combination drug approach, nucleoside reverse transcriptase inhibitors (NRTI) are considered a backbone of this therapy. Prior studies in rodents suggested that NRTI promote HIV-associated endothelial dysfunction, an initiating factor in atherosclerosis. Further, this cellular dysfunction was associated with mitochondrial injury. In cultured endothelial cells, NRTI treatment increased mitochondrial ROS production, while decreasing ATP production and the activities of mitochondrial electron transport chain (ETC) complexes I-IV. While these effects were observed for acute treatment, in other studies, we noted that when the mitochondria were exposed to low doses of NRTI, damaged mitochondria were removed through a process known as mitophagy. Thus, our hypothesis was that with chronic treatment, this repair mechanism may be overwhelmed, so as to promote premature endothelial senescence. In these studies, human aortic endothelial cells (HAEC) were exposed to chronic NRTI treatment. ROS production, cell proliferation rate and levels of senescence were determined. Our findings were that NRTI treatment increased ROS production, at least initially. Also, the rate of cell proliferation decreased from passage 1 to passage 8, and the level of NRTI-induced senescence increased. In addition, co-treatment with the mitochondrial antioxidant coenzyme (Q10) resulted in a delayed onset of senescence. In conclusion, long term NRTI treatment resulted in ROS production, reduced cell proliferation rate and premature endothelial senescence. Moreover, our findings may suggest approaches for reducing the cardiovascular side effects of NRTI therapy.

#### PS 88 Fluoride Prevents Ectopic Calcification of Vascular Cells through Inhibition of Crystal Nucleation.

A. Martin-Pardillos<sup>1</sup>, A. Millan<sup>2</sup> and V. Sorribas<sup>1</sup>. <sup>1</sup>*Laboratory of Molecular Toxicology, University of Zaragoza, Zaragoza, Spain*; <sup>2</sup>*Institute of Materials Science, CSIC, Zaragoza, Spain*. Sponsor: A. Anadon.

Fluoridation of public water to improve dental and bone health can involve a risk during degenerative processes such as ectopic calcification.

We have analysed the effect of fluoride (F) on the calcification of rat aortic vascular smooth muscle cells. Cytotoxicity in vitro was determined by a lactate dehydrogenase (LDH) assay. F did not affect cell viability at the normal plasma concentrations of fluoridation (2.5-10 μM), but surprisingly, it reduced the cell death generated during calcification conditions. 5 and 10 μM fluoride also decreased the

calcification caused by 2 mM Pi by 25 and 59% in VSCMs, respectively. A dose-response relationship of calcification inhibition with increasing concentrations of pyrophosphate (PPi) revealed that the IC50 shifted from 4.26  $\mu$ M to 2.14 in the presence of 5  $\mu$ M NaF, therefore indicating that less PPi is necessary to prevent calcification when F is present in the calcification medium. Similar effect was obtained with phosphonoformic acid.

Electron microscopy (TEM, SEM, ED and EDS) observations have revealed that the calcification deposits consist of spherulites of intergrowth particles that had an amorphous character, a low density, and a laminar particle shape, in the absence of F-. With increasing F- concentration, the deposits turn more dense and compacted, while the particle shape becomes clearly fibrillar. F is not incorporated in the deposits, therefore suggesting a modification of crystallization process and inhibition of nucleation, which could explain the prevention of calcification. This effect was similar both in living and dead (fixed) cells, which indicates an intrinsic effect of F-ions on the calcification process independent of cellular activity. Furthermore, F- decreases the Pi-induced expression of osteogenes, most likely as the consequence of the reduced calcium phosphate deposits.

In conclusion, F addition to drinking water can have a beneficial effect in preventing vascular calcification originated during hyperphosphatemic conditions.

## PS 89 Development of an *In Vitro* Multiwell Cardiovascular Microelectrode Array (MEA) Toxicity Assay with Human IPS-Derived Cardiomyocytes.

S. Qin<sup>1</sup>, J. Ross<sup>2</sup>, M. Brock<sup>2</sup>, J. Bradley<sup>1</sup>, H. Luthardt<sup>1</sup>, J. Gilbert<sup>1</sup> and C. Strock<sup>1</sup>. <sup>1</sup>Cyprotex, Watertown, MA; <sup>2</sup>Axion Biosystems, Atlanta, GA.

Cardiotoxicity represents the most common reason for attrition of compounds due to toxicity. Current *in vitro* assays fail to predict the many causes of cardiac toxicity. Cytotoxicity assays only identify the most overtly toxic compounds, while assays to measure more specific liabilities such as hERG or other ion channels measure only a specific risk target, potentially missing the overall physiological response a compound elicits in cardiac cells. Additionally, *in vivo* animal studies rely on determination of compound activity in a different species, which does not always model human responses. Therefore, an ideal assay would screen compounds in human cardiomyocytes and provide a comprehensive assessment of their effects on electrophysiology. Here we demonstrate the successful use of multiwell MEAs to screen for cardiotoxic liabilities in human IPS derived cardiomyocytes (hsCM). MEAs measure the electrical activity in cells and therefore can be used to capture the field potential of the cardiomyocytes, producing a virtual EKG. This data can then be extracted to report effects of test compounds on the different phases of the heart-beat. Response endpoints that can be reported include: field potential duration ("QT"), conduction velocity, beat rate, as well as field potential metrics (Amplitude, Slope, etc.). The recent development of the multiwell MEA has allowed for an increased throughput for cardiotoxicity screening as well as the ability to generate dose curve responses for each compound. Here we demonstrate the different electrophysiological responses observed when we test compounds with different targets and liabilities (hERG, other ion channels, etc.). The compounds tested are E4031, Nifedipine, Sotalol, isoproterenol, Ouabain, Mexiletine, ZD7288, Amitriptyline, Cisapride, Terfenadine, and Verapamil. In summary, we show that use of multiwell MEAs with hsCM is highly effective for screening test compounds for toxic liabilities.

## PS 90 Development of Improved hESC-Based High-Throughput Screening Assays for Cardiotoxicity Assessment.

H. Xian, C. Blanco, J. Lam and R. Snodgrass. VistaGen Therapeutics Inc., South San Francisco, CA.

The limitations of current pre-clinical drug testing systems contribute to the high failure rate of drugs. Unexpected human cardiotoxicity is one of the two major reasons for failure of drugs and drug candidates due to safety concerns. Incorporating human embryonic stem cell-derived cardiomyocytes (hESC-CMs) assays into the pre-clinical drug development offers the potential to improve the predictability of toxicity and efficacy testing and to decrease drug development costs. Our goal is to utilize hESC-CMs to develop reproducible and predictive assays for cardiac function and toxicity prediction. We have developed protocols that, without selection, reproducibly yield >80% hESC-CMs that function reliably in various established, and newly developed, assays relevant to cardiac drug effects. In addition, the CD172a cell surface marker enables the production of substantially pure (>95%) hESC-CMs. Here we expand our previous electrophysiological assessments, and describe the development of a series of fluorescence or luminescence based high-throughput assays that were used to assess drug-induced necrosis, apoptosis, mitochondrial toxicity and oxidative stress of hESC-CMs. These assays were validated using well-known cardiotoxic compounds. These compounds include inhibitors of

various kinases, DNA intercalating agents, hERG trafficking blockers and K<sup>+</sup> channel blockers. These assays were able to measure drug effects, with high sensitivity, consistent with known biology of the compounds. In addition, a medium throughput multi-electrode array (MEA) system was used to evaluate electrophysiological functions of the hESC-CMs. The effects of selective ion channel blockers and compounds associated with QT prolongation on field potentials and beat rates were assessed. The observed cardiac electrophysiology was reproducible and consistent with the known effects of the compounds. Our data suggest that these hESC-CM based screening systems are valuable tools for preclinical cardiac safety screening, which we believe will contribute to the efficient and rapid identification of safer drugs.

## PS 91 Vascular Effects Induced by 15nm Gold Nanoparticles in Isolated Rat Aortic Rings.

M. Gonzalez Castillo<sup>1,2</sup>, S. Salazar-García<sup>1</sup>, D. Maldonado Ortega<sup>1</sup>, G. Palestino Escobedo<sup>1</sup>, M. Ramirez Lee<sup>1</sup>, A. Mendez Mancilla<sup>1</sup> and S. F. Ali<sup>2</sup>. <sup>1</sup>Universidad Autonoma de San Luis Potosí, San Luis Potosí, Mexico; <sup>2</sup>National Center for Toxicological Research, US FDA, Jefferson, AR.

Gold nanoparticles (AuNPs) have been used in biomedicine as therapeutic tool. However, their role on the vascular physiology, have not been fully studied. The purpose of the present work was to evaluate the effects of 15 nm AuNPs on the vasculature, using a rat aortic rings model, pre-contracted with phenylephrine, a well known contractile agent. Adult male Sprague Dawley rats were sacrificed; aorta was excised, and maintained in an organic bath chamber with physiological solution. Each individual aorta rings were treated under isometric conditions, in presence and absence of endothelium (E), along with increasing concentrations (0.1-100  $\mu$ g/mL) of AuNPs. AuNPs exerted a vasodilator effect independent on E, the relaxation was exerted in the same magnitude that was found in presence of E. Relaxation induced by the Au-NPs were not dependent on nitric oxide (NO), since, L-Nitro-arginine methyl ester (L-NAME), an inhibitor of the NO production and a potent vasodilator mediator, did not block this effect. However, a pretreatment with indomethacin, an inhibitor of prostanooids synthesis, blocked partially the vasodilation induced by AuNPs, suggesting that prostanooids could be, at least in part, mediators of these actions. Further studies are underway to evaluate the mechanisms of action which are underlying the relaxation induced by AuNPs, and the implications that they could confer in the cardiovascular physiology.

## PS 92 Nano-Cerium Dioxide Exposure and Arteriolar Dysfunction: Exposure Route Dependency.

T. R. Nurkiewicz<sup>1</sup>, P. A. Stapleton<sup>1</sup>, E. M. Sabolsky<sup>2</sup> and V. C. Minarchick<sup>1</sup>.

<sup>1</sup>Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV; <sup>2</sup>Mechanical Engineering, West Virginia University, Morgantown, WV.

Nano-cerium dioxide (CeO<sub>2</sub>) is being used or developed as a fuel catalyst (diesel), a protective drug (radiation and ischemia) and as a contrast agent (medical imaging). These diverse uses possess the potential for human exposures that are beyond the well studied pulmonary route. Our laboratory has assessed the arteriolar effect of nano-CeO<sub>2</sub> 24hrs post-pulmonary exposure; however, other routes of exposure such as systemic and gastrointestinal have not been investigated. Therefore, our aim was to analyze the microvascular effects of nano-CeO<sub>2</sub> via instillation, injection, and gavage. Sprague-Dawley rats were intratracheally instilled (100  $\mu$ g), intravenously injected (100 or 900 $\mu$ g), or gavaged (100 or 600 $\mu$ g) with nano-CeO<sub>2</sub> suspended in Normosol (5% serum). 24hrs later the mesentery was harvested, and 4<sup>th</sup> or 5<sup>th</sup> order arterioles were dissected and prepared for isolated vessel experiments. Arteriolar reactivity was evaluated by determining endothelium-dependent (acetylcholine, 10<sup>-9</sup>-10<sup>-4</sup>M), and -independent dilation (spermine NONOate, 10<sup>-9</sup>-10<sup>-4</sup>M), vasoconstriction [phenylephrine (PE), 10<sup>-9</sup>-10<sup>-4</sup>M], and mechanotransduction [myogenic responsiveness (0-105 mmHg) and shear stress (0-30 $\mu$ l/min)]. Endothelium-dependent and -independent dilation for all three exposure routes (instillation: 30% and 50%, injection: 45% and 55% and gavage: 36% and 64% vs sham arterioles, respectively) was significantly impaired. Arteriolar responsiveness to PE or pressure was unaltered for the exposure routes. There was an impaired dilation in response to flow for the rats injected or gavaged (53% and 35% vs sham, respectively). This arteriolar dysfunction was exposure route dependent because little to no arteriolar dysfunction was observed in rats injected or gavaged with 100 $\mu$ g of nano-CeO<sub>2</sub> as compared in instilled rats. These results provide evidence that microvascular dysfunction is present 24hrs after nano-CeO<sub>2</sub> exposure and is dependent on the exposure route.

**PS 93 Simulated Metabolism in the Langendorff Isolated Rat Heart: A Comparison of Novel and Traditional Dosing Techniques for 5-Fluorouracil and Doxorubicin.**

J. B. Ross, K. A. Henderson, R. Borders, P. S. Hong, W. M. Black and B. M. Roche. *Battelle, Columbus, OH.*

There is a clear need for more predictive and translatable assays in early drug discovery. It is important to take a multi-scale approach to translate data to pre-clinical and clinical trials. The Langendorff isolated heart model provides a tool to assess cardiotoxicity in the whole organ in the absence of in-vivo variables. We used the Langendorff to assess both acute and latent cardiotoxicity of 5-fluorouracil (5-FU) and doxorubicin. Physiologically Based Pharmacokinetic (PBPK) models were developed to determine clinically relevant doses. A reverse extrapolation from human physiological and physiochemical parameters to rat was performed. The resulting pharmacokinetic (PK) curves led to some challenging dose considerations; both 5-FU and doxorubicin are rapidly cleared in humans and rats, never reaching a steady state. Other PK parameters such as Area Under the Curve (AUC) and the maximum concentration (Cmax) pose problems as well. AUC will accurately represent the total amount of drug over a given period of time; however, a single concentration derived from the AUC could potentially underestimate a biological response. In contrast, Cmax would greatly overestimate the total amount of drug, potentially leading to false toxicity. Computer generated dosing schemes were developed and characterized in an effort to fit the modeled PBPK curves. Initial concentrations (Cmax) were diluted with deionized water and perfused through the Langendorff system in the absence of a heart. Perfusate was collected at various time points, analyzed with HPLC, and concentration curves were generated for proof of concept. An acceptable fit was observed between the computer generated and the tested curves. This dosing technique was applied to an isolated rat heart; multiple endpoints were collected and compared to previous data collected at constant perfusion concentrations. The novel dose schemes proved to be a better representation of in-vivo concentrations in our ex-vivo model.

**PS 94 Oxidative Stress Uncovers  $\beta$ 2-Adrenergic Mediated Dilation to Curcumin Mimicked by Preventing Clathrin Endosome Formation.**

M. Frame<sup>1,2</sup>, B. Calizo<sup>2</sup>, A. M. Dewar<sup>1</sup> and S. Scarlata<sup>2</sup>. <sup>1</sup>*Biomedical Engineering, Stony Brook University, Stony Brook, NY;* <sup>2</sup>*Physiology/Biophysics, Stony Brook University, Stony Brook, NY.* Sponsor: T. Nurkiewicz.

The nutraceutical, curcumin, has anti-oxidative properties, but also is a potent adrenergic receptor (AR) agonist, with an EC50 for dilation in the nM range (beta, bAR). Our goal was to determine how oxidative stress impacted vasoactive responses to curcumin. Intravital microscopy of small arterioles in the hamster cheek pouch was performed (N=10; pentobarbital 70mg/kg i.p.). Oxidative stress (OX) was induced by applying exogenous nitric oxide for 2 minutes in the tissue bath. Before OX, dilation to micropipette applied curcumin was dose dependent, with a maximum from 10-9 to 10-6M. After OX, dilation was eliminated in the nM and higher range, and significantly left shifted to a narrow peak from 10-15 to 10-10M, which was inhibited by the  $\beta$ 2-adrenergic receptor inverse agonist, carazolol (1nM). We next tested whether preventing clathrin endosome formation with dynasore altered dilation to curcumin. Dynasore (80uM) alone eliminated dilation to curcumin in the uM range, and uncovered a dilation in the pM range. Dynasore with OX further increased the potency, and increased the efficacy of dilation to curcumin over the range 10-15 to 10-10M. To understand the mechanism of this OX induced narrow potency range, we tested whether curcumin and the bAR were internalized and co-localized using FRET in HEK cells. Before OX, curcumin was rapidly internalized (seconds), and co-localized with bAR. After OX (1mM CoCl<sub>2</sub>), curcumin was internalized, but bAR remained at the plasma membrane. Thus, in cells, OX prevented internalization of curcumin with bAR. In situ, inhibition of clathrin endosome formation mimicked and enhanced the vasoactive responses after OX. (AHA 0655908T)

**PS 95 Diminished Oxygen Supply in Microvessels following Inflammatory Oxidative Stress.**

A. M. Dewar, M. Frame, N. Zhou and C. Du. *Biomedical Engineering, Stony Brook University, Stony Brook, NY.* Sponsor: T. Nurkiewicz.

Increased heterogeneity of flow accompanies many inflammatory states, including oxidative stress (OX) with toxicant exposure or thermal injury. Red blood cell (RBC) flux along nutrient flow paths is an indicator of oxygen delivery; many inflammatory mediators result in a specifically located arteriole-venule RBC shunt pathway. Our goal was to directly measure oxy- vs deoxy-hemoglobin (HbO v

HbR) to determine whether OX induced shunt paths resulted in heterogeneity of oxygen supply. A controlled thermal burn model in the hamster cheek pouch tissue localized OX so that unequivocal control vs OX spatial locations could be observed. Adult male hamsters (N=10, isoflurane) were prepared for intravital microscopy of the cheek pouch tissue. Fluorescently labeled RBC flow markers confirmed shunt pathways after a thermocouple controlled 50 degree C 300um spot burn (same location before vs 15m-1hr after, within 500um of burn rim). Multi-wavelength laser speckle contrast imaging was used (1-2h after burn) to determine HbO and HbR at 630 and 570nm at locations within 500um of the burn rim (near) vs. locations >1mm from the burn rim (far); values of changes in HbO and HbR were obtained in [Hb] mM. Total Hb in the large vessels was consistent with a local tube hematocrit of 5-40%, as is typically found using fluorescent RBC. HbO was 30% less in perfused large arterioles near vs far from the burn, and 24% less in perfused large venules near vs far from the burn. Within the terminal arteriolar networks far from the burn, HbO is 7% higher along the shunt pathway vs the non-shunt pathway, consistent with RBC flux values. Near the burn, HbO is 71% greater along the shunt pathway vs the non-shunt pathway, also consistent with RBC flux values. Comparing HbO along shunt pathways, HbO is decreased 52% near vs far from the burn rim. Thus, in this model of inflammation, RBC flux and HbO values together suggest that a diminished oxygen shunt pathway is initiated by inflammation and maintained for several hours after the inflammatory event. (NIH HL55492; AHA 0655908T)

**PS 96 Validation of the Amphibian Metamorphosis Assay for Potential Endocrine Disrupting Chemicals with Xenopus Laevis.**

J. J. Burlingham, C. A. Jenkins, J. Pawsey, I. Taylor and L. Haynes. *Aquatic Ecotoxicology and Biodegradation, HLS, Eye, United Kingdom.* Sponsor: C. Auletta.

The new European Union Plant Protection Products Regulation (PPPR 1107/2009) identifies the need to consider whether a substance is a potential endocrine disrupter in aquatic non-target organisms and the current draft of the PPP data requirements refers to three screening assays for ecotoxicological endocrine-disrupting potential. Of these, we describe in detail our experience in the establishment and validation of the amphibian metamorphosis assay (OECD 231; OPPTS 890.1100) with the African Clawed Frog.

In this method, in order to satisfy validity criteria in the rearing phase, conditions necessary to allow tadpoles to develop from fertilisation to development stage 51 as defined by Nieuwkoop and Faber (1994) were established, and individuals selected for the exposure phase and transferred to test vessels. To establish the assay, 400 tadpoles were exposed to a range of levels of the three reference substances, thyroxine (T<sub>4</sub>) which produces stimulatory effects on the normal function of the hypothalamic-pituitary-thyroid (HPT) axis, sodium perchlorate (which retards development) and iopanoic acid (which affects hind limb development) and levels of each were verified using an appropriate analytical method. At Day 7, 80 randomly selected individuals at each exposure level were removed and assessed (body weight, developmental stage, hind limb and snout to vent length). Exposure continued for a further two weeks and the study terminated on Day 21 when all the remaining individuals were assessed as on Day 7. Following developmental stage matching, 80 individuals were selected for thyroid removal and histopathological analysis.

We found that our results were similar to the ring test results published by the OECD (Series on Testing and Assessment Document Number 77) and make a number of observations on methodology that may improve the reproducibility of these assays.

**PS 97 Mammary Gland Morphology and Gene Expression Signature of Prepubertal Male and Female Rats following Exposure to Exogenous Estradiol.**

M. Ronis<sup>1,2</sup>, I. R. Miousse<sup>1,2</sup>, N. Sharma<sup>2</sup>, J. Vantrease<sup>2</sup>, L. Hennings<sup>1</sup>, K. Shankar<sup>1,2</sup>, H. Gomez-Acevedo<sup>1,2</sup>, M. Cleves<sup>1,2</sup> and T. M. Badger<sup>1,2</sup>. <sup>1</sup>*UAMS, Little Rock, AR;* <sup>2</sup>*Arkansas Children's Nutrition Center, Little Rock, AR.*

In order to properly understand whether xenoestrogens act as true estrogen agonists, it is essential to possess a solid portrait of the physiological effects of exogenous 17 $\beta$ -estradiol (E2). Because the estrogen-dependent gene expression is one of the primary indicators of estrogenic action, we have assessed effects of three doses of exogenous E2 (0.1, 1.0 and 10  $\mu$ g/kg of body weight/day) on the mammary gland morphology and gene expression profiles of prepubertal male and female rats of both sexes compared to untreated controls. The mammary gland was more responsive to E2 treatment in males than in females with 1392 genes modulated >1.5-fold up or down relative to controls at the highest E2 dose compared to 463 genes. There

was an increase in the number of terminal end buds in males ( $P < 0.05$ ), and a corresponding increase in the expression of the gene encoding amphiregulin ( $P < 0.05$ ), a protein known to drive the differentiation of terminal end buds. In intact females, the highest dose of E2 tested induced an increase in the expression of genes encoding milk components, as well as muscle proteins. Lower doses had limited effects on gene expression. Therefore, the prepubertal rat male mammary gland is a very sensitive tissue to evaluate estrogenicity using morphological changes coupled to microarray-analysis of gene expression. Intact prepubertal females were comparatively poorly responsive to exogenous E2, although many modulated genes were common to both sexes. Supported by USDA CRIS-6251-51999-007-04S.

## PS 98 Potential Endocrine Disruption of a Drinking Water Sample from the State of São Paulo, Brazil.

M. M. Solano<sup>1</sup>, C. M. Raimundo<sup>2</sup>, I. C. Pescara<sup>2</sup>, W. F. Jardim<sup>2</sup>, D. D. França<sup>3</sup>, G. A. Quinaglia<sup>3</sup>, J. A. Anselmo-Franci<sup>4</sup>, R. G. Carolino<sup>4</sup>, J. L. Luvizutto<sup>1</sup>, G. A. Umbuzeiro<sup>5</sup> and J. V. de Camargo<sup>1</sup>. <sup>1</sup>Botucatu Medical School, Department of Pathology, São Paulo State University- UNESP, Botucatu, Brazil; <sup>2</sup>Institute of Chemistry, University of Campinas- UNICAMP, Campinas, Brazil; <sup>3</sup>Environmental Toxicology, Genotoxicity and Microbiology Division - CETESB, São Paulo, Brazil; <sup>4</sup>School of Dentistry, Department of Morphology, Stomatology and Physiology, University of São Paulo- USP, Ribeirão Preto, Brazil; <sup>5</sup>Faculty of Technology, University of Campinas- UNICAMP, Limeira, Brazil.

Many xenoestrogens, natural and synthetic estrogens may end up in the water bodies through sewage discharges. Contaminated rivers are conventionally treated by Water Treatment Plants (WTP) to produce drinking water, but emerging contaminants may remain. This study investigated the potential for endocrine disruption of a drinking water sample from a São Paulo State WTP, using two harmonized bioassays. Female rats 21 days old were exposed by gavage to drinking water extracts during 03 days (uterotrophic assay; OECD 440) or 20 days (pubertal development female rat assay, EPA 890.1450) at 33.3, 166.5, and 333.0 mL equivalent of water/kg body weight, modeling a daily ingestion of 2 L, 5 L and 10 L of drinking water by a 60 kg human being. Traces of caffeine (5.8 ug/L), estrone (1 ng/L) and atrazine (11.2 ng/L) were detected in the extracts by LC-MS/MS. Androgen or estrogen agonistic activity of the water extract resulted negative by the bioluminescent yeast assay (BLYES, BLYAS). Accordingly, both in vivo assays were negative: there was no significant increase of the uterus wet weight in the uterotrophic assay and no alteration of the moment for vaginal opening in the pubertal assay. However, the serum levels of LH, FHS, PRL and 17 $\beta$ -estradiol were altered, with a significant dose-response increase. Therefore, it has to be assumed that the tested drinking water sample induced steroidogenic dysregulation in vivo.

## PS 99 Development of Medium-Throughput Thyroperoxidase Inhibition Assays for Screening.

K. B. Paul<sup>1,2</sup>, J. M. Hedge<sup>2</sup>, K. M. Crofton<sup>2</sup>, M. W. Hornung<sup>3</sup> and S. O. Simmons<sup>2</sup>. <sup>1</sup>ORISE, US EPA, Research Triangle Park, NC; <sup>2</sup>Integrated Systems Toxicology Division, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>3</sup>Mid-Continent Ecology Division, NHEERL, ORD, US EPA, Duluth, MN.

Thyroperoxidase (TPO), the catalyst for thyroid hormone (TH) synthesis, is a target for thyroid-disruptors, including methimazole (MMI), isoflavones, benzophenone-2, and malachite green; however, no medium- to high-throughput screening methods for TPO inhibition are available. To adapt the low-throughput guaiacol oxidation assay for TPO inhibition to chemical screening, we replaced guaiacol with a fluorescent peroxidase substrate in a rat thyroid-based assay and developed an in vitro human TPO model. We tested the hypothesis that use of a peroxidase substrate (Amplex UltraRed, AUR, LifeTech) in 96- or 384-well plate formats with automated reagent delivery could increase the TPO assay throughput with thyroid microsomes. The IC<sub>50</sub> of MMI-induced TPO inhibition was reduced with AUR compared to the guaiacol assay, with average IC<sub>50</sub>s of 0.15  $\mu$ M and 5  $\mu$ M, respectively. AUR signal was stable from 30-120 min after initiation. The dynamic range of the assay with MMI was 6- to 10-fold using 96- or 384-well formats, with Z' scores of 0.75 to 0.9. A 21 chemical training set is being used to validate the assay for screening. One limitation of this model is the availability of human thyroid microsomes. Preliminary work demonstrated that lentiviral-transduction of a human cell line (HEK293T) with recombinant TPO could also be used to test for human TPO inhibition. TPO activity measured by the AUR assay in cell fractions was maximally inhibited by MMI at 100  $\mu$ M. This approach to improving and developing medium-throughput assays for thyroid-disruptor screening demonstrates the feasibility of screening 100s to 1000s of chemicals for TPO inhibition, and drastically reduces the need for animal tissue. This abstract does not necessarily reflect the policy of the US EPA.

## PS 100 High-Throughput Detection of Estrogenic Compounds Using Autonomously Bioluminescent Human Breast Cancer Cells.

T. Xu<sup>1</sup>, D. Close<sup>2</sup>, S. L. Price<sup>1</sup> and G. S. Saylor<sup>1,2</sup>. <sup>1</sup>The University of Tennessee, Knoxville, TN; <sup>2</sup>490 BioTech Inc., Knoxville, TN. Sponsor: S. Ripp.

Substantial public health concerns exist over the potential endocrine disrupting capabilities of a wide variety of untested or under-tested natural and industrial chemicals. It is clear that the development of accurate, high-throughput, and inexpensive testing regimens will be key to mitigating public concern. Here we report on the development of a novel screening assay for estrogenic activity that utilizes an autonomously bioluminescent human cell line to provide direct bioavailability data. To construct this cell line, estrogen-responsive human breast carcinoma cells (T-47D) were genetically engineered to express the full bacterial bioluminescence gene cassette (*luxCDABEfp*), generating an autonomously bioluminescent cell line (T-47D/Lux) capable of maintaining bioluminescent output independent of substrate addition. Bioluminescence emitted from T-47D/Lux cells was correlated tightly ( $R^2 > 0.99$ ) to the number of cells present in a population, permitting the use of light production dynamics as an indicator of cell proliferation. Additionally, the substrate-free nature of the lux system allowed for continuous, near real-time monitoring of the same cell population throughout exposure to the tested compounds. A significant change in bioluminescent production ( $p < 0.05$ ) compared with unexposed control was observed 3 days after exposure to concentrations of 17 $\beta$ -estradiol (E2) as low as 1 pM. The EC<sub>50</sub> for E2 in this assay was determined to be approximately 10 pM. These results are similar to those obtained using a traditional cell proliferation assay, but offer the advantage that data acquisition can be performed in a fully automated fashion since the need for sample destruction or substrate addition is removed, making it an ideal candidate for high-throughput analysis.

## PS 101 Cryopreserved Rainbow Trout Hepatocytes Model Endocrine Disruption As Detected by Protein and Gene Expression of Vitellogenin.

L. K. Markell, R. T. Mingoia, H. M. Peterson, J. P. Finn, D. L. Nabb and X. Han. DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.

The toxicity of environmental pollutants may occur through modes of action that alter normal endocrine functions, resulting in altered development, growth and reproduction of aquatic species. Consequently, there is a need to develop assay endpoints capable of identifying endocrine disruption in fish. Our lab has previously shown the utility of cryopreserved trout hepatocytes. Here we use this cell culture method to identify the potential estrogenicity of chemicals through vitellogenin (VTG) expression. This biomarker indicates an estrogenic effect when the protein is expressed by male trout hepatocytes, both in vivo in plasma and in vitro in cell culture media. To test the performance of cryopreserved trout hepatocytes, reference chemicals estradiol (E2), estrone (E1) and diethylstilbestrol (DES) were used and culture media was collected for ELISA 96-hrs post-treatment. Our results show that the levels of protein detected with cryopreserved trout hepatocytes are similar to results previously published using fresh trout hepatocytes, ranking the compounds E2  $\geq$  DES  $>$  E1. To determine whether transcriptional regulation of VTG correlated with protein expression, quantitative real-time PCR was performed. mRNA was collected from cryopreserved hepatocytes treated for 24 hours with the same doses of reference chemicals. VTG gene expression correlated well with protein expression, ranking the compounds similarly. In addition, the negative control corticosterone showed no increase in gene expression at any dose, indicating that this is a sensitive, yet specific endpoint. These studies demonstrate both ELISA and transcription-based methods can be used with cryopreserved trout hepatocytes for screening chemicals for potential estrogenic effects, enabling greater access to this model system and potentially improving the turn-around time for generating results through detection of VTG mRNA levels.

## PS 102 Permethrin Does Not Have Endocrine Disrupting Properties As Evaluated by the US EPA's Endocrine Disruptor Screening Program (EDSP) In Vivo Assays.

L. Zorrilla<sup>1</sup>, S. J. Borghoff<sup>1</sup> and T. G. Osimitz<sup>2</sup>. <sup>1</sup>Integrated Laboratory Systems, Inc, Durham, NC; <sup>2</sup>Science Strategies, Charlottesville, VA.

Permethrin, a pyrethroid insecticide, was evaluated for potential endocrine activity in 3 of 4 in vivo US EPA EDSP assays. The maximum tolerated dose (MTD) of permethrin used in these assays was selected based on the results of dose range finding studies. Sprague Dawley rats were administered permethrin in corn oil by oral gavage for 10 (Hershberger Bioassay, OPPTS 890.1400, castrated model), 21/22

(female pubertal assay, OPPTS 890.1450), or 31/32 (male pubertal assay, OPPTS 890.1500) days based on daily body weights. The Hershberger Bioassay, which evaluated agonist and antagonist androgenic activity, was negative; no significant changes in any androgen-dependent tissue weights up to the MTD of 120 mg/kg/day were observed. The male pubertal assay, administered a MTD of 120 mg/kg/day, showed no effects on male pubertal development with no differences observed in reproductive organ weights, the day of preputial separation, or serum testosterone levels compared to controls. Liver weight was significantly increased, with a decrease in thyroxine ( $T_4$ ) and a corresponding increase in thyroid stimulating hormone (TSH) compared to controls. No changes were observed in thyroid gland weights or histopathology. The female pubertal assay, administered a MTD of 150 mg/kg/day, showed no effects on female pubertal development with no differences observed in the day of vaginal opening, estrus onset, cyclicity, or reproductive organ weights. The liver and thyroid gland weights were significantly increased, and serum TSH concentrations were increased with a corresponding decrease in serum  $T_4$  following administration permethrin, however, the thyroid gland showed no histopathological changes. In summary, permethrin did not show androgen or estrogen activity in these assays, and the effects observed in the thyroid likely are secondary to liver enzyme induction, a phenomenon known to occur following repeated dosing with permethrin, and not a reflection of a direct effect on the thyroid.

### PS 103 Linking *In Vitro* Enzyme Activity To *In Vivo* Effects: Thyropoxidase Inhibition in Methimazole-Exposed Rats.

J. M. Hedge<sup>1</sup>, K. M. Crofton<sup>1</sup>, S. O. Simmons<sup>1</sup>, M. W. Hornung<sup>2</sup> and K. B. Paul<sup>1,3</sup>. <sup>1</sup>Integrated Systems Toxicology Division, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Mid-Continent Ecology Division, NHEERL, ORD, US EPA, Duluth, MN; <sup>3</sup>Oak Ridge Institute for Science Education, US EPA, Research Triangle Park, NC.

The anti-thyroid drug methimazole (MMI) inhibits thyropoxidase (TPO), the enzymatic catalyst for thyroid hormone (TH) production and a target for thyroid-disrupting chemicals. Our development of a medium-throughput screening assay for TPO inhibitors using a fluorescent peroxidase substrate (Amplex UltraRed) has instigated characterization of the relationship between *in vitro* TPO inhibition using thyroid microsomes and *in vivo* TH status. This work tested the hypothesis that TPO activity would be decreased in thyroids from rats exposed *in vivo* to MMI doses that decreased serum THs. Weanling female Long-Evans rats received MMI in corn oil (0, 0.1, 0.3, 1, 10, 20, 30 mg/kg/day po) for 4 days and were sacrificed 24 hr later. Pooled thyroid microsomes (n=8/pooled treatment) were used in the TPO inhibition assay. As a positive control, the vehicle control microsomes were exposed *in vitro* to MMI (0.015 – 200  $\mu$ M), which yielded an assay dynamic range of 6-fold, an IC<sub>50</sub> = 0.14  $\mu$ M, and Z' = 0.9. TPO was inhibited in a dose-dependent manner, up to 53% of vehicle control at 30 mg/kg/day, which corresponded to significant serum thyroxine ( $T_4$ ) decreases of 60% and thyroid gland weight increases of 64% (p<0.05). TPO inhibition in the 10-30 mg/kg/day MMI corresponded to *in vitro* MMI concentrations of 0.14-0.44  $\mu$ M. These results suggest that MMI-induced serum  $T_4$  decreases *in vivo* correspond to significant TPO activity decreases *in vitro*. Continued work will aim to strengthen understanding of the association between the degree of TH perturbation *in vivo* and the magnitude of TPO inhibition in the AUR screening assay. This abstract does not necessarily reflect the policy of the US EPA.

### PS 104 Endocrine Disruption Potential of Benfenin: Weight of Evidence Evaluation.

S. Papineni<sup>1</sup>, K. K. Coady<sup>2</sup>, S. Marty<sup>2</sup>, V. J. Kramer<sup>1</sup> and S. C. Gehen<sup>1</sup>. <sup>1</sup>Dow AgroSciences, Indianapolis, IN; <sup>2</sup>The Dow Chemical Company, Midland, MI.

Benfenin, a pre-emergent herbicide, was included on List 1 of chemicals to be screened under US EPA's Endocrine Disruptor Screening Program (EDSP). Following completion of 11 Tier 1 EDSP assays, a Weight of Evidence (WoE) evaluation was conducted using all available data to determine if benfenin has potential to interact with the estrogen, androgen or thyroid (EAT) systems following the five (5) – tiered OECD conceptual framework. For the *in vitro* assays, benfenin was negative for androgen and estrogen receptor binding, and negative in the aromatase and steroidogenesis assays but induced a weak positive response in the estrogen receptor transactivation assay (ERTA). However, this slight positive response in the ERTA assay was not corroborated in other estrogen sensitive assays estrogen receptor (ER) binding, uterotrophic, estrogen-sensitive endpoints in the female pubertal, and vitellogenin levels in the fish short-term reproduction assay (FSTRA) that were negative. Anti-androgenic and anti-estrogenic effects were observed in the pubertal assays and in the Hershberger assay only at the high dose levels. However, the WoE evaluation of the data does not support a direct interaction; rather, an indirect mode-of-action (MoA) due to enhanced liver enzyme induction and hormone

clearance appears evident. Similarly, results for thyroid effects in the pubertal assays were consistent with previously demonstrated MoA data which support an indirect MOA due to enhanced thyroxine clearance not relevant to humans. Furthermore, benfenin was negative in the amphibian metamorphosis assay designed to detect thyroid agonists and antagonists. A high-degree of coherence and consistency is observed in results from the higher-tiered data and previous toxicity studies showing no direct interaction with the endocrine system. In conclusion, the vast majority of Tier 1 studies/endpoints were clearly negative and those few positive responses were seen only at high-dose levels and were either isolated (e.g., ERTA) in nature or secondary to other effects.

### PS 105 Endocrine Exposure at Environmentally-Relevant Concentrations.

K. C. Fussell<sup>1</sup>, S. Schneider<sup>1</sup>, S. Melching-Kolmuss<sup>2</sup>, S. Gröters<sup>1</sup>, V. Strauss<sup>1</sup>, B. Siddeek<sup>3</sup>, M. Benahmed<sup>3</sup>, M. Frericks<sup>2</sup> and B. van Ravenzwaay<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Product Safety, BASF SE, Ludwigshafen am Rhein, Germany; <sup>3</sup>U895, équipe 5, Centre Hospitalier l'Archet 2, Inserm, Nice, France.

Endocrine disruption has become an important topic of public concern. Despite an increasing amount of attention, little is understood about how doses of endocrine disrupting chemicals (EDCs) at environmental concentrations affect homeostasis. To address these concerns, we performed a pre-/post-natal reproductive toxicity study to measure the developmental toxicity of low doses of three anti-androgenic compounds: vinclozolin, flutamide, and prochloraz. The tested doses were selected to mimic low-effect levels, the no observed adverse effect levels (NOAEL) for endocrine effects, and the acceptable daily intake (ADI). Despite mild maternal toxicity in parental females treated with the top dose of prochloraz, sufficient offspring were produced to evaluate the developmental effects of the three EDCs. While female offspring developed normally, the male offspring showed effects known for anti-androgens. One sensitive clinical parameter was the retention of nipples and/or areolas by male animals on PND 12. This effect was largely transient, as all had regressed by PND 21, with the exception of the offspring exposed to the flutamide top dose. The young adult male offspring displayed additional anti-androgen effects including, delayed sexual maturation and reduced male sex organ weights. These alterations were observed at the effect doses of all three anti-androgens, and at the putative flutamide NOAEL. Offspring from the flutamide top dose group had an increased incidence of developmental sexual defects including hypospadias, short penis, and cryptorchidism. No effects at all were noted at the low doses, as expected for the ADI. Assessment of sexual steroid hormones and their precursors revealed no effects at any of the dose levels. Taken together, the weight of evidence of the clinical and pathological findings suggests a lack of a non-monotonic dose-response curve.

### PS 106 Assessment of Estrogenic and Androgenic Impairment of Iowa Surface Water by Chemical Analysis and Bioassays.

S. Flor<sup>1</sup>, J. Vargo<sup>2</sup> and G. Ludwig<sup>1</sup>. <sup>1</sup>University of Iowa, Iowa City, IA; <sup>2</sup>Iowa State Hygienic Lab, Coralville, IA.

Limited data are available regarding the presence of hormones and steroids in Iowa surface water. To obtain more information about the hormonal impairment, river water samples were collected in October 2011 up- and downstream of Iowa City and Des Moines. Chemical analysis of water extracts was performed by LCMSMS using drinking water method EPA 539 that assesses equilin, estriol, 17 $\alpha$ - and 17 $\beta$ -estradiol, estrone, 17 $\alpha$ -ethynylestradiol, androstenedione, testosterone, progesterone, and 17 $\beta$ -trenbolone concentrations. For endocrine disrupting activity of the water extracts the E- and A-screen with human MCF-7 breast cancer cells (estrogenic and androgenic activity) and the H295R assay with adrenal cancer cells (interference with steroid hormone synthesis) were used. A goal of this study was to determine how well chemical testing for targeted hormones and steroids reflects the total androgenic and estrogenic activity determined by bioassay tests. Preliminary evaluation revealed that the added preservative 2-mercaptopyridine-1-oxide or a derivative that was formed during the extraction procedure was highly cytotoxic to the cells. However, extracts preserved with sulfuric acid could be used in the bioassays. The chemical analysis detected only a few hormones and those that were detected were found at low- or sub-ng/L concentrations in the Iowa surface waters. The Iowa River up- and downstream extracts showed an estrogenic activity in the E- and A-screen and the Des Moines River extracts had a small androgenic and antiestrogenic activity. The H295R hormone concentration tests revealed no obvious changes in testosterone and cortisol levels in the medium but the extracts tended to increase the estradiol levels. Additional tests with synthetic samples prepared according to the analytical test results are needed to examine whether the detected hormones alone caused these biological effects or whether other, still undetermined endocrine disrupting chemicals were involved. (Funded by ES05605 from NIEHS)

**PS 107 Endocrine Disruption: Weight of the Evidence for Low-Dose Effects of TCDD on Sperm Counts.**

K. L. Hentz, A. L. Williams and J. C. Lamb. *Exponent, Alexandria, VA.*

Considerable debate is ongoing regarding the potential for endocrine-mediated low-dose effects. One of the examples that has been presented as evidence for low dose effects is exposure to 2,3,7,8-tetrachlorodibenzo-dioxin (TCDD) and the impact on sperm counts in the male offspring. Although one epidemiological study has reported reduced sperm counts in males exposed to TCDD, the results of this study are limited by the small number of subjects, evaluation of a single sperm sample, potential differences in sexual activity, and lack of control in the collection/transport of the sperm sample. We have conducted a weight-of-the-evidence review of the toxicological studies investigating the impact of maternal TCDD exposure on sperm counts in their offspring and the results have been highly variable. Epididymal sperm counts have been reported to be reduced at doses as low as 64 ng TCDD/kg, but other studies have failed to show effects at doses of 800 ng TCDD/kg or higher. Several other animal studies have not reported effects on sperm counts at doses between 10 and 50 ng TCDD/kg, suggesting a potential threshold. While sperm effects have been reported in experimental animal studies at 64 ng TCDD/kg, this dose should not be considered a low dose because human exposures are much lower. This dose is not relevant to current human exposures to TCDD based on estimated intakes that are 100-fold lower for all dioxins and furans combined based on TEQ (toxic equivalents). Thus, discussions regarding the potential endocrine disruptive effects of TCDD on sperm counts are misleading and do not occur at the low doses experienced by general American public.

**PS 108 Effects of Pesticides on Cytochrome P450 17 (CYP17) and Androgen Receptor (AR) Function in Human H295R Adrenocortical and LNCaP Prostate Cancer Cells.**

C. Robitaille, P. Rivest and T. Sanderson. *INRS-Institut Armand-Frappier, Laval, QC, Canada.*

Exposures to endocrine disrupting chemicals, including pesticides, are thought to be contributing to the increased incidence of certain endocrine-related cancers in the human population, such as prostate cancer. Prostate cancer growth is initially androgen-dependent and under control of the nuclear androgen receptor (AR), which increases the gene transcription of proteins involved in cell proliferation, such as prostate specific antigen (PSA). CYP17 is a key enzyme in the biosynthesis of androgens and increased expression is associated with increased prostate cancer risk. We evaluated the effects of several pesticides suspected or known to modulate hormonal function in androgen-dependent LNCaP human prostate cancer cells and in an *in vitro* steroidogenesis model, the H295R human adrenocortical carcinoma cell line. Benomyl, vinclozolin and prochloraz reduced dihydrotestosterone (DHT)-stimulated LNCaP cell proliferation and nuclear AR protein accumulation concentration-dependently (0.1-30  $\mu$ M). Levels of an active phosphorylated form of AR, pAR-Ser81, were increased by 10 nM DHT, whereas benomyl, vinclozolin and prochloraz decreased these stimulated levels (after a 1 or 6 h exposure). All three pesticides reduced DHT-stimulated PSA secretion by LNCaP cells. We found AR to be expressed in H295R cells but levels of AR and pAR-Ser81 were not affected by DHT, although they were increased by 30  $\mu$ M atrazine. Benomyl and vinclozolin (10 and 30  $\mu$ M) and prochloraz (1 and 3  $\mu$ M) decreased CYP17 mRNA expression in H295R cells at sub-cytotoxic concentrations and prochloraz strongly inhibited CYP17-catalyzed conversion of pregnenolone to DHEA (24h exposure). In H295R and LNCaP cells, CYP17 protein expression was increased by atrazine (30  $\mu$ M). In conclusion, certain pesticides exert combined antiandrogenic effects in androgen-dependent prostate cancer cells at the level of CYP17 and AR, the latter by reducing AR phosphorylation at serine 81.

**PS 109 Metabolomics Characterization of the Effects of Estradiol in Human Breast Cancer Cell Lines.**

L. Zhao<sup>1</sup>, S. Odwin-DaCosta<sup>1</sup>, M. M. Vantagoli<sup>2</sup>, H. T. Hogberg<sup>1</sup>, M. Bouhifd<sup>1</sup>, A. Kleensang<sup>1</sup>, L. Smirnova<sup>1</sup>, K. Boekelheide<sup>2</sup>, J. D. Yager<sup>1</sup> and T. Hartung<sup>1</sup>. <sup>1</sup>Department of Environmental Health Sciences, Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD; <sup>2</sup>Department of Pathology and Laboratory Medicine, Brown University, Providence, RI.

Estradiol (E2 or 17 $\beta$ -estradiol) is the most potent naturally occurring estrogen. Its effects on cell function during development and in adults in a variety of tissues are mediated through estrogen receptors located in the nucleus, cytoplasm, mitochondria and at the cell membrane. Our objective is to employ high-throughput liquid chromatography mass spectrometry based metabolomics analysis to map pathways affected by estradiol in MCF-7 and T47D cells and then compare them with pathways affected by endocrine disrupting compounds (e.g. BPA and others).

Concurrent cell growth and gene expression studies are also being carried out. Cells were exposed to estradiol at different concentrations and times. Stimulation of cell growth was observed at 0.1nM in association with changes in the metabolome at 6 and 24hrs. A time course study at 100nM estradiol revealed that some metabolites were significantly altered at various time points. The metabolites and pathways most affected included metabolites from cellular energy-related pathways (e.g. Malate, Fumarate, Pyruvate) and amino acid synthesis pathways (e.g. Arginine, Valine, Ornithine, Leucine/Isoleucine, 2-Methylmalate). Further investigation is underway and should give more insight into the identification of metabolism pathways affected by estradiol and endocrine disruptors.

**PS 110 Creating *In Vitro* Test Methods for Endocrine Disruptor Risk Assessment: Assay Development.**

C. Le Sommer, S. M. Ross, P. D. McMullen, M. E. Andersen and R. A. Clewell. *The Hamner Institutes, Research Triangle Park, NC.*

Endocrine disruptor test programs in the US are moving forward to identify active compounds and prioritize them for subsequent in-life toxicity studies. Our focus is on developing *in vitro* tests for cellular responses to endocrine active substances that will be sufficient for health risk assessment without moving on to in-life toxicity tests. We have begun a research effort for the estrogen receptor (ER) pathway to: 1) map signaling pathways for estrogen mediated proliferation, 2) define the dose-response for perturbation of estrogen signaling by xenobiotics and 3) develop computational models to predict chemical effect on uterine epithelium. The first phase develops a cell-based assay in human Ishikawa endometrial cell line expressing the three major ERs: ESR1, ESR2 and G-protein coupled receptor GPER. The dose-response for 17 $\beta$ -estradiol (E2) and 17 $\alpha$ -ethynyl estradiol (EE) (0.001 – 10 nM) were examined at 1, 2, 3, 4, 5, and 6 days of exposure for proliferation and induction of protein and gene targets of ESR1, including alkaline phosphatase (ALP), proliferation associated gene GREB1 and progesterone receptor (PGR). E2 and EE increased proliferation and ALP activity by day 3 at 0.01 nM, while gene induction (GREB1, ALP, PGR) occurred earlier (day 1). Cells were also treated with selective receptor agonists PPT, DPN, and G1 targeting ESR1, ESR2 and GPER. PPT increased proliferation, ALP activity and gene expression similar to EE. DPN induced proliferation and ALP only at higher doses associated with cross-reactivity with ESR1. GPER plays a role in regulating uterine proliferative response; however, we saw no change in proliferation upon treatment with G1 alone. This may result from low GPER expression in our cells. We also conducted expression analysis of studies with Ishikawa cells from our laboratory and published sources to evaluate dose-response of GO-categories by these receptor specific ligands. *In vitro* responses have been analyzed in light of *in vivo* rodent uterotrophic assay transcriptomic data to show consistency between *in vitro* and *in vivo* assays.

**PS 111 Leaching of Chemicals with Estrogenic Activity from Packaging into Popular Lab Animal Feeds.**

D. Klein<sup>1</sup>, C. Z. Yang<sup>2</sup>, G. J. Kollessery<sup>2</sup> and G. D. Bittner<sup>1,2,3</sup>. <sup>1</sup>PlastiPure, Inc., Austin, TX; <sup>2</sup>CertiChem, Austin, TX; <sup>3</sup>University of Texas, Austin, TX. Sponsor: M. Stoner.

A robotized MCF-7 cell proliferation assay currently undergoing validation by IC-CVAM/NICEATM was used to quantify the total estrogenic activity (EA) of chemical mixtures leaching from lab animal feed bags into feed over time. A standard open-formula (low phytoestrogen AIN-93G) feed was purchased from Harlan®, Research Diets™, and TestDiet®. The TestDiet® feed was packaged in EA-Free bags recently developed by PlastiPure for PMI® LabDiet® and other customers. All diets were analyzed 0, 2, and 4 weeks after purchase. All leachates were quantified relative to the percentage of the maximum DNA produced per well induced by a test chemical with respect to the maximum DNA produced per well induced by the 17 $\beta$ -estradiol positive control (%RME2) and corrected by the cell response to the vehicle (negative) control. The significance level ( $p < 0.01$ ) to detect EA was a %RME2 value 3 standard deviations more than the VC. According to this conservative criterion, EA levels in 72 hour ethanol extracts of commercial bags for TestDiet®, Harlan®, and Research Diets™ were non-detectable (ND), significantly positive, and significantly positive, respectively. In the feed study, there was no detectable EA activity in TestDiet® feed at any time point. Feed samples from Harlan® and Research Diets™ were ND at week 0 but significantly positive following storage for 2 and 4 weeks after purchase. EA readings for Harlan® and Research Diets™ increased from week 0 to week 2 and again from week 2 to week 4. These data suggest that leaching of chemicals having EA from the non-EA free plastic packaging can alter the hormonal activity of semi-purified animal feeds. Such leaching of chemicals having EA from plastic packaging into animal feeds may impact research protocols that examine hormonally-responsive end-points.

## PS 112 Endocrine Disruption Potential of Trifluralin: Weight of Evidence Evaluation.

S. Marty<sup>1</sup>, S. Papineni<sup>2</sup>, V. J. Kramer<sup>2</sup>, S. C. Gehen<sup>2</sup> and K. K. Coady<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences LLC, Indianapolis, IN.

Trifluralin was included on List 1 for the EPA's Endocrine Disruptor Screening Program (EDSP). EDSP screens chemicals for their potential to interact with the estrogen, androgen, or thyroid pathways. A battery of 11 Tier 1 EDSP assays was completed for trifluralin and a Weight of Evidence (WoE) evaluation was conducted. **Estrogen pathway:** Trifluralin was weakly positive in the estrogen receptor (ER) transactivation assay, but it did not affect other estrogen-sensitive assays (i.e., ER binding, uterotrophic, estrogen-sensitive endpoints in the female pubertal, and vitellogenin levels in the fish short-term reproduction assay (FSTRA)). **Androgen pathway:** Trifluralin was negative for androgen receptor binding and while positive in the Hershberger assay, this result was due to enhanced testosterone metabolism. The male pubertal assay showed some indications of antiandrogenicity; however, we believe these effects were indirect. In a previous two-generation study, mating/reproductive indices, litter size/survival and reproductive organ histopathology were unaffected. The FSTRA was potentially positive; however, interpretation was complicated by overt toxicity and the absence of a cohesive link between study observations and known endocrine modes-of-action (MoA). **Thyroid pathway:** The female pubertal assay was positive for thyroid changes due to liver enzyme induction and enhanced thyroxine clearance. Thyroxine levels were decreased in the male pubertal assay, but other thyroid-related endpoints were not altered. Trifluralin increased thyroid tumors in a previous carcinogenicity study via a mode-of-action that is understood to be not relevant to humans. The amphibian metamorphosis assay was negative. Thus, there was no consistent evidence of effects on the estrogen pathway and effects on the androgen pathway did not fit a mode-of-action fingerprint for antiandrogenicity. Trifluralin alters the rodent thyroid system via an indirect effect on the liver; these effects are not expected in humans, who are quantitatively less sensitive than rats.

## PS 113 Cosmetics Products Have Detectable Estrogenic and Antiestrogenic Activity.

C. Z. Yang<sup>1</sup>, G. J. Kollessery<sup>1</sup>, M. Stoner<sup>1</sup>, A. W. Wong<sup>1</sup> and G. D. Bittner<sup>1,2</sup>. <sup>1</sup>CertiChem, Inc., Austin, TX; <sup>2</sup>The University of Texas, Austin, TX.

We have used a roboticized MCF-7 cell proliferation assay and a BG1-Luc assay undergoing validation by ICCVAM/NICEATM to quantify estrogenic activity (EA) and anti-estrogenic activity (AEA) in saline (hydrophilic), ethanol (hydrophobic), and DMSO extracts of over 50 commercially available cosmetic products. These included lipsticks, colognes, shampoos, hair conditioners and skin lotions sent to CertiChem for testing by the National Toxicology Program and the Breast Cancer Fund or purchased for testing by CertiChem from local stores. The total EA in extracts was quantified relative to the maximum response of 17 $\beta$ -estradiol (%RME2) and defined as the percentage of the maximum DNA/well produced by an extract with respect to the maximum DNA/well produced by E2 at any dilution and corrected by the cell response to the vehicle (negative) control (VC). The total AEA in extracts was quantified relative to the AEA of ICI 162,780 (%RMICI). As previously reported (see Yang et al, 2011, EHP 119:989-998), %RME2 and %RMICI values >15% are significantly (P<0.01) greater than the VC, i.e. are detectable for EA or AEA. In both MCF-7 and BG1-Luc assays, over 60% of the cosmetics products tested had easily detectable EA in either saline, ethanol or DMSO extracts. Some products exhibited AEA. When multiple extracts and tests were done on eight cosmetic samples, 7 out of 8 had detectable EA or AEA in at least one extract. Our results indicate that many cosmetics products contain components that exhibit easily detectable EA when tested on two human cell lines in vitro. EA or AEA in widely used cosmetics may account for some epidemiological data suggesting hormonal perturbations in the early onset of puberty in girls, development of uterine fibroids in adult females, and other adverse health effects (e.g., breast cancer). The study was supported by NTP and Breast Cancer Fund.

## PS 114 Use of Novel Assays to Screen Large Chemical Inventories for Functional Estrogen Receptor (ER) Activity.

K. Houck<sup>1</sup>, M. Martin<sup>1</sup>, R. Judson<sup>1</sup>, D. Rotroff<sup>1</sup>, J. Melnick<sup>2</sup>, J. Lamedin<sup>2</sup> and J. Weswick<sup>2</sup>. <sup>1</sup>NCCT, US EPA, Research Triangle Park, NC; <sup>2</sup>Odyssey Thera, San Ramon, CA.

Rapid, efficient screening assays are important for providing the means to prioritize large inventories of environmental chemicals for potential endocrine disrupting effects. Past efforts focused on transcriptional activation (TA) assays for estrogen, androgen and thyroid receptors. The complexities of nuclear receptor (NR) biology,

however, limit this approach as a comprehensive strategy to identify all NR modulators. For example, selective ER modulators can have cell type-specific activity dependent on the particular coregulator proteins expressed. We thus examined alternative, complimentary assay methodologies that provide unique functional information for chemical modulation of the ER pathway. We measured the ability of 1848 chemicals to induce ER dimerization and nuclear translocation, initial and required steps in ligand-induced activation of the ER pathway, using fluorescent imaging in intact cells at multiple time points. We also determined receptor selectivity using distinctly tagged ER $\alpha$  and ER $\beta$  receptors and found the great majority of compounds to have similar potency for both receptors. Secondly, we determined the activity of these 1848 chemicals in an ER/chromatin assay that visualizes active ER transcriptional loci and provides functional information as to the level of agonist versus antagonist activity of the ligand. Overall assay results showed chemicals could be categorized into several groups. First, there were unequivocal ER agonists active under virtually all testing conditions. Second, antagonists and partial agonists with weak or no activity in TA assays run in agonist mode were readily detected by these assays. Finally, there are spurious or artifactual results for each assay that must be taken into account when performing large scale assays such as this and are apparent by looking at data across multiple assays and formats. These results demonstrate the value of multiple, complimentary assay approaches in understanding complex biological responses with in vitro systems.

## PS 115 Effect of Technical Variation and Bioinformatics on the Biological Discovery in a Mechanistic Toxicogenomics Study.

B. Gong<sup>1</sup>, J. Xu<sup>1</sup>, Z. Su<sup>1</sup>, H. Hong<sup>1</sup>, J. Meehan<sup>1</sup>, H. Fang<sup>1</sup>, W. Ge<sup>1</sup>, S. S. Auerbach<sup>2</sup>, C. Wang<sup>3</sup>, L. Shi<sup>1</sup> and W. Tong<sup>1</sup>. <sup>1</sup>Division for Bioinformatics and Biostatistics, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>National Toxicology Program, NIEHS, Durham, NC; <sup>3</sup>Department of Molecular Medicine, City of Hope National Medical Center and Beckman Research Institute, Duarte, CA.

Whole-transcriptome sequencing using next-generation sequencing technologies, i.e., RNA-Seq, has drawn a significant attention as a ground-breaking tool for clinical application and safety assessment. However, critical assessment of RNA-seq to toxicology needs to be carefully conducted to understand whether the technology is robust and reproducible and how the choice of the bioinformatics approaches impacts study of the toxicity mechanisms and predictive toxicology. In this study, we conducted a specific study design to evaluate the impact of sequencing platforms and library preparation to the differentially expressed genes (DEGs) obtained, as well as the impact of different methods for DEG identification. Specifically, RNA samples from six rats' livers were collected, three of them were treated with aflatoxin (AFL) and the other three were matched controls. Two libraries were separately prepared for the samples and two sequencing platforms (Illumina HiSeq2500 and HiSeq2000 systems) were used. The investigation was based on the results derived from 6 different bioinformatics pipelines; each pipeline consists of a workflow including a specific genome template, mapping algorithm, quantification and normalization. Several methods for DEG identification were compared. The preliminary results show that library preparation introduces more variance than sequencing platform on gene expression quantification. Additionally, more variance has been observed for the low-expressed genes and thus increases the false positive rate in DEG identification among those genes. We proposed two filters for data reliability control prior to DEG analysis, one on the low expression level and another on high variance. Comparison was also carried out at functional module and pathway levels.

## PS 116 Structural Classification of 1848 Chemicals Evaluated for Estrogenic Activity in 13 HTS Assays.

R. Judson<sup>1</sup>, D. Rotroff<sup>1</sup>, M. Martin<sup>1</sup>, D. Reif<sup>1</sup>, K. Houck<sup>1</sup>, P. Kothia<sup>1</sup>, N. S. Sipes<sup>1</sup>, T. B. Knudsen<sup>1</sup>, M. Xia<sup>2</sup> and R. Huang<sup>2</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>NCGC, Rockville, MD.

High-throughput screening (HTS) assays are seeing increasing use for identifying chemicals that can cause toxicity via key biological pathways. However, biological complexities often mean that a single assay will fail to correctly classify all compounds for pathway activity. Here we use multiple orthogonal HTS assays to classify chemicals for their ability to interact with the estrogen receptor (ER) pathway among a structurally diverse library of 1848 chemicals, including pesticidal actives and inerts, industrial chemicals, food additives, cosmetics and drugs. The assays are: reporter gene assays in HepG2 cells selected to maximize metabolic activity, HEK293 cells, BG1 cells, CHO-K1 cells; cell-free binding assays (human, mouse, bovine); assays for ER dimerization (ER $\alpha$ -ER $\alpha$ , ER $\alpha$ -ER $\beta$ , ER $\beta$ -ER $\beta$ ) in HEK293 cells; a transcription-factor/DNA binding assay in HeLa cells; and an ER-sensitive cell proliferation assay in T47D cells. Multiple assay readouts used (fluorescence,

luminescence, sequencing, electronic impedance) allowed determination of possible assay interference. Non-ER related assays (cytotoxicity, cell stress, chemical fluorescence, unrelated endpoints) in the same engineered cells were also included. Assay data were compared with chemical structure clusters. A total of 237/1848 chemicals were active in at least 4 assays. (Note: the library was enriched in chemical classes expected to be estrogenic). This survey identified well known structural classes of estrogenic compounds including steroids, phenols, chlorobenzenes, anilines and perfluorinated alkanes. In metabolically competent assays, we also observed bioactivation in classes of compounds including permethrins and anthracene derivatives. In addition, we confirmed classes of compounds that consistently cause false activity in certain assays, including surfactants. Finally, there were novel compounds active in many assays that will require more analysis and follow-up studies to confirm their activity. This abstract does not necessarily reflect Agency policy.

## PS 117 Categorizing Tobacco Related Documents by Salient Topics for Regulatory Examination with Topic Modeling.

K. Yu<sup>1</sup>, Y. Ding<sup>1</sup>, R. Perkins<sup>1</sup>, W. Aaronson<sup>2</sup>, D. Sholtes<sup>2</sup>, Y. Tian<sup>2</sup>, G. Rochester<sup>2</sup>, X. Xu<sup>1,3</sup> and W. Tong<sup>1</sup>. <sup>1</sup>Division of Bioinformatics and Biostatistics, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>2</sup>Center for Tobacco Products, US FDA, Rockville, MD; <sup>3</sup>Department of Information Science, University of Arkansas at Little Rock, Little Rock, AR.

The FDA's Center for Tobacco Products (CTP) has received a large volume of documents from its regulated industries, and even more documents are forthcoming. The documents are unstructured and in various formats, including email, PowerPoint slides, memoranda and others. These documents contain diverse information related to such areas as marketing, safety and risk. The language is free text often containing ambiguous semantic descriptions, posing difficulty in retrieving useful information in a consistent and accurate fashion that is needed for regulatory review. Moreover, the sheer volume makes manual reading of the entire corpus impractical. To increase the review efficiency, the FDA requires submitters to include key word tags corresponding to FDA supplied question areas. The goal of this study is to identify the hidden topics or concepts from the submitted documents using topic modeling, and to assess whether the extracted topics reflect the FDA defined questions and thus facilitate review. As a pilot study, more than three thousand menthol-related tobacco documents were used to develop a topic model with latent Dirichlet allocation (LDA). The number of topics was optimized based on an information-loss approach. After generating the topics, a cosine similarity based approach was used to map FDA questions to the extracted topics. The results demonstrated that the extracted topics reflect the concepts of regulatory questions. The majority of documents clustered by topic modeling coincided with those grouped by FDA defined requests. This study demonstrates the potential utility of topic modeling as an unsupervised machine learning technique to classify the submitted documents based on the hidden topics, and thus provides an alternative means to support the review process.

## PS 118 Gene Expression Analysis to Predict the Dermal Carcinogenic Potential of Petroleum Streams.

K. Mathijs<sup>1</sup>, J. van Delft<sup>1</sup>, M. van Steensel<sup>2</sup>, K. Goyak<sup>3</sup>, H. Ketelslegers<sup>3</sup>, J. Freeman<sup>3</sup> and R. Phillips<sup>3</sup>. <sup>1</sup>Department of Toxicogenomics, Maastricht University, Maastricht, Netherlands; <sup>2</sup>Department of Dermatology, Maastricht University, Maastricht, Netherlands; <sup>3</sup>ExxonMobil Biomedical Sciences Inc., Annandale, NJ.

Certain poorly refined petroleum streams that contain high levels of polycyclic aromatic compounds have been shown to cause skin cancer in mice, as determined by the appearance of skin tumors after chronic dermal administration, which has cost and time constraints. We wish to identify biomarkers for petroleum-induced skin tumorigenesis, based on toxicogenomic responses in treated mouse skin from which predictive short-term tests can be developed. C3H/HeNcrI mice were treated dermally three times for one week with carcinogenic (C) or non-carcinogenic (NC) petroleum streams or with the solvent control. 24 h after the last treatment, sections of dorsal skin from sacrificed mice were used for immunohistochemistry (IHC), RNA and DNA isolation. Gene expression profiling using Agilent microarrays was done to select altered genes and molecular pathways related to individual test substances and substance classes for use in class prediction analyses to discriminate C from NC. No clear differences in IHC markers for hyper-proliferation, differentiation, or apoptosis were found between control, C and NC. Increased  $\gamma$ H2AX, a DNA damage marker, was found in C vs control and NC. Clear differences in gene expression profiles occurred between C and NC. Based on the gene expression profiles, correct prediction occurred; the top 10 classifier genes (which included *Cyp1a1*, *Cyp1b1*, *Nqo1*, *Ahr*, *Arnt*) are mainly involved in xenobiotic metabolism and oxidoreductase reactions. Classification based on pathway expression changes correctly predicted only NC and the highest concentrations of C; the top classifier

in the pathway analysis was the KEGG pathway "xenobiotic metabolism by cytochrome P450". Our results indicate that gene expression responses from a short-term dermal mouse study can predict C and NC petroleum streams, and that the AhR receptor pathway warrants further evaluation as a biomarker of exposure for petroleum-induced skin tumorigenesis.

## PS 119 Structure-Based Virtual Screening: Identification of New Targets for Triclosan.

D. Montes-Grajales and J. Olivero-Verbel. Environmental and Computational Chemistry Group Pharmaceutical Sciences, University of Cartagena, Cartagena, Colombia.

Triclosan (TCS; 2,4,4'-trichloro-2'-hydroxy-diphenylether) is a broad-spectrum antimicrobial agent used in personal care products. It has cytotoxic and endocrine-disrupting properties, and may be bioaccumulated from daily use. However, its impact on human health is largely unexplored with little evidence for deleterious effects in humans. A total of 248 proteins involved in different pathological processes were evaluated by *in silico* virtual screening to find new possible human protein targets for TCS. The 3D-structures of the proteins were downloaded from PDB, prepared and optimized by Sybyl X-2.0. The TCS structure was optimized by DFT at the B3LYP/6-31G level in Gaussian 0.9. Docking studies were performed in AutoDockVina 2.0 using a blind docking strategy, exhaustiveness of 25 and 10 runs. Calculated binding affinities were then employed for ranking proteins. A redocking step of 100 runs and exhaustiveness of 100, as well as the interaction analysis with Ligand Scout, LigPlot and MMV were carried out on the complexes presenting the best docking results. The greatest affinity scores were found for CDC2-like kinase 4 (CLK4,  $-8.4 \pm 0.0$  kcal/mol), oligomeric death domain complex (CRADD/PIDD,  $-8.3 \pm 0.1$  kcal/mol); progesterone receptor (PGR,  $-8.1 \pm 0.0$  kcal/mol); and estradiol 17-beta-dehydrogenase 1 (17-beta-HSD 1,  $-8.1 \pm 0.1$  kcal/mol), proteins involved in endocrine disruption and breast cancer-related processes. Validation showed our protocol predicted the binding site for the 17-beta-HSD and PGR native ligands, in agreement with crystallographic data. Moreover, TCS interacts in the same binding site occupied by the 17-beta-HSD 1 native ligand, but in a different one from that used by progesterone in PGR. Protein-ligand binding included hydrophobic and hydrogen bonding interactions. These results suggest TCS may target different proteins, probably altering pathways involved in pathophysiological disorders. Vice-Rector for Research. UniCartagena. 2011-2012. Colciencias-UniCartagena: Grants 110745921616 (2009) and 110751929058 (2010).

## PS 120 Generation of *In Vitro* Margin of Exposure (MOE) Values to Support the Postulated Mode of Action (MOA) for Selected Tobacco Smoke Toxicants.

S. A. Fiebelkorn, E. H. Cunningham, E. L. Bishop, D. M. Dillon and C. Meredith. Group R&D, British American Tobacco, Southampton, United Kingdom.

Over the last ten years there has been increasing interest in the identification and characterisation of tobacco smoke toxicants. We propose the use of a biologically relevant risk assessment framework incorporating both *in vivo* and *in vitro* data for the prioritisation of such toxicants. We have previously described the use of *in vivo* data in the generation of Margin of Exposure (MOE) values alongside Mode of Action (MOA) reviews. We have also proposed that individual toxicants are tested for activity in a battery of *in vitro* assays including *in vitro* micronucleus, Ames and mouse lymphoma assays.

MOE assessments are used as an initial tool to segregate tobacco smoke toxicants into high or low priority for risk reduction research. As recommended by EFSA, MOE values above 10,000 can be considered a low priority for risk management actions. We have generated *in vitro* MOEs for a number of tobacco smoke toxicants in conjunction with MOA reviews and *in vivo* MOEs (where suitable data is available). Where the *in vivo* MOEs generated for individual toxicants do not provide a conclusive evaluation and are split across the critical value of 10,000 (e.g. NNK and arsenic) or where the available *in vivo* data is unsuitable for MOE generation (e.g. hydroquinone and catechol), the use of *in vitro* data can provide an alternative source of information. We present here MOE data for five different tobacco smoke toxicants:

Benzo[a]pyrene: *in vitro*:  $42,469 - 3.0 \times 10^7$ ; *in vivo*:  $16,805 - 2.4 \times 10^6$ .

NNK: *in vitro*:  $1.0 \times 10^6 - 3.7 \times 10^8$ ; *in vivo*:  $338 - 3.7 \times 10^5$ .

Arsenic: *in vitro*:  $2.95 \times 10^7$ ; *in vivo*:  $13 - 4.9 \times 10^5$ .

Catechol: *in vitro* 938-12,094; *in vivo*: No data.

Hydroquinone: *in vitro*: 1651-10,304; *in vivo*: No data.

The incorporation of *in vitro* data into our suite of assessment methods allows us to generate additional MOEs to support the MOAs and provide further mechanistic understanding of individual toxicants. There is also the potential to incorporate such *in vitro* data into the future development of PBPK models for individual toxicants.

**PS 121** **Developing a Gene-Gene Interaction Network for Nonsyndromic Orofacial Clefts Using Computational Analysis.**

J. McKone, A. N. Van, E. Lachenauer and D. Johnson. *University of California Berkeley, Berkeley, CA.*

Orofacial clefts (OFCs) are caused by malformations in the closing of the lip or the soft palate. Although OFCs are considered to be one of the most common congenital birth defects, the underlying mechanisms of its etiology have yet to be clearly elucidated. This study sought to systematically determine how candidate genes previously identified in the literature interact, potentially implicating specific pathways for nonsyndromic OFC formation. OFC gene candidates were derived from genome-wide association studies (GWAS), the Comparative Toxicology Database, and Thomson Reuter's GeneGo. The compiled OFC genes were analyzed in conjunction with genes associated with the metabolic pathways of vitamin A and folic acid, factors shown to be implicated in OFC formation. Utilizing GeneGo and the candidate gene list, a gene-gene interaction network was constructed. Analysis of the network led to the identification of the TCF/LEF gene family, members of which regulate several downstream targets identified in the GWAS and/or are associated with vitamin A or folic acid metabolism. The TCF/LEF genes were shown in the network to be regulated by genes involved with the WNT signaling pathway, suggesting a mechanistic relationship between WNT signaling and orofacial cleft formation. Through computational analysis, this study proposes a potential gene-gene interaction mechanism for OFC formation via the WNT signaling pathway and ultimately identifies the TCF/LEF family as possible target gene candidates for further studies.

**PS 122** **Role of Beta-Methylamino-L-Alanine in GRIK1-Mediated Amyotrophic Lateral Sclerosis Disease Pathway.**

S. Firouzbakht, Y. Iizuka and D. Johnson. *University of California Berkeley, Berkeley, CA.*

Amyotrophic Lateral Sclerosis (ALS) is a debilitating neurodegenerative disease that affects about 30,000 people in the United States alone. Only a small fraction of cases are linked to genetics, making it likely that the overwhelming majority are induced by environmental factors. Therefore, the elucidation of a toxicity pathway is critical to the understanding of the vast majority of the ALS disease population. Amongst potential environmental exposures, neurotoxin beta-N-Methylamino-L-alanine (BMAA) has shown strong association with ALS in a small disease cluster in Guam. However, the several proposed mechanisms are insufficient in explaining the entire disease pathway. In this study, we utilized computational predictions with GeneGo, STITCH, BLAST, PubChem, and KEGG to generate the most feasible pathway for BMAA toxicity. The results from PubChem structure clustering between a highly kainate-specific ligand and BMAA- $\beta$ -carbamate revealed a statistically significant 3D Tanimoto score, implicating a comparable receptor repertoire. BLAST sequencing comparisons between GRIK1-5 and GLUL, an ALS associated gene, showed significant overlap between the two nucleotide sequences, further suggesting that kainate receptors are crucial to the ALS disease pathway. Incorporating these computational studies with current knowledge, there is compelling evidence suggesting a primary disease pathway in which BMAA- $\beta$ -carbamate binds to the kainate receptor GRIK1 at the presynaptic motor neuron, leading to increased glutamate release and subsequent neurodegeneration.

**PS 123** **Computational Analysis of a Potential Mechanistic Relationship between Depleted Uranium (DU) Exposure and Risk of Spina Bifida Cystica.**

S. Aghaee, H. Ngo and D. Johnson. *University of California Berkeley, Berkeley, CA.*

Prolonged weapon use in war zones increases the environmental levels of potentially teratogenic metals which may have a direct relationship to increased incidences of birth defects. In Fallujah, Iraq since 2003, high levels of depleted uranium (DU) in the environment and in hair samples of residents suggests that constant exposure to

DU may play a role in the alarming rates of congenital defects found in Iraqi children. One particular birth defect, Spina bifida, is a congenital defect of the spinal column with two major subclasses: spina bifida occulta and spina bifida cystica. Cystica is the most severe form of the disease but also the least prevalent. However, this has not been the case in Fallujah, Iraq where from 2003 cystica has been found to be the most prevalent form of spina bifida. The purpose of this study was to search for any commonalities between the genes and biological pathways associated with exposure to uranium and development of spina bifida cystica. Computational methods and tools utilized included the Comparative Toxicogenomics Database (CTD), PubChem, ToxNet, Pathway Commons, and unpublished exposure/defect data from Iraq. Out of the 292 genes reportedly affected by uranium exposure, 155 were also associated with spina bifida cystica. Biological pathway analysis revealed three genes, NT5E, PED, and TALDO1, associated with uranium are also involved in upstream pathways of folic acid synthesis. Research has shown that a lack of folate is known to be related to spina bifida. This study provides a broad look at the genetic and molecular similarities between response to uranium exposure and spina bifida cystica, and may offer options for preventive therapeutic interventions. Further studies examining gene ontologies of populations exposed and not exposed to depleted uranium would offer a clearer picture of the relationship between uranium and spina bifida.

**PS 124** **Computational Analysis of Catechins in Teas and Potential Relationship to Cardiovascular Health.**

C. Lei, M. Nhan, C. Ha and D. Johnson. *University of California Berkeley, Berkeley, CA.*

Consumption of green tea has been reported to have beneficial effects on a variety of health-related issues. Of interest is the beneficial differences between green, oolong, and black teas, all produced from the leaves of *Camellia sinensis*. Of the five main groups of bioactive compounds in the *Camellia sinensis* plant, catechins were found to be the most bioactive. Of the six main catechins in tea, epigallocatechin-3-gallate (EGCG), the most abundant and bioactive of the catechins was found to be in the highest concentration in green tea as compared to oolong and black teas and subsequently was considered to be the most health-relevant component. The potential health benefits of tea depend on their level of fermentation, which is correlated to the amount of oxidation the catechins undergo during processing. EGCG is most abundant in green tea, which is not fermented, and highest in fresh unprocessed leaves from *Camellia sinensis*. Green tea extract has also been reported to have increased biological activities. EGCG and pro-drugs have also been shown to be potential epigenetic modulators. DNA methylation is catalyzed by DNA methyltransferase (DNMT) with S-adenosyl-methionine (SAM) as the methyl donor. EGCG has been shown to reduce DNMT indirectly by reducing SAM and increasing S-adenosyl homocysteine (SAH) and homocysteine levels in the MCF-7 breast cancer cell line. In this study, primarily utilizing GeneGo Metadrag and MetaCore we report a proposed overlap between EGCG affected pathways and the atherosclerosis disease pathway. EGCG was found to competitively block hydroxy-3-methyl-glutaryl-CoA, and non-competitively inhibit squalene epoxidase, two rate limiting enzymes in the cholesterol biosynthesis pathway. In addition, previous animal studies have reported a decrease in LDL levels in rats given the three teas with the highest response coming from green tea treatment. This study provides an analysis of antioxidant compound levels found in tea and their relation to its effect on cardiovascular health, providing a possible explanation to the differences in beneficial effects found in different types of teas.

**PS 125** **Computational Analysis of Environmental Factors Potentially Associated with Multiple Sclerosis Susceptibility.**

F. Su, M. Gooding, G. Anderson and D. Johnson. *University of California Berkeley, Berkeley, CA.*

Multiple Sclerosis (MS), an autoimmune disease of the CNS, may have associated environmental risk factors. A relationship between distance from the equator and MS risk reinforces the belief that UVB radiation and subsequent Vitamin D synthesis act protectively. The Human Leukocyte Antigen b chain, HLA-DRB1 is activated by Vitamin D and its receptor, and a polymorphism, HLA-DRB1\*15.01, has been associated with MS susceptibility. Computational methods utilized to explore environmental factors beyond UVB radiation that might influence MS disease pathways included the Comparative Toxicogenomics Database (CTD), STITCH, GWAS data, GeneGo, and the EPA Toxic Release Inventory (TRI). Historical MS clusters in the US were identified and toxic release data obtained through TRI. Lead (Pb 2+), was found as a top contaminant among the MS clusters. Although lead has been proposed as a risk factor for MS, no previous published studies have clearly linked lead and MS. To identify and investigate genes,

cellular pathways and disease interactions, CTD was utilized with STITCH to generate association networks between genes and proteins and to identify another intermediate protein, ALAD. Binding assays show that a polymorphism of ALAD, ALAD2, causes red blood cells to bind lead more tightly and previous research has implicated ALAD as an important factor in lead susceptibility. VDR polymorphisms are also associated with lead susceptibility. Although a correlation between VDR B and higher blood, urine, and plasma lead levels has been reported, the mechanism and systemic effect of the allele are not well understood. Maps of the frequency of haplotypes in different populations for VDR B, ALAD2 and HLA-DRB1 were obtained from GWAS and correlating biological pathways involving MHCII, ALAD, and VDR were constructed with GeneGo. In combination, the relationships identified suggest that ALAD2 and VDR B haplotypes confer an individual with heightened lead susceptibility. Furthermore, the results suggest that elevated levels of lead are associated with decreased expression of HLA-DRB1 and greater risk of MS.

**PS 126 Profiling the Activity of Environmental Chemicals in Causing Testicular Dysgenesis Syndrome Using the US EPA Toxicity Reference Database (ToxRefDB).**

M. C. Leung<sup>1</sup>, K. W. McLaurin<sup>1</sup>, J. Phuong<sup>1</sup>, N. S. Sipes<sup>1</sup>, N. C. Baker<sup>1</sup>, N. Kleinstreuer<sup>1</sup>, A. M. Frame<sup>1</sup>, R. Judson<sup>1</sup>, G. R. Klinefelter<sup>2</sup>, M. T. Martin<sup>1</sup> and T. B. Knudsen<sup>1</sup>. <sup>1</sup>National Center of Computational Toxicology, US EPA, Research Triangle Park, NC; <sup>2</sup>Reproductive Toxicology Division, US EPA, Research Triangle Park, NC.

Hypogonadism, cryptorchidism, hypospadias, and testicular cancer are increasingly common male reproductive defects. Clinical and experimental evidence suggest that these defects are associated with testicular dysgenesis syndrome (TDS). We hypothesize an Adverse Outcome Pathway (AOP) framework for TDS starting with disruption of cell signaling and structural targets of the fetal testis during embryogenesis, followed by a series of key events that lead to male reproductive defects. Since understanding chemical-endpoint associations is an approach in building the AOP conceptual models, we mined 4209 guideline animal studies in EPA's ToxRefDB, which included 963 compounds tested in rats, mice, and rabbits. Testicular neoplasia was an outcome for 60 (6.2 %) chemicals. Sperm abnormalities were an outcome for 72 (9.8 %) chemicals tested in chronic and subchronic toxicity studies and 44 (5.7 %) chemicals tested in prenatal developmental and/or multigenerational fertility studies. Reductions in anogenital distance were recorded for 15 (3.5 %) chemicals tested in multigenerational studies, and 11 (1.5 %) chemicals tested caused hypospadias or cryptorchidism in developmental or multigenerational studies. The chemical classes showing the broadest activity across different TDS endpoints were pesticides (amdro, benomyl, primisulfuron-methyl, tetrachlorobenzene, and vinclozolin) and phthalates (butyl benzyl phthalate, dibutyl phthalate, and diethylhexyl phthalate) with a lowest effect level on the order of ~300 mg/kg/day. The most potent TDS-actives (17 $\beta$ -estradiol, flutazepam, and tebutimfos) produced testicular effects below 0.1 mg/kg/day. These results suggest a hierarchical pattern of male reproductive defects in ToxRefDB which can be used as an AOP anchor for TDS. [This work does not reflect EPA policy].

**PS 127 Compound Toxicity Profiling and Prioritization Using Tox21 Phase I Quantitative High-Throughput Screening (qHTS) Cytotoxicity Data.**

J. Hsieh<sup>1</sup>, A. Sedykh<sup>2</sup>, R. Huang<sup>3</sup>, M. Xia<sup>3</sup> and R. R. Tice<sup>1</sup>. <sup>1</sup>Division of the National Toxicology Program, NIEHS, NIH, Research Triangle Park, NC; <sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>National Center for Advancing Translational Sciences, Bethesda, MD.

Using in vitro data to prioritize compounds for in vivo toxicity testing is a goal of Tox21. Phase I profiled 1408 NTP compounds against 126 cell-based qHTS assays; those that measured cytotoxicity record the ability of a chemical to adversely perturb multiple cellular pathways in a concentration-response fashion. The curves from 39 cytotoxicity assays (9 human cell types, 4 rodent cell types, 13 sets of identical twin lymphoblastoid cell lines) were curated to filter noise and remove artifacts. To quantify the activity of each compound in these assays, we calculated a weighted version of Area Under the Curve (wAUC) intended to capture potency and efficacy simultaneously, as well as the conventional half-maximal activity concentration (AC50) value. The average wAUC or AC50 values across the 39 cytotoxicity assays were used to rank compounds and the rankings were compared, for 880 compounds, with available rat acute oral toxicity data. The compounds were categorized as toxic or non-toxic based on various "Globally Harmonized System of Classification and Labelling of Chemicals" (GHS) acute toxicity thresholds (50,

300, 500, 2000 mg/kg). The wAUC approach consistently prioritized more toxic compounds at the early stage (up 1% non-toxic compounds of dataset) at all thresholds. The best receiver operating characteristic (ROC) enrichment value at 1% and AUC value are 14.3 [95% CI=1.8-26.8] and 0.73 [95% CI=0.65-0.80], respectively, at a threshold of 50 mg/kg. Also, some toxic compounds (e.g., actinomycin D, colchicine, daunomycin) had higher ranks based on wAUC due to their ill-fitted curves in some of the cell lines, resulting in missing AC50 values. We conclude that the wAUC provides an additional and useful metric to estimate the toxicity potential of compounds for Tox21 qHTS assays. Based on this metric, compounds screened in Tox21 can be prioritized for more extensive testing.

**PS 128 Predicting Cellular Dynamics and Key Events in Developmental Toxicity with a Multicellular Systems Model.**

T. B. Knudsen<sup>1</sup>, M. R. Rountree<sup>1</sup>, S. Hunter<sup>2</sup>, N. C. Baker<sup>3</sup>, R. Spencer<sup>3</sup>, R. S. DeWoskin<sup>4</sup> and W. Setzer<sup>1</sup>. <sup>1</sup>NCCT, US EPA, Research Triangle Park, NC; <sup>2</sup>NHEERL, US EPA, Research Triangle Park, NC; <sup>3</sup>Lockheed Martin, Research Triangle Park, NC; <sup>4</sup>NCEA, US EPA, Research Triangle Park, NC.

Computer simulation of cellular networks is one possible solution for modeling key events in developmental toxicology. We constructed a multicellular agent-based model (ABM) of early limb-bud development in CompuCell3D ([www.compu-cell3d.org/](http://www.compu-cell3d.org/)). The model simulates key cellular behaviors (mitosis, apoptosis, adhesion, migration, chemotaxis, shape, secretion), organizing centers (AER, ZPA) and signals (FGFs, SHH, BMPs, RA). It effectively emulates hindlimb-bud development during a 42h period in mouse (Theiler stages 16-19) and 160h in human (Carnegie stages 13-16). The ABM reflects biological variability across parallel simulations for spatio-temporal expression of biochemical gradients and cell behaviors, ultimately manifesting in trajectories of outgrowth. To evaluate the model as a tool for predictive toxicology, we selected 5-Fluorouracil (5FU) as a prototype. 5FU perturbed 13 of 650 ToxCast assays based on AC50s (or LECs) at or below 15  $\mu$ M. 5FU effects observed in the assays were disruption of stem cell (mES) growth and differentiation, suppression of TGF $\beta$ 1 signaling and mitochondrial density, p53-induction, mitotic arrest, reduced cell proliferation and increased cell death. Challenging the ABM with concentration-response data derived from mES cell number produced a dose-dependent wave of mitotic arrest and apoptosis, disrupting outgrowth. Varying the dose and time of exposure localized the primary key event to arrest of SHH-expressing cells and their geometric relationships to cells expressing GREM1, a BMP antagonist maintained by SHH signals. Different outcomes emerged when perturbation of the SHH/GREM1/BMP loop was switched between mitotic arrest and excessive apoptosis, indicating the importance of considering both cellular consequences together. These findings support the application of multi-cellular ABMs as tools to translate cellular dynamics into simulation of emergent (higher order) tissue effects for predictive toxicology. [This abstract does not necessarily reflect EPA policy.]

**PS 129 Chemical Structure-Based *In Silico* Phototoxicity Prediction: An Approach from a Combination of Photochemical Properties.**

Y. Haranosono, S. Nemoto, M. Kurata and H. Sakaki. Senju Pharmaceutical Co., Ltd., Kobe, Japan.

Some photochemical properties are essential factor for prediction of phototoxicity, since phototoxicity is caused by photo-activation of the compounds. Highest Occupied Molecular Orbital – Lowest Unoccupied Molecular Orbital Gap (HLG) is a photochemical property of needful energy for photo-activation, and HLG was reported to be related with phototoxicity based on *in vitro* 3T3 Neutral Red Uptake assay (3T3 NRU assay). However there are few reports to predict of phototoxicity using photochemical property including HLG. In this research, we established the stepwise approach using Maximum-Conjugated- $\pi$ -Electron- Number ( $PEN_{MC}$ ) of the compounds in addition to HLG for *in vitro* phototoxicity prediction. HLG and  $PEN_{MC}$  were calculated by ChemDraw<sup>®</sup> and Chem3D<sup>®</sup> for total 64 compounds which were known the results of 3T3 NRU assay (32 positive and 32 negative). As step 1, we set the cut lines of HLG as follows; the compounds that have over 8.0 of HLG were determined as negative, and the compounds that have less than 5.2 of HLG were determined as positive. On the other side, the compounds that have HLG from 5.2 to 8.0 showed no predicting performance to phototoxicity, and then we defined this range of HLG as gray zone. As step 2, we employed  $PEN_{MC}$  for the gray zone compounds. We found that  $PEN_{MC}$  also indicated correlation to *in vitro* phototoxicity, and therefore set the cut lines as follows; the compounds that have 12 and more than of  $PEN_{MC}$  were determined as positive, and 11 or less of  $PEN_{MC}$  were determined as negative. This stepwise approach for phototoxicity prediction

was validated by the following results; sensitivity (84.4%), specificity (81.3%), positive rate (81.8%), negative rate (83.9%) and concordance (82.8%). We concluded that the stepwise approach with combination of HLG and PEN<sub>MC</sub> for prediction of phototoxicity is adaptable and useful for drug development as *in silico* screening, because it showed high sensitivity and negative rate from only chemical structure.

**PS 130 High-Content Screening of ToxCast Compounds for Developmental Endpoints Related to Adipogenesis and Angiogenesis.**

D. L. Filer, N. Kleinstreuer, M. Martin, K. Houck and D. Reif. *National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.*

The US EPA's ToxCast research program gathers toxicity information for over 1000 chemicals utilizing high-throughput toxicity screening (HTS) assays with human gene and protein targets to inform prioritization of chemicals with little or no toxicity information for further testing. Vala Sciences provides high content multiplexed assays utilizing quantitative digital imaging of cultured cells, tissues and small model organisms. We measured the ToxCast Phase I\_v2 chemical library, (293 unique compounds, primarily food-use pesticides with associated *in vivo* toxicity data), with 12 Vala Sciences assays in six-point concentration response from 0.013  $\mu$ M to 100  $\mu$ M. Assays examined chemical effects on embryonic stem cell differentiation, neuronal function, pancreatic  $\beta$  cell differentiation, germ layer proliferation, adipogenesis, adipocyte lipolysis, hepatic steatosis, and junctional proteins critical to developmental angiogenic processes and tumor progression. We subjected concentration response data to automated curve-fitting using modified Hill functions, outlier detection algorithms, and uncertainty analysis to determine the half-maximal activity concentration (AC50) and Lowest Effective Concentration (LEC) for each chemical/assay combination. Assays showed high reproducibility, both within triplicate replicate sets and in blinded compound replicate sets. Across the entire Phase I chemical set, 5% of chemical/assay combinations demonstrated significant (> 50% change over control baseline) activity. Early response targets in this data set provide toxicological and mechanistic insight to complement other ToxCast assays and lead to stronger predictive toxicity models. Collectively, these results add important data to ToxCastDB that will help identify and prioritize possible developmental toxicants, endocrine disruptors, liver toxicants, and carcinogens to inform targeted testing strategies. *This abstract does not necessarily reflect U.S. EPA policy.*

**PS 131 In Silico Models for Dermal Absorption from Complex Formulations.**

K. Guth<sup>1</sup>, J. E. Riviere<sup>2,3</sup>, J. Brooks<sup>2</sup>, M. Schäfer-Korting<sup>4</sup>, M. Dammann<sup>1</sup>, E. Fabian<sup>1</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany; <sup>2</sup>Toxicology Research and Pharmacokinetics, North Carolina State University, Center for Chemical, Raleigh, NC; <sup>3</sup>Institute of Computational Comparative Medicine, Kansas State University, Manhattan, KS; <sup>4</sup>Institut für Pharmazie, Freie Universität, Berlin, Germany.

Dermal exposure is a relevant parameter for risk assessment of chemicals, cosmetics and pesticides. Here, we present potential *in silico* models for prediction of dermal absorption based on realistic exposure scenarios in complex mixtures. The calculations were based on 342 individual dermal absorption *in vitro* experiments using human or rat skin samples for 56 chemicals (mainly pesticides) in more than 150 different mixtures containing up to 20 ingredients like water, organic solvents, surfactants or thickeners. The first approach was based on the Abraham solute descriptors, mixture factors (MFs) as suggested by Riviere and Brooks and the logarithmic maximal permeability coefficient (logmaxKp) as response<sup>1,2</sup>. Additionally, an indicator variable for the species (SpI) was introduced. In a second approach class variables – which bundled substance-specific information – were used in combination with mixture factors. Validation was performed in accordance with the OECD Guidance document for QSAR models. The final validated Abraham-based model comprised the solute excess molar refractivity of the penetrant, SpI and topological polar surface area of the mixture (R<sup>2</sup>:0.38, Q<sup>2</sup>Ext: 0.41). Despite the low correlation, the model was suitable to estimate Marzulli classes of penetration for unknown penetrants in specific mixtures<sup>3</sup>. Furthermore, precise prediction of mixture effects on well-known substances was possible with the substance-based approach (R<sup>2</sup>:0.75, Q<sup>2</sup>Ext: 0.73). Taken together, both applications are suitable screening tools in early stages of product development.

**PS 132 Development of Improved Salmonella Mutagenicity QSAR Models Using Structural Fingerprints of Known Toxicophores.**

L. Stavitskaya<sup>1</sup>, B. L. Minnier<sup>2</sup>, R. Benz<sup>1</sup> and N. L. Kruhlik<sup>1</sup>. <sup>1</sup>US FDA, Silver Spring, MD; <sup>2</sup>GlobalNet Services, Inc., Rockville, MD.

The current draft of the International Conference on Harmonisation (ICH) M7 guidance describes the use of *in silico* models to qualify genotoxic impurities during the drug safety evaluation and approval process. In order to attain the highest accuracy and improve the domain of applicability of the current Salmonella mutagenicity quantitative structure-activity prediction models, continuous updates to the training set must be made to accommodate new genotoxic findings. In this study, we first assessed our current Salmonella mutagenicity training set using fingerprints of known genotoxic structural alerts to determine the domain of applicability and performance characteristics of several commercial (Q)SAR models. We then enhanced the previous version of our non-proprietary training database for Salmonella mutagenicity with data for 431 new compounds harvested from FDA approval packages and the published literature, to give a total of 3965 compounds. Of the 431 chemicals, 247 are drug molecules marketed between 1970 and 2011. Data gaps within the training set were identified and, using structural features derived from known toxicophores, 141 examples containing functional groups such as azides, amine oxides, hindered epoxides, propiolactones, quinones, amine halides, diazines, azo compounds, diazoniums, sulfates, aziridine chlorides, nitrites, hydrazines, nitriles, isocyanates, and sulfur mustards were added. Moreover, the new training set was expanded to include over 40 compounds containing previously unmodeled atoms such as boron, silicon, selenium, and tin. A hierarchical clustering analysis of the final training set showed representation of an additional 44 structural clusters over which the model can make a prediction.

**PS 133 Evaluation of QSPR Models to Predict Evaporation Rates of Hazardous Chemicals from the Skin Surface.**

T. Liu, M. Rauma and G. Johanson. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

The skin serves as a barrier against hazardous agents in the environment. However, the barrier is incomplete in that chemicals may penetrate the skin and cause toxicity. The absorbed dose depends not only on the absorption rate but also the evaporation rate (assuming a fixed dose and skin area). The limited data available suggest that rates vary by several orders of magnitude between chemicals. However, there is a huge lack of data and new approaches are needed. One attractive possibility is to use quantitative structure-permeability relationship (QSPR) models. The aim of the present study was to examine different QSPR models addressing evaporation rate. We calculated evaporation rates for nine volatiles (methanol, n-propanol, acetone, methyl ethyl ketone, hexane, n-heptane, octane, benzene and toluene) at three air velocities and three air temperatures, using four semi-empirical models; McCready & Saghir, EPA, Mackay & Matsugu, and BAU. The predictions were compared with experimental data published by the EPA<sup>1</sup>. None of the four models were able to predict the evaporation rate at all wind speeds. For comparison, we also developed linear solvation energy relationships (LSER) and partial least squares projections to latent structures (PLS) models. Seven solvents were used for calibration and two to test predictive performance. The LSER and PLS models showed good correlation (R<sup>2</sup> 0.95 and 0.92) and predictive performance (Q<sup>2</sup> 0.86 and 0.95) and seem more suitable than the semi-empirical models to predict evaporation rate. The semi-empirical models, EPA and Mackay & Matsugu at higher air velocity (5.08 m/s) and lower temperature (280.35 K), showed a fair agreement between predictive and experimental values. As a result, evaporation rates can be adequately predicted from available physicochemical properties of the volatile organic compounds (VOCs).

**PS 134 Regulatory Targets of CDKN2A in Lung Epithelial Cells.**

J. Mehta and G. Acquah-Mensah. *Massachusetts College of Pharmacy and Health Sciences, Worcester, MA.*

Cyclin Dependent Kinase Inhibitor 2A (CDKN2A) is a tumor suppressor protein in humans. It is capable of inducing cell cycle arrest in the G1 and G2 phases. p16INK4a is a major component of the RB pathway. p14ARF is part of an ARF-MDM2-TP53 system that exercises a negative control on hyper-proliferative signals originating from oncogenic stimuli. ARF binds to MDM2 and blocks its cytoplasmic transfer and thereby sequesters it in the nucleus. This hinders the MDM2 action, thereby blocking degradation of p53 and thus enhancing transactivation

and apoptosis. The purpose of this study was to identify additional regulatory targets of CDKN2A in lung epithelial cells, using Bayesian networks. Using the Robust Multi-Array Average procedure, a compendium of lung epithelial cell microarray data was generated based on Gene Expression Omnibus datasets GSE 19027 and GSE 994. The best-scoring regulatory networks, given the gene expression data, were then learned using the Bayesian Network Inference with Java Objects toolkit (BANJO) for static Bayesian Network inference. A set of known regulatory relationships involving CDKN2A was used as the initial network to focus the search space. Two proposers concurred in predicting IL1RN, IL6ST, IL1RAPL1, IGFALS, and WNT10B as regulatory targets for CDKN2A. These genes are known to interact with a range of chemicals, including certain environmental toxicants. Furthermore, CDKN2A was predicted to be a direct regulator of RB1. These hypotheses warrant additional study as they lend valuable insights into the functions of CDKN2A in Chronic Obstructive Pulmonary Disease (COPD) and cancer. E2F3 was predicted, and validated in the literature, to be a regulator of MDM2 and TP53. Thus, Bayesian networks are a valuable tool for drawing signaling insights from gene expression data.

### PS 135 Irreversible Inhibition of Acetylcholinesterase by Soman.

G. S. Sirin<sup>1,2</sup> and Y. Zhang<sup>2</sup>. <sup>1</sup>ATSDR, Atlanta, GA; <sup>2</sup>New York University, New York, NY. Sponsor: P. Ruiz.

Acetylcholinesterase (AChE) is a key enzyme in the cholinergic nervous system that hydrolyses acetylcholine and terminates synaptic signals. Organophosphate compounds, such as nerve agents, can covalently inhibit AChE by phosphorylating the enzyme's catalytic serine residue. The phosphorylated adducts can either be reactivated to some limited extent by nucleophilic compounds with oxime functional unit or undergo an aging reaction. Phosphorylation and subsequent aging leads to irreversible AChE inhibition, resulting in overstimulation of the nervous system. By employing *ab initio* QM/MM molecular dynamics simulations with umbrella sampling, we characterized the phosphorylation reaction mechanism between AChE and the nerve agent soman (GD), as well as the aging mechanism of GD phosphorylated AChE. The phosphorylation reaction between AChE and GD follows an associative nucleophilic substitution mechanism that is initiated when the nucleophilic Ser200 attacks GD's phosphorus atom, with His440 acting as a general base. In the elimination step, Tyr121 of the catalytic gorge forms hydrogen bonds with the leaving fluorine atom prior to its dissociation from the active site. Once a stable covalent adduct is formed, the aging reaction begins with excision of the alkoxyl covalent bond connecting the bound GD's alkyl group to the phosphonate moiety. This cleavage is swiftly followed with a methyl group rearrangement of the alkyl group resulting in a stable tertiary carbenium, which is hydrated to an alcohol by a reactive water molecule facilitated by Tyr121. The characterized mechanisms and simulation results provide new detailed insights into this important process. Such mechanistic details are of significant interest for the development of novel strategies to reduce the toxic effects of GD poisoning by facilitating the search and design of novel compounds capable of slowing the aging of nerve-agent-inhibited AChEs as well as effective reactivators for the aged conjugates. Lastly, this work may also facilitate the design of aging-resistant pseudo-catalytic scavengers capable of sequestering nerve agents.

### PS 136 Computational Elucidation of Energetic Trends for DNA Intercalation.

H. W. German and M. J. Novak. *Chemistry, Florida Institute of Technology, W. Melbourne, FL.* Sponsor: L. Valerio.

The prediction of general energetic trends from intercalation of polycyclic aromatic compounds with DNA can provide insight into these pertinent interactions from a pharmacological and toxicological perspective. Compounds chosen for this study are nucleotide base pairs (AT, GC, AA) and two novel intercalating agents (4-azatryptanthrin and coralyne). Unfortunately, neither of these compounds have an established crystal structure when intercalated into DNA. The absence of this computational starting place gives rise to the need for a strong alternative computational method.

Since dispersion forces have been shown to drive optimal orientation based on  $\pi$ -stacking, this method utilizes the electrostatic potential (ESP) maps of both interacting species. Presented herein is our improved method that uses more pertinent variables, overcomes the weakness of a center of mass method, and improves the efficiency with which computational studies can provide insight to experimental design by relying primarily on visual intuition of the ESP alignments. The simplicity of this study leads to the decrease in the time cost and the consideration of dispersion forces increases confidence in our results.

Our computational methods utilize SPARTAN and GAUSSIAN software, a Ground State Density Functional Theory (DFT), Local Spin-Density Approximation (LSDA) method, and a 6-311++G(d,p) basis set. Initial results in-

dicate a preferential intercalation of 4-azatryptanthrin with the GC base pair over an AT base pair based on energetic stabilization due to  $\pi$ -stacking. Identification of trends such as this can be valuable in designing future experimental studies targeting GC or AT rich regions associated with genetic disorders such as Myotonic Dystrophies, Fragile X, and Friedreich's Ataxia.

### PS 137 Efficient *In Vivo* Developmental and Neurotoxicity Screen of ToxCast Phase I and II Compounds in Zebrafish.

L. Truong<sup>1,2,3</sup>, C. Miller<sup>1,2,3</sup>, D. Haggard<sup>1,2,3</sup>, G. Gonnerman<sup>1,2,3</sup>, L. Chalker<sup>1,2,3</sup>, K. Nhan<sup>1,2,3</sup> and R. L. Tanguay<sup>1,2,3</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR; <sup>2</sup>Environmental Health Sciences Center, Corvallis, OR; <sup>3</sup>Sinnhuber Aquatic Research Laboratory, Corvallis, OR.

The United States Environmental Protection Agency launched the ToxCast program to begin to predict the potential chemical toxicity of 1,078 compounds made up of pesticides, pharmaceuticals, "green" chemicals, chemicals in cosmetics and other consumer products. Early life stages are often sensitive to chemical insult, which make embryonic zebrafish an ideal platform to investigate the developmental and neurotoxicity of these compounds. We developed an efficient *in vivo* phenotypic screen using embryonic zebrafish to assess all 1,078 compounds. Using a wide range of concentrations (0.0064 to 64  $\mu$ M, 10 fold serial dilution); all compounds were assessed for developmental toxicity beginning at 6 hours post fertilization (hpf). We kept exposed embryos completely in the dark until 24 hpf, and assessed photo-motor responses using the Photo-motor Response Assessment Tool (PRAT) that we developed. PRAT quantifies individual embryonic photo-motor response following two pulses of bright light. The initial pulse normally results in pronounced movement, and the second light pulse usually produces no activity. At 120 hpf, using Viewpoint Zebrafish, we assessed photo-induced larval locomotor activity. The locomotor activity is tracked for 25 minutes (10 in the light, 10 in the dark, and 5 in the light). Afterwards, each larva was assessed for changes in a suite of 20 morphological endpoints. We have successfully conducted the phenotypic screen on all 1,078 compounds, and a summary of the results will be discussed. Collectively, we have demonstrated the efficiency of the zebrafish model as a phenotypic screening platform to identify hazardous chemicals. This research is supported by NIEHS grants P30 ES00210 and RC4ES019764.

### PS 138 *In Silico* and *In Vitro* Analyses of the Hormonal Activity of Hydroxylated Polychlorinated Biphenyl on Human Thyroid Receptor.

C. Dassuncao, O. Faroon, J. Wheeler and P. Ruiz. *DTHHS, ATSDR/CDC, Chamblee, GA.*

Hydroxylated polychlorinated biphenyl (OH-PCBs) may disrupt thyroid hormone status because of their structural similarity to thyroid hormone. However, the molecular mechanisms of interactions with thyroid hormone receptors (TRs) are not fully understood. The integrated application of omics studies, bioinformatics, and computational modeling can provide to biological systems an enhanced understanding of the mechanisms underlying the toxicity of endocrine disruptor chemicals and support the study of disease etiology and prevention. In the present study, we examined the interactions between OH-PCBs and TRs to identify critical structural features and molecular properties of OH-PCBs related to their hormonal activity and to develop quantitative structure-activity relationship (QSAR) models for the thyroid hormone activity of OH-PCBs. Molecular descriptors were computed, selected, and used to characterize the ligand-receptor binding, and subsequently develop an *in silico* model. The *in silico* model had good robustness, predictive ability, and mechanism interpretability. Lipophilic distribution, hydrophobic and electrostatic interactions between OH-PCBs and TRs are important factors governing thyroid hormone activities. The OH-PCBs with higher ability to accept electrons, ortho position of the hydroxyl group, low dipole-dipole interactions tend to have weak binding with TRs and subsequently lower thyroid hormone activities. Hence, this *in silico* model can be used as a screening tool for further targeted toxicity testing and risk assessment, generate hypotheses about potential mechanistic pathways leading to adverse outcomes, and reduce time and cost of OH-PCBs testing.

**PS 139 A Systematic Analysis of ToxCast *In Vitro* Assays Associated with *In Vivo* Hepatic Outcomes.**

J. Liu<sup>1,2</sup>, M. T. Martin<sup>1</sup>, C. Corton<sup>3</sup>, C. Wood<sup>3</sup> and I. Shah<sup>1</sup>. <sup>1</sup>NCCT/EPA, Durham, NC; <sup>2</sup>University of Arkansas, Little Rock, AR; <sup>3</sup>NHEERL/EPA, Durham, NC.

The U.S. EPA's ToxCast™ program uses hundreds of high-throughput, *in vitro* assays to screen chemicals for bioactivity. The EPA Virtual Liver project combines ToxCastDB data with guideline rodent toxicology data to map hepatic adverse outcome pathways (AOPs). Here our objective is to reveal meaningful relationships between *in vitro* assays and *in vivo* liver outcomes. 289 ToxCast phase I chemicals were organized into 15 categories based on 272 histopathological lesions reported in guideline testing studies from ToxRefDB. Based on lesions reported at the study end, 242(83.7%) chemicals produced hypertrophy, 39(13.5%) chemicals resulted in hyperplasia, and neoplastic lesions were found for 79(24.9%). We compared the AC50 concentrations of chemicals for each of the 973 ToxCast assays and identified assays with at least 10 chemicals per category and the mean potency was significantly different ( $p < 0.05$ ). Out of the 973 assays, 28/147(19%) of the high-content imaging assays (APR) had associations with 7 liver injury categories. 6/83(7.2%) multiplexed transcription reporter assays (ATG) and 15/112(13.4%) protein complementation (OT) assays were also significant for liver injury. A number of the assays such as, cell loss, enzyme induction and enzyme inhibition, were generally significant across most categories. On the other hand, some assays were quite specific to certain categories. For instance, APR\_StressKinase\_72hr\_pos (stress kinase pathway activation) and ATG\_CRE\_CIS (transcription factor DNA binding activity) were significant for chemicals that showed regeneration vs ATG\_VDRE\_CIS (nuclear receptor transcription activity) for hypertrophy. The results suggest the utility of HTS assays for screening hepatotoxicity, and for linking biological events in the pathways to specific adverse outcomes. Such assays are not only mechanistically relevant but also aid in defining cell-based toxicity signatures for rapidly screening thousands of environmental chemicals. Abstract does not represent EPA policy.

**PS 140 Interpreting QSAR Toxicity Predictions in Hazard Assessments: An Acrylamide Case Study.**

R. S. DeWoskin, L. D. Burgoon and G. M. Woodall. US EPA, Research Triangle Park, NC.

Toxicity predictions based on QSAR are used to screen large numbers of chemicals with little to no toxicity data into prioritized categories for further toxicity testing, development as "green" chemicals, or candidates for efficacious drug therapy. As databases incorporate more information on adverse pathways and potential targets, QSAR results may also contribute to hazard assessment for chemicals considered "data rich" (based on the availability of a full suite of traditional animal bioassays), but which are often "data poor" when it comes to characterizing the mode of action (MOA), severity progression, or potential adverse human clinical effects not monitored in animal bioassays. Presented here is an exercise to evaluate QSAR results within the context of extant hazard assessments on a data rich chemical, in this case, acrylamide (AA), and its less well studied active metabolite, glycidamide (GA). Results from four QSAR programs – two freeware programs (VEGA and OECD's QSAR) and two proprietary programs (MetaCore™ and Discovery Studio/TopKat™) provided considerable new information in the areas mentioned above. Potential AA and GA induced adverse effects of clinical relevance to humans were identified as well as likely biological targets for AA, GA, and analogous chemicals. The results further supported the qualitative characterization of the MOAs, potential endpoints to consider in dose-response arrays, and identification of potentially important early biomarkers to aid future bioassay or human study design. Conversely, extant AA and GA ADME data and PBPK models helped assess the likelihood of AA or GA reaching biological targets predicted by the QSAR programs. This exercise demonstrated the value of integrating QSAR results into traditional hazard assessment for improved qualitative information. The next step is to integrate high throughput screening /content (HTS/HTC) assay results into the assessment to further quantitate dose-response for a wider array of effects. [The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA]

**PS 141 Health-Related Effects Reported by Electronic Cigarette Users in Online Forums.**

M. Hua, M. Alfi and P. Talbot. Cell Biology and Neuroscience, University of California, Riverside, Riverside, CA.

Electronic cigarettes (e-cigarettes) are battery-operated devices that deliver aerosolized nicotine to users without burning tobacco. Because little data exists on their health effects, we explored the symptoms that e-cigarette use has on humans

by analyzing online user posts from three e-cigarette forums with "health and safety" sections. Basic information (location, age, and gender) and health (symptoms and doctor diagnosed signs) information were collected. A total of 405 symptoms (78 positive, 326 negative and 1 neutral) were reported in three forums. Most data analysis was performed on Electronic Cigarette Forum (ECF) posts. A total of 12 systems/anatomical regions were affected in e-cigarette users. Systems most often affected include: mouth and throat, respiratory, neurological, sensory, and digestive. The majority of negative health effects occurred in the respiratory system. We further consolidated reported symptoms into categories to determine which anatomical regions/physiological processes were most affected for each system. For consolidated data, symptoms were most frequently reported for: bronchi/lungs (e.g., wheezing, shortness of breath, difficulty breathing), throat; neurological (headaches), intestine/digestion, and sight. To analyze interactions between systems, interactomes were created with Cytoscape software. Interactions were most frequently seen between circulatory/neurological; respiratory/mouth and throat; respiratory/chest, and digestive/neurological systems. Increased blood pressure was the most frequently reported sign diagnosed by physicians treating e-cigarette users. While some positive health effects were reported, a significant proportion of the data showed a correlation with e-cigarette use and onset of adverse health effects. This study is the first to compile and quantitatively assess health data associated with e-cigarette use from online forums.

**PS 142 The Relationship Between T-Box Transcription Factors CAMK2B and PITX2 in the Expression of Collagen Protein COL4A3 in COPD.**

B. Nguyen, G. Acquah-Mensah and C. Ngo. Pharmaceutical Sciences, MCPHS, Worcester, MA.

The T-Box transcription factors are known have recently been highlighted for their expression role in epithelial cells in Chronic Obstructive Pulmonary Disease (COPD), which genes, including COL4A3, TBX2, TBX3, TBX5, PML, CFLAR, GULP1, CASP10, PAX3, BOK, and PITX2 are connected in transcriptional regulatory networks of lung epithelial cells. The type IV, alpha 3, collagen gene (COL4A3) involves into extracellular matrix construction as the major structural component of basement membrane. COL4A3 is known to have suppressed expression in COPD3. The A polymorphism of the COL4A3 is also indicated of associated with the risk of developing COPD. COL4A3's C terminus binds to autoantibodies at basement membranes in Goodpasture syndrome and is phosphorylated by calcium/calmodulin-dependent protein kinase II beta (CAMK2B), which is activated by the promyelocytic leukemia protein (PML). The paired-like homeodomain 2 (PITX2) regulates the expression of N-cadherin. N-cadherin changes the adhesion of extracellular matrix (ECM) by interacting with collagen proteins. PITX2 gene is regulated by different kinase pathways, such as MAPK and Akt. However, the relationship between these factors is still not well studied. Thus, we have come up with the question that if is PITX2 gene also regulated by CAMK2B. We conducted the study in focus on exploring the relationship between PITX2 and CAMK2B genes by applying Bayesian Network Structural Learning (BNSL). Version 2.2 of Bayesian Network Inference with Java Objects (Banjo) was employed in the study. The result was used to compare to the known interactions between COL4A3, CAMK2B, PITX2 and PML. The study has shown the possible novel phosphorylation of PITX2 by CAMK2B.

**PS 143 Validation of a Systems Toxicology Based Adverse Outcome Pathway Prediction with Functional Outcome: Effect of Exposure to 2, 4-Dinitrotoluene on Energy Metabolism and Exercise Endurance.**

M. S. Wilbanks<sup>1</sup>, K. Gust<sup>1</sup>, S. Atwa<sup>2</sup>, I. Sunesara<sup>3</sup>, S. A. Meyer<sup>2</sup> and E. J. Perkins<sup>1</sup>. <sup>1</sup>Engineer R & D Center, US Army Corps of Engineers, Vicksburg, MS; <sup>2</sup>Department of Toxicology, University of LA-Monroe, Monroe, LA; <sup>3</sup>Center of Biostatistics and Bioinformatics, University of MS Medical Center, Jackson, MS.

2,4-dinitrotoluene (2,4DNT), commonly used in industrial and explosive manufacturing processes, is known to contaminate artillery ranges, demilitarization areas and munitions manufacturing facilities leading to its listing on US EPA's Contaminant Candidate List. Previous transcriptomic and lipidomic studies identified energy metabolism as a potential target of DNT toxicity. The impact of such perturbations of energy metabolism on exercise endurance is largely unknown. We hypothesized that organism-level impacts of 2,4DNT dosing were the result of energy metabolism deficits, especially lipid metabolism, from involving interference with PPAR $\alpha$  signaling and its downstream pathways. To validate this adverse outcome pathway, we linked molecular changes caused by 2,4DNT exposure to effects

on whole animals. PPAR $\alpha$  (-/-) and wild-type (WT) mice exposed to a sublethal 2,4DNT dose (134 mg/kg/day for 14 days) or vehicle were given an exercise challenge (a forced swim) 1 day after the last dose to determine how 2,4DNT and/or PPAR $\alpha$  impairment affected overall performance. Observations were collected at multiple levels of biological organization including genes involved in fatty acid and glucose metabolism, PPAR activation and response, biochemistry (serum triglycerides and glucose), and swimming endurance. Decreased swim times were observed with DNT in WT and PPAR $\alpha$  (-/-) mice, but DNT effect was significantly less in knock-down mice indicating that knock down of PPAR $\alpha$  expression partially rescued mice from DNT-induced energy metabolism deficits. Our results support the proposed hypothesis by demonstrating that 2,4DNT's impact on energy metabolism, especially lipid metabolism, occurs via perturbation of PPAR $\alpha$  signaling resulting in reduced exercise endurance at the individual level. (Support: US Army Corps of Engineers)

## PS 144 Modelability of ToxCast Phase I Datasets.

A. Golbraikh<sup>1,2</sup>, A. Sedykh<sup>1</sup>, E. Muratov<sup>1</sup>, R. Shah<sup>2,3</sup>, W. A. Boyd<sup>4</sup>, M. Smith<sup>4</sup>, G. Zhao<sup>5</sup>, H. Zhu<sup>6</sup>, J. H. Freedman<sup>4</sup> and A. Tropsha<sup>1,2</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Sciome LLC, Research Triangle Park, NC; <sup>3</sup>SRA International, Durham, NC; <sup>4</sup>NIEHS, Research Triangle Park, NC; <sup>5</sup>AstraZeneca, Shanghai, China; <sup>6</sup>Rutgers University, Camden, NJ.

One of the problems in Quantitative Structure-Activity Relationships (QSAR) analysis is to establish, whether it is possible to build a predictive model for a given dataset. For some datasets, all attempts to build a predictive model using different sets of descriptors and QSAR/QSTR methodologies fail raising a question, whether it is possible to evaluate the dataset modelability prior to modeling. We have devised several modelability criteria such as dataset diversity, new activity cliff indices, correct classification rate (CCR) for similarity search models (ssCCR), CCR=0.5\*(sensitivity+specificity), etc. These criteria were applied to 40 binary datasets, for which QSAR models were built using Dragon 5.5 descriptors and/or ToxCast in vitro assays treated as biological descriptors, and kNN, Random Forest and SVM methods. The best modelability criterion was found to be the ssCCR, which had the correlation coefficient of 0.73 with the QSAR/QSTR model CCR. We consider a model predictive, if its CCR as well as both sensitivity and specificity are at least 0.70. We found that to satisfy this condition, ssCCR should be at least 0.68. ssCCR values were obtained for ToxCast datasets with 24 ToxRefDB in vivo assays as end points, which had at least 30 toxic compounds among 212 compounds of the curated ToxCast dataset. None of the ssCCR for these datasets was as high as 0.60 except for the rat cholinesterase inhibition assay, for which it was 0.85, and sensitivity and specificity were 0.83 and 0.88, respectively. We conclude that with the latter exception, ToxCast Phase I datasets with ToxRefDB in vivo assays as end points do not appear to be modelable using QSAR approaches. This conclusion agrees with the recent empirical observations of Thomas et al (Toxicol Sci. 2012, 128:398-417).

## PS 145 Celastrol Decreases Specificity Proteins (Sp) and Fibroblast Growth Factor Receptor-3 (FGFR3) in Bladder Cancer Cells.

G. Chadalapaka<sup>1</sup>, I. D. Jutooru<sup>1</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>Department of Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX; <sup>2</sup>CEGM, Institute of Biosciences & Technology, Houston, TX.

Bladder cancer is the ninth most common cancer worldwide and ranks 13th as a cause of cancer deaths. MVAC (methotrexate, vinblastine, adriamycin and cisplatin) chemotherapy has been extensively used for treatment of advanced bladder cancer and is accompanied by toxic side effects and, thus, it is important to develop less toxic alternate chemotherapeutic therapies and dietary management strategies for prevention of this disease. Celastrol (CSL) is a naturally occurring triterpenoid acid that exhibits anticancer activity, and in KU7 and 253JB-V bladder cells, 0.5 to 2.5  $\mu$ M CSL induced apoptosis, inhibited growth, colony formation and migration and CSL decreased bladder tumor growth in vivo. CSL also decreased expression of specificity protein (Sp) transcription factors Sp1, Sp3 and Sp4 and several Sp-regulated genes/proteins including vascular endothelial growth factor, survivin and cyclin D1. CSL also decreased fibroblast growth factor receptor-3 (FGFR3), a potential drug target for bladder cancer therapy. Results of RNA interference and knockdown of Sp proteins show that FGFR3 is a Sp-regulated gene downregulated by CSL. The mechanism of Sp downregulation by CSL was cell context-dependent due to activation of proteasome-dependent (KU7) and -independent (253JB-V) pathways. In 253JB-V cells, CSL induced reactive oxygen species (ROS) and inhibitors of ROS such as glutathione blocked CSL-induced growth inhibition and

repression of Sp1, Sp3 and Sp4. This response was due to induction of the Sp repressors ZBTB10 and ZBTB4 and downregulation of miR-27a and miR-20a/17-5p, respectively, which regulate expression of these transcriptional repressors. Thus, the anticancer activity of CSL in 253JB-V cells is due to induction of ROS and ROS-mediated induction of Sp repressors (ZBTB4/ZBTB10) through downregulation of miR-27a and miR-20a/17-5p and this is emerging as a characteristic pathway observed for many ROS inducers in cancer cells.

## PS 146 Raloxifene Potentiates the Cytotoxicity-Induced by RL91, a Second Generation Curcumin Analog, in PC3 Prostate Cancer Cells.

A. Mazumder<sup>1</sup>, M. Gould<sup>2</sup>, S. Taurin<sup>1</sup>, H. D. Nicholson<sup>2</sup> and R. J. Rosengren<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, University of Otago, Dunedin, New Zealand; <sup>2</sup>Anatomy, University of Otago, Dunedin, New Zealand.

The survival rate for men with hormone refractory prostate cancer has not changed significantly in the last 30 years. Thus there is a need for new drug treatments for this aggressive cancer. Our lab has had success with second generation curcumin derivatives as novel therapies for aggressive breast cancer. In this study we examined the combination of raloxifene and 2,6-bis(pyridin-4-ylmethylene)-cyclohexanone (RL91), a potent 2nd generation curcumin derivative as a novel treatment for hormone refractory prostate cancer (HRPC). The combination treatment showed highly potent cytotoxicity toward PC3 prostate cancer cells compared to individual treatments. Specifically, EC50 values of 2  $\mu$ M and 10  $\mu$ M were produced by RL91 and raloxifene, respectively. Moreover, this combination decreased cell number by 85% compared to control after 96 h of treatment, as determined by the sulforhodamine B assay. Raloxifene is known to modulate the activity of estrogen receptor alpha (ER $\alpha$ ) and beta (ER $\beta$ ). The activation of these receptors as well as the epidermal growth factor receptor (EGFR), is crucial for the proliferation of HRPC. To determine how raloxifene potentiates the cytotoxic effect of RL91, the localization of these receptors was examined by fluorescent microscopy. The results showed that ER $\alpha$ , ER $\beta$ , the androgen receptor (AR) and EGFR were expressed in PC3 cells. However, raloxifene treatment (10  $\mu$ M for 48 h) promoted EGFR internalization in the cytoplasm. A similar effect was also seen for ER $\beta$  where raloxifene promoted a translocation from the nucleus to the cytoplasm. However, no change was observed for either ER $\alpha$  or the AR. These results suggest that raloxifene-mediated changes in the localization of ER $\beta$  and the EGFR provide a mechanism by which raloxifene enhances the cytotoxicity of RL91 toward PC3 cells. This novel mechanism should be explored further in order to develop new therapies for HRPC.

## PS 147 Evaluation of Wild Yam (*Dioscorea Villosa*) Root Extract As a Potential Epigenetic Agent in Breast Cancer Cells.

P. Aumsuwan<sup>1,2</sup>, S. I. Khan<sup>1,3</sup>, I. A. Khan<sup>1,3</sup>, L. A. Walker<sup>1,2</sup> and A. K. Dasmahapatra<sup>1,2</sup>. <sup>1</sup>National Center for Natural Product Research, University of Mississippi, University, MS; <sup>2</sup>Department of Pharmacology, University of Mississippi, University, MS; <sup>3</sup>Department of Pharmacognosy, University of Mississippi, University, MS.

Aberrant epigenetic alterations in the genome, is believed to be a potential cause of some forms of cancer. Due to their reversibility, epigenetic modifications are considered potentially useful in drug development approaches (epi-drugs). The current available synthetic epi-drugs are non-specific and induce adverse effects. Natural products might offer advantages and find utility for cancer treatment. The present study was designed to evaluate the efficacy of wild yam root extract as a potential demethylating agent using two breast cancer cell lines, MCF-7 (Estrogen receptor positive, ER+) and MDA-MB-231 (ER negative, ER-), and a gene, *GATA-3*, a potential marker of breast cancer development. Moreover, *GATA-3* expression is methylation-specific, being higher in ER+ cells with promoter hypomethylation and insignificant in ER- with promoter hypermethylation. In this study, cells, approximately at 70 % confluency, were treated with wild yam root extract (0-50  $\mu$ g/ml) for 72h and then used for viability, mRNA, and methylation analyses. It was observed that wild yam significantly reduced viability of both cell lines and enhanced the mRNA contents of DNMTs (*DNMT1*, *3A*, and *3B*) and *GATA-3* in a dose-dependent manner. Global DNA methylation, analyzed as 5'-methyl-2'-deoxycytidine (mC) and 5-hydroxymethylcytosine (hmC), showed that mC was increased only in MCF-7 cells, whereas hmC level was reduced in both cell lines. Since hmC is generated from mC by ten-eleven-translocation (TET) enzymes, the present data suggest that enhanced expression of *GATA-3* and *DNMT* enzyme mRNAs followed by a reduction in hmC in MCF-7 and MDA-MB-231 cells are the result of interruption of TET enzyme functions in the epigenome by wild yam root extract. This plant with a long history of traditional use should be further explored with regard to its potential as an epigenetic agent in breast cancer therapy.

**PS 148 Mucosa-Associated Enteropathogenic Escherichia coli As an Internal Exposome Triggers Tumor Cell Dissemination via Macrophage Inhibitory Cytokine 1.**

H. Choi, J. Kim, S. Park, K. Do, C. Oh and Y. Moon. *Laboratory of Mucosal Exposome and Biomodulation, Department Microbiology and Immunology, Pusan National University School of Medicine and Medical Research Institute, Yangsan, Republic of Korea.*

Commensal bacterial community shifts in the pathogenic colonic environment and chronic colonization of mucosa-associated Escherichia coli (MAEC) has been linked to colonic tumorigenesis. Enteropathogenic Escherichia coli (EPEC) is one of commonly identified MAEC in colorectal cancer patients. The aim of this study is to address the contribution of MAEC colonization to human carcinogenesis. EPEC infection of cancer cell caused alterations in affect locomotion-related behaviors of cancer cell including detachment, migration, cytoskeleton rearrangement, dissemination and survival via induction of macrophage inhibitory cytokine 1 (MIC-1). Mechanistically, MIC-1 induced RhoA GTPase which mediated survival of the detached cancer cells. In terms of signaling pathway, MIC-1 triggered TGF-beta-activated kinase 1 (TAK-1), which enhanced expression of RhoA GTPase. In conclusion, mucosal EPEC enhanced MIC-1 gene expression in the human intestinal cancer cells, which was associated with enhanced tumor cell resistance to anoikis and subsequent survival via enhanced TAK-1 and RhoA GTPase (This work was supported by the Basic Science Research Program through the National Research Foundation of Korea, funded by Ministry of Education, Science, and Technology Grant 2012R1A1A2005837).

**PS 149 Ring-Substituted Analogs of 3, 3'-Diindolylmethane (DLM) Induce Apoptosis and Necrosis in Androgen-Dependent and -Independent Prostate Cancer Cells.**

A. Goldberg<sup>1</sup>, V. I. Titorenko<sup>2</sup>, A. Beach<sup>2</sup>, S. H. Safe<sup>3,4</sup> and T. Sanderson<sup>1</sup>. <sup>1</sup>Toxicology, INRS, Laval, QC, Canada; <sup>2</sup>Biology, Concordia University, Montréal, QC, Canada; <sup>3</sup>Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX; <sup>4</sup>Institute for Bioscience and Technology, Houston, TX.

We have recently reported that novel ring-substituted analogs of 3,3'-diindolylmethane (ring-DIMs), exhibit anti-androgenic and anti-proliferative activities in androgen-dependent prostate cancer cells. We hypothesized that the anti-proliferative effects of ring-DIMs may be due to their ability to induce cell death. Ring-DIMs inhibited androgen-stimulated LNCaP cell proliferation and induced apoptosis and necrosis in LNCaP and PC-3 prostate cancer cells with 2-4 fold greater potencies than DIM. DIM and the ring-DIMs increased caspases-3, -8 and -9 activity and induced PARP cleavage in both cell lines. The cytotoxicity of the most potent ring-DIM, 4,4'-dibromoDIM, but not the other ring-DIMs, was decreased by caspase-3 inhibition. The 4,4'-dibromoDIM was primarily found in the extracellular media, whereas the ring-DIMs were located intracellularly in both cell lines. Ring-DIMs were more potent inhibitors of cell growth and survival in LNCaP and PC-3 cells than DIM and the differential structure-dependent cell death mechanisms indicates ring-DIMs have clinical potential as chemopreventive and chemotherapeutic agents in prostate cancer, regardless of hormone-dependency.

**PS 150 Ellagitannins and Anthocyanins Constituents of Pomegranate Suppress Colorectal Aberrant Crypt Foci (ACF) and Inflammation: Possible Role of miR126.**

N. Banerjee<sup>1,2</sup>, H. Kim<sup>2</sup> and S. U. Mertens-Talcott<sup>1,2,3</sup>. <sup>1</sup>Toxicology, Texas A&M University, College Station, TX; <sup>2</sup>Nutrition and Food Science, Texas A&M University, College Station, TX; <sup>3</sup>Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.

The antitumorigenic efficacy of polyphenols ellagitannins and anthocyanins extracted from pomegranate (*Punica granatum* L.) has been extensively studied where cytotoxic, anti-inflammatory and antioxidant effects were demonstrated in various cancer models. The objective of this study was to investigate the role of post-transcriptional regulation of apoptotic and inflammatory biomarkers by specific microRNAs in cells treated with pomegranate polyphenols (PP).

mRNA, microRNA expression were measured by RT-PCR, protein by western blotting and multiplex bead assay. In vivo studies were performed with Sprague Dawley rats (10rats/group) that received PP (2504.74mg/L GAE) for 10 weeks and were injected with azoxymethane (AOM) subcutaneously (15 mg/kg) at weeks 3 and 4.

PP juice suppressed the number of high multiplicity aberrant crypts foci (HMAF) >4 ACF) by 42% (P<0.05) and lowered Ki67 (proliferation marker) antigen. Correspondingly, cell proliferation was also inhibited by PP (5 -25 µg/mL) in colon

cancer cells HT-29. In vitro and in vivo results were accompanied by a downregulation of expression including NF-κB, inducible nitric oxide synthase (iNOS), cyclooxygenase-2 (COX-2), vascular adhesion molecule-1 (VCAM-1) and insulin growth factor (IGF). PP also inhibited phosphorylation of PI3K/Akt, and mTOR signaling pathways. miRNA 126 is frequently lost in colon cancer and targets VCAM-1 and PI3K that are involved in inflammation and cell survival. PP increased miR126 expression in both in vitro and in vivo, corresponding to the observed decrease in VCAM-1 and PI3K. In vitro, the involvement of miR-126 was confirmed using the antagomir for miR-126, where PP reversed the effects of the antagomir.

In summary PP inhibited HT29 cell proliferation, suppressed number of HMAF formation and colon tumorigenesis through the involvement of microRNA 126-regulated pathways.

**PS 151 Dichloroacetate (DCA) Increases Radiation Sensitivity of A549 and H1299 Lung Cancer Cells.**

J. B. Watkins<sup>1</sup>, K. T. Allen<sup>1</sup>, H. Chin-Sinex<sup>2</sup>, J. D. Sherer<sup>2</sup>, J. M. Jesseph<sup>1</sup>, J. G. Foley<sup>1</sup> and M. S. Mendoca<sup>2</sup>. <sup>1</sup>Medical Sciences Program, Indiana University School of Medicine, Bloomington, IN; <sup>2</sup>Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN.

Dichloroacetate (DCA) is a synthetic small molecule inhibitor of pyruvate dehydrogenase kinase used to treat metabolic diseases with low toxicity in human patients for decades. Recent reports suggest that DCA is cytotoxic to several cancer cell types including non-small-cell lung cancers (NSCLC). The cytotoxicity to cancer cells appears to be a result of a reversal of the Warburg effect through partial restoration of mitochondrial glucose oxidation away from cytoplasmic aerobic glycolysis. With the increase in glucose oxidation, ROS production is augmented leading to the opening of the mitochondrial transition pore to release cytochrome c and apoptosis inducing-factor (AIF) into the cytoplasm. The consequence is mitochondria membrane depolarization and induction of cell death in a caspase-dependent or -independent manner. Given the potential therapeutic translation of DCA to human cancer treatment, we investigated the efficacy of DCA to sensitize NSCLC to X-ray induced killing *in vitro* after both single and fractionated X-ray exposure. Treatment with DCA decreased plating efficiency (PE) and enhanced radiation-induced cell killing by dose modification factors of 1.5 in A549 and 1.4 in H1299. The decrease in PE was not due to induction of apoptosis or necrosis. X-ray fractionation showed that DCA inhibited split-dose recovery/repair by 3.5 fold in A549 and 1.5 fold in H1299. Flow cytometry analysis with propidium iodide indicated significant cell cycle arrest at G1/S in A549 and at G2/M in H1299. The data suggest that DCA enhances X-ray-induced NSCLC cell killing through inhibition of DSB repair and/or alteration of cell cycle distribution.

**PS 152 Mango Polyphenolics Reduce Inflammation in Intestinal Colitis—Potential Involvement of the miR-126/PI3K/AKT/mTOR Pathway *In Vitro* and *In Vivo*.**

H. Kim<sup>1</sup>, N. Banerjee<sup>1,2</sup>, S. Talcott<sup>1</sup> and S. U. Mertens-Talcott<sup>1,2</sup>. <sup>1</sup>Department of Nutrition and Food Science, Texas A&M University, College Station, TX; <sup>2</sup>Interdisciplinary Program of Toxicology, Texas A&M University, College Station, TX.

Mango polyphenolics including gallic acid, mangiferin and gallotannins, have shown antioxidant, anti-inflammatory and anticarcinogenic properties in several studies. However, anti-inflammatory mechanisms relevant to the prevention of colon cancer have not been well investigated.

This study investigates the potential role of the miRNA-126/PI3K/AKT/mTOR signaling pathway in the anti-inflammatory effects of mango polyphenolics in human CCD-18Co colon-myofibroblastic cells and on DSS-induced colitis in rats. Animals were administered control juice (15.7g sugar and 0.05g citric acid/100ml) or mango juice (total phenolic content of 475.80mg/L GAE), and exposed three cycles of 3% DSS. The mRNA and protein levels were measured by RT-PCR, western blot analysis and multiplex bead assay.

In vitro mango extract and gallic acid suppressed the expressions of inflammatory mediators such as NF-κB (p65) and IL-1β and reduced the expressions of AKT and HIF1α involved in AKT/mTOR pathway at mRNA and protein level in a dose dependent manner. Correspondingly, miRNA-126, which negatively regulates the Akt/mTOR pathway, was induced by mango extract and gallic acid. In the rat colitis model, mango juice intake suppressed cell proliferation as measured by Ki-67 staining, and resulted in protection against DSS-induced colon inflammation during chronic colitis compared to control juice. The juice significantly attenuated the expressions of pro-inflammatory cytokines such as TNF-α, IL-1β, IL-6, and IL-10 at protein and mRNA level. Moreover, the phosphorylation of AKT and mTOR were suppressed, and the expression of PI3K was reduced while miRNA-126 that has a target site in the mRNA of PI3K was upregulated by the juice.

These results suggest that mango polyphenols attenuated inflammatory response by modulating the miR-126/PI3K/AKT/mTOR pathway both in vitro and in vivo, and is a potential therapeutic for colitis and colon cancer.

## **PS 153** Loss of the Tumor Suppressor Protein PTEN Contributes to Increased Nrf2 Signaling.

P. M. Shelton<sup>1</sup>, M. I. Vitolo<sup>2</sup>, S. S. Martin<sup>2</sup> and A. K. Jaiswal<sup>1</sup>. <sup>1</sup>Pharmacology, University of Maryland, Baltimore, Baltimore, MD; <sup>2</sup>Marlene and Stewart Greenebaum Cancer Center, University of Maryland, Baltimore, Baltimore, MD.

Nrf2 is a master regulator of cyto-protective genes involved in the maintenance of cellular redox balance. In recent studies, the PI3K/Akt pathway is reported to positively regulate the Nrf2 pathway. The protein phosphatase PTEN counteracts the action of PI3K by removing the phosphate from PIP3. This led us to hypothesize that loss or mutation of PTEN, an event that occurs frequently in cancers, might increase Nrf2 activity that promotes the survival and proliferation of cancer cells. In our study we investigated the role of PTEN in prostate and breast cancer, commonly reported to have either loss of heterozygosity or mutations in PTEN. Using the PTEN-null human prostate cancer cell line PC3, we found that expression of wild-type but not mutant PTEN decreased the basal and anti-oxidant induced expression of Nrf2 target genes. More common clinically, patients have loss of a single allele of PTEN. Therefore, we also investigated the Nrf2 pathway in cells heterozygosity for the PTEN gene. Using a murine prostate tumor cell line with a spontaneous loss of a single allele in PTEN (PTEN-P8, +/-) and an isogenic cell line that had deletion of the second allele (PTEN-CaP8, -/-) we found that complete loss of PTEN resulted in higher expression of the Nrf2 target genes. In order to fully address the role of PTEN haploinsufficiency that could mimic the cellular progression from benign to malignant we also looked at Nrf2 activity in the immortalized breast epithelial cell line MCF-10a that had both alleles intact (+/+), deletion of a single allele (+/-), or deletion of both alleles (-/-) of PTEN. As expected, we found that both the basal and inducible expression of the prototypical Nrf2 target gene NQO1 inversely correlated with PTEN status. Together this suggests that the loss of PTEN contributes to increased Nrf2 transcriptional activity, which likely provides cells with an altered proteome that favors oncogenesis.

## **PS 154** Formaldehyde-Induced Replication Stress Causes Activation of ATR Kinase Leading to p53-Mediated Apoptosis and Senescence in Human Lung Cells.

J. Morse, V. Wong and A. Zhitikovich. Brown University, Providence, RI.

Formaldehyde (FA) is a recognized human carcinogen with documented inhalation exposures in many occupational groups. Here we examined stress signaling pathways and cell fate decisions triggered by FA in human lung cells (normal lung fibroblasts, H460 lung epithelial cells and primary bronchial epithelial cells). We found that FA induced a rapid activation of the DNA damage-responsive ATR kinase that preferentially targeted the p53 transcription factor at low and moderate damage levels. Activation of p53 was evidenced by its strong Ser-15 phosphorylation, protein stabilization and upregulation of its target genes, such as MDM2 and CDKN1A (p21). Knockdown experiments with shRNA confirmed the p53 dependence of the gene expression responses. FA also caused a depletion of the p53 inhibitor MDM4 via its enhanced proteolysis. The use of biochemical markers of individual cell cycle phases and replication status manipulations showed that activation of ATR-p53 signaling by FA occurred exclusively in the S phase. The p53 played a major role in FA-induced apoptosis in lung epithelial cells, which was associated with upregulation of the proapoptotic gene BBC3 (PUMA). The presence of p53 was also required for permanent growth arrest (senescence) in FA-treated lung fibroblasts. Overall, our results indicate that replication stress and ATR-activated p53 are responsible for cytotoxic responses in FA-exposed human lung cells. Acknowledgements. This work was supported by grant ES020689 from NIEHS.

## **PS 155** Down-Regulation of Telomerase Activity and Shortening of Telomere Length by Polychlorinated Biphenyls (PCBs) in HL-60 Cells.

X. Xin<sup>1</sup>, S. Pl<sup>1</sup>, J. L. Schnoor<sup>1,2</sup> and G. Ludewig<sup>1</sup>. <sup>1</sup>Interdisciplinary Graduate Program in Human Toxicology, The University of Iowa, Iowa City, IA; <sup>2</sup>Department of Civil and Environmental Engineering, The University of Iowa, Iowa City, IA.

We reported that PCBs, environmental persistent organic pollutants and probable human carcinogens, can down-regulate telomerase activity in vitro in immortal human keratinocytes (HaCaT). The most efficacious congener was the dioxin-like

PCB126, a potent arylhydrocarbon receptor (AhR) agonist. To analyze whether this effect of PCB126 is tissue specific and to gain insight into the mode of action (MOA) we exposed another cell type, human promyelocytic leukemia (HL-60) cells, to PCB126 and also to PCB153, not an AhR activating congener. Both compounds reduced telomerase activity, visible after 6 days of exposure, and telomere length, to about 50% within 30 days of exposure, PCB126 more so than PCB153. This reduction in telomerase activity and telomere length was seen in both cell lines, but only HaCaT also showed a strong increase in cytochrome P450 1A1 mRNA and activity, the hallmark of AhR activation. This suggests that AhR activation may be one, but not the only mechanism for this effect of PCBs. HL-60 can differentiate which is accompanied by a reduction in telomerase activity. However, the continuous proliferation of the PCB-exposed cells makes this mechanism less likely. Telomeric repeat binding factors (TRF1, TRF2) are involved in the stabilization of telomeres. Up-regulation of TRF1/2 was seen in PCB126-exposed HaCaT, pointing to a possible mechanism. Experiments with both cell lines, representing different target tissues of PCB toxicity, are under way to elucidate the MOA of PCBs on telomeres and the possible significance of this effect on precursor cells of the hematopoietic pathway. (Supported by NIEHS P42 ES013661)

## **PS 156** Chronic Exposure to Particulate Hexavalent Chromium Disrupts Shugoshin1 Localization in Human Lung Cells.

C. Falank<sup>1</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME.

Chromosomal instability (CIN) is a hallmark of cancer and can be caused by spindle assembly checkpoint disruption or chromosome missegregation during mitosis. Hexavalent chromium (Cr(VI)) is a well-known human lung carcinogen, and has shown to induce numerical CIN, however its mechanisms for inducing aneuploidy remain unknown. In this study we are investigating whether Cr(VI) affects a key centromeric cohesion protein, Shugoshin 1 (Sgo1). Sgo1 maintains and protects centromeric cohesion in G2 and continues to maintain proper sister-chromatid cohesion during mitosis. This protection mechanism prevents sister-chromatids from prematurely separating during mitosis. Disruption of Sgo1 localization has been shown to lead to chromosome missegregation. We have found that chronic exposure to particulate Cr(VI) disrupts the localization of Sgo1 in G2 cells. Specifically, after a 24 h exposure to 0.1, 0.2, or 0.3 µg/cm<sup>2</sup> lead chromate we did not observe any changes in the percent of G2 cells with Sgo1 localization at the kinetochores. However, a 120 h exposure to the same concentrations showed a concentration-dependent decrease in the percent of G2 cells with Sgo1 localization at the kinetochores. Specifically 0.1, 0.2 or 0.3 µg/cm<sup>2</sup> disrupted localization in 36, 88, and 90% of G2 cells, respectively. Our findings suggest that particulate Cr(VI)-induced CIN is mediated through disrupting Sgo1 localization to the kinetochores during G2 cells, thus leading to chromosome missegregation and ultimately aneuploidy. This work was supported by NIEHS grant ES016893 (J.P.W.).

## **PS 157** Ultraviolet B-Irradiated L-Tryptophan Induces Human UDP-Glucuronosyltransferase 1A1 and 1A8 Expressed in the Human Skin.

R. Fujiwara, M. Kawana, E. Kouno, S. Takano, T. Narawa and T. Itoh. School of Pharmacy, Kitasato University, Tokyo, Japan.

Benzo[a]pyrene is a widespread environmental contaminant and its active metabolite, benzo[a]pyrene-7,8-dihydrodiol-9,10-epoxide, is associated with the development of ultraviolet (UV) B-induced skin cancer. While UDP-glucuronosyltransferase (UGT) is involved in the detoxification of benzo[a]pyrene, the protective role of UGT in the defensive mechanism against UVB-induced skin cancer has not been elucidated yet. Here, we investigated the effects of UVB irradiation on the expression of human UGT1A enzymes as well as on cytochrome P450 (CYP) 1A1 in HaCaT cells. Multiple UGT1A isoforms such as UGT1A1, UGT1A3, UGT1A4, and UGT1A8 were expressed in human skin and HaCaT cells. When HaCaT cells were treated with 6-formylindolo[3,2-b]carbazole (FICZ), which is one of the tryptophan derivatives formed by UVB, UGT1A1 and UGT1A8 along with CYP1A1 were significantly induced. While UVB-irradiated tryptophan also induced those enzymes, the formation of FICZ was not detected in the irradiated tryptophan solution, indicating that tryptophan derivatives other than FICZ formed by UVB might have the potential to activate the aryl hydrocarbon receptor. While UVB induces CYP1A1, increasing the bioformation of benzo[a]pyrene-7,8-dihydrodiol-9,10-epoxide from benzo[a]pyrene, it also induces UGTs, accelerating the detoxification of benzo[a]pyrene. Specific induction of skin UGT1A1 and UGT1A8 without inducing CYP1A1 might protect individuals from developing skin cancer.

**PS 158 The Cannabinoid WIN 55, 212-2 Decreases Specificity Protein (Sp) Transcription Factor and the CaP Protein eIF4E in Colon Cancer Cells.**

S. Sreevalsan<sup>1</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>VTPP, Texas A&M University, College Station, TX; <sup>2</sup>Institute of Biosciences and Technology, Texas A&M Health Science Center, Houston, TX.

The eukaryotic translational initiation factor (eIF4E) is an essential component of the cellular translational machinery and is responsible for binding ribosomes to the cap structure of mRNAs. The phosphorylated form (serine-209) of eIF4E plays a critical role in cancer cell growth and transformation. Treatment of colon cancer cells with a synthetic cannabinoid WIN 55,212-2 (WIN) inhibited cancer cell growth, induced apoptosis and downregulated specificity protein (Sp) transcription factors and Sp-regulated gene products associated with cancer cell growth (EGFR and Cyclin D1), angiogenesis (VEGF and VEGFR) and survival (survivin and bcl-2). The anticancer activity of WIN is accompanied by induction of multiple phosphatases and some of the effects of WIN are blocked by the phosphatase inhibitor sodium orthovanadate (SOV). Treatment of SW480 cells with 7.5  $\mu$ M WIN alone also decreased levels of eIF4E and co-treatment with 0.35 mM SOV blocked WIN-induced downregulation of eIF4E and knockdown of Sp proteins confirmed that eIF4E was an Sp-regulated gene. Protein phosphatase 2A (PP2A) catalyzes dephosphorylation of both eIF4E and Mnk-1, an upstream kinase that phosphorylates eIF4E. Treatment of SW480 cells with 7.5  $\mu$ M WIN and knockdown of PP2A by RNA interference blocked downregulation of eIF4E, Sp proteins and some Sp-dependent genes. Several anticancer agents inhibit Sp transcription factors by inducing zinc finger binding protein ZBTB10 and by suppressing microRNA-27a (miR27a). Treatment of SW480 cells with 7.5  $\mu$ M WIN induced ZBTB10 protein and decreased miR27a expression and knockdown of PP2A reversed these responses demonstrating that WIN-induced downregulation of Sp and eIF4E was due to PP2A-mediated disruption of miR27a:ZBTB10 axis.

**PS 159 HOTTIP, a lncRNA, Exhibits Pro-Oncogenic Activity in Pancreatic Cancer.**

I. D. Jutooru<sup>1</sup>, G. Chadalapaka<sup>1</sup>, K. Kim<sup>2</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>TAMU, College Station, TX; <sup>2</sup>IBT, Texas A&M Health Science Center, Houston, TX.

Recent studies have demonstrated that non-coding RNAs (ncRNAs) are differentially expressed and play an important role in gene regulation and influence normal and cancer cell phenotypes. About 3000 lncRNAs have been identified and some of these act as scaffolds regulating molecular (protein, RNA and DNA) interactions required for various signaling networks and this is accomplished, in part, by association with chromatin-modifying complexes. HOXA transcript at the distal tip (HOTTIP) is a 3,764-bp lncRNA transcribed from 5' tip of HOXA gene cluster and is expressed in anatomically distal cells such as hand and foot fibroblasts. Previous studies in our laboratory showed that HOTAIR is a negative prognostic marker in pancreatic cancer and this is due, in part, to interaction of HOTAIR with Polycomb Repressive Complex 2. In contrast, HOTTIP was reported to interact with MLL complexes by specifically binding to WDR5 adapter protein leading to broad loss of H3K4me3 across HOXA locus. In this study, we investigated the functional role of HOTTIP in Panc1 and L3.6pL pancreatic cancer cell lines. Knockdown of HOTTIP by RNA interference studies (iHOTTIP) resulted in ~50% reduction in cell survival within 72 hr after transfection and iHOTTIP also decreased pancreatic cancer cell migration which was determined in a Boyden chamber assay. iHOTTIP enhanced Annexin V staining and PARP cleavage associated with induction of apoptosis in both Panc1 and L3.6pL cells. Knockdown of HOTTIP also decreased expression of cyclin D1, VEGF and survivin which play an important role in cell proliferation, angiogenesis and survival. An in vivo study was performed using L3.6pL cells transfected with iHOTTIP in a mouse xenograft model and after 15 days of knockdown there was a significant reduction in tumor volumes and weights ( $\geq 70\%$ ). RNASeq analysis of HOTTIP knockdown in Panc1 cells resulted in significant (>1.5 fold) changes in expression of ~1467 genes and analysis of data suggest that HOTTIP mediated gene regulation has a critical role in pancreatic cancer progression.

**PS 160 Metformin Causes Degradation of Fatty Acid Synthase and PI3 Kinase Signaling Proteins in Pancreatic Cancer Cells through Downregulation of Specificity Protein (Sp) Transcription Factors.**

V. Vasanthakumari<sup>1</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>VTPP, Texas A&M University, College Station, TX; <sup>2</sup>IBT, TAMHSC, Houston, TX.

Metformin or N,N'-dimethyl biguanide is an oral hypoglycemic drug with a remarkable record of safety that has been prescribed worldwide for treatment of Type II diabetes. In addition to its antidiabetic property it also exhibits antineoplastic ef-

fects which include inhibition of angiogenesis through decreased levels of vascular endothelial growth factor (VEGF) and blocks cell cycle progression through decreased expression of cyclin D1. Fatty Acid Synthase (FAS) a key enzyme in lipid metabolism is overexpressed in cancer cells, which is one of the phenotypic alterations in cancer progression. Here we show that expression of FAS was significantly decreased when pancreatic cancer cells were treated with metformin. FAS expression is stimulated by growth factors and their receptors, like EGFR and IGFR. Effects of these receptors on FAS complex involve cross talk between various signal transduction pathways. One such signaling pathway include PI3kinase/ mTOR pathway. Specificity protein (Sp) transcription factors - Sp1, Sp3 and Sp4 play a complex role in malignant transformation of pancreatic cancer cells. We report for the first time that metformin downregulates specificity protein (Sp) transcription factors (Sp1, Sp3, Sp4) in cancer cells. Furthermore metformin downregulates the expression of growth factor receptors like EGFR, IGFR and phosphorylation/expression of major PI3K effectors like AKT and mTOR. Knockdown of Sp1, Sp3, and Sp4 proteins by RNA interference decreased the expression of FAS, pmTOR and pAKT indicating that FAS and these signaling proteins are regulated by Sp proteins. However when cells were pretreated with SOV (Sodium Ortho Vanadate), a phosphatase inhibitor, there was a reversal of Sp downregulation and phosphorylation of mTOR by metformin. The effects of metformin on downstream targets of PI3 kinase pathway and the specific phosphatases which play a major role in the antineoplastic effects of metformin are currently being investigated.

**PS 161 Overexpression of STAT-3 Induces Anoikis Resistance, Promotes Cell Migration, and Metastatic Potential in Cancer Cells.**

N. M. Fofaria and S. K. Srivastava. Biomedical Sciences and Cancer Biology Center, Texas Tech University Health Sciences Center, Amarillo, TX.

Anoikis is an anchorage independent cell death. Resistance to anoikis is one of the key features of the metastatic cells. In the current study, we have shown the role of STAT-3 in anoikis resistance in various melanoma and pancreatic cancer cells. Marked anoikis was induced as such in the cells that were grown in anchorage-independent conditions. The melanoma and pancreatic cancer cells that resisted anoikis were observed to have higher rate of migration as compared to the cells that were exposed to anchorage dependent growth, as observed in cell migration and invasion assays. These anoikis resistant cells also had significantly higher expression and phosphorylation of STAT-3 at Tyr 705, than the cells that were attached to the basement membrane. Treatment of these cells with IL-6, a cytokine which phosphorylates STAT-3, prevented the induction of anoikis. STAT-3 inhibitors AG490 and piplartine induced anoikis in a concentration-dependent manner, whereas IL-6 blocked anoikis. Over-expression of STAT-3 by transfection, not only increased the anoikis resistance but also protected cancer cells from piplartine-induced anoikis, confirming the role of STAT-3 in anoikis resistance. On the other hand, silencing STAT-3 decreased the potential of cancer cells to resist anoikis. Furthermore, STAT-3 (-/-) cancer cells were more sensitive to anoikis as well as to the effect of piplartine as compared to STAT-3 (+/+) cells. The STAT-3 (+/+) cells also had enhanced migration potential as compared to STAT-3 (-/-) cells. In summary, our results establish STAT-3 as a critical player that renders anoikis resistance to the cancer cells and enhance their metastasis potential. The role of STAT-3 in anoikis in breast and ovarian cancer is currently under investigation. The outcome of this study has great clinical implications as it will serve as a platform to devise rational therapeutic approaches to treat metastatic cancers. [Supported in part by R01 grants CA106953 and CA129038 (to S.K.S) awarded by the National Cancer Institute].

**PS 162 Indole and Related Compounds Exhibit AhR Antagonist/Agonist Activities.**

S. H. Safe<sup>1</sup>, A. Jayaraman<sup>2</sup>, R. Alaniz<sup>2</sup> and U. Jin<sup>2</sup>. <sup>1</sup>Texas A&M University, College Station, TX; <sup>2</sup>IBT, Texas A&M University System, Houston, TX.

Indole-derived compounds including diindolylmethane (DIM), indole-3-carbinol, tryptophan photoproducts and metabolites have been identified as agonists of the aryl hydrocarbon receptor (AHR). Indole and tryptophan metabolites tryptamine (TA) and indole 3-acetate (IAA) are produced by gut microflora and there is evidence that AHR ligands modulate gut inflammatory pathways. We therefore investigated the AHR agonist/antagonist activities of indole, TA and IAA using Ah-responsive breast and colon cancer cells as in vitro models. In MDA-MB-468 breast cancer cells TA (0-500  $\mu$ M) induced CYP1A1 mRNA and protein with an EC50 < 500  $\mu$ M; IAA and indole also induced CYP1A1 mRNA (only IAA induced CYP1A1 protein) however < 30 and < 10% of the maximal induction responses were observed at 1000  $\mu$ M concentrations of IAA and indole respectively. The effects of these compounds as inhibitors of 2,3,7,8-tetrachlorodibenzo-p-dioxin

(TCDD) induced responses were also investigated in cells treated with the indole compound alone or in combination with TCDD. Indole (500 and 1000  $\mu$ M) significantly inhibited TCDD-induced CYP1A1 mRNA and protein levels and similar results were observed for 500  $\mu$ M TA however the former compound was a significantly more potent AHR antagonist. In contrast IAA did not exhibit AHR antagonist activity. These results were somewhat variable among different cell lines however, it was evident that the major gut microbiome product, indole, was an AHR antagonist and this may impact AHR-dependent gut inflammatory pathways.

**PS 163 Tolfenamic Acid Inhibits Colon Cancer Cell and Tumor Growth and Downregulates Specificity Protein (Sp) Transcription Factors.**

S. Pathi<sup>1</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX; <sup>2</sup>Institute of Bioscience and Technology, Houston, TX.

**Introduction:** Tolfenamic acid (TA) is a nonsteroidal anti-inflammatory drug (NSAID) and is a potential chemotherapeutic agent for treatment of colon cancer; however, the mechanism of action of TA is unknown and was investigated in this study.

**Methods:** Inhibition of colon cancer cell growth and induction of apoptosis by TA was investigated using cell counting and Annexin V staining, and modulation of specificity protein (Sp) transcription factors Sp1, Sp3, Sp4 and Sp-regulated gene products was determined by western blot analysis of whole cell lysates. Mechanisms of TA-induced Sp downregulation were investigated using specific pathway inhibitors and the in vivo anticancer activity of TA was determined in athymic nude xenograft studies using RKO cells as xenografts.

**Results:** TA induced apoptosis and decreased colon cancer cell growth and this was accompanied by caspase-dependent proteolysis of Sp1, Sp3 and Sp4 and decreased expression of Sp-regulated gene products including bcl-2, survivin, VEGF, VEGFR1, cyclin D1 and c-MET. TA also inhibited colon tumor growth and decreased Sp1, Sp3, Sp4 and Sp-dependent gene product expression in tumors.

**Conclusion:** TA-induced repression of Sp transcription factors and Sp-regulated genes play a role in the cancer chemotherapeutic effects of TA. Since TA acts as anticancer agent in several tumor types, results of this study suggest for the first time that TA is a potential chemotherapeutic agent for treatment of colon cancer. Clinical applications of TA alone or in combined treatment of colon cancer are enhanced since this agent is relatively non-toxic and has previously been used as a non-steroidal anti-inflammatory drug. The prior use of TA, as an NSAID will also facilitate approval of the drug for application as a cancer therapeutic agent.

**PS 164 Ni<sup>2+</sup>-Induced Chromosome Aberrations/Gene Amplification/Gene Silencing Alter Cytoskeleton, Ca<sup>2+</sup> Distribution, and Global Gene Expression, Causing Morphol./Neoplast. Transformation of 10T1/2 Mouse Embryo Cells.**

J. R. Landolph<sup>1,3,2</sup>, A. DaSilva Pehl<sup>2,3</sup>, P. Samala<sup>1,3</sup>, S. Keliipaakaua<sup>2,3</sup> and K. Akinwumi<sup>1,3</sup>. <sup>1</sup>Department of Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA; <sup>2</sup>Department of Pathology, University of Southern California, Los Angeles, CA; <sup>3</sup>USC Cancer Center, University of Southern California, Los Angeles, CA.

Ni refinery workers inhaling Ni sulfidic ore dusts/smoking cigarettes contracted lung/nasal cancers. Inhaled Ni3S2/green NiO induced lung cancer in rats. Ni3S2/green-black NiOs induced chromosome aberrations/morph-neoplas transformation (Tx) in 10T1/2 mouse cells. Ni/MCA-Tx cell lines showed a) ect-2 gene amplification/higher ect-2 mRNA/protein, b) no DRIP80 c) no  $\beta$ -centaurin-2 mRNA. We hypothesized Ni+2 1) amplified ect-2 gene, causing higher levels of microtubules (MTs); 2) silenced  $\beta$ -centaurin-2 gene, causing higher levels of microfilaments (MFs); and 3) silenced DRIP gene, altering Ca+2 distribution/Tx 10T1/2 cells. We tested these hypotheses by staining cells with fluor. phalloidin to decorate MFs; fluor. Ab to  $\alpha$ -tubulin to decorate MTs; Fluor 3AM to stain Ca+2; DAPI to decorate nuclei; then examined cells by confocal microscopy. In non-Tx 10T1/2 cells, MFs/MTs were arranged in long fibers. In NiS/green NiO-Tx cell lines, MFs/MTs were over-expressed, aggregated in areas, absent/other areas, changing cell shapes. Low density non-Tx cells had high nuclear/low cytoplasmic Ca+2 concentrations (State I); high density near-confluent cells had low nucl./high cyto. Ca+2 (State II). Ni/MCA-Tx cell lines were largely in State II. We conclude Ni+2 ions 1) amplified ect-2/silenced  $\beta$ -centaurin-2 genes, causing over-expression of MTs/MFs, altering cell shapes, changing global gene expression; 2) silenced DRIP80 gene, altering Ca+2 distributions in Tx cells; and 3) induced mutations/methylations in 15 genes, causing differential expression of 130 genes, contributing to induction/maintenance of Tx phenotypes in Ni+2/MCA-Tx cell lines. Support: R01 ES03341/NIEHS (PI JRL); Cancer Center Core Grant 5 P30 CA09320/NCI; MS Program/Discret. Funding (JRL).

**PS 165 Benzoquinone-Induced Topoisomerase Modifications: Linking Benzene Myelotoxicity and Leukemia.**

C. L. Kuhlman, G. Tsapralis, T. J. Monks and S. S. Lau. *Southwest Environmental Health Sciences Center, Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Protein adduction by reactive electrophiles can induce structural and functional changes that contribute to toxicity and disease progression. Such electrophiles are often products of xenobiotic metabolism or generated endogenously via oxidative stress and lipid peroxidation. Relevant to this phenomenon are the redox-active and electrophilic metabolites of benzene, which are believed to contribute to its myelotoxic effects. When the benzene metabolites hydroquinone (HQ) and phenol (PHE) are administered to rats, HQ oxidizes to 1,4-benzoquinone (BQ) and in the presence of GSH gives rise to multi-GSH conjugates detectable in bone marrow. These HQ-GSH conjugates retain the ability to adduct proteins and to redox cycle. Here we report that bone marrow malondialdehyde levels in PHE/HQ treated rats are significantly elevated, indicative of lipid peroxidation and the consequent generation of other reactive electrophilic aldehydes, such as 4-hydroxy-2-nonenal (4HNE). Indeed, proteomics profiling revealed bone marrow proteins targeted by benzene metabolites and 4HNE, including 14-3-3 protein zeta/delta, protein disulfide isomerase A3, peroxiredoxin 2, and calreticulin. Adduction of topoisomerase II  $\alpha$  (topo II $\alpha$ ) has been implicated in benzene-induced leukemia, and cancer chemotherapeutic topo II $\alpha$  inhibitors are a leading cause of therapy-induced leukemia. We next reacted purified topo II $\alpha$  (6 units) with BQ (0.5  $\mu$ M) or 4HNE (1.3  $\mu$ M). A marked reduction in the ability of topo II $\alpha$  to decatenate the kDNA substrate was observed. Proteomic analysis of 4HNE-reacted topo II $\alpha$  revealed multiple amino acid sites of adduction, including K893 and K1480 adducts. Adduction of these lysine residues could impair topo II $\alpha$ -DNA binding, or inhibit topo II $\alpha$ 's ATP-dependent formation and annealing of DNA strand breaks. The consequences of BQ- and 4HNE-induced functional alterations in topo II $\alpha$  are currently under investigation.

**PS 166 Overexpression of CRM1 in Normal Human Lung Epithelial Cells Changes Cellular Morphology and Cytotoxic Responses to Tobacco-Specific Carcinogen NNK.**

C. Lu, W. Zhu and W. Gao. *The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX.*

Chromosome region maintenance 1 (CRM1), the major nuclear export receptor with a broad substrate range, is not only required for transport of many RNAs and proteins but also involved in various modulations within the cell such as mitosis, cell arrest, and apoptosis. Our recently published study showed that CRM1 played critical roles in response to tobacco-specific carcinogen, 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), in BEAS-2B cells (a normal human lung epithelial cell line). The objective of the present study was to further examine the significance of CRM1 in lung cancer development using BEAS-2B cells stably overexpressing CRM1 (BEAS-2BCRM1+ cells). The overexpression of CRM1 in BEAS-2BCRM1+ cells was confirmed by real-time PCR and western blot. As compared to BEAS-2B cells, BEAS-2BCRM1+ cells were prone to form colonies. Soft-agar assay further demonstrated increased colony formation and larger colony size in BEAS-2BCRM1+ cells in comparison with BEAS-2B cells. In addition, the cytotoxic effects in response to NNK was measured by 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTS) assay in both cells. Cells were treated with 0-500  $\mu$ M NNK for 24, 48, and 72 h. The inhibitory effects were dose and time dependent in both cells ( $p < 0.05$ ). However, BEAS-2BCRM1+ cells showed different sensitivity to NNK as compared to BEAS-2B cells. Taken together, our results indicate that CRM1 overexpression changes cellular morphology and cytotoxic response to tobacco carcinogen in human lung epithelial cells. The potential molecular mechanisms involving these changes are being evaluated to better understand the critical role of CRM1 in chemical carcinogenesis after NNK exposure.

**PS 167 ARNT Isoforms Mediate Opposing Effects on NF- $\kappa$ B Signaling.**

K. Gardella<sup>1,2</sup>, I. Muro<sup>1,2</sup> and C. Wright<sup>1,2</sup>. <sup>1</sup>Division of Pharmacology and Toxicology, The University of Texas at Austin, Austin, TX; <sup>2</sup>The Center for Molecular and Cellular Toxicology, The University of Texas at Austin, Austin, TX.

We have previously shown that the arylhydrocarbon receptor nuclear translocator (ARNT) regulates the chromatin binding activity of the RelB NF- $\kappa$ B subunit. ARNT is a transcription factor that is integral in the regulation of xenobiotic and hypoxic responses but our studies suggest that ARNT also participates in NF- $\kappa$ B

signaling. ARNT is expressed as two isoforms, isoform 1 and 3, but whether these isoforms differentially regulate NF- $\kappa$ B activity is unclear. Isoform 1 is identical to isoform 3 except for an additional 15 amino acids near the N-terminus. The extra amino acids in isoform 1 provide a phosphorylation site, which has been shown to inhibit its DNA binding. Interestingly, we have observed in lymphoid malignancies that ARNT isoform 1 is expressed at much higher levels than isoform 3 as compared to normal lymphocytes where the ARNT isoforms are expressed at equal levels. We find that ARNT isoform 1 potentiates while ARNT isoform 3 abrogates NF- $\kappa$ B activity. In light of our previous ARNT-RelB model, these opposing effects of the ARNT isoforms in NF- $\kappa$ B signaling appear to hinge on their ability to associate with RelB as ARNT isoform 3 binds much more strongly than isoform 1. Lastly, we found that the co-expression of a GFP-tagged p100 in combination with the ARNT isoforms promoted p100 nuclear translocation, possibly through a RelB bridge, resulting in diminished transactivation of NF- $\kappa$ B responsive genes. Thus, our current working model is one in which lymphoid malignancies shift toward the production of ARNT isoform 1, which in turn enhances NF- $\kappa$ B activity, as a contributing factor to their growth and survival.

## PS 168 Co-Exposure to Arsenic and Estrogen Leads to Enhanced Transformation of Normal Human Prostate Epithelial Cells.

J. Treas, T. Tyagi and K. P. Singh. *The Institute of Environmental and Human Health, Texas Tech, Lubbock, TX.*

Exposure to both arsenic and estrogen are known risk factors for prostate cancer, however the carcinogenic effect of their co-exposure is not known. Therefore, the objective of this study was to evaluate the transformation potential and its mechanism in human prostate epithelial cells by co-exposure to these two chemicals. To achieve this objective, the human prostate epithelial cells, RWPE-1 were treated for 6 months with sodium-meta arsenite and 17 $\beta$ -estradiol, both alone and in combination, at concentrations of 100 pg/mL and 100 ng/mL. Cell counts and MTT assay was performed to determine the effects on growth, and soft agar assay was performed to evaluate the cell transformation by exposure to arsenic and estrogen. Potential role of estrogen receptors and aromatase in mediating the cellular response to these chemicals was evaluated by measuring their expression at transcript level. The result of this study revealed that the growth and transformation of RWPE-1 cells were significantly greater in arsenic and estrogen co-exposed cells as compared to cells individually exposed to these two chemicals. The data of quantitative real time PCR revealed that expression of estrogen receptor beta was significantly increased whereas aromatase was significantly decreased in arsenic and estrogen co-exposed cells. These findings together with our recently published data on aberrant expression of epigenetic regulatory genes, such as, DNMTs, HDACs and MBDs in arsenic and estrogen co-exposed cells suggest that co-exposure to these two chemicals enhances carcinogenicity through epigenetic mechanisms.

## PS 169 Effects of Polycyclic Aromatic Hydrocarbons with Estrogen Receptors $\alpha$ and $\beta$ in Breast Cancer Cells.

T. T. James<sup>1,2</sup>, C. K. Sievers<sup>2</sup>, E. Shanle<sup>1,2</sup>, S. S. Hecht<sup>3</sup>, C. A. Bradfield<sup>1,2</sup> and W. Xu<sup>1,2</sup>. <sup>1</sup>Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI; <sup>2</sup>Oncology, University of Wisconsin-Madison, Madison, WI; <sup>3</sup>Masonic Cancer Center, University of Minnesota, Minneapolis, MN.

Polycyclic aromatic hydrocarbons (PAHs) are widespread environmental pollutants found in cigarette smoke, contaminated soil, vehicle exhaust, among others, known to cause adverse health effects including carcinogenesis and endocrine disruption. The metabolites of PAHs have been implicated in endocrine disruption. Some PAHs are known to have estrogenic effects by interacting with estrogen receptors (ERs). Estrogens have diverse roles including regulation of mammary gland development and morphogenesis, and maturation of uterus and ovaries. These functions are mediated by two subtypes of estrogen receptors, ER $\alpha$  and ER $\beta$ , which function in dimer forms (i.e. ER  $\alpha$ , $\beta$  homodimers and ER $\alpha$ / $\beta$  heterodimers). ER $\alpha$  is known to be proliferative while ER $\beta$  is known to be antiproliferative in the mammary gland. The estrogenic effects of PAHs have been mostly focused on their effects on ER $\alpha$ . Recently our lab reported that the monohydroxylated metabolites of naphthalene, phenanthrene and pyrene showed differential effects with ER $\alpha$  and ER $\beta$ . These PAHs were selected because they are found at high levels in contaminated environments. The ability of the PAH compounds to promote estrogenic effects were revealed by luciferase assays in isogenic reporter cell lines, competitive binding assays and bioluminescent resonance transfer (BRET) assays. The PAHs metabolites were more selective for ER $\beta$  and were able to activate ER $\beta$  target genes suggesting that these compounds can interfere with ER $\beta$  signaling in human breast cancer cells. In this study we screened additional PAHs and their monohydroxylated metabolites to determine their estrogenic effects. These studies demonstrate the impact of monohydroxylated PAHs on ER signaling and provide basis for the determination of the effects of other environmental compounds on ER. Supported by NIEHS Predoctoral Training Grant T32 ES007015

## PS 170 Alternative Splicing of ATG5 in DU145 Human Prostate Cancer Cells Inactivates Autophagy and Promotes Xenograft Tumor Growth.

D. J. Wible<sup>1,2</sup>, T. M. Calhoun-Davis<sup>2</sup>, D. G. Tang<sup>2</sup> and S. B. Bratton<sup>2</sup>. <sup>1</sup>Institute for Cellular and Molecular Biology, The University of Texas at Austin, Austin, TX; <sup>2</sup>Molecular Carcinogenesis, Virginia Harris Cockrell Cancer Research Center at The University of Texas MD Anderson Cancer Center Science Park, Smithville, TX.

Autophagy is a highly conserved pathway that targets cytoplasmic cargo to the lysosome for degradation. Excess or aberrant organelles, large protein aggregates and non-selective portions of the cytosol can be targeted by the autophagosome and delivered to the lysosome in order to maintain cellular homeostasis or survival in response to stress. In this study, we show that DU145 human prostate cancer cells alternatively splice Autophagy-related protein 5 (ATG5), an essential protein for autophagosome formation. These novel ATG5 splice forms are unable to conjugate normally to ATG12 and instead are rapidly ubiquitinated and turned over by the proteasome. The absence of ATG5-ATG12 conjugate in DU145 cells prevents autophagosome formation and autophagic degradation. Stable expression of full-length ATG5 using lentiviral infection rescued both ATG5-ATG12 conjugation and autophagy. Autophagy is currently thought to be tumor suppressive by eliminating potentially genotoxic protein aggregates and damaged organelles. However, the role it plays in tumor progression and metastasis remains unclear. To address this question, we performed subcutaneous injections of autophagy-deficient and autophagy-proficient DU145 cells into immunodeficient mice and monitored tumor formation and growth. In initial experiments, autophagy deficient tumors had a significantly longer latency period, yet grew at a faster rate than autophagy competent tumors. This suggests that autophagy can promote initial tumor establishment, while suppressing later tumor growth. Currently there are numerous clinical trials investigating the therapeutic potential of drugs that inhibit autophagy. Since it's not yet clear how these opposing aspects affect cancer metastasis, further study is essential to ensure effective therapy.

## PS 171 The Aryl Hydrocarbon Receptor Regulation during Epithelial-to-Mesenchymal Transition.

S. S. Kishinhi and S. E. Eltom. *Biochemistry & Cancer Biology, Meharry Medical College, Nashville, TN.*

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor that plays a role as a mediator of the xenobiotic signaling pathways. Recently, the AhR emerged as a major player in breast carcinogenesis. We have shown previously that ectopic overexpression of AhR in immortalized normal human mammary epithelial cells (HMEC) resulted in the development of malignant phenotypes, most notably the epithelial-to-mesenchymal transition (EMT). This EMT phenotype however, is not rigid but is in a dynamic state; with cells moving back and forth between epithelial and mesenchymal states. We asked the question whether this flux of phenotypes is due to changes in AhR levels or activity. A clone of HMEC overexpressing AhR, with either epithelial (E) or fibroblastic (F) phenotypes was compared to an empty vector (EV) control cells. We employed Western blotting, immunocytofluorescence (ICF) staining and RT-PCR techniques to assess the AhR expression as well as the epithelial and mesenchymal markers, E-Cadherin and vimentin, respectively. Our results showed that although at the mRNA levels AhR expression was similar, the AhR protein was higher in E- than in F-type cells. The AhR protein levels were always higher when cells were grown at higher density. Nuclear localization as assessed by ICF and CYP1A1 expression as assessed by RT-real time PCR, were used as surrogates for AhR activation. Our analysis showed that AhR activation was much higher in F-type cells and is more pronounced at higher cell density. In contrast, a 3h treatment with TCDD, a potent AhR agonist resulted in a steeper induction of CYP1A1 in E-type than the F-type cells, which is further enhanced at higher density. The observed difference in AhR protein levels and activity may be due to a differential stability of the protein associated with the two morphological forms, which is under investigation.

## PS 172 Expression and Role of ALDH1B1 in Pancreatic Cancer.

S. Singh<sup>1</sup>, K. Quackenbush<sup>2</sup>, A. Purkey<sup>2</sup>, J. Arcaroli<sup>2</sup>, Y. Chen<sup>1</sup>, D. J. Orlicky<sup>3</sup>, W. Messersmith<sup>2</sup> and V. Vasilou<sup>1</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, University of Colorado, Aurora, CO; <sup>2</sup>Division of Medical Oncology, University of Colorado, Aurora, CO; <sup>3</sup>Department of Pathology, University of Colorado, Aurora, CO.

Recent studies show that ALDH activity selectively defines an enhanced tumor-initiating cell population in human pancreatic adenocarcinoma. The specific ALDH isozyme(s) contributing to the high ALDH activity in these cells are unknown. We have recently shown that the mitochondrial aldehyde dehydrogenase 1B1

(ALDH1B1) is a potential biomarker for colon cancer. The aim of the current study was to examine expression and the role, if any, of ALDH1B1 in pancreatic adenocarcinoma. In normal pancreas, ALDH1B1 is abundantly expressed in glandular cells, but sparsely in the ducts (ALDH1B1 immunopositivity =  $16.7 \pm 1.7$ ). In pancreatic ductal carcinoma, we found a rather high ALDH1B1 expression in ductal cancerous tissues (ALDH1B1 immunopositivity =  $197.2 \pm 29.4$ ). Our data were also confirmed by analyzing human pancreatic adenocarcinoma tissue microarrays. Furthermore, ALDH1B1 appears to be contributing to ALDH activity in some, but not all, human pancreatic cancer explants examined. The variation of ALDH1B1 expression was also observed in 16 human pancreatic cancer cell lines. Two high and two low ALDH1B1 expressing cell lines were subjected to siRNA ALDH1B1 knockdown and cell proliferation was evaluated. High ALDH1B1 cell lines showed a 35% reduction in cell growth whereas proliferation was not affected in low ALDH1B1 cell lines. Treatment of high ALDH1B1 cells with gemcitabine resulted in greater ALDH1B1 mRNA levels and enzyme activity. In contrast low ALDH1B1 cells showed no such effect. Collectively our data show for the first time that ALDH1B1 is expressed at very high levels in pancreatic cancer and it contributes to proliferation of these tumor cells. These data suggest a potential role of ALDH1B1 in pancreatic cancer.

**PS 173 Gene Expression Changes in Human Endometrial and Mammary Cells Exposed to Tamoxifen.**

E. Hernandez Ramon<sup>1</sup>, E. Asaki<sup>2</sup>, O. Olivero<sup>1</sup> and M. C. Poirier<sup>1</sup>. <sup>1</sup>LCBG, NCI, NIH, Bethesda, MD; <sup>2</sup>Division of Computational Bioscience, CIT, NIH, Bethesda, MD.

Tamoxifen (TAM), a selective estrogen receptor modulator used for adjuvant therapy and chemoprevention of breast cancer, also increases the risk of endometrial and myometrial cancer. We hypothesized that comparison of gene expression patterns in cultured normal breast and endometrial cells may elucidate TAM-induced mechanisms. Gene expression studies in normal human mammary epithelial cells (NHMECs) exposed to 10  $\mu$ M TAM for 48 hr, using NIH DNA-oligonucleotide microarrays (Schild et al., 2003), demonstrated up-regulation of genes active in the interferon and immune-response pathways. Here we used the same NHMECs and TAM exposure conditions, and evaluated gene expression by Human Gene 1.0 ST Affymetrix expression array. Results using the Affymetrix array confirmed TAM-induced up-regulation of interferon signaling and complement pathways. Genes significantly overexpressed include some reported before (IFI27, IFIT1, IFIT3, IFI44L, IFITM1 and OAS3), and new genes involved in the same pathway (IFI44, IFI35, and IFIH1), as well as genes in the complement system (C1S, C1R and SERPING1). To contrast breast with endometrium, we used human endometrial stromal cells (HESC cells), also exposed to 10  $\mu$ M TAM for 48 hr. The primary genes up-regulated included some involved with biosynthesis of steroids (DHCR7, FDPS and MVD), and SREBF2, a sterol transcription factor. In addition, there was up-regulation of PPARG, a gene involved in cell proliferation and cancer, and down-regulation of CC1, a gene with anti-tumor activity. Expression changes of the most highly altered genes have been confirmed by qRT-PCR, and the microarray data are being subjected to extensive pathway analysis. However, these preliminary data show induction of different gene expression patterns in normal human mammary and endometrial cells exposed to TAM, confirming that immune-response pathways are induced in the breast, and showing that steroidal and proliferative pathways are induced in the endometrium.

**PS 174 Revealing the Role of Cancer Testes Antigens in Hif Signaling.**

C. Okechukwu<sup>1</sup>, A. Whitehurst<sup>2</sup>, J. Wooten<sup>2</sup> and K. Corcoran<sup>2</sup>. <sup>1</sup>Chemistry and Pharmaceutical Sciences, North Carolina Central University, Durham, NC; <sup>2</sup>Pharmacology, University of North Carolina Chapel Hill, Chapel Hill, NC. Sponsor: A. Baines.

The hypoxia-inducible factor-1 (HIF-1), is a transcription factor that responds to changes in oxygen homeostasis. Furthermore, the HIF pathway has been observed to contribute to tumor aggressiveness. The overexpression of HIF proteins has been observed to increase malignancy in tumor cells. Identifying the mechanisms that regulate HIF is essential to developing therapeutic strategies to inhibit its function. Here, we asked whether any members of the cancer-testes (CT)-antigen (CTA) family support HIF signaling. We combined an siRNA mediated loss of function approach with a luciferase reporter fused to a HIF Response Element (HRE) to determine consequences on HIF signaling following individual depletion of 120 CTAs. This screen revealed a subset of CT-antigens that positively support HIF induced transcription. This regulation appears to be at the level of the HIF1 $\alpha$  protein as depletion of a subset of these CTAs, MAGEA3/6 and IGF2BP3 reduced induc-

tion of HIF1 $\alpha$  protein. These findings suggest that CTAs may support stress signaling, particularly under hypoxic conditions and further demonstrate that CTAs may be playing functional roles in supporting tumor cell survival.

**PS 175 Aryl Hydrocarbon Receptor (Ahr)-Active Pharmaceuticals Are Selective Ahr Modulators in Triple Negative Breast Cancer Cell Lines.**

U. Jin<sup>1</sup>, S. Lee<sup>1</sup> and S. H. Safe<sup>1,2</sup>. <sup>1</sup>CEGM, Institute of Biosciences & Technology, Houston, TX; <sup>2</sup>VTPP, Texas A&M University, College Station, TX.

The aryl hydrocarbon receptor (AHR) plays an important role in multiple biological processes including regulation of drug-metabolizing enzymes, inflammatory pathways, immune responses and modulation of tumor cell formation and growth. Activation of the AHR by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) or the selective AHR modulator 6-methyl-1,3,8-trichlorodibenzofuran (MCDF) inhibited metastasis/invasion of triple negative MDA-MB-231 breast cancer cells in vitro and in vivo and identification of other antimetastatic AHR ligands was further investigated among a group of previously identified AHR-active pharmaceuticals. Treatment of BT474, MDA-MB-468 and MDA-MB-231 breast cancer cells with 4-hydroxytamoxifen, flutamide, leflunomide, mexiletine-HCl, nimodipine, omeprazole, sulindac, or tranilast gave highly variable results for their AHR agonist activity which was structure and cell context-dependent. The most striking data were observed in MDA-MB-468 cells where tranilast exhibited partial AHR agonist/antagonist activities and mexiletine inhibited TCDD-induced CYP1A1 gene expression and was a full AHR antagonist in this cell line. We also investigated the potential AHR-mediated inhibition of MDA-MB-231 cancer cell migration and invasion by this panel of pharmaceuticals using scratch and Boyden Chamber invasion assays. Only omeprazole blocked cell migration and invasion in this cell line and these responses were inhibited by knockdown of the AHR by RNA interference or co-treatment with the AHR antagonists, 3'-methoxy-4'-nitroflavone or 3,4-methoxy- $\alpha$ -naphthoflavone. These in vitro antimetastatic responses were accompanied down-regulation of the prometastatic gene CXCR4, previously been reported as an AHR ligand-inducible gene. Omeprazole and related benzimidazole analogs also exhibited anti-invasion activities in vitro suggesting that this AHR-pharmaceutical class may have clinical importance for treating advanced basal-type breast cancer that metastasizes to other tissues. (Supported by NIH-R01-CA-136571).

**PS 176 A Retrospective Analysis of Vehicle-Related Effects on Body Weight Gain and Survival from Two-Year Sprague-Dawley Rat Carcinogenicity Studies.**

R. Yeager<sup>1</sup>, C. Papagiannis<sup>2</sup>, D. Poage<sup>2</sup>, R. Pimentel<sup>2</sup>, T. Henriques<sup>1</sup>, C. Lin<sup>3</sup> and L. Shu<sup>3</sup>. <sup>1</sup>Preclinical Safety Toxicology, Abbott Laboratories, Abbott Park, IL; <sup>2</sup>MPI Research, Inc., Mattawan, MI; <sup>3</sup>Non-Clinical Statistics, Abbott Laboratories, Abbott Park, IL.

Depending on the proposed clinical indication, two-year rat carcinogenicity (CA) studies are conducted in support of the marketing application for new chemical entities (NCEs). The vehicle(s) used to formulate NCEs for the preclinical GLP rat toxicology studies are often utilized in the CA studies. Therefore, the objective of this study was to conduct a retrospective analysis of vehicle-related effects on body weight gain and survival from rat CA studies. The data set consisted of 30 individual vehicle groups, which included the following vehicles: water, methylcellulose, ad libitum diet/feed, and a lipid mixture. Survival was analyzed by the proportional hazard model and body weight gain was analyzed by the Gompertz non-linear mixed model. For males and females, there was higher variability in survival with diet compared to other vehicles. In males, there was a marginally significant ( $p = 0.069$ ) increase in survival with diet compared to water. In addition, there was a significant decrease in survival with the lipid mixture vehicle compared to all other vehicles. This significant decrease in survival with the lipid mixture vehicle corresponded with a decrease in body weight gain in this group compared to all other vehicles. In females, there was a significant increase in survival with methylcellulose compared to diet; however, there were no other significant differences in survival among other vehicle groups in females. Moreover, there was not as profound of an effect on body weight gain in females administered the lipid mixture vehicle, compared to other vehicles, as was observed in males. In conclusion, this analysis demonstrates that complex vehicle formulations, such as lipid mixtures, may affect body weight gain and survival on two-year rat carcinogenicity studies.

**PS 177** **Modifying Effect of Glycidol Fatty Acid Esters on *N*-Methyl-*N*-Nitrosourea Induced Mammary Carcinogenesis in Rats.**

Y. Cho<sup>1</sup>, T. Toyoda<sup>1</sup>, S. Onami<sup>1</sup>, Y. Mizuta<sup>1</sup>, A. Nishikawa<sup>2</sup> and K. Ogawa<sup>1</sup>.  
<sup>1</sup>Division of Pathology, NIHS, Tokyo, Japan; <sup>2</sup>Biological Safety Research Center, NIHS, Tokyo, Japan.

Glycidol fatty acid esters (GEs), trace contaminants in edible oils which are possibly formed during refining processes, have recently been detected in vegetable fat-containing products, including infant formulas. The level of GEs was ten times higher in enzymatically processed diacylglycerol-rich oil than that in the regular cooking oil containing triacylglycerols as major components. Although there is no toxicological data available yet on the GEs, the primary toxicological concern is based on the potential release of genotoxic carcinogen, glycidol from the parent esters. In the present study, to detect the modifying effects of GEs on the mammary gland, one of the carcinogenic target organs of glycidol, we pretreated 7-week-old SD rats with *N*-methyl-*N*-nitrosourea (50 mg/kg i.p.) and then administered glycidol (800 ppm) or GEs (3600 ppm, glycidol oleate (GO) or glycidol linoleate (GL)) in the drinking water for 26 weeks. The dose levels being selected on the basis of carcinogenic dose levels in rat carcinogenicity study of glycidol (37.5 and 75 mg/kg/day) and on the equal moles of the esters. In body weights, significant decrease was noted in the glycidol group compared to control group from week 2 through experimental period due to obvious decrease of water consumption. The calculated glycidol intake was 43 mg/kg per day and on the assumption that all treated GEs would be completely metabolized to glycidol, intake of glycidol in GO and GL groups was 93 and 74 mg/kg per day, respectively. The multiplicity and volume of histopathologically diagnosed mammary tumors, in particular poorly differentiated mammary carcinomas were significantly increased in the glycidol group as compared with the control. In the GO group, the multiplicity and volume of mammary tumors showed a slight tendency to increase, but no change was noted in the GL group. These results provide evidence of a mammary tumor promoting activity of glycidol, but not GEs in the present model.

**PS 178** **Spontaneous Thymoma Observed in Carcinogenicity Study of Wistar Han Rats.**

C. Maraschiello<sup>1</sup>, W. Henderson<sup>1</sup>, H. Iwata<sup>1,2</sup>, K. Weber<sup>1,2</sup>, S. Gachle<sup>1</sup> and T. Anzai<sup>1</sup>. <sup>1</sup>Harlan Laboratories, Inc., Indianapolis, IN; <sup>2</sup>AnaPath GmbH, Oberbuchsen, Switzerland.

Wistar Han rats are an appropriate model for toxicity and carcinogenicity studies in rodents and spontaneous thymoma is sometimes recorded in carcinogenicity studies of this strain of rats. The incidence of thymoma in historical control data of Harlan Laboratories is as follows: benign thymoma 0.64% for males, 2.39% for females; malignant thymoma 0.50% for males, 0.63% for females. The incidence of benign thymoma is higher in females with a range of 0% to 17.02% in these data. Histologically, these tumors commonly appear as solitary lesions with expansive growth, consisting of a mixture of thymic epithelial cells and lymphocytes with medullary differentiation. It was not always clear and requires careful consideration to distinguish between hyperplastic lesions and benign thymoma, and also between benign and malignant thymoma for many cases. In this report, we introduce typical hyperplastic lesions, thymoma and also the rarer epithelial cell type thymoma observed in Wistar Han rats.

**PS 179** **Mechanisms of Acetylugenol Nanocapsules on Melanoma Development: *In Vitro* and *In Vivo* Assays.**

C. C. Drewes<sup>1</sup>, C. G. Bexiga<sup>1</sup>, L. A. Fiel<sup>2</sup>, V. F. de Paula<sup>1</sup>, A. R. Pohlmann<sup>2,3</sup>, S. S. Guterres<sup>2</sup> and S. P. Farsky<sup>1</sup>. <sup>1</sup>Department of Clinical and Toxicological Analyses, Universidade de São Paulo, São Paulo, Brazil; <sup>2</sup>Department of Pharmacy, UFRGS, Porto Alegre, Brazil; <sup>3</sup>Department of Organic Chemistry, UFRGS, Porto Alegre, Brazil. Sponsor: S. Barros.

Eugenol displays antiproliferative and pro-apoptotic activities in different types of cancer cells, although effects of Acetylugenol (AC) and Acetylugenol Nanocapsules (NCAC) have not been elucidated. Here the role of NCAC on *in vivo* melanoma model and their actions on *in vitro* melanoma and endothelial cell cultures were investigated. Murine melanoma cells (B16F10, 8X105/100μL) were s.c. injected in the dorsal region of C57BL6 mice. Animals were i.p. or p.o. treated with Saline, AC, NCAC (50 mg/kg/day) or with their respective controls during 7 days. *In vitro* human endothelial cells (HUVEC) and melanoma cells (SK-Mel-28) were incubated with RPMI, DMSO, NC, AC or NCAC. Cell viability, nitric oxide (NO), clonogenic survival and cell adherence were monitored. Only NCAC

(100μM and 300μM), treatment reduced the endothelial and melanoma cell viability. NC and NCAC (60μM) treatments reduced the clonogenic survival only in melanoma cells and AC (30 and 60μM) treatment reduced clonogenic survival in both endothelial and melanoma cells. AC and NCAC (60μM) treatments inhibited endothelial and melanoma cells adherence. Both NC and NCAC (10, 30 and 60μM), but not AC, treatments increases the NO production by endothelial and melanoma cells. I.p. injection of NC or NCAC reduced melanoma growth, nevertheless they caused loss of weight, due to lower food intake and reduced the number of platelets. These *in vivo* toxic effects may be caused by accumulation of NC or NCAC in the peritoneum. P.o. administration of NC or NCAC reduced melanoma growth more than AC, and NC, AC or NCAC treatments decreased the number of circulating leukocytes. Together, data obtained show that i.p. route is not feasible to NC treatments, and the efficiency of NCs on tumor cell growth detected by p.o. may be due to their higher activity on clonogenic survival and adherence of melanoma cells.

**PS 180** **Natural Compounds As Chemopreventive Agents for the Inhibition of Protein Targets Involved in Cancer Induced by UV Radiation.**

W. Maldonado-Rojas, M. Ojeda-Cuello and J. Olivero-Verbel. *Environmental and Computational Chemistry Group Pharmaceutical Sciences, University of Cartagena, Cartagena, Colombia.*

Skin cancer is one of the most common worldwide, with an increasing incidence in recent years. This disease is mainly caused by excessive exposure to solar ultraviolet (UV) radiation. Currently, there is a high demand for natural chemopreventive compounds that may work on the biochemical mechanisms involved in the development of the disease. In this study, *in silico* molecular protein-ligand docking was performed with Autodock Vina to assess the interaction of 44 natural bioactive compounds with protein kinases (ERK1/TVO, p38/2YIX, JNK/2ZDT) and cyclooxygenase-2 (3LN1), widely recognized protein targets in the signaling cascades of skin tumor formation induced by UV radiation. The results showed these compounds presented theoretical binding affinity scores of similar magnitude to those recorded for known inhibitors of these proteins. The best binding affinity values were registered for cyaniding-3-rutinoside docked to ERK and JNK (-10.3±0.1 kcal/mol), and to cyclooxygenase-2 (9.7±0.1 kcal/mol). In the case of p38, the greatest affinity was found for epigallocatechin-3-gallate (-9.2±0.0 kcal/mol). The affinities obtained for the inhibitors of 1TVO, 2YIX, 2ZDT and 3LN1 were -9.4±0.0 (FR-180204), -7.0±0.0 (CE-159167), -7.3±0.0 (C46), and -10.3±0.0 kcal/mol (celecoxib), respectively. These theoretical results are good indicators that natural bioactive compounds may work as potential chemopreventive agents against skin cancer induced by UV exposure, probably by a mechanism involving their direct binding on key protein targets associated with the disease. Vice-Rectoría for Research. UniCartagena. 2011-2012. Colciencias-UniCartagena, Colombia: Grants 110745921616 (2009) and 110751929058 (2010).

**PS 181** **Genetic Polymorphism of Human Microsomal Epoxide Hydrolase As a Determinant of Polyaromatic Hydrocarbon Metabolism and Toxicity.**

X. Cai<sup>1</sup>, W. D. Hedrich<sup>1</sup>, E. M. Laurenzana<sup>1</sup>, B. E. Sell<sup>1</sup>, K. John<sup>1</sup>, A. K. Sharma<sup>2</sup>, S. G. Amin<sup>2</sup> and C. J. Omiecinski<sup>1</sup>. <sup>1</sup>Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA; <sup>2</sup>Department of Pharmacology, Hershey College of Medicine, Hershey, PA.

Microsomal epoxide hydrolase (mEH, EPHX1) is a key catalytic determinant in the formation of diol-epoxide metabolites of certain polyaromatic hydrocarbons (PAHs), noted as potent and ultimate mutagenic moieties. Epidemiological associations between EPHX1 genetic status and the incidence of certain diseases, including lung cancer, have been reported, yet the mechanistic bases for these associations remain unclear. Further, PAH diol-epoxides have never been evaluated as substrates for human EPHX1. Using enzymatic analyses, we evaluated substrate selectivity of the most common mEH genetic variants in the hydrolysis of planar vs. the highly tumorigenic non-planar fjord region PAH epoxides, together with their respective abilities to metabolize bay region and fjord region PAH diol-epoxide intermediates. Among the mEH variants, Y113/H139 wild type allele displayed highest capacity for hydrolysis of the bay region benzo[a]pyrene (BaP)-4,5-epoxide. The H113/H139 variant exhibited lowest affinity for the bioactivation of the fjord region dibenzo[a]pyrene-8,9-epoxide (-11-fold higher *K<sub>m</sub>* vs. wild type). Surprisingly, all of the human mEH variant enzymes were capable of hydrolyzing the bay region BaP-7,8-diol-9,10-epoxide, although displaying differential activity toward the fjord region dibenzo[a,l]pyrene-11,12-diol-13,14-epoxides. Results

from Comet assays and in situ DNA damage assays conducted in COS1 cells transfected with the mEH variants and treated with the corresponding epoxides generally corroborated the enzymatic activity data. Overall, these findings demonstrate marked substrate selectivity among the mEH variants with respect to PAH epoxide metabolism and provide mechanistic support for published epidemiology data suggesting that the H113 mEH allele is associated with a reduced risk of lung cancer.

## PS 182 Cotinine Levels and Gene Polymorphisms in Asthmatic Children Exposed to Tobacco Smoke in Northern Mexico.

Muñoz<sup>5</sup> and I. Poblete-Naredo<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav, Mexico City, Mexico; <sup>2</sup>Laboratorio de Contaminación y Toxicología Ambiental, UAN, Tépica, Mexico; <sup>3</sup>Laboratorio de Toxicología Genética, Instituto Nacional de Pediatría, Mexico City, Mexico; <sup>4</sup>Departamento de Pediatría, UMAE 71, IMSS, Torreón, Mexico; <sup>5</sup>Escuela de Ciencias de la Vida, ITESM-Ciudad de México, Mexico City, Mexico.

Tobacco smoke (TS) represents a serious health threat to consumers and passively exposed individuals. However, passive exposure receives much less attention than smokers. In addition, more than 700 million children worldwide are passively exposed to TS, meaning an increased risk to develop tobacco related diseases later in life; among them children with respiratory impairments, like asthmatics, are a particularly vulnerable group since the lung is the main route of TS entrance. Asthma is a multifactorial disease and the environment quality is a relevant etiology factor. We investigated children exposure to tobacco smoke in an asthmatic population (n=100 individuals; 6.98 ± 0.85 years), and non-asthmatic children (n=100, 7.1 ± 0.82 years) living in Región Lagunera, Northern Mexico. There was a statistically significant difference in urinary cotinine between the exposed and non-exposed groups. Urinary cotinine levels showed a small positive correlation between children and smoking adults (r= 0.1205 and p= 0.244). Although, cotinine levels were higher in asthmatic children compared to non-asthmatic, such difference was not statistically significant. In addition, no association between cotinine levels and asthma severity was observed in this study. As for the allelic frequencies of GSTT1 null and CYP2A6\*2 (1799 T-A) polymorphisms, were significantly different comparing TS exposed asthmatic and non-asthmatic children. This study suggests children response to passive TS exposure may be affected by asthma and GSTT1 or CYP2A6 polymorphisms (Supported by the grant SEP-Conacyt (60463) and a BBV scholarship (Conacyt-6544).

## PS 183 Identification of Genomic Regions Linked to Epigallocatechin Gallate Induced Liver Toxicity Using the Diversity Outbred Stock.

R. J. Church<sup>1</sup>, D. M. Gatti<sup>2</sup>, J. Eaddy<sup>1</sup>, P. B. Watkins<sup>1</sup>, D. Threadgill<sup>3</sup> and A. H. Harrill<sup>1</sup>. <sup>1</sup>The Hamner-UNC Institute for Drug Safety Sciences, The Hamner Institutes, Research Triangle Park, NC; <sup>2</sup>The Jackson Laboratories, Bar Harbor, ME; <sup>3</sup>North Carolina State University, Raleigh, NC.

Epigallocatechin gallate (EGCG), an abundant polyphenol in green tea, has caused idiosyncratic liver toxicity when taken as an herbal supplement. The identification of genetic risk factors utilizing mouse population-based approaches, and validated in patient cohorts, could improve clinical management of EGCG-induced liver injury. In order to map genomic loci related to EGCG induced hepatotoxicity, we utilized the Diversity Outbred (DO) stock. DO mice are derived from eight inbred founder strains and have high genetic diversity, enabling high resolution mapping in this population. We hypothesized that Quantitative Trait Locus (QTL) mapping in DO mice exposed to EGCG would allow us to identify candidate genomic regions influencing the hepatotoxicity of EGCG. Male DO mice were treated once daily, for 3 days, with EGCG (50 mg/kg i.g.) or vehicle. Twenty four hours after the final dose, animals were sacrificed and serum and liver tissue were collected. Similar to humans, EGCG treatment in DO mice precipitates wide variation in hepatotoxic response. In treated animals, serum alanine aminotransferase (ALT) fold changes (terminal compared to pre-dose) ranged from 0.46-495.5 (mean: 24.8 ± 65.4) and percent liver necrosis ranged from 0-86.8% (mean: 6.3 ± 14.1). QTL mapping in treated animals identified two suggestive loci— one on chromosome 12 and one on chromosome X. In a follow-up study, we will genotype suspected risk alleles in DNA collected by the Drug Induced Liver Injury Network (DILIN) from patients with suspected EGCG-induced liver toxicity. We have demonstrated the first application of the DO mice to the detection of xenobiotic risk alleles of toxicity responses. While further validation is needed, our data suggest that QTL mapping in DO mice may aid in identification of pharmacogenetic risk alleles for compounds causing liver injury.

## PS 184 Pharmaco-Genomics and -Genetics of 5-Fluorouracil in Koreans.

M. Yang and M. Bae. Sookmyung Women's University, Seoul, Republic of Korea.

Genetic polymorphisms of several enzymes such as dehydropyrimidine dehydrogenase (DPYD), methyltetrahydrofolate reductase (MTHFR) and thymidylate synthase (TS) have been emphasized for pharmacogenomics and -genetics of 5-FU, which has been used for half century as a representative therapy for various cancers, however, shown individual variations in its various toxicities including life-threatening toxicity. Focusing on the three genes, we performed a pharmacogenomic and -genetic study of 5-FU in a Korean population. Most of genotypes and gene expression were analyzed with 7500 Realtime PCR System (ABI). As results, we found genetic polymorphisms in DPYD-85, -1627, and -1896 sites, 5'-ER, and 3'-UTR at TS, and MTHFR-222, and -429 sites among the Korean subjects (N=133; normal, N=105; head and neck patients, N=28). There was a significant association between 3'-UTR genetic polymorphism at TS and its genetic expression (p<0.05). From 5-FU pharmacokinetic (PK) analyses, each genotype did not show any effect on PK parameters. However, the combination of genetic polymorphisms in MTHFR -222T/C, DPYD- 1896T/C and 3'-UTR at TS showed significant differences in AUC of 5-FU and 5-FU/5-FUH2 ratios (p<0.01). Therefore, this study provides association between TS expression and its 3'-UTR polymorphism. Moreover, combination of the three genetic polymorphisms of the three genes can affect PK of 5-FU in Koreans.

## PS 185 PON1 Genotypes of Black Females from the Mississippi Delta Are Different from Those in the Rest of the State and Country.

M. Dail, P. Eden, C. McDaniel, E. C. Meek and J. E. Chambers. Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.

Paraoxonase (PON1) is named for its ability to hydrolyze paraoxon, the active metabolite of the insecticide parathion. It is implicated in cardiovascular and metabolic diseases, such as Type 2 diabetes as well as tolerance of organophosphate insecticides. The human PON1 gene has several single nucleotide polymorphisms (SNPs). The SNP of an arginine (R) to glutamine (Q) substitution at codon 192 is associated with catalytic efficiency while the SNP of a methionine (M) to leucine (L) substitution at codon 55 is linked with serum levels. Since the Mississippi Delta has the highest rate of metabolic disease in the country, and a historically high use of pesticides, we compared the PON1 genotypes of black female Mississippi Delta clinic patients to those of black females from northeastern Mississippi and military populations. Genomic DNA was isolated from whole blood and the SNP codon areas were amplified by PCR. Since there is a native Alw I restriction site at codon 192, the QQ, RR, and QR SNPs yield different digest patterns. A native NlaIII restriction site at codon 55 generates different digest patterns for the LL, MM, and LM allozymes. Genotypic frequencies were different for the Q192R SNP. QR was most frequent in the military (45%) and northeastern Mississippians (50%), but RR was most frequent in the Delta group (54%). Similarly, the most common combination of polymorphisms was QRLL in the military (24%) and northeastern Mississippi groups (36%), but in the Delta group it was RRLL (48%). Using Fisher's exact test to analyze genotypic frequencies, the largest differences were between the Delta and military groups with Q192R P=0.0024 and L55M P=0.000176. When all three groups were compared, Q192R ratios were significantly different at P=0.00007 and L55M ratios at P= 0.00001. The significant differences seen in the Delta population may be associated with the region's health disparities.

## PS 186 In Vitro Toxicogenomic Screen Developed Using Genetically Diverse Mouse Inbred Cell Lines: Developing In Vivo Validations.

T. Wiltshire<sup>1</sup>, O. Suzuki<sup>1</sup>, B. B. Parks<sup>2</sup>, O. Trask<sup>2</sup>, C. Benton<sup>1</sup>, A. Frick<sup>1</sup>, N. Butz<sup>1</sup>, E. Chan<sup>1</sup>, E. Healy<sup>2</sup> and R. S. Thomas<sup>1</sup>. <sup>1</sup>Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>The Hamner Institute for Health Sciences, Durham, NC.

Cell-based assays provide unprecedented means to globally and systematically screen for drugs and chemicals likely to display high inter subject toxicity variability. Genetic determinants of toxicity identified in these screens can guide clinical trial design or identify susceptible subpopulations. Here, we developed an innovative in vitro genetic screen using mouse embryonic fibroblast (MEFs) cells isolated from 32 inbred strains and screened them against 69 different drugs and chemicals. Using high-content imaging, we measured multiplexed cell health parameters, including cell loss, mitochondrial membrane potential, and cytochrome c release at

24 and 72 hours post treatment. We looked for genetic loci significantly linked to inter-strain cellular responses to treatment and found a 1.2 Mb locus on Chr X that was significantly linked to variable cytotoxic responses to a known mitochondrial toxicant, rotenone ( $-\log P > 4.0$ ). Within this putative locus is cytochrome b-245, beta polypeptide (Cybb) gene, which encodes for a voltage-gated H(+) channel that mediates pH in the mitochondria. We conducted a series of experiments to examine the role of Cybb in mediating toxic responses to rotenone in vivo, given that mitochondrial dysfunction has been shown to underlie idiosyncratic adverse drug reactions. We found that strains belonging to different Cybb haplotypes scored differently in the treadmill exercise stress test for aerobic endurance after chronic treatment with rotenone. Our study demonstrates that cell-based genetic assays using MEFs are an effective tool for identifying genes underlying drug and chemical toxicity. Importantly, mouse strains that exhibit differential in vitro sensitivity, from a cell-based screen, also display a differential in vivo phenotype. This in vitro-to-in vivo validation is difficult, but a fundamental step toward recognition of cell-based toxicity screens.

## PS 187 P-Glycoprotein Transport in the Disposition of Neurotoxicants.

S. Lacher, K. Skagen, R. Dalton, F. Cardozo-Pelaez and E. Woodahl.  
CEHS/BMED, The University of Montana, Missoula, MT.

Background: P-glycoprotein (P-gp), encoded by the *ABCB1* (or *MDR1*) gene, is an efflux xenobiotic transporter expressed in many tissues important in xenobiotic disposition. P-gp is highly expressed at the blood-brain-barrier and protects the brain from substances circulating in the blood. Although the importance of P-gp in drug disposition is clear, its role in disposition of environmental neurotoxicants is not well understood. Our goal is to investigate the role of P-glycoprotein in neurotoxicant accumulation in the brain, particularly pesticides that have been associated with Parkinson's disease such as rotenone, maneb, paraquat, and MPP+. Methods: We used polarized kidney epithelial control cells, LLC-PK1, and *ABCB1*-transfected cells, LLC-MDR1, to characterize pesticides as substrates or inhibitors of P-gp using flow cytometry, cytotoxicity, and transepithelial permeability assays. P-gp-stimulated ATPase activity was also measured to evaluate compounds as P-gp substrates in a membrane-based system. Results: We observed weak inhibition of rhodamine-123 (R123) efflux in *ABCB1*-expressing cells by flow cytometry in the presence of 100  $\mu$ M rotenone or maneb,  $16.2 \pm 1.53$  and  $11.6 \pm 4.53\%$ , respectively. Paraquat and MPP+ showed no R123 inhibition. ATPase assays showed that rotenone is a P-gp substrate with a  $K_m = 26.7 \pm 12.9 \mu$ M and  $V_{max} = 35.8 \pm 6.5$  nmol Pi/mg protein/min. This compares to the known P-gp substrate verapamil with kinetic constants of  $K_m = 8.22 \pm 3.79 \mu$ M and  $V_{max} = 42.9 \pm 5.5$  nmol Pi/mg protein/min. Paraquat, maneb, and MPP+ showed no ATPase stimulation. Conclusions: In combination these data suggest that rotenone acts both as a substrate and a weak inhibitor of P-gp, whereas maneb acts only as a weak inhibitor. MPP+ and paraquat are neither substrates nor inhibitors of P-gp. We will further confirm these results using cytotoxicity and transepithelial permeability studies. Our studies will provide data to show the role of P-gp in the disposition of pesticides associated with Parkinson's disease.

## PS 188 Polymorphic Enzymes, Urinary Bladder Cancer Risk, and Structural Change in the Local Industry.

K. Golka<sup>1</sup>, D. Ovsiannikov<sup>2</sup>, S. Selinski<sup>1</sup>, M. Lehmann<sup>1</sup>, M. Blaszkewicz<sup>1</sup>, O. Moormann<sup>2</sup>, M. W. Haenel<sup>3</sup> and J. G. Hengstler<sup>1</sup>. <sup>1</sup>Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany; <sup>2</sup>Department of Urology, St.-Josefs-Hospital Dortmund-Hörde, Dortmund, Germany; <sup>3</sup>Max-Planck-Institut für Kohlenforschung, Mülheim an der Ruhr, Germany.

In the 1990s, the highest percentage of glutathione S-transferase M1 (GSTM1) negative urinary bladder cancer cases (70%) ever reported was observed in the greater Dortmund area. The question arose whether this uncommonly high percentage of GSTM1 negative urinary bladder cancer cases was due to environmental and/or occupational exposure decades ago. Thus, 15 years later, another study on urinary bladder cancer was performed in the same area after the coal, iron and steel industries had finally closed in the 1990s. In total 196 bladder cancer patients from a local department of urology and 235 controls with benign urological diseases were investigated by a questionnaire and genotyped for GSTM1, GSTT1 and the N-acetyltransferase 2 (NAT2) tag SNP rs1495741. The frequency of the GSTM1 negative genotype was 52% in bladder cancer cases and in the controls as well and thus much lower, compared to a previous study performed from 1992-95 in the same area (70%). NAT2 genotypes were distributed equally among cases and controls (63% slow acetylators). Less GSTT1 negative genotypes were present in cases

(17%) than in controls (20%). The normal frequency of the GSTM1 negative genotype in bladder cancer cases in the present study supports the assumption that the highly increased percentage of GSTM1 negative bladder cancer patients observed in the preceding study may be related to past occupational and environmental exposures decades ago.

## PS 189 CTNNA3 ( $\alpha$ -Catenin) Gene Variants Are Associated with Diisocyanate Asthma in Occupationally-Exposed Workers.

B. Yucesoy<sup>1</sup>, M. L. Kashon<sup>1</sup>, Z. L. Lummus<sup>2</sup>, V. J. Johnson<sup>3</sup>, K. L. Fluharty<sup>1</sup>, D. Gautrin<sup>4</sup>, J. Malo<sup>4</sup>, A. Cartier<sup>4</sup>, D. R. Germolec<sup>5</sup>, M. I. Luster<sup>1</sup> and D. I. Bernstein<sup>2</sup>. <sup>1</sup>Health Effects Laboratory Division, CDC/NIOSH, Morgantown, WV; <sup>2</sup>Division of Immunology, Allergy and Rheumatology, University of Cincinnati, Cincinnati, OH; <sup>3</sup>BRT-Burleson Research Technologies, Morrisville, NC; <sup>4</sup>Hôpital du Sacré-Cœur de Montréal, Université de Montréal, Montréal, QC, Canada; <sup>5</sup>Toxicology Branch, DNT/NIHES, Research Triangle Park, NC.

A genome-wide association study conducted recently in Korean subjects identified three CTNNA3 ( $\alpha$ -T catenin) single nucleotide polymorphisms (SNPs) (rs10762058, rs7088181, and rs4378283) associated with diisocyanate induced occupational asthma (DA). We conducted a candidate gene association study to replicate these findings in Caucasian workers. Genotyping was performed on genomic DNA, using a 5' nuclease PCR assay. Genotyping of these SNPs was performed in 410 diisocyanate-exposed and predominantly Canadian workers including: 132 workers with DA confirmed by a specific inhalation challenge (DA+); 131 symptomatic workers in whom DA was excluded by a negative challenge (DA-); and 147 HDI-exposed asymptomatic workers (AWs). CTNNA3 rs7088181 and rs10762058 SNPs were significantly associated with DA+ when compared to AWs ( $p \leq 0.05$ ) but not in comparison to DA- workers. After adjusting for potentially confounding variables of age, smoking status and duration of exposure, minor allele homozygotes of rs7088181 and rs10762058 SNPs were at increased risk for DA compared with AWs [OR = 9.05 (95% CI: 1.69, 48.54) and OR = 6.82 (95% CI: 1.65, 28.24), respectively]. In conclusion, we replicated association between two closely linked CTNNA3 gene SNPs and DA in Caucasian workers. These findings suggest that genetically altered expression of CTNNA3 might influence cellular adherence and epithelial barrier function in the airways and play a role in the pathogenesis of DA.

This work was supported in part by an NIEHS IAG (Y1-ES-0001) and NIOSH/CDC R01 OH 008795.

## PS 190 Prevalence and Functional Characterization of the NADH Cytochrome *b<sub>5</sub>* Reductase I1M\*6C>T Intronic Variant.

K. L. Blanke<sup>1,2</sup>, J. Sacco<sup>1</sup> and L. Trepanier<sup>1,2</sup>. <sup>1</sup>Department of Medical Sciences, School of Veterinary Medicine, University of Wisconsin - Madison, Madison, WI; <sup>2</sup>Molecular & Environmental Toxicology Center, University of Wisconsin - Madison, Madison, WI.

Women exposed to cigarette smoke may have an increased risk of breast cancer, although this is controversial. In addition, African American, but not Caucasian, women showed an association with smoking and breast cancer in the Carolina Breast Cancer Study (CBCS) population. We hypothesized that this could be due to race-associated genetic variability in the pathways that detoxify tobacco carcinogens such as 4-aminobiphenyl (4-ABP) and 2-amino-1-methyl-6-phenylimidazo [4,5-*b*] pyridine (PhIP). Both are mammary procarcinogens that are bioactivated to hydroxylamine metabolites, which form DNA adducts and are thought to initiate cancer. Cytochrome *b<sub>5</sub>* (CYB5A) and NADH cytochrome *b<sub>5</sub>* reductase (CYB5R3) comprise a detoxification pathway that reduces 4-ABP and PhIP hydroxylamine metabolites back to their parent compounds. The purpose of this study was to determine whether CYB5A and CYB5R3 polymorphisms were over-represented in African American women in the CBCS, and to evaluate their role in the association with smoking and breast cancer risk. Several CYB5A and CYB5R3 single nucleotide polymorphisms (SNPs) were more prevalent in African Americans than in non-African Americans in the CBCS population. One intronic SNP in CYB5R3, I1M\*6C>T, previously found in tissue samples with low *b<sub>5</sub>* reductase protein expression, was found with a minor allele frequency that was 100-fold higher in African American subjects (MAF = 0.0428,  $P < 0.0001$ ). Among smokers, this variant was significantly over-represented in African American women with breast cancer compared to same-race controls (OR 2.10, 95% CI, 1.08-4.06). The I1M\*6C>T CYB5R3 variant is being functionally characterized for promoter and repressor function using a dual-luciferase reporter assay. These studies suggest that the I1M\*6C>T intronic variant in CYB5R3 may increase the risk of breast cancer among African American women that smoke.

**PS 191 Influence of Genetics on Paraoxonase 1 Activity in Monozygotic and Dizygotic Twins.**

L. Podolefsky<sup>1</sup>, K. M. Kelly<sup>2</sup>, J. C. Murray<sup>3</sup>, T. J. Raife<sup>4</sup> and G. Ludewig<sup>1, 2</sup>.

<sup>1</sup>Grad Program in Human Toxicology, University of Iowa, Iowa City, IA;

<sup>2</sup>Occupational and Environmental Health, University of Iowa, Iowa City, IA;

<sup>3</sup>Pediatrics, University of Iowa, Iowa City, IA; <sup>4</sup>Pathology, University of Iowa, Iowa City, IA.

Paraoxonase 1 (PON1) is an important HDL-associated endogenous antioxidant found to play a major role in susceptibility to health effects from pesticides and oxidative stress. A number of gene polymorphisms influence both protein concentration and substrate specificity, as do certain lifestyle factors. However, reports about the influence of PON1 genetics have varied widely in the literature. The goal of this study was to examine the influence of genes and health data in a group of monozygotic and dizygotic twins to better understand the effect of genetics on PON1 activity levels. DNA, serum, and standard blood donation information was obtained from 6 sets of dizygotic twins and 13 sets of monozygotic twins. DNA was genotyped for polymorphisms within PON1, PON2, C-reactive protein (CRP), and tumor necrosis factor (TNF). PON1 activity was determined using phenyl acetate (PA) and CMPA [4-(Chloromethyl)phenyl acetate] as substrates, and genotyping was performed using the TaqMan-Applied Biosystems 7900 HT System. Using a general linear model, PON1 Q192R, L55M and C-108T were significantly associated with both PA and CMPA activity, with CMPA activity showing a stronger association with genetic variants. PON2 S311C was significantly associated with PA activity, but not CMPA. Activity for either substrate was not found to be associated with CRP or TNF polymorphisms. BMI was found to significantly correlate with CMPA activity, but not PA activity (correlation = -.34), while gender did not correlate with either substrate. Pair-wise analysis of all twins with identical PON genotypes showed no difference in PON activity variance between siblings, regardless of zygosity. Though other shared or variant genetic and lifestyle factors may influence PON1 activity, the findings in this twin population suggest a strong link between PON activity and specific PON polymorphisms.

**PS 192 Contribution of Environmental and Genetic Factors to Pancreatic Cancer.**

S. Chittiboyina, A. A. Bond, L. M. Kamendulis and B. A. Hocevar.

*Environmental Health, Indiana University School of Public Health, Bloomington, IN.*

Pancreatic cancer is the fourth leading cause of cancer deaths in the United States with a five year survival rate of less than 6%. Several environmental risk factors have been identified for pancreatic cancer, including dietary factors. In particular, high dietary intake of folate has been associated with a decreased incidence of pancreatic cancer, while low plasma folate levels are associated with an increased cancer risk. In conjunction with diet and lifestyle determinants, an individual's folate pathway status is determined by their genetic makeup. In the present study, we determined the expression of selected SNPs in the folate metabolic pathway in a cohort of pancreatic cancer patients and healthy related and unrelated control groups. In agreement with other cancer studies, we show that cancer cases were more likely to express the TT allele of the methylene tetrahydrofolate reductase (MTHFR) C677T polymorphism compared to controls. Expression of this allele has been associated with low folate levels and elevated homocysteine (Hcy) levels. In support of this, we found that pancreatic cancer patients display elevated serum Hcy levels in comparison to both control groups. In addition, 48% of the pancreatic cancer patients exhibited hyperhomocysteinemia, as defined by a value >15 µM/L, (range 11.15 - 26.17 µM/L), while no subjects in either control group exhibited hyperhomocysteinemia. In addition, we found that SNPs in betaine hydroxymethyltransferase (BHMT; rs 3733890) and serine hydroxymethyl transferase (SHMT; rs 1979277) exhibited significantly different distributions between the case and control groups (p < 0.05). While a clear association was not seen between cancer risk and alcohol or smoking use in our population, self reported environmental exposure data suggested an association between pancreatic cancer and exposure to welding fumes. These findings underlie the necessity to investigate further the interaction between environmental exposures and genetic factors which could provide further insight into the etiology of pancreatic cancer.

**PS 193 The Impact of CYP2S1 Single Nucleotide Polymorphisms on the Metabolic Activation of the Anticancer Prodrug, AQ4N.**

N. Bajaj, N. M. Singh and A. M. Rowland. *Chemistry and Biochemistry, NMSU, Las Cruces, NM.*

Cytochrome P450 2S1 (CYP2S1) is one of the most recent additions to the P450 superfamily of enzymes. Although its physiological role has not yet been defined, it has been shown to influence metabolism of bioactive lipids, including

prostaglandins and retinoids. CYP2S1 is predominantly expressed in extra-hepatic epithelial cells. Its expression is elevated in cancer and catalyzes the metabolic activation of the anticancer prodrug, AQ4N, under hypoxic conditions. Interestingly our lab has also demonstrated that increased CYP2S1 expression may protect against AQ4 cytotoxicity under normoxic (21% O<sub>2</sub>) conditions. The main objective of this study is to determine whether individual variability in the CYP2S1 enzyme alters sensitivity of human lung cells to AQ4N and AQ4-mediated cytotoxicity. Five published CYP2S1 allelic variants have been published: CYP2S1\*2 (R380C), CYP2S1\*3 (P466L), CYP2S1\*4 (S61N), CYP2S1\*5 (L230R). According to the NCBI database, two additional non-synonymous variants have been identified in cancer (A205T and L189F) and L189F is restricted to African American populations. We generate each of the polymorphisms in a CYP2S1-Flag mammalian expression vector, using site directed mutagenesis. Thus far, two stable lines (S61N and L189F) in bronchial epithelial cells (BEAS-2B) and four stable (S61N, R166H, A205T, and P466L) alveolar carcinoma cell lines (A549) have been made. Examination of AQ4N and AQ4 cytotoxicity in BEAS-2B cells revealed that both mutants (S61N and L189F) exhibit significantly increased cytotoxicity in response to AQ4N compared with wild type CYP2S1-Flag and pcDNA3.1 controls. Interestingly, the S61N polymorphism was significantly more sensitive to AQ4 than any of the other cell lines. This effect appears to be selective because cytotoxicity is not altered in response to a similar topoisomerase II inhibitor, mitoxantrone. We are currently testing the effects of these polymorphisms on AQ4N and AQ4 levels, using HPLC. Research funded by NIH NIGMS Grant # R25GM061222.

**PS 194 The Remarkable Genotoxic Effect of Exposure to Ethyl Tertiary Butyl Ether in ALDH2 Knockout Mice.**

R. Wang, Z. Weng, K. Ohtani, M. Suda, Y. Yanagiba and T. Suzuki. *Japan National Institute of Occupational Safety and Health, Kawasaki, Japan.*

Ethyl Tertiary Butyl Ether (ETBE) is used in gasoline for vehicles as a biofuel. ETBE exposure induced liver damage and other health effects only at high concentrations in our previous studies, and its No Observed Adverse Effect Level (NOAEL) was calculated to be 500 ppm. However, in mice without ALDH2 enzyme activity, ETBE could induce DNA damage even at the NOAEL. To find out how low concentration at which ETBE shows its genotoxic effect, we did the exposure experiment with mice at low range of ETBE concentrations. METHODS: Male Aldh2<sup>-/-</sup> (KO), Aldh2<sup>+/-</sup> (HT) as well as C57BL/6 strain (WT), at 8 weeks old were exposed to ETBE at 0, 50, 200 and 500 ppm, 6 hr/day and 5 days/week, for 9 weeks. Blood, liver, epididymides were sampled 20 hr after the last exposure, and DNA damages were analyzed with comet assay in these tissues. RESULTS: The tail intensity (TI) was used to evaluate the degree of DNA damage. In the leukocytes of WT mice, the TI value was not affected in any exposure group as compared to the control. However, the TI was significantly increased in 200 and 500 ppm groups of KO mice. Similar results were also obtained in HT mice, but there was no difference between the two types of mice. In liver cells and sperm, ETBE also induced DNA damage, but this effect was only observed in KO and HT mice as in the leukocytes. The NOAEL was 50 ppm in these types of mice. These results suggest that ALDH2 deficiency may increase the susceptibility to the health effect of ETBE exposure. We thank Ms. S. Watanabe for her assistance in the manipulation of the animals.

**PS 195 MGMT Haplotypes Alter MGMT Expression and Can Thus Affect Response to Alkylating Agents.**

M. Xu, I. Nekhayeva, C. E. Cross, C. M. Rondelli and S. Z. Abdel-Rahman. *OB/Gyn, UTMB, Galveston, TX.*

Glioblastoma (GB) is rapidly fatal. However, treatment with temozolomide (TMZ) and radiation is beneficial, but only for some patients. TMZ alkylates tumor DNA to form O6-alkylguanine (O6-AG) DNA adducts, inducing apoptosis. Because O6-AG is repaired by O6-methylguanine-DNA methyltransferase (MGMT), levels of MGMT are critical in determining tumor response to TMZ. Single nucleotide polymorphisms (SNPs) in the promoter/enhancer (P/E) region of the MGMT gene can alter its transcription and thus alter MGMT protein levels. Genetic variants are not arrayed as individual SNPs but as combinations forming specific "haplotypes". To date, no studies have determined the haplotypes structure of the P/E region of MGMT or their effect on its transcription. We sequenced 104 DNA samples from healthy individuals and identified 8 SNPs in this region (7/Y, 135/K, 290/R, 485/M, 575/M, 666/R, 777/M and 1099/Y). Using bioinformatics, we inferred the haplotypes encompassing these SNPs. We identified 21 potential haplotypes ranging in frequency from 0.39 to 0.00005, of which 10 were identified in our sample population as 20 paired haplotype combinations. We hypothesized that these haplotypes alter the regulation of MGMT transcription. Luciferase-reporter constructs containing different MGMT haplotypes were transfected into a GB cell

line and the effects of the haplotypes on *MGMT* transcription were determined using a Dual-Luciferase Reporter Assay. Compared with the most common (reference) haplotype, haplotypes 7 and 18 induced a significant 60% and 65% reduction in expression, respectively ( $P < 0.001$ ). However, haplotype 11 significantly increased expression by 70% ( $P < 0.001$ ). These data indicate that *MGMT* haplotypes regulate *MGMT* transcription and thus could play a major role in tumor response to TMZ treatment. Work is in progress to define the underlying mechanisms and to develop sensitive and specific markers that can distinguish those patients who would most be likely responsive to chemotherapy from those who would not (supported by P30 ES006676; T32-07454; 1 R03 NS065392-01 grants).

## PS 196 Associations between Genetic Polymorphisms of the Genes Mediating Inflammatory Response and Acute Pancreatitis Risk.

B. Alpertunga and G. Ozhan. *Pharmaceutical Toxicology, Istanbul University, Faculty of Pharmacy, Istanbul, Turkey.*

Acute pancreatitis is a common inflammatory disease. The reported incidence is approximately 30 to 40 per 100,000 population per year and 25% will develop severe or life-threatening complications. Inflammation is typified by the activation of immunocytes such as monocytes and macrophages, and the secretion of inflammatory mediators such as nitric oxide, prostaglandin E2, and tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ). Nitric oxide is especially controlled by the inducible nitric oxide synthases (iNOS). Prostaglandin E2 is produced from arachidonic acid metabolites by the catalysis of cyclooxygenase-2 (COX-2). TNF- $\alpha$ , thought to be the first cytokine released, is a principal mediator of immune responses. Genetic factors may play important roles in susceptibility to pancreatic injury, as well as in the severity and evolution of the inflammatory process. The aim of our study was to determine if polymorphisms in iNOS, COX-2, TNF- $\alpha$  genes were associated with acute pancreatitis. For that, three iNOS (Ser608Leu, 1173C/T, 954G/C), seven COX-2 (rs5275, rs2206593, rs4648262, rs4648261, rs2066826, rs5277, rs2745557) and two TNF- $\alpha$  (308G/A, 238 G/A) variants were determined using polymerase chain reaction-restriction fragment length polymorphism analysis in patients with acute pancreatitis and healthy controls. Odds ratios (ORs) and 95% confidence intervals (CI) were estimated. In conclusion; the association was seen with COX-2 rs5275 ( $P = 0.03$ ); specifically, patients carrying the TT genotype in comparison to patients carrying the CC genotype had a significantly lower risk of disease (OR=1.88; 95%CI:1.06-3.34). Both SNPs of TNF- $\alpha$  were not genetic risk factor for acute pancreatitis susceptibility. It was also found that iNOS Ser608Leu polymorphism was more frequent among cases with acute pancreatitis compared to controls (OR=2.88; 95%CI:1.49-5.57;  $P = 0.002$ ). We believe that the findings may be beneficial to the development of efficacious preventive strategies and therapies for inflammation-associated diseases.

## PS 197 In Vitro Toxicity of Antibacterial Silver Ions Released by Low Intensity Direct Electric Current (LIDC) Stimulation.

R. A. Shirwaiker<sup>1,2</sup>, M. E. Samberg<sup>2</sup>, Z. Tan<sup>1</sup> and N. A. Monteiro-Riviere<sup>2,3</sup>. <sup>1</sup>E. P. Fitts Department of Industrial and Systems Engineering, North Carolina State University, Raleigh, NC; <sup>2</sup>Joint Department of Biomedical Engineering, University of North Carolina at Chapel Hill and North Carolina State University, North Carolina State University, Raleigh, NC; <sup>3</sup>Nanotechnology Innovation Center of Kansas State, Kansas State University, Manhattan, KS.

Medical devices related surgical site infections and their treatment are a major cause of concern in the global healthcare system. The problem is compounded by the presence of antibiotic-resistant bacteria such as methicillin-resistant *Staphylococcus aureus* (MRSA) in healthcare environments, because infections caused by these bacteria are difficult to treat with conventional antibiotics. To prevent transmission of such infections, a prophylactic surface system that provides protracted release of antibacterial silver ions from interdigitated silver electrodes using low intensity direct electric current (LIDC) stimulation was developed and successfully validated against four pathogenic bacterial strains including *S. aureus*, *Escherichia coli*, *Enterococcus faecalis* and *Pseudomonas aeruginosa*. The objective of this study was to evaluate the toxicity of the LIDC system to human epidermal keratinocytes (HEK) and human dermal fibroblasts (HDF) with alamarBlue, using parameters proven to be antibacterial (28 $\mu$ A at 6V). It was found that 1.5h exposure to the silver ion-releasing surface system was not toxic to HEK or HDF, which suggests that the applications of the antibacterial system for surfaces that come into contact with skin epithelial cells or connective tissue for less than 1.5h are not expected to cause toxicity in vivo. The application of this technology is particularly relevant for high contact surface areas in medical devices such as stethoscopes, scalpel handles, endoscopes, and forceps that are prone to microbial contamination. In conclusion, the lack of toxicity in vitro provides support for future in vivo or clinical studies. (Supported by ArgentumCidalElectrics, Inc.)

## PS 198 Safety Assessment of Colorants Used in a Short Term Blood Contacting Medical Device—Challenges in Color Extraction Testing.

F. K. Hsia<sup>1</sup>, H. J. Beckord<sup>1</sup>, M. P. Beauchane<sup>1</sup>, C. J. Anderson<sup>2</sup>, D. R. Kent<sup>3</sup> and E. E. Reverdy<sup>1</sup>. <sup>1</sup>Corporate Toxicology and Biocompatibility Services, Boston Scientific Corporation, Maple Grove, MN; <sup>2</sup>Materials, Testing, Analysis, and Characterization, Boston Scientific Corporation, Maple Grove, MN; <sup>3</sup>Product Safety and Validation, NAMS, Northwood, OH.

Use of colorants in medical devices continues to be scrutinized by the FDA. In response to the FDA questions on a recent PMA submission and to be compliant with ISO 10993 *Biological Evaluation of Medical Devices - Part 1: Evaluation and Testing within a Risk Management Process*, Boston Scientific completed extraction studies on colorants as part of the safety assessment. The challenges and successes in demonstrating the safety of the colorants used in a short-term blood-contacting catheter are presented here. A color elution study was conducted to demonstrate the potential bioavailability of four colorants. Devices were extracted at 37°C for 24 hours in acetone. These aggressive extraction conditions maximized the potential to extract colorant and were not intended to represent clinical use. Non-volatile residue (NVR) portions of the extracts were microwave digested and then analyzed using ICP-OES against control colorant samples of known concentration. The estimated maximum amounts of extracted colorant ranged from <LOQ - 2.4 mg/device. These values together with the NVR value (0.1 mg/device) from the USP Physicochemical test were used as "worst case" estimates in the safety assessment. Variable process spike recovery results and device degradation during extraction contributed to uncertainty in the reported results. The safety assessment was conducted following ISO 10993-17: *Establishment of Allowable Limits for Leachable Substances*. The existing toxicological and biological safety data were included in the risk assessment. The threshold of toxicological concern (TTC) approach was applied for colorants with insufficient toxicological data. We concluded that the colorants used in this short-term catheter are eluted from the device at toxicologically insignificant amounts when extrapolated to the clinical exposure.

## PS 199 Comparison of Results from 2 In Vitro Cytotoxicity Tests Used in the Evaluation of Medical Devices.

D. E. Malek<sup>1</sup> and R. T. Przygoda<sup>2</sup>. <sup>1</sup>Malek Toxicology Delaware LLC, Greenville, DE; <sup>2</sup>Life Cycle Materials, Johnson & Johnson, Cincinnati, OH.

ISO 10993-1 includes an *in vitro* cytotoxicity test as part of a biological evaluation of medical devices. Two cytotoxicity tests commonly used in this evaluation are the MEM elution (ME) and Colony Formation (CF). The results from 43 samples used in medical devices were analyzed to evaluate the utility of both tests. Twenty-eight test samples also were evaluated for *in vivo* irritation, sensitization and systemic toxicity. The ME test was performed according to ISO 10993-5, section 8.2 including serial dilution of the extract, and CF test was performed according to ISO 10993-5, Annex B. The *in vivo* tests were performed according to the appropriate ISO 10993 standard. The ME and CF test results from 36 test samples showed agreement (84% agreement). Seven test samples were non-toxic in ME but toxic in the CF test (16% disagreement). Toxicity was not observed in any of the *in vivo* tests on the 12 samples that were toxic in either the ME, CF, or both cytotoxicity tests. When compared to the results of the 28 sets of *in vivo* tests, the ME test was 71 % in agreement and the CF test was 46% in agreement. Cytotoxicity was not observed in ME or CF tests for the 3 samples that failed for irritation. The results from this comparison demonstrate that *in vitro* cytotoxicity is not predictive of *in vivo* irritation, sensitization or systemic toxicity; and the lack of cytotoxicity does not guarantee acceptable *in vivo* test results. The ME test with serial dilutions is more in agreement with results from *in vivo* tests, and when toxicity is observed provides comparable results to CF test.

## PS 200 Evaluation of Sample Preparation Methods in the ISO 10993-12 Standard: Implications for the Biocompatibility Assessment of Medical Devices.

R. P. Brown, H. Dinesdurge, J. Goode and M. Ghosh. *US FDA, Silver Spring, MD.*

The ISO 10993-12 standard outlines suitable extraction conditions for the preparation of test samples for the biological evaluation of medical devices. The standard provides a list of temperature, time, and solvent conditions recommended for the preparation of extracts for toxicity testing, but no guidance is offered on which specific extraction conditions are optimal for various types of materials. The goal of this study is to identify extraction conditions that can be used to differentiate toxic from nontoxic polymeric materials in an indirect hemolysis assay without resulting

in the degradation of the material. A "toxic" material is defined in this study as one that produces a positive response in a modified MEM Elution cytotoxicity test. A wide range of polymeric materials (e.g., BUNA, nitrile, butyl, neoprene, latex, silicone rubbers; polyurethane, polyethylene, PVC) was extracted in a closed glass vial in phosphate buffered saline (PBS) using the default conditions outlined in the ISO 10993-12 standard (37°C x 24 hrs, 37°C x 72 hr, 50°C x 72 hr, 70°C x 24 hr, 121°C x 1 hr). In addition, the polymers were extracted in 5% or 50% ethanol (EtOH) or acetone at 37°C for 24 hours. The 50% EtOH extracts were diluted to 5% with PBS for the hemolysis assay. The acetone extracts were evaporated under a nitrogen stream, then reconstituted with PBS. Our results show that rigorous extraction conditions (acetone, 50% EtOH) are necessary to correctly differentiate toxic from nontoxic materials. For example, latex and BUNA were positive in the cytotoxicity assay, positive when 50% EtOH extracts were used in the hemolysis assay, but negative when extracted in PBS using the standard extraction conditions in the ISO 10993-12 standard (e.g., 50°C x 72 hrs). Since the use of acetone as an extraction vehicle resulted in the degradation of some materials, such as PVC, the use of EtOH:PBS solvent mixture represents a promising approach for preparing samples for the biological evaluation of medical device materials.

**PS 201 Can There Be a Universal Extraction Solvent for Medical Device Biocompatibility Testing? Comparison of Extraction Efficiencies among Five Solvents Used to Extract Polymeric Dental Devices.**

L. H. Moilanen<sup>1</sup>, J. K. Dahms<sup>2</sup>, B. D. Bagley<sup>1</sup> and E. F. Hope<sup>1</sup>. <sup>1</sup>Medical Department, 3M, St. Paul, MN; <sup>2</sup>3M ESPE, 3M, St. Paul, MN.

The biocompatibility of medical devices is often evaluated using extracts prepared from the final product. The selection of the most appropriate extraction solvent(s) for product chemical characterization and biocompatibility assessment remains a subject of active discussion within the medical device standards community. For this study, we examined extraction data obtained for nine experimental dental product prototypes extracted using five solvents of varying polarity to address both clinical use and exaggerated extraction scenarios. The extracted prototypes included four composite restoratives, a resin-modified glass ionomer, a polymeric polishing brush, a temporary cement, a self-etch adhesive, and a dental sealant. ISO 10993-12 compliant samples of each product were extracted in aqueous 5% ethanol solution, acetone, methanol, heptane, and 50:50 cyclohexane:isopropanol at 37°C with a target sample:solvent extraction ratio of 0.2 g/mL. Extraction time intervals ranged from 24 hours to 28 days. Gravimetric and HPLC analyses of the extracts show that in most cases use of methanol either resulted in the highest concentration of extractables or gave results similar to acetone. In the remaining cases, either acetone or water extracted the largest amount of residue. These results confirm the utility of methanol as an exaggerated solvent for many polymeric dental products, but also highlight the importance of proper solvent selection based on detailed knowledge of product chemistry.

**PS 202 Determination of Total Leachable Bisphenol A from Polysulfone Membranes in Hemodialyzers and Hemoconcentrators.**

S. M. Cho, Y. Choi, H. Luu and J. Guo. US FDA, Silver Spring, MD.

Bisphenol A (BPA) is a high-production-volume chemical widely used to manufacture polysulfone (PS), polycarbonate, epoxy resin, etc. Over the past ten years, BPA has been the subject of numerous risk assessment reviews and research worldwide because of its potential to produce adverse health effects through endocrine disruption. Although there is a significant body of literature focused on the adverse effects of BPA at low doses, there are discrepancies in the relevance and reliability of the published results. These make it difficult to properly evaluate the hazards of BPA. To reduce discrepancies and variation in research results, it is essential to establish reproducible/accurate analytical methods. In this study, we evaluated the BPA levels eluted from porous PS membranes used in hemodialyzers and hemoconcentrators using single and multiple consecutive extractions under clinically relevant extraction condition. The levels of BPA release were determined using solid phase extraction (SPE) coupled with high performance liquid chromatography-mass spectrometry (HPLC-MS). We demonstrated that it was difficult to determine the total amount of BPA released from the PS membranes using a single extraction method with finite solvent volume because of the chemical equilibrium between the extraction solution and the polymer phase. A general equation was derived to fit the BPA elution data and deepen our understanding on the equilibrium phenomenon during the extraction. The results revealed that repeated consecutive extractions of the PS membranes are needed to accurately determine the total leachable BPA in porous membranes.

**PS 203 Bisphenol A Content in Polycarbonate from Medical, Automotive and Consumer Suppliers.**

R. T. Przygoda<sup>1</sup>, J. A. Anim<sup>1</sup>, D. E. Malek<sup>2</sup> and D. J. Caldwell<sup>3</sup>. <sup>1</sup>Life Cycle Materials, Johnson & Johnson, Cincinnati, OH; <sup>2</sup>Malek Toxicology Delaware, LLC, Greenville, DE; <sup>3</sup>Worldwide Environment, Health, and Safety, Johnson & Johnson, New Brunswick, NJ.

Bisphenol A (BPA) is an organic compound used to make polycarbonate (PC) polymers and epoxy resins. The presence of BPA has the potential to produce human reproductive and developmental effects. Three sources of PC's were utilized in this study: from medical, automotive, and consumer suppliers (cups). Sterilized and unsterilized samples were extracted using ethanol (EtOH) or isopropanol (IPA) and incubated at 37 degrees C for 24 hours. Extracts were analyzed by high performance liquid chromatography (HPLC). In addition, exhaustive extraction by Soxhlet with IPA was performed on a medical grade PC. BPA was below the level of detection (0.5µg/g) in EtOH and IPA extracts with the exception of the cups. In extracts from cups, between 4 to 5.8µg BPA/g of test sample was detected, however BPA was not detected in the non-sterilized sample extracted with EtOH (limit of detection was 0.51µg). Assuming a 10g cup and the worst-case of 5.8µg BPA/g, an adult male (70kg) would be exposed to 0.829µg BPA/kg/day. Using exhaustive Soxhlet extraction with IPA, BPA was below the limit of detection (0.51µg/g) for automotive PC. Assuming a 10g sample and the worst-case of 0.5µg/g, an adult male would be exposed to 0.071µg/kg/day. The average BPA amount found in medical grade PC by exhaustive Soxhlet extraction with IPA was 0.25µg/g. For a 10g medical device, the calculated exposure for an adult male is 0.036µg/kg/day. The US FDA acceptable Daily Intake (ADI) and/or EU Tolerable Daily Intake (TDI) for BPA is 50µg/kg/day. The adult male exposures to BPA from consumer, automotive, and medical grade PC are 58, 704, and 1300 times less than US FDA ADI or EU TDI. The extractable BPA from automotive and medical grade PC was significantly less than that observed from the consumer PC.

**PS 204 Local Effects of Microelectrode Implantation in Rabbit Muscles.**

J. Yoon<sup>1</sup>, E. Cho<sup>1</sup>, S. Kim<sup>1</sup>, J. You<sup>1</sup>, Y. Kim<sup>1</sup>, E. Kwon<sup>1</sup>, B. Kang<sup>1,2</sup> and J. Che<sup>1</sup>. <sup>1</sup>Biomedical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea; <sup>2</sup>Graduate School of Immunology, Seoul National University, Seoul, Republic of Korea. Sponsor: K. Lim.

The purpose of this study was to evaluate the biocompatibility of various polymer-based microelectrodes (PBMs) after implantation in rabbit muscle tissues following a standardized method. Three types of PBMs were examined: silicone-based platinum, polyimide-based gold, and liquid crystal polymer-based gold microelectrodes. All experimental procedures followed the International Organization for Standardization (ISO) 10993-6:2007(E). Six female rabbits were used for this study. The PBMs were implanted into the left paravertebral muscle of the dorsal region of the rabbits for 12 weeks, each type being implanted into two rabbits. Control article (high density polyethylene, HDPE) was implanted in the equivalent site on the right side of each rabbit. No changes in the clinical signs, mortality, body weight, and gross findings related to the PBMs were noted. The results of histopathological evaluation suggest that the PBMs did not induce any cellular changes. Thus it could be concluded that the three types of PBMs are all non-toxic, non-irritating, and biocompatible.

**PS 205 Subchronic Systemic Toxicity of Subcutaneous Implantation of Microelectrodes in Rats.**

E. Cho<sup>1</sup>, S. Kim<sup>1</sup>, J. You<sup>1</sup>, Y. Kim<sup>1</sup>, E. Kwon<sup>1</sup>, B. Kang<sup>1</sup>, J. Che<sup>1,2</sup> and J. Yoon<sup>1</sup>. <sup>1</sup>Biomedical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea; <sup>2</sup>Graduate School of Immunology, Seoul National University, Seoul, Republic of Korea. Sponsor: K. Lim.

The purpose of this study was to evaluate the biocompatibility of various polymer-based microelectrodes (PBMs) through the subchronic systemic toxicity of subcutaneous microelectrode implantation in rats following a standardized method. Three types of PBMs were examined: silicone-based platinum, polyimide-based gold, and liquid crystal polymer-based gold microelectrodes. All experimental procedures followed the International Organization for Standardization (ISO) 10993-6:2007(E) and ISO 10993-11:2006(E). Ten female rats were used for four each groups. Control article (high density polyethylene, HDPE) and three types of PBMs were implanted subcutaneously in the same site in each group and were left in place for 13 weeks. No effects related to the microelectrodes were observed in any tested criteria, included mortality, clinical signs, body weight, food and water consumption, hematology and serum biochemistry parameters, urinalysis and ophthalmoscopy,

organ weight, gross findings, or histopathological findings. These results suggest that no subchronic systemic toxicity is induced by subcutaneous implantation of these three types of PBMs under the conditions used in this study.

**PS 206 Comprehensive Health-Based Risk Assessment of Material from an Ingestible Medical Device.**

M. A. Nascarella<sup>1</sup>, G. M. Savage<sup>2</sup>, G. Moon<sup>2</sup> and B. D. Beck<sup>1</sup>. <sup>1</sup>Gradient, Cambridge, MA; <sup>2</sup>Proteus Biomedical, Inc., Redwood City, CA.

We present an analysis of the potential toxicity of an ingestible medical device. The primary toxicological concern is an 8  $\mu\text{M}$  layer of copper (Cu), with an area of approximately 1.0  $\text{mm}^2$ , that is a component of the device's battery. The Cu content is approximately 20-33.1  $\mu\text{g}/\text{device}$ . We calculated the potential toxicological risks of Cu leached from the device, assuming a maximum use of 30 devices/event. Depending upon fluid in the stomach, an individual could have a stomach dose of approximately 219  $\mu\text{g}$  Cu, resulting in a stomach concentration ranging from 0.25-2.73  $\mu\text{g}$  Cu/mL. These concentrations may be compared to a threshold Cu concentration for gastrointestinal (GI) toxicity of 1.4  $\mu\text{g}/\text{mL}$ . In the most plausible scenario, the predicted concentration of Cu in the stomach is below the concentration associated with GI symptoms in humans, consisting of mild, reversible effects and no associated systemic toxicity. The higher potential stomach concentrations somewhat exceed the threshold concentration, but potential GI symptoms could be mitigated by ingesting the devices with food. We also estimated the potential total intake of Cu from all sources, including the device. Ingestion of the device, combined with the ingestion of median levels of Cu in food, water, and multivitamins, is estimated to be well below the 10  $\text{mg}/\text{day}$  IOM determined level of safe daily intake for the general population. We also evaluated the cytotoxicity of the extractable material from this device, based on ISO-compliant tests of device extractions using simulated gastric fluid. Using open-source software, we calculated the number of devices that would be associated with a cytotoxic effect according to ISO standards. This analysis indicated that plausible use of the devices would not lead to cytotoxic effects. Overall, we conclude that ingestion of the medical device under plausible use conditions is unlikely to present a toxicological concern for Cu.

**PS 207 Comparative Pulmonary Response to Aerosolized Humidifier Disinfectants by Intratracheal Instillation and Inhalation Exposure.**

Y. Kim<sup>1</sup>, S. Choi<sup>2</sup>, Y. Yang<sup>2</sup>, Y. Kim<sup>1</sup>, C. Song<sup>1</sup>, J. Cho<sup>1</sup>, C. Ha<sup>2</sup> and K. Lee<sup>2</sup>. <sup>1</sup>Korea Institute of Toxicology, Daejeon, Republic of Korea; <sup>2</sup>Jeonbuk Department of Non-Human Primate, Korea Institute of Toxicology, Jeongup, Republic of Korea. Sponsor: S. Park.

Mice intratracheal instillation (IT) and rat inhalation exposure (IH) were conducted to identify the toxicity of 3 representative humidifier disinfectants (products A, B, and C containing polyhexamethylene guanidine (PHMG), 5-chloro-2-methylisothiazol-3-(2H)-one/2-methylisothiazol-3(2H)-one (CMIT/MIT), and oligo(2-(2-ethoxy)ethoxyl guanidinium chloride (PGH), respectively). In mice administered by multiple 7-9 IT at 0.05 ml for 2 wk, severe necrotic obliterative bronchiolitis (OB) was found in product A and C. But no adverse treatment effect was observed in product B. In rat inhalation study (IH), necrotizing inflammation was observed in nasal cavity, larynx, trachea, and lung airways at repeated IH with product A at 0.4  $\text{mg}/\text{m}^3$  and product C at 1.75  $\text{mg}/\text{m}^3$ . However, necrotizing inflammatory lesions in the upper airways were not present in the IT due to direct administration of test substance to the lung via trachea. Granulomatous OB, bronchitis, collagenized fibrosis, alveolar bronchiolarization, and extensive squamous metaplasia were observed in product A at 10 wk IH, and product C at 7 wk IH. No treatment-related adverse effects were observed in 13 wk IH with product B at 1.80  $\text{mg}/\text{m}^3$ . Lung lesions induced by IT and IH with product A and C were comparable and no treatment-related lesions were present with product B in both IT and IH exposure. It was difficult to evaluate dose-related toxicity by IT dosing. However, IT with low dose was a useful methodology to screen and identify toxicity of test substances in this study.

**PS 208 Effect of Fuel Composition on Chemistry and Pulmonary Toxicity in Mice Exposed to Biomass Pyrolysis Vapor.**

I. Gilmour<sup>1</sup>, E. Mutlu<sup>3</sup>, B. Elizabeth<sup>1</sup>, D. Mary<sup>1</sup>, L. Copeland<sup>1</sup>, C. King<sup>1</sup>, T. Krantz<sup>1</sup>, I. George<sup>2</sup>, M. Hays<sup>2</sup>, J. Dye<sup>1</sup>, M. Higuchi<sup>1</sup> and C. Lee<sup>2</sup>. <sup>1</sup>NHEERL, US EPA, Durham, NC; <sup>2</sup>NRMRL, US EPA, Durham, NC; <sup>3</sup>CEMALB, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Biomass pyrolysis is a method to form oil through the thermal degradation of organic material in the absence of oxygen. The process results in a mix of gaseous oxides, organic vapors and particulate matter that could pose an inhalation hazard. In

this study, we characterized aerosol emissions from three different fuels (corn, pine, maple) pyrolyzed under similar conditions, and compared pulmonary and systemic toxicity endpoints in CD-1 mice after a 4h inhalation exposure. Particle number counts/cc were 37000, 48000 and 34000 for corn cob, pine and maple respectively, with median count diameters of 221, 254 and 225 nm. Particle mass was 409, 689 and 362  $\mu\text{g}/\text{m}^3$  for the three fuels, and CO measurements were 37, 39 and 45 ppm. Volatile organic analysis by GC-MS showed acrolein being 1.3, 1.7 and 2.3 ppm, with lower levels of propylene, acetone and vinyl acetate. Pulmonary responses were assessed in a plethysmograph immediately before and after exposure, as well as 4 and 24h post-exposure, when mice were euthanized. All fuels altered breathing parameters immediately following exposure, and this effect persisted at the 4h time-point for the corn cob and maple atmospheres before returning to control levels at 24h. Total protein was increased in the BALF of animals exposed to corn cob (4h and 24h post), pine (24h post), and maple (4h post), with corn having the highest effect. No other indices were affected except BALF LDH for pine, and increased hematocrits for corn cob at 24h. Because these atmospheres were considered to have high irritant characteristics, nasal lavage was also performed and although some increases in inflammatory cells were seen for the corn cob and maple atmospheres, the effects were variable. We conclude that corn cob and maple pyrolysis products seemed to have a more potent effect on pulmonary function and toxicity parameters than pine emissions. (This abstract does not reflect EPA policy).

**PS 209 Gene Expression in Bronchiolitis Obliterans-Like Lesions in Rats Exposed to 2, 3-Pentanedione.**

D. L. Morgan<sup>1</sup>, B. A. Merrick<sup>1</sup>, K. E. Gerrish<sup>2</sup>, P. S. Stockton<sup>1</sup>, J. F. Foley<sup>1</sup>, W. M. Gwinn<sup>1</sup> and G. P. Flake<sup>1</sup>. <sup>1</sup>Division of the National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>Division of Intramural Research, NIEHS, Research Triangle Park, NC.

Obliterative bronchiolitis (OB) is an irreversible lung disease characterized by progressive fibrosis in the small airways with eventual obliteration of the airway lumens. OB is most commonly associated with lung transplant rejection; however, OB has also been diagnosed in workers exposed to artificial butter flavoring (ABF) vapors. Research has been limited by the lack of an adequate animal model of OB, and as a result the mechanism is unclear and there are no effective treatments for this condition. A rat model of chemical-induced OB using the ABF component, 2,3-pentanedione (PD), was found to cause airway lesions histopathologically similar to OB lesions in humans. We used this model to evaluate changes in gene expression in the distal bronchi of rats with OB. Male Wistar Han rats were exposed to 200 ppm PD or air (controls) 6hr/d, 5d/wk for 2-wks. Distal bronchial tissues were laser microdissected from serial sections of frozen lung. In exposed lungs, both fibrotic and nonfibrotic airways were collected. Following RNA extraction and microarray analysis, differential gene expression was evaluated. In exposed nonfibrotic bronchi, 1548 genes were significantly altered relative to air-exposed controls with notable downregulation of many inflammatory cytokines and chemokines. In contrast, in PD-exposed fibrotic bronchi, 2504 genes were significantly altered with a majority of genes being upregulated in affected pathways. TGF-beta2 and downstream genes implicated in fibrosis were significantly upregulated in fibrotic lesions. Genes for collagens and extracellular matrix proteins were highly upregulated. In addition, expression of genes for peptidases and for peptidase inhibitors were significantly altered suggesting tissue remodeling that may contribute to fibrosis. These data will be used to gain a better understanding of the molecular mechanisms of OB and to identify potential therapeutic targets.

**PS 210 Polyhexamethyleneguanidine Phosphate Induces Severe Lung Inflammation, Fibrosis, and Thymic Atrophy.**

J. Song<sup>1</sup>, H. Park<sup>1</sup>, H. Yang<sup>1</sup>, M. Yang<sup>1</sup>, C. Song<sup>2</sup> and K. Lee<sup>1</sup>. <sup>1</sup>Inhalation Toxicology Center, Jeonbuk Department of Nonhuman Primate, Koeran Institute of Toxicology, Jeongup, Republic of Korea; <sup>2</sup>Korean Institute of Toxicology, Daejeon, Republic of Korea. Sponsor: S. Park.

Polyhexamethyleneguanidine phosphate (PHMG-ph) has been widely used as a disinfectant due to its strong bactericidal activity. But The Korea Centers for Disease Control and Prevention (KCDC) and Ministry of Health and Welfare reported that humidifier disinfectants might cause of the unknown pulmonary disease in 2011. The purpose of this study was to assess the potential adverse effect of PHMG-Ph, a ingredient of humidifier disinfectant, exposed to lung directly. 0.0125%, 0.0375%, and 0.0625% PHMG-Ph was instilled intratracheally into mice. Seven and fourteen days after instillation, lungs were collected and proinflammatory cytokines, chemokines and fibrotic markers were measured from lung lysates. We also performed flow cytometry to evaluate the cell distribution of thymus and RT-PCR to measure the mRNA expression associated with T cell development.

As a result, single exposure of 0.0125%, 0.0375%, and 0.0625% PHMG-Ph induced inflammatory response with increased proinflammatory cytokines and immune cell infiltration to the lungs, and interestingly, this inflammation did not resolved till the end of the experiments (14 days after instillation). The histopathology showed the both inflammation and pulmonary fibrosis exacerbated at day 14 after exposure in dose-dependent manner. Also PHMG-Ph decreased the total cell number and the CD4+/CD8+ cell proportion in thymus and induced severe medulla reduction based on histopathology data. These observations demonstrated that PHMG-Ph exposed to lung lead to pulmonary inflammation and fibrosis as well as to thymic atrophy.

## PS 211 Inhalation of a Spot Welding Aerosol Using an Adhesive Increased Airway Resistance but Not Lung Inflammation.

J. M. Antonini, A. Afshari, J. A. Thompson, J. S. Fedan, W. McKinney, T. G. Meighan, M. C. Jackson, B. T. Chen, D. Schwegler-Berry, A. Erdely, D. Frazer and P. C. Zeidler-Erdely. *NIOSH, Morgantown, WV.*

Spot welding (SW) is used in the automotive and aircraft industries where high speed repetitive welding is needed and relatively thin metal sections are welded. Epoxy adhesives are applied as sealers to the seams of the metals that are joined. SW produces complex aerosols composed of both metal and volatile compounds which may cause bronchitis and asthma in workers. The goal was to assess the effect of SW fumes on lung function and toxicity. Male Sprague-Dawley rats were exposed by inhalation to 20 mg/m<sup>3</sup> of SW aerosol in the presence of an adhesive for 4 hr/d x 8 d. Controls were exposed to air. Size distribution of the aerosol as determined by a MOUDI particle impactor was tri-modal with a MMAD of 1.66 µm in the large-fine mode, 0.30 µm in the small-fine mode, and 0.01-0.05 µm in the ultrafine mode. Two distinct particle morphologies were observed- a brownish metal particle that predominated in the small-fine particle fraction and a black, glue-like particle that was in the large-fine fraction. The metal fraction was found to be >90% Fe. Significant amounts of volatiles (e.g., benzene, toluene, others) were present, likely produced from the vaporization of the adhesive. At different times after exposure, bronchoalveolar lavage (BAL) was performed to assess lung toxicity. Lung resistance (R<sub>L</sub>) was evaluated in a separate set of animals before and after challenge with inhaled methacholine (MCh). Immediately after exposure, baseline R<sub>L</sub> was significantly elevated in the group exposed to the SW fumes. Basal R<sub>L</sub> returned to control level by 1 d after exposure. Reactivity to MCh was not affected at any time point after fume exposure. No significant increase in lung inflammation (neutrophil influx) or injury (cytotoxicity and lung epithelial permeability) was observed in BAL fluid at 1 and 5 d after exposure to SW fume. Acute inhalation of SW fumes at occupationally-relevant concentrations may act as an irritant as evidenced by the increased R<sub>L</sub> but had little effect on toxicity.

## PS 212 Cardiopulmonary Health Effects of Traffic-Related Air Pollutants in a Healthy Population.

J. E. Mirowsky<sup>1</sup>, R. Peltier<sup>2</sup>, M. Lippmann<sup>1</sup>, L. Griffith<sup>1</sup>, J. Carter<sup>3</sup>, D. Diaz-Sanchez<sup>3</sup>, W. Cascio<sup>3</sup> and T. Gordon<sup>1</sup>. <sup>1</sup>Environmental Medicine, New York University, Tuxedo, NY; <sup>2</sup>Environmental Health Science, University of Massachusetts, Amherst, MA; <sup>3</sup>US EPA, Research Triangle Park, NC.

There is emerging evidence that inhaling certain components of ambient particulate matter, specifically traffic pollutants, is associated with adverse health effects. We hypothesized that exposure to air pollution components of diesel exhaust-rich traffic, compared to cars-only traffic, produces greater adverse cardiopulmonary effects. In this case-crossover study, 23 participants were recruited to measure pulmonary function, exhaled NO, blood cytokines, heart rate variability, and blood pressure prior to, immediately after, and 24 hours after intermittent walking along 3 diverse roadways. Exposures lasted for 1.5 hours between June and September in 2011 and 2012, and personal exposures to pollutants were collected. The 3 locations differed by traffic type: the George Washington Bridge (GWB) carries truck and car traffic, the Garden State Parkway (GSP) carries only car traffic, and Sterling Forest, NY (SF) acted as a control location. Levels of PM<sub>2.5</sub>, PM<sub>10</sub>, black carbon, elemental carbon, and organic carbon were found to be highest at GWB and lowest at SF for all pollutants measured. The traffic count was similar between GSP and GWB. Using a repeated measures 2-way ANOVA, p-values were generated for time, location, and interactions between time and location. Location was a significant factor for FVC (p = 0.04) and FEV<sub>1</sub> (p = 0.05); a significant interaction term for pulse pressure was also observed (p < 0.01). Upon further analysis, systolic and pulse pressures varied significantly amongst locations when comparing the baseline and 24 hr-post measurement, while IL-1β varied amongst locations between the baseline and immediately after exposure. A trend of increasing eNO at the GWB was seen immediately after exposure, but did not reach significance (p = 0.06). These results suggest that acute effects of traffic-related pollution are observed in a small, healthy population; these effects differed by traffic type.

## PS 213 Ventricular Transcriptional Data Provide Mechanistic Insights into Diesel Exhaust-Induced Attenuation of Cardiac Contractile Response and Blood Pressure.

U. P. Kodavanti, V. L. Bass, J. Crooks, B. Vallanat, H. Ren, M. C. Schladweiler, R. F. Thomas, T. Krantz, C. King, C. J. Gordon and A. D. Ledbetter. *EPHD/NHEERL/ORD, US EPA, Research Triangle Park, NC.*

Human exposure to diesel exhaust (DE) has been associated with cardiovascular impairments however the mechanisms and the role of hypertension are not well understood. We have shown that DE reduces blood pressure (BP) and cardiac contractility in healthy normotensive Wistar Kyoto (WKY) rats. We hypothesized that DE would induce differential myocardial gene expression changes that modulate contractility in WKY and spontaneously hypertensive (SH) rats, and that lowering BP in WKY and SH with hydralazine (HYD) would increase this effect of DE. Male WKY and SH rats were treated with HYD (150 mg/L) in drinking water for 10 days prior to exposure and until necropsy. All rats were exposed to clean air or freshly-generated whole DE (1500 µg/m<sup>3</sup>), 5-hrs/day for 2-days. Systolic BP was monitored using the tail-cuff method on days -10, 0, and 2. Left ventricular genome-wide expression was analyzed using Illumina RatRef-12 BeadChips. As expected, WKY and SH rat's ventricular gene expression patterns differed markedly. Surprisingly, DE exposure caused differential expression of 256 genes in WKY but none in SH rats. In WKY rats, the effect of HYD on expression patterns were nearly identical to changes induced by DE (same genes with same directional change); while HYD was without effect on expression changes in SH rats despite lowering BP. Genes inhibited by DE or HYD in WKY were induced at baseline in SH and vice versa. These genes inhibited by DE and HYD were related to sequestration of oxidants, inhibition of proteases, and membrane stability. The genes up-regulated by DE and HYD in WKY included those involved in decreasing BP and muscle contraction as well as calcium homeostasis and apoptosis. In conclusion, acute DE exposure caused gene expression changes only in normotensive WKY rats; these changes mimicked those induced by HYD and are associated with decreased cardiac contractility and BP in healthy rats. (Abstract does not reflect USEPA policy)

## PS 214 Comparative Cardiopulmonary Toxicity of Soy Biofuel and Diesel Exhausts in Healthy and Hypertensive Rats.

M. C. Schladweiler<sup>1</sup>, V. L. Bass<sup>1</sup>, R. F. Thomas<sup>1</sup>, J. E. Richards<sup>1</sup>, D. Johnson<sup>2</sup>, D. L. Andrews<sup>4</sup>, A. Nyska<sup>3</sup>, T. Krantz<sup>1</sup>, C. King<sup>1</sup> and U. P. Kodavanti<sup>1</sup>. <sup>1</sup>EPHD/NHEERL/ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Tel Aviv University, Tel Aviv, Israel; <sup>4</sup>RCU/NHEERL/ORD, US EPA, Research Triangle Park, NC.

Increased use of renewable energy sources raise concerns about health effects of emissions from such sources. We conducted a comprehensive analysis of relative cardiopulmonary health effects of exhausts from 1) 100% soy biofuel (B100), 2) 20% soy biofuel + 80% low sulfur petroleum diesel (B20), and 3) 100% petroleum diesel (B0) in rats. Normotensive Wistar Kyoto and spontaneously hypertensive rats were exposed to these 3 exhausts at 0, 50, 150 and 500 µg/m<sup>3</sup>, 4 h/day for either 2d or 4 wk (5 d/wk) to mimic near environmental concentrations. Additionally, WKY rats were exposed for 1d and responses were analyzed 0 hr, 1d or 4d later for time course analysis. Hematological parameters, in vitro platelet aggregation, bronchoalveolar lavage fluid (BALF) markers of pulmonary injury and inflammation, ex-vivo aortic ring constriction, heart and aorta mRNA markers of atherogenesis, and serum biomarkers of acute cardiac injury as well as cytokines were analyzed. The presence of pigmented macrophages in the lung alveoli was clearly evident with all 3 exhaust exposures. Overall, exposure to all 3 exhausts produced only modest effects in most endpoints analyzed in both rat strains. BALF γ-glutamyl transferase (GGT) activity was the most consistent marker shown to be increased in both strains with all 3 fuels (B0>B100>B20) without increases in BALF neutrophils. Small inconsistent changes in aorta mRNA markers of inflammation, vasoconstriction and thrombosis, and those of serum biomarkers need to be interpreted cautiously. Our comparative evaluations show modest cardiovascular and pulmonary effects at low concentrations of all exhausts. Additionally, our study highlights the value of BALF levels of GGT activity as the most sensitive biomarker in low level inhalation studies. (This abstract does not represent USEPA policy).

**PS 215 Acute and Delayed Effects of Intermittent Ozone on Cardiovascular and Thermoregulatory Responses of Young and Aged Rats.**

A. F. Johnstone<sup>1</sup>, R. C. MacPhail<sup>1</sup>, C. Aydin<sup>2</sup> and C. J. Gordon<sup>1</sup>. <sup>1</sup>TAD, NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>Physiology, University of Uludag, Bursa, Turkey.

Ozone (O<sub>3</sub>) is associated with cardiovascular and respiratory diseases. The aged population is considered to be more sensitive to air pollutants but relatively few studies have demonstrated increased susceptibility in animal models of aging. To study the acute and delayed physiological responses to O<sub>3</sub>, core temperature (T<sub>c</sub>) and heart rate (HR) monitored by telemetry in adult (12 m) and senescent (24 m) Brown Norway rats exposed to intermittent O<sub>3</sub> (1.0 ppm, 6 hr/d for 2 consecutive d for 12 wk). T<sub>c</sub> and HR dropped precipitously in both age groups during the 1st bout of O<sub>3</sub> exposure; T<sub>c</sub> decreased from ~38 to ~35 °C while HR decreased from ~300 to ~175 b/min. These acute responses were attenuated during the 2nd day of O<sub>3</sub>. As O<sub>3</sub> exposures continued, the acute T<sub>c</sub> and HR responses abated but the aged animals were consistently less affected than the young adults throughout the 12 wk exposure period. During 5 d of recovery in home cages, both young and senescent rats displayed a fever-like ~0.5 °C elevation in daytime T<sub>c</sub>. HR was also elevated in the young adults during recovery. The rise in T<sub>c</sub> persisted for 2-3 d after O<sub>3</sub>. The O<sub>3</sub>-induced fever was marked following the 1st exposure, abated by the 3rd exposure week but then gained in magnitude throughout the remainder of the study. We postulate that inflammatory responses of the respiratory system to O<sub>3</sub> are exacerbated in younger animals, leading to accentuated acute physiological responses compared to that of senescent rats. This is an abstract of a proposed presentation and does not reflect US EPA policy.

**PS 216 Dose and Effect of Inhaled Ozone in Resting versus Exercising Human Subjects: Comparison with Resting Rats.**

G. E. Hatch, J. McKee, J. S. Brown, B. McDonnell, E. Seal, J. Soukup, R. Slade, K. Crissman and R. B. Devlin. Environmental Public Health Division, US EPA, Research Triangle Park, NC.

**Rationale:** Human controlled exposure studies have generally focused on subjects exposed to ozone (O<sub>3</sub>) while exercising. We exposed resting subjects to labeled O<sub>3</sub> (<sup>18</sup>O<sub>3</sub>, 0.4 ppm, for 2 hr) and compared O<sub>3</sub> dose and effects with our previously published study of exercising subjects.

**Methods:** We measured O<sub>3</sub> dose as the concentration of <sup>18</sup>O in cells and extracellular material of nasal, bronchial and bronchoalveolar lavage fluid (BALF) immediately post exposure and related these measurements to O<sub>3</sub> effects on inflammation, epithelial permeability and phagocytosis in the same fluids and to breathing parameters measured during the <sup>18</sup>O<sub>3</sub> exposure. A parallel study of resting subjects examined FEV<sub>1</sub> changes during and immediately following a 2 hr exposure to 0.18, 0.25, 0.3 and 0.4 ppm O<sub>3</sub>.

**Results:** Subjects exposed while resting had <sup>18</sup>O concentrations in BALF and nasal lavage that were proportional to the amount of air breathed during exposure. Significant but small changes were observed in BALF total cells and neutrophils and in BALF cell phagocytosis following resting O<sub>3</sub>, however, most indicators of O<sub>3</sub> effects that were observable in exercising subjects (including increased BALF supernatant protein, lactate dehydrogenase, interleukin-6 and low molecular weight antioxidants) were not observed in resting subjects. The <sup>18</sup>O incorporation into BALF of resting humans was similar to that of similarly exposed resting F344 rats. FEV<sub>1</sub> changes in resting human subjects showed a much attenuated response compared to exercising subjects.

**Conclusions:** Quantitative measures of alveolar O<sub>3</sub> dose and toxicity that were observed previously in exercising subjects were greatly reduced or non-observable in O<sub>3</sub> exposed resting subjects. Resting rats and resting humans have similar alveolar O<sub>3</sub> dose. **Disclaimer:** This abstract does not represent E.P.A. policy.

**PS 217 Biological Responses in Rats Exposed to Mainstream Smoke from a Heated Cigarette Compared to a Conventional Reference Cigarette.**

H. Fujimoto<sup>1</sup>, H. Tsuji<sup>1</sup>, I. Fukuda<sup>1</sup>, T. Nishino<sup>1</sup>, M. K. Lee<sup>2</sup>, R. Renne<sup>3</sup> and H. Yoshimura<sup>1</sup>. <sup>1</sup>R&D Group, Japan Tobacco Inc., Yokohama, Japan; <sup>2</sup>Scientific and Regulatory Affairs, Japan Tobacco International S.A., Geneva, Switzerland; <sup>3</sup>Roger Renne ToxPath Consulting, Sumner, WA.

The heated cigarette (HC) generates mainstream smoke (MS) primarily by vaporizing the components of the tobacco rod using a carbon heat source at the cigarette tip. Consequently, MS of HC contains markedly less chemical constituents compared to conventional (combusted) cigarettes. In this study, MS from a non-ventilated HC (nvHC) was generated under a modified Canadian Intense Regimen

(CIR) and its biological activities were compared to those of Reference (3R4F) cigarettes, using nose-only inhalation studies. In a 5-week inhalation study, female SD rats were exposed to MS of either cigarette at 600 or 1000 µg wet total particulate matter (WTPM) /L for 1 hr, 2 times/day, 7 days/week for 5 weeks. Pulmonary inflammation was significantly weaker in nvHC groups compared to 3R4F groups, based on the neutrophil counts and deviation enzyme levels in bronchoalveolar lavage fluid (BALF). After a 4-week recovery, BALF parameters of nvHC groups were similar to the air-exposed Sham group, while those of 3R4F groups remained elevated. In a 13-week inhalation study, male and female SD rats were exposed to MS from each cigarette at 200, 600, or 1000 WTPM µg/L for 1 hr/day, 7 days/week for 13 weeks. Histopathological changes in the respiratory tract were significantly lower in incidence/severity for nvHC groups, especially in respiratory epithelial hyperplasia and accumulation of pigmented macrophages in alveoli. After a 13-week recovery, the lesions were completely or partially regressed, except for accumulation of pigmented macrophages in alveoli, in both nvHC and 3R4F groups. In conclusion, nvHC demonstrated clearly and significantly lower biological activities compared to 3R4F, based on the BALF parameters and histopathology.

**PS 218 A Cross-Regulatory T Cell Response in Pulmonary Hypertension.**

G. Grunig, W. Chen, C. Hoffman, T. Gordon and S. Park. NYU Medical Center, Tuxedo, NY.

Exposure to urban air pollution (fuel emissions, particulate matter) has been associated with the exacerbation of autoimmune diseases. Our studies are focused on the mechanism of immune response induced pulmonary hypertension. We have shown that co-exposure of mice to inhaled antigen and urban particulate matter (PM) exacerbates pulmonary arterial remodeling and induces pulmonary hypertension. The current studies were performed with neutralizing anti-cytokine antibodies to identify the critical mediators for pulmonary hypertension and the interactions in the mediator-network.

Sensitized mice were intranasally challenged with either antigen (Ovalbumin) combined with urban PM2.5 (collected in New York City), or given saline. Groups of mice were injected with neutralizing anti-Interleukin (IL)-13, or anti-IL-17A/F antibodies alone or in combination, or control antibody. Right ventricular systolic pressures and immune response markers in the lungs were measured.

Intranasal challenge with antigen and urban PM significantly increased right ventricular systolic pressures. Only combined, but not single, injections with IL-13 and IL-17A/F-blockers significantly reduced this outcome. Surprisingly, injections with single neutralizing antibodies not only significantly reduced the inflammatory markers known to be regulated by IL-13 or IL-17A/F, but also revealed cross-inhibition of these markers. For example, the increased expression of the antigen presentation molecule, major histocompatibility class II (MHCII), by airway dendritic cells was inhibited by the IL-13 blocker given alone or in combination, while the IL-17A/F blocker lead to an increase in MHCII expression. Conversely, infiltration of the airways with neutrophils was inhibited by the administration of the IL-17A/F blocker given alone or in combination, while injections with the IL-13 blocker increased neutrophil influx.

In conclusion, exposure to antigen and urban PM induced pulmonary hypertension by elaborating a mixed immune response that has at least two, cross-regulatory arms that are controlled by IL-13 and IL-17A/F, respectively.

**PS 219 Capsule-Based Aerosol Generator (CBAG)—Validation in a Rat Model of LPS-Induced Nonallergic Pulmonary Inflammation.**

S. Jordan, S. Moore and R. Armstrong. Huntingdon Life Sciences, Huntingdon, United Kingdom. Sponsor: E. Moore.

Intratracheal (IT) insufflation is the principal method of delivery of inhaled drug substances to conscious non-clinical species in early drug development; however, this achieves particulate deposition dissimilar to conscious inhaled delivery and can produce artefactual toxicological and pharmacological results. The CBAG was developed(1) as an alternative to IT insufflation whilst providing representative inhalation exposure by demonstrating the effectiveness of the CBAG in the rat model of LPS-induced non-allergic airway inflammation. Rats were exposed to 0.01, 0.1 or 1.0 mg/kg of inhaled fluticasone propionate (FP) over a 20-minute period using nominally 1 mg filled hydroxypropyl methyl cellulose size 2 capsules at blend strengths of 1, 10 and 100% w/w of FP respectively. Two concurrent control groups were exposed to lactose only using the same regime. Twenty minutes after the end of the inhalation exposure the animals were challenged with either aerosolised LPS (0.1 mg/mL) for the FP groups and one control group or 0.9% w/v saline (second control group) for 30 minutes. Rats were euthanized 4hrs following the challenge

and a bronchoalveolar lavage (BAL) investigation performed. A BAL total and differential cell count was used to evaluate the efficacy of FP. Delivered doses of 0.0103, 0.117 and 0.863 mg/kg were achieved, which were within 14% of target. This resulted in a dose dependent inhibition of BAL neutrophils of 40%, 79% and 98% respectively compared with the lactose/LPS control group. In conclusion, the results give confidence that the CBAG is a viable alternative to IT methodology for studies in early drug development and has the added advantage of producing results representative of inhaled exposures.

## PS 220 Distinct Inflammatory Macrophage Subpopulations and Myeloid-Derived Suppressor Cells Accumulate in the Lung and Spleen following Exposure of Mice to Inhaled Ozone.

D. L. Laskin<sup>1</sup>, H. M. Choi<sup>1</sup>, J. D. Laskin<sup>2</sup> and M. Mandal<sup>1</sup>. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Ozone is an ubiquitous urban air pollutant known to damage the lung. Activated macrophages (MP) and inflammatory mediators they produce have been implicated in ozone toxicity. However, the phenotype and origin of these cells have not been established. In these studies, techniques in flow cytometry were used to assess macrophage subpopulations in the lung, spleen and bone marrow following ozone inhalation. Exposure of C57Bl/6 male mice to ozone (0.8 ppm, 3 h) resulted in increased bronchoalveolar lavage (BAL) protein levels after 24-72 h, indicative of alveolar epithelial injury. This was correlated with a rapid and persistent increase in the percentage of CD11b+F4/80+ inflammatory macrophages in BAL. An increase in F4/80 negative CD11b+Ly6C+Ly6G+ myeloid-derived suppressor cells (MDSCs) was also observed in BAL, a response most prominent 24 h post ozone exposure. Conversely, F4/80 positive CD11b+Ly6C+Ly6G+ MDSCs decreased in BAL after ozone exposure. We also found that ozone exposure resulted in a persistent decrease in CD11b+F4/80+ inflammatory macrophages, and a transient increase in CD11b-F4/80+Ly6C+Ly6G+ MDSCs in the spleen. In contrast, there were no changes in bone marrow cell subpopulations after ozone inhalation. Taken together, these results suggest that the spleen is a source of inflammatory MP in the lung following ozone exposure; moreover, subpopulations of MDSCs originating in the lung and the spleen may contribute to early inflammatory responses in the lung and to processes of injury and repair. Supported by NIH grants GM034310, ES004738, CA132624, AR055073, ES007148, ES005022.

## PS 221 Compare *In Vitro* Endothelial Cell Release of Endothelium Derived Vasodilators in Response to Diesel, Biodiesel Blend and Biodiesel Neat Combustion Extract.

L. Bhavaraju<sup>1</sup>, A. Williams<sup>2</sup>, T. Kormos<sup>3</sup> and M. Madden<sup>4</sup>. <sup>1</sup>Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>National Renewable Energy Laboratory, Golden, CO; <sup>3</sup>NERL, ORD, US EPA, Research Triangle Park, NC; <sup>4</sup>EPHD, NHEERL, US EPA, Chapel Hill, NC.

Diesel exhaust exposure in controlled human chamber studies found exposure induced inhibition of vasodilation. Particles emitted in exhaust can translocate into the vascular system however when particles are dissolved in solvents of various polarity the insoluble fraction separates from the soluble fraction. We collected the soluble fraction of combusted particles dissolved in DMSO for evaluation of the extract to interfere with the release of endothelium derived vasodilators. Endothelium dependent vasodilation is dependent on 6-keto PGF1alpha (6keto) a vaso-active metabolite of arachidonic acid. We have investigated the effects of diesel, biodiesel blend and biodiesel neat for a change in 6 keto release from three cell lines: endothelial hybrid cell line (EA hy 926 cells), primary human umbilical vein endothelial cells (HUVEC) and primary human coronary artery endothelial cells (HCAEC). ELISA results of EA hy 926 cells with extract exposure for 24hrs indicate a statistically significant (p<0.009) increase in 6keto from control and 100µg/mL of biodiesel neat (B100). However ELISA results from HUVEC and HCAEC exposed to extract for 6, 8 and 24hrs indicate no statistically significant change in 6keto release. QPCR data from extract exposure indicates there is no increase in markers of inflammation. However there is a measureable increase in heme oxygenase-1(HO-1) gene expression. HUVEC and HCAEC with 8hr extract exposure to B100 at 100µg/mL have over two fold increase in HO-1. The B100 particle composition analysis indicates high levels of Zn and Fe compared to biodiesel blend and diesel. In our work we address a possible mechanism for attenuation of vaso-active arachidonic acid metabolites in endothelial cells exposed to diesel, biodiesel blend and biodiesel neat particle extracts. [This is an abstract of a proposed presentation and may not necessarily reflect official US EPA Policy.]

## PS 222 Role of CD36 in Ozone (O<sub>3</sub>)-Induced Lung Injury, Inflammation, and Vascular Dysfunction.

S. Robertson, S. N. Lucas, P. Hall, M. Paffett and M. J. Campen. *University of New Mexico, Albuquerque, NM.*

Ground level O<sub>3</sub> can damage the cardiovascular system. A lack of a clear mechanism explaining O<sub>3</sub>-induced vascular health effects hinders the effectiveness of policies for achieving better health. Evidence suggests that inhaled pollutants evoke a systemic inflammatory response that causes endothelial injury and dysfunction. Using serum from O<sub>3</sub>-exposed mice, we found that circulating components impaired acetylcholine (ACh) vasorelaxation in aortas from naïve wild type (WT) mice. However, the mechanistic interaction(s) between circulating factors and endothelial cells is unknown. To address this issue we turned our attention to pattern recognition receptors (PRRs), such as CD36 (cluster of differentiation 36), as mediators of vascular abnormalities following O<sub>3</sub> exposure. PRRs are capable of detecting danger signals released by stressed or injured cells. We hypothesized that activation of endothelial CD36 following acute O<sub>3</sub> exposure mediates cross-talk between lung-derived circulating factors and vascular endothelium, culminating in endothelial dysfunction.

Female C57 wild type (WT) and CD36 knockout (KO) mice were exposed to filtered air (FA) or 1 ppm O<sub>3</sub> for 4 h. Indices of pulmonary (quantified by lavage inflammatory cells) inflammation was assessed 24 h later. The effects of exposure on ACh-induced vasorelaxation were studied using the aortic ring preparation. Parallel experiments were performed in aortas from naïve WT mice incubated with serum from exposed mice.

O<sub>3</sub>-induced infiltration of macrophages and neutrophils into the airspace in WT mice were absent in CD36 KO mice. ACh-evoked vasorelaxation of thoracic aorta of WT mice, but not CD36 KO mice, was significantly reduced after inhalation of O<sub>3</sub>. *Ex vivo* assays utilizing homologous serum demonstrated that the vascular damage caused by O<sub>3</sub>-induced circulating factors was dependent on vascular CD36 receptor expression.

Collectively, our data demonstrate that an as yet unidentified circulating factor, or factors, induced by O<sub>3</sub> exposure leads to vascular dysfunction mediated, in part, by CD36 binding in the vascular tissue.

## PS 223 *In Vitro* Endothelial Cell Model to Assess the Impact of Systemic Inflammation on Vascular Health.

M. Aragon, E. S. Colombo, M. J. Campen and S. Lucas. *Department of Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.*

Assessing the adverse vascular health effects of systemic inflammation caused by inhaled toxins has presented a substantial research challenge. Current models rely on anatomically disputable direct application of xenobiotics, especially airborne particulate matter, on cultured endothelial cells. Such assay systems fail to account for the complex interactions and toxicokinetics that occur *in vivo*. We have developed a model that takes these factors into account to better elucidate the mechanisms involved in a living system. This approach utilizes plasma or serum from exposed animals as the endothelial stimulus, as this is the component in direct contact with endothelial cells. Briefly, the serum/plasma isolated from exposed animals is incubated on endothelial cells and canonical activation pathways are assessed. In this way the endothelial cells act as a "biosensor", expressing markers of inflammation, especially cell surface adhesion molecules. In addition, nitric oxide (NO) bioavailability via electron paramagnetic resonance can be directly measured in the supernatant. We have characterized this model paradigm using primary endothelial cells from rats and mice, using known mediators (IL-6, TNF-α) to assess the range of response in order to compare endothelial cell responses to serum obtained from ozone-exposed rodents. Serum obtained 24h following exposure to 1ppm ozone for 4h caused a 2-fold increase in vascular cell adhesion molecule-1 cell surface expression on rat aortic endothelial cells, as compared to serum from filtered air-exposed rats. Similarly, we observe reductions in NO generation and elevated mRNA expression of specific markers of endothelial cell activation. The potential for this assay extends beyond the toxic effects of air pollution, with potential applications to drug safety and efficacy, as well as having prognostic value for vascular disease.

**PS 224 Interaction of Human Bronchial Epithelial Cells and Alveolar Macrophages Modifies the Innate Immune Response to Ozone.**

R. N. Bauer<sup>1</sup>, L. Mueller<sup>2</sup>, L. Brighton<sup>2</sup> and I. Jaspers<sup>1,2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Center for Environmental Medicine, Asthma, and Lung Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC.

The lining of the airway consists of airway epithelial cells and resident immune cells, which together coordinate the innate immune response to oxidant pollutants. Oxidant pollutants can damage airway epithelial cells and induce the production of soluble mediators that attract nearby immune cells, such as alveolar macrophages, and activate innate immune pathways. Using ozone (O<sub>3</sub>) as a model oxidant pollutant, we developed a human bronchial epithelial cell (HBE) and alveolar macrophage (AM) co-culture model to assess how the interaction between HBE and AM modifies the innate immune response to oxidant air pollutants. AM derived from the bronchoalveolar lavage of healthy volunteers were co-cultured with the HBE cell line 16HBEo- on transwell cell culture inserts or on transwells alone. Co-cultures, AM alone, and HBE alone were exposed to 0.4 ppm O<sub>3</sub> or clean air for 4 hours and analyzed 1 and 24 hours after O<sub>3</sub> exposure. O<sub>3</sub>-induced secretion of interleukin (IL)-1 $\beta$  and IL-8 was compared between the cultures to determine the specific cellular sources and whether the interaction between AM and HBE modifies the inflammatory response. Using flow cytometry, co-cultures or AM alone were examined for AM surface receptor expression, particularly CD44, Toll-like Receptor 4 (TLR4) and its co-receptor CD14, which recognize soluble mediators produced in response to oxidative damage. Our results suggest that co-culture of AM and HBE modifies O<sub>3</sub>-induced secretion of IL-1 $\beta$ , but not IL-8. Whereas the co-cultures had robust O<sub>3</sub>-induced IL-1 $\beta$  production, this response was blunted in both AM and HBE cultured alone. Both O<sub>3</sub>-exposed AM had altered CD14, TLR4, and CD44 expression, and co-culture further modified surface marker expression. These results suggest that HBE and AM coordinate the inflammatory response to O<sub>3</sub>, and that the interaction between HBE and AM is an important determinant of the innate immune response to inhaled oxidant pollutants.

**PS 225 Behaviour of Lactose Blends in Nonclinical Respiratory Safety Assessment Studies.**

S. Moore<sup>1</sup> and S. Cracknell<sup>2</sup>. <sup>1</sup>Huntingdon Life Sciences, Huntingdon, United Kingdom; <sup>2</sup>Huntingdon Life Sciences, East Millstone, NJ. Sponsor: D. Mitchell.

Drug/lactose powder blend range and complexity has also grown proportionally as the potency of drug molecules has increased. This review, therefore, addresses the relationship between the active drug moieties and total particulate over a range of lactose powder blend formulations before and after aerosolisation to ensure enhanced study control. Test atmosphere concentration data from studies were chemical or gravimetric analysed for drug:total particulate (TP) ratios and compared with the original blend strength (BS). Results for unmiconised blends indicated up to a 13-fold increase in drug:TP ratio for lower drug blend strengths (0.25% w/w) for non-rodent exposure systems and 9-fold for rodent systems. The fold change (FC) decreased exponentially with increasing drug BS for unmiconised blends and by 40% w/w; the FC was only 2-fold. Greater variation between different drug actives was also evident at lower blend strengths. Using stabilisers or additives resulted in a slight increase (between 0.25 and 0.50 w/w) in the drug:TP ratio over the same BS range. Comparison of 3 different lactose types indicated varying proportions of FC depending on the particle size of the lactose. Miconised Lactohale LH301 gave marginal increase in FC between BS of 0.25 and 40% w/w (1.02 to 1.11) but the FC exhibited for unmiconised Respirose SV008 gave a much greatest change over the same BS range. The FC using the same BS with different size inhalation chambers showed no difference with chamber level implying that the animals receive the same drug:lactose ratio irrespective of their position within the chamber. Comparison between the Flow-Through and Flow past chambers with different blend strengths gave a greater FC for the latter chamber type (up to 67%) due to increased lactose sedimentation related to internal geometry of the chamber. In conclusion, this approach will allow greater prediction and confidence that the gravimetric aerosol concentrations will be an accurate representation of the active drug moiety when the frequency of chemical analysis is reduced.

**PS 226 An In Vitro Cell-Based Assay to Measure the Solubilization of Indium-Containing Particles by Macrophages.**

W. M. Gwinn<sup>1</sup>, W. Qu<sup>1</sup>, R. W. Bousquet<sup>2</sup>, M. P. Waalkes<sup>1</sup> and D. L. Morgan<sup>1</sup>. <sup>1</sup>NTP Laboratory, NIEHS, Research Triangle Park, NC; <sup>2</sup>Alion Science and Technology, Research Triangle Park, NC.

Inhaled or airway-delivered indium-containing particles (ICPs) such as indium phosphide (InP) and indium tin oxide (ITO) exhibit pulmonary toxicity and are carcinogenic. Many ICPs are highly insoluble compounds which are engulfed by alveolar macrophages; however, the mechanism(s) of ICP-induced pathogenesis within the lung is unclear. We have previously shown that ICPs are cytotoxic to macrophages in vitro which is dependent upon phagolysosome acidification. In the current study, we hypothesized that macrophages phagocytose and solubilize ICPs which generates free indium ions- likely the cytotoxic constituent of ICPs. Adherent RAW 264.7 macrophages were treated with 200  $\mu$ g/ml InP particles for 24 hrs. In some groups, macrophages were pre-treated for 30 min with 5  $\mu$ g/ml cytochalasin D (cytoD), an inhibitor of phagocytosis, and then co-treated with InP + cytoD for 24 hrs. CytoD treatment blocked both the phagocytic uptake and cytotoxicity of InP particles. Cell culture supernatants were collected after 24 hrs of treatment and centrifuged to pellet any residual cells and InP particles. Cell and particle-free supernatants were then acid digested overnight and the concentration of total indium was measured using atomic absorption spectroscopy. The concentration of extracellular indium in cell culture supernatants from macrophages treated with InP particles in the absence of cytoD (91.2  $\mu$ g/L) was significantly increased and approximately 3-fold greater compared to macrophages treated with InP in the presence of cytoD (29.8  $\mu$ g/L). These data indicate that macrophages phagocytose and solubilize InP particles within lysosomes resulting in cell death and the extracellular release of free indium metal species. This cell-based assay can potentially be applied to other ICPs to determine if the in vitro macrophage solubility of different ICPs correlates with in vivo pulmonary toxicity.

**PS 227 Acute Pulmonary Heme Oxygenase-1 Protein Response to Particulate Matter in Naïve Animals As an Indicator of Allergic Adjuvant Potential.**

C. Carosino, A. Castaneda, L. E. Plummer, K. Green, Y. Zhao, K. J. Bein, A. S. Wexler and K. E. Pinkerton. Center for Health and the Environment, University of California Davis, Davis, CA.

The San Joaquin Valley (SJV) of California is home to high PM pollution and asthma symptom prevalence. Recently, source oriented sampling (SOS) approaches have been employed in the SJV to collect commonly occurring particle source combinations in the normal milieu of PM typical to the region to allow for the evaluation of their differential toxicities. Acute toxicity studies to assess differential pulmonary inflammation were performed. Additional studies were performed in an acute model of allergic airway inflammation. Studies utilized BALB/c mice, 8-10 weeks old and re-suspended particles collected and extracted by SOS methods. Naïve studies utilized dosing via oropharyngeal aspiration of 50 $\mu$ g SOS PM with tissues examined for pulmonary inflammation 24-hours post dosing. Allergic studies utilized intranasal aspiration dosing on day 1, 3, and 5 of a) vehicle control, b) 25 $\mu$ g endotoxin purified D. Farinae house dust mite allergen, HDM (allergic control), or c) HDM and 15 $\mu$ g SOS PM (45 $\mu$ g total dose). Animals were challenged on day 11, 12, and 13 with allergen alone and tissues collected on day 14. All allergen-treated animals exhibited cellular profiles indicative of an allergic response with elevations in leukocytes characterized by neutrophils, lymphocytes and eosinophils. Heme oxygenase-1 (HO-1) protein levels in homogenized pulmonary tissue of acutely exposed naïve mice were quantified as a biomarker of oxidative stress. Analysis of correlations revealed large associations between total cell, lymphocytic, eosinophilic and neutrophilic pulmonary inflammation in allergic animals in contrast to HO-1 protein levels in the tissue of acutely exposed naïve animals. Cellular inflammation in naïve acute studies did not correlate with HO-1 protein and did not accurately predict adjuvant potential. These studies suggest that pulmonary HO-1 levels in naïve acute studies and existing archived tissue may be a valuable indicator of particle adjuvant potential. Support: CARB/EPRI

**PS 228 Toxic and Mutagenic Effects of World Trade Center Dust on Cultured Human Lung Cells.**

A. M. DiLorenzo, C. Lambrousis, S. Choi and P. Rivera. Montclair State University, Montclair, NJ.

The terrible events of the September 11, 2001 World Trade Center (WTC) tragedy left many dead, injured, devastated and emotionally scarred. The effect of this tragic event was noticed even a decade later in many upper-respiratory complica-

tions resulting from the exposure to the toxic dust. The purpose of these experiments was to investigate the extent of cellular damage resulting from WTC dust exposure. This research project was conducted with cultured human lung fibroblast cells exposed to WTC dust. To determine if cell proliferation levels were affected, cultured cells were exposed to WTC dust at various concentrations ranging from 2.5 to 250 parts per million (ppm) in simulated physiological stress environments. LD 50 had previously been determined in choosing sample concentrations. Decreased serum levels were also utilized to mimic stress conditions which were to be correlated to the stress levels experienced in the exposed human population. The cultures under the various conditions were studied using both Cell Titer 96 Aqueous Non-radioactive Assay and Caspase Glo 3/7 Assay (Promega). Results indicated that cell proliferation levels decreased as WTC dust concentrations increased reaching a peak at 250ppm. This pattern persisted regardless of stress induced serum level. The serum concentrations used were 10% Fetal Bovine Serum (FBS), which represented a non-stressed system, with 2.5 and 1% FBS concentrations used to simulate stressed environments. Assessment for apoptosis, programmed cell death, resulted in higher than baseline levels in cells exposed to WTC dust in both MRC-5 (male) and WI-38 (female) human lung fibroblasts. In summary, results determined that exposure to WTC dust led to decreased cell proliferation and increased apoptosis levels. These findings evidence need for future research regarding possible mutagenic properties of World Trade Center dust. Further clarification of the small differences seen relative to gender of the exposed sample lung cells is also needed.

## PS 229 Dose Response to Sacramento Particulate Matter.

L. S. Van Winkle, D. Anderson, K. E. Pinkerton, F. Tablin, D. Wilson, K. J. Bein and A. S. Wexler. *University of California Davis, Davis, CA.*

Particulate matter (PM) exposure contributes to respiratory diseases and cardiopulmonary mortality. The toxicity of PM could be related to sources, such as vehicle exhausts, and composition, such as abundance of polycyclic aromatic hydrocarbons (PAHs). We exposed adult male balb/c mice, via oropharyngeal aspiration, to a range of doses of PM<sub>2.5</sub> collected during the winter in downtown Sacramento near a major freeway interchange (SacPM). Because the relative contribution of PAHs in SacPM might be important, and since filter extraction may alter PM biological effects, we tested two PM preparation methods (sonication/spin-down and sonication/lyophilization) at 10, 50 and 100 µg doses and analyzed the lung tissue response at 24 hrs after dosing. We analyzed 1) leukocytes and total protein in BALF, 2) airway-specific and whole lobe expression of PAH sensitive genes (CYP1B1 and CYP1A1) and IL-1b and 3) lung histology. We found both PM extraction methods stimulated similar biological responses, but the spin-down method was more robust at producing IL-1b and CYP1B1 gene responses and the lyophilization method induced whole lung CYP1A1. Neutrophils in the BALF were increased 5-fold at 50 µg and 10-fold at 100 µg. Total protein in the BALF was significantly increased at both the 50 and 100 µg doses. Histopathology scores were dose responsive and more robust in mice treated with spin-down derived PM. CYP1B1 gene expression in whole lung increased 3-fold at the 50 and 100 µg dose for this method as well, but was increased less than 1.5-fold for the lyophilization method. In microdissected airways all doses of the spin-down PM increased CYP1B1 gene expression significantly, but the lyophilized PM did not change CYP1B1. We conclude 1) the method of filter extraction can influence the degree of biological response at a given dose, 2) for SacPM the minimal effective dose for this strain of mouse and route of exposure is 50µg and 3) P450s in airways and the lung parenchyma have differential ability to be upregulated in response to PAH-containing PM. (Supported by California Air Resources Board)

## PS 230 Subchronic Inhalation Exposure of Rats to Libby Amphibole and Amosite Asbestos: Effects at 1 and 3 Months Postexposure.

G. A. Willson<sup>1</sup>, D. E. Dodd<sup>2</sup>, K. Roberts<sup>2</sup>, H. G. Wall<sup>1</sup>, J. M. Cyphert<sup>3</sup>, A. M. Jarabek<sup>4</sup> and S. H. Gavett<sup>4</sup>. <sup>1</sup>Experimental Pathology Laboratories, Inc., Research Triangle Park, NC; <sup>2</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>Curriculum in Toxicology, University of North Carolina School of Medicine Chapel Hill, Chapel Hill, NC; <sup>4</sup>US EPA, Research Triangle Park, NC.

Increased asbestosis, lung cancer, and mesothelioma rates are evident after exposures to Libby amphibole (LA). To support dosimetry model development and compare potency, a subchronic nose-only inhalation study (6 hr/d, 5 d/wk, 13 wk) was conducted in male F344 rats. Rats were exposed to air (control), LA (LO, MED, HI; 1.01, 3.33, 10.08 mg/m<sup>3</sup>; 300, 701, 4050 fibers/cc), or amosite (AM; 3.35 mg/m<sup>3</sup>; 1035 f/cc). Toxicity endpoints, pathology, and fiber burden evaluation

were determined 1 d and 1, 3, and 18 mo post-exposure. Previously reported results (Dodd, SOT 2012) showed comparable inflammatory and fibrogenic responses 1 d after exposure to MED LA and AM. Here we report BAL neutrophils were increased in HI LA and AM groups at 1 mo, but only in HI and MED LA groups at 3 mo. Macrophages were decreased in the HI and MED LA groups at 3 mo. AM and MED LA groups had comparable increases in BAL LDH and protein at 1 and 3 mo. Lung tissue cytokine production and activation of pro-fibrotic and cellular growth signaling pathways were also comparable between AM and MED LA. Histopathological examination of the lung found a minimal increase in alveolus inflammation, interstitial fibrosis, bronchiolization, and foreign body presence in both AM and LA groups compared to controls. Alveolus inflammation was most severe in HI LA rats at 1 and 3 mo compared to all other exposure groups. Only HI LA rats had bronchiole epithelial hyperplasia, but only 1 mo after exposure. These results show comparable fibrogenic responses 1 and 3 mo after subchronic exposure of rats to LA and AM asbestos. Tissue fiber burdens are being measured to support dosimetry model development of deposition and clearance (Asgharian, SOT 2012; Jarabek, SOT 2013); comparison of responses between fibers may change based on dosimetry modeling. (This abstract does not represent US EPA policy)

## PS 231 Exposure to Sumas Mountain Chrysotile Induces Similar Gene Expression Changes As Libby Amphibole but Has Greater Effect on Long-Term Pathology and Lung Function.

J. M. Cyphert<sup>1,2</sup>, A. Nyska<sup>3</sup>, R. K. Mahoney<sup>4</sup>, M. C. Schladweiler<sup>2</sup>, U. P. Kodavanti<sup>2</sup> and S. H. Gavett<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, UNC School of Medicine, Chapel Hill, NC; <sup>2</sup>EPHD, NHEERL, US EPA, Research Triangle Park, NC; <sup>3</sup>Sackler School of Medicine, Tel Aviv University, Timrat, Israel; <sup>4</sup>EMSL Analytical, Inc., Libby, MT.

This study was designed to provide understanding of the toxicity of naturally occurring asbestos (NOA) including Libby amphibole (LA), Sumas Mountain chrysotile (SM), El Dorado Hills tremolite (ED) and Ontario ferroactinolite cleavage fragments (ON). Rat-respirable fractions (aerodynamic diameter ≤ 2.5 µm) were prepared by water elutriation and a dose of 1.5 mg/rat delivered via a single intratracheal (IT) instillation. Bronchoalveolar lavage (BAL), gene expression, histopathology, and lung function were analyzed 1 d, 3 mo, or 15 mo post-instillation.

One day after exposure, although inducing less acute inflammation than other samples, LA and SM induced a greater degree of lung injury. A similar trend was also observed in gene expression profiles, as both LA- and SM-exposed rats differed significantly from dispersion media (DM) controls. Changes were suggestive of dysregulation of both extracellular matrix and fibrosis pathways. By three months, most BAL parameters had returned to DM control levels. However, significant time-dependent fibrosis was evident in rats exposed to LA or SM. By 15 months, the greatest fibrotic changes were observed in SM-exposed rats; while no fibrosis was noted in the cleavage-fragment or DM control group (SM>LA>ED>ON=DM). Consistent with the greatest degree of fibrosis, only SM-exposed rats exhibited persistent, long-term changes in lung function parameters. These data demonstrate that, in the rat, SM resulted in more significant long-term effects after a single IT exposure than LA. This study suggests that there may be cause for concern for people at risk of being exposed to NOA from the Sumas Mountain landslide, and highlights the need for further study of sites where NOA is present. (This abstract does not represent U.S. EPA policy).

## PS 232 Lack of Sex Difference in Nasal Glutathione Response to Naphthalene.

J. A. Cichocki<sup>1</sup>, L. S. Van Winkle<sup>2</sup>, G. J. Smith<sup>1</sup> and J. B. Morris<sup>1</sup>. <sup>1</sup>Toxicology, University of Connecticut, Storrs, CT; <sup>2</sup>Veterinary Medicine, University of California Davis, Davis, CA.

At concentrations of 10 ppm or greater, naphthalene (NA) is a nasal carcinogen inducing respiratory adenomas in male and olfactory neuroblastomas in female rats, respectively. The proposed carcinogenic mode of action includes metabolic activation via CYP450 to an electrophile with subsequent glutathione depletion, escape of electrophile, and covalent binding. Respiratory and olfactory mucosa are tumor target sites and both contain NA CYP450 activating capacity; the activity in olfactory exceeds that in respiratory mucosa by 3-fold. To fully define the effect of NA on nasal glutathione, male and female F344 rats were exposed to 0, 10, or 30 ppm NA for 1, 4, or 6 hours. Following exposure, nasal olfactory and respiratory tissues were analyzed for reduced/oxidized glutathione levels (GSH/GSSG). Female control rats had twice the levels of GSH compared to male controls, but NA exerted similar effects on GSH in both genders. GSH was depleted at all times; in females,

respiratory and olfactory mucosal levels were ~45 and 70% of control levels (respectively) after 10 or 30 ppm, an effect that did not correlate with local CYP450 activation rates. Similar trends were seen for male rats. To fully define the concentration response, rats were exposed to 0, 0.5, 1, 3, 10, or 30 ppm NA for 4 hours. Significant GSH depletion occurred at all exposure levels in respiratory and olfactory mucosa with maximal depletion (about 30 and 60% of control levels, respectively) occurring at or above 1 ppm. Similar trends were seen in both males and females. NA, at concentrations well below those shown to be carcinogenic, causes significant depletion of GSH in the nose. The degree of GSH depletion in different nasal regions does not correlate with activation rates, suggesting that other factors contribute to the GSH response. No sex difference was observed in GSH response, suggesting that the sex difference in tumor response cannot be attributed to this step in the carcinogenic mode of action. (Supported by the Naphthalene Research Council)

**PS 233 Acetaminophen at Low Doses Depletes Airway Glutathione and Alters Respiratory Reflex Responses.**

G. J. Smith, J. A. Cichocki, J. E. Manautou and J. B. Morris. *Toxicology Program, University of Connecticut, Storrs, CT.*

In the past three decades the prevalence of asthma has more than doubled. The reasons for this increase are unknown. Several hypothetical mechanisms have been proposed, but none have been proven. The "acetaminophen (APAP) hypothesis", first derived from epidemiological data, postulates that pediatric use of acetaminophen, by decreasing lung antioxidant defenses, increases asthma risk. APAP (N-acetyl-para-aminophenol, is an analgesic thought to be safe at therapeutic doses. APAP is activated by CYP450 to a reactive intermediate that conjugates with, and depletes, the important antioxidant, glutathione (GSH). To determine if this occurs in the airways, female C57Bl/6J mice were administered APAP (ip) at non-hepatotoxic doses (30, 60, or 100 mg/kg) followed by measurement of tissue non-protein sulfhydryl (NPSH) (~90% of which is GSH). A dose and time dependent reduction in NPSH levels occurred with maximal depletion to ~60% of control at 1 hr in the liver, and at 2 hrs in the lung, trachea, and nose. Inhalation exposure to reactive electrophilic vapors, such as acrolein, stimulates the trigeminal nerve Transient Receptor Potential A1 (TRPA1) receptor and elicits the sensory irritation response. (The role of TRPA1 has been confirmed in our model via use of TRPA1 knockout mice.) Acrolein acts at intracellular N-terminal cysteines of the TRPA1 receptor; we reasoned that APAP, by decreasing GSH would increase the amount of acrolein available to interact with TRPA1. APAP (100 mg/kg 1 hr prior to acrolein exposure) increased the irritation response by 75% over that of acrolein alone. Nasal NPSH levels in acrolein/APAP exposed mice were reduced to 88, 69, and 59% of control at 30, 60, and 100 mg/kg, respectively. These results suggest that APAP, at near therapeutic doses, causes depletion of airway GSH to levels sufficient to modulate acute respiratory responses. These findings lend support to the APAP hypothesis. (Supported by the UConn Presidents Research Award)

**PS 234 Upper Respiratory Lesions in Rats Administered Amiodarone Hydrochloride Solution Orally for 4 Days by Intraesophageal Dosing: Absence of the Lesion by Intragastric Dosing.**

S. Ogata, Y. Nezu, T. Watanabe, S. Takada, Y. Tani and W. Takasaki. *Medicinal Safety Research Laboratories, Daiichi-Sankyo, Tokyo, Japan.*

Upper respiratory (UR) tract can be damaged by compounds administered orally. Retrograde exposure of nasal passage to dose formulation from the esophagus has been suggested as one of the toxicological mechanisms (Damsch et al. *Toxicol Pathol*, 2011). However, literatures are limited with this toxicity of orally administered drugs in clinical use and the toxicological significance remains unclear. Amiodarone hydrochloride (AM) is an antiarrhythmic agent administered orally and intravenously in clinical use. We demonstrated AM induces UR lesions in rats by gavage dosing for 4 days with a metallic tube. Retrograde exposure of the nasal passage to dose formulation was suggested because incidence of the lesion was higher in the posterior nasal passage than the anterior one (Ogata et al., *JSTP Annual Meeting*, 2011). Furthermore, irritability of the dose formulation to nasal epithelium was confirmed based on induction of UR lesions after single intranasal dosing (Ogata et al., *JSOT Annual Meeting*, 2012). To examine the effect of the dosing procedure on the lesions, rats were administered 150 mg/kg AM by a catheter instead of a metallic tube and the UR lesions were compared histopathologically with those obtained in the former study with a metallic tube. In this study, no UR lesions were observed in rats given AM with a catheter. Cmax and AUC was

equivalent between dosing procedures with the catheter and metallic tube after a single dose. The results suggest that the UR lesions in rats given AM by a metallic tube is not attributable to systemic exposure alone. Dependence on metallic tube dosing may suggest low toxicological relevance of the UR lesions. Furthermore, catheter dosing would be an option to evaluate toxicological significance of gavage-related UR lesion, with equivalent Cmax and AUC obtained by metallic tube dosing, and without possible concern specific to dosing from parenteral or feeding routes.

**PS 235 A High-Fructose Diet Attenuates Adaptation of Nasal Epithelium to Subacute Ozone Exposure in Mice.**

J. Harkema<sup>1,2</sup>, P. Brooks<sup>1</sup>, K. M. Allen<sup>1,2</sup>, M. Dereski<sup>1</sup>, R. Lewandowski<sup>1,2</sup>, D. Jackson<sup>1</sup>, L. Bramble<sup>1,2</sup> and J. G. Wagner<sup>1,2</sup>. <sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>US EPA Great Lakes Air Center for Integrated Environmental Research, East Lansing, MI.

**INTRODUCTION:** Ozone (O<sub>3</sub>) is a common oxidant air pollutant and inhaled respiratory toxicant. Repeated inhalation exposures to high ambient concentrations of O<sub>3</sub> cause an adaptive epithelial change, mucous cell metaplasia (MCM), in the nasal airways of laboratory rodents and nonhuman primates. Since airway mucus is a known anti-oxidant, MCM with increases in mucus-secreting cells, is a defensive response of airway epithelium to minimize further oxidant injury caused by inhaled irritants. Unhealthy diets associated with the metabolic syndrome may adversely affect the host's normal response to inhaled pollutants. The present study was designed to determine the effect of a high fructose diet (HFD) on the adaptive MCM response of nasal epithelium to O<sub>3</sub>. **METHODS:** C57/Bl6 male mice were exposed to 0 (controls) or 0.5 ppm O<sub>3</sub>, 4h/day, for 24 consecutive week days. Half of the mice were fed a normal diet (ND) and the other half were fed a HFD. Mice were sacrificed 24h after the last day of O<sub>3</sub> exposure. Nasal tissues were processed for light microscopy and morphometric analysis. **RESULTS:** No exposure-related nasal lesions were found in filtered air-exposed control mice fed either diet. ND-fed mice exposed to O<sub>3</sub> developed marked MCM in nasal transitional epithelium that was accompanied by a mucosal influx of eosinophils. In contrast, HFD-fed mice had minimal nasal MCM and few mucosal eosinophils (85 and 60% less, respectively, compared to ND mice) after O<sub>3</sub> exposure. **CONCLUSIONS:** In mice, a HFD significantly altered the MCM adaptation of nasal epithelium to O<sub>3</sub> exposure. Underlying mechanism(s) responsible for this diet-induced alteration in host response and its possible human health implications are yet to be determined. Funded by USEPA RD83479701.

**PS 236 Morphometric Assessment of Concentration- and Time-Dependent Injury in the Nasal Airways of Rats Exposed to Chlorine Gas.**

A. M. Jarabek<sup>2</sup>, A. Watkins<sup>1</sup> and J. Harkema<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>US EPA, Research Triangle Park, NC.

Chlorine (Cl<sub>2</sub>) is an oxidizing chemical used in industrial processes and as a household disinfectant. It is also an inhaled toxicant that causes airway injury, ranging from minor irritation to death, depending on exposure conditions. Due to its toxicity and availability, Cl<sub>2</sub> is considered a chemical threat agent. Understanding the airway pathology of inhaled Cl<sub>2</sub> is critical to both preventing and treating its toxicity. In rodents, the nose is a primary target organ for inhaled Cl<sub>2</sub>. Risk assessment approaches rely on the daily concentration times time (C x t) product for extrapolation of effect levels across studies of different duration (Haber's Rule). This Cl<sub>2</sub> inhalation study in rats was designed to determine the contribution of daily C x t product and exposure duration to the severity of nasal injury. Cl<sub>2</sub> was one of the gases on which Haber's Rule was based, but emerging understanding of its pathobiology suggests that the relationship does not hold. We hypothesized that the daily C x t product does not capture the occurrence and magnitude of Cl<sub>2</sub>-induced toxicity. Rats were exposed to equivalent combinations of daily C x t inhaled Cl<sub>2</sub> for acute (6 ppm for 1 h; 1 ppm for 6 h; 0.25 ppm for 24 h) or subacute and subchronic (1 ppm, 6h/d for 5d, 10d or 90d) durations. The amount of histochemically stained mucosubstances in nasal transitional epithelium was morphometrically determined as a quantitative measure of the severity of Cl<sub>2</sub>-induced mucous cell metaplasia (MCM). Only rats subacutely or subchronically exposed to Cl<sub>2</sub> developed this lesion and the magnitude of MCM markedly increased with duration. Our results indicate that daily C x t product alone is not a good estimator of Cl<sub>2</sub>-induced MCM and exposure duration is an important determinant of the risk to Cl<sub>2</sub>-induced nasal toxicity. Funded by EP-12-C-000052. (The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.)

**PS 237 Diacetyl-Induced Respiratory and Olfactory Toxicity in Mice: Influence of Ubiquitination, Gender, and Dicarboxyl/L-Xylulose Reductase Gene Knockout.**

A. F. Hubbs<sup>1</sup>, K. L. Fluharty<sup>1</sup>, M. P. Goravanahally<sup>2,1</sup>, R. J. Edwards<sup>2,1</sup>, M. L. Kashon<sup>1</sup>, L. Sargent<sup>1</sup>, R. R. Mercer<sup>1</sup>, M. C. Jackson<sup>1</sup>, A. M. Cumpston<sup>1</sup>, W. T. Goldsmith<sup>1</sup>, J. S. Fedan<sup>1</sup>, R. D. Dey<sup>2</sup>, L. A. Battelli<sup>1</sup>, T. Munro<sup>1</sup>, W. B. <sup>1</sup>HELD, NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV.

The  $\alpha$ -dicarbonyl butter flavoring, diacetyl (2,3-butanedione), is associated with flavorings-related constrictive bronchiolitis in workers who make or use flavorings. Diacetyl causes protein damage in a process believed to be dependent upon the  $\alpha$ -dicarbonyl structure. A protective response to damaged protein is ubiquitination with subsequent proteasomal processing. Diacetyl is also metabolized to the less reactive  $\alpha$ -hydroxyketone, acetoin, by dicarbonyl/L-xylulose reductase (Dcxr). We examined the role of Dcxr and gender on acute toxicity of inhaled diacetyl by exposing Dcxr knockout and wildtype mice of both sexes to diacetyl at target concentrations of 0, 100, 200 or 300 ppm for 6 hr. At 1 day post-exposure, endpoints were semi-quantitative histopathology and morphometric measurement of ubiquitin immunofluorescence in nose and lung sections. Ubiquitin was principally localized to nasal and intrapulmonary airways, increased in large bronchioles at concentrations  $\geq 100$  ppm, and in the nose at 300 ppm. Diacetyl-induced ubiquitin in the nose and lung was modified by both gender and Dcxr. In lung histopathology, diacetyl caused vacuolation of airway epithelium of large bronchioles at concentrations  $\geq 100$  ppm. In olfactory bulb (OB) of male mice inhaling 300 ppm diacetyl, mRNA expression of inflammatory mediators and olfactory marker protein (Omp), a marker of olfactory neuron axons, were assayed by real-time PCR. Diacetyl elevated Il6, Cxcl2, and Tnfa and decreased Omp in OB. The data suggest that ubiquitin expression is a sensitive biomarker of diacetyl-induced protein damage in airway epithelium. Further, diacetyl causes neuroinflammation and potential loss of axons of olfactory neurons in OB, suggestive of neurotoxicity.

**PS 238 Subchronic Exposure to Ambient Particulate Matter Induces Oxidative Stress Responses in Brain Tissue of ApoE-/- Mice.**

L. B. Mendez<sup>1</sup>, A. J. Keebaugh<sup>1</sup>, L. Chen<sup>2</sup>, M. Lippmann<sup>2</sup> and M. T. Kleinman<sup>1</sup>. <sup>1</sup>University of California Irvine Irvine, CA; <sup>2</sup>New York University, New York, NY.

Exposure to particulate matter (PM), present in urban environments, has been shown to induce pro-inflammatory and oxidative stress responses in the central nervous system (CNS) of apolipoprotein E knockout (ApoE-/-) and Balb/c mice. In this study oxidative stress responses in different subcellular fractions of the ApoE-/- mouse brains were evaluated after a subchronic exposure to fine ( $\leq 2.5$   $\mu$ m) concentrated ambient particles (CAPs). Apo E-/- mice were exposed to either CAPs or particle-free air for 5 hours a day, 5 days per week, for a period of 6 months. The whole-body inhalation exposures were conducted in two urban cities (Seattle, WA and Detroit, MI) with distinct sources and chemical composition of PM. Brain tissue was collected after the exposures were completed and analyzed for biomarkers of oxidative stress. The antioxidant glutathione was reduced in the brains of mice exposed to CAPs in Michigan but not in Washington. In contrast the lipid peroxidation product 4-hydroxyalkenal (HNE) was significantly increased in the membrane fraction of brain tissue of mice exposed to CAPs in Washington but not in Michigan. No significant differences were observed in protein carbonyl levels, a biomarker of protein oxidation, although the levels were slightly higher in the cytoplasmic fraction of brain tissue from animals exposed to CAPs when compared to controls regardless of exposure site. The results suggest that PM from different sources can modulate oxidative stress responses in a distinct fashion and that different subcellular fractions in the brain can be more susceptible to the effects of PM.

**PS 239 Co-Exposure to Ultrafine Particulate Matter and Ozone Causes Electrocardiogram Changes Indicative of Increased Arrhythmia Risk in Mice.**

N. Kurhanewicz<sup>1</sup>, R. McIntosh-Kastrinsky<sup>1</sup>, L. Walsh<sup>2</sup>, A. K. Farraj<sup>2</sup> and M. S. Hazari<sup>2</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Environmental Public Health Division, US EPA, Research Triangle Park, NC.

Numerous studies have shown a relationship between acute air pollution exposure and increased risk for cardiovascular morbidity and mortality. Due to the inherent complexity of air pollution, recent studies have focused on co-exposures to better understand potential interactions. This study was designed to evaluate the cardiac effects of concentrated ambient fine (PM<sub>2.5</sub>) and ultrafine (UFP) particles with and without ozone (O<sub>3</sub>) co-exposure. We hypothesized that ozone co-exposure

would enhance the acute effects of particles, particularly UFP. Conscious unrestrained C57BL/6 mice implanted with radiotelemeters were exposed by whole-body inhalation to either 250  $\mu$ g/m<sup>3</sup> PM<sub>2.5</sub> or 100  $\mu$ g/m<sup>3</sup> UFP with or without 0.3 ppm O<sub>3</sub> (4hrs); separate groups were exposed to either filtered air or O<sub>3</sub> only. Heart rate (HR) and electrocardiogram (ECG) were recorded continuously before, during and after exposure. Control animals experienced a decrease in HR during exposure. Neither PM<sub>2.5</sub> nor UFP alone caused any HR change; however with O<sub>3</sub> co-exposure, HR remained transiently elevated above control levels. Exposure to UFP+O<sub>3</sub> caused decreased PR-interval, a transient increase in QRS, and increased QTc. PM<sub>2.5</sub> alone caused QRS to decrease and O<sub>3</sub> alone caused a decrease in QRS interval and QTc. There were no other significant differences in the ECG parameters measured of any groups. Lastly, only animals exposed to UFP+O<sub>3</sub> had an increase in the number of non-conductive P-waves; there were no differences in other arrhythmia counts. These data suggest that O<sub>3</sub> co-exposure might worsen the stress response to PM, especially UFP, and cause repolarization heterogeneity in the heart, which increases the risk for arrhythmogenesis. As such, this indicates that the cardiovascular effects of particle and gas co-exposures are not easily characterized, potentially increasing the complexity of risk assessment. (This abstract does not reflect EPA policy)

**PS 240 An Air-Liquid Interface *In Vitro* Approach for Studying Toxic Effects of Exhaust Emissions Using a Heavy Duty Truck.**

I. M. Kooter<sup>1</sup>, M. Alblas<sup>1</sup>, J. van Triel<sup>2</sup>, A. Jedynska<sup>1</sup>, M. Steenhof<sup>1</sup>, M. Houtzager<sup>1</sup> and M. van Ras<sup>1</sup>. <sup>1</sup>EELS, TNO, Utrecht, Netherlands; <sup>2</sup>TAP, TNO Triskelion, Zeist, Netherlands. Sponsor: R. Woutersen.

Classically *in vitro* diesel exhaust (DE) studies have been performed with submerged cell cultures which are exposed to collected DE particles. Major drawback of this exposure method is that cells are not exposed to the whole complex and dynamic mixture of compounds DE is composed of. In recent years, air-liquid interface exposures have become more widely used, enabling *in vitro* exposures to mixtures of gases and particles. The main objective of this study was to investigate the feasibility of exposing human lung epithelial cells at the air-liquid interface to complete DE generated by a heavy-duty truck in the state-of-the-art TNO power train facilities.

Human epithelial lung cells (A549) were directly exposed at the air liquid interface to DE generated by a heavy-duty Euro III truck (turbo diesel model 2002). The truck was tested at a steady-state cycle at a speed of ~70 kmh<sup>-1</sup> to simulate free-flowing traffic at a motorway on a transient engine dynamometer. Cells were exposed to DE for 1.5 hours. After a 24 hours post-incubation period, cells were analysed for markers of oxidative stress (glutathione levels, GSH; heme oxygenase 1 protein levels, HO-1), cytotoxicity (lactate dehydrogenase release, LDH; Alamar Blue assay) and inflammation (interleukine-8 protein levels, IL-8).

DE exposure resulted in a decreased cell viability (significantly decreased Alamar Blue levels in the incubation medium and slightly increased LDH levels), and an increased oxidative stress response (significantly increased HO-1 levels and reduced GSH/GSSH ratio). However, the pro-inflammatory response seemed to decrease (non-significant decrease in IL-8).

The results presented here demonstrate that our *in vitro* exposure approach is indeed well suited for testing complex particulate and gaseous pollutant mixtures from diesel trucks. Our results confirm previous *in vitro* studies showing cytotoxicity and oxidative stress responses due to DE exposure.

**PS 241 Comparative Toxicity of Soy Biodiesel and Diesel Emissions in Healthy and Allergic Mice.**

S. H. Gavett<sup>1</sup>, M. A. Williams<sup>1</sup>, J. M. Cyphert<sup>2,1</sup>, E. H. Boykin<sup>1</sup>, M. E. Daniels<sup>1</sup>, L. B. Copeland<sup>1</sup>, D. L. Andrews<sup>3</sup>, J. H. Richards<sup>1</sup> and I. Gilmour<sup>1</sup>. <sup>1</sup>EPHD, NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>Curriculum in Toxicology, UNC School of Medicine, Chapel Hill, NC; <sup>3</sup>Research Cores Unit, Proteomic Research Core, US EPA, Research Triangle Park, NC.

Toxicity from combustion of 100% soy-based biodiesel (B100) was compared to that of petrodiesel (B0) or a 20% biodiesel / 80% petrodiesel mix (B20) in healthy and house dust mite (HDM)-allergic Balb/c mice. Exhaust from combustion of B0, B20, or B100 was diluted to target concentrations of 50, 150, or 500  $\mu$ g/m<sup>3</sup> as determined by real-time Tapered Element Oscillating Microbalance. Studies in healthy mice showed greater levels of MIP-2 and neutrophils in bronchoalveolar lavage (BAL) fluid 2 hr after a single 4 hr exposure to B0 compared with exposure to biodiesel emissions (air control neutrophils = 1x, B0 = 11.9x, B20 = 4.4x, B100 = 2.1x). However these differences were attenuated 24 hr after exposure and no consistent differences were observed 2 or 24 hr after 5 d (4 hr/d) or 4 wk (5 d/wk) exposures. Mice sensitized and challenged intranasally with HDM and exposed to B0, B20, or B100 for 4 wk (5 d/wk) had no emissions-related differences in airway

hyperresponsiveness to MCh aerosol (determined by total lung resistance in anesthetized, paralyzed and ventilated mice). Non-significant trends of decreased eosinophils and IL-5 in BAL fluid were found after exposure to the 500 µg/m<sup>3</sup> concentration of all 3 fuels. Proliferative responses of peribronchiolar lymph node cells in response to HDM antigens in vitro were not significantly affected by exposure to fuel emissions. We conclude that alternative soy biofuel emissions have comparable or reduced adverse effects relative to diesel emissions in healthy mice or a mouse model of allergic asthma. (This abstract does not represent U.S. EPA policy.)

**PS 242 Mechanisms Underlying Anti-Inflammatory Effects of Selective Diindolylmethane Compounds Using RAW264.7 Cells.**

M. F. Afzali<sup>1</sup>, G. P. Dooley<sup>1</sup>, S. H. Safe<sup>2</sup>, W. H. Hanneman<sup>1</sup> and M. E. Legare<sup>1</sup>.  
<sup>1</sup>Center for Environmental Medicine, Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO; <sup>2</sup>Center for Environmental and Genetic Medicine, Institute of Biosciences and Technology, Texas A&M Health Sciences, Houston, TX.

Chronic inflammation has been associated as the root cause of many serious illnesses including heart disease, Alzheimer's disease and many cancers. Tolfenamic Acid (TA) a non-steroidal anti-inflammatory (NSAID) drug has been shown to have multiple anti-inflammatory effects in RAW264.7 murine macrophages. This study compares the anti-inflammatory effects of selected diindolylmethane (DIM) compounds in activated RAW264.7 cells. Results indicate a significant decrease in production of prostaglandin E (2), D (2) and F (2). In addition, there was a decrease expression of mediators of inflammation including cyclooxygenase-2 (COX-2) in LPS-induced RAW 264.7 cells. These results underscore the potential use for these DIM compounds in ameliorating inflammation in disease processes and therapeutic regimens.

**PS 243 Fyn Kinase Inhibitors Attenuate Manganese Nanoparticles Induced Neuroinflammatory Signaling in BV2 Microglial Cells and Primary Microglia.**

K. Kanthasamy, N. Panicker, A. Ngwa, C. Jeffery, M. Neal, A. Kanthasamy and V. Anantharam. Iowa State University, Ames, IA.

Manganese (Mn) nanoparticles are currently used in a multitude of industrial and biomedical applications, including magnetic resonance imaging, high capacity batteries, industrial coatings, biosensors, plastics, ultrahigh density storage devices, nanofibers, and catalysts. Yet, the potential impacts of these particles on human health and the environment are not well understood. Notably, the cellular mechanisms underlying Mn nanoparticle induced neurotoxicity are yet to be identified. Because nanoparticles are similar in size to microbes, we hypothesize that Mn nanoparticles exposure may activate phagocytic microglial cells to induce a neurotoxic response. We exposed BV2 microglia and primary microglial cultures to various doses of Mn nanoparticles and then measured inflammatory markers. Exposure of 0-50 µg/mL Mn nanoparticles to BV2 microglia over 24 hr period resulted in a dose-dependent increase in iNOS, ROS, TNFα, IL-6, IL-12, and RANTES levels. Additionally, Mn nanoparticles induced over a threefold increase in ROS generation in primary microglial cells. Interestingly, Mn nanoparticles also activated the non-receptor tyrosine kinase Fyn in BV2 microglia. In order to determine whether Fyn kinase plays a role in the Mn induced inflammatory response, we tested a series of Fyn kinase inhibitors, including rosmarinic acid, dinitro-rosmarinic acid and caffeic acids. Rosmarinic and caffeic acids showed EC50s of 33 and 32 µM, respectively, against Mn induced iNOS activation. In addition, Fyn kinase inhibitors significantly blocked Mn-nanoparticle induced TNFα, IL-6, IL-12 release and ROS generation, indicating that Fyn kinase may play a central role in the Mn nanoparticle neuroinflammation and oxidative stress. Taken together, our results demonstrate that Mn nanoparticles activate microglial cells via a Fyn kinase dependent mechanism and that Fyn kinase inhibitors may serve as efficacious therapeutic agents against the metal nanoparticle induced neuroinflammatory insult (supported by NIH grants ES10586 and NS65167).

**PS 244 Proinflammatory Cytokines Present in the Tumour Microenvironment Induce Phenotypic Change in Colorectal Cancer Cell Lines.**

S. Patel and N. J. Gooderham. Surgery and Cancer, Imperial College London, London, United Kingdom.

Colorectal cancer (CRC) is the third most common cancer worldwide with metastatic disease responsible for high mortality rates. The cellular microenvironment is modified during malignancy to support tumor development and metastasis, however mechanisms by which this occurs remain unclear. Previous data from

our laboratory has shown an overexpression of cytochrome P450 (CYP) drug metabolizing enzymes 1B1 and 2E1 and pro-inflammatory cytokines interleukin (IL) 1β and IL6 in neoplastic tissue resected from colorectal cancer patients compared to matched non-neoplastic controls. In the current study, the presence of these cytokines in the tumour microenvironment was investigated in vitro using two CRC cell lines HCT116 and SW480, differing in metastatic potential. Treatment with conditioned media from activated THP1 monocytes, known to secrete an array of cytokines (including IL6, IL1β and TNFα), was able to induce the invasive properties of the metastatic cell line HCT116 as measured using wound and migration chamber assays. Treatment with IL6 alone (0-1000 pg/ml) was also shown to promote cell motility and invasion in a bell-shaped dose response, characteristic of cytokine function. The non-metastatic cell line SW480 did not respond to the conditioned media and was more resistant to IL6, generating a response only at the higher doses. Additionally, CYP 1B1 and 2E1 expression were increased following treatment with the conditioned media as well as with IL6 on its own. Taken together, these data indicate that pro-inflammatory cytokines, in particular IL6, are able to cause phenotypic change in CRC cells by inducing CYP expression and promoting ability for the cells to migrate and invade surrounding tissue, thus demonstrating the important role of tumor microenvironment in disease progression.

**PS 245 A Novel Anti-Inflammatory Peptide: Potential Therapy of Sepsis Induced by Bacterial Endotoxin.**

U. Wormser<sup>1</sup>, M. Aschner<sup>2</sup>, Y. Finkelstein<sup>3</sup>, E. Proscura<sup>1</sup>, B. Brodsky<sup>1</sup> and E. Shapira<sup>1</sup>. <sup>1</sup>Institute of Drug Research, The Hebrew University, Jerusalem, Israel; <sup>2</sup>Department of Pharmacology, Center for Molecular Toxicology, and the Kennedy Center for Research on Human Development, Vanderbilt University School of Medicine, Nashville, TN; <sup>3</sup>Neurology and Toxicology Service and Unit, Shaare Zedek Medical Center, Jerusalem, Israel.

Sepsis is a syndrome of infection complicated by vital organ dysfunction and considered one of the leading causes of mortality in intensive care units. It is characterized by a generalized inflammatory response caused by systemic activation of macrophages and other immune and microvascular endothelial cells. The present study demonstrates the efficacy of a novel anti-inflammatory peptide termed IIMM1 in ameliorating sepsis induced by the bacterial endotoxin lipopolysaccharide (LPS). A single injection of the peptide 3 days prior to lethal dose of LPS increased animal survival by 60%. Shorter or longer intervals between IIMM1 and LPS administration reduced peptide efficacy. LPS-induced increase in liver, kidney and spleen mass was reverted by peptide treatment. Thioglycolate-induced peritonitis, expressed by increased number of macrophages in the peritoneal cavity, was reduced by 38% in IIMM1-treated mice. A bell-shape dose-response effect was observed in both peritonitis and sepsis models reaching maximal effect at 1mg/kg. Chemical modifications such as omission of the C- or N-terminal residues weakened the anti-inflammatory activities of the peptide. Serum levels of interleukin 6 and tumor necrosis factor alpha were reduced by 32% and 53%, respectively, in IIMM1-treated mice intoxicated by LPS. Similar cytokine profile was observed in LPS-activated peritoneal macrophages treated in vitro with the peptide. In view of these data IIMM1 is a promising drug candidate for treatment of sepsis induced by bacterial endotoxin.

**PS 246 S-Adenosylhomocysteine Inhibits NF-κB Activity in the Nucleus of Hepatocytes and Confers Sensitivity to TNF Cytotoxicity.**

W. Watson<sup>1</sup>, T. Burke<sup>1</sup> and C. McClain<sup>1,2</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY.

Chronic alcohol exposure results in liver injury that is largely driven by inflammatory cytokines such as tumor necrosis factor-α (TNF). Hepatocytes are normally resistant to the cytotoxic effects of TNF, but they become sensitized to TNF by chronic alcohol exposure. Recently we reported that the decrease in the ratio of S-adenosylmethionine (SAM) to S-adenosylhomocysteine (SAH) that occurs with alcoholic liver injury renders hepatocytes sensitive to TNF cytotoxicity. The purpose of the present study was to determine whether inhibition of the transcription factor NF-κB contributed to TNF-induced cell death in hepatocytes with high levels of SAH. HepG2 cells were pre-incubated with a combination of adenosine plus homocysteine to increase SAH levels. Following stimulation with TNF, viability was determined by the MTT assay, and activation of the NF-κB pathway was assessed by measuring degradation of cytosolic IκB, translocation of NF-κB to the nucleus, and expression of an NF-κB -dependent reporter gene as well as endogenous targets of NF-κB related to cell death. The results showed that NF-κB was indeed inhibited in cells with high SAH, and that this inhibition occurred at the level of the nucleus; the cytoplasmic inhibitor IκB-α was degraded and NF-κB translocated to the nucleus in response to TNF stimulation of HepG2 cells in both control cells and in

cells with high SAH levels. Nuclear NF- $\kappa$ B was not transcriptionally active, however, when SAH levels were high. As a result, I $\kappa$ B- $\alpha$  was not re-synthesized and NF- $\kappa$ B remained in the nucleus. It is likely that cross-talk with other transcription factors is perturbed under these conditions, resulting in still other changes in gene expression.

**PS 247** **Cyanobacterium *Anabaena* sp. Lipopolysaccharide (LPS) Elicits Release of MIP- $\alpha$ , Interleukin-6, and Matrix Metalloproteinase-9 from Rat Brain Microglia *In Vitro*.**

D. Macadam<sup>1</sup>, M. L. Hall<sup>1</sup>, D. Feher<sup>2</sup>, P. Williams<sup>2</sup> and A. M. Mayer<sup>1</sup>.  
<sup>1</sup>Pharmacology, Midwestern University, Downers Grove, IL; <sup>2</sup>Chemistry and Biochemistry, University of Hawaii at Manoa, Honolulu, HI.

We recently reported that freshwater cyanobacterium *Anabaena*LPS (AnaLPS) elicited release of superoxide anion (O<sub>2</sub><sup>-</sup>), thromboxane B<sub>2</sub> (TXB<sub>2</sub>), and tumor necrosis alpha (TNF- $\alpha$ ) by rat microglia (BMG) *in vitro* (The Toxicologist CD 126 (S-1), 2012). We hypothesized that AnaLPS-activated BMG might additionally release the cytokine interleukin-6 (IL-6), the chemokine MIP-1 $\alpha$  (MIP-1 $\alpha$ ), and the matrix metalloproteinase-9 (MMP-9) *in vitro*. **Methods:** AnaLPS was prepared by hot phenol/water extraction. BMG were isolated from neonatal rats, and treated *in vitro* with 0.1-10<sup>5</sup> ng/mL AnaLPS at 35.9 °C for 17 hours. TNF- $\alpha$ , MIP-1 $\alpha$  and IL-6 were determined by Milliplex® MAP rat cytokine/chemokine immunoassays, and MMP-9 by zymography. **Results:** MIP-1 $\alpha$ , TNF- $\alpha$ , and IL-6 generation were observed at AnaLPS >10 ng/mL (MIP-1 $\alpha$ ), and > 1,000 ng/mL, respectively. In contrast, MMP-9 release was significant at AnaLPS 10,000 ng/mL. **Conclusions:** Treatment of BMG with AnaLPS confirmed previously reported TNF- $\alpha$  release, and furthermore demonstrated for the first time the release of MIP-1 $\alpha$ , IL-6 and MMP-9. Taken together, our results suggest that *in vitro* proinflammatory mediator release by cyanobacterial AnaLPS-treated BMG is complex, including lipids (TXB<sub>2</sub>), free radicals (O<sub>2</sub><sup>-</sup>), cytokines (TNF- $\alpha$  & IL-6), chemokines (MIP-1 $\alpha$ ) and enzymes (MMP-9), all of which might play a yet unknown role in the putative immunotoxicity of AnaLPS *in vivo*. Continued investigation of AnaLPS chemistry and immunotoxicology are currently ongoing in our laboratories. Supported by Midwestern University and the University of Hawaii at Manoa.

**PS 248** **Spleen As a Source of Inflammatory Macrophages: Role in Acetaminophen-Induced Hepatotoxicity.**

M. Mandal<sup>1</sup>, A. Dragomir<sup>1</sup>, H. M. Choi<sup>1</sup>, J. D. Laskin<sup>2</sup> and D. L. Laskin<sup>1</sup>.  
<sup>1</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Environmental & Occupational Medicine, UMDNJ-RWJMS, Piscataway, NJ.

Activated macrophages (MP) have been implicated in the hepatotoxicity of acetaminophen (APAP). However, the origin of these cells has not been established. Splenic monocytes (mono)/MP have been shown to accumulate at inflammatory sites following tissue injury. In the present studies, we analyzed the contribution of splenic mono/MP to liver inflammation and injury induced by APAP. Mice were fasted overnight prior to administration of APAP (300 mg/kg, i.p.) or PBS. Spleen, bone marrow (BM) and liver were collected 24-96 h later and analyzed by flow cytometry and immunofluorescence for the presence of activated mono/MP. APAP intoxication was associated with a time-dependent increase in CD11b+Ly6C+ proinflammatory MP, and a decrease in F4/80+ resident MP in the liver; this was correlated with a significant decrease in CD11b+F4/80+Ly6C-Ly6G- resident mono/MP in the spleen at 24 and 48 h post APAP, with no effect on BM mono/MP. Conversely, CD11b+F4/80+Ly6C+ inflammatory mono/MP increased in the spleen after 48-96 h, but decreased in the BM. To assess the role of splenic mono/MP in APAP hepatotoxicity, we used splenectomized (spx) mice. APAP-induced hepatotoxicity was significantly decreased in spx mice, as measured by decreases in serum transaminases. Histologic evidence of hepatic necrosis was also reduced. This was associated with a significant decrease in inflammatory mono/MP subsets (CD11b+F4/80-Ly6C+ and CD11b+F4/80+Ly6C+) in the BM at 24 h post APAP when compared to sham control mice. In addition, in spx mice, a decrease in CD11b+F4/80+Ly6C+Ly6G+ myeloid derived suppressor cells (MDSCs) was observed in BM at 96 h post-APAP. Taken together, these results indicate that splenic mono/MP contribute to early inflammation and hepatotoxicity induced by APAP. Moreover, removal of the splenic reservoir of mono/MP results in emigration of MDSCs out of the BM following APAP administration and this may contribute to tissue repair. Supported by NIH GM034310, ES004738, CA132624, AR055073, ES007148, ES005022.

**PS 249** **Exaggerated Hepatotoxicity of Acetaminophen (APAP) following Administration of Clodronate Liposomes Is Associated with the Persistence of Classically-Activated Macrophages in the Liver.**

A. Dragomir<sup>1</sup>, R. Sun<sup>1</sup>, M. Mili<sup>1</sup>, J. D. Laskin<sup>2</sup> and D. L. Laskin<sup>1</sup>. Joint Graduate Program in Toxicology, Rutgers University/UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Toxic doses of APAP are known to cause centrilobular hepatic necrosis. Evidence suggests that classically and alternatively activated macrophages play distinct roles in APAP-induced hepatotoxicity. In the present studies, we investigated the effects of macrophage depletion using clodronate liposomes (CL) on activated macrophage subpopulations accumulating in the liver in response to APAP intoxication. Mice were administered empty liposomes (EL) or CL (100  $\mu$ L, i.v.) 48 h before APAP (300 mg/kg, i.p.) or PBS control. In mice pretreated with EL, increases in serum transaminases and hepatic necrosis were observed within 24 h; this was correlated with hepatic accumulation of CD11b+Ly6C+ classically activated macrophages in the liver and increased expression of galectin-3, a marker for these cells. These effects were significantly increased in mice pretreated with CL at 72 and 96 h post APAP, and were associated with increases in CD11b+Ly6C+F4/80-/inflammatory monocytes in the bone marrow, suggesting a potential origin of these cells. In contrast, APAP-induced expression of the alternative macrophage activation markers Fizz-1 and Ym1, and the anti-inflammatory cytokine IL-10, were significantly reduced in livers of mice treated with CL when compared to EL. Expression of TNF- $\alpha$ , the chemokine CCL2, and its receptor CCR2, cytokines critical for repair of APAP-induced injury, were also decreased in CL-pretreated mice relative to EL-treated mice. Taken together, these results suggest that increased APAP-induced hepatotoxicity following macrophage depletion using CL is due, in part, to persistent accumulation of classically activated macrophages in the liver. Supported by NIH GM034310, ES004738, CA132624, AR055073 and ES005022.

**PS 250** **Bone Marrow Inflammation Precedes Delayed Myelosuppression from Hexahydro-1-Nitroso-3, 5-Dinitro-1, 3, 5-Triazine (MNX) Induced in Rats.**

S. Jalgama<sup>1</sup>, V. M. Kale<sup>2</sup>, M. S. Wilbanks<sup>3</sup>, E. J. Perkins<sup>3</sup> and S. A. Meyer<sup>1</sup>.  
<sup>1</sup>Toxicology, University of Los Angeles Monroe, Monroe, LA; <sup>2</sup>College Pharmacy, Roseman University Health Science South Jordan, UT; <sup>3</sup>US Army Engineer Research & Development Center, Vicksburg, MS.

MNX (hexahydro-1-nitroso-3, 5-dinitro-1, 3, 5-triazine), an environmental nitroreduced product of munitions RDX, contaminates military sites. Our previous studies identified bone marrow (BM) and spleen as hematological targets of acute oral exposure to MNX in rats in the form of splenic hemosiderosis and loss of BM Granulocyte Macrophage Colony Forming Cells (GM-CFCs). To address whether delayed loss of GM-CFCs and blood granulocytes (NOAELs 24, 47 mg/kg resp) at 14 days after exposure to MNX is due to persistence of early hematological effects or is late-onset due to required expression period, female Sprague-Dawley rats were orally gavaged with MNX from 0 to 94 mg/kg and different toxicological endpoints were evaluated over a time course at 2, 7, 10, 12, and 14d. Significant decrease in relative spleen weight and increased macrophage activity in splenic red pulp at 2d ( $\geq$  47 mg/kg); and persistent splenic hemosiderosis at 2d ( $\geq$  47 mg/kg), 7d (NOAEL 24 mg/kg) and 14d were observed. A significant increase in blood granulocytes and circulating levels of RANTES, a leukocyte chemokine, indicate that an acute inflammatory response occurs at 2d after exposure to MNX. Also, persistent BM macrophage infiltration was observed in MNX (94 mg/kg) treated rat iliums (24h, 2d and 10d) and activation of NF $\kappa$ B signaling pathway in BM cells was evident at 10d. Further, significant increase in adherent BM mesenchymal stromal cell colonies constituting macrophages, endothelial cells and fibroblasts was observed in MNX (94 mg/kg) treated rats. Collectively, these data suggest that while splenic effects are early onset and persist for at least 14d, myelosuppression is delayed until 10d presumably due to development of inhibitory effects of preceding BM inflammation on myelopoiesis. (Support: DoD/CDMRP, US Army Corps of Engineers)

**PS 251** **Reversibility of Prostate Fibrosis in Response to Bacterial-Induced Chronic Inflammation.**

L. Wong<sup>1</sup>, P. Hutson and W. A. Bushman. University of Wisconsin-Madison, Madison, WI.

Introduction: Benign prostatic hyperplasia (BPH) and its associated lower urinary tract symptoms (LUTS) are common in aging men. Chronic inflammation and increased stromal collagen are common features observed in BPH. Recent study has

shown that the collagen content is correlated with the degree of LUTS and tissues stiffness, suggesting a role of prostate fibrosis in BPH/LUTS. Using the bacterial-prostatic inflammation mouse model, we have shown that prostatic inflammation induces collagen content. The goal of this study is to investigate the reversibility of prostate fibrosis during bacterial-induced chronic inflammation.

**Methods:** We transurethrally instilled uropathogenic E-coli into adult C3H/HeOuJ male mice to induce chronic inflammation in the prostate. Naïve, saline and E-coli instilled animals were sacrificed after 1 month. Other animals were treated with Baytril in drinking water to resolve the infection and underwent an additional 2-month resolution. The prostate tissues were used for bacterial culture and measurement of hydroxyproline level as collagen content using high-pressure liquid chromatography.

**Results:** The uropathogenic E-coli was present in the prostates of all E-coli infected animals after 1-month post-instillation and treatment of Baytril completely resolved the bacterial infection. We further found that hydroxyproline content in the prostates was significantly increased in the E-coli infected mice compared to the saline. Infected mice treated with Baytril with an additional 2-month resolution had a significant increase in hydroxyproline level in the prostates compared to the saline, but the level was significantly lowered to the E-coli infected prostates.

**Conclusion:** This study suggests that prostate fibrosis in response to bacterial-induced chronic inflammation is only partially reversed. Given that prostate fibrosis is suggested to strongly associate with the loss of prostate compliance and the development and progression of BPH/LUTS, an understanding on the mechanisms of the irreversible collagen deposition is required for improvement of therapeutic treatment.

## PS 252 Topical Application of TRPV1 Antagonist Effectively Inhibits PTD-Induced Sensitization in Murine Skin.

K. Lim, K. Jung, W. Jang and Y. Park. *AMOREPACIFIC Co. R&D Center, Gyeonggi-do, Republic of Korea.*

Transient receptor potential vanilloid type 1 (TRPV1) is expressed in the skin and plays a role in migration of dendritic cells to lymph nodes in allergic diseases. However, it has been unaddressed if TRPV1 blockade can suppress chemical-induced contact dermatitis. 1,4-toluenediamine (PTD) and 1,4-phenylenediamine (PPD) are widely used as permanent hair dye but repeated use of PTD can induce contact hypersensitivity by the induction of regulatory T cells in the draining lymph node and of inflammation in the exposed skin. In this study, the inhibitory effect TRPV1 antagonist, PAC-14028 on PTD-induced dermatitis and dendritic cell (DC) function was explored. This study was performed according to the method of nonradioactive local lymph node assay using flow cytometry. Groups of mice (N=4-5) were treated with 25 µl of the PTD alone, PAC-14028 alone, PTD and PAC-14028 or vehicle alone on the dorsal area of both ears daily for 3 consecutive days (Day 1, 2 and 3) and were sacrificed at Day 6. The local response was measured by ear swelling and by histological examinations (H&E staining). We also used immunohistochemistry staining and western blot assays to evaluate the activation of specific inflammation makers and key mediators of signaling pathway in the mouse skin. The DCs migration markers in the draining lymph nodes were analysed by flow cytometry. TRPV1 antagonist suppressed PTD-induced edema in skin and proliferation of lymphocyte and inhibits the migration of CD11c+ DC and CD207+ Langerhans cells (LC) to the draining lymph nodes (LNs).

## PS 253 Comparative Inflammatory Effects of Differential Particulate Matter Species in an OVA-Sensitization and Challenge Model.

M. A. Williams<sup>1</sup>, M. J. Daniels<sup>1</sup>, E. H. Boykin<sup>1</sup>, T. Smith<sup>1</sup>, N. Hykal-Coates<sup>2</sup>, L. B. Copeland<sup>1</sup>, D. L. Andrews<sup>2</sup>, J. H. Richards<sup>1</sup> and L. Gilmour<sup>1</sup>.

<sup>1</sup>Environmental Public Health Division, US EPA, Research Triangle Park, NC;

<sup>2</sup>Research Core Unit, US EPA, Research Triangle Park, NC.

Exposure to respirable ambient particulate matter (APM) provokes allergic immunity that may also occur on exposure to environmental diesel exhaust particles (eDEP) or emission source DEP (cDEP). Our hypothesis tested whether APM, eDEP or cDEP provide immune adjuvancy in an antigen (OVA) sensitization and challenge model. We assayed for oxidative stress, inflammatory and cytokine analytes in BALF, assay of lung infiltrating cells, assay of serological analytes (total IgE, IgG1, IgG2a), and antigen-specific recall responses of primary lymph node cells (pLNC). All PM species increased markers of airway or allergic inflammation. However, eDEP or cDEP sensitized mice had lower levels of superoxide dismutase as compared APM, without affecting other oxidative stress markers (p<0.005). By contrast, all PM species enhanced eosinophil and neutrophil infiltration to the lung as compared saline or OVA alone (p<0.001). These effects for APM (p<0.005) and cDEP (p<0.05) were concordant with enhanced levels of pro-Th2 cytokines like

IL-5 in BALF. Assay of isotype class-switching was less informative. All PM species partially augmented total IgE as compared saline, but not when compared to LPS control or each other, and dampened secretion of IgG2a (p=0.07) and IgG1 (p=0.059) as compared low-dose LPS/OVA. In OVA-specific recall responses, pLNC proliferation was enhanced in mice sensitized with eDEP and particularly cDEP, which provoked robust IL-5 and IL-13 secretion (p<0.01). We conclude that all PM species provoked airway and allergic inflammation. However diesel PM, and particularly cDEP were most effective in sensitizing mice and driving Th2-type cytokine and OVA-specific responses ex vivo. This study supports the realization that respirable PM differentially provoke allergic inflammation, and provides new insights on signaling changes contributing to these effects. This abstract does not reflect US EPA policy.

## PS 254 Role of Ortho-Phthalaldehyde in IgE-Induced Airway Hyperresponsiveness As a Hapten and an IgE-Selective Adjuvant-Like Activity in Mice Treated with Ovalbumin.

Y. Ishihara<sup>1</sup>, M. Nakao<sup>1</sup>, T. Morinaga<sup>1</sup>, G. Hasegawa<sup>1</sup>, M. Yamaguchi<sup>1</sup>, T. Nishikawa<sup>2</sup> and H. Kawashima<sup>3</sup>. <sup>1</sup>Public Health, Kurume University, Kurume, Japan; <sup>2</sup>Surgical Pathology, Tokyo Women's Medical University, Tokyo, Japan; <sup>3</sup>Microbiology & Immunology, University of Shizuoka, Shizuoka, Japan.

**[Purpose]** We previously reported that ortho-phthalaldehyde (OPA) disinfectant induces acute inflammation and enhances allergen-specific IgE production without allergen-specific IgG in ovalbumin (OVA)-sensitized mice. However, etiology of this disorder is not fully understood. The purpose of this study is to explore relationship between airway hyperresponsiveness and host immunity in OPA-treated OVA sensitized mice. **[Methods]** Female ICR mice were divided into five groups; OPA + OVA group, aluminum hydroxide (Alum) +OVA group, OPA group, OVA group, and Control group. The mice were sensitized twice with OVA and challenged with OVA inhalation one day prior to testing airway responsiveness to acetylcholine (Ach) under anesthesia. **[Results]** Airway hyperresponsiveness to Ach was observed in the OPA + OVA and Alum +OVA groups compared with the responses observed in the OPA, OVA and control groups. OPA-specific IgE and IgG antibodies and OVA-specific IgE antibody increased markedly, whereas OVA-specific IgG antibody did not increase in the OPA + OVA group due to the masking of OVA's antigenicity for IgG production by the aldehyde group of OPA. **[Conclusion]** These results strongly suggest that OPA functions as both a hapten and an allergen-specific, IgE-selective adjuvant, leading to significant airway inflammation and hyperresponsiveness to Ach.

## PS 255 Dual Oxidase Modulates Airway Neutrophil Recruitment in Allergic Airways.

S. Chang<sup>1,2</sup>, A. L. Linderholm<sup>2</sup>, H. Grasberger<sup>3</sup> and R. W. Harper<sup>2</sup>. <sup>1</sup>Pharmacology Toxicology, University of California Davis, Davis, CA; <sup>2</sup>Internal Medicine, University of California Davis, Davis, CA; <sup>3</sup>Internal Medicine, University of Michigan, Ann Arbor, MI.

**Introduction/Rationale:** Reactive oxygen species (ROS) plays an important role in maintaining lung homeostasis. However dysregulation of ROS, specifically hydrogen peroxide, has been linked to respiratory diseases such as chronic obstructive pulmonary disease, cystic fibrosis and asthma. Dual Oxidase (DUOX) is an NADPH oxidase, whose function is regulated production of hydrogen peroxide, localized to the lung epithelium. DUOX activity and expression are upregulated by IL-4 and IL-13 which are key cytokines in allergic airways. Interestingly, the role of DUOX in asthma has never been evaluated in vivo. The objective of this study was to determine the role of DUOX derived hydrogen peroxide in asthmatic airways, using a DUOX system knock out mouse. **Methods:** Wild-type and dual DUOX A1/DUOX A2 knockout mice were sensitized with ovalbumin (day 0 and 14) and subsequently exposed to aerosolized ovalbumin for a period of 2 weeks to evaluate the role of DUOX in allergic asthma. Measurement of forced expiratory nitric oxide concentrations, airway compliance, live cell counts, bronchoalveolar lavage fluid (BALF) cell differentials and histology were performed and compared between the two groups. **Results:** Wild-type mice with functional DUOX had a greater influx of neutrophils than knockout mice when subjected to ovalbumin as observed in BALF as well as semi quantitative counts in lung tissue. **Conclusion:** These findings suggest that DUOX derived hydrogen peroxide has an important role in signaling neutrophils into allergic airways.

This research was supported by NIH(R01 HL085311& R01 HL085311-S1).

**PS 256 Epithelial-Derived Hypoxia Inducible Factor-1 $\alpha$  Plays a Role in Programming the Innate Immune Response of the Lung.**

K. Greenwood, S. P. Proper, Y. Saini, D. Jackson-Humbles, J. G. Wagner, J. Harkema and J. J. LaPres. *Michigan State University, East Lansing, MI.*

Allergic airway disease (AAD) involves a complex interaction between various cell types within the lung, including inflammatory and epithelial cells. The inherent inflammation of AAD also leads to localized hypoxia. Communication between inflammatory cells, such as macrophages and T cells, and the epithelia in these hypoxic conditions is hypothesized to be critical to the progression of AAD. To characterize the role of epithelial-mediated hypoxia-induced signaling in AAD, epithelial and lung-specific conditional hypoxia inducible factor-1 $\alpha$  (HIF1 $\alpha$ ), HIF2 $\alpha$ , and HIF1 $\alpha$  and HIF2 $\alpha$  (HIF1/2 $\alpha$ ) knockout mouse models were created. Previous research in our lab has shown that the HIF1 $\alpha$ -deficient (HIF1 $\alpha$  $\Delta/\Delta$ ) mice exhibit an exacerbated response to the ovalbumin (OVA) model of AAD. To determine the role of HIF2 $\alpha$  in AAD and characterize possible compensation between the two HIFs following OVA challenge, recombination was induced early in post-natal development and control and HIF-deficient mice were then sensitized/challenged with OVA via a standard paradigm. In contrast to the HIF1 $\alpha$  $\Delta/\Delta$  model, the HIF2 $\alpha$  $\Delta/\Delta$  mice displayed no increase in eosinophil infiltration, T helper 2 cytokines, or airway resistance following OVA treatment. The HIF2 $\alpha$  $\Delta/\Delta$  mice appear phenotypically identical to OVA-treated littermate controls. Interestingly, when HIF1/2 $\alpha$  $\Delta/\Delta$  mice were sensitized/challenged with OVA, these animals appeared similar to HIF2 $\alpha$  $\Delta/\Delta$  and littermate controls, suggesting that HIF2 $\alpha$  plays a role in the exacerbated inflammation observed in the HIF1 $\alpha$  $\Delta/\Delta$  model. These data suggests that epithelial-derived HIF signaling plays an important role in establishing the immunity of the lung and that a proper balance between the two HIFs is required for a normal inflammatory response. The observed changes in the inflammatory response of the various models also suggest that early life exposures that alter the expression or function of HIF1 $\alpha$  and/or HIF2 $\alpha$  might have profound effects on the lung's response to toxicant challenge upon reaching adulthood.

**PS 257 ODSH Improves Survival in PA Pneumonia by Increased Bacterial Clearance and Reduced Lung Injury.**

L. Sharma<sup>1</sup>, J. Wu<sup>1</sup>, V. Patel<sup>1</sup>, R. Sitapara<sup>1</sup>, N. Rao<sup>3</sup>, T. P. Kennedy<sup>4</sup> and L. L. Mantell<sup>1,2</sup>. <sup>1</sup>*St. John's University, New York, NY;* <sup>2</sup>*The Feinstein Institute for Medical Research, Manhasset, New York, NY;* <sup>3</sup>*University of Utah, Salt Lake City, UT;* <sup>4</sup>*Pulmonary and Critical Care Medicine, Georgia Health Sciences University, Augusta, GA.*

Nosocomial Pneumonia (NP) or Hospital Acquired Pneumonia (HAP) is associated with infections originated from the hospital borne pathogens. Resistance against antimicrobial agents is the most common feature of these infections which results in persistent infection leading to high mortality rates and therapeutic costs. Due to the involvement of multidrug resistant bacteria, alternative or supportive therapies are required. *Pseudomonas aeruginosa* (PA), gram negative pathogen, is one of the prominent pathogens associated with NP. PA pneumonia increases the secretion of inflammatory cytokines, neutrophil infiltration and subsequent lung damage. HMGB1, one of the inflammatory cytokines, has been shown to play important roles in PA lung infections. HMGB1 can compromise innate immunity by impairing phagocyte function mediated by its receptors TLR2 and TLR4. Heparin, a well-known anticoagulant, exhibits anti-inflammatory properties that are independent of anticoagulant property. 2-O, 3-O -desulfated heparin (ODSH), heparin, has been proven to have anti-inflammatory properties with minimal anticoagulation effect. ODSH has been shown to reduce lung injury in sterile inflammation and reducing inflammatory lung damage. In this study, we examined the effect of ODSH on PA pneumonia. Here we demonstrate that ODSH not only reduces PA-induced lung injury, illustrated by reduced total protein content in lung lavage fluids, it also significantly increases bacterial clearance. This improved lung injury and bacterial clearance resulted in marked improvement in overall survival of the mice with PA infection. The attenuation in lung injury and improved bacterial clearance was associated with reduced airway HMGB1. In addition, ODSH inhibits binding of HMGB1 with receptors TLR2 and TLR4. These data indicate a novel role of ODSH in the treatment of PA pneumonia.

**PS 258 Role of Mannose-Binding Lectin in the Pulmonary Response to Ozone.**

J. Ciencewicki, K. E. Gerrish, P. Bushel and S. R. Kleeberger. *NIEHS, Research Triangle Park, NC.* Sponsor: *D. Harbourt.*

Ozone is a common pollutant and a potent oxidant in many areas of the country. Inhalation causes airway hyperactivity, lung hyperpermeability, inflammation and cell damage in humans and laboratory animals, and exposure to ozone has been as-

sociated with exacerbation of asthma, altered lung function, and mortality. Currently the mechanisms of ozone-induced lung injury and differential susceptibility are not fully understood. Ozone exposure induces a number of pro-inflammatory events in the lung, some of which are mediated by the innate immune system. We hypothesized that mannose binding lectin (MBL), which plays a central role in the activation of the complement pathway of innate immunity, is needed to elicit some of the pro-inflammatory events caused by ozone-mediated activation of the innate immune system. Wild-type (Mbl<sup>+/+</sup>) and MBL deficient (Mbl<sup>-/-</sup>) mice were exposed to ozone (0.3 ppm) for 24, 48, and 72 hours. Compared to Mbl<sup>+/+</sup> mice, significantly less neutrophilic infiltration and the neutrophil attractants CXCL2 (MIP-2) and CXCL5 (LIX) were found in the lungs of Mbl<sup>-/-</sup> mice exposed to ozone. We then used mRNA microarray analyses to gain additional mechanistic insight to the role of MBL in this model. We identified significant differences in expression response profiles and networks at baseline and after exposure between Mbl<sup>+/+</sup> (WT) and Mbl<sup>-/-</sup> (KO) mice, providing potential roles for MBL at steady-state and in the innate immune pulmonary response to ozone inhalation. For example, we found gene enrichment for lipid metabolism and hematological disease at baseline, and innate immunity and cell morphology after ozone exposure. These novel findings demonstrate that MBL function contributes to ozone-induced pulmonary inflammation and may be mediated through the activation of the complement cascade.

Research supported by intramural research program at NIEHS.

**PS 259 Anti-Inflammatory Effect of Imipramine in Silica-Induced Inflammation.**

R. Biswas, R. Hamilton and A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

Environmental or occupational exposure to silica particles over an extended period of time is associated with the development of progressive inflammation and silicosis. Silicosis remains a prevalent health problem throughout the world. Currently, treatment choices for silicosis are limited and at present there is no cure for the disease. Therefore, it is essential to investigate potential therapeutic agents in silicosis treatment. Imipramine (IMP) is an approved tricyclic antidepressant, and a lysosomotropic agent. The aim of this study was to determine the protective effect of IMP on silica-induced inflammation and determine the mechanism by which IMP inhibits inflammation. C57BL/6 wild-type (WT) mice were used throughout the study. The protective effect of IMP was evaluated in vitro and 24 hours and 42 days following silica exposure in vivo. Silica was administered once a week for 4 weeks and IMP was delivered for 42 days via osmotic pumps implanted subcutaneously. Collagen levels were determined by hydroxyproline content. IMP treatment decreased collagen levels compared to the silica-exposed group. Lung histopathology improved on IMP treatment. WT mice were pretreated with IMP 25 mg/kg, and subsequently exposed to silica 1mg/kg during the in vivo acute study. IMP inhibited silica-exposed neutrophil infiltration, IL-1 $\beta$  and IL-6 in the lavage fluid. For in vitro experiments, WT alveolar macrophages (AM) were pretreated with 25  $\mu$ M IMP and subsequently exposed to LPS (20 ng/ml) and silica (100  $\mu$ g/ml). IMP was highly effective in blocking silica-induced inflammasome activation without any toxic effects on AM. The effect of IMP on acid sphingomyelinase (A-SMase) was determined since A-SMase has been associated with acute lung injury. A-SMase was significantly inhibited by IMP treatment. The results demonstrate that IMP inhibits silica-induced inflammation and IMP may be exhibiting anti-inflammatory properties through its effect on lysosomes. The work was supported by NIH grants P20 RR017670 and R01 ES 15294

**PS 260 Higher Susceptibility of Male Mice to Diesel Exhaust Neurotoxicity.**

L. G. Costa<sup>1,2</sup>, G. Giordano<sup>1</sup>, A. Engstrom<sup>1</sup>, C. S. Weldy<sup>3</sup>, F. Farin<sup>1</sup> and T. J. Kavanagh<sup>1</sup>. <sup>1</sup>*Department Environmental Occupational Health Sciences, University of Washington, Seattle, WA;* <sup>2</sup>*Department of Neuroscience, University of Parma, Parma, Italy;* <sup>3</sup>*Division of Cardiology, University of Washington, Seattle, WA.*

In addition to increased morbidity and mortality caused by respiratory and cardiovascular diseases, air pollution may also contribute to CNS diseases. Traffic-related air pollution is a major contributor to global air pollution, and diesel exhaust (DE) is its most important component. DE contains more than 40 toxic air pollutants and is a major constituent of ambient particulate matter (PM), particularly of ultrafine-PM. Limited information suggest that exposure to DE may cause oxidative stress and neuroinflammation in the CNS. We hypothesized that males may be more susceptible than females to DE neurotoxicity, because a lower level of expression of paraoxonase 2 (PON2), an anti-oxidant mitochondrial enzyme. Acute exposure to DE (250  $\mu$ g/m<sup>3</sup> for 6h) causes significant oxidative stress (lipid peroxidation as determined by the malonyldialdehyde assay) in several brain regions (particularly the olfactory bulb, the hippocampus and the cerebellum) and the ef-

fect is consistently higher in male mice than in females. A number of pro-inflammatory cytokines (IL-1 alpha, IL-1 beta, IL-3, IL-6, TNF-alpha) were also measured in olfactory bulb and hippocampus by the Luminex xMAP® technology. Levels of all cytokines increased significantly in both brain regions upon acute DE exposure, and in most cases gender differences were present. For example, in the hippocampus, levels of IL-6 increased by 18-fold and 8-fold in male and female mice, respectively. Such differences may also be due to a gender-dependent, differential expression of PON2, which has been shown to have anti-inflammatory actions in the periphery, and may have similar effects in the CNS. These findings indicate that acute exposure to DE causes oxidative stress and neuroinflammation in several brain regions, and suggests that gender plays an important role in modulating susceptibility to DE neurotoxicity, with male mice being more sensitive (Supp. in part by DEOHS).

**PS 261 Pilot Study Using an Alzheimer's Disease Animal Model to Assess the Role of Particulate Matter Exposure in Neuroinflammation and Amyloid Production.**

S. Lung<sup>1</sup>, L. B. Mendez<sup>2</sup> and A. Campbell<sup>1</sup>. <sup>1</sup>Pharmaceutical Science, Western University of Health Science, Pomona, CA; <sup>2</sup>Medicine, University of California Irvine, Irvine, CA.

Alzheimer's Disease (AD) is a neurodegenerative disease that is associated with severe memory loss and dementia. One of the major pathological markers for AD is formation of senile plaques, which are composed of amyloid beta peptides derived from amyloid precursor protein (APP). In this pilot study, we examined the effect of exposure to fine particulate matter (PM2.5) on proinflammatory markers and potential association with enhanced amyloid levels. Mice with the human Swedish mutation (Tg2576) in the APP gene and wild-type control animals were exposed to filtered air or PM2.5. Brain APP levels, NF-κB activation, and IL-1β levels were determined. Microglia and TLR2 activation in hippocampus were demonstrated. Brain levels of Aβ40 and Aβ42 were also assessed. Results showed APP levels were expressed only in brains of Tg2576 mice and not in wild type animals. The Aβ40 and Aβ42 brain level after PM2.5 exposure showed upregulation. NF-κB activation was also increased in the brain of both wild type and transgenic animals after PM2.5 exposure. IL-1β increased only in transgenic mice exposed to PM2.5. In transgenic animals, the hippocampus region showed enhanced staining for both TLR-2 and microglia after PM2.5 exposure compared to filtered air. The results of our pilot study suggest PM2.5 exposure may lead to the activation of innate immune response mediated by NF-κB pathway. The upregulation of Aβ levels in the brain of PM2.5 exposed animals suggest that there could be a link between PM2.5 exposure and enhancement of amyloid production. The results of this pilot project justify the need for a more extensive study assessing the effect of particulate matter on potentiating amyloid pathology in AD.

**PS 262 Subchronic Exposure to Deltamethrin Causes Hippocampal Neuroinflammation and Deficits in Learning and Memory.**

M. M. Hossain and J. Richardson. *Environmental and Occupational Medicine, Robert Wood Johnson Medical School, Piscataway, NJ.*

Previously, we have reported that in vitro exposure of neuroblastoma cells to deltamethrin causes apoptosis through the ER stress pathway, leading to calpain and caspase-3 activation (Hossain and Richardson, 2011). Others have found that acute high-dose deltamethrin (12.5 mg/kg) exposure causes hippocampal apoptosis in adult rats (Wu and Liu, 2000). However, little is known about the effects of longer-term lower level exposure that does not result in acute poisoning. Here, we investigated the effects of deltamethrin at a dose of 3mg/kg every 3 days for 2 months on hippocampal ER stress, neuroinflammation, and learning and memory in adult mice. Deltamethrin treatment did not result in over toxicity. However, we observed increased spectrin cleavage in the hippocampus of deltamethrin-treated mice, indicating activation of calpain. Deltamethrin also significantly increased the hippocampal mRNA expression of glial fibrillary acidic protein (GFAP; 23%) and the pro-inflammatory cytokines tumor necrosis factor-alpha (121%) and Interleukin-1 alpha (96%), indicating an ongoing neuroinflammatory process. Finally, we found that subchronic deltamethrin exposure causes profound deficits in hippocampal-dependent learning and memory in the Morris water maze, which was accompanied by a decreased mRNA expression (30%) and protein level (39%) of nerve growth factor (NGF), respectively. Together, these data suggest activation of the ER stress pathway and neuroinflammation by repeated exposure to deltamethrin may contribute to the down-regulation of NGF in the hippocampus, which may result in subsequent impairment in learning and memory in mice. Supported by NIH ES015991 and ES005022.

**PS 263 Ambient Endotoxins Possible Links to Toll-Like Receptors Gene Polymorphisms in Puerto Rican Asthmatics.**

M. G. Ortiz-Martínez<sup>1,2</sup> and B. D. Jiménez-Vélez<sup>1,2</sup>. <sup>1</sup>Biochemistry, University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico; <sup>2</sup>Center for Environmental and Toxicological Research, University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.

African Dust Storms also referred as Events (ADE) are believed to be associated to high prevalence of respiratory diseases such as asthma in Puerto Rico (PR). Endotoxins (ENX) have been previously reported as constituents associated with ADE particulate matter (PM). These ENX and related compounds are known to promote pro-inflammatory responses in lung cells and in susceptible individuals. Since ENX have been shown to work through the following receptors, we have evaluated a number of Toll-like receptors (TLR2/4) as well as the co-receptor, Cluster of Differentiation 14 (CD14) single nucleotide polymorphisms (SNPs) in the Puerto Rican population. Contradictory results exist, which link SNPs to increased asthma prevalence and/or risk in some populations. A total of 6 SNPs have been evaluated in the Puerto Rican asthmatic population. TLR2 (+596C/T, +6686T/A, +399A/G), TLR4 (+896A/G, +1196C/T) and CD14 (+1188C/G) SNPs were measured in 62 asthmatics and 59 non-asthmatic controls using Taqman® probes through a genotyping assay (Real Time PCR). Minor allele frequencies (n=121) were determined for those variants as 0.35, 0.37, 0.32, 0.07, 0.06 and 0.09, respectively. Two (+596C/T and +399A/G) TLR2 SNPs showed to be more represented in the asthmatic group (89% and 65%), combining C/T plus T/T and A/G plus G/G genotypes, respectively. TLR4 SNP +896A/G analysis revealed only 1 G/G genotype (2%) on the asthmatic group. The CD14 SNP was similarly represented in both groups. The identification of specific TLR SNPs will be valuable to understand action mechanisms of environmental ENX, which have been associated with the triggering of asthma in PR. Moreover, it will help to reveal the relevance of TLR pathway genes as potential candidates for gene-environment interactions in Puerto Ricans. Study approved by the UPR-MS-IRB (#A8570111) and supported by MBRS-RISE Grant R25GMO61838.

**PS 264 Cytotoxicity Effect and Utilization of *Mytilus edulis* Shell in the Diet of *Clarias gariepinus*.**

A. A. Idowu<sup>1</sup> and S. O. Ayoola<sup>2</sup>. <sup>1</sup>Aquaculture and Fisheries Management, Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria; <sup>2</sup>Marine Sciences, University of Lagos Akoka, Lagos, Lagos, Nigeria.

Five isonitrogenous diets (100% DCP compounded feed, 75% DCP Compounded feed and 25% *Mytilus edulis* shell, 50% DCP Compounded feed and 50% *Mytilus edulis* shell, 25% DCP compounded feed and 75% *Mytilus edulis* shell, 100% *Mytilus edulis* shell) were formulated. The *Mytilus edulis* shell was washed, sun dried for 5 days and later grinded and added to the feed and were fed to 150 juveniles of *Clarias gariepinus* which were distributed into 15 different plastic bowls. Ten specimens were stocked in each of the plastic bowls and they were fed twice daily for an experimental period of 12 weeks. In the cytotoxicity, five fishes were picked randomly from each triplicate and their blood collected carefully with syringe from the anal region and kept in sample bottles. The blood was smeared on slides and were air-dried for 24 hours, fixed in ethanol for 20 minutes and followed by 10% Giemsa staining. Each fish had 2000 erythrocytes examined and to detect micronuclei in erythrocytes, the slides were analysed using a 1000X oil-immersion lens. This implies that *Mytilus edulis* shell can be utilized best with compounded feed at a ratio of 50 to 100%. Therefore, this ratio should be adopted by fish farmers whose intention is to increase the calcium mineral level of their fishes. The obtained results for micronucleus reveals that T1 (25% MES) had the highest number of micronucleated cells while the rest (T2, T3, and T4) including the control had no significant differences. Results for BN reveal that T1 having the highest number of BN and T0 (control) having the least number of BN. While in LB, BL, and NT there were no significant differences in all the treatments. From the results it showed that *Mytilus edulis* shell (MES) has no toxins since there are less micronucleus and other aberrations in the haematopoietic cells. Hence, *Mytilus edulis* shell can be included from 50 – 100%.

**PS 265 Using a Sequence Homology-Based Predictive Strategy to Address Current Demands for Focused Toxicity Testing in Ecological Risk Assessment.**

C. LaLone<sup>1</sup>, D. L. Villeneuve<sup>1</sup>, L. D. Burgoon<sup>2</sup>, C. Russom<sup>1</sup>, H. Helgen<sup>4</sup>, J. Berninger<sup>3</sup>, J. Tietge<sup>1</sup>, M. Severson<sup>1</sup>, J. Cavallin<sup>5</sup> and G. T. Ankley<sup>1</sup>. <sup>1</sup>US EPA, Duluth, MN; <sup>2</sup>US EPA, Research Triangle Park, NC; <sup>3</sup>National Research Council, Duluth, MN; <sup>4</sup>Computer Sciences Corporation, Duluth, MN; <sup>5</sup>ORISE Research Participation Program, Duluth, MN.

The lack of resources available for comprehensive toxicity testing, international interest in limiting the quantity of animals used in testing, and a mounting list of anthropogenic chemicals produced world-wide have led to the exploration of innovative means for identifying chemicals that are potentially hazardous to the environment and its inhabitants. Predictive toxicological approaches, which utilize publically available, a priori, knowledge of a chemical and its known molecular, cellular, or whole organism interactions, show promise for focusing current toxicity testing strategies. Using modern bioinformatic techniques, we have created a computational tool, which mines the extensive genomic and proteomic sequence repositories available through the National Center for Biotechnology Information and strategically compares homology metrics associated with primary and secondary protein sequences/structural domains across taxa. These comparisons are used to identify and rank species most likely to be susceptible to a chemical acting through a known molecular initiating event and can therefore aid in designing toxicity studies for species of concern. This presentation will identify the domains of applicability for this tool and describe examples related to predicting species sensitivities to pharmaceuticals and pesticides. An assessment of honey bee sensitivity to various pesticides will demonstrate the applicability of this tool for existing questions in risk assessment. The contents of this abstract neither constitute nor reflect official US EPA policy.

**PS 266 Alteration in Behaviour, Histoarchitecture of Liver, Lung, and Kidney of Male Wistar Rats Exposed to Open Refuse Dump.**

P. U. Nwoha<sup>1,2,3</sup>, G. E. Waritimi<sup>2</sup>, A. D. Atoni<sup>2</sup>, F. Onyije<sup>2</sup> and O. M. Ijomone<sup>1</sup>. <sup>1</sup>Anatomy and Cell Biology, Obafemi Awolowo University, Ile-Ife, Nigeria; <sup>2</sup>Human Anatomy, Niger Delta University, Wilberforce Island, Nigeria; <sup>3</sup>Environmental Neurobiology and Toxicology, Centre for Scientific Investigations and Training, Owerri, Nigeria.

Household wastes are disposed in the open in Nigeria, and most third world countries. These could have serious consequences on the health of humans and animals in the vicinity. Yet not much is known on the effects of such exposure on behaviour, and organs of the body. The present work exposed weaned male Wistar rats to open refuse dump continuously for five months. During this period the rats were housed in a building on the dump, kept in clean plastic cages, fed normal rat chow, and provided clean drinking water. Control rats were housed in Niger Delta University Animal Holding. At the end of the period, behaviour of the rats was tested on Open, and Elevated plus maze, for exploratory activity and for anxiety respectively. The animals were sacrificed, liver, lung, kidney dissected, examined macroscopically, and prepared for histological examination with H & E staining. Data obtained and analysed with student t-test showed that rats exposed to refuse dump spent significantly less time in open arms of the elevated plus maze than their unexposed controls ( $p < 0.05$ ). Organs showed massive infiltration with fat, while the histology showed destruction of the radial liver architecture, thinning and collapse of alveolar wall of lung, and tubular wall of the kidney. Thus indicating that such exposure could induce anxiety, and massive destruction of organs of the body, leading to serious health consequences.

Key words: refuse exposure, anxiety, destruction, liver, lung, kidney

**PS 267 In Vitro Fish Metabolism Using Rainbow Trout Liver S9 Fractions to Evaluate the Bioaccumulation Potential of Fragrance Ingredients.**

G. Adamson<sup>1</sup>, H. Laue<sup>2</sup>, K. J. Jenner<sup>3</sup>, H. Gfeller<sup>2</sup>, S. Kern<sup>2</sup>, J. W. Nichols<sup>4</sup> and A. Natsch<sup>2</sup>. <sup>1</sup>Givaudan US, East Hanover, NJ; <sup>2</sup>Givaudan Schweiz AG, Duebendorf, Switzerland; <sup>3</sup>Givaudan UK Ltd., Ashford, United Kingdom; <sup>4</sup>US EPA, Duluth, MN.

Bioaccumulation in aquatic species is a critical endpoint in the evaluation of novel chemicals as part of PBT assessment (persistent, bioaccumulative, and toxic) by the U.S. EPA. In vivo determination of the bioconcentration factor (BCF) requires the use of large numbers of animals. Predictive models are commonly used if no in vivo

BCF data are available. These models generally acknowledge the possibility that biotransformation can reduce the extent of accumulation. Lacking measured data, however, modeled biotransformation rates are commonly set equal to zero. In vitro systems have been proposed as alternative methods that can be used to provide metabolic data needed to refine BCF computer model estimates.

The goal of our study was to determine the in vitro metabolic stability of common chemical classes of fragrance ingredients (esters, alcohols and ketones) using rainbow trout liver S9 fractions and to use in vitro clearance rate to model the bioaccumulation potential. Metabolic stability was determined by monitoring the disappearance of the parent molecule by GC MS and metabolite formation by GC-MS and LC-MS.

Slow enzymatic turnover was found with isolongifolanone (CAS 23787-90-8). The ester serenolide (477218-42-1) was transformed rapidly. Alcohols like Ambermax (929625-08-1) and ketones like spirogalbanone (224031-70-3) were transformed moderately to rapidly. Metabolic routes, identified by selective use of cofactors and metabolite identification, involve ester cleavage, hydroxylations, reductions and conjugation with glucuronic acid and glutathione. When clearance rates measured in vitro were used as inputs to the BCF model a good correlation was observed between predicted BCFs and measured in vivo values. In vitro S9 metabolism data in combination with new refined BCF models are a valuable tool to assess bioaccumulation potential as part of a weight-of-evidence approach for chemical registrations.

**PS 268 The Role of Aquaporin 3 in the Uptake of Arsenite through the Intestine of the Atlantic Killifish (*Fundulus heteroclitus*).**

D. Jung<sup>1,2</sup>, M. A. Adamo<sup>2</sup>, R. M. Lehman<sup>2</sup>, R. Barnaby<sup>1</sup>, B. P. Jackson<sup>3</sup>, J. R. Shaw<sup>4,2</sup> and B. A. Stanton<sup>1,2</sup>. <sup>1</sup>Microbiology and Immunology, Geisel School of Medicine at Dartmouth, Hanover, NH; <sup>2</sup>Mount Desert Island Biological Laboratory, Salisbury Cove, ME; <sup>3</sup>Earth Sciences and Chemistry, Dartmouth College, Hanover, NH; <sup>4</sup>School of Public and Environmental Affairs, Indiana University, Bloomington, IN.

Aquaglyceroporins (AQPs) are proteins that mediate movement of water and small solutes across cellular membrane. Previously, we cloned kAQP3a from the gill of the killifish (*Fundulus heteroclitus*), an environmental sentinel species. kAQP3a, the only AQP expressed in gill, is the first AQP3 described that does not transport arsenite. This finding accounts for the low levels of cellular arsenite in gill of killifish exposed to environmental arsenite. Another homolog of AQP3 (kAQP3b), which transports arsenic, was identified as the consensus from a transcriptome database. In this study, we sought to identify the AQPs in the intestine, a major route of arsenite uptake. First, we examined AQP mRNA expression by qRT-PCR in the killifish intestine. Among the AQPs examined, only AQP3 was significantly expressed above background levels. Western blot studies with a polyclonal antibody that did not discriminate among kAQP3 variants, revealed that kAQP3 abundance was higher in killifish acclimated to FW compared to SW. Intriguingly, whereas only kAQP3a was expressed in the intestine of FW killifish, both kAQP3a and a new variant, kAQP3c, were expressed in the intestine of SW fish. When kAQP3c was transfected into HEK293T cells, cells took up arsenic as effectively as cells transfected with kAQP3b. When we examined arsenic levels in the intestine of FW fish and SW fish exposed to 1000 µg/L arsenite for 72h, the amount of arsenic detected in the intestine of SW fish was higher than the amount detected in FW fish. Results indicate that arsenite uptake in the killifish mostly likely occurs via ingestion, and that killifish acclimated to SW take up more arsenite than FW acclimated fish, because kAQP3c expression is up-regulated in SW fish and because SW fish drink more water than FW fish.

**PS 269 Characterization of DCOIT Bioaccumulation Mechanism via In Vitro Incubation with Rainbow Trout Liver S9.**

F. Zhang, D. L. Rick, M. Bartels and G. A. Hazelton. <sup>1</sup>Global Environmental Health Sciences, Tulane University, New Orleans, LA; <sup>2</sup>Tulane Cancer Center, Tulane University, New Orleans, LA; <sup>3</sup>Department of Biomedical Sciences, Tulane University, New Orleans, LA; <sup>4</sup>Department of Sociology, Washington State University, Pullman, WA; <sup>5</sup>Mary Queen of Vietnam Community Development Corporation, New Orleans, LA.

4, 5-Dichloro-2-(n-Octyl)-4-Isothiazolin-3-one (DCOIT) is an important biocide widely used in a variety of industrial processes. In supporting DCOIT regulatory registration, a bioaccumulation study in bluegill sunfish was conducted with 14C-DCOIT and indicated the bioconcentration factor (BCF) was 750 ml/g with less than 1 % of radioactivity in tissues attributed to DCOIT. To understand the findings in the in vivo fish bioaccumulation study, the in vitro metabolism of DCOIT was examined by using rainbow trout liver S9 (Fish S9) and glutathione (as protein

surrogate) in the presence or absence of NADPH. The potential metabolites including glutathione conjugates were identified and quantified via LC/MS-MS methodologies and radioactivity counting, and the protein binding activity of DCOIT was also quantified. Overall, more than nineteen metabolites (all chlorine-free) were identified with a majority of these metabolites conjugated to glutathione or cysteine. Incubations containing Fish S9 and DCOIT in the absence of glutathione resulted in much higher protein binding than those incubations containing glutathione. This demonstrated that glutathione present in the incubation medium acts as a useful surrogate of endogenous Fish S9 proteins to competitively react with DCOIT (or DCOIT active metabolites). The results from the present study provide evidence that the BCF value measured in vivo can be attributed to ring-opened metabolites binding high molecular weight tissue fractions- likely the sulphhydryl moieties in proteins. These data confirm that parent DCOIT does not bioaccumulate in fish, but the parent molecule is extensively metabolized to metabolites which were bound to high molecular weight components of the fish tissue (i.e., proteins).

## PS 270 Zinc Content Determines the Toxicity of Tire Leachate in *Girardia tigrina*.

R. Sneed, E. Coleman and E. Rice. *Biology, Chemistry, and Physics, University of the District of Columbia, Washington DC.* Sponsor: P. Ganey.

The practice of recycling old tires into various outdoor structures such as playground surfaces and landfill liners poses the risk of tire components moving into local watersheds and possibly affecting aquatic organisms. In this study we tested the hypothesis that the zinc content of tire leachate is a significant factor in its toxicity to *Girardia tigrina* (Girard, 1850), a freshwater planarian common to North American waterways. Planarians were cultured in tire leachate containing either 49.5 mg/L of zinc (BALT) or 0.13 mg/L (FRESH) of zinc or a control of extraction medium (EM) over a time period of 24 hours. All planarians in the BALT group died within 24 hours while no planarians died in either the FRESH or EM groups. To verify that zinc was the causative agent in the observed toxicity, planarians were maintained in a solution containing an equivalent amount of zinc (from zinc sulfate) for 24 hours. The survival rate of planarians in this group was not significantly different from the survival rate observed in the BALT group. These data strongly indicate zinc as the toxic agent. In addition to the lethality demonstrated by both high-zinc solutions, planarians displayed signs of distress indicated by increased activity, writhing, and loss of motor coordination prior to death when compared to controls, suggesting that neurotoxicity may be the mechanism of action. Future studies will examine the dose-response relationship of zinc toxicity in *G. tigrina* as well as evidence of neurotoxicity. (Support: NSF Award 0928444.)

## PS 271 Harmonizing Use of the 3Rs in Fish Toxicity Testing.

C. Willett<sup>1</sup>, S. Belanger<sup>2</sup>, M. Embry<sup>3</sup>, T. Iguchi<sup>4</sup>, M. Halder<sup>5</sup>, A. Lillicrap<sup>6</sup>, H. Rufli<sup>7</sup>, L. Touart<sup>8</sup> and S. Zok<sup>9</sup>. <sup>1</sup>The Humane Society of the United States, Gaithersburg, MD; <sup>2</sup>Procter & Gamble, Cincinnati, OH; <sup>3</sup>Health and Environmental Sciences Institute, Washington DC; <sup>4</sup>National Institute for Basic Biology, Okazaki, Japan; <sup>5</sup>ECVAM, Joint Research Centre, Ispra, Italy; <sup>6</sup>Norwegian Institute for Water Research, Ecotoxicology and Risk Assessment, Oslo, Norway; <sup>7</sup>Ecotoxolutions, Basel, Switzerland; <sup>8</sup>Office of Science Coordination and Policy, US EPA, Washington DC; <sup>9</sup>BASF, Ludwigshafen, Germany.

Pursuit of methods that refine, reduce or replace animals is often discussed in the context of human health hazard and risk assessment; however, several approaches that are in common use for human health are more frequently being applied in ecological hazard and risk assessment as well. Organized testing frameworks such as tiered frameworks or integrated strategies can be used to prioritize information needs and focus testing on tests that would be the most informative for a given regulatory need. Specific application of integrated strategies has been used to minimize fish used for acute toxicity testing, for example the limit and threshold approaches. There are principles that can be applied to specific test protocols that minimize animal use, for example the use of historical controls where appropriate or using statistical analyses to define the minimum individuals needed to obtain statistically significant results. Computer modeling can assist in extrapolating information from one species to another or in predicting acute toxicity, bioaccumulation and other biological activity in fish. While limited embryo, ex-vivo, and in vitro approaches are currently used in fish toxicity testing, opportunities exist for expanding the repertoire, particularly in the area of 'omics technologies. This presentation will describe these approaches as currently applied and present recommendations for improving the application and harmonization of 3Rs approaches to fish toxicity

testing, as presented in Chapter 5 of the Fish Toxicity Testing Framework Guidance Document prepared by the Organization of Economic Cooperation and Development (August 2012).

## PS 272 Concentrations of Metals Associated with Crude Oil from the BP Macondo Well in Sediments and Fish from the Northeastern Gulf of Mexico.

A. C. Nichols, D. A. Steffy and L. J. Morgan. *Physical and Earth Sciences, Jacksonville State University, Jacksonville, AL.*

To investigate if metals associated with crude oil from the BP Macondo Well were entering the marine food chain, sediment and scad mackerel (*TRACHURUS LATHAMI*) samples were analyzed by ICP for five of these metals: chromium, nickel, lead, thallium and vanadium. Samples were collected from the carbonate shelf along the west coast of Florida in fall, 2010. A subset of these samples was collected from the western Florida Panhandle. This area was south of the Florida beaches where tar balls washed ashore during the summer of 2010. Nickel levels in samples from this subset ranged from 2.85 to 11.18 micrograms/g in dry sediments, and 0.00 to 0.86 micrograms/g in dry fish tissues. Chromium levels in samples from this area ranged from 7.08 to 12.43 micrograms/g in sediments, and from 0.00 to 0.76 micrograms/g in scad. Vanadium levels ranged from 3.32 to 10.07 micrograms/g in sediments. Vanadium was the only one of these metals not detected in any of the fish. Lead levels ranged from 1.13 to 5.89 micrograms/g in sediments, and 0.00 to 0.36 micrograms/g in scad. Thallium appears to be biomagnified in scad, as concentrations in fish ranged from 0.72 to 1.42 micrograms/g, while sediment levels ranged from 0.00 to 0.30 micrograms/g.

## PS 273 The Effect of Tributyltin (TBT) on Zebrafish Sexual Differentiation.

C. L. McGinnis. *Quinnipiac University, Hamden, CT.*

Tributyltin (TBT), an antifouling agent, has been implicated in the masculinization of fish species worldwide, however the molecular mechanism is not fully understood. Our lab has previously examined the actions of TBT as an endocrine disruptor in zebrafish (*Danio rerio*) and determined, in vitro, that TBT inhibits zER specific activity in a dose dependent manner and may potentially act through the RXR portion of the PPAR-RXR (peroxisome proliferator-activated receptor gamma - retinoid X receptor alpha) heterodimer. Additionally, zebrafish were exposed to increasing concentrations of TBT and sexual differentiation genes were analyzed via qPCR. Results from qPCR focused our experimental efforts on the candidate gene, SRY-box containing gene 9a (Sox9a). Sox9a is a key regulator in mammalian testis differentiation, where it is shuttled to the nucleus upon differentiation; this appears to be a conserved mechanism across fish, marsupials and placental mammals. Developing zebrafish embryos were exposed to 1pM and 2.5pM TBT from 10 days post hatch (dph) to 90 dph and sampling was done at 25, 35, 40, 45, 60 and 90 dph. Fish were treated three times per week with either TBT, estrogen or vehicle. Following treatments, immunohistochemical (IHC) analysis was performed to assess Sox9a nuclear or cytoplasmic localization.

## PS 274 Heavy Metal Response in *Daphnia magna*: An Ecologically-Relevant Nonmodel Organism.

S. Roy and M. E. Pfrender. *Biology, University of Notre Dame, Notre Dame, IN.*

Environmental health issues have become a major focus of ecotoxicology research over the last decade. Due to rapid industrialization and urbanization, ecosystems are currently, and into the foreseeable future, under the threat of potential damage. In order to mitigate these risks, environmental scientists build predictive models to gauge the impact of pollutants, perform risk assessment studies to measure water quality, and protect organisms from potential damage due to the effects of pollutants.

One major pollutant is heavy metal. Since aquatic systems are the major sinks of industrial effluents they are often more highly impacted by heavy metals than area terrestrial ecosystems. Numerous studies on individual organisms and populations have demonstrated the effects of acute exposure to metal pollutants, but few studies are available that show the consequences of long-term low dose metal exposure to aquatic organisms.

In regular risk assessment practice, acute and high dose/concentration exposure is a common approach to predict which metal/chemical has potentially harmful effects on a particular organism. This approach is informative, but not predictive of the long-term low dose/concentration scenario that is more likely happening in our

day-to-day life. Further, aquatic toxicity tests have historically been largely limited to model organisms. However, not all organisms show the same physiological response to a particular metal/chemical making these assessments species specific. Our approach is to use quantitative genetics/genomics tools applied in an ecological relevant non-model organism to determine the genetic basis and mechanisms of response to a common, toxic metal pollutant. We use *Daphnia magna*, a widespread freshwater invertebrate, as a model organism to understand and interpret the genetic mechanisms of response to cadmium.

**PS 275 Characterization of the Hepatic Metabolome of Migrating Sockeye Salmon in British Columbia, Canada.**

J. P. Benskin<sup>1,2</sup>, M. G. Ikonomou<sup>2</sup>, N. Veldhoen<sup>3</sup>, C. Dubetz<sup>2</sup>, C. C. Helbing<sup>3</sup> and J. R. Cosgrove<sup>1</sup>. <sup>1</sup>Product Development, AXYS Analytical Services Ltd., Sidney, BC, Canada; <sup>2</sup>Fisheries and Oceans Canada, Institute of Ocean Sciences, Sidney, BC, Canada; <sup>3</sup>Biochemistry and Microbiology, University of Victoria, Victoria, BC, Canada.

The health of British Columbia wild sockeye salmon (*Onchorhynchus nerka*) is of increasing concern due to recent extreme variation in the number of fish returning to spawn annually. Causes of this variability are unclear but may be related to contaminant or viral exposures, climate change, or food shortages. Two key migratory routes for Pacific sockeye are the Fraser and Skeena River watersheds. These watersheds represent highly contrasting environments for spawning salmon; the former flows through populous and industrialized regions of Vancouver, while the latter flows through fairly remote regions with little industrial input. A recent comparison of hepatic mRNA profiles between Fraser and Skeena sockeye revealed stark differences in estrogen-associated signaling in Skeena fish, despite these fish spawn in a relatively pristine environment. In contrast, the status of hepatic gene transcripts for Fraser River sockeye showed normal reproduction-related changes in estrogen-associated signaling. To expand upon available toxicological endpoints and further define potential sources of exposure resulting in the observed hepatic mRNA profiles in Skeena River salmon, we compared aspects of the hepatic metabolome of fish from both populations. A total of 186 metabolites from 6 different metabolite classes were measured using a recently developed assay. Molecular targets included acylcarnitines (n=40), amino acids (n=21), glycerophospholipids (n=90),  $\Sigma$ hexose, sphingolipids (n=15), and biogenic amines (n=19). Major metabolites quantified in Sockeye salmon liver included glycine, carnitine, phosphatidylcholine acyl-alkyl C38:6, and sphingomyeline C24:1. The combined transcriptomic and metabolomic data provides a comprehensive molecular profile of fish health, and sheds light on the biochemical changes arising from alteration of estrogen-associated signaling.

**PS 276 Elevated Metals and Organic Concentrations Linked to Biomarkers' Alterations in Organisms Exposed to Mining Effluent.**

O. T. Olubambi and V. Wepener. Centre for Aquatic Research, Department of Zoology, University of Joburg, Johannesburg, South Africa.

The Blesbokspuit wetland, South Africa, continuously receives diffuse and point source releases of mining effluent till date. Results are presented from a first time study conducted in the system on metals and organic bio-accumulation in sediments, residents and transplanted organisms. A suite of biomarkers assay was also carried out in bio-indicators. During the 2008 low and high flow periods, resident catfish, *Clarias gariepinus* and tilapia, *Tilapia sparrmanii* species were collected from 5 sites in a field survey. During the 2009 high flow, a transplantation study (active bio-monitoring - ABM) was conducted using laboratory reared *Tilapia* spp. at four of the five sites in cages for four weeks. Biomarkers of exposure: cytochrome P-450 (CYT-P450) and acetylcholine esterase (AChE) and biomarkers of effect: catalase (CAT) and superoxide dismutase (SOD) responses were determined in all samples. Metal and organic concentrations measured varied among sites and were elevated ( $p < 0.05$ ) during the field survey high flow than the low flow in most cases. This was always high for both periods in Site 1 which is upstream and close to mine dumps. Biomarkers were found altered both in resident and transplanted organisms at all sites. For example, triggered CAT activity and inhibition of SOD both indicative of oxidative stress was observed. CYT-P450 and AChE activities inhibition, which indicates organometallic and pesticides exposure was also observed. Biomarker responses were similar for both resident and transplanted fishes for the high flow periods ( $p < 0.05$ ). Site 5 (reference site) generally showed the least altered responses during the field survey low flow but not during the high flow and ABM. Biomarkers were able to successfully demonstrate biological effects from toxicants in the system. It was possible to link these effects to observed elevated metal and organic concentrations found in bio-indicators. This approach can be applied within the proposed integrated management plan for the Blesbokspuit as well as other catchments.

**PS 277 Effects of Two Progestins, Norethindrone and Levonorgestrel, on Reproduction in a Marine Fish, *Tautoglabrus adspersus*.**

L. Mills<sup>1</sup>, D. Borsay Horowitz<sup>1</sup>, G. Zarogian<sup>1</sup>, B. Rashleigh<sup>1</sup>, B. W. Riffle<sup>2</sup> and S. C. Laws<sup>2</sup>. <sup>1</sup>Atlantic Ecology Division, US EPA, ORD, NHEERL, Narragansett, RI; <sup>2</sup>Toxicology Assessment Division, US EPA, ORD, NHEERL, Research Triangle Park, NC.

Endocrine-active pharmaceuticals that enter the aquatic environment through sewage effluent may have unintended impacts on reproduction in fish, which in turn may affect the sustainability of exposed populations. Laboratory experiments were conducted with the marine fish cunner (*Tautoglabrus adspersus*) to evaluate whether norethindrone (NOR) and levonorgestrel (LNG) affected reproduction in spawning adults. Both progestins are used in human contraceptive formulations and have been detected in low (ng/L) concentrations in aquatic environments. Synthetic progestins in aquatic environments are of special concern because some fish use natural progesterones as pheromones to coordinate reproduction, and evidence suggests progestins may be selectively taken up through the gills in some species. Reproductive endpoints of egg production, viability and fertility were assessed daily in spawning cunner treated with NOR or LNG (nominal concentrations of 0, 0.075 or 0.75 mg/kg) by oral gavage on days 0, 4, 8, 12 and 16 of the experiment. All fish were sacrificed on day 17 and gonadosomatic index (GSI) was determined. In NOR-treated fish, egg production per gram female was significantly reduced relative to controls at both concentrations, while egg fertility and viability was notably decreased, although not significantly, only in the 0.75 mg/kg treatment. GSI was significantly reduced in both males and females from the 0.75 mg/kg treatment. Female mortality in this treatment group was more than twice that in controls, indicating an increase in male aggression. In LNG-treated cunner, no significant effect was seen on egg production, fertility, viability, or GSI compared to control fish. Results indicate some progestins can impact fish reproduction, even in short-term exposures. Research is planned to determine if these fish selectively take up progestins from the aquatic environment. This abstract does not reflect U.S. EPA policy.

**PS 278 Effects of Fungicides on Honey Bee Development and Behavior.**

L. A. Hoooven. Oregon State University, Corvallis, OR.

Pesticides may contribute to the health challenges facing honey bees. Bees experience chronic exposures through contaminated beeswax and stored pollen and honey. There is a need to study possible sublethal or delayed effects from such exposures, which may ultimately result in the collapse of the colony. Fungicides are thought to have little effect on insects, and are routinely sprayed while bees are pollinating crops. Multiple fungicides are transported with pollen into the colony, and some are known to persist in beeswax. Beekeepers suspect that fungicides may have an effect on honey bee development, and some laboratory tests have demonstrated adverse effects of fungicides on bee larvae. We have developed laboratory methods to chronically expose young adult bees to pesticide-contaminated beeswax, in concentrations similar to those found in hives. By using Noldus Ethovision to track the behavior of bees on video, we have found that the major contaminants of beeswax, including the fungicide chlorothalonil, delay behavioral development as measured by the initiation of circadian activity rhythms. Young adult bees consume pollen and secrete proteinaceous brood food and royal jelly to feed developing larva and the queen. In semi-field experiments, we fed pollen spiked with fungicides to colonies of bees, similar to field concentrations. By evaluating colonies weekly, we found that chlorothalonil and iprodione affect larval development, and ziram affects queen health several weeks after initial exposure. These results suggest that chronic contact exposure through wax and ingestion of fungicides through pollen may target the development and social function of young worker bees, and may have detrimental effects on the colony.

**PS 279 The Mediterranean Gecko, *Hemidactylus turcicus* (Gekkonidae : Squamata)—An Alternative Model for the Study of Redox Potential.**

M. Y. Farooqui and R. Bloom. Biology, University of Texas Pan American, Edinburg, TX.

Glutathione and similar sulfhydryl groups play an important role in redox cycling in mammals. In this study we have investigated the role of sulfhydryls in the Mediterranean Gecko, *Hemidactylus turcicus* (Gekkonidae : Squamata). Concentrations of hepatic sulfhydryls were determined in the field controls and the geckos maintained at various temperatures. Concentrations of sulfhydryls in livers

of field controls were  $46.3 \pm 5$   $\mu\text{moles/g}$  and were significantly elevated (141 and 151 % of controls) in geckos maintained at 15 and 100°C, respectively. Female geckos had significantly higher (139 %) concentrations of sulfhydryls than did the males. This study indicates that this oxidative biochemical pathway is operative in geckos. Geckos may provide a very inexpensive alternative animal model for redox studies.

## PS 280 Recent Emergence of Perfluorohexanoate in Tap, River, and Sea Water in Japan.

N. Saito, K. Sasaki and S. Tsuda. *Iwate Institute of Environmental Health Sciences, Morioka, Japan.*

Environmental waters such as river water (RW) and sea water (SW) are expected to be the major exposure sources of Perfluoroalkyl acids (PFAA) to humans via tap water (TW) and food fish. At the 2012 Annual Meeting of SOT, we reported the trend in PFAA contaminations in Japanese RW and TW from 2003 to 2010, based on the results of measurement of Perfluorocarboxylates (from C5 to C12 carbon backbone) and perfluorosulfonates (CS4, CS6, CS8 and CS10). The major PFAA (C6, C8, C9 and CS8) concentrations in both RW and TW were always highest in Kinki area. In 2010 extremely high RW C6 concentrations (46 and 24  $\mu\text{g/L}$ ) were detected in the lower reaches at the foot of a fluorochemical plant, where extremely high concentrations of C8 (67 and 24  $\mu\text{g/L}$ ) had been detected in 2003. From 2003 to 2010, Kinki showed drastic reduction of RW C8 concentration to one tenth. C6 concentration in TW in 2007 showed as low as 2.3 % of RW in 2010 compared to 42.3% for that of C8. The conclusion there was that the release of C6 to the environment had begun recently from the source in Kinki. In the present study, we measured PFAA (from C4 to C16; and CS4, CS6, CS8 and CS10) in RW (12 locations) and TW (6 locations) in the Kinki area and costal SW around Japan (31 locations) collected in 2011 using LC-MS/MS. The highest RW Perfluorocarboxylates (from C4 to C10) were detected in the lower reaches at the foot of the fluorochemical plant (for C6: 49 and 43  $\mu\text{g/L}$ ). The highest TW C6 concentration in the 2011 samples was 2.85 ng/L, which was greater than the highest C6 concentration (1.51 ng/L) in the 2007 samples. The highest SW C6 concentration in Kinki was far greater than the samples from the other areas and was 129 ng/L. From these results it was concluded that C6 release from the source to the river of recent onset is rapidly contaminating surrounding SW and gradually contaminating TW in the nearby areas.

## PS 281 Distributions of Metals (Cadmium, Lead, Iron, Manganese, Zinc, and Copper) in Water, Aquatic Plant, and Fish.

K. A. Abdou<sup>1</sup>, A. S. Mahmoud<sup>2</sup>, M. S. Housen<sup>1</sup> and K. I. Ahmed<sup>1</sup>. <sup>1</sup>Department of Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Beni Suef University, Beni Suef, Egypt; <sup>2</sup>Department of Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Assiut University, Assiut, Egypt. Sponsor: A. Kadry.

Concentrations of cadmium (Cd), lead (Pb), iron (Fe), manganese (Mn), zinc (Zn) and copper (Cu) were measured in water, Ceratophyllum demersum (C. demersum) aquatic plant, Clarias lazera fish (C. lazera) collected from nine sampling stations along El Ebrahimia canal and two districts located at the east bank of the Nile in the province of Beni Suef, Egypt during 2009-2010.

Atomic Absorption analysis revealed that the studied metals were higher than the limit of detection (LOD) in all the examined samples. In water, Pb had the highest concentration among the metals detected in seven of the nine tested locations (0.3 - 0.9 ppm). The concentrations of Pb, Fe, and Mn were above the maximum Egyptian permitted limits in all tested sites, while Zn and Cu concentrations were below the permitted limits (4 mg/l and 2 mg/l) in the nine districts. Comparisons were made of the metal concentrations in water and aquatic plants with those in the catfish tissues obtained from water. The metal concentrations found in the C. demersum aquatic plant samples taken in the nine studied districts were distributed in this order;  $\text{Mn} > \text{Zn} > \text{Cu} > \text{Pb} > \text{Fe} > \text{Cd}$ , and were higher than the water. In fish, metals accumulated in the various examined tissues at several levels, but the metal concentrations in muscles (edible part) were below the metal levels in the other organs (nonedible) in the fish samples. The concentrations of Cd, Pb and Fe in fish tissues were above the international standard, while the concentrations of Mn, Zn and Cu were below this standard. The high concentrations of these metals in water, aquatic plants and fish in El Ebrahimia canal may be the result of both anthropogenic activities producing industrial, agricultural and domestic waste and accidental pollution incidents.

## PS 282 Cytochrome P450 Monooxygenases Expression in Human Epithelial Lung Cell Lines.

M. Niehof and T. Hansen. *Fraunhofer ITEM, Hannover, Germany.* Sponsor: C. Dasenbrock.

The pulmonary epithelium is the first barrier for airborne xenobiotics and inhaled drugs. Cytochrome P450 monooxygenases (CYP) participate in metabolic inactivation of xenobiotics. Beyond that some compounds require enzymatic activation to exert their toxic effects or their desirable functions. The bronchial epithelial cell line Calu-3 and the type II-like pulmonary epithelial cell line A549 serve as cell culture models for the human respiratory epithelium. So far, there is little information regarding their metabolic properties especially for Calu-3 cells. The goal of this study was to further characterize both cell lines regarding their basal and inducible CYP isoform expression.

CYP expression was determined using real-time reverse transcription quantitative polymerase chain reaction (RT-qPCR). Basal expression of CYP1B1, CYP1A1, CYP2D6, CYP2B6/7, CYP3A5, and CYP2J2, and slight amounts of further CYPs were detected in both cell lines, which is consistent with expression in the human lung.

Furthermore, potential CYP inducers were analyzed. Omeprazole acts on aryl hydrocarbon receptor (AhR) activation and induced CYP1A1 and CYP1B1 in both cell lines. Rifampicin acts on pregnane x receptor (PXR) and phenobarbital acts predominantly on constitutive androstane receptor (CAR), however, both receptors are not expressed in the lung. Accordingly, both agents did not induce any CYP in these cells. Besides PXR, dexamethasone acts on glucocorticoid receptors and we found induction of members of the CYP3A family, mainly CYP3A7 in Calu-3 cells, and CYP3A5 and CYP3A7 in A549 cells. CITCO is known to act as a CAR agonist and is normally used to induce CYP2B6/7. However, it is a potent inducer of CYP1B1 in Calu-3 cells, and of CYP1A1 and CYP1B1 in A549 cells.

Thus, Calu-3 cells and A549 cells express a broad range of CYPs with preserved inducibility and are valuable models of the airway epithelial barrier for metabolic in vitro experiments.

## PS 283 Role of Renal Proximal Tubule P450 Enzymes in Chloroform-Induced Nephrotoxicity.

S. Liu<sup>1,2</sup>, Y. Yao<sup>1</sup>, S. Lu<sup>1</sup>, X. Ding<sup>1</sup>, C. Mei<sup>1</sup> and J. Gu<sup>1</sup>. <sup>1</sup>Wadsworth Center, Albany, NY; <sup>2</sup>Changzheng Hospital, Shanghai, China.

The kidney is a primary target for numerous toxicants. Cytochrome P450 enzymes (P450s), responsible for the metabolic activation of various chemical compounds, are predominantly expressed in proximal tubules in the kidney. However, the specific role of proximal tubule P450s in chemical-induced nephrotoxicity is unclear. The aim of this study was to test the hypothesis that renal proximal tubule P450s are critical for the metabolic activation and nephrotoxicity of chloroform. To test this hypothesis, we have developed two new mouse models, one having proximal tubule-specific deletion of the cytochrome P450 reductase (Cpr) gene (the enzyme required for all microsomal P450 activities), named kidney-Cpr-null, and the other with proximal tubule-specific rescue of CPR activity in a model with global suppression of CPR activity in all extra-renal tissues, named extra-renal Cpr-low. The kidney-Cpr-null, extra-renal-Cpr-low, Cpr-low, and wild-type (WT) control mice were treated with a single oral dose of chloroform at 200 mg/kg. Blood, liver and kidney samples were obtained at 24 h after the treatment. Kidney toxicity was assessed by measuring serum levels of BUN and creatinine, and by pathological examination. The blood and tissue levels of chloroform were also determined. Chloroform-induced proximal tubular lesions and increases in BUN and creatinine levels were observed in all four genotypes, but the severity of toxicity was less in kidney-Cpr-null and Cpr-low mice, compared to WT and extra-renal-Cpr low mice, respectively. There was no significant difference in chloroform levels in the blood, liver, or kidney, between kidney-Cpr-null and WT mice, or between extra-renal-Cpr-low and Cpr-low mice. These findings indicate that local P450 dependent metabolic activation plays an important role in renal toxicity induced by chloroform. Our results also demonstrate the utility of these novel mouse models for studies on the renal toxicity of other chemicals.

## PS 284 Green Tea Epigallocatechin Gallate Inhibits Drug Metabolizing Enzymes by Covalent-Binding to the Proteins and Formation of Protein Aggregates.

Z. Weng and Q. Shi. *Division of Systems Biology, US FDA, NCTR, Jefferson, AR.* Sponsor: X. Yang.

Green tea supplements have been reported to cause hepatotoxicity but the mechanisms of the toxic metabolite, epigallocatechin gallate (EGCG), are unknown. In this study, the rat liver microsomes were treated with 1 - 100  $\mu\text{M}$  EGCG for 30

min, and the EGCG-binding proteins were affinity purified and probed with antibodies against glyceraldehyde-3-phosphate dehydrogenase (GAPDH), actin, cytochrome P450 (CYP) 1A1, CYP1A2, CYP2B1/2, CYP2E1, CYP3A, catechol-O-methyltransferase (COMT) and microsomal glutathione transferase 1 (MGST1). All but actin and soluble COMT were positively detected at  $\geq 1 \mu\text{M}$  EGCG, indicating EGCG selectively bound to a subset of proteins including membrane-bound COMT. The binding correlated well with inhibition of CYP activities, except for CYP2E1 whose activity was unaffected despite evident binding. When microsomes were probed on Western Blots, all but the actin and CYP2E1 antibodies showed a significant reduction in binding at  $\geq 1 \mu\text{M}$  EGCG, suggesting that a fraction of the indicated proteins formed aggregates that were not recognizable by antibodies against the intact proteins. Protein aggregate formation was also observed in Coomassie Blue-stained SDS-PAGE gels. EGCG effects were partially abolished in the presence of 1 mM glutathione. We conclude that EGCG inhibits drug metabolizing enzymes by covalent-binding to the target proteins and formation of protein aggregates.

## PS 285 Metabolism of Rutaecarpine in Freshly Isolated Hepatocytes from Rats and Mice.

T. Jeong, D. Lee, D. Oh, J. Kim, Y. Jahng and M. Kang. *Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea.*

Rutaecarpine is an alkaloid originally isolated from *Evodia rutaecarpa* that has been used for the treatment of gastrointestinal disorders in Asia. In the present study, Phase I and Phase II metabolisms of rutaecarpine were investigated in freshly isolated hepatocytes from rats and mice. The results indicated that the metabolism of rutaecarpine in rats and mice was different. When rutaecarpine was incubated with fresh hepatocytes isolated from either rats or mice for 2 hr, 5 major Phase I metabolites were observed in both hepatocytes with different extents. Likewise, the production of sulfate conjugates also showed difference. In rat hepatocytes, 4 sulfate conjugates were observed, whereas only two conjugates were observed in murine hepatocytes. The results indicated that the species selection would be concerned in the process of preclinical investigation. Supported by a grant from National Research Foundation of Korea (2010-00266220).

## PS 286 Effects of Intestinal Microflora on Oral Pharmacokinetics of Baicalin in Normal and Antibiotic-Treated Mice.

D. Oh, M. Kong, J. Kim, M. Kang, W. Kang and T. Jeong. *Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea.*

Baicalin (baicalein-7-glucuronide) is an ingredient of *Scutellaria baicalensis* Georgi that has been used as one of the most popular herbs in Korea for treatment of inflammation, cardiovascular diseases, hypertension, and microbial infections. In the present study, effects of intestinal microflora on oral pharmacokinetics of baicalin were investigated in normal SPF and antibiotic-treated mice. To control the number of intestinal bacteria, mice were pre-treated orally with erythromycin, oxytetracycline and cefadroxil for 3 consecutive days, followed by an oral administration with 100 mg/kg baicalin. Then baicalin and its possible metabolites in serum were determined by using liquid chromatography/electrospray ionization mass spectrometry. By the pre-treatment with antibiotics, the number of intestinal microflora was significantly reduced. In addition, serum concentrations of baicalin and its metabolite, baicalein-6-glucuronide, were remarkably changed by treatment with antibiotics when compared with control mice. These results indicated that the intestinal microflora might have a critical role in modulating oral pharmacokinetics of baicalin. Supported by the grant from KFDA (09172KFDA996) and from National Research Foundation of Korea (2010-00266220).

## PS 287 Role of Intestinal Microflora in Oral Pharmacokinetics of Baicalin in a Germ-Free Mouse Model.

J. Kim<sup>1</sup>, D. Oh<sup>1</sup>, M. Kang<sup>1</sup>, W. Yun<sup>2</sup>, H. Kim<sup>2</sup> and T. Jeong<sup>1</sup>. <sup>1</sup>Pharmacy, Yeungnam University, Gyeongsan, Republic of Korea; <sup>2</sup>Biomedical Mouse Resource Center, KRIBB, Ochang, Republic of Korea.

Baicalin and its aglycone baicalein are bioactive flavonoids originally isolated from the root of *Scutellaria baicalensis* Georgi, a medicinal plant that has been used for the treatment of inflammation, hypertension, cardiovascular and allergic diseases. In the present study, role of intestinal microflora in baicalin metabolism was investigated following a single oral administration with 100 mg/kg baicalin in germ-free and control mice. Baicalin and its metabolites were determined by HPLC coupled with a tandem mass spectrometry. Serum concentrations of baicalin and its

metabolite in germ-free animals were significantly lower than those in control mice having normal intestinal microflora. Likewise, transient hepatotoxicity induced by baicalin in germ-free mice was significantly different from that in control mice. These results indicated that the intestinal microflora might play a key role in metabolism of baicalin orally ingested. Supported by the grant from KFDA (09172KFDA996) and from National Research Foundation of Korea (2010-00266220).

## PS 288 Importance of Chirality Considerations in Risk Assessments: Enantiomer-Specific Pharmacological Metabolism with Rainbow Trout (*Oncorhynchus mykiss*) S9.

K. Connors<sup>1</sup>, B. Du<sup>1</sup>, P. N. Fitzsimmons<sup>2</sup>, C. K. Chambliss<sup>1</sup>, J. W. Nichols<sup>2</sup> and B. W. Brooks<sup>1</sup>. <sup>1</sup>Baylor University, Waco, TX; <sup>2</sup>US EPA, Duluth, MN.

Enantiomers are capable of having significantly different biological effects, selectivity for receptors/transporters/enzymes, potency, and biodegradation rates. Differences in environmental fate, bioavailability and toxicity have also been reported. Despite this knowledge, enantiomers are often treated as a single chemical entity in environmental monitoring and risk assessment. Enantiomer-specific differences in pharmaceuticals are especially well documented within mammalian literature. Finding a way to leverage existing pharmaceutical safety data and pharmacology information through biological "read-across" may aid our ability to perform more accurate environmental assessments. In this study, we examined the comparative metabolism of R, S and the racemate of three pharmaceuticals (propranolol, ibuprofen and fluoxetine) in rainbow trout liver S9 using a substrate depletion approach. An isotope dilution liquid chromatography tandem mass spectrometry (LC-MS/MS) method was employed for quantitation of parent chemical concentrations. Differential substrate depletion rates were observed for propranolol enantiomers. The fastest clearances rates were observed with rac-propranolol, followed by S and R-propranolol, respectively. Ibuprofen appeared to undergo limited metabolism; however, the resulting depletion curves did not differ statistically from those obtained for denatured controls. No substrate depletion was observed for rac, R or S fluoxetine. Mammalian clearance rates will be compared and risk assessment implications discussed.

## PS 289 The Role of Interstrain Differences in Trichloroethylene Metabolism in Kidney Effects in Mice.

H. Yoo, B. U. Bradford, L. B. Collins, O. Kosyk, S. Shymonyak, W. M. Bodnar, L. M. Ball, A. Gold and L. Rusyn. *Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Trichloroethylene (TCE) is a well-known environmental and occupational toxicant contaminating air, water, and soil. The U.S. EPA recently issued the final IRIS assessment of TCE and classified TCE as carcinogenic to humans. Still, several issues critical for assessing human health risks from TCE remain unresolved, such as (1) the amount of glutathione (GSH)-conjugated metabolites formed in various tissues, and possible inter-individual and inter-species differences; and (2) the mode of action involved in kidney toxicity/carcinogenesis. The aim of this study was to use a panel of inbred mouse strains to investigate the relationship between inter-strain differences in TCE metabolism and kidney toxicity. TCE (600 mg/kg/day, in 5% Alkamuls EL-620 in saline) was administered by gavage to male mice (6-8 weeks old) from 7 inbred strains (129S1/SvImJ, A/J, BTBR T+tf/J, C57BL/6J, CAST/EiJ, NOD/ShiLtJ, NZW/LacJ) for 5 days. Liver, kidney, and serum were collected at 2 and 8 hrs after the last dose. Quantification of S-(1,2-dichlorovinyl)glutathione (DCVG), S-(1,2-dichlorovinyl)-L-cysteine (DCVC), and trichloroethanol (TCOH) was performed. In addition, blood urea nitrogen, kidney-to-body weight ratio, proximal tubular cell proliferation, expression of peroxisome proliferator marker genes (*Ppara*, *Acox1*, and *Cyp4a10*), kidney injury molecule-1 in kidney were evaluated. Inter-strain variability in the levels of DCVG, DCVC, and TCOH in liver, serum, and kidney were observed. Overall, the level of TCOH was 10,000-fold greater than that of DCVG and DCVC in both liver and kidney. In conclusion, the inter-strain differences in TCE metabolism provide a mechanistic basis for examining the inter-strain differences in TCE organ-specific toxicity. This work was supported by the Superfund Basic Research Program grant P42 ES005948.

**PS 290 Interpretation of Multiroute Data for Chloroform-Induced Renal Toxicity in Rats and Mice Using an Updated Physiologically-Based Pharmacokinetic Model.**

A. F. Sasso<sup>1</sup>, P. M. Schlosser<sup>2</sup>, G. L. Kedderis<sup>6</sup>, M. Genter<sup>3</sup>, J. E. Snawder<sup>4</sup>, Z. Li<sup>1</sup>, S. Rieth<sup>1</sup> and J. C. Lipscomb<sup>5</sup>. <sup>1</sup>National Center for Environmental Assessment, US EPA, Washington DC; <sup>2</sup>National Center for Environmental Assessment, US EPA, Research Triangle Park, NC; <sup>3</sup>Department of Environmental Health and Center for Environmental Genetics, University of Cincinnati, Cincinnati, OH; <sup>4</sup>NIOBH, CDC, Cincinnati, OH; <sup>5</sup>National Center for Environmental Assessment, US EPA, Cincinnati, OH; <sup>6</sup>Independent Consultant, Chapel Hill, NC.

Chloroform (CF) is a trihalomethane present in drinking water as a byproduct of disinfection, and the kidney is one of the targets of toxicity in experimental animals. Since CF induces toxic effects via production of reactive metabolites, proper characterization of metabolism is essential for risk assessment. A revised physiologically-based pharmacokinetic (PBPK) model, in conjunction with benchmark dose (BMD) modeling, was used to interpret rat and mouse renal toxicity markers in three oral and inhalation studies. Large species differences in potency as a function of external dose became minimal when expressed in terms of a renal dose metric (daily mg CF metabolized per L cortex), indicating that species differences in susceptibility may be primarily mediated by toxicokinetics, rather than differences in toxicodynamics. The external BMD result for nuclear enlargement was 6 ppm for the mouse, but 40 ppm for the rat—a 7-fold difference. When the measure of dose was changed from inhaled concentration to the renal dose metric, the BMD result becomes 62 mg/L in the mouse, and 47 mg/L in the rat—a difference of 30%. Since results derived from drinking water data were also consistent with inhalation data, the work presented here increases confidence in the PBPK model, and the use of site-specific chloroform metabolism as the internal dose-metric. The views expressed in this publication are those of the authors and do not represent the views and policies of their respective Agencies

**PS 291 The Use of Cytochrome P450-Embedded Nanodisks to Enhance Metabolism and Elimination of Chemical Toxicants.**

M. Malfatti<sup>1</sup>, E. Kuhn<sup>1</sup>, A. Kohlgruber<sup>1</sup>, Y. Li<sup>2</sup>, K. Lam<sup>2</sup> and M. Coleman<sup>1</sup>. <sup>1</sup>Lawrence Livermore National Laboratory, Livermore, CA; <sup>2</sup>University of California Davis, Davis, CA.

Exposure to toxic chemicals and how to eliminate them from the body is a topic of great concern. Developing safe and effective methods that can mitigate exposures is critical for responding to many different exposure scenarios. In this study we are capitalizing on the body's endogenous detoxification capabilities by supplementing existing metabolic enzymes to increase the natural capacity for transforming toxic agents into less harmful constituents. We are developing a novel system that packages cytochrome P450 proteins, liposomes, and telodendrimer into nanodisks, in an effort to enhance the metabolism of toxic chemicals into inactive compounds. Microsomes expressing human cytochrome P4503A4 (CYP3A4) were combined with POPC lipid and 1% telodendrimer, comprised of an octamer of cholic acid linked to the terminal end of a linear 5kDa PEG molecule. Assembly of CYP3A4 telodendrimer nanodisks (TND) was achieved after overnight incubation at 4° C. Activity of CYP3A4 in the TND was assessed by fluorescent intensity, using the P450-Glo assay (Promega), and determined to be 57.0 FU. This was comparable to the CYP3A4 positive control of 64.8 FU, indicating successful incorporation of functional CYP3A4 into the TND. Functional stability was assessed by monitoring TND-CYP3A4 activity over time at 4° C. TND-CYP3A4 activity was stable for 7 days post assembly. After 7 days, activity decreased by 42% and remained at that level for the 24-day study duration. In vitro metabolism tests demonstrated that the TND was able to metabolize the model substrate testosterone to 6 $\beta$ -OH-testosterone at rates comparable to the CYP3A4 microsomal control incubations. These results indicate that this system has the potential to improve one's ability to detoxify chemicals. Further studies are needed to determine the capability of the TNDs to metabolize chemicals in vivo.

This work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344 and supported by LLNL LDRD 11-ERD-012.

**PS 292 Sulfonation of 1-Methyl-Phenanthrene and 9-Ethyl-Phenanthrene in Human Hepatoma (HepG2) Cells.**

M. Huang, I. A. Blair and T. M. Penning. Centers of Excellence in Environmental Toxicology and Cancer Pharmacology, Department of Pharmacology, University of Pennsylvania, Philadelphia, PA.

Exposure to petrogenic polycyclic aromatic hydrocarbons (PAHs) in the food-chain is the major human health hazard associated with the Deepwater Horizon gulf-oil spill. Risk assessment is based on the assumption that petrogenic and pyrogenic

PAHs have similar toxicological profiles yet information on the metabolism of petrogenic PAHs is lacking. We report the metabolic fate of 1-methyl-phenanthrene and 9-ethyl-phenanthrene as representative alkylated petrogenic PAHs in human hepatoma (HepG2) cells. The structures of the metabolites were identified by HPLC-UV-fluorescence detection and LC-MS/MS. Both 1-methyl-phenanthrene and 9-ethyl-phenanthrene showed the formation of O-sulfated mono-phenols, O-sulfated bis-phenols, O-sulfated dihydrodiols, and O-sulfated catechols. The identification of these sulfate conjugates supports metabolic activation of 1-methyl-phenanthrene and 9-ethyl-phenanthrene by P450 and AKR isozymes followed by metabolic detoxification by SULT isozymes. (Supported by U19ES020676-01 to TMP)

**PS 293 N-Acetyltransferase 1 (NAT1) Expression and Activity during Keratinocyte Differentiation and Cell Cycle Progression.**

J. Bonifas and B. Blömeke. Environmental Toxicology, University of Trier, Trier, Germany.

N-acetyltransferase 1 (NAT1) dependent N-acetylation is an important detoxification pathway for arylamines including certain dyes. Proliferating keratinocytes have high N-acetylation capacities, but the influence of differentiation on NAT1 is not clear.

Keratinocyte differentiation is associated with an arrest of cells in the G0/G1 phase of the cell cycle. In order to analyze NAT1 regulation in the different cell cycle phases we synchronized HaCaT keratinocytes by serum starvation (83 $\pm$ 4% G0/G1) and re-addition for 20hrs (66 $\pm$ 1.7% S-phase) as well as by double thymidine block (68 $\pm$ 2% G0/G1, 72 $\pm$ 6% S-Phase) and analyzed NAT1 activity, protein and mRNA expression. In line with the high N-acetylation capacity of the skin, NAT1 activity was, compared to S-phase, elevated (about 40 $\pm$ 2%) in the G0/G1 phase, which is the predominant state of keratinocytes in the epidermis. NAT1 protein levels were also higher in G0/G1 phase, while NAT1 promoter P1 dependent steady state mRNA levels were not enhanced.

In the next step, we differentiated the keratinocyte cell line HaCaT and primary keratinocytes in vitro and analyzed NAT1 mRNA expression and NAT1 activity. With increasing differentiation we found no NAT1 variation after in vitro differentiation and detected NAT1 protein staining throughout the entire epidermis using human skin slices.

These results indicate that in vitro differentiated keratinocytes do not lose N-acetylation capacity, although cell proliferation is terminated, possibly due to high NAT1 activities in G0/G1 phase arrested cells. However, variations of the keratinocyte cell cycle phase distribution may influence NAT1 activity and thereby detoxification capacities.

**PS 294 Characterization of Peroxidase Activity in SkinEthic™ Reconstructed Skin Models Compared with Ex Vivo Human Skin Samples.**

J. Eilstein, G. Lereaux, A. Garrigues-Mazert, J. Meunier and D. Duché. L'Oréal Research & Innovation - Advanced Research, Aulnay-sous-Bois, France. Sponsor: E. Dufour.

Skin metabolism is becoming a major consideration in the development of new cosmetic ingredients, skin being the first organ exposed to them. Consequently, the use of ex vivo samples of normal human skin (NHS) or reconstructed human skin models (skin models) as alternative tools to animal testing requires to characterize and compare their abilities to metabolize xenobiotics. In this work, we determined if they possessed a functional peroxidase activity. Previous studies showed that NHS and skin models from SkinEthic™ Laboratories such as Episkin™, SkinEthic-RHE™ and the full thickness model of Episkin™ expressed the mRNAs of several peroxidase isoforms (mainly in GPx and COX families). The catalytic activity of these enzymes was measured from dose-response studies using cumene hydroperoxide as substrate. Apparent Vmax, Km and ratio Vmax/Km (assessing metabolic clearance) were calculated for each biological model from 2-phenyl-2-propanol quantification. Results showed that in NHS and skin models, a peroxidase activity was demonstrated to be functional and that the obtained enzymatic parameters could be influenced by the lack of the glutathione co-factor. To conclude, a peroxidase activity is present and functional in NHS and skin models which can be easily used for studying the biotransformation process of peroxides and assessing their impact on cellular biomarkers.

**PS 295 Covalent Thiol Adducts Arising from Cocaine and Morphine Biotransformation.**

K. J. Schneider and A. P. DeCaprio. *Department of Chemistry & Biochemistry and International Forensic Research Institute, Florida International University, Miami, FL.*

Covalent protein adduction, which can underlie drug toxicity and/or reflect exposure, is largely unstudied in the case of illicit drugs of abuse. This research investigates the formation of protein adducts resulting from cocaine and morphine biotransformation using *in vitro* assay systems. Human liver microsomal preparations were incubated for 1.5 or 6 h with cocaine or morphine in the presence of thiol-containing trapping agents at 37°C, pH 7.4. Thiols included N-acetylcysteine (NAC), glutathione (GSH), and a synthetic hexapeptide (AcPAACAA). Microsomes were removed by centrifugation and supernatants were subjected to LC-MS/MS analysis for characterization of metabolites and adducts. Isomeric hydroxycocaine adducts from thiol adduction on the arene ring were the major products with all three model thiols. Eight isomers of cocaine-adducted NAC were separated and characterized. While the structural complexity of adducted GSH and model peptide diminished the ability to separate isomers, MS/MS data supported adduct structures analogous to those with NAC. With morphine, two distinct metabolites were identified as the likely species responsible for thiol adduction, the known reactive metabolite morphinone and a novel metabolite, morphine quinone methide. Reaction between morphinone and NAC formed two isomeric products which underwent secondary reduction to form three additional stereoisomeric products. Likewise, morphine quinone methide formed two structural isomers, although no secondary reduction was noted. Individual structural isomers of morphine adducts with GSH and AcPAACAA could not be isolated; however, morphine-derived adduction products were nevertheless present. Analysis using recombinant cytochrome P450s determined that formation of cocaine adduction products was mediated by CYPs 1A2, 2C19, and 2D6, while those from morphine were produced by CYP3A4. Results obtained from this study enhance the existing knowledge of illicit drug metabolism and demonstrate novel mechanisms for covalent protein modification by these compounds.

**PS 296 The Enantioselective Oxidation of 2, 2', 3, 3', 6, 6'-Hexachlorobiphenyl (PCB136) by Liver Microsomes Is Species Dependent.**

H. Lehmler, X. Wu and A. Kammerer. *Department of Occupational and Environmental Health, College of Public Health, The University of Iowa, Iowa City, IA.*

The adverse neurodevelopmental effects of chiral PCBs, such as PCB 136, are mediated by the enantiospecific sensitization of Ryanodine receptors and may be influenced by enantioselective PCB metabolism. Since the enantioselective disposition of PCBs is only poorly investigated, we tested the hypothesis that the enantioselective oxidation of PCB 136 to hydroxylated metabolites by liver microsomes is species dependent. Racemic PCB 136 was incubated with liver microsomes obtained from different species (i.e., male guinea pig, hamster, monkey, mouse, and rabbit; female dog) or pooled human liver microsomes. According to gas chromatographic analysis, 2,2',3,3',6,6'-hexachlorobiphenyl-4-ol (4-136) was the major metabolite in incubations with monkey, rabbit and human microsomes. 2,2',3,3',6,6'-Hexachlorobiphenyl-5-ol (5-136) was the major metabolite in incubations using dog, guinea pig, hamster and mouse microsomes. 4-136 to 5-136 ratios were 0.1, 0.1, 0.1, 13, 0.6, 1.7 and 1.8 for dog, guinea pig, hamster, monkey, mouse, rabbit and human microsomes, respectively. Furthermore, enantioselective analyses showed species-dependent difference in the enrichment pattern of atropisomers of 4-136 and 5-136. Taken together, these observations suggest that species-dependent enantioselective metabolism needs to be considered in studies investigating the developmental neurotoxicity of PCBs and other chiral pollutants.

**PS 297 CYP2F1 Expression and Activity Toward Naphthalene in a CYP2A13/2F1-Humanized Mouse Model.**

L. Li<sup>1</sup>, K. Jia<sup>1</sup>, Y. Wei<sup>1</sup>, L. V. Winkle<sup>2</sup> and X. Ding<sup>1</sup>. <sup>1</sup>Health Research Inc., Albany, NY; <sup>2</sup>Center for Health and the Environment, University of California Davis, Davis, CA.

The aim of this study is to characterize the expression and activity of CYP2F1, a human P450 expressed preferentially in the respiratory tract, using a recently generated CYP2A13/2B6/2F1-transgenic (TG) mouse model. CYP2F1 has been proposed to metabolize several lung toxicants, including naphthalene. However, conclusive data on how efficient CYP2F1 is in the bioactivation of these compounds are still unavailable, as it has been difficult to obtain functional CYP2F1 protein

through heterologous expression. Both CYP2F1 and CYP2A13, but not CYP2B6, are expressed in the lung and nasal mucosa (NM) of the TG mice. The level of CYP2A13 protein was 100 and 0.2 pmol/mg protein in nasal and lung microsomes, respectively, of the TG mice. The level of CYP2F1 protein was not determined previously, for lack of a suitable CYP2F1 standard. Here, using a newly developed LC-MS/MS method, we have determined that the level of CYP2F1 was 8 and 2 pmol/mg protein in nasal and lung microsomes, respectively, of the TG mice. To determine the activity of CYP2F1, we further crossed the TG mouse to a newly generated Cyp2abfgs-null (null) mouse, in which all mouse Cyp2abfgs genes are deleted, and the naphthalene bioactivating activities of nasal and lung microsomes were substantially decreased. In the resultant CYP2A13/2B6/2F1-humanized mice (TG/null), nasal and lung microsomal activity toward naphthalene was significant higher than in the null mice (2-fold for lung and 8-fold for NM). Thus, CYP2A13 and/or CYP2F1 are active toward naphthalene in the humanized mouse. Further analysis of the activities in the humanized mice provided evidence that, while the activity in the NM was primarily contributed by CYP2A13, the activity in the lung was mainly contributed by CYP2F1.

**PS 298 Effect of Vinclozolin Exposure during Pregnancy on *In Vitro* Testosterone Metabolism.**

F. G. García-Montes de Oca, M. L. Lopez-Gonzalez, D. C. Escobar-Wilches and A. Sierra-Santoyo. *Toxicology, CINVESTAV-IPN, Mexico City, Mexico.*

Vinclozolin (V) is a fungicide used for agricultural settings. V is classified as an endocrine disruptor by inhibiting competitively the androgen receptor. V exposure during pregnancy alters morphogenesis of the masculine reproductive system. V regulates liver cytochrome P450 (CYP) expression and may affect the biotransformation of endogenous substances, such as testosterone (T) which is an important hormone during pregnancy. There is no information about the effect of V exposure during pregnancy on testosterone metabolism. The objective of this study was to evaluate the effect of V exposure during the pregnancy on *in vitro* testosterone metabolism. Pregnant Wistar rats were orally administered with V at the dose of 150 mg/kg/d from gestational days 14 to 21 suspended in corn oil. Two control groups were included, pregnant and non-pregnant rats in oestrus phase and received only vehicle. Animals were sacrificed at 2 h after last dose by asphyxia with CO<sub>2</sub>. Liver was removed and processed to obtain microsomes to carry out *in vitro* enzyme assays using T as substrate. T and its metabolites were analyzed by HPLC. The pregnancy decreased 50% the liver total CYP content as well as the formation of metabolites 7 $\alpha$ -hydroxytestosterone (-OHT), 16 $\beta$ -OHT, androstenedione (AD) and 6 $\beta$ -OHT, 78, 40, 97 and 28%, respect to non-pregnant rats. V exposure significantly decreased the weight gain during pregnancy and increased 27% the content of total CYP, respect to the non-treated pregnant group. Moreover, V increased the formation of 7 $\alpha$ -OHT, 2 $\beta$ -OHT, 16 $\beta$ -OHT, AD, 6 $\beta$ -OHT and 16 $\alpha$ -OHT, 1.7-, 1.7-, 3.0-, 1.5-, 4.3- and 1.7-fold, respectively. These results suggest that V affects the pregnancy by reducing weight gain and modulates liver CYP expression. In addition, they also suggest that V exposure during pregnancy may alter the biotransformation of testosterone and affecting physiological processes regulated by this hormone. These effects may represent another mechanism of action associated to V exposure during the pregnancy.

**PS 299 *In Vitro* Metabolism of Benzo[a]pyrene and Dibenzo[Def, P]Chrysene in Rodents and Humans.**

S. Hanson-Drury<sup>1</sup>, S. R. Crowell<sup>1</sup>, J. Soelberg<sup>1</sup>, R. A. Corley<sup>1</sup> and D. E. Williams<sup>2</sup>. <sup>1</sup>Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous and often carcinogenic contaminants released into the environment during natural and anthropogenic combustion processes. Benzo[a]pyrene (BaP) is the prototypical carcinogenic PAH, and dibenzo[def,p]chrysene (DBC) is a less prevalent, but highly potent transplacental carcinogenic PAH. Both are metabolically activated by isoforms of the cytochrome P450 (CYP450) enzyme superfamily to form reactive carcinogenic and cytotoxic metabolites. Metabolism of BaP and DBC was studied in hepatic microsomes of male Sprague Dawley rats, naïve and pregnant female B6129SF1/J mice, and female humans, corresponding to available pharmacokinetic data. Michaelis Menten saturation kinetic parameters were calculated from substrate depletion data. Maximum rates of metabolism (V<sub>MAX</sub>, nmol/min/mg microsomal protein) and rates of intrinsic clearance (CL<sub>INT</sub>, ml/min/kg body weight) were higher for BaP than DBC, regardless of species. Clearance for both BaP and DBC was highest in naïve female mice (1705 and 182 ml/min/kg) and lowest in female humans (27.2 and 7.5 ml/min/kg). Clearance rates of BaP and DBC in male rat (52.2 and

18.8 ml/min/kg) were more similar to female human than to female mice. Clearance of DBC in pregnant mice (136 ml/min/kg) was reduced compared to naïve mice, possibly contributing to elevated tissue concentrations and residence times observed in pharmacokinetic data. These parameters have been used in the development of physiologically based pharmacokinetic (PBPK) models of PAH exposure and dosimetry for rodents and humans, which accurately describe available pharmacokinetic data. Supported by Award Number P42 ES016465 from the National Institute of Environmental Health Sciences.

**PS 300 Hyperoxia Attenuates Cytochrome CYP1B1 Expression in Human Bronchial Epithelial Cell BEAS-2B: Implications for Oxygen-Mediated Lung Injury.**

D. Dinu, C. Chu, W. Jiang, B. Shivanna, X. Courouci and B. Moorthy.  
*Pediatrics, Baylor College of Medicine, Houston, TX.*

Supplemental oxygen, used to treat premature infants with pulmonary insufficiency, contributes to the development of bronchopulmonary dysplasia (BPD) in animal models and infants by mechanisms that are not entirely known. We recently observed that cyp1b1-null mice are less susceptible to hyperoxic lung injury, suggesting a pro-oxidant role for CYP1B1. Hyperoxia inhibits the growth of the cells, and  $\beta$ -naphthoflavone (BNF) was reported to protect cells from hyperoxic injury. This study tested the hypotheses: 1. hyperoxia attenuates endogenous and BNF inducible CYP1B1 expression in human lung cell line, BEAS-2B; 2. downregulation of CYP1B1 protects cells from hyperoxic injury while overexpression augments the damage.

BEAS-2B cells treated with DMSO (control) or BNF were maintained in room air or hyperoxia for 24, 48, and 72 h. CYP1B1 promoter activity, mRNA and protein expression were evaluated. Cell proliferation, cell viability, apoptotic markers and reactive oxygen species were assessed.

BEAS-2B cells expressed endogenous CYP1B1 protein, which was diminished by about 50% by 24 or 48 h of hyperoxia. BNF induced CYP1B1 mRNA and protein expression. Hyperoxia attenuated endogenous and BNF inducible CYP1B1 protein expression and mRNA expression. Also, hyperoxia attenuated luciferase driven CYP1B1 promoter activity. BNF had minimal improvement in cell viability. Downregulation of CYP1B1 using siRNA improved cell viability in hyperoxia, and overexpression of CYP1B1 was associated with a significant decrease in viability.

Our finding that hyperoxia decreases CYP1B1 protein, mRNA and promoter expression suggests transcriptional or post-transcriptional mechanisms. The finding that downregulation of CYP1B1 improves cell viability, while the overexpression decreases the cell viability supports the role of CYP1B1 as pro-oxidant in hyperoxic injury. As CYP1B1 appears to contribute to lung injury mediated by hyperoxia, understanding the mechanisms of regulation of CYP1B1 may lead to new strategies to prevent or treat BPD.

**PS 301 Metabolism of Deltamethrin (DLM) and Trans-Permethrin (TPM) by Human Hepatic and Intestinal Preparations.**

B. G. Lake<sup>1</sup>, R. J. Price<sup>1</sup>, B. Ing<sup>1</sup>, M. Scott<sup>1</sup>, R. N. Hines<sup>2</sup>, H. J. Clewell<sup>4</sup>, D. W. Gammon<sup>5</sup>, N. Assaf<sup>3</sup>, M. Yoon<sup>4</sup>, S. S. Anand<sup>6</sup> and T. G. Osimitz<sup>7</sup>. <sup>1</sup>LFR Molecular Sciences, Leatherhead, United Kingdom; <sup>2</sup>Medical College of Wisconsin, Milwaukee, WI; <sup>3</sup>Valent Biosciences, Libertyville, IL; <sup>4</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>5</sup>FMC, Ewing, NJ; <sup>6</sup>DuPont Haskell, Newark, DE; <sup>7</sup>Science Strategies LLC, Charlottesville, VA.

Pyrethroids can be metabolised by both cytochrome P450 (CYP) and carboxylesterase (CES) enzymes. DLM and TPM metabolism was studied using the substrate depletion approach in pooled human hepatic S9, microsomes and cytosol and intestinal S9 fractions. Studies with liver S9 in the presence and absence of NADPH indicated that DLM was metabolised mainly by CES enzymes, whereas TPM was metabolised by both CES and CYP enzymes. Rates of DLM and TPM clearance in liver microsomes were 22.3 and 11.9 ml/min/mg protein, respectively, and in liver cytosol were 2.6 and 5.3 ml/min/mg protein, respectively. The hepatic clearance of both pyrethroids is thus due to both microsomal and cytosolic enzymes. Addition of cofactors for glucuronidation and sulfation did not enhance the metabolism of DLM and TPM by hepatic S9, suggesting that the rate limiting step for hepatic clearance of both pyrethroids is predominantly due to phase I enzymes and not to phase II enzymes. Rates of DLM and TPM clearance by intestinal S9 were 0.6 and 0.8 ml/min/mg protein, respectively. Rates of pyrethroid metabolism were not reduced in the absence of NADPH, suggesting that both compounds are largely metabolised by only intestinal CES enzymes. The metabolic data obtained with human tissue fractions will be used to develop PBPK models for DLM and TPM (Supported by CAPHRA).

**PS 302 Biological Impact of a Dysfunctional CYP1/AhR Auto-Regulatory Feedback Loop.**

E. Wincent<sup>1,2</sup>, A. Kubota<sup>2</sup>, A. R. Timme-Laragy<sup>2</sup>, M. E. Hahn<sup>2</sup>, A. Rannug<sup>1</sup> and J. Stegeman<sup>2</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Biology Department, Woods Hole Oceanographic Institution, Woods Hole, MA.

The toxicity of slowly metabolized AHR agonists (e.g., dioxins) can be explained by their persistent activation of the receptor, whereas transient AHR activation by readily metabolized chemicals leads to toxicity through cytochrome P4501 (CYP1)-dependent bioactivation of PAHs to toxic products. Still, CYP1A inhibition has been shown to amplify carcinogenic and teratogenic effects of PAHs, emphasizing the complex relationship between CYP1 induction and toxicity. The endogenous and proposed physiological ligand 6-formylindolo[3,2-b]carbazole (FICZ) has the highest AHR affinity found to date and is an almost perfect substrate for CYP1A, resulting in an efficient auto-regulatory feedback of its actions. The importance of CYP1/AHR feedback regulation to in vivo responses to FICZ are unknown.

We tested the hypothesis that blocking CYP1A expression would result in FICZ becoming toxic in vivo. Studies were performed using zebrafish (zf; Danio rerio) embryos with morpholino knockdown of CYP1A (CYP1A-KD) or AHR2 (AHR2-KD). Zf embryos were exposed to vehicle (DMSO) or FICZ (10 or 100nM) starting at 24 hr post fertilization (hpf), and morphology was monitored from 54 to 96 hpf. In the CYP1A-KD embryos FICZ caused a dose-dependent increase in the incidence and severity of pericardial edema and circulation failure, and increased lethality. Hatching frequency was reduced and swimbladder inflation abolished. In control-KD and AHR2-KD embryos, FICZ (100nM) had no significant morphological effects.

The results show that a functioning CYP1/AHR feedback loop is crucial for regulation of AHR signaling by a potential physiological ligand. Considering the large number of chemicals and drugs known to inhibit CYP1s, we suggest a novel mechanism of toxicity whereby chemicals inhibit the metabolism of FICZ, resulting in prolonged activation of the AHR. [FORMAS grant 2011-963; NIH grants R01ES015912, F32ES017585, and R01ES006272; JSPS Postdoctoral Fellowship for Research Abroad 820]

**PS 303 Metabolism and Disposition of 2-Ethylhexyl-P-Methoxycinnamate in Male and Female Harlan Sprague-Dawley Rats and B6C3F<sub>1</sub>/N Mice After Gavage and Intravenous Administration.**

S. Waidyanatha<sup>1</sup>, R. Snyder<sup>2</sup>, Y. Hong<sup>2</sup>, S. Watson<sup>2</sup>, S. Black<sup>2</sup>, B. McIntyre<sup>1</sup> and J. Mathews<sup>2</sup>. <sup>1</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC; <sup>2</sup>RTI International, Research Triangle Park, NC.

2-Ethylhexyl-*p*-methoxycinnamate (EHMC) was nominated to the National Toxicology Program for toxicological evaluation based on its presence as one of the most common active ingredients in sunscreens. Therefore, the current study was undertaken to investigate the metabolism and disposition of [<sup>14</sup>C]EHMC in male and female Harlan Sprague Dawley rats and B6C3F<sub>1</sub>/N mice 24 h or 72 h following gavage and intravenous administration. Intravenous doses to male rats and mice were 8 mg/kg. Gavage doses of 8, 80 or 800 mg/kg to rats were mostly excreted in urine (73-80% in 72 h), with 3-8% of the radioactivity recovered in feces and 1-4% as CO<sub>2</sub>; volatiles accounted for less than 0.25% of the radioactivity for the 800 mg/kg dose. Radioactive residues in tissues were <1% of the dose. There were no sex or route differences in disposition in rats. In male and female mice administered 8 mg/kg gavage and intravenous doses of EHMC, radioactivity was excreted mostly in urine (57-73% in 72 h), recovery in CO<sub>2</sub> and volatiles traps was only 2-4% and 1%, respectively, and tissues contained <0.3% of the radioactivity 72 h post dosing without any apparent sex- or route-related differences in disposition. Urinary metabolites following gavage administration of 800 mg/kg EHMC were associated with hydrolysis of the ester and hydroxylation of the ring; no parent EHMC was detected in urine. The metabolites 2-ethylhexanol and 2-ethylhexanoic acid, which are developmental toxicants, were identified by GC-MS in plasma from rats 1 and 2 h following a gavage dose of 800 mg/kg EHMC. These data indicate that oral doses of EHMC are well absorbed, completely metabolized and excreted chiefly in urine with no species or sex difference. [Supported by NIH, N01ES75563]

**PS 304 Immunochemical Characterization of Xenobiotic-Metabolizing Enzyme Expression in Adult Rat Testis.**

R. R. Gilibili<sup>1</sup>, W. A. Vogl<sup>2</sup>, T. K. Chang<sup>1</sup> and S. M. Bandiera<sup>1</sup>. <sup>1</sup>Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; <sup>2</sup>Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada.

Relatively little is known about the protein expression of xenobiotic-metabolizing enzymes, such as cytochrome P450 (CYP) and epoxide hydrolase (EH) in rat testis. These enzymes are expressed in liver and many other organs, and are known to play an important role in the oxidative biotransformation of various endogenous and exogenous compounds. Some xenobiotics such as benzo[a]pyrene are bioactivated to form genotoxic and/or carcinogenic metabolites. Formation of reactive metabolites in the testis could cause severe adverse effects on steroidogenesis and germ cell development. In the present study, we characterized the expression of various xenobiotic-metabolizing enzymes in adult rat testis using immunoblot and immunohistochemical analyses. Testicular microsomes prepared from adult male Sprague-Dawley rats were separated using SDS-PAGE and electrophoretically transferred onto membranes and probed with different antibodies. Immunoblot results indicated that CYP1B1, CYP2A1, NADPH-cytochrome P450 reductase, and EH were expressed in testicular microsomes isolated from adult rats. By comparison, CYP1A1, CYP1A2, CYP2B1, CYP2E1, CYP2D1, CYP2D2, CYP2C6, CYP2C7, CYP2C11, CYP2C12, CYP2C13, CYP3A1, CYP3A2, CYP4A1, CYP4A2 and CYP4A3 were not detected in the testicular microsomal samples. In addition, tissue sections were prepared from frozen adult rat testis and probed with antibodies to CYP1B1, CYP2A1, NADPH-cytochrome P450 reductase, and EH. Fluorescent staining indicated that CYP1B1 and CYP2A1 were expressed in interstitial cells, which are comprised mainly of Leydig cells, but not in seminiferous tubules. In contrast, EH and NADPH-cytochrome P450 reductase were expressed in both interstitial cells and in seminiferous tubules. In summary, among the CYP enzymes studied, only CYP1B1 and CYP2A1 were detected in testicular microsomes and appeared to be confined to interstitial cells.

**PS 305 Demographic Differences by Age, BMI, Gender, and Disease States of Phase I and Phase II Enzyme Activities in Cryopreserved Human Hepatocytes.**

T. Moeller, C. Six, S. Dennell, T. Rose and C. Watt. *Celsis In Vitro Technologies, Halethorpe, MD.* Sponsor: M. Xia.

Human hepatocytes are a key in vitro reagent for making predictions of in vivo drug metabolism, interactions and intrinsic clearance in drug discovery and development. However, inter-individual differences in drug metabolizing enzyme activities complicate pharmacokinetics, leading to varying efficacy and drug-drug interactions. To delineate the potential influences, we have reviewed phase I (CYP1A2, 2A6, 2C9, 2C19, 2E1 and 3A4) and phase II (UGT and SULT) enzymatic activities as they relate to age, BMI, gender and ethnicity. The data was generated using cryosuspension hepatocytes with specific substrates (CYP1A2: phenacetin, 2A6: coumarin, 2C9: tolbutamide, 2C19: mephenytoin, 2E1: chlorzoxazone, 3A4: testosterone, UGT: 7-hydroxycoumarin and SULT: 7-hydroxycoumarin) near Km concentrations, as well as with multiple enzyme substrate 7-ethoxycoumarin (ECOD). From a minimum of 180 donors, several statistically significant trends were observed. For age-dependent differences, a loss of activity was observed for ECOD and CYP2C19, and an increase in CYP1A2 activity as the age increased from 1 to 89 years old. As BMI increased, ECOD, CYP1A2 and CYP2C19 decreased between the range of 14 and 53. As for gender-related differences, men showed higher activities in ECOD and CYP2E1. Diabetic donors had lower CYP2C9, CYP2C19 and CYP3A4 activities compared to non-diabetics. Overall, choosing appropriate hepatocyte preparations for metabolism studies as a reflection of "average" are dependent upon gender, age, BMI and disease states in many drug metabolizing enzymes.

**PS 306 Metabolism of Benzo(a)pyrene (BaP) and Fluoranthene (FLA) in Gastrointestinal Tract Subcellular Fractions of the APC<sup>Min</sup> Mouse.**

K. L. Harris, P. V. Rekha Devi, D. L. Digges, A. C. Huderson, J. A. Mantey, L. D. Banks, M. S. Niaz and A. Ramesh. *Biochemistry & Cancer Biology, Meharry Medical College, Nashville, TN.*

The objective of the present study was to investigate whether subcellular fractions (nuclear, cytosolic, mitochondrial, and microsomal) from the gastrointestinal (GI) tract of a colon cancer mouse model were capable of metabolizing BaP, a combustion byproduct, which is released into the environment from automobile exhausts, cigarette smoke, and industrial emissions. A significant intake of BaP is also expected in people who consume barbecued foods, and diet rich in saturated fat. In

this study, subcellular fractions (SCF) were isolated by differential centrifugation from a tumor-bearing APC<sup>Min</sup> mouse induced by subchronic doses of 50µg/kg BaP and incubated with either BaP or FLA (3µM each) alone or in combination and appropriate control groups. Subsequent to incubation, samples were extracted with ethyl acetate and analyzed for BaP and FLA metabolites by reverse-phase HPLC with fluorescence detection. The SCF from tumor tissues metabolized BaP to a greater extent than those from the non-tumor tissues. The rate of BaP metabolism (pmol of metabolite/min/mg protein) was found to be more when fractions from BaP-pretreated mice were exposed to BaP alone. The SCF from BaP-pre-exposed mice generated greater proportion of BaP 7,8-diol, BaP 3,6- and 6,12-diones compared to other experimental groups. Furthermore, SCF from BaP-pretreated mice produced greater proportion of FLA 2, 3-diol, and 2, 3 D FLA when fractions were incubated with FLA alone or a combination of BaP and FLA. Our studies revealed that the tumor SCF were competent to metabolize BaP and FLA either individually or as a binary mixture. The metabolism of BaP and FLA as a consequence of prior or simultaneous exposure to BaP may influence the growth of tumors. Our findings are of relevance to long-term dietary intake of these toxicants and the consequent acceleration of the GI tract carcinogenesis process in humans (supported by 5R01CA142845-02, 1F31ES017391-01, 1F31ES019432-01A1, 5R25GM059994-11 and SREB grants).

**PS 307 Studies of Styrene, Styrene Oxide and 4-Hydroxystyrene Toxicity in CYP2F2 Knockout and CYP2F1 Humanized Mice Support Lack of Human Relevance for Mouse Lung Tumors.**

G. Cruzan<sup>1</sup>, J. Bus<sup>2</sup>, J. A. Hotchkiss<sup>2</sup>, R. Sura<sup>2</sup>, M. Banton<sup>3</sup> and S. Sarang<sup>4</sup>. <sup>1</sup>ToxWorks, Bridgeton, NJ; <sup>2</sup>Dow Chemical Company, Midland, MI; <sup>3</sup>LyondellBasell Company, Houston, TX; <sup>4</sup>Shell International, Houston, TX.

Styrene (S) is lung tumorigenic in mice but not in rats. In previous mode of action (MOA) studies, S and its alkene-oxidized metabolite styrene oxide (SO) were not lung toxic in CYP2F2(-/-) [knockout] mice, indicating S-induced mouse lung tumors are mediated through mouse-specific CYP2F2-generated cytotoxic ring-oxidized metabolite(s) producing repeated localized cytotoxicity in Clara cells and associated cumulative cell proliferation in lung bronchioles. This conclusion is consistent with the observation that 4-hydroxystyrene (4HS) is toxic to Clara cells in mice at doses lower than S or SO. The human relevance of the CYP2F MOA was assessed by insertion of a human CYP2F1, 2A13, 2B6 transgene into CYP2F2(-/-) mice; CYP2F1 expression and activity were confirmed in the transgenic (TG) mice. No evidence of cytotoxicity or increased cell proliferation (BrdU labeling) was seen in TG mice treated with either S or SO (200 mg/kg/day ip for 5 days), while cytotoxicity was apparent and BrdU labeling was increased ~10-fold in wild-type (WT) mice. Consistent with the hypothesis, 4HS (60 or 105 mg/kg ip for 5 days) increased BrdU labeling 5-10 fold in WT mice, and was attenuated to less than a 3 fold increase in KO mice and a 2-4 fold increase in TG mice. The limited response of 4HS in both KO and TG mice suggests that direct administration of high doses of 4HS are either intrinsically lung toxic or are capable of limited metabolism by either CYP2F1 and/or other lung CYPs in KO and TG mice to lung toxic metabolite(s). Regardless of the MOA of the limited 4HS toxicity in KO or TG mice, these findings indicate that the CYP2F-mediated tumorigenic MOA in WT mice is not operative for S, SO, or for 4HS putatively derived from metabolism of S by CYP2F1 in humans, and thus S-induced mouse lung tumors are unlikely to be relevant to human risk.

**PS 308 Metabolism and Disposition of Bisphenol AF in Male and Female Harlan Sprague-Dawley Rats following Gavage and Intravenous Administration.**

T. Fennell<sup>1</sup>, R. Snyder<sup>1</sup>, P. Patel<sup>1</sup>, S. Black<sup>1</sup>, J. Mathews<sup>1</sup>, M. Mercado-Feliciano<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>Pharmacology and Toxicology, RTI International, Research Triangle Park, NC; <sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC.

Bisphenol AF (BPAF) is used as a cross linking agent in polymers. BPAF was nominated to the National Toxicology Program for toxicological evaluation based on its moderate production levels, structural similarity to bisphenol A, and lack of adequate toxicity data. The current study was undertaken to investigate the metabolism and disposition of [<sup>14</sup>C]BPAF in male and female Harlan Sprague Dawley (HSD) rats. Following gavage administration of 3.4, 34 or 340 mg/kg to male rats, the administered dose was mostly excreted in feces (73-80%) with < 6% of the dose recovered in urine and cage rinse at 72 h. Radioactivity in tissues was 0.2-1.5% of the dose 72 h post dosing compared to 7% at 24 h following a dose of 34 mg/kg.

Urinary excretion at 72 h post administration was higher in females (~15%) compared to males (~4%) following a 34 mg/kg dose. Distribution of an intravenous dose of 34 mg/kg was similar to that following gavage, but with less excreted in urine in both males (0.62% for intravenous vs. 4.32% for gavage) and in females (7% for intravenous vs. 15% for gavage). About 52% of a 340 mg/kg gavage dose was excreted in bile by 24 h, indicating that high excretion in feces is not due mostly to unabsorbed BPAF. BPAF glucuronide (major metabolite), diglucuronide, glucuronide-sulfate, and sulfate were identified in bile using LC/MS/MS. This study demonstrated that BPAF is well absorbed following gavage administration in rats, metabolized by glucuronidation and sulfation, and excreted mainly in feces. [Supported by NIH, N01ES75563].

**PS 309 Absorption, Distribution, Metabolism, and Excretion Studies of *n*-Butylbenzenesulfonamide in Harlan Sprague-Dawley Rats following Gavage Administration.**

S. Black<sup>1</sup>, S. Watson<sup>1</sup>, J. Mathews<sup>1</sup>, C. Rider<sup>2</sup> and S. Waidyanatha<sup>2</sup>.  
<sup>1</sup>Pharmacology and Toxicology, RTI International, Research Triangle Park, NC;  
<sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC.

*n*-Butylbenzenesulfonamide (NBBS) is used as a plasticizer and an antifungal agent. There is high potential for human exposure to NBBS due to its likely occurrence in drinking water and leaching from NBBS-containing products. The limited toxicity data in rodents suggests that NBBS can cause toxicity to the hematopoietic, nervous, and male reproductive systems. The present studies were conducted to investigate the clearance of NBBS in male Harlan Sprague Dawley (HSD) rat and B6C3F1/N mouse hepatocytes in vitro and metabolism and disposition of NBBS following gavage administration in HSD rats in vivo. The half-lives of disappearance of NBBS (1  $\mu$ M) in rat and mouse hepatocytes were  $136 \pm 24$  and  $320 \pm 41$  min, respectively. Following gavage administration of ring-labeled [<sup>14</sup>C]NBBS to male HSD rats at 2 and 200 mg/kg and sacrificed at 72h, NBBS was excreted primarily in urine (70-76%) with feces accounting for about 12% of the administered dose. Retention in tissues was 5-7% at 72 h, with no tissue exhibiting high concentrations of radioactivity relative to blood. Profiling of urine showed presence of numerous metabolites; however, the parent NBBS was not observed. Some of the polar metabolites were diminished upon treatment with  $\beta$ -glucuronidase or acylase, indicative of glucuronides and mercapturates, but minimal changes were observed after sulfatase treatment. In conclusion, NBBS is well absorbed following gavage administration and metabolized to products including glucuronides and mercapturates. [Supported by NIH, N01ES75563].

**PS 310 Biotransformation of BDE-47 to Potentially Toxic Metabolites Is Predominantly Mediated by Human CYP2B6: Implications for Interindividual Variability in Metabolism and Retention of BDEs.**

J. R. Olson<sup>1</sup>, M. S. Gross<sup>2</sup>, M. L. Feo<sup>3</sup>, S. T. Singleton<sup>1</sup>, A. L. Crane<sup>1</sup>, B. P. McGarrigle<sup>1</sup>, E. Eljarrat<sup>3</sup>, D. Barcelo<sup>3</sup> and D. S. Aga<sup>2</sup>.  
<sup>1</sup>Pharmacology and Toxicology, University at Buffalo, Buffalo, NY; <sup>2</sup>Chemistry, University at Buffalo, Buffalo, NY; <sup>3</sup>Environmental Chemistry, IDAEA CSIC, Barcelona, Spain.

Recent studies suggest that bioactivation by oxidative metabolism may add considerably to the neurotoxic potential of polybrominated diphenyl ethers (PBDEs), but critical data are lacking on PBDE metabolism in humans. The purpose of this study was to characterize the in vitro metabolism of 2,2',4,4'-BDE (BDE-47), the most abundant PBDE detected in human serum, by human liver microsomes (HLMs) and recombinant human cytochrome P450s (CYPs), and to identify the CYP(s) that are active in the oxidative metabolism of BDE-47. Human CYPs (CYP1A1, 1A2, 1B1, 2A6, 2B6, 2C8, 2C9, 2C19, 2D6, 2E1, 3A4) were incubated with BDE-47 (20  $\mu$ M) and metabolites were measured and characterized using GC/MS/MS. For kinetic studies, CYP2B6 and pooled HLMs were incubated with BDE-47 (0-60  $\mu$ M). CYP2B6 was the predominant CYP capable of forming six different OH-BDEs, including 3-OH-BDE-47, 5-OH-BDE-47, 6-OH-BDE-47, 2'-OH-BDE-66, 4-OH-BDE-42, and 4'-OH-BDE-49. GC/MS analysis also revealed formation of novel metabolites, di-OH-BDE-47 and di-OH-dioxin. Kinetic studies of BDE-47 metabolism by CYP2B6 and pooled HLMs found  $K_m$  values ranging from 4.1-6.9  $\mu$ M and 7.8-13  $\mu$ M, respectively, indicating the high affinity towards the formation of OH-BDEs. Interindividual variability in the in vitro metabolism of BDE-47 will be assessed utilizing CYP2B6 genotyped HLMs, with up to a 100-fold range in the level of CYP2B6 activity, and recombinant polymorphic variants of human CYP2B6 (\*4, \*5, \*6, \*7, \*18). Our findings support the predominant role of CYP2B6 in the metabolism of BDE-47 and suggest that in addition to variable exposures to PBDEs, genetic variability in CYP2B6-specific metabolism may contribute to interindividual variability in the body burden of PBDEs and the formation of potentially toxic metabolites. (NIEHS, grant # ES021554)

**PS 311 Coculture of Antigen-Presenting Cells and Keratinocytes Increases Responsiveness to Prohaptens.**

J. Hennen<sup>1</sup>, C. Cohrs<sup>1</sup>, A. John<sup>2</sup>, A. Seidel<sup>2</sup> and B. Blömeke<sup>1</sup>.  
<sup>1</sup>Department of Environmental Toxicology, University Trier, Trier, Germany; <sup>2</sup>Biochemical Institute for Environmental Carcinogens, Prof. Dr. Gernot Grimmer Foundation, Grosshansdorf, Germany.

Small chemical compounds can induce sensitization to humans that results in tolerance or allergic contact dermatitis after repeated skin exposure. A subgroup of chemicals (prohaptens) can induce an immune response only following metabolic activation, e.g. by cytochrome P450 (CYP). Related in vitro assays currently consist of either skin cells or dendritic cells (DC) but importance of cross talk between these two cell types including xenobiotic metabolism is becoming even more evident (Modi et al., 2012). To study this cross talk in more detail we established a coculture model consisting of THP-1 cells as DC-like cells and HaCaT keratinocytes (Hennen et al., 2011). Upregulated expression of costimulatory molecule CD86 was clearly increased in coculture after incubation with prohaptens and depended on phase I/II enzyme activity. It is not known whether proximate or ultimate metabolites are transported between these two cell types or whether coculture enhances THP-1 responsiveness towards prohaptens. As relevant metabolites have not been identified for most prohaptens, we used the strong sensitizer benzo[a]pyrene (B[a]P) as model prohapten. In single cultured THP-1 cells, B[a]P neither induces CYP1 enzymes nor CD86 expression, whereas in coculture with HaCaTs CYP1A1 (>100-fold) and CYP1B1 (13-fold) as well as CD86 are clearly induced. In preliminary experiments, we could detect several B[a]P metabolites in both HaCaT and THP-1 supernatants, but the suspected ultimate metabolite was only formed in HaCaT cells and in coculture as indicated by the presence of B[a]P tetrol in the supernatants. Whether and how metabolites are transported needs further investigation, but results indicate that both cell types are needed for the activation of antigen-presenting cells and likely sensitization.

**PS 312 Early Vertebrate Origin of ALDH1B1 from ALDH2 Gene and Inactivation of ALDH1B1 by Heteromerization with ALDH2\*2.**

B. C. Jackson<sup>1</sup>, R. S. Holmes<sup>3</sup>, D. S. Backos<sup>1</sup>, P. Reigan<sup>1</sup>, D. C. Thompson<sup>2</sup> and V. Vasilou<sup>1</sup>.  
<sup>1</sup>Department of Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO; <sup>2</sup>Department of Clinical Pharmacy, University of Colorado Anschutz Medical Campus, Aurora, CO; <sup>3</sup>School of Biomolecular and Physical Sciences, Griffith University, Nathan, QLD, Australia.

Vertebrate ALDH2 genes encode mitochondrial enzymes capable of metabolizing acetaldehyde and other biological aldehydes in the body. Mammalian ALDH1B1, another mitochondrial enzyme sharing 72% identity with ALDH2, is also capable of metabolizing acetaldehyde but has a tissue distribution and pattern of activity distinct from that of ALDH2. Bioinformatic analyses of several vertebrate genomes were undertaken using known ALDH2 and ALDH1B1 amino acid sequences. Phylogenetic analysis of many representative vertebrate species (including fish, amphibians, birds and mammals) indicated the presence of ALDH1B1 in many mammalian species and in frogs (*Xenopus tropicalis*); no evidence was found for ALDH1B1 in the genomes of birds, reptiles or fish. Predicted vertebrate ALDH2 and ALDH1B1 subunit sequences and structures were highly conserved, including residues previously shown to be involved in catalysis and coenzyme binding for human ALDH2. Studies of ALDH1B1 sequences supported the hypothesis that the ALDH1B1 gene originated in early vertebrates from a retrotransposition of the vertebrate ALDH2 gene. Given the high degree of similarity between ALDH2 and ALDH1B1, it is surprising that individuals with an inactivating mutation in ALDH2 (ALDH2\*2) do not exhibit a compensatory increase in ALDH1B1 activity. We hypothesized that the similarity between the two ALDHs would allow for dominant negative heterotetramerization between the inactive ALDH2 mutants and ALDH1B1. Computational-based molecular modeling studies examining predicted protein-protein interactions indicated that heterotetramerization between ALDH2 and ALDH1B1 subunits was highly probable and may partially explain a lack of compensation by ALDH1B1 in ALDH2\*2 individuals.

**PS 313 Epigallocatechin-3-Gallate Abrogates Cytotoxicity and DNA Damage Induced by Benzo[a]pyrene in Lung Epithelial Cells.**

W. Zhu, W. Gao and Q. Cai. The Institute of Environmental and Human Health, Lubbock, TX.

Epigallocatechin-3-gallate (EGCG) is an active component isolated from green tea which has chemopreventive and anticancer properties. However, the molecular mechanisms of EGCG in these processes are still not very clear. The objective of the

present study is to evaluate the potential protective effects of EGCG on benzo[a]pyrene (BaP)-induced cytotoxicity and DNA damage in BEAS-2B, a human normal lung epithelial cell. BEAS-2B cells were treated with vehicle control (0.1% DMSO), BaP or BaP+EGCG for 24 hours. The cytotoxicity, cell cycle, benzo[a]pyrene diol epoxidation (BPDE)-DNA adducts, and mRNA expression levels of cytochrome P450 (CYPs) were determined by MTT assay, flow cytometry, high performance liquid chromatography (HPLC), and quantitative real-time PCR (qRT-PCR), respectively. BaP induced cell growth inhibition in a dose-dependent manner; while EGCG dose-dependently reversed this inhibition ( $P < 0.05$ ). The flow cytometry analysis showed that BaP caused significant G2/M phase arrest compared to controls, however, increased S phase and decreased G2/M phase were observed in cells co-treated with BaP and EGCG compared to BaP group ( $P < 0.05$ ). BEAS-2B cells exposed to BaP had a significant induction of BPDE-DNA adducts when compared with controls ( $P < 0.01$ ). Moreover, these adducts were diminished significantly by EGCG treatment with an 80% reduction. CYP1A1 and CYP1B1 expression levels analyzed by qRT-PCR dramatically increased after BaP exposure compared to controls (CYP1A1: 130.2-folds; CYP1B1: 6.0-folds;  $P < 0.001$ ). EGCG significantly reduced BaP-induced CYP1A1 and CYP1B1 expression (CYP1A1: 1.6-folds; CYP1B1: 1.2-folds; BaP vs. BaP+EGCG,  $P < 0.05$ ). On the other hand, CYP1A2 and CYP3A4 did not show any changes among the control, BaP-treated, and BaP and EGCG co-treated groups. In summary, BaP-induced adverse effects could be prevented by EGCG, suggesting a possible chemopreventive role for this natural polyphenol against the development of lung cancer.

### PS 314 17 $\beta$ -Estradiol Benzoate and Bisphenol A Suppress Xenobiotic-Metabolizing Enzyme Expression in Adult Rat Testis.

S. M. Bandiera, R. R. Gilibili and T. K. Chang. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.*

Previous studies showed that 17 $\beta$ -estradiol benzoate (EB) (at 4  $\mu$ mol/kg) decreased testicular expression of cytochrome P450 1B1 (CYP1B1) in adult male rats. Bisphenol A (BPA) is an endocrine disrupting chemical that has been reported to exert estrogenic activity in vitro and in vivo. In the present study, we investigated the effect of treatment with EB and BPA at varying dosages on the expression of CYP and other xenobiotic-metabolizing enzymes in rat testis. In Experiment 1, five groups of adult male Sprague-Dawley rats ( $n = 4$  per group, except for control,  $n = 5$ ) were injected sc with EB (0.004, 0.04, 0.4 or 4  $\mu$ mol/kg) or vehicle (propylene glycol, 1ml/kg), once daily for 14 days. Immunoblot analysis indicated that treatment with EB at 0.004, 0.04, 0.4 or 4  $\mu$ mol/kg decreased testicular CYP1B1 (by 15, 56, 70 and 80 %), CYP2A1 (by 48, 79, 97 and 95%) and CYP17A1 (by 15, 44, 94 and 98 %) protein levels, respectively, when compared with vehicle-treated rats. The constitutive expression of EH and NADPH-cytochrome P450 reductase was not affected by EB at 0.004  $\mu$ mol/kg, but EH (by 56, 70 and 80 %) and NADPH-cytochrome P450 reductase (by 53, 58 and 48 %) protein levels were decreased following EB treatment at 0.04, 0.4 and 4  $\mu$ mol/kg, respectively. In Experiment 2, adult male rats ( $n = 4$  per group) were injected sc with saline, vehicle (propylene glycol, 1ml/kg) or BPA at 400, 800 or 1600  $\mu$ mol/kg, once daily for 14 days. Treatment with BPA at 400, 800 or 1600  $\mu$ mol/kg decreased CYP1B1 (by 51, 87 and 89%), CYP2A1 (by 79, 92 and 92%), EH (by 50, 67 and 67%) and NADPH-cytochrome P450 reductase (by 43, 67 and 67%) protein levels, respectively, when compared with saline- or vehicle-treated rats. CYP17A1 protein levels were decreased by 49% by BPA at 400  $\mu$ mol/kg dose and were not detectable at other BPA doses. In conclusion, testicular expression of CYP1B1, CYP2A1, CYP17A1, EH and NADPH-cytochrome P450 reductase was down-regulated by exogenous estradiol and BPA, at higher dosages, produced a similar effect.

### PS 315 Acute Lead Exposure Induces Cardiotoxicity In Vivo and In Vitro Rat Model through the Cytochrome P450 1A1 Signaling Pathway.

H. M. Korashy, M. A. Ansari and Z. H. Maayah. *Pharmacology & Toxicology, King Saud University, Riyadh, Saudi Arabia.* Sponsor: S. Al-Bakheet.

Lead (Pb2+) is a naturally occurring systemic toxicant heavy metal that has been reported to affects several organs in the body including the kidneys, liver, central nervous system, and the cardiovascular system. However, Pb2+-induced cardiotoxicity has never been investigated yet and the exact mechanism of Pb2+ associated cardiotoxicity has not been studied. Therefore, the current study was designed to investigate the potential effect of Pb2+ to induce cardiotoxicity in vivo and in vitro rat model and explore the molecular mechanisms and the role of cytochrome P4501A1 (CYP1A1) in Pb2+-mediated cardiotoxicity. For these purposes, Wistar albino rats were treated with Pb2+ (25, 50 and 100 mg/kg, i.p.) for three days to study its effect on physiological and histopathological parameters of cardiotoxicity. On the other hand, rat cardiomyocyte H9c2 cell line, which was utilized as an in vitro model, were incubated with increasing concentration of Pb2+ (25, 50, and

100  $\mu$ M) and the expression of hypertrophic genes,  $\alpha$ - and  $\beta$ -myocin ( $\alpha$ -MHC and  $\beta$ -MHC) and CYP1A1 were determined at the mRNA and protein levels using real-time PCR and Western blot analysis, respectively. Our results showed that Pb2+ significantly induced cardiotoxicity and heart failure as evidence by increase cardiac enzymes, lactate dehydrogenase and creatine kinase-MB) and changes in histopathology *in vivo*. In addition, Pb2+ treatment induced  $\beta$ -MHC whereas inhibited  $\alpha$ -MHC mRNA levels in a time- and dose-dependent manner *in vivo* and *in vitro*. Importantly, these changes were accompanied with a proportional increase in the expression of CYP1A1 mRNA and protein expression levels, suggesting a role for the CYP1A1. The direct evidence for the involvement of CYP1A1 in the induction of cardiotoxicity by Pb2+ was evidenced by the ability of CYP1A1 blocker, resveratrol, to significantly inhibit the Pb2+-modulated  $\beta$ -MHC and  $\alpha$ -MHC mRNAs. It was concluded that acute lead exposure induced cardiotoxicity through CYP1A1 mediated mechanism.

### PS 316 Reciprocal Roles of Cytochromes P4501a1 and 1A2 in Lung Carcinogenesis Mediated by Polycyclic Aromatic Hydrocarbons (PAHs) in Mice.

W. Jiang<sup>1</sup>, L. Wang<sup>1</sup>, G. Zhou<sup>2</sup>, X. Couroucl<sup>1</sup> and B. Moorthy<sup>1</sup>. <sup>1</sup>*Pediatrics, Baylor College of Medicine, Houston, TX;* <sup>2</sup>*Institute of Biosciences and Technology, Texas A&M University Health Science Center, Houston, TX.*

Humans are constantly exposed to polycyclic aromatic hydrocarbons (PAHs). Cytochrome P4501A (CYP1A) enzymes play important roles in the activation of PAHs such as 3-methylcholanthrene (MC) to DNA-binding metabolites, which in turn mediate carcinogenesis in target organs such as lung. In this study, we tested the hypothesis that CYP1A1 and 1A2 have reciprocal roles in PAH-mediated tumorigenesis. Eight week-old female wild type (WT) (A/J) mice or mice lacking the gene for CYP1A1 or CYP1A2 on the A/J background were treated with a single dose of MC (40  $\mu$ mol/kg), or vehicle (corn oil), and liver and lung tumors were studied after 28 weeks. While 100% of WT or Cyp1a2-null mice exposed to MC showed lung tumors after 28 weeks, about 80% of the Cyp1a1-null mice showed lung tumors. However, there were striking differences in the Cyp1a1-null and Cyp1a2-null mice in regard to lung tumor multiplicities. The WT mice treated with MC had about 15 lung tumors/animal. On the other hand, the Cyp1a2-null mice displayed about 40 lung tumors/animal, while the Cyp1a1-null mice showed about 2-3 tumors/mouse. DNA adduct studies at early time points (8 days) showed increased MC-DNA adducts in lungs of Cyp1a2-null mice compared to WT mice, and decreased adduct formation in the Cyp1a1-null mice, supporting the hypothesis that DNA adducts are early biomarkers of PAH-mediated carcinogenesis. Overall, our results suggest that CYP1A1 contributes to the formation of tumorigenesis by PAHs, while CYP1A2 protects against carcinogenesis mediated by PAHs, presumably through its role in PAH detoxification. In conclusion, our results strongly suggest that CYP1A1 and 1A2 could be novel candidates for cancer prevention and therapy through either inhibition of CYP1A1 or induction of CYP1A2. (Supported by NIH grant ES009132.)

### PS 317 Activity-Based Protein Profiling of Metabolizing Enzyme Ontogeny and Response to PAH Exposure in Rodents and Humans.

N. Sadler<sup>1</sup>, S. R. Crowell<sup>1</sup>, A. Wright<sup>1</sup>, D. E. Williams<sup>2</sup> and R. A. Corley<sup>1</sup>. <sup>1</sup>*Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA;* <sup>2</sup>*Oregon State University, Corvallis, OR.*

Activity-based protein profiling (ABPP) has recently emerged as a post-genomic technology for characterizing functional proteins in complex biological systems. This approach applies chemical activity-based probes that monitor the functional activity of enzymes under physiological conditions, thereby providing high-content proteomic information beyond the reach of standard gene- and protein-expression profiling. We have previously developed a suite of activity based probes that display broad coverage across mouse and human phase I and II metabolizing enzymes. Each probe contains three moieties: (1) a reactive group that forms a covalent bond to a functional P450 through a mechanism-based reaction, (2) a binding group that targets a probe towards P450s, and (3) an alkyne (C2) handle to exploit the bio-compatible click chemistry reaction for attachment of an enrichment moiety or fluorescent reporter. In this study, we measured enzyme activity at key life stages in mouse, including fetal development, normal adulthood, and pregnancy, as well as in human fetal tissues. Additionally, we compared the effects of exposure to the transplacental carcinogenic polycyclic aromatic hydrocarbon (PAH) dibenzo[def,p]chrysene (DBC) on enzyme activity in the mouse. We have determined that the activity of most hepatic phase I enzymes associated with PAH metabolism (e.g., CYP 1A1, CYP2E1, epoxide hydrolase) was reduced by 2-10 fold during pregnancy in mice. By incorporating these reductions in enzyme activity

into a physiologically based pharmacokinetic (PBPK) model, along with normal changes in anatomy and physiology, we were able to describe the significantly elevated concentrations of DBC in blood and tissues of pregnant mice versus naïve mice, following equivalent exposures. We additionally report, for the first time, developmentally driven changes in enzyme activity in both mice and humans. Supported by Award Number P42 ES016465 from the NIEHS, and DOE Laboratory Directed R&D Project 90001.

### PS 318 Elucidating the Catalytic Mechanisms of the Novel Styrene Detoxification System in *Pseudomonas* Bacteria.

N. Okonkwo and G. T. Gassner. *Chemistry and Biochemistry, San Francisco State University, San Francisco, CA.* Sponsor: E. Bayliss.

As the world becomes more polluted with styrene-based polymers, it is essential to consider how the 28 million tons of Styrofoam and commercial plastics produced in the United States impact human health. Styrene and its metabolites act as biological membrane disrupters and intracellularly where they are transformed by cytochrome p450 isoforms to styrene oxide and vinylphenol, which have biological activity as pulmonary and hepatic poisons. This toxic vinyl benzene is a danger to living systems and for this reason we focused our research on the styrene detoxification pathway in *Pseudomonas* bacteria. The first enzyme, styrene monooxygenase (SMO), a two component flavoenzyme with an NADH specific reductase, SMOB, and a FAD specific epoxidase, SMOA, catalyzes the epoxidation of styrene to yield styrene oxide. Here, SMOB binds NADH and oxidized FAD as substrates and catalyzes the reduction of FAD by a hydride-transfer mechanism. Many details of the SMOB catalyzed flavin reduction and transfer still need to be explained. This research evaluates the catalytic mechanism of N-terminally histidine-tagged styrene monooxygenase reductase (N-SMOB) from *Pseudomonas putida* S12 bacteria. Over expression of N-SMOB in *E. coli* BL21(DE3) cells produces high amounts of the enzyme, which we purified using nickel affinity chromatography. A Spectromax190 microplate reader was used to measure the rate at which the hydride ion is transferred from NADH to FAD at 340nm. Previous data showed the native SMOB enzyme follows a sequential mechanism under identical conditions. However, preliminary data of N-SMOB at 10 °C suggests that a double displacement reaction with NADH as the leading substrate could be prevalent mechanism. These studies of N-SMOB at 10°C provided estimates of the Km of NADH, Km of FAD and Vmax of N-SMOB at 5.0 uM, 3.7 uM, and 38.0 uMs<sup>-1</sup>, respectively. Through the use of high resolution kinetic analysis at 30°C, we confirm that the double displacement mechanism is the preferred reaction for N-SMOB and these findings will be used to elucidate the flavin-transfer reaction.

### PS 319 Impact of Liver-Specific Loss of Cytochrome P450 Reductase on the Expression and Function of Intestinal P450 Enzymes.

Y. Zhu<sup>1</sup>, X. Ding<sup>1</sup>, C. Fang<sup>2</sup> and Q. Zhang<sup>1</sup>. <sup>1</sup>Wadsworth Center, Albany, NY; <sup>2</sup>American Clinical Solutions, Tampa, FL.

Tissue-specific deletion of the cytochrome P450 reductase (CPR) gene in either liver or intestine leads to upregulation of many P450 genes in the tissue with the Cpr deletion. The aim of this study was to test whether a loss of hepatic CPR would also lead to upregulation of P450 expression in the small intestine (SI). We found that in the liver-specific Cpr-null (LCN) mouse, SI expression of CYP2B, 2C and 3A proteins was increased, by 2- to 3-fold, relative to that in wild-type (WT) mice. This increase was accompanied by increases in rates of SI microsomal metabolism of lovastatin (LVS), a CYP3A substrate (by 2.1-fold). The overall impact of the loss of hepatic P450 function and the increase in SI P450 expression on systemic clearance of orally administered LVS was dependent on LVS dose: the rates of clearance were increased at an LVS dose of 5 mg/kg, unchanged at 25 mg/kg, but decreased at 50 mg/kg, in the LCN mice, compared to WT mice. Thus, we show for the first time that hepatic CPR/P450 deficiency leads to compensatory increases in SI P450 expression and capacity of first-pass metabolism of oral drugs; this finding may aid in the prediction of drug exposure in patients with compromised hepatic P450 function. We also found that SI FGF15 and IBABP mRNA levels were significantly lower (by 15- and 5-fold, respectively) in LCN than in WT mice, while the levels of PXR and FXR mRNAs were unchanged. Furthermore, treatment of mice with FGF19 (the human counterpart of mouse FGF15) abolished the difference between WT and LCN mice in SI CYP3A levels. Thus, SI FGF15 may play a previously unrecognized, direct role in the regulation of SI P450 expression. Overall, our results not only provide the basis for further mechanistic studies of physiological regulation of SI P450 expression, but will also help with data interpretation for numerous studies utilizing the LCN mouse model to determine roles of hepatic P450s in the disposition of orally administered drugs.

### PS 320 Organ-Specific *Ugt1* Locus Profiling in Defining the Toxic Response Towards Irinotecan Anticancer Drug Therapy.

S. Chen, V. Devaraj, M. Fagan and R. H. Tukey. *Laboratory of Environmental Toxicology, Departments of Chemistry & Biochemistry and Pharmacology, University of California San Diego, La Jolla, CA.*

Irinotecan (CPT-11) has been used as a first line drug in the treatment of colorectal cancer. However, its efficacy and safety is compromised because of severe late onset diarrhea, a result of enterocyte toxicity from the active metabolite SN-38. SN-38 is inactivated primarily by hepatic UGT1A1 catalyzed glucuronidation to form SN-38 glucuronide, which is excreted via the biliary ducts into the gastrointestinal (GI) tract, where it serves as a substrate for bacterial  $\beta$ -glucuronidase. Free SN-38 is then re-absorbed by entry through the GI tract. Since an abundance of the UGT1 proteins are rich in the GI tract, it was important to examine the association between SN-38 glucuronidation and the pending intestinal tissue damage resulting from CPT-11 therapy. To carry out these experiments, we have generated mouse models targeting deletion of the *Ugt1* locus specifically in liver (*Ugt1<sup>ΔHep</sup>*) and the intestines (*Ugt1<sup>ΔGI</sup>*). Wild type (*Ugt1<sup>WT</sup>*), *Ugt1<sup>ΔHep</sup>*, and *Ugt1<sup>ΔGI</sup>* adult male mice were treated by the intraperitoneal route with CPT-11 daily for four constitutive days. At a daily dose of 75 mg/kg, survival curves of the *Ugt1<sup>ΔHep</sup>* mice showed a 50% lethality rate, comparable to the LD50 values of CPT-11 treated *Ugt1<sup>WT</sup>* mice. Deletion of the *Ugt1* locus in hepatic tissue had no impact on liver or GI toxicity when compared to wild type mice. Alternatively, *Ugt1<sup>ΔGI</sup>* mice were highly susceptible to CPT-11-induced diarrhea, developing severe ileocolitis. At a CPT-11 dose of 25 mg/kg, bloody diarrhea was observed in all *Ugt1<sup>ΔGI</sup>* mice and was associated with 100% lethality, while no diarrhea or lethality was observed in *Ugt1<sup>ΔHep</sup>* or *Ugt1<sup>WT</sup>* mice at that dose. Thus, intestinal expression of the UGT1A proteins is critical towards the detoxification of SN-38. Regulation of the intestinal UGT1A1 gene may serve as a target for improving the therapeutic index and efficacy associated with CPT-11 treatment. (Supported by USPHS grants ES010337 and CA171008)

### PS 321 Selective Criteria for Determining Catalytic Competency in CYP3A4: A Combined Docking and Pharmacophore Study on Triazole Fungicide Metabolism.

D. T. Chang<sup>1</sup>, C. M. Grulke<sup>1</sup>, M. Goldsmith<sup>1</sup>, J. F. Kenneke<sup>2</sup>, S. Rawat<sup>3</sup>, S. A. Marchitti<sup>2</sup>, C. S. Mazur<sup>2</sup>, K. Holm<sup>1</sup>, M. B. Phillips<sup>1</sup>, Y. Tan<sup>1</sup>, R. Tornero-Velez<sup>1</sup> and C. C. Dary<sup>4</sup>. <sup>1</sup>National Exposure Research Laboratory, US EPA, Research Triangle Park, NC; <sup>2</sup>National Exposure Research Laboratory, US EPA, Athens, GA; <sup>3</sup>Student Services Authority, Athens, GA; <sup>4</sup>National Exposure Research Laboratory, US EPA, Las Vegas, NV.

Cytochrome P450 (CYP) 3A4 is one of the major isoforms of enzymes that catalyzes via Phase I oxidation a wide variety of endogenous and exogenous compounds (i.e., broad substrate specificity) including environmental xenobiotics like chiral pesticides. In particular, several chiral pesticides are well-known to undergo differential kinetics within the homochiral environment of biological systems. The current ability to model such metabolic processes within physiologically-based pharmacokinetic model from an exposure-dose perspective is limited by specific chiral information coupled together with accurate kinetic data. With available in-house stereospecific (i.e., individual stereoisomer) *in vitro* data, we have utilized a ligand-based approach to develop a prototype CYP3A4 pharmacophore model for triazole fungicides based on the observed stereoselective CYP3A4 clearance. The developed model was further used to discriminate between single isomeric configurations thereby enriching the dataset and providing further criteria on putative ligand-receptor interactions. We also utilized a combined pharmacophore and docking approach within the CYP3A4 binding cavity (2V0M PDBID) to provide estimates on putative ligand stereoselective rate constants for a test set of triazole compounds. Observations and comparisons between high and low binding affinity poses as well as homolytic dissociation bond energy estimates at purported sites of metabolism indicate that this method may be helpful for selecting catalytically competent ligand substrates for CYP3A4 and thereby reducing the uncertainty within exposure-based pharmacokinetic models of chiral substrates. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

### PS 322 Chlorpyrifos Affects Specific Types of Zebrafish Larval Behavior If Administered during Distinct Developmental Time Periods.

H. Richendrer and R. Creton. *MCB, Brown University, Providence, RI.*

Pesticides are widely used in agriculture and are found ubiquitously in the environment. While adults have enzymes that are able to break down pesticides, developing embryos lack the necessary enzymes for toxicant removal. Low doses of organophosphate pesticides during early embryonic development in animal models

and in humans have been documented to affect brain development and behavior. It is important to determine at which stages of development embryos are most affected by the exposure to organophosphate pesticides. Using zebrafish as a model system for pesticide exposure is advantageous because embryos can be exposed to organophosphates immediately after fertilization and large numbers of larvae can be used for high-throughput behavioral analysis. Behaviors such as swim speed, preference for edge of a well, and avoidance of a moving stimulus can be quickly obtained. In the present study, employing a high-throughput assay unique to our lab, we show that exposure to low doses of a widely used organophosphate, chlorpyrifos, affect discrete behaviors if administered during specific developmental time periods. The results indicate that even low levels of chlorpyrifos have the potential to impact behavior when administered during critical periods of development and these behavioral abnormalities are emerge from pesticide exposure during different critical points. The results of the present study have the potential to affect food consumption guidelines, especially in pregnant women. Future studies will include larval zebrafish confocal brain imaging to detect neural patterning changes after chlorpyrifos exposure.

### PS 323 The Ahr Pathway and Aromatic Hydrocarbon-Mediated Teratogenicity in the Atlantic Killifish.

R. T. Di Giulio<sup>1</sup>, C. W. Matson<sup>2</sup> and B. W. Clark<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC; <sup>2</sup>Baylor University, Waco, TX.

Exposure of developing fish to polycyclic aromatic hydrocarbons (PAHs) and halogenated aromatic hydrocarbons (HAHs) results in a suite of defects including cardiac malformation, pericardial and yolk sac edema, craniofacial defects and hemorrhaging. Several populations of Atlantic killifish (*Fundulus heteroclitus*) on the Atlantic coast of the United States are resistant to the developmental toxicity caused by PAHs and HAHs; this resistant phenotype displays strong down-regulation of the aryl hydrocarbon receptor (AHR) pathway. The AHR is known to mediate many toxic responses to PAHs and HAHs in vertebrates. A single AHR has been identified in mammals, but killifish and other fish species have multiple AHRs and their roles in contaminant response and development are not clear. In this study, translation-blocking and splice-junction morpholino gene knockdown was used to determine the roles of AHR1 and AHR2, as well as CYP1A, in mediating cardiac teratogenesis induced by  $\beta$ -naphthoflavone (BNF), benzo[k]fluoranthene (BkF), and 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB-126). Here we report that AHR2 and not AHR1 knockdown resulted in rescue of cardiac teratogenicity induced by BNF, BkF, and PCB-126 in laboratory-reared offspring of non-adapted of parents from unpolluted sites. Knockdown of CYP1A enhanced the toxicity of PAHs but not PCB126. Furthermore, knockdown of AHR2 partially rescued the severe cardiac teratogenicity caused by extracts of sediments from the Atlantic Wood (AW) Superfund site (Elizabeth River, VA, USA), a site heavily contaminated with a complex mixture of creosote-derived PAHs (and home to a resistant population of killifish). These data demonstrate that AHR2 is an important mediator of cardiac teratogenesis caused by multiple aryl hydrocarbons in killifish and suggest that suppression of the AHR pathway through modulation of AHR2 is a plausible mechanism for PAH resistance in adapted fish. CYP1A, which is recalcitrant to induction in the AHR down-regulated AW population, appears to play a protective role against PAH developmental toxicity.

### PS 324 Characterization of glo1 Gene Expression during Development and Alterations Induced by Atrazine Exposure in Zebrafish.

G. Ryan<sup>1</sup>, G. J. Weber<sup>1</sup>, S. M. Peterson<sup>1</sup>, M. S. Sepulveda<sup>2</sup> and J. L. Freeman<sup>1</sup>. <sup>1</sup>Health Sciences, Purdue University, West Lafayette, IN; <sup>2</sup>Forestry and Natural Resources, Purdue University, West Lafayette, IN.

Atrazine is a commonly used herbicide that is an endocrine disruptor and a suspected carcinogen. Although atrazine was recently banned by the European Union for widespread contamination risks in potable water supplies, this herbicide is still commonly used in the United States with a current maximum contaminant level (MCL) of 3 ppb. The health risks associated with this MCL are currently being reviewed by the Environmental Protection Agency, but the mechanisms of atrazine toxicity are not well defined. In this study, we are using [1] global gene expression analysis to identify altered genes, [2] in situ hybridization to qualitatively analyze spatial gene expression throughout development, and [3] quantitative PCR (qPCR) to assess gene expression levels of specific targets throughout development in the zebrafish model system. In a previous study completed in our laboratory, zebrafish were exposed to 0.3, 3, or 30 ppb atrazine or a control treatment throughout development (1-72 hours post fertilization [hpf]). This analysis showed that expression alterations were enriched with genes associated with neuroendocrine development and function, cell cycle regulation, and carcinogenesis. From this list of genes, glyoxylase 1 (GLO1) was targeted for further study. GLO1 is part of the glyoxylase system which converts methylglyoxal to S-D-lactoylglylutathione. Upregulation of

GLO1 is linked to cell proliferation and is associated with various cancers in humans. To further our understanding of this genetic target, expression was analyzed at five developmental time points: 24, 36, 48, 60, and 72 hpf. In situ hybridization and qPCR were coupled to determine spatial and quantitative gene expression of glo1 throughout development under normal conditions and after atrazine treatment. This data is furthering our understanding of glo1 expression during development and alterations induced by atrazine exposure.

### PS 325 Developmental Effects of 6-Formylindolo[3, 2-B]Carbazole in Birds.

M. E. Jönsson<sup>1</sup>, S. Shaik<sup>1,2</sup>, A. Rannug<sup>2</sup> and B. Brunström<sup>1</sup>. <sup>1</sup>Environmental Toxicology, Uppsala University, Uppsala, Sweden; <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Birds show a strikingly large species variation in susceptibility to developmental toxicity of dioxins and coplanar polychlorinated biphenyls (PCBs). The chicken is the most sensitive to these compounds among avian species, while e.g. the Japanese quail is much more resistant. Such differences are proposed to depend on binding affinity of dioxin to the aryl hydrocarbon receptor (AHR), i.e., the degree of sensitivity is linked to variation in a few amino acids in the ligand binding domain of avian AHRs. The proposed endogenous AHR ligand 6-formylindolo[3,2-b]carbazole (FICZ) has high AHR binding affinity and causes strong transient induction of CYP1 mRNA in human cells and zebrafish embryos. In *Xenopus tropicalis* tadpoles FICZ is almost as potent an inducer of CYP1A as in zebrafish embryos. However, *Xenopus* tadpoles are much less sensitive to PCB126-induced toxicity than zebrafish embryos. The goal of the present study was to determine mRNA expression responses and other effects of FICZ in developing birds. Peanut oil-lecithin emulsions with or without FICZ were injected into the yolks of day-4 chicken embryos (0, 2, 20, or 200  $\mu$ g FICZ/kg egg) and day-3 quail embryos (0, 2, or 200  $\mu$ g FICZ/kg egg). Twenty four hours post-injection CYP1A4 and CYP1A5 showed dose-dependent induction by FICZ in both chicken and quail, and the degree of induction was similar in the two species. The CYP1B1 level in both species and the CYP1C1 level in chicken were unaffected by FICZ exposure. In chicken embryos exposed to 200  $\mu$ g FICZ/kg the CYP1A levels remained induced in liver and thymus 13 days post-injection (day 17). Furthermore, liver lesions were observed in 48% of these animals, suggesting that FICZ is toxic at high doses. Our results suggest that while there is a large species variation in sensitivity to dioxin-like compounds the strong AHR activation by FICZ is evolutionary conserved, indicating an important physiological function. Funding: The Swedish Research Council Formas and Carl Tryggers Stiftelse.

### PS 326 Aryl Phosphate Esters within a Major PentaBDE Replacement Induce Cardiotoxicity in Developing Zebrafish Embryos: Potential Role of the Aryl Hydrocarbon Receptor.

D. Volz<sup>1</sup>, S. McGee<sup>1</sup>, A. Konstantinov<sup>2</sup> and H. Stapleton<sup>3</sup>. <sup>1</sup>University of South Carolina, Columbia, SC; <sup>2</sup>Wellington Laboratories, Guelph, ON, Canada; <sup>3</sup>Duke University, Durham, NC.

Firemaster 550 (FM550) is an additive flame retardant formulation of brominated and aryl phosphate ester (APE) components introduced in 2004 as a major replacement for the commercial polybrominated diphenyl ether mixture (known as PentaBDE) used primarily in polyurethane foam. Due to rapid adoption, certain FM550 components have been detected at elevated concentrations within indoor environments. However, little is known about the potential effects of FM550-based ingredients during early vertebrate development. Therefore, we first screened the developmental toxicity of each FM550 component using zebrafish as an animal model. Based on these initial screening assays, we found that exposure to triphenyl phosphate (TPP) or mono-substituted isopropylated triaryl phosphate (Mono-ITP) – two APEs comprising almost 50% of FM550 – resulted in targeted effects on cardiac looping and function during embryogenesis. As these cardiac abnormalities resembled aryl hydrocarbon receptor (AHR) agonist-induced phenotypes, we then exposed developing embryos to TPP or Mono-ITP in the presence or absence of a selective AHR antagonist (CH223191) or AHR2-specific morpholino. Based on these studies, we found that CH223191 blocked the cardiotoxic effects of Mono-ITP but not TPP, while AHR2 knockdown failed to block the cardiotoxic effects of both components. Moreover, using a cell-based human AHR reporter assay, we found that Mono-ITP (but not TPP) exposure resulted in a significant increase in human AHR-driven luciferase activity at similar nominal concentrations as a potent reference AHR agonist ( $\beta$ -Naphthoflavone). Overall, our findings suggest that two major APE components of FM550 induce severe cardiac abnormalities during early vertebrate development, raising questions about the potential health risks of these APEs resulting from indoor exposure.

**PS 327 Cytochrome P450 Gene Transcripts in Early Development of Zebrafish *Danio rerio*.**

J. Stegeman, A. Kubota, B. Woodin, E. Hawley, Z. Janes, B. Lemaire and J. Goldstone. *Biology, WHOI, Woods Hole, MA.*

Understanding the roles of cytochromes P450 (CYPs) in zebrafish is important to the use of this non-mammalian model in toxicological, pharmacological and carcinogenesis research. In this study, we determined whether maternally derived transcripts for many CYP genes are present in zebrafish oocytes, and how levels change up to the mid-blastula transition (MBT) (3 hours post fertilization, hpf), focusing on genes involved in xenobiotic and endobiotic metabolism. The maternal contribution to transcript abundance in the eggs varied greatly among CYP genes examined. CYP2V1 showed the highest levels in the oocytes, followed by CYP20 and CYP1A. The transcript levels of all CYPs examined were similar between unfertilized eggs and fertilized eggs at < 2 cell stage (prior to the first division). Many of CYPs including CYP1B1, 1C1, 1C2, 2P6, 2R1, 2AA4, 11C1, 17A2, and 26A1 showed significant increases in their transcript levels at 3 hpf (1,000 cells). In contrast, CYP1A and the steroidogenic CYPs 11A1, 17A1, and 19A1, showed constant levels of transcript from egg to 3 hpf. Other CYPs, including CYP2V1, 2AA3, 3C1, and CYP51 showed an increasing trend at 2 hpf (64 cells), well before the MBT. We also examined the effect of exposure to an aryl hydrocarbon receptor agonist, 3,3',4,4',5-pentachlorobiphenyl (PCB126) on transcript levels of CYP1 and selected other genes in oocytes. Exposure of females to waterborne PCB126 caused increases in the transcript levels of CYP1A, 2AA3, 3C1, 11A1, and CYP51 genes in eggs as compared to those from vehicle-exposed females. The results reveal maternal transcript deposition of a suite of CYP genes in the egg, and also show that temporal patterns of CYP transcript levels during early development from egg to the MBT differ substantially among different CYP genes. Maternal exposure to chemical was shown to cause change in the transcript deposition of some CYPs in the eggs. [Support: JSPS Postdoctoral Fellowships for Research Abroad no. 820 (A.K.), and NIH Superfund Research Program grant P42ES00738 (J.S.)]

**PS 328 Benzo[a]pyrene Exposure Effects on Reproductive Success, Development, and Transcriptome in Zebrafish.**

K. L. Willett<sup>1</sup>, C. Thornton<sup>1</sup>, J. Corrales<sup>1</sup>, X. Fang<sup>1</sup>, M. White<sup>1</sup>, K. Mislan<sup>1</sup>, L. Ballard<sup>2</sup> and B. E. Scheffler<sup>2</sup>. <sup>1</sup>Pharmacology and Environmental Toxicology, University of Mississippi, University, MS; <sup>2</sup>Genomics and Bioinformatics, USDA ARS, Stoneville, MS.

Benzo[a]pyrene (BaP) is an environmentally relevant carcinogenic and endocrine disrupting compound that causes multigenerational effects in mammals. We hypothesized that, like in humans, BaP exposure would adversely affect zebrafish gene expression, reproduction and cause quantifiable pathologies across generations. Adult zebrafish (2 females x 2 males, N=10 replicate tanks per treatment) were fed 2% body weight/day flake food treated with 0, 11.6, 110, 1086 µg BaP/g flake (equivalent to 0, 0.23, 2.2, and 22 µg BaP/g fish/day) for 22 days. Parental gonad pathology and reproductive success, and F1 and F2 survival and morphological abnormalities were measured. The total number of eggs produced and fertilization success was non-significantly reduced in a dose-dependent manner, and parental ovarian atresia was significantly decreased. Mortality was significantly increased in F1 larvae whose parents were exposed to 2.2 and 22 µg BaP/g fish by 48 and 56 hours post-fertilization (hpf), respectively. High dose BaP F1 fish hatched sooner (48 hpf) compared to control (56 hpf). Body and tail shape and swim bladder were negatively impacted after parental exposure to 2.2 and 22 µg BaP/g fish. Moreover, differential gene expression by RNA-Seq of embryos and larvae was documented after a seven day parental embryonic water-borne BaP exposure. As expected, CYP1 genes in 96 hpf BaP-exposed embryos were induced as was vtg7. Based on these results, BaP negatively impacted zebrafish reproduction and development. Supported by NIEHS R21ES019940.

**PS 329 Molecular Pathway of Neurotoxicity Caused by Developmental Exposure to Bisphenol A in Embryonic Zebrafish.**

S. R. Das<sup>1</sup>, K. S. Saili<sup>1</sup>, S. M. Bugel<sup>1</sup>, M. M. Corvi<sup>1</sup>, S. C. Tilton<sup>2</sup>, K. M. Waters<sup>2</sup> and R. L. Tanguay<sup>1</sup>. <sup>1</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR; <sup>2</sup>Computational Biology and Bioinformatics, Pacific Northwest National Laboratory, Richland, WA.

Bisphenol A (BPA) is an endocrine disrupting compound widely used in consumer product manufacturing. Developmental exposure to 0.1 µM BPA results in a hyperactive phenotype in zebrafish larvae and impairment of learning in adults. The

mode of action underlying these effects presumably involves impacts on nervous system development through activation of classical estrogen receptors (ERs) or other receptors such as estrogen related receptor gamma (ERR3) and G-protein coupled estrogen receptor (GPER). Transient knockdown of ERR3 using an antisense morpholino rescued the hyperactive phenotype in the zebrafish larvae suggesting a role of ERR3 in the developmental toxicity induced by BPA. We further used global mRNA and miRNA expression analysis to investigate the transcriptional effects of BPA exposure and to identify candidate genes and signaling pathways that mediate the observed behavioral response. Zebrafish embryos were exposed to either of 0.1% DMSO, 0.1 µM BPA, 0.1 µM 17β-estradiol, 0.1 µM GSK4716 (an ERR3 agonist) from 8 hours post fertilization (hpf) to 24 hpf. At 24 hpf RNA was isolated to identify transcriptional changes that precede behavioral response using a 135K NimbleGen microarray platform. Functional analysis of differentially expressed genes revealed CREB and prothrombin activation as top canonical pathways impacted by both BPA and E2 exposure, and suppressed expression of key genes involved in nervous system development and function. For miRNA expression analysis, total RNAs isolated at 24 hpf after exposure to either 0.1% DMSO or 0.1 µM BPA were labeled and hybridized onto a Exiqon miRCURY LNA miRNA array (v. 11). The expression of a number of miRNAs was altered by BPA exposure. These results provide insight into potential modes of action underlying BPA's neurodevelopmental toxicity in zebrafish. **PS 330 Methylmercury-Induced Notch Signaling Points to a Role for Muscle Targets in Motor Nerve Development in *Drosophila*.**

C. T. Mahapatra<sup>2</sup>, M. D. Rand<sup>1</sup>, G. Engel<sup>1</sup> and A. Delwig<sup>1</sup>. <sup>1</sup>Environmental Medicine, University of Rochester, Rochester, NY; <sup>2</sup>College of Agriculture, Purdue University, West Lafayette, IN.

Methylmercury (MeHg) is a ubiquitous environmental toxicant that targets the developing fetal nervous system. Despite a wide variety of toxic mechanisms ascribed to MeHg, its specificity for neural targets is not completely understood. Previous work in mammalian and insect cells has shown that MeHg induces expression of Notch pathway target genes, notably the Enhancer of split m-delta (E(spl)mδ) gene. We have shown earlier that MeHg induction of E(spl)mδ can occur independent of the Notch receptor and thus may directly influence neural development. In this study we examine the effects on MeHg on E(spl) gene expression in parallel with neural development events in the *Drosophila* embryo. We now show that E(spl)mδ is specifically upregulated in MeHg-exposed embryos. We exclude the possibility that MeHg-induced E(spl)mδ expression is a by-product of a general stress response or a shift in developmental timing. MeHg phenotypes are apparent in the outgrowth of the embryonic intersegmental and segmental motor nerves. Genetic manipulations causing overactivity of the Notch pathway in neurons can mimic these phenotypes. Unexpectedly, induced expression of E(spl)mδ in neurons does not cause a failure of motor nerve outgrowth. We now demonstrate that endogenous E(spl)mδ expression localizes to developing muscle and that E(spl)mδ overexpression in embryonic muscle causes a segmental nerve phenotype similar to MeHg treatment. Closer examination shows altered patterning in muscle fields stemming from either MeHg treatment or E(spl)mδ overexpression. In contrast, targeting expression of the closely related E(spl)mγ to developing muscle shows no embryonic phenotype, whereas E(spl)mγ targeted to neurons is embryonic lethal. In summary these data highlight a novel mechanism whereby MeHg can engage the activity of a Notch pathway target gene to alter coordinated development of muscles and motor neurons.

**PS 331 Effects of Benzo[a]pyrene on Early Zebrafish Development.**

K. M. Alharthy, F. T. Booc, J. Corrales, C. Thornton and K. L. Willett. Department of Pharmacology and ETRP, University of Mississippi, Oxford, MS.

Benzo[a]pyrene (BaP) is a ubiquitous environmental contaminant that is an endocrine disrupting and carcinogenic high molecular weight polycyclic aromatic hydrocarbon. Our previous work found that BaP significantly decreased fish brain aromatase (CYP19b) expression, a key enzyme in steroidogenesis. We hypothesized that BaP deregulates the steroid hormone hypothalamus-pituitary-gonad feedback loop adversely affecting reproductive development and physiology. Zebrafish embryos were exposed to waterborne concentrations of BaP (0, 10, and 50 µg/L) for 96 hours postfertilization (hpf). Fifty µg/L BaP significantly increased mortality compared with the control and 10 µg/L groups at 24, 48, 72, and 96 hpf, whereas mortality was not significantly increased until 96 hpf in the 10 µg/L BaP group. In order to quantitate effects on larval estrogen and testosterone concentrations, larvae were collected at 48, 72, 96, 168 and 504 hpf. Histopathological assessment of gonad maturation was done on paraffin embedded and sectioned fish at 28, 32, 35, and 52 days post fertilization. In a treatment-blinded morphological assessment of larvae at 96 hpf, the high BaP dose significantly decreased the body length, optic vesicle, and swim bladder size while increasing pericardial and abdominal edema

compared to control and 10 µg/L treatments. Body and tail shape and fin malformation scoring also indicated a dose-dependent adverse impact of BaP-treatment on development. Results extend previous studies highlighting the adverse impacts on early development of BaP-exposure. (Supported by NIEHS R03 ES018962)

**PS 332 Drosophila CYP6g1 and Its Human Homolog CYP3A4 Confer Tolerance to Methylmercury during Development.**

M. D. Rand<sup>1</sup>, J. A. Lowe<sup>1</sup> and C. T. Mahapatra<sup>2</sup>. <sup>1</sup>*Environmental Medicine, University of Rochester, Rochester, NY;* <sup>2</sup>*College of Agriculture, Purdue University, West Lafayette, IN.*

The fetal nervous system is a well-known primary target for methylmercury (MeHg) toxicity. Despite knowledge of numerous cellular processes that are affected by MeHg, the mechanisms that ultimately influence tolerance or susceptibility to MeHg in the developing fetus are not well understood. Using transcriptomic analyses of developing brains of MeHg tolerant and susceptible strains of *Drosophila*, we previously identified members of the cytochrome p450 (CYP) family of monooxygenases/oxidoreductases as candidate MeHg tolerance genes. CYP genes encode Phase I enzymes best known for xenobiotic metabolism in the liver as well as synthesis and degradation of essential endobiotics, such as hormones and fatty acids, that are critical to normal development. We now demonstrate that natural and induced variation in expression CYP genes can strongly influence MeHg tolerance in the developing fly. We show that modulating expression of a single CYP, CYP6g1, specifically in neurons or the fat body (liver equivalent) is sufficient to rescue *Drosophila* development in the presence of MeHg in the diet. Furthermore, we identify CYP3A4 as a human homolog of CYP6g1 and show that it similarly confers MeHg tolerance when ectopically expressed in flies. Finally, pharmacological induction of endogenous CYPs with caffeine also results in elevated tolerance to MeHg in developing flies. These findings establish a previously unidentified role for CYPs in modulating MeHg toxicity and point to a potentially conserved role of CYP genes to influence susceptibility to MeHg toxicity across species.

**PS 333 Systems Approaches to Define the Developmental Toxicity of Polybrominated Diphenyl Ethers.**

M. T. Simonich, L. Truong, S. M. Bugel, B. C. Goodale, W. Bisson, D. C. Koch, S. K. Kolluri and R. L. Tanguay. *Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR.*

Polybrominated diphenyl ethers (PBDEs) are high production volume flame retardants used in a number of consumer products. PBDEs are ubiquitous environmental pollutants due to their widespread usage, persistence and lipophilicity. Developmental exposure to PBDEs is associated with a number of neurological and developmental effects in humans and wildlife. A major complexity in assessing the hazard and risk posed by PBDEs is the diversity of chemical congeners; chemical structure-toxicity relationships are not established for these compounds. Our hypothesis was that developmental toxicity of PBDEs is highly structure dependent and that the molecular targets of these compounds are distinct. We performed rapid throughput assessment of PBDE developmental and neurotoxicity in zebrafish with PBDE congeners 47, 77, 99, 100, 153, 154, and 183. All exposures were from 6 until 120 hours post fertilization (hpf) at which time larvae were assessed for photo-induced locomotor activity and changes in a suite of 20 morphological endpoints. Preliminary global gene expression data suggested that some PBDE congeners may activate the aryl hydrocarbon receptor (AHR). We used our AHR PAS domain homology model for molecular docking analysis, which predicted that PBDE 47, 77, and 99 would bind to the human and zebrafish AHR. Immunohistochemistry confirmed CYP1A induction for PBDE 77 and PBDE 99. Mammalian AHR dependent *in vitro* reporter assays supported these results. Finally, PBDE exposures in AHR2 null fish confirmed that AHR2 is necessary for PBDE 77, and 99 neuro and developmental toxicity. Collectively these data indicate that some PBDEs induce toxicity primarily via activation of the AHR, while others act through uncharacterized AHR-independent pathways, and we are now positioned to identify these distinct mechanisms of PBDE action. This research is supported by NIEHS grants P30 ES00210, T32 ES07060 and RC4ES019764.

**PS 334 Evaluating Morphological, Neurological, and Gene Expression Changes in Response to Developmental PAH Exposures.**

A. Knecht and R. L. Tanguay. *Oregon State University, Corvallis, OR.*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants present in urban air, dust, and soil resulting from incomplete combustion of organic materials or fossil fuels. It is widely recognized that PAHs pose risks to

human health, especially for the developing fetus and infant where PAH exposures have been linked to low birth weight and in-utero mortality and lower intelligence. Using the embryonic zebrafish model, we evaluated the developmental and neurotoxicity after exposure to two PAHs: benzo[a]pyrene (B[a]P) and dibenzo[a,l]pyrene (DB[a,l]P). Dechorionated embryos were exposed from 6 to 120 hours post fertilization (hpf) to a broad concentration range of PAHs and assessed for mortality and 20 unique endpoints at 120 hpf. Using the Viewpoint Zebrafish, we identified that larvae exposed to B[a]P exhibited a hyperactive phenotype. To determine if this behavioral defect persists throughout development, a subset of exposed animals were raised to adulthood and assessed for learning and memory deficiencies using shuttleboxes. Previously, we have demonstrated that exposure to PAHs resulted in an induction of the oxidative stress genes set. Using the Seahorse Extracellular Flux Analyzer, we measured oxidative stress *in vivo* in 24hpf embryos exposed to PAHs from 6 – 24 hpf. The Seahorse results confirm the presence of oxidative stress and that exposure to PAHs cause decreased oxygen consumption rates and acidification rates suggesting the presence of mitochondrial damage. To explore what transcriptional events are occurring prior to the onset of developmental and neurotoxicity, a global gene expression analysis using RNA-seq was performed on 48 hpf embryos exposed to 1 and 10ppm B[a]P and 10ppm DB[a,l]P. Analysis of our collective data will be discussed and provide insight into potential mechanism of action for some PAHs. This research was supported by the NIEHS grants P42 ES016465 and P30 ES000210.

**PS 335 Defining Pathways of Polycyclic Aromatic Hydrocarbon Developmental Toxicity in Zebrafish Using Systems-Based Transcriptional Profiling.**

B. C. Goodale<sup>1</sup>, S. C. Tilton<sup>2</sup>, A. Knecht<sup>1</sup>, A. Swanson<sup>1</sup>, K. Anderson<sup>1</sup>, K. M. Waters<sup>2</sup> and R. L. Tanguay<sup>1</sup>. <sup>1</sup>*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR;* <sup>2</sup>*Computational Biology and Bioinformatics, Pacific Northwest National Laboratory, Richland, WA.*

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous in the environment as components of fossil fuels and by-products of combustion. Defining toxicity mechanisms for this large family of multi-ring structures and substituted derivatives is a substantial challenge. In addition to the well-studied carcinogenic properties of several PAHs such as benzo(a)pyrene, reports of cardiac and developmental effects have increased concern about health risks of exposure to PAHs. Some PAHs induce toxicity via activation of the aryl hydrocarbon receptor (AHR), while others act through uncharacterized AHR-independent pathways. We employed the zebrafish model to rapidly assess developmental toxicity, global transcriptional responses and AHR activation in embryos exposed to parent, oxygenated PAHs (OPAHs) and environmental mixture samples during development. Using comparative analysis of mRNA expression profiles from microarrays with embryos exposed to benz(a)anthracene (BAA), dibenzothiophene (DBT) and pyrene (PYR), we identified expression biomarkers and disrupted biological processes that precede developmental abnormalities. These transcriptional responses were associated with PAH body burdens in the embryos detected by GC-MS. We found that uptake data was essential for discerning molecular pathways from dose-related differences, and identified two primary toxicity profiles. While BAA disrupted transcripts involved AHR signaling and vasculogenesis, DBT and PYR misregulated ion homeostasis and muscle-related genes. Biomarkers of these toxicity pathways are under investigation with a diverse group of OPAHs, and comparative analysis of embryos exposed to OPAHs with different proposed molecular mechanisms using RNA-seq will expand and refine pathways of PAH-induced developmental toxicity. This research is supported by NIEHS grants P30ES00210, P42ES016465 and T32ES07060.

**PS 336 Ebselen As a Countermeasure for Nitrogen Mustard Vesicant-Induced Toxicity.**

J. D. Laskin<sup>1</sup>, Y. Jan<sup>1</sup>, D. E. Heck<sup>2</sup>, R. P. Casillas<sup>3</sup> and D. L. Laskin<sup>4</sup>. <sup>1</sup>*Environmental & Occupational Medicine, UMDNJ-RWJMS, Piscataway, NJ;* <sup>2</sup>*Environmental Health Science, New York Medical College, Valhalla, NY;* <sup>3</sup>*MRI Global, Kansas City, MO;* <sup>4</sup>*Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.*

Mechlorethamine (HN2), a nitrogen mustard vesicant, is a bifunctional alkylating agent commonly used as a model to study sulfur mustard-induced lung injury. Previously, we reported that HN2 selectively targeted antioxidants in lung A549 epithelial cells including the selenoprotein thioredoxin reductase (TrxR) forming intra- and inter-molecular cross links. This resulted in dimer and oligomer formation, and enzyme inactivation, a process contributing to oxidative stress and toxicity. In this study, we examined the effects of ebselen, a selenium-containing antioxidant, on HN2-induced toxicity. In A549 cells, HN2 was found to be cytotoxic

(LD50 = 25  $\mu$ M). Both pre- and post-treatment with ebselen (50  $\mu$ M) significantly attenuated HN2-induced toxicity. This was correlated with reduced inhibition of TrxR enzyme activity and decreased formation of TrxR dimers and oligomers. Ebselen treatment was found to induce TrxR protein expression in A549 cells, suggesting that inhibition of toxicity was due to both reduced TrxR damage and increased TrxR enzyme activity. Using purified rat liver TrxR, ebselen also protected against enzyme inactivation by HN2. This was due to a decrease in HN2 binding to the catalytic residues on TrxR, thus preventing enzyme inactivation. Taken together, our data suggest that ebselen has the potential to be an effective countermeasure for HN2-induced lung injury. Support: NIH grants AR055073, ES004738, CA132624, ES05022 and GM034310.

### PS 337 Identification of Thioredoxin As a Molecular Target for Sulfur Mustard Analog Vesicants.

Y. Jan<sup>1</sup>, I. Wohlman<sup>2</sup>, D. E. Heck<sup>3</sup>, R. P. Casillas<sup>4</sup>, D. L. Laskin<sup>2</sup> and J. D. Laskin<sup>1</sup>. <sup>1</sup>Environmental & Occupational Medicine, UMDNJ-RWJMS, Piscataway, NJ; <sup>2</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ; <sup>3</sup>Environmental Health Science, New York Medical College, Valhalla, NY; <sup>4</sup>MRIGlobal, Kansas City, MO.

The thioredoxin system, composed of thioredoxin reductase, thioredoxin and NADPH, is a cellular disulfide reduction system important in antioxidant defense and cell growth control. We reported previously that thioredoxin reductase is a target of both monofunctional [2-chloroethyl ethyl sulfide (CEES)] and bifunctional (HN2, nitrogen mustard) vesicating agents. These vesicants were found to covalently bind to selenocysteine/cysteine residues in the redox centers of the enzyme, leading to its inactivation and toxicity. Thioredoxin contains two catalytic cysteine and three structural cysteine residues. In these studies, we determined if vesicants also target thioredoxin. Both CEES and HN2 treatment were found to cause time- and concentration-dependent inhibition of thioredoxin in A549 cells. Western blot analysis revealed that a band corresponding to tetramers of thioredoxin was present in HN2-, but not CEES-treated cells, suggesting that HN2 caused inter-molecular thioredoxin cross-links. Using recombinant enzyme and mass spectrometry, we found that both CEES and HN2 alkylated cysteine and lysine residues on thioredoxin, including cysteine-32 and cysteine-35 in the redox center of the enzyme. In addition, several inter-peptide cross links were identified in HN2-treated thioredoxin, providing a mechanism for the formation of thioredoxin tetramers in A549 cells. These data demonstrate that thioredoxin is a molecular target of sulfur mustard vesicants. Agents that can reactivate the thioredoxin system may be effective countermeasures for sulfur mustard-induced tissue injury. Support: NIH grants AR055073, ES004738, CA132624, ES05022 and GM034310.

### PS 338 Novel Therapeutic Compounds YEL001 and YEL002 Mitigate Radiation-Induced Toxicity Authors.

Y. Rivina and R. H. Schiestl. Pathology; Environmental Health Sciences, Radiation Oncology, University of California Los Angeles, Los Angeles, CA.

The possibility of a radiation disaster from a nuclear detonation or accident has existed for over 50 years and spawned much of the basic research in radiobiology in the 1950-60s. The recent Fukushima accident was yet another reminder that there remains a dire need to develop novel therapies against radiation-induced toxicities. Here we report on the development of two novel radiation countermeasure therapies: Yel001 and Yel002. These small, biologically active, drug-like molecules were uncovered in the DEL high throughput assay reducing radiation-induced cyto- and geno-toxicity in yeast. Radiation-modulating activity was further confirmed in yeast plate-based DEL Assay: addition of either Yel001 or Yel002 to irradiated cultures reduced cell death and genomic instability. Further, Yel compounds increases survival to 75% in vivo following an LD100/30 dose of ionizing radiation (IR) with the first therapeutic injection administered 24 hours post exposure followed by injections at 48, 72, 96, and 120 hours. Additionally, treatment with Yel001 and Yel002 compounds reduces radiation-induced leukemia from 90% to 50% and 40% respectively. Of note, treatment with either Yel001 or Yel002 reduced spontaneous leukemia rate from 10% to 0%. Treatment with Yel002 following IR accelerates the recovery of the hematopoietic cells after sub-lethal exposures. In addition, treatment with Yel002 reduces EMS, MMS, UV, cigarette smoke extract as well as nitrogen mustard induced toxicity as well as genotoxicity showing a broad application spectrum. Toxicity has not been observed in neither in vitro or in vivo administrations. Overall, Yel compounds have much potential as stockpile therapies for radiation-induced lethality and cancer: they are highly effective when administered up to 24 hours post exposure, they reduce radiation-induced sequelae such as leukemia, and appear to have an acceptable toxicity profile.

### PS 339 Show Bispyridinium Nonoximes Direct Interactions with Muscle-Type Nicotinic Acetylcholine Receptors?

H. Thiermann, T. Seeger, F. Worek and K. V. Niessen. Bundeswehr Institute of Pharmacology and Toxicology, Munich, Germany.

Objective: In poisoning with some organophosphorus nerve agents, e.g. soman, therapeutic efficacy of oximes is limited. For such cases, a direct intervention at nicotinic acetylcholine receptors (nAChR) might be an alternative. Studies with the bispyridinium non-oxime MB327 (1,1'-(propane-1,3-diyl)bis(4-tert-butylpyridinium) di(iodide)) demonstrated a therapeutic effect against soman in vitro and in vivo. As MB327 was found to interact most probably with muscle-type nAChRs, improved therapeutic efficacy could possibly be achieved with compounds that show enhanced activity. To identify potential candidates, homologous series of substituted and non substituted analogues (linker C1-C10) of MB327 were investigated in binding and functional assays. In addition, their inhibitory activity was assessed with human acetylcholinesterase (AChE).

Experimental procedures: In competition radioligand binding assays, the influence on [3H]epibatidine binding sites of Torpedo californica nAChR was investigated. Functional assessments were performed with cell-free electrophysiology based on solid supported membranes (SSM). AChE inhibitory properties of the compounds were assayed with a modified Ellmann assay using haemoglobin-free human erythrocyte ghosts.

Results: MB327 and several bispyridinium structure analogues exhibit no regular displacement curves at [3H]epibatidine binding sites. Compounds with unsubstituted pyridinium ring and long linkers (> C7) show regular competition but no intrinsic effect. Inhibition of human AChE (IC50 < 1  $\mu$ M) for both bispyridinium compound series (unsubstituted and with p-tert-butyl in both pyridine rings) was observed with increasing distance between the pyridinium N (> C9 and > C6 respectively).

Conclusion: The interaction with [3H]epibatidine binding sites and functional improvement of Torpedo californica nAChRs depend on the substitution and C-linker between the pyridine N. Further research is necessary for better understanding how these compounds interact with the nAChR.

### PS 340 Novel Pyridinium Oximes Offer Neural Protection in the Central Nervous System against Nerve Agent Surrogates.

R. B. Pringle<sup>1</sup>, E. C. Meek<sup>1</sup>, H. W. Chambers<sup>2</sup>, J. M. Gearhart<sup>3</sup> and J. E. Chambers<sup>1</sup>. <sup>1</sup>College Veterinary Medicine, Mississippi State University, Mississippi State, MS; <sup>2</sup>Biochemistry, Molecular Biology, Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS; <sup>3</sup>AFRL, Wright-Patterson AFB, Dayton, OH.

Organophosphates (OPs), including nerve agents, target the cholinergic system via inhibition of acetylcholinesterase (AChE), with subsequent overstimulation resulting in neural damage and potential detrimental long-term effects. The efficacy of novel pyridinium oxime reactivators, created with moieties to increase blood-brain barrier penetration, was tested using highly relevant sarin and VX surrogates. Glial fibrillary acidic protein (GFAP; an indicator of neural damage) and monoamines (dopamine, serotonin (5-HT) and their metabolites) were measured in select brain regions via immunohistochemistry and HPLC, respectively. Adult male rats were treated ip with high, sub-lethal doses of surrogates for sarin or VX, nitrophenyl isopropyl methylphosphonate (NIMP; 0.325mg/kg) or nitrophenyl ethyl methylphosphonate (NEMP; 0.4mg/kg), respectively. Surrogate treatment was followed after 1 hr by im administration of novel oxime (0.1mmol/kg). Seizure activity was monitored, and kainic acid (KA; 10mg/kg) served as a positive control. Administration of KA or surrogate (NIMP or NEMP) significantly (p<0.05) increased GFAP expression compared to control animals. Two different formulations of oxime (bromide vs. mesylate salt) attenuated seizures and reduced GFAP levels over NIMP or NEMP treatments alone to levels near those of controls (p<0.05) in both the piriform cortex and dentate gyrus region of the hippocampus, while 2-PAM did not provide protection. Serotonergic activity was also altered in several brain regions, including the piriform cortex (significant increase in both 5-HT and 5-HIAA; p<0.05), one hr after NIMP treatment, with early markers of oxidative stress (isoprostanates) also being tested. These results indicate the potential therapeutic efficacy of these oximes and suggest this innovative chemistry may protect against neural damage induced by OPs. Supported by Defense Threat Reduction Agency: 1.E0056\_08\_AHB\_C

**PS 341** **Sulforaphane Induces Antioxidants and Glutathione-S-Transferase A1 and Protects against Vesicant-Induced Toxicity in Mouse Keratinocytes.**

R. G. Udasin<sup>1,4</sup>, M. Shakarjian<sup>2,3</sup>, V. Mishin<sup>4</sup>, D. E. Heck<sup>3</sup>, R. P. Casillas<sup>5</sup>, D. L. Laskin<sup>1,4</sup> and J. D. Laskin<sup>1,6</sup>. <sup>1</sup>Joint Graduate Program in Toxicology, Rutgers University/UMDNJ, Piscataway, NJ; <sup>2</sup>Department of Medicine, UMDNJ-RWJMS, Piscataway, NJ; <sup>3</sup>Department of Environmental Health Science, New York Medical College, Valhalla, NY; <sup>4</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ; <sup>5</sup>MRI Global, Kansas City, MO; <sup>6</sup>Environmental & Occupational Medicine, UMDNJ-RWJMS, Piscataway, NJ.

Sulfur mustard and the related skin vesicant nitrogen mustard (mechlorethamine hydrochloride, HN2) are bifunctional alkylating agents known to cause oxidative stress and persistent tissue damage including blistering. In the present studies we determined whether HN2-induced oxidative stress and cytotoxicity in mouse keratinocytes could be mitigated by upregulating antioxidant enzymes. Sulforaphane (SFN), an isothiocyanate found in cruciferous vegetables including broccoli, is a well characterized inducer of antioxidants and phase II metabolizing enzymes through a pathway mediated by the transcription factor nuclear factor-erythroid 2-related factor 2 (Nrf2). Treatment of PAM212 mouse keratinocytes with HN2 inhibited keratinocyte growth (IC<sub>50</sub> = 1.0  $\mu$ M). Pretreatment of the cells with 3  $\mu$ M SFN for 3 hours protected against growth inhibition (IC<sub>50</sub> = 6.0  $\mu$ M). SFN also protected primary mouse epidermal keratinocytes from HN2 (IC<sub>50</sub> = 2.0  $\mu$ M and 30  $\mu$ M with and without SFN, respectively). SFN also decreased HN2-induced phosphorylation of histone H2A.X, a marker of DNA damage, in PAM212 cells. SFN was functionally active causing Nrf2 to translocate from the cytosol to the nucleus. This was associated with a marked increase in expression of the antioxidants heme oxygenase-1, thioredoxin reductase 1, and NADPH quinone oxidoreductase-1, as well as the phase II metabolizing enzyme glutathione-S-transferase A1. Taken together, these data indicate that oxidative stress is important in HN2-induced toxicity in mouse keratinocytes and that SFN may be an effective countermeasure against vesicant-induced toxicity. Supported by NIH grants AR055073, ES004738, CA132624, GM034310 and ES005022.

**PS 342** **Effects of Delayed Treatment with a Centrally Active Oxime on Acetylcholinesterase and Survival following Sarin Intoxication.**

T. Shih, R. K. Kan, T. M. Myers and I. Koplovitz. *Research Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Organophosphorus (OP) nerve agents (NA), such as sarin, irreversibly inhibit the enzyme acetylcholinesterase (AChE), which leads to an excess of acetylcholine in the synapses, causing numerous toxic effects, such as convulsions, respiratory distress, and death. The current NA treatment regimen includes 2-pralidoxime (2-PAM) to reactivate NA-inhibited AChE. The quaternary structure of 2-PAM, however, does not allow it to cross the blood brain barrier to reactivate brain AChE and to mitigate CNS toxicity. We have shown earlier that the tertiary oxime monoisonitrosacetone (MINA), when given soon after NA exposure, provided some AChE reactivation in the brain, enhanced survival and mitigated the seizure activity following NA exposure. In this study, we evaluated the efficacy of delayed MINA therapy in reactivating brain AChE and enhancing survival following lethal sarin intoxication. For the reactivation study, guinea pigs were treated with MINA (30, 60, or 120 mg/kg, im) 30 min after one LD<sub>90</sub> of sarin, and AChE was assessed 60 min later. MINA was capable of producing a dose-related reactivation of brain (from 5.8 to 27.4% recovery) and peripheral tissue (from 4.1 to 21.0% recovery) AChE activity that was inhibited by sarin. In a 24-hour survival study, animals were challenged with 3 x LD<sub>50</sub> of sarin and treated 1 min later with intramuscular atropine (0.5 mg/kg) and 2-PAM (25 mg/kg), and MINA (56 mg/kg, im) was given as an adjunct at 1, 3, 5, 15, or 30 min after sarin. Treatment with atropine and 2-PAM at 1 min resulted in 67% mortality, while additional therapy with MINA ensured 100% survival anytime from 3 to 30 min. These findings suggested that delayed therapy with a centrally active AChE reactivator for up to 30 min following lethal exposure to sarin is still capable of reactivating NA-inhibited AChE and saving lives. Thus, inclusion of a CNS penetrating oxime in the therapeutic regimen for OP NA intoxication is beneficial even when the therapy would be delayed.

**PS 343** **Novel Oximes That Penetrate the Blood-Brain-Barrier (BBB) and Reactivate Organophosphate (OP) Inhibited Acetylcholinesterase (AChE).**

E. C. Meek<sup>1</sup>, H. W. Chambers<sup>2</sup>, R. B. Pringle<sup>1</sup>, J. E. Chambers<sup>1</sup> and J. M. Gearhart<sup>3</sup>. <sup>1</sup>College of Veterinary Medicine, Mississippi State University, Mississippi State, MS; <sup>2</sup>Department of Biochemistry, Molecular Biology, Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS; <sup>3</sup>AFRL, Wright-Patterson AFB, Dayton, OH.

Inhibition of AChE following exposure to toxic OPs (nerve agents and pesticides), results in the overstimulation of the nervous system. The approved therapies include an oxime, e.g. 2-PAM, to reactivate OP inhibited AChE; however these oximes have little, if any ability to cross the BBB. A series of novel pyridinium oximes has been synthesized that incorporate moieties that increase BBB penetration and AChE reactivation. Oximes were screened *in vitro* for their ability to reactivate AChE inhibited by a sarin surrogate, phthalimidyl isopropyl methylphosphonate (PIMP), or a VX surrogate, nitrophenyl ethyl methylphosphonate (NEMP), which phosphorylate AChE with the same moiety as sarin or VX, as well as with paraoxon, the active metabolite of the insecticide parathion. Rat brain homogenate was incubated with a concentration of OP that yielded about 80% AChE inhibition, followed by an oxime (0.1mM) and AChE activity measured. *In vitro* AChE reactivation varied among oximes but was similar for each of the nerve agent surrogates; PIMP 14-79%, and NEMP 23-76%, but differed for paraoxon 16-93%. Oxime lipophilicities ranged from 0.009 to 2.244 ( $K_{ow}$ ) and were greater than for 2-PAM (0.006). A subset of oximes that demonstrated AChE reactivation  $\geq 40\%$  *in vitro* were selected for testing *in vivo* in rats with the nerve agent surrogates. A high sublethal dose of a stable sarin surrogate, nitrophenyl isopropyl methylphosphonate (NIMP) (0.325mg/kg) or NEMP (0.4mg/kg) was administered ip, yielding about 80% brain AChE inhibition, followed by an im injection (0.1mmol/kg) of an oxime at the time of peak brain AChE inhibition (1hr). Twelve of 25 novel oximes tested yielded 10-35% brain AChE reactivation and attenuated OP induced seizures, indicating their ability to cross the BBB, reactivate brain AChE and thus demonstrating their therapeutic potential. Supported by DTRA: 1.E0056\_08\_AHB\_C

**PS 344** **Toxicokinetics of ST-246, an Antiviral Product Developed for the Treatment of Human Pathogenic Orthopoxvirus Infection, in Cynomolgus Monkeys.**

M. Trinh<sup>1</sup>, A. Amantana<sup>2</sup>, J. M. Leeds<sup>2</sup>, Y. Chen<sup>2</sup>, K. Honeychurch<sup>2</sup>, D. E. Hruby<sup>2</sup>, B. M. Saville<sup>3</sup>, C. Chang<sup>1</sup>, J. F. Marier<sup>1</sup> and M. Beliveau<sup>1</sup>. <sup>1</sup>Pharsight Consulting Services, Pharsight Corporation, Montréal, QC, Canada; <sup>2</sup>SIGA Technologies, Inc., Corvallis, OR; <sup>3</sup>Charles River Laboratories Preclinical Services, Reno, NV.

Smallpox is still considered a serious bioterror threat even though worldwide surveillance and vaccination eradicated the virus from the natural environment. ST-246 is an antiviral drug developed for the treatment of pathogenic orthopoxvirus infections (includes smallpox and monkeypox). Efficacy trials previously demonstrated that treatment of monkeypox virus-infected monkeys with ST-246 provided significant survival benefit at doses  $\geq 3$  mg/kg. Once daily, 6-h IV infusions of 3, 10 and 30 mg/kg ST-246 were administered for 14 days in a total of 19 male and female cynomolgus monkeys. Toxicokinetic (TK) parameters of ST-246 were evaluated with non-compartmental analysis methods on Day 1 and 14. Mean AUC<sub>0-24</sub> and C<sub>max</sub> increased in a dose-proportional manner on Day 14, with values ranging from 6839 to 76908 ng.h/mL and 904 to 12827 ng/mL, respectively. The accumulation ratio (AUC<sub>0-24</sub> Day 14 vs. Day 1) ranged from 1.00 to 1.54, suggesting minimal accumulation after repeated dosing. Mean CL (415 to 766 mL/h/kg) were consistent with liver blood flow in a typical 5-kg monkey (612 mL/h/kg). Mean V<sub>ss</sub> (1200 – 2503 mL/kg) were markedly higher than the total body water in a typical 5-kg monkey (693 mL/kg), suggesting extensive distribution in peripheral tissues. Steady state concentrations (range: 285 to 3205 ng/mL) were markedly higher than *in vitro* inhibitory concentrations associated to 50% of the maximum effect (IC<sub>50</sub>) against monkeypox virus and different variola strains (10.8 and 12.3 ng/mL, respectively). Overall, ST-246 displayed favorable TK parameters, such as dose-proportional increase in exposure, limited accumulation following repeated dosing, and extensive distribution in peripheral tissues.

**PS 345 Prediction of Human Equivalent Dose (HED) of Levofloxacin (LEVO) in New Zealand White Rabbits (NZW) to Support Efficacy of Combination Treatment with Novel Therapeutics against Inhalation Anthrax (IA).**

M. Beliveau<sup>1</sup>, A. L. Menard<sup>1</sup>, J. F. Marier<sup>1</sup>, J. T. Troyer<sup>2</sup> and E. K. Leffel<sup>2</sup>.  
<sup>1</sup>Pharsight Consulting Services, Pharsight Corporation, Montréal, QC, Canada;  
<sup>2</sup>PharmAthene, Inc., Annapolis, MD.

Regulatory agencies have suggested that novel therapeutics for treatment of IA do not diminish the efficacy of the standard-of-care (SOC) antibiotics in combination therapy, which would be the likely treatment. The NZW is an accepted animal model for IA where the SOC LEVO is both well tolerated, efficacious and where benefits of combination therapy would therefore need to be demonstrated. However, for proper demonstration of the added benefit of the new drug, the administered dose of LEVO must not be supra-therapeutic. Therefore, a HED of LEVO in NZW must be used. The objective of the current analysis was to determine pharmacokinetic (PK) parameters of LEVO in NZW and to determine the NZW dose equivalent to the HED of 7.14 mg/kg (500 mg QD) for IA. LEVO was administered to NZW by either PO or IV bolus administration and blood for PK analysis was collected at various times up to 48h post dose. Plasma samples were assayed for concentrations of LEVO using a validated LC/MS/MS method. Following calculation of PK parameters such as clearance (CL) and volume (Vss) by standard non-compartmental methods, the NZW HED was extrapolated from the clinical dose using the following equation:  $\text{Dose}_{\text{rabbit(HED)}} = (\text{HED}/\text{CL}_{\text{human}}) \times \text{CL}_{\text{rabbit}}$  where the HED = 500 mg and the  $\text{CL}_{\text{human}}$  was taken from the literature (175 mL/min). Following IV dosing, mean  $\text{CL}_{\text{rabbit}}$  and Vss of LEVO were 17.7 mL/min/kg and 1619 mL/kg, respectively. Bioavailability in NZW was dose dependent and ranged from 37.9% to 79.7%. Using  $\text{CL}_{\text{rabbit}}$ ,  $\text{CL}_{\text{human}}$  and the HED, the dose of LEVO in NZW corresponding to the HED was 50.5 mg/kg IV. If administered PO, the NZW HED would range from 53.8 mg/kg to 63.1 mg/kg. In conclusion, the above results suggest that LEVO IV dosing of 50.5 mg/kg or PO dosing of 53.8 to 63.1 mg/kg in NZW in combination with novel anthrax therapeutics are expected to allow sufficient demonstration of any added benefit of the novel drug.

**PS 346 The Beneficial Effect of a Treatment with Macrophages on Sulfur Mustard Cutaneous Burns.**

S. Dachir<sup>1</sup>, D. Kamus-Elimeleh<sup>1</sup>, R. Sahar<sup>1</sup>, E. Fishbine<sup>1</sup>, R. Gez<sup>1</sup>, J. S. Graham<sup>2</sup>, A. Eisenkraft<sup>3</sup>, V. Horwitz<sup>1</sup> and T. Kadar<sup>1</sup>. <sup>1</sup>Pharmacology, Israel Institute for Biological Research, Ness Ziona, Israel; <sup>2</sup>Office of the Commander, USAMRICD, Aberdeen Proving Ground, MD; <sup>3</sup>NBC Protection Division, Ministry of Defense, Tel Aviv, Israel.

Sulfur mustard (HD) is a potent vesicant that its toxicology has been for many years a subject for research, yet, the exact mechanism of its toxicity is still elusive and treatment is only partially effective. Macrophages are known to play an essential role in almost every stage of wound healing and there is evidence for their beneficial effects in treating decubital ulcers and deep sterna wound infections in human. This study was aimed to investigate the efficacy of a treatment with activated macrophages in ameliorating acute and long-term HD induced skin injuries in the hairless guinea pig (HGP) model. HGP were exposed to HD vapor creating superficial dermal skin lesions. They were treated with either a single or multiple intra-dermal injections of human activated macrophages (hAMS) into the wound bed. Clinical and histological evaluations were conducted up to four weeks post-exposure. A single intra-dermal injection into the wound bed administered early (15min or 6hr) after exposure inflicted an initial positive effect on the extent of the damage, demonstrating a temporal decrease in clinical symptoms, reduced number of acidophilic epithelial cells and less micro-vesications compared to untreated control. Repeated injections with hAMS (15min, 48hr and 7d post-exposure), decreased significantly the wounds' area and improved the integrity of the barrier function as expressed by trans-epidermal water loss measurements up to 10 days. Still, at 21 days there were no differences between the experimental groups. The results demonstrated a beneficial effect of macrophages on HD induced lesions. Further investigation is required to determine whether macrophages are required during the early phase of wound development or during the late phase of scar formation and remodeling. This work was supported by the US Army Medical Research and Material Command under award #: W81XWH-08-2-0128.

**PS 347 Comparative Anticonvulsant Effects of Diazepam in Rats Exposed to DFP, Paraoxon and the Chemical Warfare Nerve Agent Soman.**

R. K. Kan, J. A. Leuschner, T. T. Dao, S. W. Kaski, J. F. Irwin, C. Acon-Chen, C. R. Braue, E. A. Johnson, H. Hoard-Fruchey and T. Shih. *Pharmacology, USAMRICD, Aberdeen Proving Ground, MD.*

Diazepam is routinely used to control organophosphate-induced seizures. The present study was designed to evaluate the effectiveness of diazepam to control seizures induced by soman (GD), diisopropylfluorophosphate (DFP) and paraoxon. Prior to experimentation, animals were instrumented with cortical electrodes for monitoring brain activity. Animals exposed to GD (180 ug/kg, sc) were pretreated with HI-6 (125 mg/kg, ip) 30 min prior to GD challenge and treated with atropine methylnitrate (2.0 mg/kg, im). Animals exposed to DFP (4.0 mg/kg, sc) were pretreated with pyridostigmine (0.026 mg/kg, ip) 30 min prior to DFP challenge and treated with atropine sulfate (AS; 0.2 mg/kg, im) and 2-PAM (25 mg/kg, im). Animals exposed to paraoxon (1.05 mg/kg, sc) were treated with AS (2.0 mg/kg, im) and 2-PAM (25 mg/kg, im). In all cases, diazepam (10 mg/kg, im) was given at 40 min after the onset of seizures. Diazepam was effective in terminating DFP- and paraoxon-induced seizures, but it was ineffective in terminating GD-induced seizures. In addition, neuropathology in animals treated with diazepam at 40 min after DFP or paraoxon-induced seizures was markedly reduced at 24 hr after seizure onset. In contrast, diazepam treatment at 40 min after the onset of seizures-induced by GD did not prevent or attenuate brain injury. DFP and paraoxon models were developed as surrogate animal models for nerve agent (NA) biomedical research for evaluation of putative therapeutics. The difference in the effectiveness of diazepam in controlling seizures and reducing neuropathology induced by GD, DFP or paraoxon indicates that DFP and paraoxon are not suitable simulants for NA biomedical research, at least not for screening of potential anticonvulsants to control on-going seizures. Novel anticonvulsants that are effective in terminating seizures induced by DFP or paraoxon may not be efficacious against NA-induced seizures.

**PS 348 Determination of Cholinesterase Levels in the Blood and Brain following Galantamine Administration in the Guinea Pig Model.**

C. Wilhelm<sup>1</sup>, A. Moulder<sup>1</sup>, G. Platoff<sup>2</sup>, D. Jett<sup>2</sup>, D. Yeung<sup>2</sup> and M. C. Babin<sup>1</sup>. <sup>1</sup>Battelle, Columbus, OH; <sup>2</sup>CounterACT Program, NIH OD, Bethesda, MD.

The CounterACT Program at the National Institutes of Health is investigating galantamine hydrobromide (GAL) as a treatment for organophosphorus nerve agent (NA) intoxication and is establishing a dose response representation to determine optimal doses for future efficacy studies. GAL is a reversible acetylcholinesterase (AChE) inhibitor that crosses the blood-brain barrier and is presently approved for the treatment of mild to moderate Alzheimer's disease. It has shown some efficacy against NA toxicity in animal studies. Ongoing studies are investigating the efficacy of GAL when administered either as a pre-treatment or post-treatment and when used in conjunction with standard NA treatments atropine and 2-PAM (pralidoxime). The objective of this study was to correlate clinical biomarkers and pharmacodynamics with clinical observations after treatment with GAL. Blood and brain levels of GAL and ChE inhibition were determined at various time-points along with standardized clinical observations. Cohort A used 36 animals with six dose levels of 0, 2, 4, 8, 12 and 16 mg/kg and serial blood collections from 5 minutes to 24 hours post treatment. These samples were assayed to determine the percent AChE activity at seven time-points. Cohort B used 144 male Hartley guinea pigs with six dose levels of 0, 2, 4, 8, 12 and 16 mg/kg with designated sacrifice time-points on 4 animals for each dose level at 5, 30, 60 min, 2, 4 and 24 hours post treatment. Clinical observations showed a trend of increasing severity of clinical observations as the dose level increased. All clinical signs started at 5 minutes post treatment and all animals were normal by the 24 hour post treatment time-point. Significant observations of toxicity were present at and above the 12 mg/kg dose level, combined with the greatest inhibition of AChE. Inhibition of AChE was seen at the 5 minute time-point (post treatment) with results showing a dose dependent inhibition from low to high dose levels.

**PS 349 Characterization of Protein Adducts of Nitrogen Mustards As Potential Exposure Biomarkers.**

V. R. Thompson and A. P. DeCaprio. *Department of Chemistry & Biochemistry and International Forensic Research Institute, Florida International University, Miami, FL.*

Protein adducts are useful as longer-term biomarkers of exposure to electrophilic xenobiotics, including chemical warfare agents (CWA) and their metabolites. The purpose of this study was to characterize protein adducts of the nitrogen mustards

HN-2 and HN-3 as potential exposure biomarkers. Limited data exist on HN adducts to protein thiols but not other nucleophilic sites such as lysine and histidine. Initial *in vitro* experiments used three model peptides (AcPAAXAA; X = C, K, or H) incubated with HN-2 and -3 (100-fold molar excess) at pH 7.4, 37°C to mimic physiological conditions. Adduct formation was monitored by LC-QQQ-MS/MS analysis at various incubation times. Rapid adduction by both agents occurred at all three nucleophilic sites. Major reaction products included S- and N-(2-chloroethylaminoethyl) adducts (determined by MS isotopic ratios) and S- and N-(2-hydroxyethylaminoethyl) hydrolysis products. Adduct stability was assessed by extended incubation of modified peptides after removal of unreacted agent via C<sub>18</sub> SPE. LC-MS/MS analysis demonstrated that adducts were stable for up to three weeks. In addition, hemoglobin (Hb) as a model protein was incubated with HN-2 at a mustard:protein molar ratio of 100:1. LC-QTOF MS demonstrated a mass shift on each Hb subunit corresponding to up to two modifications. Trypsin digestion of modified protein followed by LC-MS/MS confirmed adduction at C, K, and H. Finally, *in vitro* results were compared to *in silico* calculations (Gaussian 03W software) to predict relative electrophilic reactivity of HN-2 and -3 with protein nucleophiles. Calculated parameters showed good concordance to the experimental data with regard to kinetics and comparative adduct formation. Results of this study confirm that nitrogen mustards can stably adduct nucleophilic protein sites including lysine and histidine. Current work involves assessing the specificity of binding in both Hb and serum albumin, with the ultimate goal of developing adduct-based biomarkers for these important potential CWA.

### PS 350 Glucocorticoid Exposure Primes the Neuroinflammatory Response to the Nerve Agent DFP in a Model of Gulf War Illness.

K. A. Kelly<sup>1</sup>, D. B. Miller<sup>1</sup>, S. M. Lasley<sup>2</sup> and J. P. O'Callaghan<sup>1</sup>. <sup>1</sup>CDC-NIOSH, Morgantown, WV; <sup>2</sup>University of Illinois College of Medicine, Peoria, IL.

We have shown previously that chronic exposure to the glucocorticoid corticosterone, (CORT), at levels associated with high physiological stress, can prime the CNS proinflammatory response to neurotoxic insults. Persistent sickness behavior, a prominent component of Gulf War (GW) Illness, is associated with neuroinflammation. Veterans of the 1991 GW were exposed to the stresses of war, prophylactic treatment with the reversible acetylcholinesterase (AChE) inhibitor, pyridostigmine bromide (PB), the insect repellent, DEET, and, potentially, acutely to the nerve agent sarin. Previously, we showed that subchronic CORT pretreatment primed the CNS to mount a neuroinflammatory response to these GW exposures when provoked 24 h after the termination of CORT treatment. Here, we investigated the persistence of this priming effect on neuroinflammation and the minimal amount of CORT required to produce the priming response. Male C57BL/6 mice were pretreated with chronic (14 days) PB (2mg/kg/day, s.c.) and DEET (30 mg/kg/day, s.c.), as well as subchronic CORT (200 µg/ml in drinking water on days 7-14) or acute CORT (20 mg/kg, s.c., 2 injections, 7 h interval on day 14) exposures. Acute doses (days 15 or 45) of the sarin surrogate and irreversible AChE inhibitor diisopropyl phosphorofluoridate (DFP, 4 mg/kg, i.p.) or known inflammogen lipopolysaccharide (LPS, 2 mg/kg, s.c.) were used to provoke neuroinflammation. We found that both acute and chronic CORT exposure greatly augmented neuroinflammation in response to LPS and DFP. Marked neuroinflammation in response to DFP was found even when the exposure was 30 days after the cessation of the subchronic CORT treatment (a time point equivalent to 6 years in humans). Our findings are suggestive of a possible critical and yet unrecognized link between the stressful environs of the 1991 GW theater and agent exposure(s) unique to this war, exposures in which the CNS is primed to amplify future exposure to pathogens, injury or toxicity. (Supported by CDMRP W81XWH-09-2-0098)

### PS 351 Evaluation of Selected Organoselenium Analogs of Ebselen As Protective Agents against HN2 Toxicity in A-431 Skin Cells.

M. A. Pino<sup>1,2</sup>, B. Billack<sup>2</sup> and M. Pietka-Ottlik<sup>3</sup>. <sup>1</sup>Basic Sciences, TouroCOM, New York, NY; <sup>2</sup>Pharmaceutical Sciences, St. John's University, New York, NY; <sup>3</sup>Division of Organic and Pharmaceutical Technology, Faculty of Chemistry, Wrocław University of Technology, Wrocław, Poland.

Our lab has previously demonstrated that the organoselenium compound ebselen (EB-1) possesses the ability to reduce the cytotoxicity of mechlorethamine (HN2), a sulfur mustard surrogate, *in vitro*. The main objective of the present study was to determine the extent to which three structurally related compounds, namely EB-2, EB-3 and EB-4, could mimic this effect in human epidermoid carcinoma cells (A-431). Using MTT cell viability analysis, we found that in the absence of any test analog, a reproducible and robust cell death was observed in the cells following incubation with HN2 (25 µM, 24 h), while cells treated with test analog alone (15,

30 or 60 µM) for a similar period of time were generally unaffected. When incubated in the presence of both HN2 and test analog for 24 h, we observed that all analogs reduced HN2 toxicity to varying degrees, with the EB-4 analog being the most effective. An examination of cellular morphology using light microscopy analysis confirmed cytoprotection among cells treated with organoselenium analogs. It is noteworthy that all analogs of EB-1, at a test concentration of 60 µM, were capable of reducing the levels of HN2-induced thiobarbituric acid reactive substances (TBARS), suggesting an antioxidant activity. Among the EB-1 analogs tested, EB-4 was found to be the most potent at reducing TBARS while EB-2 was the least potent in this regard. Taken together, these data identify a cadre of organoselenium analogs which are active against a mustard gas surrogate *in vitro*. Future studies are warranted to determine whether or not said compounds will be effective at reducing mustard-related injury *in vivo*.

### PS 352 Hydroxamate Inhibition of EMMPRIN, an MMP Inducer, after Mustard Exposure.

A. S. Rodrigues<sup>1</sup>, A. Miller<sup>1</sup>, R. A. Hahn<sup>1</sup>, M. Patel<sup>1</sup>, C. Lacey<sup>2</sup>, A. N. Pillai<sup>2</sup>, S. Young<sup>2</sup>, R. A. Flowers<sup>2</sup>, N. Dennisova<sup>1</sup>, M. A. Gallo<sup>3</sup>, D. R. Gerecke<sup>1</sup>, K. K. Svoboda<sup>4</sup>, N. D. Heindel<sup>2</sup> and M. K. Gordon<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, EMSOP, Rutgers University, Piscataway, NJ; <sup>2</sup>Department of Chemistry, Lehigh University, Bethlehem, PA; <sup>3</sup>Environmental and Occupational Health, UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ; <sup>4</sup>Biomedical Sciences, Baylor College of Dentistry, Texas A&M University, Dallas, TX.

Mustards are blistering agents injuring the eye, skin and lungs. Corneal mustard injury causes separation at the epithelial-stromal border, resulting in epithelial sloughing. ADAM17 is a transmembranous enzyme that cleaves collagen XVII, a transmembranous hemidesmosomal component that is part of the anchoring complex riveting the epithelium to the stroma. ADAM17 is activated in rabbit corneal organ cultures immediately after nitrogen mustard (NM) exposure, and persists 24 hr post exposure, correlating with the degree of epithelial-stromal separation. To promote epithelial-stromal integrity after mustard exposure, two hydroxamates were tested for their inhibition of ADAM17 to reduce collagen XVII cleavage. The hydroxamates olvanil OH (NDH4409) or retro olvanil 8 (NDH4417) were applied 4 times to organ cultures over the course of 22 hrs, beginning 2 hours post NM exposure. Epithelial sloughing at 24 hr was reduced. Surprisingly, only NDH4417 significantly inhibited ADAM17 activity. However, both drugs reduced matrix metalloproteinase-9 (MMP-9). To further evaluate why corneal epithelial-stromal integrity was preserved after NM exposure, the effects of each drug on expression of EMMPRIN was tested. EMMPRIN is an MMP inducer. EMMPRIN was greatly upregulated after mustard exposure. Both NDH4409 and NDH4417 significantly reduced EMMPRIN expression. Our data indicate that hydroxamates inactivate ADAM17 and MMPs, and may also preserve corneal epithelial-stromal integrity by attenuating the vesicant-induced upregulation of the MMP-inducer EMMPRIN. Supported by UMDNJ-Rutgers Counteract Center of Excellence NIAMS U54AR055073; NIH NEI EY009056; and NIEHS P30ES005022

### PS 353 Sulfur Mustard Induces Cytotoxicity and Apoptosis in Mouse Skin Hair Follicles.

L. Joseph<sup>1</sup>, J. A. Cervelli<sup>1</sup>, G. M. Composto<sup>1</sup>, M. C. Babin<sup>2</sup>, R. P. Casillas<sup>3</sup>, P. J. Sinko<sup>1</sup>, D. R. Gerecke<sup>1</sup>, D. L. Laskin<sup>1</sup>, J. D. Laskin<sup>4</sup> and D. E. Heck<sup>5</sup>. <sup>1</sup>Rutgers University, Piscataway, NJ; <sup>2</sup>Battelle, Columbus, OH; <sup>3</sup>MRI Global, Kansas City, MO; <sup>4</sup>UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ; <sup>5</sup>New York Medical College, Valhalla, NY.

Sulfur mustard (SM), a potent vesicant, damages follicular and interfollicular epidermis. We examined the effects of SM vapor on pilosebaceous units in dorsal skin of 5 wk old male SKH1-Hr mice. Control skin contains prominent sebaceous glands, atypical hair shafts, isolated utriculi, and small follicular cysts. Fatty acid synthase and proliferating cell nuclear antigen (PCNA) were expressed in sebocytes. PCNA was also expressed in hair root sheaths and dermal papillae. Three to seven days following SM exposure, alterations in the pilosebaceous unit were evident including epithelial cell karyolysis within hair root sheath, infundibulum and isthmus, as well as loss of sebocytes. Utriculi, some with connections to the skin surface, and engorged dermal cysts were observed. One day post SM exposure phosphoroylated H2A.X (γH2A.X), a DNA damage marker, and cleaved caspase-3, a marker of apoptosis, were expressed in the pilosebaceous unit and epidermis. Although evident in the pilosebaceous unit, PCNA was not expressed in the interfollicular epidermis. Decreased numbers of pilosebaceous units and increased numbers of inflammatory cells were observed surrounding utriculi and cysts 3 days post SM. Decreased expression of γH2A.X, PCNA, and fatty acid synthase was noted, whereas cleaved caspase-3 was upregulated in the hyperplastic hair root sheath. By 7 days post SM, there were no hair follicles or sebaceous glands within the wound;

only remnants, including utriculi and large follicular cysts. By 14 days, follicular cysts within the hyperplastic epidermis were greatly enlarged. Significant amounts of PCNA and cleaved caspase-3 were expressed in cells surrounding the follicular cysts. Taken together, these data indicate that the hair follicle is an important target contributing to SM-induced skin injury. Support: NIH AR055073, ES004738, CA132624, GM034310, and ES005022.

### PS 354 Acute Respiratory and Neurological Toxicity in Rats following Inhalational Exposure to Lethal Doses of Soman.

B. Wong, M. Perkins, G. Murphy, D. A. Alves, A. M. Rodriguez, J. Devorak, R. K. Kan, J. A. Leuschner, T. Dao and A. M. Sciuto. *USAMRICD, Aberdeen Proving Ground, MD.*

Soman (GD) is a potent chemical warfare nerve agent (CWNA). GD irreversibly inhibits acetylcholinesterase (AChE), resulting in accumulation of the neurotransmitter acetylcholine (ACh). High ACh at synapses results in prolonged stimulation of muscarinic and nicotinic receptors leading to cholinergic crises. This study developed a novel head-out inhalation exposure system to serve as a realistic and applicable model for a mass casualty-type scenario to study the development of acute respiratory and neurological toxicity. GD vapor (520, 560, 600 and 825 mg×min/m<sup>3</sup>) was generated in a saturator cell and carried by filtered N<sub>2</sub> into a customized glass exposure chamber. Male rats (250-300 g) were restrained in head-out exposure tubes and exposed to GD for 4-10 minutes. The probit analyzed LC<sub>50</sub> of vaporized GD was 593.1 mg×min/m<sup>3</sup>. A majority of the animals developed severe cholinergic responses followed by convulsions and died within 4-8 min post-exposure (PE). Mild to severe convulsions and muscular fasciculations were observed up to 24 h in animals exposed to 560 and 600 mg×min/m<sup>3</sup>. GD exposures produced significant, concentration-dependent inhibition in cardiac blood AChE activity. AChE activity was inhibited in bronchoalveolar lavage (BAL) fluid, lung and whole brain tissues. Rats exposed to a 600 mg×min/m<sup>3</sup> exhibited severe brain damage in the piriform cortex, neocortex, dentate hilus, amygdala and thalamus. Analyses of lung tissue showed morphologic changes in alveolar histiocytosis, hemorrhage and inflammation consisting of neutrophilic exudate. Respiratory and neurological toxicity induced by GD vapor was determined by clinical observations, histopathology and biochemical analyses of tissues 24 h PE. We integrated novel technologies in inhalation toxicology and physiology to evaluate CWNA toxicity to develop an improved model suitable for testing medical countermeasures in a mass casualty scenario.

This research was supported by the Defense Threat Reduction Agency project #3.F0014.

### PS 355 Inflammatory Profile and Macrophages Population in Sulfur Mustard (SM)-Exposed Skin Wound Repair.

Y. Chang<sup>1</sup>, M. Soriano<sup>1</sup>, J. D. Laskin<sup>2</sup>, R. P. Casillas<sup>3</sup>, M. K. Gordon<sup>1</sup> and D. R. Gerecke<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, EOHHS, Rutgers University, Piscataway, NJ; <sup>2</sup>UMDNJ-RWJMS, Piscataway, NJ; <sup>3</sup>MRI Global, Kansas City, MO.

Cutaneous SM induced injury is characterized by a severe inflammatory response and delayed wound repair. Development of quantifiable inflammatory biomarkers is needed for screening anti-inflammatory drugs against SM injury. Since most inflammatory marker studies with SM exposed skin are only available for early time points (less than 24h), we extended this study to 7 days to better understand the inflammatory profile induced by SM. We examined the macrophage population and inflammatory profile using the mouse ear vesicant model (MEVM). RT-PCR data showed neutrophil collagenase/MMP8 was significantly unregulated 6h, 12h, and 168h post-SM exposure and macrophage elastase/MMP12 was significantly unregulated at 24h post SM exposure, increasing as time progressed. Immunohistochemical studies using a macrophage specific marker, F4/80 identified increased numbers of macrophages at 72h and 168h post-SM exposure. RT-PCR data showed early upregulation of IL6, IL1b, CCL3, CCL4, CXCL2, CXCL5, CXCL7 and CXCR4. Upregulation at 72 h post-SM exposure included: IL1r1, IL2rg, IL4ra, IL10ra, CSF2rb2, Tnfrsf1b, and Tnfsf11. Using a mouse cytokine/chemokine multiplex protein assay, we showed upregulation and persistent expression of IL6 and KC/CXCL1, and downregulation of IL10. CCL2 significantly increased over time beginning at 24h post-SM exposure. CCL3, GCSF, and IP10/CXCL10 were significantly increased at 72h and 168h post-SM exposures. These findings suggest that the cytokine/chemokines pattern we observed may be related to the persistent macrophage population that is generally seen in SM-exposed skin wounds. In addition, this inflammatory profile may be useful as in vivo biomarkers for evaluating anti-inflammatory drugs against SM-induced skin injury. This work is supported by ES005022, EY09056, and AR05507

### PS 356 Activation of the Endoplasmic Reticulum Stress and Unfolded Protein Responses for Protection against Sulfur Mustard-Induced Skin Injury.

D. R. Gerecke<sup>1</sup>, J. D. Wang<sup>1</sup>, J. D. Laskin<sup>2</sup>, M. K. Gordon<sup>1</sup> and Y. Chang<sup>1</sup>. <sup>1</sup>Pharmacology and Tox, EOHHS, Rutgers University, Piscataway, NJ; <sup>2</sup>UMDNJ-RWJMS, Piscataway, NJ.

The endoplasmic reticulum (ER) stress response, a cell survival pathway upregulated when cells are under severe stress, contributes to the pathogenesis of various diseases. It triggers the unfolded protein response (UPR) which initiates ER-to nucleus signaling pathways to protect against cell death via several types of UPR sensor proteins. One of these, ATF6, is proteolytically cleaved and translocated into the nucleus to regulate gene expression. Skin exposed to the vesicant sulfur mustard (SM) results in increased expression of specific chaperone proteins. We performed time course studies with SM using the mouse ear vesicant model (MEVM) and showed progressive histopathologic changes including edema, separation of the epidermis from the dermis, prolonged inflammation, and delayed wound repair from 24h to 168h post exposure. This study explored the contribution of UPR and increased ER chaperones in ER stress induced by SM injury. RT-PCR analysis of the ER stress survival gene GRP78; UPR gene ATF6; and ER stress apoptotic gene CHOP, demonstrated at least a 2 fold increase as time progressed. Western blot analysis confirmed upregulation of GRP78 and CHOP as time progressed. Both the full length cytoplasmic ATF6 and the 50 kDa cleaved nuclear fragment of ATF6 were increased after 24h post SM. Immunofluorescent data showed cytoplasmic staining at 24h post exposure and significant nuclear staining in the proliferating keratinocytes at 168h post exposure. Double-labeled immunofluorescent studies of GRP78 and CHOP indicated GRP78 staining in the basal, proliferating keratinocytes. In contrast, expression of CHOP was greater in the outermost migrating cells. These data suggest the ER stress response and UPR are activated in the proliferating keratinocytes to protect cells against SM induced skin injury. This work is supported by ES005022, EY09056, and AR055073.

### PS 357 Detection of Sulfur Mustard or Half Mustard-Induced DNA Adducts in Human Skin Cells.

K. Kehe, V. Schrettl, D. Steinritz and H. Thiermann. *Bundeswehr Institute of Pharmacology and Toxicology, München, Germany.* Sponsor: A. Bürkle.

Introduction: Sulfur mustard (SM) and 2-chloroethyl ethylsulfide (CEES) are bi- and monofunctional DNA alkylating agents, respectively. SM is an old chemical warfare agent causing blisters (vesicant). Both chemicals react with N7 guanine. SM will form 7-Hydroxyethylthioethylguanine for SM and CEES 7-ethyl thioethylguanine for CEES. A specific monoclonal antibody (2F8) exists which detects SM and CEES adducts at N7 position.

Aim: The 2F8 antibody was used to develop a slot blot technique for detection of SM and CEES exposure in human keratinocytes (HaCaT cells).

Methods: HaCaT cells were exposed with different concentrations of SM or CEES (30 min). After exposure, cells were scraped and DNA was isolated, normalized and transferred to a Nylon membrane using slot blot technique. After incubation with 2F8 antibody, the DNA adducts were visualized with DAB staining.

Results: DNA adducts were detected after CEES and SM exposure below 30 µM which is the vesicant threshold.

Conclusion: The presented technique is potentially able to confirm SM or CEES exposure in blister roofs of exposed patients.

### PS 358 Differential Inhibition of Cytoplasmic and Mitochondrial Thioredoxin and Thioredoxin Reductase by Nitrogen Mustard in A549 Lung Epithelial Cells.

I. Wohlman<sup>1</sup>, Y. Jan<sup>2</sup>, D. E. Heck<sup>3</sup>, R. P. Casillas<sup>4</sup>, D. L. Laskin<sup>1</sup> and J. D. Laskin<sup>2</sup>. <sup>1</sup>Pharmacology & Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ; <sup>3</sup>Environmental Health Science, New York Medical College, Valhalla, NY; <sup>4</sup>MRI Global, Kansas City, MO.

The thioredoxin system, consisting of thioredoxin reductase (TrxR) and thioredoxin (Trx), plays an important role in cellular antioxidant defense. Both cytosolic (TrxR1, Trx1) and mitochondrial (TrxR2, Trx2) forms of the enzymes have been identified in mammalian cells. Previously, we reported that the bifunctional nitrogen mustard vesicant, mechlorethamine (HN2), targeted cytosolic TrxR1 by alkylating catalytic residues in the enzyme's redox centers. In the present studies, we compared the effects of HN2 on the cytoplasmic and mitochondrial forms of TrxR and Trx in A549 lung epithelial cells. HN2 treatment was found to cause a concentration- and time-dependent inhibition of the activities of both cytoplasmic and

mitochondrial forms of TrxR and Trx. HN2 was significantly more efficient in inhibiting cytosolic, when compared to mitochondrial forms of the enzymes. For TrxR1 and TrxR2, the IC50's for inhibition of enzyme activity were 2.7  $\mu$ M and 14.3  $\mu$ M, respectively. Immunoblot analysis of subcellular fractions from control cells on denaturing SDS-PAGE showed TrxR (57 kDa) and Trx (14 kDa) monomers. HN2 treatment cross-linked Trx1 and Trx2 forming tetramers, and TrxR1 and TrxR2 forming dimers and oligomers. These data demonstrate that HN2 can target the thioredoxin system in cytosolic and mitochondrial fractions of A549 cells by cross-linking proteins. Disruption of this system in lung cells provides a mechanism for nitrogen mustard-induced oxidative stress and toxicity. Support: NIH grants AR055073, ES004738, CA132624, ES005022 and GM034310.

**PS 359 Nitrogen Mustard (NM)-Induced Pulmonary Injury and Inflammation Are Associated with Alterations in Histone Methylation and Acetylation.**

A. Venosa<sup>1</sup>, R. Malaviya<sup>1</sup>, J. D. Laskin<sup>2</sup> and D. L. Laskin<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

NM (mechlorethamine hydrochloride) is a highly toxic vesicant which acts by alkylating DNA and proteins and generating oxidative stress. The lung is known to be a major target for NM. Exposure to NM results in rapid structural changes including perivascular edema and thickening of the alveolar wall followed by bronchiolization of the epithelium which progresses to lung fibrosis. We have previously shown that inflammatory mediators including reactive nitrogen species and tumor necrosis factor- $\alpha$  contribute to NM-induced lung injury. Expressions of genes for these mediators, as well as antioxidants, are known to be regulated by methylation and acetylation of histones. In these studies we determine if NM-induced injury and inflammatory/antioxidant protein expression is associated with histone modification. Lung samples were collected 1 d – 28 d after exposure of male Wistar rats to NM (0.125 mg/kg, intratracheal) or PBS control. NM intoxication resulted in increased expression of inducible nitric oxide synthase, cyclooxygenase-2 and heme oxygenase-1 in the lung within 1 d, a response which persisted for 28 d; Mn-superoxide dismutase was also up regulated beginning at 7 d. Analysis of lung homogenates by western blotting using specific antibodies revealed that this was correlated with a time-dependent increase in acetylation on histone 3 lysine 9 (H3K9Ac) which returned to baseline by 28 d. In contrast H3K4 methylation decreased 1 d – 7 d post-NM; this was followed by an increase at 28 d. Additionally, whereas H3K36 methylation increased beginning 3 d post-NM and persisted up to 28 d, increases in H3K27 methylation were only evident 28 d after NM exposure. These data suggest that NM-induced lung injury leads to specific alterations in chromatin structure which may contribute to pro-inflammatory and antioxidant gene expression. Supported by NIH Grants AR055073, ES004738, CA132624, GM034310, and ES005022.

**PS 360 Dose Modulation of a Potential Therapeutic for Neovascularization from Ocular Exposure to Sulfur Mustard.**

M. L. Meade<sup>1</sup>, J. J. Schlager<sup>2</sup> and M. C. Babin<sup>3</sup>. <sup>1</sup>Henry M Jackson Foundation, Wright-Patterson AFB, OH; <sup>2</sup>711th Human Performance Wing, Wright-Patterson AFB, OH; <sup>3</sup>Battelle Biomedical Research Center, Jeffersonville, OH.

Sulfur mustard is a potent alkylating agent affecting the skin, respiratory tract and eyes. Ocular exposure to HD can result in long term injuries including corneal neovascularization (NV) and blindness. The immunosuppressant, cyclosporine A, has shown promise for protecting epithelial cells against apoptosis in *in vitro* experiments. To investigate the effects of cyclosporine A *in vivo*, two studies were conducted, an initial long term study for 112 days, and a 28 day study using the white rabbit ocular model to evaluate the effects of different concentrations of cyclosporine A. The right cornea was insulted with 0.4  $\mu$ l (0.51 mg) of neat HD while using the left as a control. Cyclosporine was administered beginning at five days post exposure for three weeks decreasing the frequency throughout the regimen. Clinical assessments, including stromal damage and corneal thickness were performed throughout the study. Following the study, corneas were harvested and shipped to Wright Patterson AFB for quantitative proteomic analysis. In the initial 16 week study, cyclosporine performed significantly better than did no treatment or other potential therapeutics thought to aid in NV prevention. H&E staining shows continued inflammation in the stroma in the untreated eyes at 15 weeks post exposure, while the cyclosporine treated eyes appear normal. A follow up study using differing concentrations of cyclosporine A was also performed. The clinical assessment data acquired during this study showed that all concentrations of cyclosporine performed well in eliminating stromal opacity at 28 post exposure compared to no treatment. The 2% cyclosporine group performed better than other concentrations

in preventing NV with only one animal in the group experiencing NV at the conclusion of the study. Quantitative proteomics of the epithelium and endothelium of the corneas also showed protein expression levels consistent with the unexposed eyes in the 2% cyclosporine group.

**PS 361 Development and Optimization of *In Vitro* Models of Chemical Ocular Injury for High-Throughput siRNA Screening.**

J. G. Lehman, S. L. Beach, R. D. Causey and A. L. Ruff. US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.

Chemically induced ocular injuries are considered one of the few true ocular emergencies based on their high potential to inflict rapid and significant tissue damage. Currently there are no specific therapeutics to treat chemically induced corneal injury, and there is a pressing need to rapidly screen therapeutics to discover a treatment. Understanding of the molecular mechanisms of this injury is necessary to aid in rational therapeutic development. We intend to utilize high throughput small inhibitory RNA (siRNA) screening to elucidate the mechanisms of chemical cornea injury and to identify therapeutic targets. Herein we present the development of the *in vitro* models for this screening effort. Two immortalized human corneal epithelial cell lines will be used for screening: SV40 large T antigen immortalized corneal epithelial cells (SHECs) and telomerase immortalized corneal epithelial cells (TCECs). Hydrofluoric acid (HFA) is used for the induction of chemical injury. The major conditions optimized included cell line plating density, exposure dose, and transfection conditions. Matrices of these conditions were evaluated to ensure optimal target knockdown without sacrificing cell viability. Transfection conditions were optimized using siRNA targeting cyclophilin b, and knockdown was assessed using the QuantiGene Plex assay, a bead based assay using hybridization to amplify specific mRNAs allowing for quantification. A dose-response study of HFA injury was performed, and the HFA-induced production of the cytokines was evaluated by multiplex bead-based assay for a panel of 30 cytokines. Once optimized, these models will be used to screen subgenomic siRNA libraries targeting HF-induced ocular inflammation.

**PS 362 Multirray Gene Expression Approach Analyzing Cultured Primary Human Astrocytes and Neurons following Chemical Warfare Nerve Agent Exposure.**

C. Rothwell, S. Swayze, J. E. Dillman and H. Hoard-Fruchey. USAMRICD, Gunpowder, MD.

Chemical warfare nerve agents (CWNAs) are irreversible organophosphorus cholinesterase inhibitors that cause seizure. Within 24 h of CWNA exposure, neuronal degeneration, astrocytic activation and cellular death can be observed in various brain regions. In this study, we investigated the effects of CWNA exposure on primary cultures of neurons and astrocytes to determine direct molecular alterations in the absence of CWNA-induced seizure activity. Cultured primary human astrocytes were exposed to 100  $\mu$ M of the CWNAs sarin, soman, VX, or VR and harvested at 24 h. Similarly, cultured primary human neurons were exposed to 100  $\mu$ M soman or VX and harvested at 24 h. Total RNA was isolated from exposed cells, processed for microarray analysis, and hybridized to Affymetrix Human Genome U133 Plus 2.0 arrays. Principal component analysis (PCA) of the astrocyte data did not show distinct profile differences based on agent type, indicating few if any significant differences in transcript expression in response to agent exposure. However, PCA of the neuronal data showed a distinct profile difference based on agent type. For both cell types, the dataset was filtered by agent type, and an analysis of variance (ANOVA) was performed using agent as the factor. Using these combined data, the pathways significantly affected by agent type in cultured human primary neurons were identified. The genes differentially expressed in response to soman exposure mapped to canonical pathways containing inflammatory molecules. Using the same samples, real-time PCR was utilized to provide quantitative measurements of gene transcription across genes associated with the human immune response. These data suggest a non-cholinergic effect of soman that induces transcriptional expression of inflammatory molecules as well as components of the GABA pathway. In addition, these data suggest that an in-depth analysis of *in vivo* transcriptomic data focusing on the GABA pathway may reveal new targets within that pathway for improved medical countermeasures to these toxic agents.

**PS 363 MicroRNA Microarray Analysis of Human-Induced Pluripotent Stem Cell-Derived Neurons and Cardiomyocytes following Exposure to the Organophosphate Nerve Agents Soman and VX.**

E. K. Yego, J. F. Dillman and H. Hoard-Fruchey. *Research Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Chemical warfare nerve agents (CWNA) are potent cholinesterase inhibitors that may also have non-cholinesterase effects. Several in vivo studies have demonstrated CWNA-induced damage in the brain and heart following CWNA exposure. The mechanisms of this damage have been a critical area of research for the development of medical countermeasures. This study utilized microRNA (miRNA) analysis to evaluate potential direct cellular effects of the nerve agents soman (O-Pinacolyl methylphosphonofluoridate) or VX (o-ethyl-s-[2 (diisopropylamino) ethyl]) on human-induced pluripotent stem cell (iPSC)-derived neurons and cardiomyocytes. This approach was taken since miRNA expression changes are stimulus specific and no previous studies of miRNA profiles have been conducted for CWNA exposure. Cells were treated with soman or VX at concentrations of 0  $\mu$ M, 0.1  $\mu$ M or 100  $\mu$ M for either 1 hr or 6 hr. Following treatment, isolated total RNA was processed for miRNA microarray analysis and analyzed for significant changes. Soman- and VX-treated samples were analyzed separately. Principal component analysis (PCA) was used to identify major sources of variability in the dataset. PCA analysis of neurons identified differences in miRNA expression only for cells exposed for 6 hr to soman. Targets that were significantly altered under these conditions were miR-2277, miR-1910 and miR-1972. miR-2277 was significantly altered in soman- and VX-exposed neuron data sets that were analyzed by both time and dose. Minimal sample variability was observed with cardiomyocytes as determined by PCA analysis. One-way ANOVA with time as the factor identified miR-3178 as the only target that was altered significantly by both soman and VX in cardiomyocytes. This miRNA modulates several targets including complexin-1 and splicing factor-1. This study demonstrates the feasibility of using miRNA microarray analysis for the study of CWNA cellular effects.

**PS 364 Toxidromes—A Decision-Making Tool for Early Response to Chemical Mass Exposure Incidents.**

M. Kirk<sup>1</sup>, P. J. Hakkinen<sup>2</sup>, J. S. Ignacio<sup>3</sup>, O. Kroner<sup>4</sup>, A. Maier<sup>4</sup> and J. Patterson<sup>4</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA; <sup>2</sup>National Library of Medicine, Bethesda, MD; <sup>3</sup>Department of Homeland Security, Washington DC; <sup>4</sup>TERA, Cincinnati, OH.

A common language to describe and recognize clinical manifestations of toxic chemical exposures is essential for emergency responders and hospital first receivers to be prepared to provide rapid and appropriate medical care for victims of industrial chemical mass exposures and terrorist attacks. In these situations, when the identity of the chemical is not known, first responders need a tool to rapidly evaluate victims and identify the best course of treatment. Military and civilian emergency response communities use a "toxic syndrome" (toxidrome) approach to quickly assess victims and determine the best immediate treatment when information on chemical exposures is limited. Toxidromes can be defined by a unique group of clinical observations, such as vital signs, mental status, pupil size, mucous membrane irritation, and lung and skin examinations. Data on over 20 toxidrome systems were evaluated to identify salient features and develop a consistent lexicon for use by state, local, tribal, territorial, and federal first responders and first receivers. A workshop of over 40 practitioners and experts in emergency response, emergency medicine, and medical toxicology developed names and definitions for 12 unique toxidromes that describe and differentiate the clinical signs and symptoms from exposures to chemicals. These toxidromes focus on acute signs and symptoms caused by inhalation and dermal exposures. Each toxidrome is characterized by exposure routes and sources, organs/systems affected, initial signs and symptoms, underlying mode of action, and treatment/antidotes. Toxidrome names and definitions are designed to be readily understood and remembered by users. Communication in a crisis requires accurate and succinct terms that can quickly convey the health conditions of patients. These toxidromes lay the foundation for a consistent lexicon, that if adopted widely, will improve response to chemical mass exposure incidents.

**PS 365 Activation of DNA Damage Repair Pathways in Response to Nitrogen Mustard-Induced DNA Damage and Toxicity in Skin Keratinocytes.**

S. Inturi<sup>1</sup>, N. Tewari-Singh<sup>1</sup>, C. Agarwal<sup>1</sup>, C. W. White<sup>2</sup> and R. Agarwal<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO; <sup>2</sup>Pediatrics, University of Colorado Denver, Aurora, CO.

Alkylating agent nitrogen mustard (NM), a structural analog of chemical warfare agent sulfur mustard (SM), upon exposure to tissues, forms adducts and crosslinks with DNA, RNA and proteins. The major mechanism of NM-induced toxicity involves DNA interstrand crosslinks (ICL) formation resulting in either induction of cell cycle arrest to facilitate DNA damage repair or cell death, in the case of inadequate repair. Consistently, NM (0.75  $\mu$ M) exposure in mouse epidermal JB6 cells decreased cell growth and caused S-phase arrest by 16 h after exposure. Cells were then released to G2-M phase by 24 h and resumed normal cell cycle progression by 48 h after exposure. Repair of NM-induced DNA ICLs involves formation of DNA double strand breaks (DSB). Our studies showed an increase in comet tail extent moment starting between 4 and 8 h of NM exposure, as well as an increase in levels of DNA DSB repair molecules (phospho H2A.X and p53, rad50 and XRCC1). The repair of DNA double strand breaks occurs via homologous recombination repair (HRR) or through the non homologous end joining pathway (NHEJ). The activation of the HRR pathway was evidenced by formation of Rad51 foci at 4 h after NM exposure, and activation of NHEJ pathway was indicated by increases in phospho and total DNA-PK levels. To confirm this, NHEJ and HRR pathways were inhibited by using DNA-PK inhibitor NU7026 and Rad51 siRNA, respectively. Inhibition of NHEJ did not result in a significant decrease in total cell number after 48 h of NM exposure and also did not affect the NM-induced S-phase arrest at 16 h. However, inhibition of the HRR pathway caused a 28% decrease in cell number, and a lack of NM-induced S-phase arrest, probably leading to an increase in the observed cell death. These studies indicate that HRR may be a key pathway involved in repair of NM-induced DNA DSBs. These findings may be useful in developing new therapeutic strategies against NM-induced skin toxicity.

**PS 366 Progression of Injury and Toxic Effects following Nitrogen Mustard Exposure in SKH-1 Hairless and C57BL/6J Mice Skin: Clinical and Pathological Significance.**

N. Tewari-Singh<sup>1</sup>, A. K. Jain<sup>1</sup>, S. Inturi<sup>1</sup>, D. J. Orlicky<sup>2</sup>, C. W. White<sup>3</sup> and R. Agarwal<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO; <sup>2</sup>Pathology, University of Colorado Denver, Aurora, CO; <sup>3</sup>Pediatrics, University of Colorado Denver, Aurora, CO.

Lack of availability of relevant skin injury models and clinically applicable biomarkers are major limitations in developing therapies to rescue skin injury and vesication by chemical warfare agent sulfur mustard (SM). Consequently, we conducted studies to establish useful clinical and histopathological endpoints with primary vesicating agent nitrogen mustard (NM). NM possesses strong vesicating and alkylating properties and causes damage to cellular macromolecules, exerting severe skin toxicity comparable to SM. Our comprehensive studies employing NM (3.2 mg) exposure for 12, 24, 72 and 120 h in both SKH-1 and C57BL/6J mice showed clinical sequelae of toxicity, including visible microblistering (12-24 h), edema (12-120 h), erythema (12-24 h), and hyper- and hypopigmentation, wounding, xerosis and scaly dry skin (72-120 h) that were comparable in both the mouse strains, and similar to those reported with SM in humans. In addition, 40% mortality was observed by 120 h after NM exposure in C57BL/6J mice. H&E stained skin sections of both mice showed that NM (12-120 h recovery) caused increased skin bi-fold thickness; histopathological effects such as hyperproliferation, microvesication, epidermal and dermal necrosis, denuding and scab formation, and parakeratosis (24-120 h), hypercornification (12-120 h), acanthosis and re-epithelialization (72-120 h); increase in inflammatory cells; and red blood cell extravasation into the dermis. These histopathological effects with NM were comparable to those reported in humans and other animal species with SM, and were quantified as percent of skin sections showing these effects, fold increases in histopathologic abnormalities, and prevalence among mice (% that showed these effects). These NM-induced effects are novel clinically relevant biomarkers to be used in screening and optimization of rescue therapies for skin injuries due to NM and SM in humans.

**PS 367 Long-Range Assessment and Treatment of Lung and Systemic Injury in Rats Exposed to Inhaled Sulfur Mustard.**

D. S. Olivera, T. R. Varney, D. A. Alves, K. Whitten, V. I. Morthole, R. K. Kan, J. L. Collins, J. B. Simons, J. L. Devorak, A. M. Rodriguez, C. M. Bowens, A. M. Witriol, E. A. Lyman, R. R. Deckert, S. L. Russell and A. M. Sciuto. *Analytical Toxicology, USAMRICD, Gunpowder, MD.*

Sulfur mustard (HD) causes severe chemical burns to the skin, eyes, and airways. HD was used as a chemical warfare agent (CWA) in the Iran/Iraq conflict, and more than half of surviving HD-exposed casualties suffer from permanent lung injuries. The mechanisms and timing of the development of these pathologies are poorly defined, and there is no effective antidote. Rats were intubated and ventilated for 10 min with nebulized HD or vehicle to achieve doses of 0, 0.5, 1.75, 2.25, and 3 mg/kg. Pulmonary function was analyzed by whole-body plethysmography. Rats were euthanized at various time-points  $\leq$  6 months post-exposure, blood chemistry was analyzed, broncho-alveolar lavage fluid was analyzed for cytokines/ redox state, and lungs were subjected to pathologic analysis. The data show high correlation between blood gas perturbations, upper airway necrosis and pulmonary function in the 24 h to 48 h after the 3 mg/kg HD exposure. In longer-ranging animals, the 3 to 7 wks period was a significant challenge because 15% of the 3 mg/kg group and 10% of the 2.25 mg/kg group died suddenly or required withdrawal from the study during this time. Alveolar exudates, edema, oxidative stress, and inflammation peaked at 3 wks and correlated with changes in pulmonary function and respiratory distress. Therefore, the first day and the second to third wks post-exposure may be crucial windows in the progression of HD inhalation injury, and treatment at these times may be the best approach. Based on this, we have evaluated single and multiple infusions of mesenchymal stem cells as a treatment and have found success in reducing HD-induced edema, necrosis, inflammation, and death at 5 wks post-exposure. This study provides the first long-term examination of HD-induced lung injury and systemic effects, and demonstrates the feasibility of stem cell therapies for treatment of HD inhalation injury.

**PS 368 Therapeutic Efficacy of Serum-Derived Human Butyrylcholinesterase against Topical Challenges of VX in the Hartley Guinea Pig.**

T. Snider<sup>1</sup>, J. D. Johnson<sup>1</sup>, K. G. McGarry<sup>1</sup>, G. H. Van der Zwaag<sup>1</sup>, R. L. Malek<sup>2</sup>, B. Peterson<sup>2</sup> and A. N. Nunley<sup>2</sup>. <sup>1</sup>Battelle, Columbus, OH; <sup>2</sup>Chemical Biological Medical Systems/Medical Identification and Treatment Systems, Frederick, MD.

The protective efficacy of human serum butyrylcholinesterase (HuBChE) was assessed in the guinea pig against topical challenges of VX. Male Hartley guinea pigs with jugular catheters were clipped on the left flank and challenged with neat VX at multiples of the 24-hr median lethal dose (LD<sub>50</sub>). Two hours after challenge, animals received either 1.04 mL/kg saline or HuBChE at 26 mg/1.04 mL/kg by intravenous (IV) infusion. Blood samples were collected at 5 min before challenge, 5 min before therapy, and 48 and 96 hr after challenge, and assayed for acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) activity. Clinical signs, recorded for up to 96 hr after challenge, indicated that VX rapidly penetrated skin. The protective ratio of HuBChE, 2.8, was calculated as the LD<sub>50</sub> determined by probit analysis among IV therapy-receiving guinea pigs (0.39 mg/kg) divided by the LD<sub>50</sub> for unprotected guinea pigs (0.14 mg/kg). VX was lethal to all guinea pigs challenged at 4x and 8x LD<sub>50</sub>. AChE activity among survivors, likely through VX dissociation, rebounded to more than 80% of the baseline value by 96 hr. BChE activity among survivors increased after therapy and remained at more than 30 times endogenous levels over the 4-day study. In a follow-on study, the therapeutic window was characterized by fixing the topical VX challenge dose at the LD<sub>15</sub> (0.34 mg/kg) and changing the time interval to IV therapy. Probit modeling indicated that 50% lethality would be expected after a 4.3 hr delay post-challenge of HuBChE therapy. Blood AChE activity profiles declined with delay in therapy followed by a rebound among survivors. BChE activity increased after therapy and remained at 30 to 54 times endogenous levels over the 4-day study. This work was conducted under the CBRNIAC Contract No. SF0 700-00-D-3180, Delivery Order 0599, Task 789.

**PS 369 A Comparative Study of Biomarkers of Nitrogen Mustard-Induced Skin Injury in Male SKH-1 Hairless and C57BL/6J Mice.**

A. K. Jain<sup>1</sup>, N. Tewari-Singh<sup>1</sup>, S. Inturi<sup>1</sup>, D. J. Orlicky<sup>2</sup>, C. W. White<sup>3</sup> and R. Agarwal<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO; <sup>2</sup>Pathology, University of Colorado Denver, Aurora, CO; <sup>3</sup>Pediatrics, University of Colorado Denver, Aurora, CO.

Sulfur mustard (SM) is a primary vesicating warfare agent that upon exposure causes severe skin injuries. Currently, we lack effective antidote against SM-induced skin injuries, in part due to lack of appropriate animal model(s) that can be used for mechanistic and efficacy studies in laboratory settings. Our earlier studies have established biomarkers related to inflammation and vesication in SKH-1 hairless mice using 2-chloroethyl ethyl sulfide (CEES), an SM analog. However, CEES is a monofunctional alkylating agent that is less toxic than SM. Therefore, to develop a more relevant skin injury model, we have now used nitrogen mustard (NM); a primary vesicant and a bifunctional alkylating agent that induces toxic effects comparable to SM. We compared the effect of NM (3.2 mg) exposure for 12, 24, 72 and 120 h in SKH-1 hairless and C57BL/6J mice. NM caused significant increases in skin microvesication, cell proliferation, apoptotic cell death, inflammatory cells (neutrophils, macrophages, and mast cells) and MPO activity in both mouse strains. However, in SKH-1 mice there was a more prominent increase in epidermal thickness, macrophages and mast cell infiltration, relative to that seen in C57BL/6J mice. NM also caused collagen degradation at early time points (12-24 h) with a decrease in collagen trichrome staining and an increase in dermal thickening, due, at least in part, to edema. However, at later time points (72 and 120 h), dense collagen staining with reduced dermal edema was observed, indicating a healing process. This study indicates that both mouse strains have comparable susceptibility to NM injury, as shown by inflammation and vesication. However, some inflammatory responses were more pronounced in NM-induced skin injury in SKH-1 mice. These newly established biomarkers in a more accessible and relevant NM skin injury model should aid in identifying effective therapies for treatment of skin injuries due to NM and SM.

**PS 370 24 h LD<sub>50</sub> for Subcutaneous Exposure to Chemical Warfare Nerve Agents in Rats: Comparison across Multiple Age Groups.**

L. K. Wright, R. B. Lee, S. H. Robertson, K. M. Licht, M. F. Stone, M. C. Moffett and L. A. Lumley. *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

In a mass casualty situation involving the release of chemical warfare nerve agents (CWNA), infants, children and adolescents are likely to be exposed. These subgroups of the population may be more susceptible than adults to the toxicological effects of CWNA exposure because of their closer proximities to a ground source, smaller body masses, higher respiratory rates, greater skin permeabilities and immature brains and metabolic systems. Unfortunately, there have only been a handful of studies on the effects of CWNA in younger animals, and more research is needed to confirm this hypothesis. Using a stagewise, adaptive dose design, we determined the 24 h LD<sub>50</sub> for subcutaneous (sc) exposure to sarin (GB), as well as VX, in both male and female Sprague-Dawley rats at five different time points during their development (postnatal day [PND] 7, 14, 21, 42 and 70). For males, the 24 h LD<sub>50</sub> for both GB and VX increased from PND 7 thru PND 42 and then slightly decreased at PND 70. Similar results were observed for females; however, fewer significant differences between age groups were observed. Regardless of CWNA, no significant differences were observed between males and females for any age group. Thus, younger rats are more susceptible to the lethal effects of subcutaneously administered CWNA than older rats. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. The experimental protocol was approved by the Animal Care and Use Committee at the United States Army Medical Research Institute of Chemical Defense (USAMRICD), and all procedures were conducted in accordance with the principles stated in the Guide for the Care and Use of Laboratory Animals and the Animal Welfare Act of 1966 (P.L. 89-544), as amended. This research was supported by interagency agreement between the Biomedical Advanced Research and Development Authority and USAMRICD.

**PS 371 Mechanisms of Vesicating Agent Nitrogen Mustard-Induced Skin Injury in SKH-1 Hairless Mice.**

D. Kumar<sup>1</sup>, N. Tewari-Singh<sup>1</sup>, S. Inturi<sup>1</sup>, C. Agarwal<sup>1</sup>, A. K. Jain<sup>1</sup>, D. Dhar<sup>1</sup>, C. W. White<sup>2</sup> and R. Agarwal<sup>1</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO; <sup>2</sup>Pediatrics, University of Colorado Denver, Aurora, CO.

Lack of a comprehensive understanding of molecular mechanisms and signaling pathways involved in skin injuries due to chemical warfare agent sulfur mustard (SM)- is a major limitation in developing mechanism-based therapies for rescue of skin injuries by vesicating agents. Our recent studies in SKH-1 hairless mice show that exposure to nitrogen mustard (NM; 3.2 mg) for 12, 24, 72, 120 or 168 h triggers an inflammatory response, vesication, apoptotic cell death, and either initiation of healing or 40% mortality by 168 h of exposure. Both SM and NM vesicant-induced tissue injury is mainly due to alkylating properties, with DNA damage resulting from direct toxicity and/or oxidative stress. In this study we extended our efforts to identify the mechanism/s involved in NM-induced toxic response at 12-120 h after exposure. In skin tissue of SKH-1 mice, NM exposure caused p53 ser15 phosphorylation and increased p53 accumulation, both indicating DNA damage. Our results also showed that NM exposure, with recovery for 12-168 h, induced expression of inflammatory mediators COX-2 and iNOS in mouse skin, and >2-fold increase in expression of protease MMP-9, that may contribute to NM-induced vesication. NM exposure, with recovery for 12-168 h, also was associated with phosphorylation of mitogen-activated protein kinases (MAPKs; ERK1/2, JNK, and p38) and increased oxidative stress, as indicated by enhanced 4-HNE (lipid peroxidation) and DMPO protein adduct formation. Our results thus far indicate that NM induces activation of upstream signaling pathways including MAPKs and oxidative stress that could, in part, be responsible for DNA damage, cell death, and expression of inflammatory and proteolytic mediators contributing to the inflammatory response and vesication. These molecular targets could be useful in developing therapeutic interventions against NM- and SM-related skin injuries.

**PS 372 Ovarian Hormones Affect the Physiological Response to VX in Female Rats.**

C. Smith, L. K. Wright, J. E. Schwartz, S. H. Robertson, K. M. Licht and L. A. Lumley. *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.* Sponsor: J. McDonough.

Chemical warfare nerve agents (CWNAs), such as VX, irreversibly bind to acetylcholinesterase, which induces a "cholinergic crisis" that causes numerous physiological events including seizures and death. Females are historically an understudied subset of the population, largely because of conflicting data related to the effects of CWNAs both within groups of females and in comparison to males. The profound impact of circulating ovarian hormones on biological processes is well known, and parsimony suggests that these hormones contribute to these observed differences. To date, few studies have investigated the impact of naturally circulating ovarian hormones in animals exposed to CWNAs. In the current study, we examined the effects of VX (1.0 x LD<sub>50</sub>) in female rats that had their ovaries removed (OVEX) or left intact. The estrous cycles of females left intact were monitored, and they were further divided by stage of the cycle (estrus or diestrus). Results show that females in estrus survived for a significantly longer period of time than OVEX rats. Seizure activity was also significantly different, with 5/8 OVEX, 2/8 diestrous, and 0/8 estrous female rats exhibiting seizures. These data suggest that ovarian hormones, including estrogen, progesterone, and their metabolites, which rise the evening before estrus, offer protection against the seizure-inducing and lethal effects of VX. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. The experimental protocol was approved by the Animal Care and Use Committee at the United States Army Medical Research Institute of Chemical Defense and all procedures were conducted in accordance with the principles stated in the Guide for the Care and Use of Laboratory Animals and the Animal Welfare Act of 1966 (P.L. 89-544), as amended. This research was supported by the U.S. Army's In-house Laboratory Independent Research (ILIR) program.

**PS 373 Inflammatory Response following Neurogenic Cardiotoxicity Induced by Exposure to the Chemical Warfare Agent Soman.**

H. Hoard-Fruchey, C. J. Smith, M. A. Guignet, J. F. Irwin, T. L. Dao, J. A. Leuschner, E. A. Johnson, J. F. Dillman and R. K. Kan. *US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Chemical warfare nerve agents (CWNAs) are potent inhibitors of cholinesterase activity, causing inhibition of acetylcholinesterase and accumulation of acetylcholine (ACh) at synaptic junctions. Excess ACh causes hyperstimulation of the central and

peripheral cholinergic systems, and seizure activity ensues in susceptible brain regions. Because of the extensive neuronal damage and death caused by the resulting seizure activity, studies of CWNA-induced injury have focused primarily on the effects to the central nervous system with few studies focused on other organ systems. Previous studies have demonstrated cardiac damage following exposure to seizurogenic doses of the CWNAs soman and sarin. Following acute exposure to soman, up to 88% of rats display cardiac lesions in the interventricular septum and left ventricular wall. To initiate molecular characterization of soman-induced cardiotoxicity, we used multiplex immunoassays to determine concentrations of inflammatory and cardiac markers altered in left ventricle samples from rats exposed to a seizurogenic dose of soman. Increased concentrations of cytokines such as IL-1 beta, IL-4, IL-5, IL-13, and IFN gamma were observed within 24 hours of soman-induced seizure. Cytokine IL-6 concentrations peaked 3 hr after soman-induced seizure, indicating early involvement of inflammatory response in cardiac tissue. Chemokines MCP-1 and CXCL1 also increased, indicating that signals for neutrophil and monocyte recruitment to cardiac tissue are present following soman exposure. In addition, increases in TIMP-1 and VEGF concentrations within 6 hr of soman exposure suggest that cardiac injury occurs within hours of seizure initiation and that in response, repair mechanisms are activated. These results support development of anti-inflammatory medical countermeasures to treat the peripheral as well as the central effects of chemical warfare nerve agents.

**PS 374 Development of an Inhalation Exposure System to Control Concentration and Time Profile of a Test Gas to Evaluate the Predictivity of "Toxic Load" Models.**

B. A. Wong, R. James, B. C. Sharits and L. M. Sweeney. *Naval Medical Research Unit - Dayton, Wright Patterson Air Force Base, OH.*

For dose calculations of an inhaled toxic material, a time-varying concentration scenario is generally modeled as a constant concentration times a specified duration (step profile) that yields the same cumulative exposure, such as in the toxic load model ( $C_n \times T$ ). The adequacy of the toxic load model to predict mortality from a realistic exposure scenario based on step profile laboratory experiments is under review. An inhalation exposure system was set up to provide separate pulses of a test atmosphere at different concentrations and time durations as a first approximation of a time varying exposure.

A test atmosphere was generated by mixing a test gas from a cylinder (hydrogen cyanide in oxygen and nitrogen) with clean air to a target concentration. A combination of two generation systems, one at a high target concentration and one at a low target concentration was used to produce a specified change in concentration. The two generation systems could be switched on and off to insert a time gap between the two exposure concentrations, if desired. Precision mass flow controllers were used to control the flow of test gas and dilution air to achieve the target concentrations. Electric solenoid valves were used to change the different gas flows for precise timing. A Fourier Transform Infrared Spectrometer was used to measure the test material concentration in the exposure air entering the breathing zone of the test subject. A 12-port nose-only exposure unit was used to expose animals to the test atmosphere. Three basic patterns were generated, a single constant concentration for a defined time duration, a high concentration and low concentration pulse with no separation, and a high concentration and low concentration with a clean air gap between pulses. Test generation results showed excellent control of time and concentration of the exposure atmospheres.

**R 375 A Decade of Nanotoxicology: Where Do We Stand Now?**

S. M. Hussain and J. J. Schlager. *Air Force Research Laboratory, US Air Force, Wright-Patterson, Dayton, OH.*

The last ten years have seen an explosion in the development and evolution of nanotoxicology. This milestone of a decade of research provides a great opportunity to look back and evaluate both the progress made, as well as identify challenges that can potentially plague future research. Early studies had few materials to work with. However, advances in material science have resulted in a large array of nanomaterials (NM) with controlled size, shape, and surface functionalities. From early on, it became apparent that the unique properties associated with NMs, (i.e., primary size, agglomeration patterns, crystal structure, shape, etc.) can dictate the observed effects. Systematic evaluation of toxicity mechanisms necessitated development of novel tools to assess NM physicochemical properties that include: enhanced microscopy techniques, dynamic and static light scattering, and quantitation of cellular uptake. However, adaptation of such characterization tools within the nanotoxicity community has been slow, due to convoluted literature reports of the same NM property measured with different techniques. Recently, the question of dosimetry has become a focus of inquiry due to such conflicting reports. Experiments are being performed to evaluate and compare the effect of dosage by

mass, surface area, and number of particles. However, the evaluation of aggregation state has largely ignored the structure of aggregation, which can substantially influence NM mass exposure and uptake. In addition, another challenge in nanotoxicity is the lack of strategies to accurately extrapolate *in vitro* results to predict *in vivo* responses. This generates the need for enhanced cell model development and implementation in nanotoxicity research. The emerging field of nanotoxicology has made remarkable progress over the past decade and holds immense promise for the next. The focus of this discussion will be to highlight the current state of nanotoxicity and determine key gaps in dosimetry, interpretation of characterization to decipher mechanistic toxicity, and translating data to reliable assessment of human exposure and risk.

### **R** 376 **Predicting Human Thorough QT (TQT) Study Outcomes with Nonclinical Data—How Good Are We and How Good Do We Need to Be?**

J. Valentin<sup>1</sup>, O. Della Pasqua<sup>2</sup>, J. Koerner<sup>3</sup>, D. Leishman<sup>4</sup>, L. Ewart<sup>1</sup> and M. Krucoff<sup>5</sup>. <sup>1</sup>AstraZeneca, Macclesfield, United Kingdom; <sup>2</sup>Leiden University, Leiden, Netherlands; <sup>3</sup>US FDA, Silver Spring, MD; <sup>4</sup>Lilly, Greenfield, IN; <sup>5</sup>Duke University Medical Center, Durham, NC.

The ability to predict and thus prevent drug-induced ventricular arrhythmia and Torsades de Pointes (TdP) is a significant public health issue and a primary focus of regulatory safety pharmacology studies. Data are generated both nonclinically (via hERG, ECG, APD studies) and clinically primarily via a thorough QT study (TQT). The speakers in this roundtable session will consider the predictive value of each of these studies individually and their utility as a panel overall. Specifically, speakers will discuss concordance between nonclinical and clinical data for safety pharmacology endpoints; discuss optimization of nonclinical study design and data collection; identify opportunities for data from additional metrics; and discuss perspectives on the collection and use of nonclinical data to inform clinical trials. The panelists will also be challenged to identify strengths and weaknesses in current testing approaches and propose recommendations to improve or modify these approaches in the future. Participants will be engaged in these discussions and provide input in the debate of the predictive value of nonclinical QT studies as well as the potential for alternative assays or extrapolations to improve our ability to anticipate clinical outcome.

### **HH** 377 **Diesel and Gasoline Exhaust and Cancer.**

A. M. van Erp<sup>1</sup>, J. D. McDonald<sup>3</sup>, R. O. McClellan<sup>2</sup> and E. Garshick<sup>4</sup>. <sup>1</sup>Health Effects Institute, Boston, MA; <sup>2</sup>Toxicology and Human Health Risk Analysis, Albuquerque, NM; <sup>3</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>4</sup>Veterans Administration Boston Health Care System, Boston, MA.

In 1989, the International Agency for Research on Cancer (IARC) classified whole diesel exhaust as a "probable human carcinogen" and whole gasoline engine exhaust as a "possible human carcinogen." Since then, stringent regulations on diesel engine emissions have been introduced, and there have been significant developments in engine technology and introduction of ultra-low sulfur fuel resulting in marked reductions in the hazardous components in diesel exhaust. These changes are expected to provide substantial benefits to air quality and human health. The time course for realizing the benefits will be related to the rate at which old engines are replaced with new technology. In June 2012, IARC re-evaluated the carcinogenic hazard of diesel and gasoline exhaust based on new information that has become available from studies in humans and animals, which has led to the current designation of diesel exhaust as a "known human carcinogen." This session provides a historical overview of diesel engine technology and emissions, and the significant changes that have occurred over the past decades. We also take a look at what is known about the health effects of diesel and gasoline exhaust and its public perception over the years. We provide a detailed characterization of the June 2012 IARC Working Group re-evaluation of the carcinogenic hazard classification of diesel exhaust and gasoline emissions, both regarding the toxicologic and epidemiologic evidence, and discuss potential implications of the new hazard classification for public policy. Although the Working Group discussed whether to distinguish between "traditional diesel exhaust" and "new technology diesel exhaust" in the cancer hazard assessment, they concluded that this was not possible due to a lack of data on health effects associated with exposure to new technology diesel exhaust.

### **EC** 378 **From New Submissions to Competitive Renewals: Different Phases of Grant Writing.**

C. E. Sulentic<sup>1</sup> and B. L. Kaplan<sup>2</sup>. <sup>1</sup>Wright State University, Dayton, OH; <sup>2</sup>Michigan State University, East Lansing, MI.

Grant writing is a challenging endeavor. One must effectively communicate the significance, innovation, and approach of their research project in a clear, but concise manner with appropriate grammar. While there are some aspects of grant writing that apply regardless of the grant application phase, such as a clearly stated hypothesis and specific aims, the style, and required elements of the various phases of the grant writing process can differ significantly. Thus, the goals of this session are to discuss the various phases of the grant writing process, including preparing a new application versus a competitive renewal, composing the rebuttal and revised grant application, how best to create a "new" grant if a grant has not been funded after two review cycles, and an overview of the review process, and choosing the best scientific review group. Three speakers from NIEHS and a well-funded fourth speaker, who is also an experienced grant reviewer, will expertly cover these topics and participate in a panel discussion at the end of the session.

### **PS** 379 **Erionite Induces Th-17 Pathway Cytokines *In Vitro* and *In Vivo*.**

N. Zebedeo and J. Pfau. Idaho State University, Pocatello, ID.

Erionite is a fibrous zeolite with similar morphological and physical properties to amphibole asbestos. Erionite can also cause malignant mesothelioma and other diseases similar to what is seen in individuals who have been exposed to asbestos. There is little known about how erionite affects the immune system or whether it is associated with systemic autoimmune diseases.

Given these similarities to amphibole asbestos, the hypothesis of this study is that erionite will evoke autoimmune reactions similar to what has been seen upon asbestos exposure. Certain cytokine profiles from macrophages and lymphocytes that may indicate autoimmunity were examined after exposure to asbestos. The cytokines belonging to the Th17 pathway have been implicated in the development of pathologies in some autoimmune diseases.

*In vitro* exposures were done using bone marrow derived macrophages from a cell line and macrophages and lymphocytes from spleens of C57BL/6 mice. Mice were also exposed *in vivo* through peritoneal injections for 1, 3 and 7 days. Cytokines from peritoneal fluid and splenocyte cultures were examined using ELISAs.

Data has shown that erionite causes an increased production of cytokines belonging to the Th17 profile including IL-17, IL-6 and TNF- $\alpha$ . This may be a marker that indicates autoimmune reactions associated with erionite. There are populations in the United States that may be at risk to developing diseases due to erionite exposure. Understanding the mechanism of disease caused by erionite can provide targets for therapies and help implement regulations on its use.

### **PS** 380 **Resistance to Asbestos-Induced Apoptosis with Continuous Exposure to Crocidolite on a Human T Cell.**

T. Otsuki<sup>1</sup>, M. Maeda<sup>2</sup>, S. Yamamoto<sup>1</sup>, N. Kumagai-Takei<sup>1</sup>, S. Lee<sup>1</sup>, H. Mastuzaki<sup>1</sup> and Y. Nishimura<sup>1</sup>. <sup>1</sup>Hygiene, Kawasaki Medical School, Kurashiki, Japan; <sup>2</sup>Biofunctional Chemistry, Graduate School of Natural Science and Technology, Okayama University, Okayama, Japan.

We have been investigating the immunological effects of asbestos. The establishment of a low-dose and continuously exposed human T cell line, HTLV-1 immortalized MT-2, to chrysotile (CB) revealed reduction of CXCR3 chemokine receptor and production of IFN- $\gamma$  that caused a decline of tumor immunity. These effects were coupled with upregulation of IL-10, TGF- $\beta$ , and BCL-2 in asbestos-exposed patients. To observe the immunological effects of crocidolite (CR) on human T cells, a trial to establish a low-dose and continuously exposed model was conducted and compared with a previously reported CB-exposed model (MT-2CB). Transient exposure of MT-2 original cells to CB or CR induced a similar level of apoptosis and growth inhibition. The establishment of a continuously exposed subline to CR (MT-2CR) revealed resistance against CR-induced apoptosis and upregulation of the BCL-2/BAX ratio similar to that recorded for MT-2CB. Both sublines showed reduced production of IFN- $\gamma$ , TNF- $\alpha$ , and IL-6 with increased IL-10. cDNA microarray with network/pathway analyses focusing on transcription factors revealed that many similar factors related to cell proliferation were involved following continuous exposure to asbestos in both MT-2CB and MT-2CR. These results indicate that both CB and CR fibers affect human T cells with similar degrees even though the carcinogenic activity of these substances differs due to their chemical and physical forms. Trials to identify early detection markers for asbestos exposure or the occurrence of asbestos-inducing malignancies using these findings may lead to the development of clinical tools for asbestos-related diseases and chemoprevention that modifies the reduced tumor immunity.

**PS 381 Effect of Asbestos Exposure on Regulatory Role of NK Cells for Expanded Autologous CD4<sup>+</sup> T Cells.**

Y. Nishimura, N. Kumagai-Takei, H. Matsuzaki, S. Lee and T. Otsuki. *Hygiene, Kawasaki Medical School, Kurashiki, Japan.*

We have studied about effect of asbestos exposure on anti-tumor immunity to date, which demonstrated altered function of natural killer (NK) cells exposed to asbestos, showing decreased cytotoxicity against cancer cells with altered expression of NK cells receptors. Recently, it has been become known that NK cells show cytotoxicity for not only abnormal cells but also healthy autologous cells, by which NK cells play a regulatory role in immune response. Therefore, the present study examined effect of asbestos exposure on regulatory role of NK cells for CD4<sup>+</sup> or CD8<sup>+</sup> T cells. Human peripheral blood mononuclear cells (PBMCs) were cultured in IL-2-supplemented media with or without chrysotile B asbestos or silica, while CD4<sup>+</sup> or CD8<sup>+</sup> T cells were freshly sorted from PBMCs magnetically, and cultured upon stimulation by antibodies to CD3 and CD28. After 7 days, expanded CD4<sup>+</sup> or CD8<sup>+</sup> T cells were cultured with CD3-CD56<sup>+</sup> NK cells isolated from harvested PBMCs by flow cytometry for a day. The culture with NK cells caused a decrease in the percentage of viable CD4<sup>+</sup> T cells. However, CD4<sup>+</sup> T cells cultured with NK cells exposed to asbestos, but not with silica-exposed those, showed more decrease in viable cells, compared with control culture. In addition, the expression levels of cell surface CD25 and CXCR3, activation and effector markers respectively, decreased in those CD4<sup>+</sup> cells. In contrast, CD8<sup>+</sup> T cells did not show alteration in percentage of viable cells and expression of FasL and CXCR3 by culture with NK cells. These results indicate that asbestos-exposed NK cells show enhanced function to regulate expanded CD4<sup>+</sup> T cells, in which effector cells are reduced more. The enhanced regulatory function might lead to insufficient anti-tumor response.

**PS 382 Long-Term Exposure of Asbestos on MT-2 Cell Affects Cell Cycle Progression and Cell Death.**

S. Lee<sup>1</sup>, H. Matsuzaki<sup>1</sup>, M. Maeda<sup>2</sup>, N. Kumagai-Takei<sup>1</sup>, Y. Nishimura<sup>1</sup> and T. Otsuki<sup>1</sup>. <sup>1</sup>*Hygiene, Kawasaki Medical School, Kurashiki, Japan;* <sup>2</sup>*Laboratory of Functional Glycobiology, Department of Biofunctional Chemistry, Division of Agricultural and Life Science, Graduate School of Environmental and Life Science, Okayama University, Okayama, Japan.*

Asbestos is a silicate mineral that causes serious illness such as malignant mesothelioma and lung cancer. Regulatory T cells (Treg), are known as a suppressor of immune activity and cause a less anti tumor immunity. We have hypothesized that asbestos causes less immune reaction including tumor immunity through the enhancement of Treg function. Here we used MT-2 cell line, an HTLV-transformed human FoxP3 positive Treg model cell line, and established 7 sub-cell lines from original MT-2. They were exposed to 3 kinds of asbestos (Chrysotile A, Chrysotile B and Crocidolite) at low concentration (10 µg/ml or 25 µg/ml) for long term (more than 8 months). Microarray analysis revealed that transcriptional factor FoxO1 was remarkably decreased in these all of sub-cell lines. Since FoxO1 regulates expression of several cell cycle regulatory molecules, in this study we focused on the cell cycle regulation in these sub-cell lines. Real time PCR analysis showed cyclin dependent kinase (CDK) inhibitors, p21Cip1, p57Kip2, p18Ink4c, p19Ink4d were decreased and CyclinD1 was remarkably increased in these sub-cell lines. Western blot analysis also showed us p21Cip1 was decreased and CyclinD1 was increased in these sub-cell lines. Annexin V/PI staining showed some sub-line cells contained more living cells than original MT-2. We detected significantly less Fas-ligand mRNA expression in all sub-cell lines. These results suggested that long-term exposure of asbestos might accelerate cell cycle progression, and decrease cell death, and conduct them increase. Abnormal proliferation of Treg may down regulate tumor immunity. Further study is required to elucidate whether the down regulation of FoxO1 is implicated cell cycle progression in these sub-cell lines.

**PS 383 Difference in Functional Property of CD8<sup>+</sup> Lymphocytes between Patients with Pleural Plaque and Malignant Mesothelioma.**

N. Kumagai-Takei<sup>1</sup>, Y. Nishimura<sup>1</sup>, M. Maeda<sup>2</sup>, H. Matsuzaki<sup>1</sup>, S. Lee<sup>1</sup>, T. Kishimoto<sup>3</sup>, K. Fukuoka<sup>4</sup>, T. Nakano<sup>4</sup> and T. Otsuki<sup>1</sup>. <sup>1</sup>*Department of Hygiene, Kawasaki Medical School, Kurashiki, Japan;* <sup>2</sup>*Department of Biofunctional Chemistry, Graduate School of Natural Science and Technology, Okayama University, Okayama, Japan;* <sup>3</sup>*Okayama Rosai Hospital, Okayama, Japan;* <sup>4</sup>*Division of Respiratory Medicine, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan.*

[Background and Purpose] We have demonstrated effect of asbestos on in vitro development of cytotoxicity in CD8<sup>+</sup> lymphocytes, and reported the property of CD8<sup>+</sup> cells in people positive for pleural plaque (PL), a mark of asbestos exposure, last year. In the present study, CD8<sup>+</sup> lymphocytes of malignant mesothelioma

(MM) patients as well as PL-positive people were examined by flow cytometry. [Materials and Methods] Freshly prepared PBMCs were assayed for cell number of CD3<sup>+</sup>CD8<sup>+</sup> cells and percentages of granzyme B<sup>+</sup>, perforin<sup>+</sup>, and CD45RA<sup>+</sup> cells in CD8<sup>+</sup> lymphocytes by flow cytometry. PBMCs were stimulated with PMA/ionomycin for 4h and assayed for percentages of IFN-γ<sup>+</sup>, CD107a<sup>+</sup>, granzyme B<sup>+</sup> and perforin<sup>+</sup> cells in CD8<sup>+</sup> lymphocytes. [Results] CD3<sup>+</sup>CD8<sup>+</sup> cells in PL and MM showed lower cell number than those of healthy volunteers (HV). There was no difference in % CD107a<sup>+</sup>, showing degranulation, and % IFN-γ<sup>+</sup> cells in stimulated CD8<sup>+</sup> lymphocytes among three groups. Although % granzyme B<sup>+</sup> cells in fresh CD8<sup>+</sup> lymphocytes of PL and MM were similar to that of HV, % perforin<sup>+</sup> cells of PL and MM was higher than that of HV. However, the stimulated CD8<sup>+</sup> lymphocytes of MM showed more decrease in % perforin<sup>+</sup> cells than those of the other groups. The CD8<sup>+</sup> lymphocytes of PL and MM groups showed higher percentages of CD45RA<sup>+</sup> cells than that of HV. [Discussion] These results indicate that PL and MM groups share increase in CD45RA<sup>+</sup> and perforin<sup>+</sup> CD8<sup>+</sup> cells, suggesting effect of asbestos on tumor immunity. In addition, the results indicate the enhanced decrease in perforin<sup>+</sup> CD8<sup>+</sup> cells of MM after stimulation, implying impairment in stimulation-induced cytotoxicity.

**PS 384 Cadmium Exposure Effects on the Class- Switch Recombination in Burkett's Lymphoma Cell Lines.**

V. Poltoratsky. *Pharmaceutical, St. John's University, Queens, NY.* Sponsor: L. Trombetta.

Cadmium is an environmental and industrial pollutant, which enhances susceptibility to pathogens and autoimmune disease. It has been demonstrated that exposure to cadmium modulates the human humoral and cell-mediated immunity. Exposure to cadmium in high doses causes a decrease in B and T cell concentrations and exposure to low doses causes selective inhibitory effect on immunoglobulin isotypes. While the effect of the high concentrations of cadmium in induction of the oxidative stress and apoptosis is well documented, the effect of lower cadmium concentrations on modulating humoral immune response has not been fully understood.

It has been previously demonstrated that low concentrations of cadmium specifically inhibit the miss matched repair pathway, by inhibiting the ATPase activity of MSH2 and MSH6 proteins (Clark and Kunkel, 2004). On other hand, Msh2 and Msh6 deficient mice are defective in class switch recombination (Wiesendanger et al, 2000). In this study, we suggested that exposure to the low concentrations of the cadmium is affecting mismatch repair and the class switched recombination in B lymphocytes, due to its effects on the MSH2 and MSH6 proteins.

Here we tested the effect of low concentrations of cadmium on the miss matched repair and class switched recombination in human B cells. Cadmium at micromolar concentrations inhibited CSR in Burkett's lymphoma cells but did not significantly affect the mRNA level of the activation induced cytosine deaminase and MSH2 and MSH6 genes. The study also covered relations between cadmium concentrations and mismatch repair activity.

**PS 385 Arsenic Species Have Differential Impacts on *Pseudomonas aeruginosa* Induced Immune Response in Human Bronchial Epithelial Cells.**

E. Notch, R. Barnaby, B. Coutermarsh, V. Taylor, B. Jackson, T. Hampton and B. Stanton. *Geisel School of Medicine at Dartmouth, Hanover, NH.*

Arsenic is the number one environmental contaminant of concern with regard to human health. In animal and epidemiological studies arsenic exposure has been associated with a variety of deleterious health outcomes. *In utero* and early life stage arsenic exposure has been linked to lung disease, including acute and chronic bacterial infections, and chronic obstructive pulmonary disease, all of which are associated with *Pseudomonas aeruginosa* (Pa) infection. Animal models have also shown that chronic arsenic exposure decreased immune response to viral challenge. However, little is known about the mechanisms by which these alterations occur or the relative contributions of different arsenic species. This study examined the impacts of inorganic sodium arsenite (iAs<sup>III</sup>) and two major metabolites, monomethylarsonous acid (MMA<sup>III</sup>) and dimethylarsenic acid (DMA<sup>V</sup>), on Pa induced cytokine secretion by primary human bronchial epithelial cells (HBEC, n=4 donors). HBEC cells did not metabolize iAs<sup>III</sup>, MMA<sup>III</sup> or DMA<sup>V</sup>. Exposure of HBEC to 10ppb iAs<sup>III</sup> for 6 days did not alter Pa induced cytokine secretion. In contrast, 10ppb DMA<sup>V</sup> for 6 days significantly decreased IL-8, IL-6, CXCL1 and CXCL2 secretion after Pa stimulation compared to cells exposed to Pa alone. Exposure to 10ppb MMA<sup>III</sup> increased Pa induced IL-8, and Gro-b secretion. HBEC exposed to DMA<sup>V</sup> also had significantly decreased mRNA levels of IL-8, IL-6, CXCL1 and CXCL2 after Pa stimulation. These data provide the first evidence of arsenic species dependent alterations of the immune response of HBEC to infection by Pa. IL-8, IL-6, CXCL1 and CXCL2 are key proinflammatory cytokines that recruit monocytes, macrophages and neutrophils to clear Pa. Thus, MMA<sup>III</sup> and DMA<sup>V</sup>-induced

changes in cytokine secretion by HBEC in response to *Pa* are likely to contribute to the observation that exposure to arsenic dramatically increases the incidence of acute and chronic bacterial infections. Supported by Dartmouth Superfund Program P42 E507373.

**PS 386 Evidence for Low-Dose Suppression of T Cell Proliferation by Arsenite in Certain Normal HPBMC Donors *In Vitro*.**

F. T. Lauer, K. Liu, L. G. Hudson and S. W. Burchiel. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

Arsenic exposures in the United States and elsewhere in the world have been associated with numerous chronic diseases. People are exposed to arsenic via drinking water, diet, and air vectors. Arsenic exposure is now considered a top environmental public health concern worldwide. Several epidemiologic studies have shown that T cell proliferation is suppressed in individuals exposed to arsenic via drinking water. Previous studies in our laboratories have shown that sodium arsenite suppresses T cell proliferation in HPBMC obtained from normal donors. We have previously reported that some individuals respond to extremely low concentrations (<1 nm) of sodium arsenite when exposed to T cell mitogens (phytohemagglutinin, PHA) and arsenite *in vitro* for 72 hrs. We have now extended these studies to additional individuals and have examined additional assays for assessing T cell proliferation, including PHA-induced 3H-thymidine incorporation and a flow cytometry-based CFSE assay. Using the CFSE assay, we are examining differentially affected T cell subsets. In addition, the work has been extended to the activation of human T cells using anti-CD3/anti-CD28 beads. We find excellent agreement between the results obtained using 3H-thymidine incorporation and CFSE. In this poster we will demonstrate examples of the inter-individual variations in responses to arsenic and polycyclic aromatic hydrocarbons (PAHs) as well as potential synergistic interactions between these chemical classes of agents.

This work was supported by NIH 1R01ES019968-01A1.

**PS 387 The Aryl Hydrocarbon Receptor and Th17 Polarization: Relevance of Receptor Affinity.**

M. D. Hayes<sup>1</sup>, A. Smith<sup>2</sup>, I. Kimber<sup>1</sup> and R. J. Dearman<sup>1</sup>. <sup>1</sup>*Faculty of Life Sciences, Manchester University, Manchester, United Kingdom;* <sup>2</sup>*MRC Toxicology Unit, Leicester, United Kingdom.*

There are in mice well-characterized strain differences in responsiveness of the aryl hydrocarbon receptor (AhR) to its archetypal ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin that result from genetic variants of AhR displaying variable affinities. Thus, C57BL/6 are categorized as being very responsive, with DBA strain mice being the least responsive. Importantly, the human AhR is defined as being of low affinity comparable with the DBA strain receptor. The AhR is expressed relatively ubiquitously but in T cells it is restricted to the T helper (Th) 17 and T regulatory cell subsets. Furthermore, it has been reported that AhR activation is required for optimal Th17 cell polarization. However, such studies have used exclusively the high affinity C57BL/6 strain. We have investigated whether the class of AhR affects optimal *in vitro* polarization of Th17 cells using various mouse strains including an AhR null mouse. Th (CD4<sup>+</sup>) cells were isolated by negative selection from the peripheral lymph nodes of naive mice and polarized into Th17 cells with anti-CD3 and anti-CD28 antibodies and cytokines interleukin (IL)-6, IL-1 $\beta$  and TGF- $\beta$ . Th17 cell differentiation was assessed as a function of mRNA and protein expression for key IL-17 cytokines and the frequency of IL-17<sup>+</sup> cells by intracellular cytokine staining. Using an AhR antagonist (CH-223191), the majority of Th17 cell activity was shown to be dependent upon AhR ligation in all wild type mouse strains (C57BL/6, DBA and BALB/c), regardless of AhR affinity phenotype. Residual Th17 responses (IL-17A<sup>+</sup> cells and IL-17A and IL-17F mRNA and protein) were detected in all strains and in AhR null mice. These data demonstrate that natural ligands can stimulate Th17 development through the AhR and that also relative AhR affinity appears not to influence the impact of natural agonists on Th17 polarization. These data suggest that despite their low affinity receptor, endogenous AhR ligands could play a major role in driving human Th17 cell differentiation.

**PS 388 2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) Reduces *Leishmania major* Burdens in Mice but Not in Macrophages *In Vitro*.**

R. E. Teagarden, J. L. Lenberg, A. R. Dunn and G. K. DeKrey. *Biological Sciences, University Northern Colorado, Greeley, CO.*

A previous study by Bowers et al. (*Am. J. Trop. Med. Hyg.*, 75: 749, 2006) reported significantly lower parasite burdens in *L. major*-infected C57BL/6 mice when pre-treated with TCDD at a dose of 40  $\mu$ g/Kg or higher. This result was unexpected

given that 1) TCDD suppresses T helper cell responses in mice, and 2) resistance to *L. major* infection in mice normally depends upon appropriate T helper cell function. To explain this, we hypothesized that TCDD reduces *L. major* burdens in mice by a mechanism that does not involve T cells. Severe combined immunodeficient (SCID) mice were treated with peanut oil or TCDD (50 or 200  $\mu$ g/Kg) one day prior to infection with 10<sup>4</sup> stationary phase *L. major* promastigotes. A dose- and time-dependent reduction of lesion size and lesion parasite numbers was observed with the greatest effect on day 45 in the highest dose group: 12% of control ( $p < 0.05$ ) and 2% of control, respectively. These results suggested that T cells are not required for reduced *L. major* burdens in TCDD-treated mice. Because macrophages are the primary host cell for *L. major* *in vivo*, we hypothesized that TCDD reduces *L. major* burdens in mice by inhibiting macrophage infection. Using a WST-1 cell viability assay and mouse RAW 264.7 cells, we found that TCDD exposure (0 or 10<sup>-10</sup> to 10<sup>-7</sup> M for up to 48 hours) did not significantly change macrophage viability. Using light microscopy and starch-elicited C57BL/6 mouse peritoneal macrophages, we found that TCDD exposure (0 or 10<sup>-10</sup> to 10<sup>-7</sup> M for 48 hours) did not significantly change the number of intracellular parasites (4.2 *L. major*/infected macrophage, overall) at 24 hours after infection with stationary phase promastigotes. These results suggest a mechanism other than altered parasite uptake by macrophages or macrophage cytotoxicity to explain reduced parasite burdens in TCDD-treated mice.

**PS 389 Carbamate Pesticides Induce Apoptosis in Human NK-92CI Cells.**

Q. Li, M. Kobayashi and T. Kawada. *Department of Hygiene and Public Health, Nippon Medical School, Tokyo, Japan.*

Purpose:

Carbamate pesticides are widely used throughout the world in agriculture as fungicides and insecticides. We previously found that ziram, a dithiocarbamate fungicide, significantly inhibited natural killer (NK) activity in a dose-dependent manner (1). To explore the mechanism of carbamate pesticide-induced inhibition of NK activity, we investigated carbamate pesticide-induced apoptosis and its underlying mechanism in human NK cells.

Methods:

NK-92CI cells, a human NK cell line, were treated with carbaryl (insecticide), maneb (fungicide), thiram (fungicide), and ziram (fungicide) at different concentrations for 2-24 h at 37°C. Apoptosis was determined by FITC-Annexin-V/PI staining. To explore the mechanism of apoptosis, intracellular levels of active caspases 3 and mitochondrial cytochrome-c release were determined by flow cytometry (2-3).

Results and Conclusions:

Ziram and thiram significantly induced apoptosis in NK-92CI cells in a dose- and time-dependent manner. Maneb also significantly induced apoptosis in NK-92CI cells at higher concentrations (more than 20  $\mu$ M). On the other hand, carbaryl, a carbamate insecticide, showed a very weak effect on apoptosis in NK-92CI cells even at 40  $\mu$ M. Moreover, ziram and thiram significantly increased the intracellular level of active caspase 3 and Z-VAD-FMK, a caspase inhibitor, partially but significantly inhibited the apoptosis, respectively. Ziram and thiram also significantly caused mitochondrial cytochrome-c release. These findings indicate that carbamate pesticides can induce apoptosis in NK-92CI cells, and the apoptosis is mediated by both the caspase-cascade and mitochondrial cytochrome-c pathways. The strength of the apoptosis-inducing ability differed among these pesticides, and the order was as follows: thiram, ziram > maneb > carbaryl.

**PS 390 PCB126 Inhalation Reduces the Number and Function of Lymphocytes in Rats.**

A. B. Shimada, W. S. Cruz, A. Nakasato and S. H. Farsky. *Clinical and Toxicological Analysis, University of São Paulo, São Paulo, Brazil.* Sponsor: S. Moraes Barros.

Polychlorinated biphenyls (PCBs) are persistent organic pollutants and ubiquitous environmental contaminants that resist to degradation and accumulate in the food-chain. PCB126 was widely used in industrial processes and is the most potent aryl hydrocarbon receptor agonist. Once respiratory tract is an important pathway of PCB 126 absorption, this work aimed to investigate the effects caused in the immune system by PCB126 inhalation in rats. Male Wistar rats were exposed to

PCB126 at doses of 0.1; 1 or 10 µg/kg of body weight, for 15 days, by nasal instillation. Control animals were exposed to vehicle (saline + 0.5% DMSO). Five hours following the last exposure, animals were killed and bone marrow and blood leukocytes were evaluated as following: a) total number cells by hemocytometer; b) differential bone marrow cells were evaluated by anti-granulocyte, CD3 and CD45R expression analyzed by flow cytometer and differential leukocyte blood cells were quantified in stain smear; c) the expression adhesion molecules on circulating lymphocytes membranes were evaluated by flow cytometer at basal or *in vitro* fMLP stimulation conditions (N-formyl-methionine-leucine-phenylalanine; 10-8M; 1 hour). All the experiments were conducted according to Ethics Committee in Animal Experiments approved by protocol number CEUA/FCF/315. Exposure to 10 µg/kg of PCB126 reduced the number of total circulating leukocytes and bone marrow cells, which reflected reduced CD45 labeled lymphocytes in the bone marrow cells and lymphocytes in the blood. Exposure to 1 or 10 µg/kg of PCB126 reduced the expression of CD62L on circulating lymphocytes at basal conditions and *in vitro* fMLP stimulation impaired CD18 and CD31 expression in these cells. Our data indicates that PCB126 exposure modify the pattern of adhesion molecules expression by blood lymphocyte and it may affects the lymphocytes production, maturation or traffic between the body compartments. These effects may affect the host defense, as lymphocytes are pivotal cells in the immune response. Financial support: FAPESP and CNPq.

### PS 391 Alternariol Induces Differentiation of Macrophages.

A. Solhaug<sup>1</sup>, C. Wisbech<sup>1</sup>, T. E. Christoffersen<sup>2,3</sup>, L. Olsen<sup>2</sup>, T. Lea<sup>2</sup>, L. L. Vines<sup>4</sup>, J. Pestka<sup>4</sup>, J. A. Holme<sup>5</sup> and G. S. Eriksen<sup>1</sup>. <sup>1</sup>Norwegian Veterinary Institute, Oslo, Norway; <sup>2</sup>Norwegian University of Life Sciences, Ås, Norway; <sup>3</sup>Ostfold University College, Halden, Norway; <sup>4</sup>Michigan State University, East Lansing, MI; <sup>5</sup>Norwegian Institute of Public Health, Oslo, Norway.

Mycotoxins are often found, as contaminants of food and feed, and may pose a risk for disease in humans and animals. Mycotoxins sometimes aberrantly affect the immune system and cause immune stimulation as well as immune suppression. The fungi *Fusarium* and *Alternaria* often co-occur in grain, and mixtures of mycotoxins are often more potent than the level of the pure well known toxins (eg. the trichothecenes from *Fusarium*) would indicate. The objective of this study was therefore to examine the potential immune effects of a frequently co-occurring mycotoxin, alternariol (AOH; *Alternaria* toxin). RAW 264.7 mouse macrophages as well as primary peritoneal mouse macrophages and human primary macrophages were therefore used as a model system. AOH was found to induce DNA damage, abnormal nuclei and cell cycle arrest in RAW 264.7 cultures. However, only low levels of cell death were observed. Instead the cells were found to change morphology into star-shaped cells, with increased expression of several cell surface receptors (CD80, CD11b, MHCII) increased TNF-alpha secretion as well as increased endolytic activity. Interestingly, the cells entered a senescent state after prolonged AOH exposure, possibly as a response to the different stresses induced by this mycotoxin. In contrast to RAW 264.7, peritoneal mouse macrophages and human primary macrophages do not proliferate in culture and as a likely consequence, did not exhibit abnormal nuclei upon AOH exposure. Interestingly, AOH was found to change the morphology and most of the cells got a dramatically elongated or a star-like shape, with no increase in cell death which is possibly associated with phenotypic changes. AOH-induced differentiation of macrophages might contribute in part to the observed effects of mycotoxins mixtures on the immune system.

### PS 392 Analysis of Epigenetic Reprogramming of CD8<sup>+</sup> T Cell Responses by Developmental Aryl Hydrocarbon Receptor Activation.

B. Winans<sup>1</sup>, A. Nagari<sup>2</sup>, M. Chae<sup>2</sup>, W. Kraus<sup>2</sup> and B. Lawrence<sup>1</sup>. <sup>1</sup>University of Rochester Medical Center, Rochester, NY; <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX.

The developing immune system is susceptible to environmental insults, leading to altered immune function later in life. The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor that acts as an environmental sensor and binds many dioxins and polychlorinated biphenyls (PCBs), pollutants to which humans are constantly exposed. AhR also plays a role in the development and function of the immune system. Human and animal data demonstrate that early life exposure to AhR-binding ligands leads to persistent alterations in immune function, supporting the idea that inappropriate AhR activation influences the developing immune system. In order to study the susceptibility of the immune system to perturbation by AhR signaling, our laboratory uses 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) as a model developmental immunotoxicant and influenza A virus as a prototypical human pathogen. Mice exposed to TCDD during development have persistently reduced clonal expansion and differentiation of CD8<sup>+</sup> T cells. This

functional alteration is due to direct AhR signaling in the offspring, and results from a direct effect on hematopoietic cells. Furthermore, this altered function occurs without detectable changes in lymphoid organ cellularity or the distribution of immune cell subpopulations in naïve animals. These findings suggest the novel idea that inappropriate activation of AhR influences the epigenetic regulation of the developing immune system, leading to persistent changes in immune function. To test this idea directly we have examined genome-wide DNA methylation patterns in naïve and activated CD8<sup>+</sup> T cells isolated from developmentally exposed mice, and correlated these with changes in gene expression. These novel data provide an important framework for understanding how changes in epigenetic marks, cued by developmental exposure, may affect gene expression and T cell function.

### PS 393 DES and Methoxychlor Metabolite, HPTE, Induction of Cell Death and Alteration of Thymocyte Development: Timing of Induction of Apoptosis.

C. Broussard, L. Leung Liu, C. Zambrano, F. Mourad, Z. Muscato and P. Escalante. *Biology, University of La Verne, La Verne, CA.*

Estrogen and putative endocrine-disrupting chemicals, such as diethylstilbestrol (DES) and methoxychlor, induce death of thymocytes and alter T cell development. Such alterations have the potential to profoundly affect the functioning of the immune system in the long term, particularly when they occur during gestation. We have previously shown that exposure of embryonic thymocytes to two EDCs, DES and hydroxyphenyl-trichloroethane (HPTE; the primary physiological metabolite of methoxychlor), results in death of the thymocytes and alteration of the development of T cells. We undertook the current study to elucidate the mechanism of action of DES and HPTE. C57BL/6 embryonic thymocytes were cultured in the presence of DES or HPTE in an assay that mimics the *in vivo* process of positive selection. Using Annexin V and propidium iodide staining we identified the time course for induction of cell death in the treated thymocytes. By six hours of treatment with DES or HPTE, thymocytes began to express markers of apoptosis, Annexin V+ and PI-. In addition, we assessed the induction of caspase activity, a later event in the apoptotic pathway. The induction of caspase activity distinguished the cell death we observed from other forms of cell death including necrosis and necroptosis. Our results suggest that death induced by DES and HPTE is rapid (beginning by 6 hours of exposure) and caspase-dependent, hallmarks of signal-mediated death induction.

### PS 394 Genetic Alterations by Prenatal Exposure to Mercury.

K. L. Kracke, D. L. Shirley and J. F. Nyland. *Pathology, Microbiology & Immunology, University of South Carolina School of Medicine, Columbia, SC.*

**Background:** Mercury (Hg) is an ubiquitous environmental toxicant which bioaccumulates and can produce many biological effects, including on the nervous and immune systems. Because Hg can cross the placenta and concentrates in the fetal compartment, the developing fetus is particularly vulnerable. We hypothesize that developmental exposure to Hg will cause immunological changes, leading to an increased susceptibility to, or exacerbation of, immune disorders later in life. Therefore, we exposed pregnant female mice to low doses of Hg for a short duration and examined the genetic effects related to immune function in the offspring. **Methods:** Pregnant BALB/c mice were exposed to Hg (200 µg/kg HgCl<sub>2</sub> in PBS by subcutaneous injection) or vehicle control every other day from gestation day (GD) 5 to GD15. Female offspring remained with the dam until weaning and were euthanized at 8 weeks of age with no further exposures to Hg. Splenic RNA was isolated using RNeasy (Qiagen), then gene expression changes quantitated by microarray (Affymetrix). Gene expression data were analyzed with GeneSpring and differences in expression levels interrogated through Ingenuity Pathway Analysis software.

**Results:** We found that a number of genes were differentially expressed when mice were prenatally exposed to Hg. Focusing on cytokines, macrophage activation, and regulatory T cells, we found that expression of IL-1, CTLA4, CX3CL1 and IGHM was upregulated at least two fold with prenatal Hg exposure.

**Discussion:** In this project, we demonstrate that prenatal Hg exposure can produce lasting programming changes in the immune system. Increased expression of pro-inflammatory cytokine IL-1 has been associated with autoimmune disorders, while pro-inflammatory chemokine CX3CL1 has been associated with microglial (macrophage-lineage cells of the brain) activation. These changes may increase the

risk of developing autoimmune disorders or the possibility of exacerbating existing immune disorders later in life. Future studies will include examining sex differences in the effects of prenatal Hg exposure effects.

### PS 395 Cannabinoid Receptors and PPAR-Gamma Interactions in Endocannabinoid-Modulated Differential CD8<sup>+</sup> T Cell Responses.

S. T. Pike<sup>1</sup>, R. B. Crawford<sup>1</sup>, B. L. Kaplan<sup>1,2</sup> and N. E. Kaminski<sup>1,2</sup>. <sup>1</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Endogenous cannabinoids (endocannabinoids), eg, anandamide (AEA), bind cannabinoid receptors, CB1 and CB2, and modulate immune responses. In addition, PPAR $\gamma$ -dependent but cannabinoid receptor-independent suppression of immune responses has been reported by endocannabinoids; however, the relationship between cannabinoid receptor-dependent and independent events is poorly characterized. In addition, phytocannabinoids, but not endocannabinoids, have been shown to both enhance and suppress immune function. Using AEA and an in vitro model mimicking the CD8<sup>+</sup> T cell response to early HIV infection, we are seeking answers to two questions: 1) Do endocannabinoids differentially modulate CD8<sup>+</sup> T cell responses? and 2) What roles do cannabinoid receptor-dependent and independent signaling play in these effects? In this model, the percentage of interferon-gamma (IFN $\gamma$ ) producing CD8<sup>+</sup> T cells activated by a HIVgp120-expressing antigen presenting cell line is measured. These studies showed that in the presence of sub-optimal activation (Vh groups <28% CD8<sup>+</sup>IFN $\gamma$ <sup>+</sup> cells), AEA significantly (~10%) enhanced IFN $\gamma$  production. Under supra-optimal activation conditions (>68%), the CD8<sup>+</sup> T cell response decreased by ~5%. If activation was optimal (between 28% and 68%), little AEA-effect was observed. In addition, enhanced responses were AEA concentration-dependent. Using CB1-/-/CB2-/- mice, an increased baseline CD8<sup>+</sup> T cell response (~8%) was observed compared to wild type mice, but an AEA-induced increase above this response was not evident. Surprisingly, addition of a PPAR $\gamma$  antagonist over a range of activation levels was additive (~5%) to AEA-induced T cell effects. Overall, our results show endocannabinoids differentially modulate immune responses with cannabinoid receptors involved in the initial activation of CD8<sup>+</sup> T cells. In addition, the AEA effects were PPAR $\gamma$ -dependent. (Supported in part by R01DA020402 & F32DA030167)

### PS 396 Perinatal Exposure to Bisphenol A through Maternal Diet Alters Allergen-Induced Lung Inflammation in Adult Offspring.

E. O'Brien<sup>1</sup>, D. Dolinoy<sup>1</sup>, M. Peters-Golden<sup>2</sup>, Z. Zaslona<sup>2</sup> and P. Mancuso<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, MI; <sup>2</sup>Internal Medicine, School of Medicine, University of Michigan, Ann Arbor, MI.

Bisphenol A (BPA), a monomer of polycarbonate plastics and epoxide resin, is a high production volume chemical that has been implicated in asthma pathogenesis when exposure occurs to the developing fetus. However, few studies have examined the effect of in utero and early-life BPA exposure on the pathogenesis of asthma in adulthood. Using an allergen-induced model of asthma, we examined whether perinatal BPA exposure through maternal diet alters lung inflammation in adult offspring by measuring cellular recruitment, cytokine production, lipid mediator production, and serum IgE levels. Two weeks before mating, BALB/c dams were randomly assigned to a diet containing low (50 ng BPA/kg diet), medium (50  $\mu$ g), or high (50 mg) levels of BPA or a BPA-free control diet. Dams remained on the assigned diet throughout gestation and lactation until postnatal day 21 when offspring were weaned onto the BPA-free diet. Twelve-week-old offspring were sensitized to ovalbumin with alum by intraperitoneal injection and subsequently challenged with aerosolized ovalbumin to induce an allergic inflammatory response. Offspring exposed to medium or high levels of BPA exhibited increased serum anti-ovalbumin IgE levels compared to controls, while animals exposed to the low dose displayed increased lymphocyte recruitment, RANTES production, and TNF- $\alpha$  and IFN- $\gamma$  production from splenocytes. Offspring exposed to low or high doses of BPA exhibited decreased macrophage, neutrophil, and eosinophil recruitment and decreased production of TNF- $\alpha$ , IFN- $\gamma$ , IL-4, IL-13, cysteinyl leukotrienes, and prostaglandin D2. Our data show that perinatal BPA exposure has quantitatively different effects on various measures of allergen-induced inflammation. These data indicate that perinatal BPA exposure does not worsen allergen-mediated inflammation in the adult lung, but suggests that exposure may increase inflammation on a systemic level.

### PS 397 Direct Evidence of Altered Conformation and Evidence for a Binding Site on TLR3 for Ethanol at Relevant Concentrations.

S. B. Pruett<sup>2</sup>, V. Le<sup>1</sup>, E. Lewis<sup>1</sup>, S. Gwaltney<sup>1</sup>, B. Manikantan<sup>1</sup> and A. Shack<sup>2</sup>. <sup>1</sup>Chemistry, Mississippi State University, Mississippi State, MS; <sup>2</sup>Basic Sciences, Mississippi State University, Mississippi State, MS.

The mechanism by which ethanol causes a complex array of changes in animal models and humans has been vigorously debated and investigated for more than 50 years. Some progress has been made on the direct effects of ethanol on conformation and function of receptors for neurotransmitters, which apparently cause many of the neurological effects of ethanol. However, there has been no similar investigation of any component of the immune system. We selected TLR3 for this purpose because its 3-dimensional structure has been published, it forms dimers in solution in the presence of ligand which is also the initial event in signaling in vivo, the cytokines and other inflammatory mediators induced by this receptor are inhibited substantially by ethanol, and TLR3 plays an important role in innate immunity to viruses. We used molecular docking software (Autodock 4.2) to determine that there is a highly probable binding site for ethanol in both human and mouse TLR3, and they are at different locations. They are not within the ligand binding region of the molecule, so they should not directly affect ligand binding (though indirect effects are possible). We used circular dichroism to evaluate the dose-response effects of ethanol on the conformation of human or mouse TLR3 with ligand (poly I:C). The difference in rotation of light (millidegrees) in control and ethanol treated samples at 220 nm exhibits a biphasic concentration-response pattern with a peak at ~40 mM (a concentration which is not uncommon in human binge drinkers) and the lowest value at ~80-100 mM (a near lethal concentration of ethanol). The concentration at the peak of the response curve is near the binding constant calculated by the docking software, suggesting that conformational change may be related to the ethanol binding site on TLR3. This is the first report that ethanol at relevant concentrations alters the conformation of an immunological receptor.

### PS 398 Developmental Aryl Hydrocarbon Receptor (AhR) Activation Attenuates Hematopoietic Stem Cell (HSC) Capacity to Undergo Lymphocyte Differentiation.

L. Ahrenhoerster, P. A. Lakatos and M. D. Laiosa. Zilber School of Public Health, University of Wisconsin—Milwaukee, Milwaukee, WI.

HSCs are the foundational cells of the blood system, responsible for balancing self-renewal and differentiation into mature effector cells. Environmental exposures to the HSCs in utero can profoundly affect future development of immune diseases. Indeed, transplacental exposure to 2,3,7,8 Tetrachlorodibenzo-p-dioxin (TCDD) leads to numerous later-life immunological deficits. TCDD mediates this developmental immunotoxicity by binding to and activating the AHR, which is an important regulator of immunological development and function. Given the centrality of hematopoiesis in immune development throughout the life-course, we investigated the effect AHR activation by TCDD has on murine HSCs. Since it is known that the AHR maintains HSCs in a state of non-proliferative quiescence, we hypothesized that persistent developmental AHR activation modulates HSC differentiation capacity and self-renewal ability. To test this hypothesis, pregnant dams were exposed to 3  $\mu$ g/kg TCDD or vehicle control. On gestational day 14.5, lineage negative, cKit<sup>+</sup>, Sca-1<sup>+</sup> (LSK) cells were harvested, quantified, and placed into T-lymphocyte differentiation cultures using a limiting dilution approach. We found approximately 2.5 fold more LSKs present in fetuses exposed to TCDD in utero. Measuring potential, we found approximately 1 in 17 vehicle-exposed LSKs had the capacity to undergo T-cell differentiation while only 1 in 39 did if developmentally exposed to TCDD. These effects are mediated by the AHR in the individual fetuses as supported by studies conducted in offspring from AHR<sup>+/+</sup> crosses. Specifically, the T-cell differentiation potential of LSKs from TCDD-exposed AHR<sup>-/-</sup> fetuses approximates that of vehicle-exposed wild type LSKs. Conversely, the TCDD-exposed AHR<sup>+/+</sup> and AHR<sup>+/+</sup> siblings produce LSKs with a diminished T-cell precursor potential. These data suggest that developmental AHR activation in HSCs reprograms the balance between self-renewal and differentiation, potentially affecting future immune system development and function.

**PS 399 Immunotoxicity of the Nasal Associated Lymphoid Tissue Induced by the Black Mold Toxin Satratoxin-G in Rhesus Monkeys.**

S. A. Carey<sup>1</sup>, V. M. Takala<sup>1</sup>, D. M. Hyde<sup>2</sup>, J. Pestka<sup>1</sup> and J. Harkema<sup>1</sup>.  
<sup>1</sup>Michigan State University, East Lansing, MI; <sup>2</sup>University of California Davis, Davis, CA.

Damp Building-Related Illnesses (DBRI) include many respiratory and immunological symptoms etiologically linked to exposure to *Stachybotrys chartarum*, a black mold that grows in water-damaged indoor environments. The mechanisms by which airborne exposure to *S. chartarum* causes immune dysfunction remain poorly understood. Epidemiological evidence suggests that children may be particularly vulnerable to the harmful effects of airborne toxicants. To assess the potential risk of nasal injury and immunotoxicity in children, we developed an *in vivo* model of intranasal mycotoxin exposure in juvenile monkeys, whose nasal airways are morphologically and functionally similar to those of children. We recently reported that intranasal exposure to Satratoxin-G (SG), a trichothecene mycotoxin produced by *S. chartarum*, causes apoptosis of olfactory sensory neurons. The present study tests the hypothesis that intranasal exposure to SG causes apoptosis of the nasal associated lymphoid tissue (NALT). Juvenile male rhesus macaques received either a single intranasal instillation of 20 µg SG (n=3), or daily instillations of 5 µg SG (n=3) for four consecutive days in the right nasal passage. Saline vehicle was administered to the left nasal passage. Left and right nasal passages were sectioned and preserved for light microscopic, immunohistochemical, and morphometric analyses of the NALT. Both single dose and repeated dose exposure to SG caused atrophy of the NALT, resulting in a 19% (single) and 70% (repeated) reduction in the area of NALT along the nasal septum in the SG-exposed nasal passages, compared to the respective saline-exposed nasal passages. NALT apoptosis was identified morphologically and using immunohistochemistry for caspase-3. SG exposure caused a 2.75-fold increase in caspase-3 immunoreactivity in septal NALT compared to saline exposure. The results in this model provide new insight into a potential mechanism of immune dysregulation associated with exposure to damp indoor environments.

**PS 400 Prenatal Exposure to Benzo(a)pyrene Confers an Enhanced Susceptibility of Macrophage Membranes to Microbial Infection.**

R. S. Clark<sup>1</sup>, A. Ramesh<sup>2</sup>, M. Maguire<sup>1</sup> and D. B. Hood<sup>1</sup>. <sup>1</sup>Neuroscience and Pharmacology, Environmental Health Disparities and Medicine, Center for Molecular and Behavioral Neuroscience, Meharry Medical College, Nashville, TN; <sup>2</sup>Biochemistry and Cancer Biology, Meharry Medical College, Nashville, TN.

The purpose of this study was to elucidate the mechanism of benzo(a)pyrene, [B(a)P]-induced immune suppression by determining whether exposure suppresses macrophage function and alters membrane components to increase susceptibility to infection. C57BL and SCID times pregnant dams were exposed to varying concentrations of B(a)P by oral gavage on embryonic days 14-17. An *ex vivo* macrophage experimental model system was generated from offspring spleen where monocyte differentiation, phagocytic activity, ROS production and modulation of lipid raft cholesterol homeostasis were quantified. Exposure-induced modulatory effects on differentiation was quantified by adhesion assays in the presence or absence of GM-CSF then verified using CD11, F4/80 antibodies and a WST-1 assay. Macrophage respiratory burst activity detection was performed by incubating PMA-stimulated macrophages with dihydrorhodamine, an ROS intermediate sensitive probe. ROS intermediate production was measured by flow cytometry. To determine whether B(a)P modulates lipid raft homeostatic cholesterol levels, lipid rafts from cultured macrophages were isolated by discontinuous sucrose gradient centrifugation and the lipid fractions were verified by CD59 and CD55, two lipid raft proteins. In parallel the fractions were analyzed by HPLC for B(a)P metabolites. The preliminary results demonstrate that *in utero* B(a)P exposure suppresses macrophage functional indices and alters macrophage lipid raft cholesterol levels in offspring. Future studies are directed at establishing whether B(a)P increases macrophage susceptibility to microbial infection.

**PS 401 The CpG Adjuvant Increases Immune Responses to Ovalbumin (OVA) following Sublingual Immunization in C57/BL6 Mice.**

L. A. Coney<sup>3</sup>, A. Parlapiano<sup>2</sup>, A. Curran<sup>5</sup>, G. Bannish<sup>4,1</sup>, M. Perpetua<sup>1</sup>, J. Doughty<sup>1</sup>, A. Beavis<sup>1</sup> and E. Dadey<sup>2</sup>. <sup>1</sup>Biologics and Biomarker Analysis, Huntingdon Life Sciences, East Millstone, NJ; <sup>2</sup>MonoSol Rx, LLC, Warren, NJ; <sup>3</sup>Group Strategic Marketing, Huntingdon Life Sciences, Huntingdon, United Kingdom; <sup>4</sup>Group Strategic Marketing, Huntingdon Life Sciences, East Millstone, NJ; <sup>5</sup>Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ.

The sublingual route of administration has been demonstrated to modulate humoral responses. A protease resistant, phosphorothioate CpG oligonucleotide induces TH1 immune responses through a TLR9-mediated activation of B lymphocytes and dendritic cells and was used as an adjuvant to evaluate its utility in sublingual immunizations. Mice were immunized sublingually with either 4.0ug or 175ug ovalbumin in the presence of 0.5ug or 8.8ug CpG adjuvant on up to 4 occasions (Days 1, 8, 22, 29) and terminated on Day 36. As a control, additional cohorts of animals were treated with vehicle or dosed intraperitoneally (i.p.) with ovalbumin in incomplete Freund's adjuvant (IFA), or ovalbumin in CpG adjuvant. Robust immune responses were observed in the control animals with either IFA or CpG adjuvant on Days 22 and 36. No antibody responses specific to OVA were observed with sublingual dosing on Day 22 in both groups and on Day 36 with 4.0ug OVA and 0.5ug CpG. In contrast, detectable specific antibody responses to OVA were observed on Day 36 with sublingual dosing of 175ug OVA and 8.8ug CpG in 3 of 4 animals. The response was clearly positive but notably lower in magnitude compared to i.p. immunization. Flow cytometry evaluation of B lymphocyte subsets, NK lymphocytes, and T lymphocyte subsets in the spleen revealed no detectable systemic changes. Finally, ELISpot evaluation of splenic cells stimulated with an OVA peptide generated detectable responses in 2 of 4 animals in both the control group using CpG adjuvant and high dose sublingual group. In conclusion, these results are consistent with the known TH1 effects of the CpG adjuvant in C57/bl6 mice and demonstrate the ability to generate a humoral response via sublingual immunization under these conditions.

**PS 402 Effects of Early Life Farm Exposure on Phenotype and Functional Properties of Dendritic Cells and Contribution to the Risk of Disease.**

H. Kääriö<sup>1</sup>, J. Nieminen<sup>2</sup>, K. Huttunen<sup>1</sup>, M. Hirvonen<sup>1,3</sup>, J. Pekkanen<sup>3</sup>, O. Vaarala<sup>2</sup> and M. Roponen<sup>1</sup>. <sup>1</sup>Environmental Science, University of Eastern Finland, Kuopio, Finland; <sup>2</sup>Viral Diseases and Immunology, National Institute for Health and Welfare, Helsinki, Finland; <sup>3</sup>Environmental Health, National Institute for Health and Welfare, Kuopio, Finland. Sponsor: M. Viluksela.

Dendritic cells (DCs) are the major antigen presenting cells that play a central role in the induction of the cellular immune response. Exposure to farm-associated microbes might alter DC numbers or accelerate their maturation, thereby enhancing the development of healthy immune tolerance that would protect against allergic sensitization and disease. In early childhood still immature DCs are very susceptible to environmental exposure. Therefore, the objective of this study was to investigate if numbers or functional properties of DCs in 4.5 year old Finnish children (a selected part of a European birth cohort study, EFRAIM) are associated with the farm exposure and/or atopic outcome. Myeloid DC1 (mDC1, CD11c<sup>+</sup>CD11c<sup>+</sup>), mDC2 (CD141<sup>+</sup>), plasmacytoid DC (pDC, CD123<sup>+</sup>CD303<sup>+</sup>), monocytes (CD14<sup>+</sup>), functional markers (CD80, CD86, TLR4) and intracellular cytokines (IL-6, TNF-α) were analyzed by flow cytometry per se and following 6 hour stimulation with lipopolysaccharide. The frequency of subpopulation mDC1 was lower in non-asthmatic children who had lived in farm environment, as compared to non-farmer children. Also, lower frequency of pDC subpopulation was associated clearly with food atopy. Consequently, the ratio of pDC/mDC1 was lower in children with food atopy. Other associations between DC phenotype/function and atopy were more complicated and dependent on the type of the atopy/sensitisation and the selected IgE cut-off concentration. The main conclusions are that 1) the farm exposure seems to reduce the frequency of circulating mDC1 cells, possibly affecting the antigen-presenting function of the exposed children, 2) the reduced number of pDC cells predisposes children to the development of food atopy and 3) the definition of atopy is crucial when associations between DCs and atopy are studied.

**PS 403 Role of PKC Beta in Allergen-Induced CD86 Expression and IL-8 Release in THP-1 Cells.**

V. Galbiati, M. Marinovich, E. Corsini and C. L. Galli. *DiSFeB, Università degli Studi di Milano, Milan, Italy.*

Protein kinase C (PKC) is a family of twelve serine-threonine kinases, involved in signal transduction of hormones, neurotransmitters, and cytokines. We have found an age-related alteration in PKC signaling and TNF- $\alpha$  release in epidermal cells exposed to different stimuli, including contact allergen DNCB. We demonstrated an age-related decrease in the receptor for activated C kinase (RACK-1) expression, which underlies defective PKC  $\beta$  activation and age-related functional deficit in Langerhans cells (LC) responsiveness (1). It has been indeed demonstrated that LC cannot migrate from the epidermis when PKC  $\beta$  is inhibited, indicating that PKC  $\beta$  transduces the signal for migration of LC from the epidermis (2).

The purpose of this study was to investigate the role of RACK-1 and PKC  $\beta$  in contact allergen-induced CD86 expression and IL-8 release. The human promyelocytic cell line THP-1 was used as surrogate of dendritic cells, while dinitrochlorobenzene (DNCB), p-phenylenediamine (PPD) and diethylmaleate (DEM) were used as reference allergens. CD86 expression was evaluated by FACS analysis and IL-8 release by commercially available ELISA. The selective cell-permeable inhibitor of PKC  $\beta$ , the specific kinase isoform interacting with RACK-1, and the broad PKC inhibitor GF109203X, completely prevented allergen-induced CD86 expression and significantly modulated the release of IL-8 (50% reduction). The use of a RACK-1 pseudosubstrate, which directly activates PKC, resulted in a dose-related increase in CD86 expression and IL-8 release. These effects were not due to cytotoxicity, as assessed by lactate dehydrogenase leakage, or to endotoxin contamination of RACK-1 pseudosubstrate, as assessed using polymyxin B. Overall, we demonstrate a role of PKC  $\beta$  and RACK-1 in allergen-induced CD86 expression and IL-8 production, confirming the pivotal role of PKC in immune cell activation.

**PS 404 Perfluorooctanoic Acid Exposure Suppresses T-Independent Antibody Responses.**

J. DeWitt<sup>1</sup>, N. Creech<sup>1</sup>, Q. Hu<sup>1</sup>, W. Williams<sup>2</sup> and R. Luebke<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, East Carolina University, Greenville, NC; <sup>2</sup>Cardiopulmonary & Immunotoxicology Branch, Research Triangle Park, NC.

Exposure to  $\geq 3.75$  mg/kg of perfluorooctanoic acid (PFOA) for 15d suppresses T-dependent antibody responses (TDAR), suggesting that T helper cells and/or B cells/plasma cells may be impacted. This study evaluated effects of PFOA exposure on the T cell-independent antibody response (TIAR) to dinitrophenyl-ficoll (DNP). Adult female C57BL/6 mice were given 0, 0.94, 1.88, 3.75, or 7.5 mg/kg of PFOA in drinking water for 15d and immunized with 1  $\mu$ g of DNP in 0.2 ml of sterile saline on d11 of dosing. Seven days after immunizations and 3d after dosing ended, animals were euthanized and bled; sera were evaluated for IgM anti-DNP titers by ELISA. PFOA exposure did not alter body or lymphoid organ weights. Mean (log2) IgM serum titers of animals dosed with  $\geq 1.88$  mg/kg PFOA were statistically suppressed, on average, by 10% relative to control responses. Splenic B and T cell subset phenotypes were evaluated in separate groups of animals dosed with 0, 3.75 or 7.5 mg/kg of PFOA for 10, 13, or 15d. Animals exposed for 13 or 15d were immunized with sheep erythrocytes on d11 of dosing. In animals exposed for 15d, the mean percentage of B cells was increased by all doses. Within the CD3+ T cell population, the following changes were observed in the mean percentage of cells: CD4+CD8- T cells were increased at doses of 3.75 and 7.5 mg/kg after 10, 13, and 15d of exposure; CD4+CD8+ T cells were increased after 13d of exposure across all doses relative to 10 and 15d of exposure; CD4-CD8+ and CD4-CD8- T cells had dose and duration interactions, with no clear effect of dose or duration of exposure. Overall, PFOA exposure did not reduce splenic B or T cell populations. Suppression of TDAR and TIAR, in the absence of obvious lymphocyte subpopulation loss, suggests that effects on humoral immunity are likely mediated, at least in part, by disruption of normal B cell/plasma cell function. This abstract does not represent EPA policy.

**PS 405 African Dust Fine PM Induce the Expression of GSTp, HO-1, IL-6 and IL-8 in BEAS-2B.**

R. I. Rodríguez<sup>1,2</sup> and B. D. Jiménez-Vélez<sup>1,2</sup>. <sup>1</sup>Biochemistry, University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico; <sup>2</sup>Center for Environmental and Toxicological Research, University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.

African dust travels seasonally across the Atlantic Ocean and impacts Puerto Rico increasing the airborne particulate matter (PM) load and the probability of developing an oxidant atmosphere over the Island. The impact of this global event on the general health of Puerto Ricans is still uncertain. We evaluated the generation of reactive oxygen species (ROS) by African dust (ADE) atmospheric load on bronchial epithelial cells (BEAS-2B). In addition, we also measured antioxidant [Glutathione-S-Transferase (GSTp); Heme Oxygenase 1, (HO-1)] and pro-inflammatory (Interleukins, IL-6 and IL-8) gene expressions in cells exposed to PM organic extracts. Cells were treated with extracts (50 $\mu$ g/ml) from ADE and Non-ADE and the contribution of metals determined using 50  $\mu$ M deferoxamine mesylate (DF). Cells were co-treated with N-acetyl-L-cysteine (NAC) to evaluate the extract oxidant capacity. The rate of ROS formation was monitored with 2'7 dichlorofluorescein diacetate for 2 hrs reading fluorescence every 15 min. Quantitative fluorogenic amplification of cDNA was performed using the TaqMan Gene Expression Assays. ADE and Non-ADE induce the generation of ROS, which was significantly reduced with DF. GSTp and HO-1 mRNA expression increased 6 and 8-folds respectively after 4 hrs with ADE extract treatment. The use of DF or NAC significantly reduced both GSTp and HO-1 expression. ADE extracts also induced IL-8 mRNA (7 folds) and IL-6 (5 folds) after 8 hrs. DF or NAC co-treatments similarly reduced cytokine expression confirming the importance of metals in the extracts. African dust arriving Puerto Rico increases local concentrations of trace elements and other constituents in ambient PM<sub>2.5</sub>, which generate ROS and induce the expression of antioxidant and inflammatory gene responses as demonstrated in vitro by the use of BEAS-2B. **PS 406 Aminogluthethimide-Induced Immune Changes and Idiosyncratic Drug Reactions.**

W. Ng and J. Uetrecht. Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.

Aminogluthethimide (AMG) is an aromatic amine aromatase inhibitor associated with a high incidence of idiosyncratic blood dyscrasias, especially agranulocytosis. Despite evidence for immune involvement, the mechanisms of idiosyncratic drug reactions (IDRs) are poorly understood. Animal models of IDRs represent an essential tool to study these reactions; however, like humans, treating animals with drug alone does not usually induce an IDR. Conversely, studying the lack of response may be crucial to understanding why only certain people develop an IDR to a specific drug. Therefore, the objective of this study was to characterize the immune response of Brown Norway rats treated with 125 mg AMG/kg/day and to determine whether immune suppression may prevent the induction of IDRs. An early increase in peripheral blood neutrophils in AMG-treated rats corresponded to changes in the bone marrow that were consistent with an increase in the myeloid cell population. Expression of CD62L on neutrophils decreased at both 24 and 48 hours after AMG treatment, which suggests neutrophil activation, and this was followed by elevated serum levels of Gro/KC and MCP-1. In the spleen, increased proliferation was observed in the white pulp after 14 days of AMG treatment, which was attributed to CD4+ T-cells; however, this may be a local response because it did not extend to the auricular lymph nodes. Furthermore, an early increase in IL-17-expressing CD4+ T-cells in the spleen of the AMG-treated was followed by increased expression of IL-10 after 48 hours, which could modulate the immune response. These results suggest that the major immune response to AMG involves the innate immune system. Although there is some evidence to suggest activation of an adaptive immune response, further investigation of how the innate and adaptive immune interact may provide a better understanding of the mechanisms of IDRs. This research was funded by grants from the Canadian Institutes of Health Research.

**PS 407 The Dermal Exposure to Silica Nanoparticles Induces IgE-Mediated Hypersensitivity.**

T. Hirai<sup>1</sup>, Y. Yoshioka<sup>1</sup>, H. Takahashi<sup>1</sup>, K. Ichihashi<sup>1</sup>, N. Nishijima<sup>1</sup>, T. Yoshida<sup>1</sup>, H. Nabeshi<sup>2</sup>, T. Yoshikawa<sup>1</sup>, S. Tsunoda<sup>3,4</sup>, K. Higashisaka<sup>1</sup> and Y. Tsutsumi<sup>1,3,4</sup>. <sup>1</sup>Laboratory of Toxicology and Safety Science, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan; <sup>2</sup>National Institute of Health Science, Tokyo, Japan; <sup>3</sup>Laboratory of Biopharmaceutical Research, National Institute of Biomedical Innovation, Osaka, Japan; <sup>4</sup>MEI Center, Osaka University, Osaka, Japan.

To fully utilize the potential benefits of nanomaterials (NMs), it is crucial to evaluate the hazard associated with NMs on human health. Previously, we reported that amorphous silica nanoparticles (nSPs), one of the most frequently used NMs in cosmetics, could penetrate the skin barrier and might have potential risk to enhance allergic responses (Hirai T et al. Part. Fibre Toxicol. 2012). Thus, to ensure the safety of nSPs, it is needed to investigate the effect of dermal exposure to nSPs on allergic diseases. Here, we identified hazard of dermal exposure to nSPs using atopic dermatitis (AD) model mice. The mixture of mite extract antigen (Dp) and nSPs with diameter of 30 nm (nSP30) were swabbed on upper back and both ears for 4 weeks. To evaluate whether nSP30 affects severity of Dp-induced AD, ear thickness and Dp-specific immune responses were measured. Dermal exposure to nSP30 did not affect Dp-induced ear swelling, indicating that nSP30 did not aggravate AD-like skin lesion. The levels of Dp-specific IgE were also not affected by dermal exposure to nSP30. In contrast, the level of Dp-specific IgG in nSP30 (Dp+) groups were significantly lower than those in Dp alone. Furthermore, we showed that the decrease of IgG levels in nSP30 (Dp+) groups induced IgE-mediated hypersensitivity in Dp-mediated anaphylaxis model. Recent epidemiologic study revealed that allergen exposure through the epidermis is important factor to initiate not only AD but also other allergic diseases such as asthma and food allergy. Considering our results together, it is important to examine the relationship between the dermal exposure to NMs and initiation of allergic diseases more precisely.

**PS 408 Effects of Clozapine on the Bone Marrow and Immune Cells in Rodents and Humans: Implications for Drug-Induced Agranulocytosis.**

A. R. Lobach and J. Uetrecht. *Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Clozapine is a very effective antipsychotic agent, but its use is limited by the risk of drug-induced agranulocytosis. At the start of treatment, the majority of clozapine patients display evidence of an inflammatory response paired with elevated neutrophil counts. These immune changes appear to be accompanied by changes in the bone marrow, specifically a faster release of neutrophils to the blood. To further investigate these immunomodulatory effects, studies were carried out in rats focused on the peripheral blood and bone marrow responses.

Methods: Rats were treated with clozapine for up to 10 days and bone marrow was collected at study endpoint. Flow cytometry was employed to measure changes in the balance of myeloid, lymphoid, and erythroid compartments in the bone marrow. Progenitor cell changes in vivo were assessed by the methylcellulose assay. Patient studies have been initiated in which the T cell response (ie. Th1/2, Th17, Treg) at the start of clozapine therapy will be monitored in the blood using flow cytometry.

Results: Clozapine treatment in rats was found to significantly elevate the number of mature myeloid cells in the bone marrow. This increase was found to be due to an upstream increase in the number of myeloid progenitor cells. Furthermore, these progenitor cells were observed to favor the formation of granulocyte (G) colonies over macrophage (M), or mixed GM colonies.

Conclusions: Clozapine alters the normal production of hematopoietic cells in the rat bone marrow by promoting the formation of granulocyte colonies. This is reflected in the blood as an increase in neutrophil counts, which is also observed in patients at the start of therapy. The mechanism of clozapine-induced agranulocytosis remains unclear; however, other studies suggest that it may be the result of clozapine-induced neutrophil apoptosis. Clozapine-induced agranulocytosis may occur in cases where this damage leads to an immune response, which doesn't resolve with tolerance. This research was supported by grants from the Canadian Institutes of Health Research.

**PS 409 A Mechanistic Analysis of Silica Nanoparticle-Induced Immune-Modulating Effect in Murine Dendritic Cells.**

H. Takahashi<sup>1</sup>, Y. Yoshioka<sup>1</sup>, T. Hirai<sup>1</sup>, K. Ichihashi<sup>1</sup>, N. Nishijima<sup>1</sup>, T. Yoshida<sup>1</sup>, H. Nabeshi<sup>2</sup>, T. Yoshikawa<sup>1</sup>, S. Tsunoda<sup>3,4</sup>, K. Higashisaka<sup>1</sup> and Y. Tsutsumi<sup>1,3,4</sup>. <sup>1</sup>Graduate School of Pharmaceutical Sciences, Osaka University, Laboratory of Toxicology and Safety Science, Suita, Japan; <sup>2</sup>National Institute of Health Science, Setagaya, Japan; <sup>3</sup>National Institute of Biomedical Innovation, Laboratory of Biopharmaceutical Research, Ibaraki, Japan; <sup>4</sup>Osaka University, MEI center, Suita, Japan.

Nanomaterials (NMs) exhibit unique physicochemical properties and innovative functions, and they are increasingly being used in a wide variety of fields. Ensuring the safety of NMs is now an urgent task. Recently, we reported that amorphous silica nanoparticles (nSPs), one of the most widely used NMs, induced immune modulating effect via the cross-presentation (CP) in murine dendritic cells (DCs). Here we investigated the mechanism of nSP-induced CP in DCs for the development of safer nSPs. It is known that CP is induced by internalized antigens entered the cytosol via endosomes, and these antigens are then degraded by proteasomes. To examine whether this pathway is necessary for nSP-induced CP, we investigated the effect of the potent proteasome inhibitor lactacystin on nSP-induced CP. Lactacystin treatment strongly inhibited nSP-induced CP. In addition, we analyzed the effect of cellular uptake of nSPs on the induction of CP. Because some reports have shown that scavenger receptor (SR) was related to the uptake of nSPs, we examined nSP-induced CP after treatment with Poly I, which is a SR inhibitor. nSP-induced CP was inhibited with Poly I treatment. These results suggest nSPs enhanced CP in proteasomes- and SR-dependent manner. We believe a detailed analysis of the mechanisms of nSP-induced CP will be invaluable for the design of safe nSPs.

**PS 410 Programmed Death-1 Receptor Interactions with Its Ligands May Play a Role in Inhibiting Drug-Induced Liver Injury Mediated by the Adaptive Immune System.**

K. Semple, P. Ryan, M. Chakraborty, W. R. Proctor and L. Pohl. *Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, National Heart, Lung and Blood Institute, Bethesda, MD.*

Although clinical evidence suggests that many cases of serious idiosyncratic drug-induced liver injury (SIDILI) are mediated by hepatic protein adducts of drugs and the adaptive immune system, detailed experimental proof for this mechanism of toxicity has remained elusive due to the lack of animal models. We have hypothesized that SIDILI is as rare in animals as it is in humans due at least in part to the tolerogenic nature of the liver, which consists of multiple negative regulators of the adaptive immune system. One negative regulatory pathway that may play a role in modulating the incidence of SIDILI involves the interaction of programmed death-1 receptor (PD-1) on the surface of activated T and B cells with its ligands (PD-L1 and PD-L2) found on a variety of other cells. This possibility has now been tested in an established murine model of halothane-induced liver injury. Twenty-four hours after female Balb/cJ mice were treated with halothane, analysis of the liver revealed perivenous necrosis and an infiltration of CD4+ and CD8+ T cells as well as neutrophils and eosinophils determined by flow cytometry. Further study revealed that T cells expressed PD-1 on their surface, while neutrophils and eosinophils too a lesser extent expressed PD-L1, but not PD-L2 on their surface. These findings suggest that neutrophils may play a role in directly regulating the adaptive immune system. This possibility can be tested in vitro and in vivo by modulating the activities PD-L1 and PD-1 and may have a role in determining susceptibility to SIDILI that is mediated by cells of the adaptive immune system.

**PS 411 In Vitro Characterization of Immunostimulation by siRNA-Lipid Nanoparticles.**

P. Kasperkovitz, R. Duncan, B. Bettencourt, J. Harrop, G. Warner and S. Barros. *Amylam, Cambridge, MA.*

The treatment of human diseases using RNA interference (RNAi) therapeutics requires efficacious and safe delivery of short interfering RNA (siRNA) to target tissues. A well-established strategy for systemic delivery is formulation of siRNA in lipid nanoparticles (LNP). Our current multi-component lipid formulation has been shown to be highly efficient for liver delivery and silencing of therapeutically relevant gene targets. Similar to liposomal drug products, siRNA-LNP delivery can also cause minor transient increases in serum cytokines or complement activation in a small subset of patients. The aim of this study was to systematically assess factors influencing cytokine responses to siRNA-LNP *in vitro* to obtain insight into the mechanistic basis of immunostimulation. We established a consistent healthy

blood donor pool that gave us the unique opportunity to analyze both population heterogeneity and response consistency by repeat-characterization of single donors (41 donors, mean 3.7 visits per donor). Whole blood was incubated *in vitro* with siRNA-LNP and plasma levels of 13 cytokines were determined using multiplex analysis. As anticipated, we observed considerable variability in cytokine responses between donors. For large-scale analysis of 13-dimensional cytokine data, we applied Principal Component Analysis (PCA) to reduce redundancy among variables and to identify data patterns. We found that Principal Components 1 and 2 captured ~85% of variance in our dataset. Moreover, individual donors could be sub-classified into three categories (High, Intermediate, Low) based on responsiveness to siRNA-LNP. Using an algorithm to analyze the reliability of our subclassification, we demonstrated that donor sensitivity to *in vitro* siRNA-LNP immunostimulation was consistent over time. Our data suggest that the observed heterogeneity in sensitivity to siRNA-LNP immunostimulation is due to stable, intrinsic immune differences.

#### **PS 412 Characterization of Suppression of the Innate Immune System by Sodium Methylthiocarbamate.**

W. Tan, B. Jan, X. Deng, M. Gadson and S. B. Pruett. *Basic Sciences, Mississippi State University, Mississippi State, MS.*

Sodium methylthiocarbamate (SMD) is the most widely used soil fumigant in the US. The parent compound and its major breakdown product – methylisothiocyanate (MITC) have been reported to suppress innate immunity in animal models. Our studies indicated that both SMD and MITC altered pro- and anti-inflammatory cytokine and chemokine production in a mouse sepsis model, and increased mortality in a similar manner at 72 hr. Experiments described here were conducted to understand the mechanisms by which SMD alters innate immunity. In NF- $\kappa$ B reporter mice, both SMD and MITC decreased the signal strength of NF- $\kappa$ B, which clearly suggested that the NF- $\kappa$ B pathway was inhibited by both compounds. Therefore, it is important to determine how SMD alters NF- $\kappa$ B signaling. Early studies showed that *in vivo* administration of SMD decreased the concentration of reduced glutathione in mouse peritoneal macrophages, which indicated that SMD administration induced oxidative stress. NF- $\kappa$ B signaling is known to be sensitive to oxidative stress. However, our studies showed that neither BSO nor NAC altered the signal inhibition of NF- $\kappa$ B induced by SMD, which indicated that other mechanisms are more important. Interestingly, NF- $\kappa$ B p65 was not altered by SMD. In contrast, NF- $\kappa$ B p50 was downregulated at the level of mRNA expression in microarray analysis. Meanwhile, microarray analysis indicated that other pathways could be potentially involved in the suppression of innate immune responses induced by SMD, such as hormone pathways, recognition receptors of bacteria and viruses, and others. Therefore, further studies are necessary to determine the interaction of these impaired pathways after methylthiocarbamate treatment. This work was supported by grant R01ES013708 from the National Institute of Environmental Health Sciences.

#### **PS 413 Submicrometer-Sized Iron Oxide Particles and Inflammation.**

A. M. Nilsen and D. Mihaylova. *Norwegian University of Science and Technology, Trondheim, Norway.*

Iron-containing nano- and sub-micrometer particles are increasingly used in daily life products such as clothes and paint as well as in nanomedicine. Thus, it is of importance to find if such particles might cause harmful inflammatory responses. The aim of the study was to determine if two types of iron oxide particles activate isolated immune cells and initiate inflammatory responses in blood, and if they differ in their potential for doing so.

We compared two super paramagnetic iron oxide particle types (100 nm and 1  $\mu$ m diameter) functionalized with carboxyl or glucuronic acid carboxyl and determined if they activate human monocytes in culture or activate cells and initiate inflammatory responses in human whole blood. Activation of the immune cells were determined by quantification of secreted cytokines by ELISA and multi-plex, by induced expression of surface proteins (CD11b) on monocytes and granulocytes in whole blood using flow cytometry and by determining activation of the complement system (TCC) by ELISA.

The results suggest that the 100 nm beads caused a dose dependent activation of isolated monocytes as seen by elevated levels of secreted IL-1 $\beta$  and TNF- $\alpha$  6h after adding the beads. Multi-plex confirmed the increase in IL-1 $\beta$  and demonstrated in addition an elevation in IL-2, IL-6, GM-CSF and IFN- $\gamma$ . The 1  $\mu$ m beads were found much less potent in inducing the secretion of these pro-inflammatory cytokines. Priming of the cells using LPS (100 pg/ml for 2h) gave very minor effects

on the cytokine responses to the particles. From the whole blood analysis it was found that the 100 nm beads at the highest concentration (100  $\mu$ g/ml) caused an elevated level of CD11b on both monocytes and granulocytes, activated complement, and increased the secreted levels of IL-1 $\beta$ , IL-2, IL-6 and TNF- $\alpha$ . The 1  $\mu$ m beads gave no cytokine changes compared to the negative control except for an activation of the complement system that was similar to the smaller beads. The functionalized 100 nm iron oxide particles seem to induce a higher inflammatory response in human monocytes and whole blood than the 1  $\mu$ m beads.

#### **PS 414 A 28-Day Inhalation Immunotoxicity Study of Methyl Isothiocyanate in Female B6C3F1 Mice.**

J. Weinberg<sup>1</sup>, D. Kirkpatrick<sup>1</sup>, V. Peachee<sup>2</sup>, V. Piccirillo<sup>3</sup>, A. Jonynas<sup>3</sup> and J. Hauswirth<sup>3</sup>. <sup>1</sup>WIL Research, Ashland, OH; <sup>2</sup>ImmunoTox, Inc., Richmond, VA; <sup>3</sup>MITC Task Force, Washington DC.

The objective of this study was to evaluate potential immunotoxic effects of methyl isothiocyanate (MITC) when administered via whole-body inhalation to female B6C3F1 mice for 28 consecutive days. MITC is the active metabolite of metam sodium, an organosulfur compound used as a soil fumigant for protection against soil fungi and nematodes. Groups of 10 female mice were exposed to target vapor concentrations of 0, 1, 3 and 10 ppm. All animals were immunized with an intravenous injection of sheep red blood cells (sRBC) on study day 24. A concurrent positive control group received once daily intraperitoneal injections of cyclophosphamide monohydrate (CPS) at a dosage level of 50 mg/kg/day on study days 24-27. All animals were observed at the midpoint of exposures for signs of toxicity. Body weights were recorded twice weekly and food consumption was recorded weekly. A gross necropsy was conducted on all animals on study day 28. Spleen and thymus weights were recorded at necropsy. Immunotoxicity assessment was based on the results of a splenic antibody-forming cell (AFC) assay to assess the T-cell dependent antibody response. There were no MITC-related effects on survival, body weights, food consumption, macroscopic findings or spleen and thymus weights. An increase in eye closure was observed in mice at the 3 and 10 ppm exposure levels. Spleen cellularity, specific activity (AFC/106 spleen cells) and total activity (AFC/spleen) of splenic IgM antibody-forming cells to the T cell-dependent antigen sRBC were unaffected. CPS administration resulted in an expected suppression of the humoral component of the immune system. There was no suppression of the humoral component of the immune system when female B6C3F1 mice were exposed to concentrations of 1, 3 and 10 ppm MITC vapor by whole-body inhalation for 28 consecutive days. In the absence of MITC-related effects on the AFC response, the No-Observed-Effect-Concentration (NOEC) on the immune system was greater than 10 ppm.

#### **PS 415 Activation of the Aryl Hydrocarbon Receptor during Development Leads to an Altered Cd4<sup>+</sup> T Cell Response to Influenza Virus.**

L. Boule<sup>1</sup> and B. Lawrence<sup>2,1</sup>. <sup>1</sup>Immunology, Microbiology, and Virology, University of Rochester Medical Center, Rochester, NY; <sup>2</sup>Environmental Medicine, University of Rochester Medical Center, Rochester, NY.

Recent reports suggest developmental exposures to certain pollutants lead to lower antibody responses to childhood immunizations, but the mechanism by which this occurs is unknown. An intracellular receptor activated by a variety of chemicals is the transcription factor aryl hydrocarbon receptor (AhR). It is expressed by many cell types, including immune cells, and can alter their function upon activation. Previously, we have shown that developmental triggering of the AhR by one of its most potent ligands, the pollutant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), results in a decrease in the class-switched antibody response to influenza virus infection. CD4<sup>+</sup> T cells differentiate into various effector subsets dependent on the environment in which they are activated. CD4<sup>+</sup> T cells that secrete IFN $\gamma$  and express the transcription factor TBet are defined as Th1 cells, and these Th1 cells are critical effectors in the class-switched antibody response to influenza virus. We examined the CD4<sup>+</sup> T cell response to influenza virus in developmentally exposed mice and found that there are fewer activated and virus-specific CD4<sup>+</sup> T cells in the draining lymph nodes of infected adult mice that were developmentally exposed to TCDD. In addition, there are fewer Th1 cells in the MLN of these mice. Conversely, the percentage of CD4<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>+</sup> regulatory T cells (Tregs), responsible for suppressing immune responses, is increased the MLNs of developmentally exposed mice. This is the first report in the context of an influenza virus infection that AhR activation during development disrupts the normal function and differentiation of CD4<sup>+</sup> T cells, an effect of which may lead to decreased antibody responses to both infections and immunizations.

**PS 416 Exposure to Triclosan Augments the Allergic Response to Ovalbumin in a Mouse Model of Asthma.**

C. M. Long<sup>1,2</sup>, J. Franko<sup>3</sup>, M. L. Kashon<sup>1</sup>, K. L. Anderson<sup>1</sup>, A. E. Hubbs<sup>1</sup>, E. Lukomska<sup>1</sup>, B. J. Meade<sup>1</sup> and S. Anderson<sup>1</sup>. <sup>1</sup>HELD/ACIB, CDC-NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV; <sup>3</sup>Bethany College, Bethany, WV.

During the last decade there has been a remarkable and unexplained increase in the prevalence of asthma. These studies were conducted to investigate the role of dermal exposure to triclosan, an endocrine-disrupting compound, on the hypersensitivity response to ovalbumin (OVA) in a murine model of asthma. Triclosan has had widespread use in the general population as an antibacterial and antifungal agent and is commonly found in consumer products such as soaps, deodorants, toothpastes, shaving creams, mouth washes, and cleaning supplies. For these studies, BALB/c mice were exposed dermally to concentrations of triclosan ranging from 0.75-3% (0.375-1.5 mg/mouse/day) for 28 consecutive days. Concordantly, mice were intraperitoneally injected with OVA (0.9 ug) and aluminum hydroxide (0.5 mg) on days 1 and 10 and challenged with OVA (125 ug) by pharyngeal aspiration on days 19 and 27. Compared to the animals exposed to OVA alone, increased spleen weights, OVA-specific IgE, Interleukin (IL)-13 cytokine levels, and lung eosinophils were demonstrated when mice were co-exposed to OVA and triclosan. Statistically significant increases in OVA-specific and non-specific airway hyperreactivity (AHR) were observed for all triclosan co-exposed groups when compared to the vehicle and OVA controls. In these studies exposure to triclosan alone was not demonstrated to be allergenic, however co-exposure with a known allergen resulted in enhancement of the hypersensitivity response to that allergen, suggesting that triclosan exposure may augment the allergic responses to other environmental allergens.

**PS 417 Oral Exposure to Genistin but Not Daidzein Increased Natural Killer (NK) Cell Activity in Female B6C3F1 Mice.**

T. Guo<sup>1</sup>, R. D. Brown<sup>2</sup> and J. F. Zheng<sup>2</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Virginia Commonwealth University, Richmond, VA.

Genistin (GIN), the glycoside form of phytoestrogen genistein (GEN), is the predominant isoflavone found in soy products. The objective of this study was to determine if exposure to GIN (2, 6 or 20 mg/kg) by daily gavage for 28 days modulated immune responses in female B6C3F1 mice in comparison with daidzein (DAZ), another soy isoflavone. There were no significant changes in the body weight and absolute weights of thymus, spleen, lungs, kidneys, or liver in either GIN or DAZ-treated mice. However, exposure to GIN increased relative kidney weight (20 mg/kg; 11%). In contrast, exposure to DAZ decreased relative spleen weight (2 mg/kg; 21%; 6 mg/kg; 24%; 20 mg/kg; 24%), relative kidney weight (6 mg/kg; 15%), relative liver weight (6 mg/kg; 14%; 20 mg/kg; 14%), and relative lung weight (20 mg/kg; 24%). In the thymus, GIN exposure increased the percentages of CD4+CD8+ cells (2 mg/kg; 22%; 20 mg/kg; 26%) and CD44-CD25- cells (20 mg/kg; 5%) but decreased the percentages of CD4+CD8- cells (20 mg/kg; 28%), CD4-CD8- cells (2 mg/kg; 41%; 20 mg/kg; 41%), and CD44-CD25+ cells (20 mg/kg; 53%). Exposure to DAZ increased the percentages of CD44-CD25- cells (2 mg/kg; 5%) while decreased that of CD4+CD8- cells (2 mg/kg; 30%), CD44-CD25+ cells (2 mg/kg; 51%), and CD44-CD25+ cells (2 mg/kg; 71%; 6 mg/kg; 45%; 20 mg/kg; 43%). In the spleen, GIN exposure increased the percentages of NK cells (20 mg/kg; 86%), T cells (20 mg/kg; 74%), and neutrophils (2 mg/kg; 148%) while DAZ exposure increased the percentages of T cells (20 mg/kg; 112%), CD4+ T cells (20 mg/kg; 58%), CD8+ T cells (6 mg/kg; 69%; 20 mg/kg; 133%) but decreased the percentage of neutrophils (20 mg/kg; 48%). In correlation with observed increased %NK cells, exposure to GIN but not DAZ increased NK cell activity. Taken together, the differential effects of GIN and DAZ suggest that both the estrogenic and non-estrogenic properties of these compounds contribute to their immunomodulatory roles (Supported in part by NIEHS contract NO1-ES05454).

**PS 418 Neural Autoimmunity and Low-Level Mercury Exposure.**

C. Wright, D. L. Shirley and J. F. Nyland. Pathology, Microbiology & Immunology, University of South Carolina School of Medicine, Columbia, SC.

Multiple Sclerosis (MS) is an autoimmune disease of the central nervous system (CNS) involving demyelination; the mechanism of disease pathology involves stimulated auto-reactive T cells that are elicited against myelin proteins and primarily strikes more women than men. Mercury (Hg), a heavy metal found in many consumer products and as an environmental contaminant, affects the immune system,

although there is little data linking low-level Hg exposure to the development of autoimmunity. Contrarily, high-level Hg exposure has proven to be toxic to the human CNS, specifically on neurons and glial cells. Since glial cells are CNS-resident immune lineage cells, we hypothesized that low-level Hg pre-exposure will increase neural autoimmunity in the animal model of MS, experimental autoimmune encephalomyelitis (EAE), induced with myelin oligodendrocyte glycoprotein (MOG). Adult C57BL/6 male mice were first pre-treated with HgCl<sub>2</sub> or PBS every other day by subcutaneous injection for 2 weeks pre-disease induction, then divided into 3 groups: (1) Hg only, (2) disease (MOG<sub>35-55</sub> peptide) only, and (3) Hg+ disease. Clinical scores were recorded daily until day 25 when mice were euthanized. Brain, spinal cord, and spleen tissues were collected and analyzed for 9 cytokines (pro- & anti-inflammatory) using a multiplex assay. Hg alone raised levels of both pro-inflammatory and anti-inflammatory cytokines in the spinal cord; however, in diseased animals, Hg did not have the same effects and only increased IFN- $\gamma$  in the brain. Low-level Hg alone is insufficient to prompt disease in males but exposure does upregulate cytokine levels in the CNS (IFN- $\gamma$ ) when disease is present. These data indicate that low-dose Hg interacts with components of the CNS milieu, specifically cytokine-producing cells of the immune system. Future studies will focus on exploring sex-specific effects of disease severity with Hg pre-treatment in female mice of the same animal model.

**PS 419 Modulation of HIV<sub>GP120</sub>-Specific T Cell Responses by  $\Delta^9$ -Tetrahydrocannabinol *In Vitro* and *In Vivo*.**

W. Chen<sup>1,3</sup>, B. L. Kaplan<sup>2,3</sup>, S. T. Pike<sup>3</sup> and N. E. Kaminski<sup>2,3</sup>. <sup>1</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Approximately 25% of HIV patients use marijuana for its putative therapeutic benefit; however, it is unknown how cannabinoids affect the immune status of immunocompromised HIV patients. A surrogate *in vitro* mouse model was established to investigate the effects of cannabinoids on the early stages of the anti-HIV response. Specifically, T cell responses to HIV<sub>gp120</sub> were induced using gp120-expressing antigen presenting cells and target cells. CD8<sup>+</sup> T cell proliferation and gp120-specific IFN $\gamma$  production were observed, which was suppressed or enhanced by  $\Delta^9$ -tetrahydrocannabinol (THC), the predominant psychoactive compound in marijuana, depending on the magnitude of cellular activation. To further determine the molecular mechanisms by which THC differentially modulates T cell responses, PMA/ionomycin (Io) or anti-CD3/CD28 were used as stimuli. THC suppressed or enhanced IFN $\gamma$  or IL-2 production under optimal or suboptimal activation, respectively, but increased intracellular Ca<sup>2+</sup>, regardless of the activation levels, suggesting that appropriate or excessive Ca<sup>2+</sup> affected T cell activation differentially. To determine whether THC has similar effects *in vivo*, a mouse model to stimulate HIV<sub>gp120</sub>-specific response has also been established. Vector plasmid VRC2000 or gp120-expressing plasmid VRC<sub>gp120</sub> was injected intramuscularly into mice. The gp120-specific IFN $\gamma$  response was detected by ELISPOT, when splenocytes were restimulated with the pool of gp120-derived peptides 81-84, which were identified as the putative immunodominant ones among 211 tested peptides. The THC effect on the gp120-specific response *in vivo* will be characterized. Overall, our data will provide in-depth understanding of cannabinoid effects on HIV antigen-specific T cell responses *in vitro* and *in vivo*. (Supported by NIH DA07908)

**PS 420 Cannabinoid Enhancement of Humoral Immunity in CB<sub>1</sub>/CB<sub>2</sub> Null Mice Is Correlated with Enhanced Splenic Norepinephrine (NE) Concentration.**

T. J. Simkins<sup>1,2,3</sup>, K. J. Lookingland<sup>2,3</sup> and B. L. Kaplan<sup>1,2,3</sup>. <sup>1</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Neuroscience Program, Michigan State University, East Lansing, MI.

Cannabinoid compounds, such as  $\Delta^9$ -tetrahydrocannabinol (THC), are immune suppressive as evidenced, in part, by their ability to inhibit T cell-dependent B cell responses. In response to sheep erythrocytes, THC suppresses immunoglobulin M (IgM) antibody production in a cannabinoid receptor (CB) 1 and/or CB2-dependent manner. Moreover, previous studies demonstrated that the magnitude of IgM production in response to sheep erythrocytes was higher in CB1/CB2 null mice as compared to wild type mice, suggesting endogenous cannabinoid control of humoral immunity. Thus, the focus of the present studies was to determine the mechanisms by which cannabinoids regulate humoral immunity. A direct comparison of female and male wild type and CB1/CB2 null mice demonstrated that CB1/CB2 null mice produce more circulating IgM and IgG, even in the absence of immune

sensitization. In response to various antigens, including influenza and lipopolysaccharide (LPS), CB1/CB2 null mice also produced more IgM. It has been demonstrated that NE engagement of  $\beta 2$  adrenergic receptor ( $\beta 2$ AR) on B cells is part of the normal physiological mechanism that contributes to antibody production, and in fact, splenic NE concentration and  $\beta 2$ AR expression on B cells were higher in CB1/CB2 null mice as compared to wild type mice. These results provide a correlation between splenic NE concentration and antibody production, suggesting the possibility that cannabinoid-mediated suppression of NE release from splenic sympathetic neurons contributes to cannabinoid-induced inhibition of antibody responses. (Supported in part by NIH DA007908).

**PS 421 Differential Effects of Delta(9)-Tetrahydrocannabinol on NF $\kappa$ B Activation in T Cell-Dependent Humoral Immune Response in Humans.**

T. Ngaotepprutaram<sup>1,2</sup>, B. L. Kaplan<sup>1,2</sup> and N. E. Kaminski<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center of Integrative Toxicology, Michigan State University, East Lansing, MI.

Delta(9)-Tetrahydrocannabinol (THC), a major psychoactive constituent found in marijuana, modulates immune function. Previously, our laboratory demonstrated that THC inhibits humoral immune responses to T cell-dependent antigens in mice by suppressing sheep erythrocyte or CD40 ligand (CD40L)-induced immunoglobulin M (IgM) secretion and antibody forming cell (AFC) response. CD40 is constitutively expressed on B cells, whereas CD40L is induced in activated T cells. Thus, the objective of this study was to investigate the role of the CD40-CD40L interaction in THC-mediated suppression of the T cell-dependent humoral immune response in humans. These studies show that THC suppressed the anti-CD3/CD28-induced DNA binding activity of NFAT and NF $\kappa$ B, two transcription factors critical in the upregulation of CD40L in activated human CD4<sup>+</sup> T cells. An assessment of the effect of THC on proximal T cell-receptor signaling induced by anti-CD3/CD28 revealed modest impairment of sustained elevation in intracellular calcium, but no significant effect on the phosphorylation of Zap70, PLC $\gamma$ , Akt, and Gsk3 $\beta$ . Additional findings, using an in vitro T cell-dependent antibody response model, which employs cell surface-expressed CD40L and recombinant cytokines [interleukin (IL)-2, IL-6, and IL-10], to induce B cell responses demonstrated that THC suppressed STAT3, but not NF $\kappa$ B activation in B cells. Moreover, THC impaired B cell activation and proliferation, ultimately resulting in suppression of IgM AFC response. Collectively, these findings suggest that THC exhibits stimulation- and/or cell type-specific selectivity in NF $\kappa$ B inhibition, and identifies many aspects of the multi-faceted mechanism by which THC suppresses T cell-dependent humoral immunity in humans. Supported in part by DA07908 and Royal Thai Government Scholarships.

**PS 422 Phenotypic Comparison of Leukocyte Populations between Wild Type and Aryl Hydrocarbon Receptor (AhR) Null Rat in the Developing and Mature Spleen and Thymus.**

R. B. Crawford<sup>1</sup>, N. Joshi<sup>1</sup>, R. S. Thomas<sup>2</sup> and N. E. Kaminski<sup>1</sup>. <sup>1</sup>Department of Pharmacology & Toxicology and Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

The immunotoxic effects produced by dioxin and dioxin-like polycyclic aromatic hydrocarbons are mediated through the AhR; however, little is known concerning the role of the AhR in the development or functionality of the immune system. The objective of the present study was to investigate whether targeted deletion of the AhR in the Sprague-Dawley rat altered the leukocyte composition within the developing (3 weeks) and/or mature (8 weeks) thymus or spleen of male and female rats. No significant differences were observed between AhR null and wild type rats in the spleen or thymus body to organ weight ratios or cellularity of the thymus or spleen at 3 or 8 weeks of age. Similarly, leukocyte populations as characterized by comprehensive phenotyping using multiple panels of antibodies directed against specific cell surface proteins (i.e., B cells, T cell subtypes, monocyte-derived lineages, neutrophils and NK cells) using flow cytometry showed no significant differences in the cellular composition of the thymus between the wild type and AhR null rat. Similar analysis of the spleen showed an increase in the CD8<sup>+</sup>NK<sup>+</sup> (NKT) population at week 3 in the AhR null rat. A trend toward an increase in NKT cells was also present at week 8 but this difference was not statistically significant. These studies show that targeted deletion of the AhR in the Sprague-Dawley rat has minimal effects on the leukocyte composition of the developing and mature rat thymus and spleen. (Supported in part by the Dow Chemical Company)

**PS 423 Differential Expression Kinetics of miRNA Involved in Allergic Chemical Sensitization following Dermal Exposure in a Murine Model.**

S. Anderson<sup>1</sup>, K. Beezhold<sup>2</sup>, E. Lukomska<sup>1</sup>, J. Richardson<sup>1</sup>, C. M. Long<sup>1</sup>, K. Anderson<sup>1</sup>, J. Franko<sup>3</sup>, B. J. Meade<sup>1</sup> and D. H. Beezhold<sup>1</sup>. <sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>University of Pittsburgh, Pittsburgh, PA; <sup>3</sup>Bethany College, Bethany, WV.

Allergic disease is an important occupational health concern with work related asthma and allergic contact dermatitis among the most frequently diagnosed occupational illnesses. The development of rapid and sensitive methods for hazard identification of the responsible agents is critical. MicroRNAs (miRNAs) are small non-coding RNAs 20-22 nucleotides long whose primary function is to regulate gene expression by functioning as endogenous inhibitors of protein translation. Allergic disease is characterized by an imbalance between Th1 and Th2 cytokines; however the role of posttranscriptional mechanisms like the ones regulated by miRNAs is just starting to be explored. These studies describe the kinetics of miRNA expression during the sensitization phase of an allergic response following dermal exposure to prototypical chemical sensitizers in a mouse model. Using microarray and other data, six miRNAs were identified for further analysis with RT-PCR including mi-21, 22, 210, 155, 133a, and 27b. These data demonstrate that miRNAs may have a central role early in the allergic response focused on establishing the fine balance of Th1 versus Th2 responses to chemical sensitizers. Identification of unique miRNA expression profiles may help to elicit the mechanisms by which exposure to sensitizing chemicals induce immune cell activation and can potentially help to identify biomarkers for new treatments and preventions.

**PS 424 Potential for Immune Sensitization following Dermal Exposure to Indium Tin Oxide.**

B. J. Meade<sup>1</sup>, E. Lukomska<sup>1</sup>, K. Brock<sup>2</sup>, C. M. Long<sup>1</sup>, K. Anderson<sup>1</sup> and S. Anderson<sup>1</sup>. <sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV.

Pulmonary disease including pulmonary fibrosis, emphysema and pulmonary alveolar proteinosis has been observed in workers in the indium industry. The mechanisms underlying this disease and its natural history have not been fully elucidated. Among other findings, following inhalation exposure to Indium-tin Oxide (ITO) animal studies have revealed hyperplasia of mediastinal lymph nodes and granulomas of mediastinal nodes and bronchus-associated lymphoid tissue. These studies were undertaken to investigate the potential for ITO to induce immune sensitization using the mouse Local Lymph Node Assay. Furthermore studies were conducted following exposure to both intact and abraded skin to begin to evaluate the potential for dermal penetration of the nanoparticles. BALB/c mice (5 animals/per group for both intact and abraded skin groups) were exposed to either vehicle (dimethyl sulfoxide), increasing concentrations 2.5%-10% ITO (90:10 indium oxide/tin oxide, particle size <50 nm) or positive control (30% alpha-hexylcinnamaldehyde). A dose response was observed in both groups reaching statistical significance and a SI of 4 in the 5% intact dose group (EC3 value of 2.6). Students t-test showed no statistical differences when responses were compared between intact and breach skin exposures at the same dose levels. These studies demonstrate the potential for ITO to induce sensitization following dermal exposure and suggest that the particles may have similar bioavailability through intact and abraded skin.

**PS 425 Rat Bioassay of Diisocyanate Asthma: Comparison of Thresholds of the Asthmagenic Response and Pulmonary Irritation.**

J. Pauluhn. Toxicology, Bayer Pharma AG, Wuppertal, Germany.

Occupational exposure to polymeric diphenylmethane-diisocyanate (MDI) and the more volatile toluene-diisocyanate (TDI), known human asthmagens, can be attributed to two potential routes: the skin and the respiratory tract. Both routes were systematically compared in the Brown Norway (BN) rat MDI asthma model. Induction utilized either 2 topical exposure sessions or inhalation exposures on 5 consecutive days at concentration x exposure time (C x t) relationships of 1000, 5000, and 10000 mg MDI/m<sup>3</sup> x min using exposure durations of either 10- or 360-min. This was followed by four 30-min inhalation challenges to 40 mg MDI/m<sup>3</sup> on every alternate follow-up week. This comparison revealed that a 'high dose' dermal exposure is markedly more efficacious to produce 'asthmatic rats' than a repeated high-dose/high-concentration inhalation protocol. Therefore, further testing was focusing solely on the topical route for induction. Under otherwise similar conditions, rats were challenged to 80 mg TDI/m<sup>3</sup>. This overcomes the loss of dose due to the vapor retention in the upper airways of rats and associated drop in

ventilation. Two independent methods were used to characterize the asthma-like response at the last challenge, the analysis of pulmonary inflammatory by bronchoalveolar lavage (BAL) and physiologic endpoints showing changes in respiration delayed in onset. The most distinct outcomes characterizing the asthmatic response in this bioassay were increased neutrophils in BAL and the delayed respiratory response. These data demonstrated further that the vigor of asthma-like response after challenge is clearly dependent on the inhalation elicitation dose ( $C \times t$ ) of pre-challenged rats to attain the asthmatic state. This relationship of the elicitation response served as basis for the dose-response analysis and estimation of the benchmark NOAEL. After adjustments accounting for differences exposure durations, in the rat-to-human pulmonary doses, and the intra-human variability, the resultant threshold  $C \times t$  of asthmatic rats and humans converged into the same threshold limit value.

**PS 426 Identification of Novel Exposure and Lung Cancer Gene Markers in Carbon Nanotube-Exposed Human Lung Epithelial Cells.**

T. A. Stueckle<sup>1</sup>, A. Mishra<sup>1</sup>, R. Derk<sup>1</sup>, T. Meighan<sup>1</sup>, V. Castranova<sup>1</sup>, Y. Rojanasakul<sup>2</sup> and L. Wang<sup>1</sup>. <sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV.

Concern for increased risk of CNT-induced lung cancer has arisen due to asbestos-like high aspect ratio, pulmonary persistence and fibrosis. Our previous study found that chronic in vitro exposure to dispersed single (D-SWCNT) and multi wall CNT (D-MWCNT) resulted in neoplastic transformation in human small airway epithelial cells (SAEC). Genome profiling identified oncogene signaling mechanisms in CNT SAECs that were quite different from asbestos-exposed (ASB) SAEC. Few in vivo studies identified whole lung gene markers associated with MWCNT exposure, but did not compare CNT vs. asbestos genetic response. Here, toxicogenomic profiling with correlation feature selection strategies identified particle-specific, key gene markers from our previous study. D-SWCNT, D-MWCNT, ASB, ultrafine carbon black (UFCB) and control SAEC genome profiles were subjected to comparative marker and class neighbor analyses followed by multistep cross validation to identify genes with highly correlated expression for each treatment. Specific treatment markers and genome profiles were subjected to Ingenuity Pathway and Biomarker Analysis to determine both specific markers performance and identify disease markers. Gene marker subsets and disease markers were validated using rtPCR and protein expression. Here, we present robust SWCNT, MWCNT, ASB and UFCB specific gene marker sets for in vitro chronically exposed SAEC. Matching our original analysis, both D-MWCNT and D-SWCNT markers were associated with lipid metabolism and cancer while ASB and UFCB centered on inflammatory response and senescence, respectively. Biomarker Analysis identified known lung and other cancer markers (MYC, PPARG) in CNT SAECs which differed from inflammation-associated cancer markers (IL-1B) in ASB SAECs. In conclusion, toxicogenomic profiling in a chronic in vitro exposure model identified particle-specific gene markers and known lung cancer markers which can potentially aid in assessing CNT exposure and detection of early disease markers.

**PS 427 ROS Evaluation for Series of CNTs Using ESR Method and Its CNT Concentration Effects.**

S. Tsuruoka<sup>1</sup>, K. Takeuchi<sup>2</sup>, K. Koyama<sup>2</sup>, F. Tristan-Lopez<sup>1</sup>, H. Matsumoto<sup>3</sup>, N. Saito<sup>4</sup>, Y. Usui<sup>4</sup>, M. Endo<sup>1</sup>, M. Terrones<sup>1</sup>, D. W. Porter<sup>5</sup> and V. Castranova<sup>5</sup>. <sup>1</sup>ENCs, Shinshu University, Nagano, Japan; <sup>2</sup>Faculty of England, Shinshu University, Nagano, Japan; <sup>3</sup>Department of Organic and Polymeric Materials, Tokyo Institute of Technology, Meguro, Japan; <sup>4</sup>Department of Applied Physical Therapy, Shinshu University, Nagano, Japan; <sup>5</sup>NIOSH, Morgantown, WV.

Carbon nanotubes (CNTs) are becoming important materials in industries. It is a concern that CNTs may induce carcinogenic responses through pulmonary exposure. It has been recently reported that CNTs scavenge ROS, which is utilized for toxicological evaluations. Although the electron charge transfer seems the noticeable phenomena of toxicological chemical reactions, any comprehensive evaluation of ROS scavenging capabilities using a variety of CNTs has not been demonstrated well. The present work specifically investigates ROS scavenging capabilities using the series of CNTs and their derivatives: more than 15 kinds of CNTs. Those ROS scavenging properties were measured by ESR with DMPO. Highly crystallized, mechanically chopped, mechanically de-bulked, and metal doped CNTs were evaluated (Group A). Furthermore, several of commercially available CNTs (Group B) were compared with Group A. Interestingly the ROS scavenging rate was not significantly influenced by mechanical treatments, but depended on crystallization at high temperature. Very thin DWCNTs showed elimination of OH radical almost, implying existence of diameter threshold. The ratio of CNTs to DMPO influenced

the scavenging rate of CNTs but not titanium dioxide, as a higher concentration of CNTs showed the lower scavenging rate, this suggests that DMPO is partly adsorbed on the CNT surface and decreases the activity. The results suggest that the electron transfer on the CNT surface is the fundamental mechanism of ROS scavenging. Dangling bonds are not a key factor for scavenging, though. ROS is affected by CNT/DMPO ratio.

**PS 428 The Biological Response to Carbon Nanotubes in the BEAS-2B Cell Line Is Affected by Medium Conditions.**

H. Haniui<sup>1</sup>, N. Saito<sup>2</sup>, Y. Matsuda<sup>3</sup>, Y. Usui<sup>4</sup>, K. Aoki<sup>1</sup>, S. Takanashi<sup>1</sup>, S. Kobayashi<sup>1</sup>, H. Nomura<sup>1</sup>, M. Okamoto<sup>1</sup> and H. Kato<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Shinshu University School of Medicine, Matsumoto, Japan; <sup>2</sup>Department of Applied Physical Therapy, Shinshu University School of Health Sciences, Matsumoto, Japan; <sup>3</sup>Clinical Pharmacology Educational Center, Nihon Pharmaceutical University, Ina-machi, Japan; <sup>4</sup>Research Center for Exotic Nanocarbons, Shinshu University, Matsumoto, Japan. Sponsor: T. Kadota.

There are many reports on the use of an SV-40/adenovirus-transformed normal human bronchial epithelial cell line (BEAS-2B) to evaluate nanomaterials, especially multi-walled carbon nanotubes (MWCNT). However, the results have been controversial; one explanation is that while some experimental culture media contained serum, others did not. Here, we clarified the influence of serum on the BEAS-2B response to MWCNT compared with that on normal human bronchial epithelial cells (NHBE; Cell application) and studied its effect on MWCNT endocytosis. Cytotoxicity and cytokine secretion profiles of MWCNT on BEAS-2B cells or NHBE were examined in media with or without serum (Ham's F12 containing 10% fetal bovine serum [Ham's F12] and serum free growth medium [SFGM]). Cellular uptake of MWCNT was observed by fluorescence microscopy and analyzed by flow cytometry. We also examined if MWCNT uptake was suppressed by two kinds of endocytosis inhibitors. BEAS-2B cells cultured in Ham's F12 and NHBE cultured in SFGM exhibited similar biological responses to internalized MWCNT in terms of cell growth inhibition and cytokine secretion. BEAS-2B cells cultured in SFGM did not internalize MWCNT, and the IC<sub>50</sub> value of this cell line was 10 times higher than that in Ham's F12. MWCNT uptake was suppressed both by clathrin- and caveolae-mediated endocytosis inhibitors for BEAS-2B cells cultured in Ham's F12 and NHBE in SFGM. We conclude that the BEAS-2B cell line in serum-containing medium exhibits clathrin- and caveolae-mediated endocytosis of MWCNT, and displays the biological responses suitable for safety assessment of nanomaterials as a model of NHBE.

**PS 429 Evaluation of the Effect of Carbon Nanotubes on the Expressions of Endothelial Genes Implicated in Different Pathways of Cellular Death.**

O. Janouskova<sup>1</sup>, M. Orecna<sup>2</sup>, T. Tegegn<sup>2</sup>, S. Lacerda<sup>2</sup>, K. Holada<sup>1</sup> and J. Simak<sup>2</sup>. <sup>1</sup>First Faculty of Medicine, Charles University, Prague, Czech Republic; <sup>2</sup>Division of Hematology, CBER, US FDA, Rockville, MD.

Carbon nanotubes (CNTs) are attractive for various nanomedicine applications including their intravascular use. Therefore, the vascular biocompatibility of CNTs is a critical safety issue. Here we investigate the effect of carboxylated multi-walled CNTs (M60COOH) and their pristine counterparts (M60) on cultured human umbilical vein endothelial cells (HUVECs) by evaluating the changes in the expression of selected genes with known involvement in autophagy, apoptosis or necrosis. We have utilized Death PathwayFinder RT<sup>2</sup> Profiler PCR Array (Qiagen), to monitor expression of 84 selected genes. HUVECs were treated for 24 h with 100 µg/ml of M60 or M60COOH. Controls included HUVECs with serum starvation, or treatment with 1 µM camptothecin for 24h, or incubation with 1 mM H<sub>2</sub>O<sub>2</sub> for 2h. The cDNA was constructed from isolated RNA and the level of gene expression was analyzed by real time PCR using the PCR Array Data Analysis software (Qiagen).

Out of 84 monitored genes just 40 genes changed the expression significantly ( $P < 0.05$ ) often only after one or two treatments. The Bonferroni correction reduced the number of significantly changed genes to 14. Expression profiles after treatment with M60 and M60COOH differed ( $P < 0.05$ ). Both nanomaterials up-regulated different proapoptotic genes. In contrast to M60, only M60COOH up-regulated autophagy related genes for NFKB1, SQSTM1, and INS. Comparably, these gene array results complement our previous finding of a significant accumulation of the autophagosome protein marker LC3B in M60COOH but not in M60 treated HUVECs.

Our study suggests that the screening of mRNA levels of cell death pathway genes may be a valuable complementary tool in the testing of cellular toxicity of nanomaterials. However, further gene selection, standardization and validation of assays are required.

**PS 430 Carboxylated Multiwalled Carbon Nanotubes Induce mTOR Independent Autophagosome Accumulation in Endothelial Cells by Blockade of Autophagic Flux.**

M. Orecna<sup>1</sup>, S. Lacerda<sup>1</sup>, O. Janouskova<sup>2</sup>, T. Tegegn<sup>1</sup>, K. Holada<sup>2</sup> and J. Simak<sup>1</sup>. <sup>1</sup>Division of Hematology, CBER, US FDA, Rockville, MD; <sup>2</sup>First Faculty of Medicine, Charles University, Prague, Czech Republic.

Carbon nanotubes (CNTs) are attractive for various nanomedicine applications including their intravascular use. Therefore, the vascular biocompatibility of CNTs is a critical safety issue.

We have previously shown that in contrast to their pristine counterparts M60, carboxylated multiwalled carbon nanotubes M60COOH at 100µg/ml induced increase in the LC3B autophagosome protein marker in cultured human umbilical vein endothelial cells (HUVECs). Here we investigate a mechanism of this process. The autophagosome accumulation in M60COOH treated HUVECs was visualized by Laser Scanning Confocal Microscopy (LSCM) using immunodetection of the LC3B as well as in HUVECs transfected with Promo<sup>TM</sup> Autophagy Sensor LC3B-Green Fluorescent Protein using the baculovirus BacMam 2.0 technology. Moreover, western blotting (WB) analysis confirmed accumulation of LC3B in M60COOH treated HUVECs. The autophagosome accumulation can be caused either by induction of autophagy or by blockade of autophagic flux. The WB analysis of p62 (SQSTM1), a protein which is preferentially degraded by autophagy, showed that the induction of autophagy by serum starvation caused a significant decrease in p62 protein levels, while no change in p62 was observed in M60COOH treated HUVECs. The classical pathway of induction of autophagy involves inhibition of the mTOR kinase. The WB analysis of the mTOR substrate p-p70S6K showed no changes in levels of phosphorylation of this protein after M60COOH treatment. In addition, the LSCM kinetic study of HUVECs treated with Alexa555-conjugated M60COOH indicated the autophagic flux blockade. Our results showed that the accumulation of autophagosomes in HUVECs induced by M60COOH likely resulted from the blockade of autophagic flux, rather than induction of autophagy. This presentation reflects the views of the author and should not be construed to represent FDA's views or policies. (2CR grant LH12014)

**PS 431 Effects of the Protein Corona on the Interaction of Carbon Nanotubes with Blood Platelets.**

S. Lacerda<sup>1</sup>, L. L. Diduch<sup>2</sup>, M. Orecna<sup>1</sup>, T. Tegegn<sup>1</sup>, E. Karnaukhova<sup>1</sup> and J. Simak<sup>1</sup>. <sup>1</sup>US FDA, Bethesda, MD; <sup>2</sup>NIST, Gaithersburg, MD.

With the potential uses of carbon nanotubes (CNTs) in medicine and related CNT toxicity concerns, the importance of CNT-protein interaction studies cannot be stressed enough. We have shown that CNTs activate store operated calcium entry in blood platelets (De Paoli Lacerda SH et al, ACS Nano 2011). Here, we investigate how the PLT-activating effect of multiwalled carboxylated-CNTs (M60COOH) is influenced by interaction of M60COOH with different human proteins: albumin (HSA), fibrinogen (FBG), Gamma-globulins (HGG) and histone H1 (H1). Pymol molecular visualization was used to determine protein dimensions, electrostatic potential surfaces, and the number of aromatic residues available for binding to the M60COOH. Dissociation constants  $K_D = 0.049, 0.053, 0.079$  and  $0.165$  mg/mL for H1, FBG, HSA and HGG, respectively, were calculated for binding of these proteins to M60COOH. Circular dichroism revealed that the secondary structure of the studied proteins changed upon binding to M60COOH surface. Platelet (PLT) aggregometry showed that pre-incubation of M60COOH with HSA, HGG, and FBG reduced PTL-aggregating effect compared to bare M60COOH. In contrast, pre-incubation of M60COOH with H1 markedly increased their PLT-aggregating activity which was comparable to the effect of 20µM TRAP. In addition, the flow cytometry analysis of PTL membrane microparticles (CD41+CD62P+MP) showed that H1-M60COOH induced marked increase in CD41+CD62P+MP release compared to bare M60COOH. It is likely that positively charged H1 strongly interacts with the negatively charged plasma membrane of PTLs enhancing the nanopenetration of CNTs through the platelet plasma membrane. FBG leads M60COOH to self-assembly resulting in loss of the CNT surface area for interaction with PTLs which possibly explains the decrease in PLT-aggregating activity of FBG-treated M60COOH. In conclusion, binding of different proteins to CNTs greatly modulate their interactions with blood platelets. This presentation reflects the views of the author and should not be construed to represent FDA's views or policies.

**PS 432 Genotoxicity of Multiwalled Carbon Nanotubes.**

S. H. Reynolds<sup>1</sup>, C. Dinu<sup>2</sup>, D. T. Lowry<sup>1</sup>, M. L. Kashon<sup>1</sup>, A. F. Hubbs<sup>1</sup>, B. Stanley<sup>3</sup>, J. L. Salisbury<sup>4</sup>, J. Mastovich<sup>5</sup>, B. Kristin<sup>3</sup>, J. Sturgeon<sup>5</sup>, M. Keane<sup>1</sup>, C. Lorenzo<sup>1</sup> and L. Sargent<sup>1</sup>. <sup>1</sup>CDC/NIOSH, Morgantown, WV; <sup>2</sup>West Virginia University, Morgantown, WV; <sup>3</sup>NSA, Knoxville, TN; <sup>4</sup>Mayo Clinic, Rochester, MN; <sup>5</sup>RJ Lee, Monroeville, PA.

Carbon nanotubes have many unique applications in industry and medicine. Although the low density and small size of carbon nanotubes makes respiratory exposures to workers likely during the production or use of commercial products, the genotoxicity is not fully investigated. We have previously shown mitotic spindle aberrations in cultured primary and immortalized human airway epithelial cells exposed to single-walled carbon nanotubes (SWCNT). In order to investigate whether mitotic spindle damage was unique to SWCNT, we examined mitotic spindle aberrations following dosing of cells to multi-walled carbon nanotubes (MWCNT) at concentrations anticipated in the workplace. MWCNT induced a dose responsive increase in disrupted centrosomes, abnormal mitotic spindles and aneuploid chromosome number. The data further showed that monopolar mitotic spindles comprised 95% of the disrupted mitoses. Cell cycle analysis demonstrated a greater number of cells in G1 and S-phase in MWCNT-treated compared to diluent control, indicating a G1/S block in the cell cycle. The monopolar phenotype of the disrupted mitotic spindles and the G1/S block in the cell cycle is in sharp contrast to the multi-polar spindle and the G2 block in the cell cycle observed in SWCNT-induced disruption. Three dimensional reconstructions showed carbon nanotubes integrated with the microtubules, the DNA and within the centrosome structure. The lower doses did not cause cytotoxicity or apoptosis 24 hours after exposure; however, after 72 hours, significant cytotoxicity was observed in the MWCNT-exposed cells. One month following exposure, MWCNT-treated cells had a dramatic increase in both size and number of colonies. Our results demonstrate significant disruption of the mitotic spindle by MWCNT at occupationally relevant doses.

**PS 433 Loss of Epithelial Monolayer Integrity following Exposure of Primary Human Airway Cells to Multiwalled Carbon Nanotubes.**

Garantzotis<sup>1</sup>. <sup>1</sup>Division of Bioinformatics and Biostatistics, National Center for Toxicological Research, US FDA, Jefferson, AR.

Pulmonary health effects due to inhaled multi-walled carbon nanotubes (MWCNT) have been a growing concern, as MWCNT become more widely used due to their unique physical and chemical properties. Studies have implicated MWCNTs in the pathogenesis of pulmonary fibrosis and inflammation. Airway epithelia are crucial for the maintenance of airway homeostasis and epithelial injury leads to airway remodeling and inflammation. We therefore tested the effect of MWCNT on airway epithelial integrity. In vivo mouse exposure to MWCNTs induced loss of airway columnar and ciliated epithelium within 7 days, and changes consistent with airway epithelial metaplasia. We then explored the mechanism for these changes in vitro. Bronchial epithelial cells (BECs) were obtained from healthy human volunteers via bronchoscopy, grown on E10+ electrode arrays until confluent, and electrical resistance across monolayers was measured continuously for 7 days after treatment with either dispersion medium, nanographene shape control (12ug/ml), or MWCNT (3 or 12 ug/ml). MWCNT treatment induced a significant reduction in epithelial resistance over time, suggesting breakdown of monolayer integrity, as well as alterations in cell morphology, but cytotoxicity was observed only in the higher MWCNT dose. Epithelial-mesenchymal transition was ruled out by western blotting, RT-PCR and staining for relevant markers. Microarray analysis revealed that MWCNT induced significant downregulation of cornulin, cadherins, and keratins, as well as upregulation of genes involved in retinoid signaling. These results suggest that MWCNT disrupt airway epithelial integrity through cytotoxicity and metaplasia linked to by retinoid-related dedifferentiation.

**PS 434 Human Pleural Mesothelial MeT-5A Cells Are a Limited In Vitro Model for Detection of Potential Asbestos-Like Genotoxic Effects of Multiwall Carbon Nanotubes.**

C. Ziemann, S. Reamon-Büttner, A. Hackbarth, H. Brockmeyer, H. Rahmer and B. Bellmann. *Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany.* Sponsor: C. Dasenbrock.

Multiwall carbon nanotubes (MWCNT) are nanomaterials with important technological impact. But, depending on diameter and length some MWCNT may induce fiber-like toxicity/genotoxicity, similar to asbestos. Thus, a project funded by

the German Federal Ministry of Education and Research (contract No. 03X0109A) focuses on potential adverse biological effects and toxicity determining characteristics of divers MWCNT, both *in vivo* and *in vitro*, using long fiber amosite asbestos (LFA) as positive control. Since mesothelial cells are targets for adverse effects of asbestos, notably mesothelioma development, human SV40-transformed, non-malignant pleural mesothelial MeT-5A cells were initially chosen as *in vitro* model. In this study part, their usefulness for investigation of potential asbestos-like adverse effects of MWCNT *in vitro* was characterized. Proliferation parameters and a MWCNT-optimized lactate dehydrogenase assay indicated concentration-dependent cytotoxicity of LFA (2, 10 and 20  $\mu\text{g}/\text{cm}^2$ ) in MeT-5A cells. LFA also induced DNA-strand breaks and oxidative DNA-damage in the hOGG1-modified comet assay. For determination of MWCNT-related aneugenic effects/spindle fiber damage, basal frequency of micronuclei, chromosome aberrations, and altered meta-, ana- and telophase morphology was firstly determined. MeT-5A cells exhibited highly variable chromosome numbers (6.5% cells with normal 46 chromosomes), a markedly higher spontaneous micronucleus frequency, compared to rodent bone marrow erythrocytes (~15-fold) and V79 cells ~5-fold), and a high frequency of aberrant mitosis stages (bridges, lagging chromosomes, multipolar divisions). In conclusion, MeT-5A cells are a limited *in vitro* model to study potential asbestos-like effects of MWCNT. Cells are responsive to asbestos, but demonstrate marked genomic instability and thus limited significance concerning genotoxic effects. LP9 and LP9/TERT-1 cells are thus currently characterized as alternative models.

#### PS 435 Multidisciplinary Approach to Determination of C<sub>60</sub> Fullerene Presence in Lipid Membranes.

K. A. Russ<sup>1</sup>, P. T. Williamson<sup>3</sup>, P. Elvati<sup>2</sup>, A. Dews<sup>1</sup>, T. Adzemovic<sup>1</sup>, M. Ray<sup>1</sup>, A. Violi<sup>2</sup>, P. Smith<sup>4</sup> and M. A. Philbert<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, University of Michigan, Ann Arbor, MI; <sup>2</sup>Mechanical Engineering, University of Michigan, Ann Arbor, MI; <sup>3</sup>Centre for Biological Sciences, University of Southampton, Southampton, United Kingdom; <sup>4</sup>Institute for Life Sciences, University of Southampton, Southampton, United Kingdom.

The incorporation of C<sub>60</sub> fullerenes into cell membranes was confirmed by computational modeling, <sup>31</sup>P and <sup>2</sup>H solid-state NMR, and transmission electron microscopy. Computational modeling shows that the free energy required for C<sub>60</sub>s to exist in or near the lipid bilayer is lowest when the C<sub>60</sub> is positioned between the lipid tails of the membrane. Static <sup>31</sup>P and <sup>2</sup>H solid-state NMR were used to study the interaction of the C<sub>60</sub> with model lipid bilayers composed of deuterated 1-palmitoyl-2-oleoylphosphatidylcholine. Temperature-dependent <sup>31</sup>P NMR spectra show that C<sub>60</sub>s are able to enter the membrane. Reduced magnetic deformation in the <sup>31</sup>P spectra suggests that C<sub>60</sub>s increase the rigidity of the membrane. Increased motional averaging in the phosphate groups and reduction in quadrupolar splitting (resulting in a higher density of motions occurring on the microsecond timescale in the glycerol backbone) were also seen with increasing concentrations of C<sub>60</sub>s. Transmission electron microscopy (TEM) shows C<sub>60</sub>s are able to enter the cell via three mechanisms: endocytosis (well-known), diffusion through the membrane, and an unknown mechanism allowing entry into the nucleus. Freeze fracture TEM images of RAW 264.7 immortalized cells show decreasing C<sub>60</sub> aggregate size with increasing proximity to the membrane as well as structures within the membrane space. This multidisciplinary approach clarifies some of the complex questions of nanomaterial-membrane interaction. Alteration of membrane composition via the addition of C<sub>60</sub>s may alter the structure/function of the cell. Further research will elucidate interactions between C<sub>60</sub> and receptors in the membrane that may in turn alter the normal functions of the cell. Supported by ES 08846, U01 ES020128-01, NIEHS Training Grant T32-ES007062-26 and NSF-CAREER Award CBET 0644639.

#### PS 436 Single-Walled Carbon Nanotubes Increase Influenza Virus Infectivity in Lung Cells.

P. Sanpui<sup>1</sup>, J. Loeb<sup>1</sup>, J. Lednický<sup>1</sup>, N. B. Saleh<sup>2</sup> and T. Sabo-Attwood<sup>1</sup>. <sup>1</sup>Department of Environmental & Global Health, University of Florida, Gainesville, FL; <sup>2</sup>Department of Environmental Engineering, University of South Carolina, Columbia, SC.

Possibility of engineered nanoparticles to influence the behavior of infectious agents, such as influenza A viruses (IAV) can have critical consequences. We are mainly interested in single-walled carbon nanotubes (SWNTs) because of their ever-increasing use in consumer products and structural resemblance with asbestos that may be relevant to their long-term health effects. Here, we aim to identify mechanisms controlling the immune response of lung epithelial cells (LEC) exposed to SWNTs and determine their influence on IAV infection. We concentrate on the role of toll-like receptors (TLRs) which are activated by pathogens to stimulate production of immune proteins. To examine the impact of SWNTs on TLRs and immune genes, LEC were exposed to SWNTs for 24 hours and expression of

84 genes were quantified using a TLR-selective array. Results revealed an immunosuppressive profile with 3 genes (CLEC4E, CD14, CSF3) being significantly downregulated. Since exposure to IAV results in a robust immune response we investigated whether SWNTs could enhance IAV infectability. LEC were exposed to SWNTs for 24 hours followed by co-incubation with H1N1 IAV. After immunofluorescence staining with an H1N1-specific antibody, we observed that LEC pre-exposed to SWNTs had significantly higher levels of IAV infection (~10%). These results were consistent with the quantified number of virus particles released into the cell culture media as determined by a titer assay showing an increase of 5.6 times over cells exposed to IAV only. To investigate the impact of SWNT on immune response, we measured secretion of a panel of cytokines (TNF $\alpha$ , IFN $\gamma$ , G-CSF, GM-CSF, IL1 $\alpha$ , IL8, IP10, Rantes) in media of exposed cells. The overall profiles showed that cytokines induced by IAV were repressed or enhanced in presence of SWNT. Overall results from these studies indicate that SWNTs have the potential to increase the susceptibility of lung cells to IAV infection and modulate IAV-associated classical immune response.

#### PS 437 Accumulation of Lipids and Oxidatively Damaged DNA in Hepatocytes Exposed to Particles.

P. Moller, L. K. Vesterdal, P. H. Danielsen, J. K. Folkmann, L. F. Jespersen, M. Roursgaard and S. Loft. Department of Public Health, University of Copenhagen, Copenhagen K, Denmark. Sponsor: M. Campen.

Exposure to particles has been suggested to generate hepatosteatosis by oxidative stress. We investigated lipid accumulation in cultured human hepatocytes (HepG2) and rat liver after exposure to Printex 90 carbon black (CB) particles. HepG2 cells were exposed to particles for 3 h and subsequently incubated for another 18 h to manifest lipid accumulation. There was a concentration-dependent increase after exposure to CB (50 and 100  $\mu\text{g}/\text{ml}$ ), which was only observed after co-exposure to oleic/palmitic acid. Similar results were observed in HepG2 cells that were exposed to diesel exhaust particles (SRM2975), fullerenes C60 or single-walled carbon nanotubes. All four types of particles at a concentration of 25  $\mu\text{g}/\text{ml}$  generated oxidatively damaged DNA, assessed as formamidopyrimidine (FPG) sensitive sites by the comet assay, in HepG2 cells after 3 h exposure. We have previously shown that a single oral exposure to 0.64 mg/kg of CB increased the level of 8-oxo-7,8-dihydro-2'-deoxyguanosine in the liver of rats (Danielsen et al., Toxicol Sci 118: 574-585, 2012). Recently we have assessed the level of hepatosteatosis by Oil Red staining in lean and obese Zucker rats that had been exposed to 0.064, 0.64 or 6.4 mg/kg of CB by a single oral administration (Folkmann et al., Toxicol Sci 129:98-107, 2012). There was slightly increased lipid load in the liver after exposure to 0.64 mg/kg (P=0.077) and statistically significant increased lipid load in lean Zucker rats that had received 6.4 mg/kg of CB (P<0.05). This was not associated with increased iNOS staining in the liver, indicating that the oral CB exposure was associated with hepatic steatosis rather than steatohepatitis. The obese Zucker rats had higher level of lipid load compared to the lean counterparts, whereas the oral CB exposure did not affect the lipid load level. In conclusion, our results indicate that exposure to particles is associated with accumulation of lipids in hepatocytes, concomitantly with signs of oxidatively damaged DNA.

#### PS 438 IL-4 and IL-13 Suppress IL-1 $\beta$ Production by Human THP-1 Macrophages after Exposure to Multiwalled Carbon Nanotubes.

K. A. Shipkowski, A. J. Taylor and J. C. Bonner. Toxicology, North Carolina State University, Raleigh, NC.

Introduction: Multi-walled carbon nanotubes (MWCNT) are prominent in the field of nanotechnology due to their novel properties, but represent a potential health hazard for human lung disease as mice exposed to MWCNT develop pulmonary inflammation and fibrosis. It has also been shown that mice with allergen-induced lung inflammation, driven largely by the Th2 cytokines interleukin (IL)-4 and IL-13, are susceptible to MWCNT-induced fibrosis. IL-1 $\beta$  is a pro-inflammatory cytokine secreted by MWCNT-activated macrophages via multi-protein scaffolds known as inflammasomes. In this study, MWCNT were evaluated as a stimulator of IL-1 $\beta$  expression by human THP-1 macrophages in the presence of IL-4 or IL-13 to model the microenvironment in allergic asthma. Methods: THP-1 cells, a human monocytic cell line, were activated with vitamin D3, differentiated with 12-O-tetradecanoylphorbol 13-acetate (TPA), primed with lipopolysaccharide (LPS), and dosed with either MWCNT alone (1-100  $\mu\text{g}/\text{mL}$ ) or MWCNT with IL-4 or IL-13 (10 ng/mL). IL-1 $\beta$  mRNA and protein levels were measured via TaqMan quantitative real-time RT-PCR and ELISA, respectively. Protein levels of phosphorylated and total STAT-6, an intracellular transducer of IL-4 and IL-13, were measured by Western blotting. Results: THP-1 cells treated with MWCNT showed a dose-dependent increase in IL-1 $\beta$  mRNA and protein levels. IL-1 $\beta$  induction was

significantly greater in differentiated cells, showing that activation of THP-1 cells increases their response to MWCNT stimulation. Cells co-exposed to IL-4 or IL-13 showed a significant decrease in MWCNT-induced IL-1 $\beta$  levels. Western blotting showed that IL-13, but not MWCNT, activated STAT-6 in THP-1 cells. Conclusions: IL-4 and IL-13 suppress MWCNT-induced expression of IL-1 $\beta$  in macrophages via STAT-6 phosphorylation. Our data suggest that Th2 cytokines up-regulated in asthma inhibit the innate immune response of macrophages to carbon nanotubes. (Funded by NIEHS RC2 ES018772 and R01 ES020897)

**PS 439 Zinc Oxide Surface Modification of Multiwalled Carbon Nanotubes Enhances Chemokine and Growth Factor Production in Human Monocytes and Lung Fibroblasts *In Vitro*.**

A. J. Taylor<sup>1</sup>, C. K. Devine<sup>2</sup>, G. N. Parsons<sup>2</sup> and J. C. Bonner<sup>1</sup>. <sup>1</sup>*Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC;* <sup>2</sup>*Department of Chemical and Biomolecular Engineering, North Carolina State University, Raleigh, NC.*

Carbon nanotubes, a product of emerging nanotechnologies, are gaining increasing attention due to possible health risks from occupational and environmental exposures. Previous studies with rodents have shown that MWCNTs stimulate the production of pro-fibrogenic growth factors such as transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1) & platelet-derived growth factor (PDGF) *in vivo*. Thin-film coating of MWCNT with metal oxides by a process called atomic layer deposition (ALD) modifies and enhances the functionality of MWCNTs in electronics and engineering. We hypothesize that metal oxide surface coating of MWCNT with zinc oxide (ZnO) alters the production of pro-inflammatory cytokines & chemokines as well as pro-fibrogenic growth factors by human monocytes (THP-1) and human lung fibroblasts (HLF-16Lu). To test our hypothesis MWCNTs were coated with ZnO via ALD. THP-1 and HLF-16Lu were exposed to coated or uncoated MWCNT for 24 hr and then we measured mRNAs levels (via RT-PCR) of the growth factors PDGF and TGF- $\beta$ 1, the pro-inflammatory cytokine IL-1 $\beta$ , and the mononuclear cell chemokine CXCL10. THP-1 cells exposed to ZnO-coated MWCNTs showed a 6-fold increase in IL-1 $\beta$  mRNA expression, and ~2-fold increase in TGF- $\beta$ 1 mRNA and PDGF mRNA levels. In the HLF-16Lu fibroblasts, ZnO-coated MWCNTs increased the mRNA expression of TGF- $\beta$ 1 3-fold and CXCL10 6-fold but proved to be cytotoxic at higher doses. Uncoated MWCNTs had no effect on any of the target mediators in either cell line. Our findings indicate that surface modification of MWCNTs with ZnO enhances the production of pro-fibrogenic proteins by macrophages and fibroblasts *in vitro*. These findings suggest that MWCNT modified by ALD coating with ZnO could increase the toxicity and pathogenicity of MWCNT in the lung.

**PS 440 Metabolomic Analysis of Liver Cells Exposed to Carbon Nanotubes and Graphene Oxide.**

W. M. Henderson<sup>1</sup>, D. Bouchard<sup>1</sup>, X. Chang<sup>2</sup>, I. Chowdhury<sup>3</sup>, B. Foster<sup>2</sup>, S. Aronson<sup>2</sup> and Q. Teng<sup>1</sup>. <sup>1</sup>*National Exposure Research Laboratory, Office of Research and Development, US EPA, Athens, GA;* <sup>2</sup>*Student Service Authority Contractor to US EPA, Athens, GA;* <sup>3</sup>*Grantee to US EPA via National Research Council Cooperative Agreement, Athens, GA.*

Carbon nanotubes (CNTs) and other graphenic nanomaterials are being used extensively in industrial, consumer, and mechanical applications based in part on their unique structural, optical and electronic properties. Due to the widespread use of these nanoparticles (NPs), human and ecological exposure is probable and inevitable. To determine the effects CNTs and graphene oxide (GO) have on biochemical processes, metabolomics-based profiling of human (C3A) and zebrafish (ZFL) liver cells was utilized. Cell cultures were exposed to 0, 10, or 100 ng/mL of covalently or non-covalently modified nanomaterial for 24 and 48 hrs while particle size distribution, charge, and aggregation kinetics were monitored concurrent with exposure studies. Following NP exposure, metabolites were extracted and derivatized prior to GC/MS analysis or lyophilized and buffered for 1H NMR analysis. Acquired spectra and chromatograms were subjected to multivariate analysis to determine the consequence of NP exposure on the metabolite profile of C3A and ZFL cells. The resulting scores plots illustrated temporal and dose dependent responses to all classes of NPs tested. Loadings plots coupled with univariate analysis were then used to identify metabolites of interest. Preliminary data suggest that CNT and GO exposure causes perturbations in processes involved in cellular oxidation as well as fluxes in lipid metabolism and fatty acid synthesis. Dose-response

trajectories are apparent for each nanomaterial tested and spectral components related to both dose and NP modifications were determined. Correlations of the significant changes in metabolites will aid in identifying potential biomarkers associated with carbonaceous nanoparticle exposure in both humans and ecologically relevant species.

**PS 441 Physical Characterization of Multiwalled Carbon Nanotubes for Inhalation Studies.**

B. T. Chen, D. Schwegler-Berry, W. McKinney, S. Stone, J. L. Cumpston, S. Friend, D. W. Porter, V. Castranova and D. Frazer. *PPRB, NIOSH, Morgantown, WV.*

Animal inhalation studies have reported that adverse pulmonary, cardiovascular, and immune reactions may result from exposure to multi-walled carbon nanotubes (MWCNTs). At the present time, however, there is little guidance for adequate sampling and characterization of MWCNT aerosols for evaluating exposures and obtaining an applicable dose metric for risk assessment. This is mainly because MWCNTs tend to agglomerate and form complex structures making them difficult to characterize. To address this problem, we conducted detailed sampling and characterization studies of MWCNTs that had similar particle morphologies to those found in the workplace. Representative samples were collected using filters, a cascade impactor, and direct reading instruments, and they were used for microscopic observation, gravimetric analysis, and real-time monitoring. Particle number distributions on a filter (0.008–0.10 particles/ $\mu$ m<sup>2</sup>), and mass distributions using an impactor (0.1–0.3 mg on peak stages) were determined. Microscopic analyses indicated that MWCNTs can be classified into three shape categories: irregular, isometric, and fibrous particle structures. Each particle structure contained a mean of 18 nanotubes, and 1  $\mu$ g of MWCNTs contained 2.7 x 10<sup>6</sup> particle structures composed of 4.9 x 10<sup>7</sup> individual nanotubes. Impactor measurements showed that the mass median aerodynamic diameter of the aerosol was 1.5  $\mu$ m with a geometric standard deviation of 1.67. The shape factor of individual fibers was 1.94–2.71, and the isometric particles had an effective density of 0.71–0.88 g/cm<sup>3</sup>. Results also indicated that real-time particle number counts were realistic, but without an index of agglomeration, they were insufficient for adequate risk assessment. Information from this study can be used to estimate initial lung burden and to design an improved lung deposition model that considers three individual MWCNT particle shapes. The described methods can be used as guidance for sampling and characterizing other engineered nanoparticles.

**PS 442 Cellular Responses Induced by Single-Wall Carbon Nanotubes with Varying Physical Properties in Alveolar Epithelial Cells.**

K. Fujita<sup>1,2</sup>, M. Fukuda<sup>2</sup>, S. Endoh<sup>2</sup>, H. Kato<sup>1,2</sup>, N. Shinohara<sup>1,2</sup>, R. Nagano<sup>2</sup>, M. Horie<sup>3</sup>, S. Kinugasa<sup>1,2</sup>, H. Hashimoto<sup>1</sup> and A. Kishimoto<sup>1,2</sup>. <sup>1</sup>*AIST, Tsukuba, Japan;* <sup>2</sup>*TASC, Tsukuba, Japan;* <sup>3</sup>*University Occupational Environmental Health, Kitakyushu, Japan.*

Concern over the influence of carbon nanotubes (CNTs) on human health has risen due to advances in the development of nanotechnology. Some studies have shown that unpurified CNTs induced high levels of cellular responses than those of purified CNTs. They suggest that the residual metals involved in CNTs attribute to induction of oxidative stress. Here, we examine our hypothesis that the physicochemical properties of single-wall carbon nanotubes (SWCNTs) may have important implications for biological responses. We have developed novel dispersion procedure of CNTs with their different physical properties in culture medium. *In vitro* cytotoxicity assays were performed on human alveolar epithelial cell lines (A549) using impurity-free SWCNTs with varying physical properties and commercial SWCNTs with residual metals as a reference. Cell viability, apoptosis, intracellular reactive oxygen species (ROS) generation, cell cycle distribution, and cellular uptake of SWCNTs were investigated. Impurity-free SWCNTs with their different physical properties (CNT-1, CNT-2) and SWCNTs containing trace amounts of metals (CNT-3) did not cause significant inhibition of cell proliferation, induction of apoptosis and arresting cell cycle progression. On the other hand, all samples significantly increased level of the intracellular ROS production after 24h incubation. These results show that residual metals involved in SWCNTs may not be a definitive parameter for induction of oxidative stress. The relatively short line shape of SWCNTs small bundles were observed in the vacuoles of cells exposed to CNT-1. The relatively long line shape of SWCNTs large bundles were observed in the cytoplasm and vacuoles of cells exposed to CNT-2. A large number of aggregated SWCNTs with punctate structures were observed in the cytoplasm and vacuoles of cells exposed to CNT-3. We suggest that the physical properties of SWCNTs are closely related to the cellular uptake and induction of oxidative stress.

**PS 443 Sonolytic Degradation of Pluronic® Surfactants to Toxic Byproducts: Implications for Nanotoxicity Testing.**

R. K. Draper<sup>1,2</sup>, R. Wang<sup>1,2</sup>, H. Tyler<sup>1</sup>, S. Beck<sup>1</sup>, S. Vakili<sup>1</sup>, S. Li<sup>1</sup> and P. Pantano<sup>2</sup>. <sup>1</sup>Molecular & Cell Biology, University of Texas at Dallas, Richardson, TX; <sup>2</sup>Chemistry, University of Texas at Dallas, Richardson, TX.

Poloxamers (known by the trade name Pluronic®) are triblock copolymer surfactants that contain two polyethylene glycol blocks and one polypropylene glycol block of various sizes. Poloxamers are widely used as nanoparticle dispersants for nanotoxicity studies wherein nanoparticles are sonicated with a dispersant to prepare suspensions. It is known that poloxamers can be degraded during sonication and that reactive oxygen species contribute to the degradation process. However, the possibility that poloxamer degradation products are toxic to mammalian cells has not been well studied. We report here that aqueous solutions of poloxamer 188 (Pluronic® F-68) and poloxamer 407 (Pluronic® F-127) sonicated in the presence or absence of multi-walled carbon nanotubes (MWCNTs) can become highly toxic to cultured cells. Moreover, toxicity correlated with the sonolytic degradation of the polymers. These findings suggest that caution should be used in interpreting the results of nanotoxicity studies where the potential sonolytic degradation of dispersants was not controlled.

**PS 444 Effects of Carbon Black Nanoparticles on Human Pulmonary Cell Lines and Precision Cut Lung Slices.**

T. Hansen<sup>1</sup>, J. Kopf<sup>1</sup>, O. Danov<sup>1</sup>, M. Ströbele<sup>3</sup>, A. Braun<sup>1</sup>, K. Sewald<sup>1</sup>, P. Steinberg<sup>4</sup> and H. Fehrenbach<sup>2</sup>. <sup>1</sup>Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany; <sup>2</sup>Research Center Borstel, Borstel, Germany; <sup>3</sup>Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany; <sup>4</sup>University of Veterinary Medicine Hannover, Hannover, Germany. Sponsor: C. Dasenbrock.

Carbon black nanoparticles (CBNPs) are among the most abundantly used nanomaterials and have been reported to cause adverse health effects after inhalation exposure. The aim of this study was to compare the effects of Printex® 90 and acetylene soot particles in human pulmonary cell lines (16HBE14o-, Calu-3, A549) and precision cut lung slices (PCLS) of mice, rats and humans using a wide concentration range. Particle size distribution in the cell culture medium was determined by dynamic light scattering. Viability assays were LIVE/DEAD® staining and WST-1 assay for PCLS and WST-8 and neutral red assay for cell lines. CBNP-induced formation of reactive oxygen species (ROS) was assessed in A549 and 16HBE14o-cells by flow cytometry using the DCFH-DA assay. Furthermore, the effect of CBNP exposure on the transepithelial electrical resistance (TEER) was investigated in Calu-3 cells after 24, 48 and 120h treatment with 10 and 50 µg/ml CBNPs. With PCLS, the inflammatory response was assessed by measuring pro-inflammatory cytokines (i.e. IL-1α, TNF-α, IL-8). Both CBNPs tested were not toxic in physiologically relevant concentrations. Significant cytotoxicity was observed in the WST-8 assay for both CBNPs at 50 µg/ml after 48h, whereas no effects were found in the neutral red assay. Increased ROS formation was observed with both CBNPs after 24 and 48 h. Interestingly, acetylene soot particles cause significant TEER reduction at both dose levels and all time points tested whereas Printex® 90 reduced the TEER only after 120h at the high dose. Neither Printex® 90 nor acetylene soot particles induced the secretion of proinflammatory cytokines in mouse and rat PCLS. In conclusion, the combination of in vitro and ex vivo models provides a valuable tool to assess the acute irritation and inflammation effects of CBNPs on lung tissue.

**PS 445 Rho-Kinases Are Involved in Caspase-1-Mediated IL-1β Secretion following In Vitro Exposure to Multiwalled Carbon Nanotubes and Asbestos in Human Monocyte.**

S. Kanno<sup>1</sup>, S. Hirano<sup>2</sup>, S. Chiba<sup>1</sup>, H. Takeshita<sup>1</sup>, T. Nagai<sup>1</sup>, M. Takada<sup>1</sup> and T. Mukai<sup>1</sup>. <sup>1</sup>Department of Legal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; <sup>2</sup>Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Japan.

It has been reported that fibrous particles such as asbestos and carbon nanotubes (CNT) trigger interleukin (IL)-1β release through NLRP3 inflammasome in phagocytotic cells. GTPase effector Rho-kinases (ROCK1, and 2), are known to be associated with the organization of the actin cytoskeleton during phagocytosis. In this study we examined whether ROCKs are involved in asbestos- or multi-walled CNT (MWCNT)-induced IL-1β release in human monocytic THP-1 cells. THP-1 were differentiated to macrophages by PMA and were exposed to crocidolite, MWCNT or lipopolysaccharide (LPS) in the presence or absence of Y27632 (ROCKs inhibitor) or Z-YVAD (caspase-1 inhibitor). Concentrations of IL-1β in

the culture medium were measured using ELISA. Cell-associated MWCNT or asbestos were assayed by turbidimetry. Protein levels of ROCK1 and ROCK2 were analyzed by western blotting. Treatment with PMA increased expression of ROCK1, whereas that of ROCK2 was not changed in THP-1 cells. Exposure of the cells to asbestos or MWCNT provoked IL-1β secretion the secretion was suppressed by either Y27632 or Z-YVAD, whereas LPS-induced IL-1β secretion was inhibited only by Z-YVAD, but not by Y27632. These results indicate that IL-1β secretion was increased by caspase-1 activation and ROCKs are involved in both asbestos- and MWCNT-induced IL-1β secretion. On the contrary, treatment with Y27632 did not change the amount of those fibrous particles associated with the cells. To further examine the effect of ROCK1 and ROCK2 on asbestos and CNT-induced IL-1β secretion, differentiated THP-1 were transfected with siRNA to knockdown ROCKs. siRNA designed for both ROCK1 and ROCK2 decreased asbestos- or MWCNT-induced IL-1β secretion and did not change LPS-induced IL-1β secretion, indicating that ROCKs are implicated in fiber-induced inflammatory responses.

**PS 446 Multiwalled Carbon Nanotubes Damage the Mitochondria to Increase Reactive Oxygen Radical Production, Activate NF-κB Signaling to Induce Inflammatory Cytokines, and Stimulate Transforming Growth Factor β1 and Platelet-Derived Growth Factor Expression to Promote Fibroblast-to-Myofibroblast Transformation.**

X. He<sup>1</sup>, S. Young<sup>2</sup>, D. Schwegler-Berry<sup>2</sup>, W. P. Chishom<sup>3</sup>, J. E. Fernback<sup>4</sup> and Q. Ma<sup>1</sup>. <sup>1</sup>Toxicology and Molecular Biology Branch, NIOSH, Centers for Disease Control and Prevention, Morgantown, WV; <sup>2</sup>Pathology and Physiology Research Branch, NIOSH, Centers for Disease Control and Prevention, Morgantown, WV; <sup>3</sup>Exposure Assessment Branch, NIOSH, Centers for Disease Control and Prevention, Morgantown, WV; <sup>4</sup>Chemical Exposure & Measuring Branch, NIOSH, Centers for Disease Control and Prevention, Cincinnati, OH.

Carbon nanotubes (CNTs) are novel material with unique electronic and mechanical properties. Here, we report that multi-walled carbon nanotubes (MWCNT) have potent, dose-dependent toxicity on cultured human cells. Molecular characterization revealed that MWCNT induced substantial ROS production and mitochondrial inner membrane depolarization at sub-toxic doses. MWCNT stimulated the secretion of a panel of inflammatory cytokines and chemokines (TNFα, IL-1β, IL-6, IL-10 and MCP1) from macrophages (Raw264.7) by activating the canonical NF-κB signaling pathway. Activation of NF-κB signaling involves rapid degradation of IκBα, nuclear accumulation of NF-κBp65, binding of NF-κB to specific DNA-binding sequences, and transactivation of target gene promoters. Finally, MWCNTs induced the production of fibrogenic growth factors TGFβ1 and PDGF that function as paracrine signals to promote the transformation of lung fibroblasts into myofibroblasts, a key molecular step in the development of lung fibrosis. These results demonstrated that MWCNT elicit multiple and intertwining molecular signaling events involving oxidative damage, inflammatory cytokine production, and myofibroblast transformation, which potentially underlie the toxicity and fibrosis in human lungs by MWCNTs.

**PS 447 Functionalization-Associated Effects of Carboxylated Fullerenes on Cellular Aging.**

J. Gao and I. Rashi. Bioscience Division, Los Alamos National Laboratory, Los Alamos, NM.

The systematic evaluation of critical cellular responses such as apoptosis, cellular proliferation, reproductive clonogenicity and cell cycle responses in lung cells by distinctly functionalized fullerenes demonstrated that fullerene-mediated responses are dependent on their ability to perturb cell division that ultimately impact cellular fate. Moreover, we postulate that the observed cellular responses were charge and functionalization specific, in that the positively charged fullerenes were cytotoxic as opposed to the negatively charged fullerene. Interestingly, the negatively charged fullerenes inhibited cellular apoptosis and necrosis. On further investigation we discovered that, depending on the functionalization, the negatively charged fullerenes could induce senescence in bronchial epithelial cells, a cellular response that we have previously reported as a potential toxicological endpoint of fullerenes in dermal cells. We demonstrate that the observed non-cytotoxic or cyto-protective effect of fullerenes may in fact be due to a more novel function of fullerenes to induce premature senescence in cells. In the present study we utilized immortalized but not tumorigenic human bronchial epithelial cells (Beas-2b) and normal human-derived bronchial epithelial cells (NHBE) to perform a systematic evaluation of the effect of a suite of positively and negatively charged engineered fullerenes on key biological

responses. We found that the biological response(s) elicited by fullerenes on interaction with lung cells may depend upon their ability to perturb cell cycle checkpoints potentially inducing senescence. Further elucidation of the underlying molecular mechanisms involved in this senescence response indicated the involvement of GADD45a, p16, p21 and p53a, a response characteristic of cells undergoing senescence. Finally, we correlated the physicochemical properties of engineered fullerenes with the observed biological responses to obtain a better understanding of property-dependent bioactivity of fullerenes.

#### PS 448 An In Vitro Assay Detects Enhancement of Mouse T Cell Sensitization to Ovalbumin by Carbon Nanoparticles.

D. E. Lefebvre<sup>1</sup>, B. Pearce<sup>1</sup>, E. Chomyshyn<sup>1</sup>, N. Ross<sup>1</sup>, S. Halappanavar<sup>2</sup>, A. F. Tayabali<sup>2</sup>, I. Curran<sup>1</sup> and G. S. Bondy<sup>1</sup>. <sup>1</sup>Bureau of Chemical Safety, Food Directorate, Health Products and Food Branch, Health Canada, Ottawa, ON, Canada; <sup>2</sup>Environmental Health Science and Research Bureau, Environmental and Radiation Health Sciences Directorate, Healthy Environments and Consumer Safety Branch, Health Canada, Ottawa, ON, Canada.

**RATIONALE AND SCOPE:** Previous studies suggested that some nanomaterials can promote allergic sensitization. At present there are no in vitro tools to study this risk. The hypothesis was that an in vitro screening assay could be developed to assess the adjuvant activity of agglomerated carbon black nanoparticles (CBNP). **EXPERIMENTAL PROCEDURES:** DO11.10 transgenic mice have a T cell receptor which recognizes the ovalbumin (OVA) protein from chicken egg. Splenic leukocytes from these mice were cultured with 0, 0.012, 0.12, 1.2 or 12 µg/mL CBNP, OVA, or OVA with CBNP. T cell mitosis rate was quantified by flow cytometry on day 3 post-exposure. T helper (Th1/Th2) cytokine production was measured by qPCR and ELISA. **RESULTS:** Printex 90 and Aldrich carbon CBNP products were characterized. These powders consisted of micron-sized agglomerates made up of 22 nm and 39 nm diameter CBNP base particles, respectively. Following sonication in saline RP-10 solution, the fraction of agglomerates smaller than 220 nm was purified by filtration for cell exposure. These particles did not induce T cell mitosis, and they did not modify this parameter during the response to OVA. These CBNP alone did not induce Th1/Th2 cytokine expression. However, OVA in combination with 12 µg/mL of either Printex 90 or Aldrich carbon significantly increased the allergy-related Th2 cytokines IL-4, IL-10 and IL-13 compared with OVA alone ( $p \leq 0.05$ ;  $n = 3-5$ /group). This was concurrent with a decrease in the Th1 transcription factor Stat4. Lower CBNP doses had no effect. **CONCLUSIONS:** An in vitro immunotoxicology tool was developed. At the highest dose, carbon nanoparticles enhanced allergy pathways in mouse immune cells responding to ovalbumin. This assay will be used to further characterize nanomaterials for risk assessment purposes.

#### PS 449 Role of Transforming Growth Factor-β1 Pathway in Carbon Nanotube Stimulated Collagen Production in Human Lung Cells.

A. Mishra<sup>1,2</sup>, T. A. Stueckle<sup>1</sup>, R. Derk<sup>1</sup>, V. Castranova<sup>1,2</sup>, Y. Rojanasakul<sup>2</sup>, J. Yuan<sup>3</sup> and L. Wang<sup>1,2</sup>. <sup>1</sup>Pathology and Physiology Research Branch, Health Effects Laboratory Division, NIOSH, Morgantown, WV; <sup>2</sup>School of Pharmacy, West Virginia University, Morgantown, WV; <sup>3</sup>School of Public Health, Hebei United University, Tangshan, China.

Accumulated studies have shown that carbon nanotubes (CNT) induce rapid and progressive lung fibrosis in animal models but the mechanisms are not clear. Following CNT exposure transforming growth factor β (TGF-β), a pro-fibrogenic mediator, was induced both in vivo and in vitro models and was correlated with in vivo fibrosis and in vitro collagen induction. To understand the signaling mechanism of this fibrogenic response, we investigated the contribution of TGF-β signaling in CNT-induced collagen production, a hall mark of fibrosis, using cultured human lung cells and determined the role of TGF-β receptor-Smad (TGF-βR1-Smad) signaling as a potential mechanism for CNT-induced fibrosis. Human lung epithelial (BEAS2B) cells and fibroblast (CRL1490) cells were exposed to doses relevant to in vivo exposure (0.02-0.6 µg/cm<sup>2</sup> in vitro ~ 10-80 µg/mouse lung) of well characterized and dispersed multi-walled CNT (MWCNT), single walled CNT (SWCNT) and ultrafine carbon black (UFCB). Protein expression was measured by immunofluorescence, western blotting and ELISA. Present results indicate: 1) CNT exposure caused induction of TGF-β1 production in lung epithelial cells; 2) TGF-β, TGF-βR1, p-Smad-2, and collagen type I were overexpressed in CNT-exposed fibroblast cells; 3) collagen I stimulating effects of MWCNT were partially blocked in TGF-βR1 and Smad-2 knockdown fibroblast cells. In conclusion, CNT stimulate lung fibroblasts to induce collagen I in vitro through activation of the TGF-β R1-Smad Signaling pathway.

#### PS 450 Factors Associated with the Releasability of Carbon Nanotubes (CNTs) from Nanocomposites in Potential Consumer or Industrial Applications.

M. Kovochich, R. Avnani and A. K. Madl. *ChemRisk, Aliso Viejo, CA.*

Engineered nanomaterials offer innovative advancements for a wide range of industrial and consumer product technologies which promise to have global economic impact. Engineered nanomaterials in composites (nanocomposites) are currently being used in applications ranging from basic consumer goods to critical national defense technologies, with carbon nanotubes (CNTs) being popular for nanocomposites due to their enhanced mechanical, thermal, and electrical properties. With comparisons of CNTs to other high aspect ratio fibers, some concerns have been raised regarding the potential implications for exposure and health risk of nanocomposites containing CNTs. We hypothesized that the physical and chemical interactions between CNTs and the composite matrix, as well as settings in which nanocomposites are handled will influence the release of these nanomaterials. We analyzed available data on the release of CNTs from different composites as a result of various stressors. Although no release was detected under UV weathering conditions, CNT surface aggregation was detected in thermoplastic and epoxy composites compared with cementitious material. Matrix type, nanomaterial dispersion within the matrix, and chemical bonding were critical determinants for releasability. Mechanical stress tests such as cutting, grinding, sanding, and abrasion showed both positive and negative releasability results. Taken together, data indicate that physical, chemical, and environmental factors can affect the release of CNTs from nanocomposites including the location of the CNTs within the matrix, the chemical and physical bonding between the CNTs and the matrix, as well as the physical stress applied to the matrix. Analytical methods distinguishing release of CNTs versus matrix nanoparticles are critical to characterizing nanomaterial exposure. Understanding the factors that play a role in the release of CNTs will aid in technological development and safe handling of nanocomposites while minimizing any potential health risks.

#### PS 451 In Vitro Endothelial Exposure to Carbon Nanotubes Produce Reactive Oxygen Species.

Y. Rodriguez Yanez<sup>1</sup>, I. Poblete-Naredo<sup>1</sup>, B. Chavez-Munguia<sup>2</sup>, B. Cisneros<sup>3</sup> and A. Albores<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav, Mexico City, Mexico; <sup>2</sup>Infectomics and Molecular Pathology, Cinvestav, Mexico City, Mexico; <sup>3</sup>Genetic and Molecular Biology, Cinvestav, Mexico City, Mexico.

Recent studies are focused to carbon nanotubes (CNT) effects on blood coagulation, and have demonstrated that CNT are able to induce platelet aggregation and vascular thrombosis. However, there is little information on CNT effects on fibrinolysis. Therefore, we investigated the role of CNT on fibrinolysis and their contribution to elicit a prothrombotic process in vascular endothelium and the reactive oxygen species (ROS) participation. In the present study we examined the CNT oxidative potential by ROS production and the induction of fibrinolysis-related gene expression in human umbilical vein endothelial cells (HUVEC) isolated from the vein of the umbilical cord. Primary HUVEC cultures were exposed to single-walled carbon nanotubes (SWCNT) at 5, 25 and 50 µg/ml during 24 h, and oxidation potential (free-cell dithiotreitol oxidation assay), cytotoxicity (propidium iodide stain) and cell morphology (transmission electron microscopy, TEM) were assessed. SWCNT exposure resulted in concentration-dependent changes: a) oxidation potential increases that suggest a ROS increase and, b) viability decreases. Additionally, morphological changes in mitochondria, chromatin and nucleus were observed by TEM. It is expected that the oxidative stress caused by ROS may affect the transcription of the fibrinolysis related genes, activators: tissue- and urokinase-activator, tissue kallikrein, [tPA, uPA, KLK1]); and inhibitors: plasminogen activator inhibitor type 1 and kallistatin [serpine1, serpin4]), altering the physiological fibrinolysis pathway in the vascular endothelium (Supported by grants SSA/IMSS/ISSSTE/CONACYT grant 162391 and ICyTDF51/2012, YRY received a Conacyt scholarship 203482).

#### PS 452 Transport of Inhaled MWCNT to the Pleura, Respiratory Muscles and Systemic Organs.

R. R. Mercer, A. F. Hubbs, J. F. Scabilloni, L. Wang, L. A. Battelli, V. Castranova and D. W. Porter. *PPRB, NIOSH, Morgantown, WV.*

Inhalation exposure studies of mice were conducted to determine if multi-walled carbon nanotubes (MWCNT) distribute to the parietal pleura, respiratory musculature and systemic organs. Male C57BL/6J mice were exposed in a whole-body inhalation system to a 5 mg/m<sup>3</sup> MWCNT aerosol for 5 hours/day for 12 days (4 times/week for 3 weeks). At 1 day and 48 weeks after the 12 day exposure period,

mice were anesthetized and lungs and systemic tissues were preserved by whole body vascular perfusion of paraformaldehyde while inflated with air. A separate, clean-air control group was studied. Sirius Red stained sections from lung, diaphragm, chest wall, heart, kidney and liver were analyzed. Enhanced darkfield microscopy and morphometric methods were used to detect and count MWCNT in tissue sections. Counts in tissue sections were expressed as number of MWCNT per cm<sup>2</sup> of tissue (mean±SE, N=8 mice per group). Although agglomerates account for approximately 60% of lung burden, only singlet MWCNT were observed in diaphragm, chest wall and systemic tissues. At one day post exposure, the average length of singlet MWCNT in diaphragm was comparable to that of singlet MWCNT in the lungs 5.6 ± 0.6 versus 5.1 ± 0.6 μm, respectively. There were 26 ± 13 and 134 ± 25 per cm<sup>2</sup> in tissue sections of diaphragm at 1 day and 48 weeks post exposure, respectively. On average, there were 18 ± 5 and 50 ± 20 per cm<sup>2</sup> singlet MWCNT observed in systemic organ tissue sections at 1 day and 48 weeks, respectively. The burden of singlet MWCNT in parietal pleura, respiratory musculature and systemic organs at 48 weeks post exposure was significantly higher than at 1 day post exposure. Results demonstrate that inhaled MWCNT, which deposit in the lungs, are transported to the parietal pleura, the respiratory musculature and the systemic organs in a singlet form and accumulate with time following exposure.

#### PS 453 Genotoxicity of Long, Tangled Carbon Nanotubes in Mice.

J. Catalán<sup>1,2</sup>, H. Järventaus<sup>1</sup>, S. Suhonen<sup>1</sup>, K. Siivola<sup>1</sup>, C. Moreno<sup>2</sup>, E. Rossi<sup>1</sup>, J. Koivisto<sup>1</sup>, E. Vanhala<sup>1</sup>, H. Wolff<sup>1</sup>, H. Alenius<sup>1</sup>, K. Savolainen<sup>1</sup> and H. Norppa<sup>1</sup>. <sup>1</sup>Nanosafety Research Centre, Finnish Institute of Occupational Health, Helsinki, Finland; <sup>2</sup>University of Zaragoza, Zaragoza, Spain.

Long, needle-like multiwalled carbon nanotubes (MWCNTs) have been described to induce inflammation, genotoxic effects and mesothelioma in the respiratory system of mice, but the mechanisms behind these adverse effects are not well understood. The stiffness of the CNTs has been suggested to play a crucial role in their clearance from the lungs, affecting their toxicity. We have earlier observed that long, needle-like MWCNTs increase DNA damage in murine lungs. To find out whether the shape of the CNTs could affect their genotoxic properties, we examined here whether also long, but tangled MWCNTs (outer diameter 8-15 nm; Cheaptubes Inc), administered either by pharyngeal aspiration or inhalation, could be genotoxic in C57BL/6J mice locally in the lungs or systematically in peripheral leukocytes and bone marrow erythrocytes. Cell samples were collected 24-h after a single pharyngeal aspiration (0.02-4 mg/ml) or a 4-day inhalation exposure (4 h/day; 17.5 mg/m<sup>3</sup>) to the MWCNTs. DNA damage was assessed by the comet assay in bronchoalveolar lavage (BAL) cells and lung cells. DNA double strand breaks were assessed by the γ-H2AX assay in peripheral leukocytes and (after pharyngeal aspiration) in lung cells. Micronuclei, a biomarker of chromosome damage, were analyzed in bone marrow polychromatic erythrocytes sampled 24 h after the end of the inhalation exposure. No significant dose-dependent increase in DNA damage (comet assay) was seen in the BAL or lung cells of mice treated by pharyngeal aspiration or by inhalation exposure. The long, tangled MWCNTs neither induced systemic genotoxic effects in peripheral leukocytes or bone marrow. Our findings suggest that the stiffness of long MWCNTs is a central characteristic with respect to their genotoxicity in vivo, with thinner and flexible tangled MWCNTs, which tend to form agglomerates, showing no genotoxic effects. (Funded by the Finnish Work Environment Fund)

#### PS 454 High-Fat Diet Leads to Increased Lung Inflammation and Airway Resistance following Multiwalled Carbon Nanotubes Exposure.

T. A. Brown. Center for Environmental Health Sciences, University of Montana, Missoula, MT.

Obesity has become a worldwide epidemic responsible in large part for the rising costs of health care. Obesity leads to systemic low-grade inflammation increasing risk for the development of diseases such as diabetes, but the link for respiratory disease is less clear. We investigated the effect of a high fat diet on lung inflammation and lung physiology when exposed to multi-walled carbon nanotubes (MWCNT). Nanomaterials, including MWCNT, are used in an increasing number of consumer products. Given their small dimensions with large surface area and often very unique properties with high deposition efficiency they can induce significant immune responses in the lung. In this study, C57BL/6 mice were kept on a high fat diet for 6 weeks and then exposed to MWCNT, via oropharyngeal instillation. Measurements were taken 24 hr later to determine changes in inflammation and respiratory physiology, specifically lung resistance. Mice given particle on the high fat diet had significantly increased levels of IL-1β, a pro-inflammatory cytokine produced by the inflammatory complex the inflammasome, as well as increased lung resistance compared to mice on the control diet given particle. In order

to further investigate inflammatory changes due to the high fat diet additional studies examined the influx of inflammatory cells in response to MWCNT exposure. Mice on the high fat diet exposed to MWCNT had a greater influx of neutrophils and eosinophils compared to control diet mice exposed to particle. These results indicate that a high fat diet leads to an increase inflammatory response with measurable physiological alterations in the lungs when exposed to MWCNT. This work was supported by NIH grants RC2 ES018742 and P20 RR017670.

#### PS 455 Multiwalled Carbon Nanotubes Cause Mild Inflammation in the Aorta without Pulmonary Toxicity in a Rapidly Aging Mouse Model.

K. Luyts, S. Smulders and P. Hoet. *Environment and Health, Kuleuven, Leuven, Belgium.*

Exposure to ambient particulates has been shown to cause co-morbidity in elderly. Brain and muscle ARNT-like protein-1 (Bmal1) clock gene-deficient mice, with an accelerated aging and prothrombotic phenotype, were used to study the pulmonary and cardiovascular toxicity of multiwalled carbon nanotubes (CNTs). At the age of 8 weeks, wildtype and knockout Bmal1 mice were oropharyngeally aspirated once weekly during 5 consecutive weeks with 6.4 μg (32 μg in total), 25.6 μg (128 μg in total) of CNTs or the vehicle as control.

Cell counts in the bronchoalveolar lavage fluid indicated no inflammatory response 24 hours or 2 months after the last aspiration despite the presence of particle-laden macrophages. Cytokine measurements in lung homogenates showed trends for IL-1β, IL-6 and KC increases only in the wildtype mice aspirated with 128 μg CNTs but this response disappeared after 2 months.

In wildtype mice, aspiration of 128 μg CNTs caused a non-significant decrease in platelet and red blood cell counts, no significant differences for the aPTT and PT clotting tests were found and clotting factor FVIII was (non-significantly) decreased 24 hours after the last aspiration and increased 2 months later. In the Bmal1 knockout mice, FVIII was increased after 24 hours but decreased after 2 months.

A macrophage staining (MAC-3) on sections of the aorta showed endothelial activation and vascular inflammation in 60% of the 128 μg dosed knockout animals. There were no changes observed in the aortas of the wildtype mice.

In this study we showed that multiple dosing (5 weekly doses) of CNTs induced a mild vascular inflammation in the high dosed Bmal1 knockout mice in the absence of pulmonary toxicity.

ENPRA Project NMP4-SL-2009-228789

#### PS 456 Investigation of the Pulmonary Bioactivity of Double-Walled Carbon Nanotubes.

T. M. Sager<sup>1</sup>, M. Wolfarth<sup>1</sup>, D. W. Porter<sup>1</sup> and T. Steinbach<sup>2</sup>. <sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>Experimental Pathology Laboratories, Sterling, VA.

Nanotechnology is one of the world's most promising new technologies. In turn, carbon nanotube production is estimated to reach into the millions of tons within the decade. Our laboratory has previously established that exposure to multi-walled carbon nanotubes (MWCNT) causes lung inflammation and fibrosis in mice after pharyngeal exposure. However, the bioactivity of double-walled carbon nanotubes (DWCNT) has not been determined. In this study we explored the hypothesis that DWCNT would promote pulmonary toxicity by analyzing the pulmonary bioactivity of the DWCNT. To test this hypothesis, male mice (C57BL/6J) were given a single dose of one of the following by pharyngeal aspiration: 1) 0.9% saline with 0.3% (w/v) carboxymethyl cellulose (CMC; vehicle control), or 2) DWCNT (0-40 μg/mouse) suspended in vehicle [0.9% saline with 0.3% (w/v) CMC]. Whole lung lavage (WLL) was conducted at 1 and 7 days post-exposure. Lungs of non-lavaged animals were also collected and processed for histopathologic analysis at 7 and 56 days post-exposure. The results show the DWCNT exposure caused a dose-dependent increase in WLL polymorphonuclear leukocytes, indicating that DWCNT exposure initiates pulmonary inflammation. DWCNT exposure also caused a dose-dependent increase in LDH activity as well as albumin levels in WLL fluid, indicating that DWCNT exposure promotes cytotoxicity as well as decreases in the integrity of the blood-gas barrier in the lung. Also, at 56 days post-exposure, the presence of fibrosis was noted in the highest dose exposure group (40 μg/mouse). In conclusion, this study provides insight into the previously uninvestigated pulmonary bioactivity of DWCNT exposure. The results confirm that DWCNT exposure does promote inflammation and fibrosis in the lung. The results also indicate that DWCNT have a similar pulmonary bioactivity as the previously studied MWCNT.

## PS 457 Multiwalled Carbon Nanotube-Induced Lung Tumors.

L. Sargent<sup>1</sup>, D. W. Porter<sup>1</sup>, D. T. Lowry<sup>1</sup>, L. A. Battelli<sup>1</sup>, K. Siegrist<sup>1</sup>, M. L. Kashon<sup>1</sup>, B. T. Chen<sup>1</sup>, D. Frazer<sup>1</sup>, L. Staska<sup>2</sup>, A. E. Hubbs<sup>1</sup>, W. McKinney<sup>1</sup>, M. Andrew<sup>1</sup>, S. Tsuruoka<sup>3</sup>, M. Endo<sup>3</sup>, V. Castranova<sup>1</sup> and S. H. Reynolds<sup>1</sup>. <sup>1</sup>CDC/NIOSH, Morgantown, WV; <sup>2</sup>Integrated Laboratory Systems, Durham, NC; <sup>3</sup>Shinshu University, Nagano, Japan.

Carbon nanotubes have many promising applications. Although the low density and small size of carbon nanotubes makes respiratory exposures to workers likely during the production or use of commercial products, there is limited data on carcinogenicity of inhaled multi-walled carbon nanotubes (MWCNTs). We have therefore utilized a two stage initiation/promotion protocol to determine whether inhaled MWCNTs act as a complete carcinogen and/or promote the growth of cells with existing DNA damage. Six week old, male, B6C3F1 mice received a single dose of either methylcholanthrene (MC, 10 µg/g BW, i.p.) or vehicle (corn oil). One week after i.p. injections, mice were exposed by inhalation to MWCNTs (5 mg/m<sup>3</sup>, 5 hours/day, 5 days/week) or filtered air (controls) for a total of 15 days. The B6C3F1 mouse used in this study has intermediate susceptibility to lung carcinogenesis, and data obtained will have relevancy to existing human lung tumor data because lung tumors in this mouse strain exhibit many molecular and morphological similarities to human pulmonary tumors. At 17 months post-exposure, mice were euthanized and examined for lung tumor formation. Twenty percent of the filtered air controls, 33% of the MWCNT-exposed, and 50% of the MC followed by air-exposure, had a mean of one tumor per mouse. By contrast, 100% of the mice which received MC followed by MWCNTs had tumors with an average of 3.6 tumors per mouse. Additionally, mice exposed to MWCNTs or MC followed by MWCNTs had larger tumor volumes than their corresponding air-exposed control groups. Our preliminary data suggests that MWCNT exposure promotes the growth of spontaneously and chemically initiated lung cells, resulting in the development of lung tumors. In this study, mouse MWCNT lung burden approximates feasible human occupational exposures. Therefore, the results of this ongoing study indicate that caution should be used to limit human exposures to MWCNTs.

## PS 458 Toxicological Evaluation of Pulmonary Exposure to Graphenes of Different Sizes.

J. R. Roberts<sup>1,2</sup>, A. Kenyon<sup>1</sup>, S. S. Leonard<sup>1,2</sup>, N. R. Fix<sup>1</sup>, D. W. Porter<sup>1,2</sup>, T. M. Sager<sup>1,2</sup>, M. Wolfarth<sup>1</sup>, B. M. Yingling<sup>2,1</sup>, I. S. Chaudhuri<sup>3</sup>, A. Kyrilidis<sup>3</sup>, S. A. Bilgesu<sup>1</sup>, R. R. Mercer<sup>1,2</sup>, D. Schwegler-Berry<sup>1</sup>, V. Castranova<sup>1</sup> and A. Erdelyi<sup>1,2</sup>. <sup>1</sup>NIOSH, Morgantown, WV; <sup>2</sup>WVU, Morgantown, WV; <sup>3</sup>Cabot Corporation, Billerica, MA.

Research on the uses and manufacturing of nano graphene has increased dramatically in the past decade. Thus, worker inhalation of graphene nanopowders is likely. The goal of this study was to evaluate the lung toxicity of three non-oxidized graphene (Gr) samples of different sizes [20 µm lateral x 7-10 nm thick (Gr20), 5 µm lateral x 7-10 nm thick (Gr5), and <2 µm lateral x 1-2 nm thick (Gr1)]. Gr samples were diluted in physiological dispersion medium (DM) and characterized for size, surface reactivity, and free radical generation *in vitro*. Male C57BL/6J mice received 4 or 40 µg of Gr1, Gr5, or Gr20, or 40 µg of carbon black (CB; particle control), or DM (vehicle control) by aspiration. Mice were sacrificed at 4 hr (day 0), 1, 7, and 28 days post-exposure. Lung lavage was performed, the fluid and cells were retained, and indices of lung injury and inflammation were examined. Particle/aggregate size ranged from ~ 5-300 µm, 0.5-60 µm, and 0.2-5µm for Gr20, Gr5, and Gr1, respectively, with CB being similar to Gr1. Electron spin resonance (ESR) indicated that all Gr samples and CB had low to no surface reactivity as compared to a positive control (α-quartz). *In vitro*, ESR showed all Gr samples induced free radical production by mouse monocytes with significantly greater response in Gr20- and Gr5-treated cells compared to Gr1- and CB-treated cells. Indices of lung injury in lavage fluid were increased for the 40 µg doses of Gr20 and Gr5 on days 0, 1, and 7 when compared to control. Gr1 (40 µg) produced an increase only at day 7. Increased lung injury in the CB group was comparable to Gr20 and Gr5 on days 1 and 7. Injury decreased in all groups by day 28. Inflammation was elevated in the 40 µg Gr20, Gr5, Gr1 and CB groups on day 1, but only in the 40 µg Gr20 and Gr5 groups on days 0 and 7. In summary, the larger Gr particles appeared to produce more toxicity at the early time points post-exposure when compared to controls.

## PS 459 A 28-Days Repeated Dose of Multiwalled Carbon Nanotubes (MWCNTs) in Sprague-Dawley Rats.

J. Sung<sup>2</sup>, B. Choi<sup>2</sup>, K. Song<sup>2</sup>, J. Kim<sup>2</sup>, K. Ahn<sup>3</sup>, G. Lee<sup>3</sup>, J. Lee<sup>5</sup>, J. Shin<sup>5</sup>, J. Lee<sup>1</sup>, K. Jeon<sup>4,3</sup> and I. Yu<sup>1</sup>. <sup>1</sup>Institute of Nanoparticle Safety Research, Hoseo University, Asan, Republic of Korea; <sup>2</sup>Bioconvergence Department, KCL, Incheon, Republic of Korea; <sup>3</sup>Mechanical Engineering, Hanyang University, Ansan, Republic of Korea; <sup>4</sup>HCT, Icheon, Republic of Korea; <sup>5</sup>Occupational Lung Diseases Institute, Korea Workers' Compensation Welfare Service, Icheon, Republic of Korea.

There is a lack of available information on the human health and environmental hazards of MWCNTs. For this reason, the current study investigated the inhalation toxicity potential of MWCNTs. Eight-week-old rats were divided into 4 groups (10 rats in each group), including the fresh air control (0 mg/m<sup>3</sup>), low-concentration group (0.2 mg/m<sup>3</sup>), middle concentration group (0.5 mg/m<sup>3</sup>), and high-concentration group (1.0 mg/m<sup>3</sup>), and exposed to MWCNTs for 5 days (6 hrs/day) in nose-only inhalation exposure system. Then the rats were allowed to recover for 1 and 3 months by ceasing the exposure. At the end of the study, the rats were subjected to a full necropsy. Cellular differential counts and inflammatory measurements, such as albumin, lactate dehydrogenase (LDH), total protein, and cytokines were also monitored in the a cellular bronchoalveolar lavage (BAL) fluid of the rats exposed to the MWCNTs for 28 days. Histopathological, hematological and clinical chemistry examinations indicated that there were no significant findings related to MWCNT exposure after 28 days of MWCNT inhalation exposure.

## PS 460 Toxic Effects of MWCNT *In Vivo* and *In Vitro*.

A. Schlichting<sup>1</sup>, C. Ziemann<sup>1</sup>, A. Leonhardt<sup>2</sup>, R. Susanne<sup>1</sup>, S. Dirk<sup>1</sup> and B. Bernd<sup>1</sup>. <sup>1</sup>Fraunhofer ITEM, Hannover, Germany; <sup>2</sup>Leibniz Institute for Solid State and Materials Research, Dresden, Germany. Sponsor: C. Dasenbrock.

Multiwall carbon nanotubes (MWCNT) are discussed to exhibit a toxic potential depending on their length and fiber-like shape. For this reason, potential adverse biological effects *in vivo* (rat) and *in vitro* (human peritoneal mesothelial LP9/TERT-1 cells) of MWCNT are investigated in a project funded by the German BMF (contract No. 03X0109A). In this project MWCNT data are compared with long amosite asbestos as a positive control and more particle-like MWCNT (Baytubes®, milled MWCNT, and Printex 90) as negative controls. For this study custom made MWCNT with different length and diameter were produced. To investigate the carcinogenic potential of these MWCNT, they were suspended in artificial lung-like medium using a sonotrode. The separated MWCNT were applied to the rats by intraperitoneal injection. In addition to the carcinogenicity study, the proliferation of cells in the diaphragm was investigated as a short time screening test after 3 month, using a BrdU method. To determine cytotoxicity *in vitro* LP9/TERT-1 cells were incubated for 24h with the same MWCNT, suspended in culture medium, and the toxic potential was estimated by cell counting and subsequent calculation of the relative increase in cell count (RICC). Suspension, size, and distribution of MWCNT were always monitored by SEM. CNT3 (length: 8.57 µm; diameter: 0.085 µm) and long amosite (length: 13.95 µm; diameter: 0.39 µm) led to significant thickening of the diaphragm, as compared to the negative control. With CNT2 (length: 10.24 µm; diameter: 0.04) a high amount of BrdU positive cells were noted. In the *in vitro* study part both CNT1 (length: 7.91 µm; diameter: 0.037 µm), CNT2, CNT3 and long amosite asbestos mediated strong reduction in cell number, compared to the particle controls, indicating a marked cytotoxic potential. In conclusion, some MWCNT mediate enhanced proliferation in rat diaphragm which may result in mesothelioma development and certain MWCNT exhibit a cytotoxic potential in mesothelial cells *in vitro*.

## PS 461 Carbon Nanotubes Enhance Metastatic Growth of Lung Carcinoma via Up-Regulation of Myeloid-Derived Suppressor Cells.

M. Shurin<sup>1</sup>, A. V. Tkach<sup>2</sup>, E. Kisin<sup>2</sup>, T. Khaliullin<sup>2</sup>, S. Stanley<sup>2</sup>, D. Gutkin<sup>1</sup>, A. Star<sup>4</sup>, Y. Chen<sup>4</sup>, G. Shurin<sup>1</sup>, V. Kagan<sup>3</sup> and A. A. Shvedova<sup>2</sup>. <sup>1</sup>Department of Pathology, University of Pittsburgh, Pittsburgh, PA; <sup>2</sup>PPRB, HELD, NIOSH, Morgantown, WV; <sup>3</sup>Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA; <sup>4</sup>Department of Chemistry, University of Pittsburgh, Pittsburgh, PA.

Expanding applications of nanomaterials, particularly carbonaceous nanoparticles (CNP), in new technologies, consumer products and biomedicine, imply their increasing levels of manufacturing. There are numerous attempts to utilize nanoparticles for better delivery of drugs and nucleic acid-based therapeutics to disease sites in the lung, particularly to the lung epithelium. The inhalation of drug nano-for-

mulations propelled the development of new strategies in therapy of several human lung diseases such as asthma, cystic fibrosis, chronic obstructive pulmonary disease, lung cancer, tuberculosis, etc. Safety and lack of adverse health effects remain the major pre-requisites for broader applications of these novel technologies. Toxicological assessments of nano-particles typically are performed on normal animals. Thus possible effects of CNP on tumor growth have not yet been considered. The immune system safeguards the host from infections and malignancies. Recognition and undesirable interactions of CNP with cells of the immune system may lead to immunomodulation, hence increasing the host's susceptibility to infections and cancer. Here, we show that single wall carbon nanotubes (SWCNT) promote metastatic establishment and growth of Lewis lung carcinoma in C57BL/6J mice. The effect was mediated by increased local and systemic accumulation of myeloid-derived suppressor cells (MDSC), as their depletion abrogated pro-tumor activity in vivo. These data are important for the design of novel theranostics platforms with modules capable of depleting or functionally suppressing MDSC to ensure effective immunosurveillance in the tumor microenvironment.

**PS 462 IL-33 Modulates Chronic Airway Resistance Changes Induced by Multiwalled Carbon Nanotubes.**

X. Wang, J. Shannahan and J. M. Brown. *Pharmacology & Toxicology, East Carolina University, Greenville, NC.*

As the field of nanotechnology rapidly grows, the potential health hazards for human exposure rise. We have previously demonstrated that oropharyngeal instillation of multi-walled carbon nanotubes (MWCNTs) in C57BL/6 mice leads to increases in total respiratory system resistance (R) and Newtonian resistance (Rn), which is a measure of central airway resistance. In this study, we hypothesized that IL-33, a critical immune system alarmin, modulates mechanisms of pulmonary toxicity following exposure to MWCNTs. We assessed lung histology and pulmonary function in C57BL/6 and IL-33<sup>-/-</sup> mice 30 days following oropharyngeal aspiration of MWCNTs. The total number of bronchoalveolar lavage cells and the recruitment of neutrophils was increased in C57BL/6 mice following MWCNT exposure. In contrast, IL-33<sup>-/-</sup> mice exposed to MWCNTs did not demonstrate alterations in bronchoalveolar lavage cell content. Furthermore, C57BL/6 mice displayed increased inflammation around the airways demonstrated by histopathology which was unseen in IL-33<sup>-/-</sup> mice. To determine if these histopathological changes impact airway resistance, MWCNT exposed C57BL/6 were challenged with cumulative doses of methacholine (Mch) between 1.5 mg/ml and 24 mg/ml. Aerosolized Mch increased R and Rn in a dose-dependent manner in all groups with MWCNT instilled C57BL/6 mice responding with significantly higher R and Rn compared to control C57BL/6 mice. Importantly, increases in R and Rn induced by MWCNT were dependent on IL-33, as there was no significant difference between MWCNT treated and control IL-33<sup>-/-</sup> mice. In conclusion, these results indicate IL-33 plays an important role in pulmonary toxicity induced by MWCNT by influencing airway resistance via an inducible inflammatory response. This work supported by NIH RO1 ES019311.

**PS 463 Pulmonary Toxicity Assessment of Multiwalled Carbon Nanotubes after Single Intratracheal Instillation in a One-Year Bioassay of Rats.**

M. Naya, N. Kobayashi, K. Honda, M. Ema and J. Nakanishi. *National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan.*

Well-dispersed multi-wall carbon nanotubes (MWCNTs) were instilled intratracheally at dosage of 1.0 or 2.6 mg/kg body weight to male Wistar rats. A negative (vehicle) control, 0.5 mg/mL Triton X-100 was administered in a similar manner. After instillation, the bronchoalveolar lavage fluid (BALF) was assessed for the inflammatory biomarkers, and the lung, liver, kidney, spleen, and cerebrum were examined histopathologically at 1-day, 3-day, 1-week, 4-week, 3-month, 6-month, and 12-month post-exposure. Transient pulmonary inflammatory responses were observed up to 3-month post-exposure. In the histopathological examination, 1.0 and 2.6 mg/kg of MWCNTs deposited in the lungs were phagocytosed by the alveolar macrophages and these macrophages were accumulated in the alveoli up to 12-month post-exposure. There was no evidence of chronic inflammation, such as angiogenesis or fibrosis which induced by MWCNT instillation. These results suggest that MWCNTs were being processed and cleared by alveolar macrophages.

**PS 464 Thirteen-Week Inhalation Toxicity Study with a Multiwall Carbon Nanotube Test Material in Wistar Rats.**

D. Schuler<sup>1</sup>, K. L. Reed<sup>2</sup>, M. P. DeLorme<sup>2</sup>, Y. Okazaki<sup>1</sup>, Y. Muro<sup>4</sup>, H. J. Chevalier<sup>3</sup> and D. B. Warheit<sup>2</sup>. <sup>1</sup>Harlan Laboratories Ltd., Fuellinsdorf, Switzerland; <sup>2</sup>DuPont Haskell Lab, Wilmington, DE; <sup>3</sup>Anapath GmbH, Oberbuchsitzen, Switzerland; <sup>4</sup>Showa Denko K.K., Tokyo, Japan.

A subchronic inhalation toxicity study of an inhaled vapor-grown multiwall carbon nanotube (MWCNT) test substance was conducted in male and female Wistar rats. The test sample was composed of > 99.5% carbon, containing limited (Fe) catalyst metals; BET surface area measurements of ~25 m<sup>2</sup>/g; and average lengths/diameters of 9 µm and 100 nm, respectively. Four groups of rats per sex were exposed nose-only, 6 h/day, for 5 days/week to aerosol concs. of 0, 0.013 (low), 0.055 (mid) or 0.53 (high) mg/m<sup>3</sup> MWCNT (MMAD ranging from 0.85 – 1.64 µm) over a 91-day period and evaluated 1 day later. Toxicity evaluations included clinical and histopathology methods, and bronchoalveolar lavage fluid (BALF) analyses. Additional control and high exposure groups were evaluated at 3 months PE. Results demonstrated that MWCNT exposures produced no significant adverse extrapulmonary effects. Absolute and relative lung weights were increased in high exposure conc. vs. controls and to a lesser extent after the recovery period. The results of BALF studies demonstrated increased GGT, LDH and ALK PHOS levels vs. controls in mid/high exposure groups. In addition, increased numbers of BALF cells were recovered at 0.53 mg/m<sup>3</sup> MWCNT. Principal histopathological findings consisted of granulomatous lesions in centriacinar regions of male/female rats exposed to 0.53 mg/m<sup>3</sup>, and in some females at 0.055 mg/m<sup>3</sup>. The lesion was characterized by aggregation of pulmonary macrophages and focal pulmonary hypertrophy/hyperplasia of lung epithelial cells. In the nasal cavities, an increase of eosinophilic inclusions in the respiratory/olfactory epithelium was noted at 0.53 mg/m<sup>3</sup> which was followed by the olfactory epithelial injury in the recovery animals. Based on the findings in respiratory tract tissues (lungs and nasal cavities), the overall LOAEL was considered to be 0.055 mg/m<sup>3</sup>, and the corresponding NOAEL was determined to be 0.013 mg/m<sup>3</sup> under the conditions of this study.

**PS 465 Carbon Nanotube Dosimetry: From Workplace Exposure Assessment to Inhalation Toxicology.**

M. Dahm<sup>1</sup>, B. T. Chen<sup>2</sup>, M. E. Birch<sup>1</sup>, D. E. Evans<sup>1</sup>, M. K. Schubauer-Berigan<sup>1</sup>, T. Hulderman<sup>2</sup>, S. A. Bilgesu<sup>2</sup>, H. D. Leonard<sup>2</sup>, W. McKinney<sup>2</sup>, D. Frazer<sup>2</sup>, J. M. Antonini<sup>2</sup>, D. W. Porter<sup>2</sup>, V. Castranova<sup>2</sup>, P. C. Zeidler-Erdely<sup>2</sup> and A. Erdely<sup>2</sup>. <sup>1</sup>NIOSH, Cincinnati, OH; <sup>2</sup>NIOSH, Morgantown, WV.

Relevant dosimetry for toxicology studies involving multi-walled carbon nanotubes (MWCNT) has not been well described due to a lack of detailed occupational exposure assessments. In response, exposure assessment findings from U.S.-based MWCNT manufacturers and users were extrapolated to results of an inhalation study in mice. Inhalable and respirable personal breathing zone (PBZ) samples from 9 facilities were collected for the mass concentration of elemental carbon. Upon analysis, 95% of the PBZ samples found exposure concentrations to be <10 µg/m<sup>3</sup> with an average inhalable concentration of 8.5 µg/m<sup>3</sup>. At facilities where respirable and inhalable PBZ samples were collected, respirable samples were approximately 25% of the inhalable size fraction. Using 10 µg/m<sup>3</sup>, standard worker ventilatory parameters, and assuming 11% alveolar deposition, alveolar deposition was calculated to be 10.56 µg/d. Extrapolation to mouse equivalence by surface area equals 5.2 ng/d. In complement, a 19 d inhalation exposure to MWCNT with daily alveolar depositions of 1250 ng (=240 d of human exposure at 10 µg/m<sup>3</sup>), 125 ng (=24 d), and 12.5 ng (=2.4 d) was conducted. Mice were sacrificed at day 0, 3, 28, and 84 post-exposure. Pulmonary cytotoxicity (LDH activity) and polymorphonuclear cell (PMN) influx were evident at the high dose through day 84. For the middle dose, no PMN influx was evident and cytotoxicity was significant only at day 0. Lung inflammatory gene expression was increased at the high and middle dose. Alveolar macrophages harvested after exposure and stimulated with LPS showed enhanced cytokine release at the high dose and day 0 for the middle dose. No exposure effects were observed at the lowest dose. These results show a no effect dose lies somewhere in between the middle (=456 d at 10 µg/m<sup>3</sup>) and low dose (=45.6 d). The findings stress the importance of exposure assessment when extrapolating results of animal MWCNT exposures to potential human outcomes.

**PS 466 Pharmacokinetics and Pharmacodynamics of C60 and Nanosilver in Nonpregnant, Pregnant, and Lactating Rats.**

R. Snyder<sup>1</sup>, S. Sumner<sup>1</sup>, S. Black<sup>1</sup>, A. Lewin<sup>1</sup>, R. Tyl<sup>1</sup>, M. Levine<sup>1</sup>, C. J. Wingard<sup>2</sup> and T. Fennell<sup>1</sup>. <sup>1</sup>Discovery Sciences, RTI International, Research Triangle Park, NC; <sup>2</sup>Department of Physiology, East Carolina University, Greenville, NC.

Pregnancy and lactation represent periods in which the female and her offspring may be more sensitive to adverse effects from exposure to nanoparticles. The distribution of nanoparticles during pregnancy and lactation has not been comprehensively investigated. We therefore examined the absorption, distribution, and excretion of C60 and two sizes of nanosilver (NS) in nonpregnant, pregnant, and lactating rats. Rats were dosed via tail vein injection with [<sup>14</sup>C]C60 solubilized with polyvinylpyrrolidone (PVP) in saline. [<sup>14</sup>C]C60 was administered to pregnant rats on gestational day (gd) 11, 15, or 18 and lactating rats on postnatal day (pnd) 8. Nonpregnant and pregnant rats (gd 18) were dosed via tail vein injection (1 mg/kg) or oral gavage (10 mg/kg) with 20 nm or 110 nm NS stabilized with PVP in water, equivalent doses of silver acetate, or vehicle. Urine, feces, blood, and tissues were collected following dosing, and quantitative whole body autoradiography of [<sup>14</sup>C]C60 was conducted. The largest portion of the [<sup>14</sup>C]C60 derived radioactivity was detected in the liver (~29%), lung (~31%), and spleen (~5%) after a single iv dose in the pregnant rat, and detected in the liver (~54%), lung (~8%), and spleen (~4%) in the lactating rat. Radioactivity was above background for many additional tissues. Less than 1% of the radioactivity recovered was found in urine and feces at all time points for the pregnant rats. The majority (55%) of the recovered oral 110 nm NS dose was found in feces after 48 hr. Following iv dosing, 11% of the dose was recovered in feces for the 110 nm NS and 27% for the 20 nm NS. The highest concentration of nanosilver was found in the spleen for both sizes of NS. Plasma cytokine and urinary 8-hydroxydeoxyguanosine levels were determined. This study demonstrated substantial differences in the retention of C60 compared with nanosilver. (Supported by NIEHS U19ES019525)

**PS 467 Signal Transducer and Activator of Transcription 1 (STAT-1) Suppresses Pulmonary Inflammation following Allergen Sensitization & Exposure to Multiwalled Carbon Nanotubes.**

E. E. Anderson Thompson, A. J. Taylor, E. E. Glista-Baker, B. C. Sayers and J. C. Bonner. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

Multi-walled carbon nanotubes (MWCNT) pose a potential risk to human health, especially in individuals with pre-existing lung diseases such as asthma. A key factor in asthma is an imbalance of T-helper type 1 (Th1) and type 2 (Th2) cells. STAT-1 is a transcription factor that maintains Th1 development. We postulated that mice deficient in STAT-1 would be susceptible to ovalbumin (OVA) allergen challenge and display increased airway disease to MWCNT. STAT-1<sup>-/-</sup> and wildtype (WT) mice were sensitized to OVA by i.p. injection on days 0 & 12, followed by OVA intranasal challenge on days 26, 28, & 32. On day 34, mice were exposed to 4 mg/kg MWCNT or saline/0.1% pluronic surfactant by oropharyngeal aspiration. Necropsy was performed 1 & 21d post-MWCNT exposure. Lungs were lavaged to collect inflammatory cells and bronchoalveolar lavage fluid (BALF), right lung was collected for RNA & protein, and left lung for histopathology. Ashcroft scoring of H&E-stained lung sections revealed that OVA-sensitized STAT-1<sup>-/-</sup> mice displayed significantly greater inflammation compared to vehicle control treated STAT-1<sup>-/-</sup> mice at 21 d, and this was not exacerbated by MWCNT. However, BALF differential cell counts revealed that OVA-sensitized STAT-1<sup>-/-</sup> mice treated with MWCNT had significantly increased numbers of neutrophils & eosinophils compared to similarly treated WT mice at 21 d. Quantitative morphometry of Alcian blue PAS & trichrome stained lung sections revealed that the OVA-sensitized STAT-1<sup>-/-</sup> mice also produced significantly more airway mucus and collagen after exposure to MWCNT. ELISA performed on BALF showed significant increases in the pro-fibrogenic mediators IL-1 $\beta$ , TGF- $\beta$ 1, and osteopontin in the OVA sensitized STAT-1<sup>-/-</sup> mice treated with MWCNT at 21d. Taken together, these results suggest that STAT-1 suppresses the exacerbation of lung disease by MWCNT in individuals with asthma. (Funded by NIEHS RC2 ES018772 and R01 ES020897)

**PS 468 Resolution of Inflammatory and Surfactant Alterations Mediated by Carbon Black and Silver Nanospheres.**

D. Botelho<sup>1</sup>, S. Sarker<sup>2</sup>, F. Chung<sup>3</sup>, A. Porter<sup>3</sup>, S. Schwander<sup>2</sup> and A. Gow<sup>1</sup>. <sup>1</sup>Toxicology, Rutgers The State University of New Jersey, Piscataway, NJ; <sup>2</sup>UMDNJ, Piscataway, NJ; <sup>3</sup>Imperial College London, London, United Kingdom.

Environmental exposure to engineered nanomaterials (ENMs) is on the rise, in particular inhalation exposure. The consequences of ENM interaction with the lung are not well understood, including the effects on function and inflammation. We

have examined how carbon and silver nanospheres interact with the lung lining and alter pulmonary function and inflammation. C57Bl6/J male mice were intratracheally instilled with saline (control), low (0.05  $\mu$ g/g) or high (0.5  $\mu$ g/g) doses of either silver or carbon black 15nm nanospheres. Lung histology, cytology, surfactant composition and function, inflammatory gene expression, and pulmonary function were measured at 1, 3, and 7 days post exposure. One-day post exposure, high dose carbon black resulted in a classic inflammatory response: increased neutrophilia ( $19 \pm 0.002$  v.  $2.5 \pm 0.0004 \times 10^3$  cells), increased cytokine production (IL-1 $\beta$  2.6 and IL-6 1.7 mRNA fold induction vs control), peribronchial infiltration, and increased low-pressure lung elastance. Low dose carbon black did not differ significantly from control. Examination of these markers 3 days post exposure shows a classic injury response with neutrophilia ( $28.7 \pm 6.1$  vs  $2.7 \pm 0.2 \times 10^3$  cells) and increased macrophage numbers ( $139 \pm 0.006$  v.  $147 \pm 2.6 \times 10^3$  cells at day 1 v. 3). At day 7, neutrophilia has resolved, while macrophage numbers remain high ( $198 \pm 5.6 \times 10^3$  cells). Carbon nanospheres persist within recruited macrophages. Neither low nor high dose silver particles resulted in inflammation 1 day post exposure. There was significantly increased tissue stiffness compared to control, which was paralleled by reduced surfactant function and disrupted surfactant protein expression. Lung function begins to resolve 3 days post exposure to silver particles; however, there is a delayed inflammatory response which is resolving by day 7. These data suggest that silver nanoparticles may have a unique toxicological profile that is dependent upon disruption of lung function.

**PS 469 Biocompatibility of Graphene Nanoplatelets in Terminal Arterioles.**

S. Chowdhury<sup>1</sup>, M. Frame<sup>1</sup>, A. M. Dewar<sup>1</sup>, S. Kanakia<sup>1</sup>, J. Touissant<sup>1</sup>, W. Moore<sup>2</sup> and B. Sitharaman<sup>1</sup>. <sup>1</sup>Biomedical Engineering, Stony Brook University, Stony Brook, NY; <sup>2</sup>Radiology, Stony Brook University, Stony Brook, NY. Sponsor: T. Nurkiewicz.

Carbon-based nanomaterials are currently being tested for a range of medical uses from drug delivery vehicles to contrast enhancing agents for magnetic resonance imaging (MRI). Ensuring biocompatibility is essential for each compound and formulation. Our goal was to evaluate the microvascular effect of graphene nanoparticles known as graphene oxide nanoplatelets (GNPs). The hydrophobic GNPs (20-60nm by 15-35nm, 3-4nm thick) were water-solubilized via non-covalent functionalization with 3.5 mg/ml of the biocompatible natural polymer dextran (GNP-Dex). Adult male hamsters (N=11) were anesthetized (isoflurane) and prepared for intravital microscopy observation of the cheek pouch tissue terminal arterioles; these arterioles control nutrient flow. GNP-Dex (0-50mg/ml) were micropipette applied to small terminal arterioles (~10um dia., 30s), where 0 mg/ml was dextran alone, 2.5mg/ml was the projected therapeutic circulation dose, and 50mg/ml was the highest expected i.v. injection dose when used as a drug delivery or MRI contrast agent. Based on the pipette delivery conditions, the dose of 50mg/ml would expose that arteriole to 127 pg of GNP-Dex. GNP-Dex induced a dose dependent dilation (EC50  $6.9 \pm 0.6$ mg/ml, maximal dilation  $70 \pm 2\%$  increase from baseline). Dextran alone was not vasoactive. We next tested whether acute exposure to 50mg/ml induced endothelial dysfunction, a hallmark sign of cardiovascular inflammation. Comparing before vs. after GNP-Dex exposure, dilator (acetylcholine, 10-4M) and constrictor (phenylephrine, 10-4M) responses were unchanged, unlike our prior work with single-walled carbon nanotubes, which induced a profound endothelial dysfunction. Thus, the direct effect of GNP-Dex is dilation, but there is no residual adverse effect of this formulation on terminal arteriole control of tone. (NIH HL55492; AHA 0655908T; Wallace H. Coulter Foundation)

**PS 470 In Vitro Penetration of Amine Terminated Dendrimer Nanoparticles into Pig and Human Skin.**

M. E. Kraeling<sup>1</sup>, V. D. Topping<sup>1</sup>, X. Gao<sup>1</sup>, O. A. Ogunsola<sup>1</sup>, K. Schlick<sup>2</sup>, E. Simanek<sup>2</sup>, S. Man<sup>3</sup>, A. K. Patri<sup>3</sup>, R. L. Sprando<sup>1</sup> and J. J. Yourick<sup>1</sup>. <sup>1</sup>Office of Applied Research and Safety Assessment, US FDA, Laurel, MD; <sup>2</sup>Department of Chemistry, Texas Christian University, Fort Worth, TX; <sup>3</sup>Nanotechnology Characterization Laboratory, SAIC-Frederick, Frederick National Laboratory for Cancer Research, Frederick, MD.

Dendrimers are highly branched stable polymeric nanoparticles with terminal functional groups capable of binding other molecules. There is concern about the potential for dendrimers to increase skin absorption of ingredients currently considered safe in cosmetics. We evaluated the skin penetration of amine-terminated generation 3 (G3), generation 4 (G4), generation 5 (G5) and generation 6 (G6) polyamidoamine (PAMAM) dendrimer nanoparticles (positive surface charge). Alexa Fluor 568 (~1 equivalent per dendrimer) was conjugated to terminal amines on PAMAM dendrimers via amide bonds for confocal imaging. Free unconjugated

fluorophore was removed by ultrafiltration followed by gel filtration, and characterized. Dendrimers were applied (0.2% concentration) in aqueous solutions or cosmetic emulsion formulation onto viable pig or human cadaver skin assembled in diffusion cells. After a 24 hour exposure, the skin surface was washed to remove unabsorbed dendrimer. The extent of skin penetration was determined by laser scanning confocal microscopy. Most fluorescence from the applied dendrimers appeared on or in the stratum corneum, in hair follicles, or in folds of both pig and human skin. Fluorescence appeared in the upper regions of the epidermis of pig skin with the small generation dendrimers using both the solution and emulsion application. Fluorescence also appeared deeper in the dermal layers of pig skin when smaller generation dendrimers were applied at a higher dose. In human skin, small generation dendrimers penetrated skin at the low and high dose application. Dendrimers applied in emulsions did not penetrate beyond the stratum corneum of human skin. Further studies will examine dendrimer surface functionalization on skin penetration.

**PS 471 Identifying Data Gaps and Prioritizing Research Areas Necessary for Risk Assessment of Multiwalled Carbon Nanotubes.**

K. Fedak, A. Turner, A. Harris and D. Burch. *ICF International, Durham, NC.*

The pace of chemical hazard assessment has not maintained pace with the introduction of new chemicals into the market place, with much of the growth in consumer products applications. As a result, scientists must prioritize resources towards research that fills key data gaps and enables better risk assessment and management. The application of the first step of an iterative comprehensive environmental assessment (CEA) process is used to describe hazard and identify research priorities as well as inform risk management decisions for a range of different chemicals, products, and technologies. The CEA framework allows risk assessors to evaluate the state-of-the-science regarding a new chemical for application in hazard assessment. A case study on an emerging nano-enabled consumer product—multiwalled carbon nanotube flame retardant coatings on upholstery textiles—was conducted using the CEA framework to identify what is known and not yet known about the substance. Side-by-side information on decabromodiphenyl ether (decaBDE), a non-nanoenabled flame retardant that is currently in the process of being phased out, was presented as a comparison to illustrate the suitability of available MWCNT data for informed risk assessment and risk management decisions. For each material, the case study synthesized the available data on primary and secondary contaminants, analytical techniques, fate and transport processes, cumulative and aggregate exposure, and ecological and human health impacts throughout the life cycle of the product. The case study was subsequently used as an informative tool in a stakeholder-involved collective judgment process to identify data gaps and prioritize research areas critical to future risk assessment of MWCNTs and carbon nanomaterials in general.

**PS 472 Association of Rice and Grain Consumption with Urinary Concentrations of Total Arsenic and Dimethylarsinic Acid in US Adults.**

Y. Wei<sup>1</sup>, J. Zhu<sup>2</sup> and A. Nguyen<sup>1</sup>. <sup>1</sup>Department of Community Medicine, Mercer University School of Medicine, Macon, GA; <sup>2</sup>Department of Mathematics and Computer Science, Fort Valley State University, Fort Valley, GA.

Exposure to inorganic arsenic in the general population occurs mainly from drinking water and food sources. In the United States, levels of exposure are relatively low and the drinking water might not be the main source of exposure, compared to those endemic regions where the pump well water has been used as drinking water supply. To this end, we examined the association between dietary intake and urinary concentrations of arsenic in the U.S. adult population, aged 20-85 years, in the 2003-2006 National Health and Nutrition Examination Survey. Total arsenic (tAs) and dimethylarsinic acid (DMA) were detected in urine of 99% and 87% of the study participants, respectively, and were analyzed in the study. Statistical analyses were performed using SAS 9.3. To control for urine dilution in spot urine samples, creatinine-adjusted urinary concentrations of tAs and DMA were determined. Urinary concentrations of tAs and DMA were categorized into low and high exposure groups by a cutoff value of 50th percentiles. A significantly higher percentage of high exposure to both arsenic species was found in participants who consumed rice and grain  $\geq$  once per week, compared to the reference group with consumption

< once per week (55.67% vs. 45.33% for tAs;  $p < 0.0001$  and 59.61% vs. 43.48% for DMA;  $p < 0.0001$ ). Logistic regression analysis revealed a statistically significant association between rice and grain consumption and urinary concentrations of tAs [adjusted OR=1.39 (1.03, 1.87)] and DMA [adjusted OR=1.97 (1.41, 2.74)] after adjustment for age, gender, race, family income, education, seafood intake (the main source of organic arsenic), and source of drinking water. This study demonstrated that rice and grain consumption contributed to inorganic arsenic exposure in U.S. adults. Racial groups consuming high amounts of rice and grain showed significantly higher exposure to arsenic, especially to DMA.

**PS 473 Prenatal Exposure to Inorganic Arsenic in Gómez Palacio, Mexico, Links to Contaminated Drinking Water.**

J. E. Laine<sup>2</sup>, M. Rubio-Andrade<sup>4</sup>, A. F. Olshan<sup>2</sup>, M. Styblo<sup>3</sup>, G. G. Garcia-Vargas<sup>4</sup> and R. C. Fry<sup>1</sup>. <sup>1</sup>Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>3</sup>Nutrition, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>4</sup>Facultad de Medicina, Universidad Juárez del Estado de Durango, Gómez Palacio, Mexico.

Exposure to inorganic arsenic (iAs) from drinking water is a global public health problem, however much is still unknown about the amount of exposure in susceptible populations, such as pregnant women. The aim of this study is to examine arsenic (As) exposure levels in a new prospective cohort in Gómez Palacio, Mexico. IAs and its methylated metabolites (e.g. methylarsonic acid (MMA) and dimethylarsinic acid (DMA)) were measured in a cohort of pregnant women in Gómez Palacio, Mexico. Levels of As in drinking water and urine were measured using hydride generation atomic absorption spectrometry (AAS). In the case of urine analysis, As species were separated by cryotrapping in liquid nitrogen prior to AAS detection. All women had detectable levels of As in their drinking water ( $n=202$ ). The mean iAs concentration in drinking water was 24.5  $\mu\text{g/L}$ , with a range of 0.46  $\mu\text{g/L}$  to 236  $\mu\text{g/L}$ . Over half ( $n=107$ ) of women's household samples had values that were above the WHO's safe drinking water guidelines of 10  $\mu\text{g/L}$ , and 21 percent were above the MCL (50  $\mu\text{g/L}$ ) for Mexico. There was an association with iAs in drinking water and urine ( $p < 0.01$ ). Most women ( $n=188$ ) had detectable levels of As in their urine. Mean concentrations were 46.7  $\mu\text{g/L}$ , 6.8  $\mu\text{g/L}$ , and 35.3  $\mu\text{g/L}$  for total iAs, total MMA and total DMA, respectively. These data show that pregnant women are exposed to iAs in their drinking water in Mexico. Findings from this study support the need for further investigation into the association of health effects from prenatal exposure to arsenic contaminated drinking water.

**PS 474 Is the Relationship Between Prenatal Exposure to Polychlorinated Biphenyls (PCB) and Birthweight Attributable to Pharmacokinetics?**

M. Verner<sup>1,2</sup>, R. McDougall<sup>3</sup>, A. Glynn<sup>4</sup>, M. E. Andersen<sup>5</sup>, H. J. Clewell<sup>5</sup> and M. P. Longnecker<sup>6</sup>. <sup>1</sup>Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Faculty of Engineering and Applied Science, University of Ontario Institute of Technology, Oshawa, ON, Canada; <sup>4</sup>Swedish National Food Administration, Uppsala, Sweden; <sup>5</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>6</sup>Epidemiology Branch, National Institutes of Environmental Health Sciences, Research Triangle Park, NC.

Epidemiologic studies have reported an association between exposure to PCBs and reduced birthweight. However, gestational weight gain is associated negatively with PCB levels during pregnancy and positively with birthweight, so whether the reported association is mainly driven by noncausal, pharmacokinetic effects is unclear. We evaluated the influence of gestational weight gain on the association between PCB exposure and birthweight using a previously developed physiologically based pharmacokinetic (PBPK) model that was modified to account for the relations between maternal weight and fat gain and birthweight. We ran Monte Carlo simulations to generate realistic profiles of blood PCB-153 levels throughout pregnancy. The association between PCB-153 levels and birthweight was evaluated in the simulated population using linear regression analyses. We observed a small negative association between maternal blood levels and birthweight. In models that did not adjust for maternal weight gain, at delivery, a 69 g decrease in birthweight was observed for each 10-fold increase in blood PCB-153. However, the effect size was reduced to 8 g when we adjusted for gestational weight gain. Results from this study suggest that the association between prenatal exposure to PCBs and birthweight is strongly confounded by gestational weight gain. Epidemiologic studies on lipophilic persistent organic pollutants that do not control for gestational weight gain may strongly overestimate the size of the association.

**PS 475 Association of Serum Levels of PCBs with IL-8 mRNA Expression in Blood Samples from Asthmatic and Nonasthmatic Japanese Children.**

M. Tsuji<sup>1,2</sup>, T. Kawamoto<sup>2</sup>, C. Koriyama<sup>3</sup>, S. Akiba<sup>3</sup>, C. Vogel<sup>1</sup>, Y. Hsu-Sheng<sup>2</sup> and F. Matsumura<sup>1</sup>. <sup>1</sup>Department of Environmental Toxicology and the Center for Health and the Environment, University of California Davis, Davis, CA; <sup>2</sup>Department of Environmental Health, University of Occupational and Environmental Health, Kitakyusyu, Japan; <sup>3</sup>Department of Epidemiology and Preventive Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan.

Polychlorinated biphenyls (PCBs) are one of the most commonly found toxins in the environment. One suggested outcome of PCB exposure during early developmental periods in humans is childhood asthma. The primary objective of the current study was to clarify the causal relationship between PCB exposure and development of childhood asthma through the development of reliable biomarkers. Blood samples from fifteen asthmatic children and an equal number of non-asthmatic children (averaging 2 years of age) were collected and analyzed for select marker expression using qRT-PCR. At the time of collection, an interview included questions about the number of siblings, duration of breast feeding, smoking habits of parents, the parental history of allergic diseases and history of allergies of the study subjects.

Among biomarkers examined IL-8 expression was significantly correlated to serum levels of PCB #163+#164 (P=0.022), #170 (P=0.046), #177 (P=0.022), #178 (P=0.022) and #180+#193 (P=0.046) in a dose-dependent manner, which was found only among asthmatic children. In contrast to IL-8, significant correlations between COX-2 mRNA levels and individual congener levels were recognized only among control subjects, and not among asthmatic subjects.

In conclusion, the most important finding from the current study is that there exist significant correlations between children's exposure to PCBs and the occurrence of childhood asthma, which could be recognized by the use of a reliable biomarker such as IL-8 and selecting certain individual PCB congeners.

**PS 476 Pulmonary Function Testing in Emergency Responders.**

S. Harbison, G. Johnson, J. McCluskey, P. Xu, S. Morris, J. Wolfson and R. D. Harbison. *Environmental and Occupational Health, University of South Florida, Tampa, FL.*

Emergency responders may be exposed to a variety of fumes, gases, and particulates during the course of their job that may affect pulmonary function (PF) and may require the use of respiratory protection. This investigation used occupational health monitoring examination data to characterize PF in a population currently employed as emergency responders in the state of Florida. PF tests for workers (n=127) who required health examinations to ensure fitness for continued respirator use were compared to NHANES III Raw Spirometry subjects (n=9,792) to determine if decreased PF was associated with employment as an emergency responder. Mean FVC and FEV1 values were determined and multivariate regression was used to evaluate the impact of emergency responder status on PF after adjusting for confounders. Emergency responders produced a higher mean FVC of 5.11L (95%CI 4.95-5.26) compared to a mean NHANES III subject value of 4.01L (95%CI 3.99-4.03) (p<0.0001). Emergency responders also produced a higher mean FEV1 of 4.06L (95%CI 3.92-4.19) compared to a mean NHANES III subject value of 3.21L (95%CI 3.19-3.23) (p<0.0001). Stratification by age, sex, height, and smoking history yielded similar results. Multivariate regression analysis demonstrated significant predictors of FEV1 included age, height, sex, smoking history, and emergency responder status (p<0.0001). Significant predictors of FVC included age, height, sex, and emergency responder status (p<0.0001). The direction of effect for emergency responder status was beneficial for lung function (parameter estimates 0.45L FEV1 and 0.54L FVC). Logistic regression was used to determine the effect of PF predictors on generating and FEV1/FVC ratio less than 0.8. Emergency worker status was not associated with the production of a FEV1/FVC ratio less than 0.8. The modest increase in PF observed in emergency responders in multivariate analysis is likely due to a combination of effective exposure controls in the workplace and the healthy worker effect among aging workers.

**PS 477 Association between Copper, Iron, and Zinc Levels in Private Wells and Birth Defects Prevalence in North Carolina.**

A. P. Sanders<sup>1</sup>, T. A. Desrosiers<sup>1,2</sup>, A. H. Herring<sup>1</sup>, D. Enright<sup>2</sup>, A. F. Olshan<sup>1</sup>, R. E. Meyer<sup>2</sup> and R. C. Fry<sup>1</sup>. <sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC; <sup>2</sup>State Center for Health Statistics, Division of Public Health, Raleigh, NC.

Environmental metals including copper, iron and zinc are typically considered essential metals that are able to cross the placental barrier from mother to fetus. In excess, however, many essential metals are developmental toxicants. In this population-based study, we assessed the association between essential metal concentrations in private well water and birth defect prevalence in North Carolina. We conducted an ecologic study including 3,923 infants born between 2003 and 2005 with selected birth defects (cases) identified by the North Carolina Birth Defects Monitoring Program, and 347,587 non-malformed infants (controls). Residence at birth as well as over 20,000 measurements of metal concentrations in residential wells were geocoded. Analyses were conducted at the Census Tract level. Prevalence ratios (PR) with 95% confidence intervals (CI) were calculated to estimate the association between average concentration of each metal within Census Tracts and the prevalence of birth defects, adjusted for maternal age and race. The highest quartile of iron exposure was associated with a higher prevalence of conotruncal heart defects (PR: 2.2; 95%CI: 1.1-4.1) and a decreased prevalence of chromosomal defects (PR: 0.5; 95%CI: 0.3-0.9). In addition, the highest quartile of zinc exposure was associated with a higher prevalence of heart defects (PR: 2.3; 95%CI: 0.7-7.1) and reduction defects of the limbs (PR: 1.7; 95%CI: 0.8-3.5). Sensitivity analyses revealed similar associations. Our findings suggest evidence of a possible relationship between levels of environmental metals in drinking water and specific birth defects. Further research is needed to evaluate the potential associations. Given the known health effects of in utero metal exposure, these data suggest that it would be prudent for pregnant women relying on private wells for drinking water to have their wells tested.

**PS 478 Lack of an Association between Cumulative Exposure to Diacetyl and Changes in Pulmonary Health among Workers at a Food Flavorings Manufacturer.**

C. J. Ronk, D. M. Hollins, M. J. Jacobsen, A. M. Foda, D. A. Galbraith and D. J. Paustenbach. *ChemRisk, San Francisco, CA.*

Declines in metrics of pulmonary health have recently become a topic of interest for researchers studying the health effects of inhalation exposures to food flavorings such as diacetyl. To study the effects that occupational exposures to food flavorings may have on declines in the metrics, forced expiratory volume in one second (FEV1) and forced vital capacity (FVC), we examined data on a cohort of workers at a food flavorings manufacturer. Data were extracted from medical records, pulmonary health records, employment records, and industrial hygiene records to assess and estimate changes in FEV1 and FVC over time in relation to cumulative exposure to diacetyl and time worked in job positions that involve the handling and use of diacetyl and other food flavorings. Through the use of these data, tenure in various job tasks was calculated and linked with industrial hygiene data on diacetyl to form a job-exposure matrix and estimates of cumulative exposure (e.g., dose). For this analysis, total cumulative exposure for each worker was estimated by summing area-specific cumulative exposures (i.e., time spent in each work area multiplied by the median 8-hour time weighted average of diacetyl measured in those areas). Generalized estimating equation (GEE) models were used to evaluate the associations between cumulative dose to diacetyl and declines in FEV1 and FVC. GEE models were adjusted for obesity status, change in weight, hypertension status, age, race/ethnicity, gender, and smoking status. It was found that cumulative dose did not significantly affect changes in FEV1 (p=0.42) or FVC (p=0.34). The associations between tenure at the facility and changes in FEV1 and FVC were not statistically significant (p=0.79 and p=0.40, respectively). Tenure in positions that handled food flavorings was not associated with changes in FEV1 (p=0.49) or FVC (p=0.56). In this cohort of food flavoring manufacturing workers, changes in FEV1 and FVC over time were not affected by exposure to diacetyl.

**PS 479 DDT/DDE and Breast Cancer: NHANES 1999-2004 Analyses and a Meta-Analysis.**

S. Z. Ingber, F. Scinicariello, H. R. Pohl, H. G. Abadin and H. Murray. *DTHHS, ATSDR/CDC, Chamblee, GA.* Sponsor: P. Ruiz.

The biological basis for an investigation of dichlorodiphenyltrichloroethane (DDT) exposure and breast cancer risk stems from research indicating that DDT has estrogenic effects in both in vitro and animal systems. A meta-analysis report published in 2004 by Lopez Cervantes et al. found no relationship between DDE and breast cancer.

The objective of this study was: (1) to update the Lopez Cervantes meta-analyses and, (2) to analyze NHANES 1999–2004 data for any relationship between DDE exposure and breast cancer prevalence.

**Methods** Meta-Analyses: PubMed and Web of Science databases were searched for studies published through June 2012 assessing DDT exposure and breast cancer. From the 500 studies screened, 40 studies were used for the meta-analyses to quantify the summary Odds Ratios (OR) for breast cancer to DDT exposure in the highest versus the corresponding lowest exposed group. Both random and fixed effect models were used. Heterogeneity across studies was calculated using the I<sup>2</sup> measure of inconsistency. Heterogeneity was resolved through stratification analyses by study design, tissue sample type, and control population. Publication bias was assessed by the Begg and Egger tests.

**Survey Analyses:** Data from NHANES 1999–2004 female participants aged 20 years and older for levels of DDE were analyzed in relation to self-reported breast cancer (n=51). Logistic regression models were adjusted for age, race/ethnicity, education, alcohol intake, smoking status, body mass index and c-reactive protein.

**Results:** Slightly elevated, but not statistically significant summary ORs were found for the selected studies for DDE (1.05; 95%CI: 0.93 – 1.18) and DDT (1.02; 95%CI: 0.92 – 1.13). Logistic regression of NHANES data showed that women in the higher serum DDE tertile had a not-statistically significant OR (0.89; 95% CI: 0.27 – 2.94; p= 0.75) to have breast cancer compared to those in the lowest serum DDE tertile.

**Conclusion:** The existing information does not support the hypothesis that exposure to DDT/DDE increases the risk of breast cancer in humans.

#### PS 480 Assessing Model Prediction Quality for a Dynamic Population Simulation Model (DPSM).

J. P. Monteleone<sup>1</sup>, R. Gunawan<sup>1</sup> and K. Lee<sup>2</sup>. <sup>1</sup>Pharsight Corporation, Cary, NC; <sup>2</sup>JT International SA, Geneva, Switzerland.

An increasing amount of tobacco-control literature use DPSMs to predict changes in tobacco-related excess mortality (EM) and smoking prevalence (SP), typically using point estimates as model inputs. Point estimate information is often criticized because estimates are based on limited data and difficult to defend resulting in potentially questionable model predictions. One method for testing prediction quality is sensitivity analysis (SA), which tests predictions using specific values for point estimates. Unfortunately, for complex models, only limited subsets of values are typically tested. An alternative method uses a prediction interval (PI), which provides information on the expected distribution of the predictions from numerous randomly generated sets of point estimates. In this study, these methods for assessing prediction quality were evaluated using a tobacco-related DPSM from the literature. After reproducing the DPSM, a SA was performed using the author's simulation scenarios (consisting of a limited selection of point estimate model inputs). A PI was also constructed by applying a uniform distribution to the minimum and maximum values for each of the model inputs and randomly drawing samples (using Monte Carlo simulation) to create 1,000 unique sets of model inputs. Predictions for EM or SP were simulated annually for the years 2010 to 2050. A 90% PI plot was created by removing the highest and lowest 5% of the predicted values for each of the 40 years. When the two approaches were compared, most of predictions from the author's SA fell within the PI, while the SA results were constrained to only a small region of the PI, most likely because only a limited number of scenarios were tested. Furthermore, the PI demonstrated how variability among multiple model inputs can interact with each other by illustrating expected variability in the EM or SP predictions. A PI approach may therefore prove robust and efficient, compared to SA, in assessing how well point estimate model inputs predict outcomes from complex simulation models.

#### PS 481 Multiple Myeloma Risk and Benzene Exposure among Pliofilm Workers—A Reanalysis Using an Internal Reference Group.

S. Lamm<sup>1</sup>, J. Britt<sup>2</sup> and R. James<sup>2</sup>. <sup>1</sup>Consultants in Epidemiology and Occupational Health, Washington DC; <sup>2</sup>ToxStrategies, Tallahassee, FL.

The Pliofilm worker cohort (Rinsky et al., 2002) is comprised of 1,291 benzene-exposed and 554 unexposed workers with follow-up for leukemia and multiple myeloma (MM) mortality through 1996. Five of the exposed workers and three of the unexposed workers died from MM. Prior risk analyses of this benzene cohort were limited to the exposed cohort using U.S. death rates as the external reference population. We propose, for this cohort whose unexposed group is 43% the size of the exposed population (545/1,291 = 43%), that the risk analysis be done by using the unexposed population as an internal reference group. The crude mortality ratio (CMR) for MM for the exposed population (5/1,291 = 0.004) is 0.4 % (95% CI, 0.1-0.9), and CMR for the unexposed population (3/554=0.005) is 0.5% (95% CI, 0.1-1.6). The relative risk is 0.72 (95% CI, 0.17-2.98; Fisher two-tailed p-value, 0.70). When the analysis is limited to males as all the MM deaths were male,

the relative risk is 0.62 (95% CI, 0.15-2.59, Fisher two-tail p-value = 0.45). The CMR analysis indicates that the MM risk in benzene-exposed workers is actually not greater than that of the unexposed. The marginally lower difference seen here is not significant. These results, like others reported in the literature, reinforce the importance of examining an internal reference group analysis when evaluating the potential risks associated with occupational chemical exposures. Analytic use of an internal reference population reduces bias from the healthy worker effect or other risk factors associated with employment.

#### PS 482 Expression of DNA Repair Genes in Breast Cancer Tumors from Puerto Rican Women.

J. L. Matta<sup>1</sup>, L. Morales<sup>1</sup>, A. Cruz<sup>2</sup>, M. Bayona<sup>3</sup>, J. Dutil<sup>4</sup>, A. Gjyshi<sup>5</sup>, A. Monteiro<sup>5</sup> and E. Suarez<sup>6</sup>. <sup>1</sup>Pharmacology Physiology and Toxicology, Ponce School of Medicine and Health Sciences, Ponce, Puerto Rico; <sup>2</sup>Hematology-Oncology Fellowship Program, SJCH with VACHS, San Juan, Puerto Rico; <sup>3</sup>US FDA, Division of Epidemiology/OSB/CDRH, Silver Spring, MD; <sup>4</sup>Biochemistry, Ponce School of Medicine and Health Sciences, Ponce, Puerto Rico; <sup>5</sup>H. Lee Moffitt Cancer Center, Tampa, FL; <sup>6</sup>Cancer Epidemiology Program, University of Puerto Rico, Ponce, Puerto Rico.

DNA repair is a critical defense system in the human body aimed at protecting the integrity and stability of the genome from the harmful effects of cancer-causing agents. Specific genetic alterations in DNA repair genes have been clinically associated with risk, survival, aggressiveness, and treatment outcome of breast cancer (BC). Even though diminished DNA repair capacity is recognized as a risk factor for BC, no studies to date have identified gene expression profiles in tumors from Puerto Rican women. Study participants were women with histopathologically confirmed primary BC (n =35) and normal breast tissue obtained during cosmetic surgery (n=2). Tumors were snap frozen in liquid nitrogen and RNA was extracted. Microarrays data were obtained from Affymetrix Plus 2.0 chip to assess whole genome gene expression. The assessment of differentially expressed genes was performed using Permutation method with 5% false discovery rate. Genome-wide gene expression levels were initially measured using the Affymetrix Plus 2.0 array, and DNA repair genes showing significant changes in expression levels were validated by RT-PCR. Most of the DNA repair genes were over expressed. Twenty-three candidate DNA repair genes were found to be differentially expressed (including PARP-1, therapeutic target). Of these 21 were overexpressed and 2 were underexpressed (p<0.001). This is the first report of DNA repair candidate genes in Puerto Rican women with BC, a population with mixed ancestry. Supported by grants S06 GM008239-20, 1SCA157250-2 and 5U56CA126379 from the NCI Center to Reduce Health Disparities and NIH-MBRS Program (NIGMS).

#### PS 483 Investigation of Route-Dependent Exposure and Metabolism of Bisphenol A (BPA) in Neonatal Mice following Oral and Subcutaneous Administration of <sup>3</sup>H-BPA.

D. Draganov<sup>1</sup>, D. Markam<sup>2</sup>, D. Beyer<sup>3</sup>, J. Moore<sup>1</sup>, T. Riehl<sup>1</sup>, J. Waechter<sup>2</sup>, S. Dimond<sup>4</sup>, R. Shiotsuka<sup>5</sup>, K. Ehman<sup>6</sup> and S. Hentges<sup>7</sup>. <sup>1</sup>Metabolism, WIL Research, Ashland, OH; <sup>2</sup>The Dow Chemical Co., Midland, MI; <sup>3</sup>Bayer Healthcare AG, Wuppertal, Germany; <sup>4</sup>SABIC, Pittsfield, MA; <sup>5</sup>Bayer Material Science, Pittsburgh, PA; <sup>6</sup>TRS, Inc., Charlottesville, VA; <sup>7</sup>ACC, Washington DC.

Orally administered bisphenol A (BPA) undergoes efficient first-pass metabolism in the liver to produce inactive metabolites, including BPA-glucuronide (BPA-G) and BPA-sulfate (BPA-S). The current study was conducted to evaluate the pharmacokinetics of BPA and its conjugated metabolites, specifically BPA-G and BPA-S, in juvenile mice following a single oral or subcutaneous (SC) administration. This study had 3 phases: 1) Mass-balance phase in which effective dose delivery procedures for oral or SC administration of <sup>3</sup>H-BPA to post natal day (PND) 3 mouse pups were developed; 2) Pharmacokinetic phase during which systemic exposure to total <sup>3</sup>H-BPA-derived radioactivity in female PND 3 mice was established; and 3) Metabolite profiling phase in which two groups of 50 female PND 3 mice received either a single oral or SC dose of <sup>3</sup>H-BPA at 400 µg/kg bw with ≈ 4.4 mCi/kg bw of radioactivity. Blood was collected from 5 pups/route/time point at 5, 10, 20, and 30 minutes, and 1, 2, 3, 4, 6, and 24 hours post-dosing and processed to plasma. The plasma samples were pooled by group and time point and profiled by HPLC with fraction collection. Fractions were analyzed for total radioactivity and data used to generate radiochromatograms and integrate individual peaks. The identity of the BPA, BPA-G and BPA-S peaks was confirmed using authenticated standards and LC-MS/MS analysis. Metabolic profiles and key parameter as AUC<sub>0-24hr</sub> and C<sub>max</sub> were derived for free-BPA, BPA-G and BPA-S. The result of this study revealed that female PND 3 mice have metabolic capacity to metabolize BPA to BPA-G, BPA-S and other metabolites after both routes of administration and that systemic exposure to free-BPA is route-dependent as the plasma concentrations were lower following oral administration compared to SC injection.

**PS 484 Disposition and Kinetics of Tetrabromobisphenol A (TBBPA) in Female Wistar-Han Rats.**

G. A. Knudsen, J. M. Sanders, A. M. Sadik and L. S. Birnbaum. *Toxicology and Toxicokinetics, NCI at NIEHS, Research Triangle Park, NC.*

Tetrabromobisphenol A (TBBPA) is the brominated flame retardant with the largest production volume (~150,000 tons/year), representing nearly 60% of all worldwide demand for brominated flame retardants. TBBPA is used in printed circuit boards, ABS plastic casings, and laminates. Studies were conducted to characterize the disposition and toxicokinetic profile of TBBPA in female Wistar-Han rats following single oral bolus (25, 250 or 1,000 mg/kg) or intravenous (25 mg/kg) administration. All dosing solutions provided 50  $\mu\text{Ci/kg}$  of [ $^{14}\text{C}$ ]-labeled TBBPA. Following oral administration of [ $^{14}\text{C}$ ]-TBBPA the primary route of elimination of radioactivity was in feces; dose recoveries in 72h were  $95.7 \pm 3.5\%$ ,  $94.3 \pm 3.6\%$  and  $98.8 \pm 2.2\%$ , respectively. After a single IV administration of 25 mg/kg of [ $^{14}\text{C}$ ]-TBBPA, ~10% of the administered radioactivity was eliminated in the feces within 6h. Recoveries in urine ranged from 0.2-2% of dose. Less than 0.1% of the administered [ $^{14}\text{C}$ ]-radioactivity was detected in tissues collected at 72h following oral doses. Preliminary toxicokinetic profiles were estimated based on total [ $^{14}\text{C}$ ]-radioactivity detected in whole blood. Oral dosing (250 mg/kg) resulted in a rapid absorption of compound, with an apparent  $\text{C}_{\text{max}}$  occurring at 3h post-dose and the subsequent distribution phase was consistent with a one-compartment model. Following IV administration (25 mg/kg), [ $^{14}\text{C}$ ]-radioactivity concentrations in whole blood decreased rapidly with less than 2% of the administered radioactivity remaining at 6h post dose. The time-concentration profile for total [ $^{14}\text{C}$ ]-radioactivity following IV administration of [ $^{14}\text{C}$ ]-TBBPA was consistent with a two compartment model. These early results suggest low systematic bioavailability. These data indicate that TBBPA has a similar ADME/TK profile in female Wistar-Han rats as that reported for male Fischer-344 rats. This research was supported in part by the Intramural Research Program of NIH/NCI; this abstract may not reflect official NIH policy.

**PS 485 Investigation of BPA-Glucuronide As a Substrate for Human BCRP, MDR1, MRP2, and MRP3 Transporters.**

M. V. Driscoll and A. L. Slitt. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Bisphenol A (BPA) is a chemical used in plastic manufacturing that is present in polycarbonate bottles, food containers, and resins that line metal cans. Exposure to BPA occurs mainly through consumption of food products that are in direct contact with plastics and polycarbonates. Recently, BPA exposure in humans has been linked to the development of obesity and diabetes, as well as having effects on reproductive health and cancer. BPA is metabolized to BPA-glucuronide (BPA-gluc) and BPA-sulfate by Phase II enzymes and is eliminated by ATP-binding cassette (ABC) transporters. In humans, BPA-gluc is predominantly excreted through urine, whereas in rodents, it is excreted through bile into feces. One class of ABC transporters, multidrug resistance-associated proteins (MRPs) is thought to be involved in BPA clearance. There are nine known human MRPs (MRP1-9), and mouse orthologs exist for all human MRP genes except MRP8. Multidrug resistance protein (MDR1) and breast cancer-resistant protein (BCRP) are also possible transporters for BPA metabolites. However, despite numerous studies, the mechanism of BPA metabolite clearance remains unclear. In this study we examined whether BPA-gluc is a substrate for human xenobiotic transporters BCRP, MDR1, MRP2, or MRP3. Membranes expressing human BCRP, MDR1, MRP2, or MRP3 were used in a colorimetric ATPase assay. The amount of inorganic phosphate ( $\text{P}_i$ ) released from BPA-gluc-stimulated ATP hydrolysis was measured. Preliminary data suggest that BPA-gluc is a substrate for MRP3 ( $\text{K}_m$ : 48.2  $\mu\text{M}$ ). Furthermore, BPA-glucuronide is a potential activator of MRP2 at low concentrations, with an ATPase transporter activation >30% at 0.046  $\mu\text{M}$ , but inhibits transport at higher concentrations. Low to negative percent ATPase activation values for MDR1 strongly suggests that MDR1 is inhibited by BPA-glucuronide. As differences exist between rodents and humans, identification of the ABC transporters involved in BPA clearance will be an important tool in the pharmacokinetic assessment of BPA.

**PS 486 A Physiologically-Based Pharmacokinetic Model for Bisphenol A in Rats at Different Developmental Ages.**

X. Yang, D. R. Doerge and J. W. Fisher. *National Center for Toxicological Research, US FDA, Jefferson, AR.*

Bisphenol A (BPA) is an industrial chemical that has been used in the manufacture of a wide variety of consumer products such as hard plastic products and the lining of metal food and beverage cans. Widespread exposure to BPA has raised public health concerns about BPA in food and the environment. A physiologically based

pharmacokinetic model (PBPk) was developed to describe the pharmacokinetic behavior of BPA and its metabolites (Phase II conjugates) in adult and neonatal rats. The model was calibrated using published BPA studies on in vitro hepatic and intestinal metabolism, in vivo biliary excretion of BPA metabolites, and in vivo serum time course data after oral and intravenous administration of BPA. Metabolism of BPA in the small intestine was predicted to substantially reduce the oral bioavailability of BPA and enterohepatic recirculation of BPA metabolites was predicted to prolong the systemic levels of BPA and its metabolites. The dosimetry of the aglycone BPA was age-dependent, in part, because of immature phase II metabolism in neonatal rats.

**PS 487 Dose-Response Relationship of an Environmental Mixture of Pyrethroids following an Acute Oral Administration in the Rat.**

M. F. Hughes<sup>1</sup>, D. G. Ross<sup>1</sup>, J. M. Starr<sup>2</sup>, E. J. Scollon<sup>1,3</sup>, M. J. Wolansky<sup>4</sup>, K. M. Crofton<sup>1</sup> and M. DeVito<sup>1,5</sup>. <sup>1</sup>ORD/NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>ORD/NERL, US EPA, Research Triangle Park, NC; <sup>3</sup>OPP/HED, US EPA, Arlington, VA; <sup>4</sup>University of Buenos Aires, Buenos Aires, Argentina; <sup>5</sup>NIEHS/INTP, Research Triangle Park, NC.

Human exposure to multiple pyrethroid insecticides may occur because of their wide use on crops and for residential pest control. To address the potential risk from exposure to pyrethroids, it is important to understand their toxicity and disposition in target organs such as the brain and surrogates such as the blood. The objective of this study was to compare motor activity with pyrethroid concentrations in blood and brain of rats after oral administration of a pyrethroid mixture. Male Long-Evans rats were dosed with a mixture of  $\beta$ -cyfluthrin (12.9% of dose), cypermethrin (28.8%), deltamethrin (3.4%), esfenvalerate (2.7%) and *cis*- (20.9%) and *trans*-permethrin (31.3%) in corn oil at one of seven doses (maximum total pyrethroid dose = 27.4 mg/kg). From 2 to 3 h post-administration, gross motor activity was assessed. At 3.5 h, blood and brain were collected and analyzed for parent pyrethroid using HPLC-tandem mass spectrometry. There was a linear dose-related increase in concentrations of the pyrethroids in blood and brain. Cypermethrin (56-62%) and *cis*-permethrin (57-70%) were the predominant pyrethroids detected in blood and brain, respectively, at all dose levels. The pyrethroids with the lowest percentage in tissue were *trans*-permethrin (0.6-2.7%) and  $\beta$ -cyfluthrin (0.4-1.2%) in blood and deltamethrin (1.1-3.5%) and esfenvalerate (2.4-4.7%) in brain. The approximate ED<sub>30</sub> for decrease in motor activity was 300 ng/ml and 200 ng/g of total pyrethroid in blood and brain, respectively. More research is needed to understand the dosimetry of pyrethroids in blood and brain of rat and how this relates to neurotoxic effect. (This abstract does not represent U.S. EPA or NIEHS/INTP policy).

**PS 488 Partition Coefficients of Deltamethrin (DLM) and Cis-Permethrin (CIS) in Male Sprague-Dawley Rats.**

M. Amarani<sup>1</sup>, D. Gullick<sup>1</sup>, P. Sethi<sup>1</sup>, T. Mortuza<sup>1</sup>, T. Osmitz<sup>2</sup>, S. S. Anand<sup>3</sup>, D. W. Gammon<sup>4</sup>, C. A. White<sup>1</sup>, J. V. Bruckner<sup>1</sup> and B. S. Cummings<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Science Strategies, LLC, Charlottesville, VA; <sup>3</sup>DuPont Haskell, Newark, DE; <sup>4</sup>FMC, Ewing, NJ.

Pyrethroid insecticides are widely used to control a wide variety of pests in and around homes, food handling establishments, in mosquito control, and in agriculture. Partition coefficients are essential to the construction of PBPk models, because of their role in determining systemic distribution. The main aim of this study was to determine tissue:blood partition coefficients ( $\text{K}_t:\text{p}$ ) of two commonly used pyrethroids, DLM and CIS. In vitro plasma to RBC partition coefficients, as determined by HPLC analysis, ranged from 0.7 to 1.0 for DLM, and 1.1 to 1.7 for CIS. The steady state levels of both DLM and CIS were obtained in vivo by constant infusion (0.36 mg/hr) using subcutaneous implantation of Alzet<sup>TM</sup> pumps, combined with oral loading doses of 34 mg/kg for DLM, or 150 mg/kg for CIS given 4 hr after the implantation of the pump in male rats. The time to reach steady-state was determined by analyzing blood samples collected by tail vein puncture 24, 48 and 72 hr post loading. Rats were sacrificed at 72 hr and blood and tissues collected and analyzed for DLM and CIS using a modified GC-MS method. DLM levels in plasma after 72 hr of constant infusion were 960 ng/mL, compared to 222 ng/mL in brain, 272 ng/mL in liver, 132 ng/mL in muscle and 1,384 ng/mL in fat. This corresponded to  $\text{K}_t:\text{p}$  values of 0.23 for brain, 1.45 for fat, 0.28 for liver and 0.14 for muscle. In contrast, the CIS level in plasma was 78 ng/mL, compared to 43 ng/mL in brain, 27 ng/mL in liver, 107 ng/mL in muscle and 1,625 ng/mL in fat. These corresponded to  $\text{K}_t:\text{p}$  of 0.55 for brain, 20.78 for fat, 0.34 for liver and 1.37 for muscle. These data show that both pyrethroids are sequestered in fat, and that differences exist in  $\text{K}_t:\text{p}$  for DLM and CIS, as  $\text{K}_t:\text{p}$  values were generally higher for CIS. Supported by the Council For Advancement of Pyrethroid Human Risk Assessment.

**PS 489 Preliminary Toxicokinetics of N-Butylbenzenesulfonamide after a Single Intravenous or Gavage Administration to Harlan Sprague-Dawley Rats and B6C3F1/NMice.**

S. Hong<sup>1</sup>, S. Gibbs<sup>1</sup>, S. Graves<sup>1</sup>, D. Kobs<sup>1</sup>, C. Rider<sup>2</sup>, A. Martone<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>Battelle Memorial, Columbus, OH; <sup>2</sup>Division of National Toxicology Program, NIEHS, Research Triangle Park, NC.

N-butylbenzenesulfonamide (NBBS) is a common plasticizer with limited toxicity data that has been detected in environmental samples. A preliminary toxicokinetic study was conducted in Harlan Sprague Dawley rats and B6C3F1/N mice following a single intravenous (2 mg/kg) and gavage (2 or 200 mg/kg) administration of NBBS, and plasma and brain toxicokinetics were evaluated. Intravenous and gavage TK profiles of NBBS were characterized by a one-compartment kinetic model in both rats and mice. Following intravenous administration, male and female elimination ( $k_{10}$ ) half-life values were 0.300 and 0.387 hours, respectively, in rats, and 0.383 and 0.268 hours, respectively, in mice. Following gavage administration, male and female elimination half-life values were 0.657 and 1.11 hours (2 mg/kg) and 4.88 and 3.86 hours (200 mg/kg), respectively, in rats, and 1.21 and 0.494 hours, respectively, in mice. Male and female AUC<sub>∞</sub> values following gavage administration were 43.0 and 166 hr\*ng/mL (2 mg/kg) and 17,800 and 46,800 hr\*ng/mL (200 mg/kg), respectively, in rats indicating saturation of elimination kinetics around 200 mg/kg. The absolute bioavailability of NBBS after gavage administration at 2 mg/kg was 13% and 39% for male and female rats, respectively. AUC<sub>∞</sub> values for male and female mice after gavage administration were 20,000 and 15,500 hr\*ng/mL, respectively. The absolute bioavailability of NBBS after gavage administration to mice at 200 mg/kg was 25% for both sexes. NBBS was extensively distributed into the brain with concentrations similar to plasma in mice but greater than plasma in rats. [Supported by NIH, HHSN273201000016C]

**PS 490 Gestational and Lactational Physiologically-Based Pharmacokinetic (PBPK) Models for the Herbicide Atrazine in Rats: Development and Optimization.**

Z. Lin<sup>1,2</sup>, J. W. Fisher<sup>3</sup> and N. M. Filipov<sup>1,2</sup>. <sup>1</sup>Physiology and Pharmacology, University of Georgia, Athens, GA; <sup>2</sup>Interdisciplinary Toxicology Program, University of Georgia, Athens, GA; <sup>3</sup>National Center for Toxicological Research, US FDA, Jefferson, AR.

Atrazine (ATR) is a widely used chlorotriazine herbicide that is commonly detected in the environment and in human specimens, including pregnant women's urine, umbilical cord blood and breast milk. To help address concerns about reported adverse effects of ATR exposure during development, gestational and lactational PBPK models for ATR in the rat were developed. The models accounted for potential differences in the metabolism of ATR in dams, fetuses, and neonates and between single and repeated daily oral exposures and incorporated binding of ATR and its major metabolite didealkylatrazine (DACT) with target tissue (maternal/neonatal brain and fetus), plasma proteins, and red blood cells. Model predictions correlate well with recently reported measured data on the concentrations of ATR and its metabolites in maternal/neonatal plasma, tissue, fetus, and milk following repeated daily oral exposure to the dam during gestation, lactation, or both, including with data from a study (lactational exposure) not used for model calibration. The model simulations indicate that: (1) the fetus is exposed to ATR and DACT at levels that are similar to maternal plasma levels, (2) the neonate is exposed mostly to DACT at levels about two-thirds of the maternal plasma DACT levels and (3) gestational carryover of DACT greatly affects neonatal dosimetry up until mid-lactation. Hence, excessive exposure to ATR and/or its metabolites during pregnancy or early lactation may be of particular concern. These models provide insights into designing and interpreting early life toxicity and pharmacokinetic studies with this herbicide and could be used in fetal and neonatal tissue dosimetry prediction and for improvement of ATR's exposure assessment.

**PS 491 Characterization of the Fate of  $\beta$ -Hexabromocyclododecane (HBCD) in Mice.**

J. M. Sanders, G. A. Knudsen, A. M. Sadik and L. S. Birnbaum. *NIH/NCI, Research Triangle Park, NC.*

1,2,5,6,9,10-Hexabromocyclododecane (HBCD) is a high production volume cycloaliphatic used primarily as an additive flame retardant in polystyrene foam building materials. Commercial HBCD mixtures contain three major stereoisomers, alpha ( $\alpha$ ), beta ( $\beta$ ) and gamma ( $\gamma$ ), at a typical ratio of 1.2:0.6:8.2. Toxicity (e.g. developmental neurotoxicity, immune effects, liver hypertrophy, and endocrine disruption) in rodents exposed to HBCD mixtures may be affected by differential kinetics of the isomers. Previous work from our laboratory demonstrated

that  $\alpha$ -HBCD has greater bioavailability and potential for accumulation in mice than  $\gamma$ -HBCD. The present investigation provides comparative disposition data for  $\beta$ -HBCD to support toxicological evaluations of HBCD mixtures. In these studies, a single dose of [<sup>14</sup>C]-labeled  $\beta$ -HBCD (3 mg/kg), administered orally, was absorbed rapidly in the female C57BL/6 mouse. The C<sub>max</sub> for  $\beta$ -HBCD-derived radioactivity in blood and other assayed tissues, except adipose, was observed 3 hours following gavage. Approximately 90% of the total dose was eliminated in urine and feces by 24 h postdosing. The extent of dose absorption was  $\geq 85\%$  based on HPLC analysis of feces extracts and comparison of oral and iv excretion data.  $\beta$ -HBCD-derived metabolites were excreted in urine and feces. Approximately 8% of the total dose was excreted in feces as  $\gamma$ -HBCD. Oral administration of either 30 or 100 mg/kg of  $\beta$ -HBCD resulted in initial slower rates of [<sup>14</sup>C] elimination; however, cumulative excretion data were similar across the dosing range 4 days following gavage. Residual concentrations of [<sup>14</sup>C] in tissues of these mice were highest in adipose and liver.  $\beta$ -HBCD-derived radioactivity accumulated in these tissues following four consecutive daily doses of 3 mg/kg by gavage. In conclusion,  $\beta$ -HBCD, like  $\gamma$ -HBCD, was extensively metabolized, rapidly excreted, and had less potential for accumulation in tissues over time in female C57BL/6 mice than  $\alpha$ -HBCD. (Research supported in part by Intramural Research Program of NIH/NCI; abstract may not reflect official NIH policy).

**PS 492 OATs and OATPs Are Involved in the Disposition of Perfluoroalkyl Sulfonates in Rats.**

W. Zhao<sup>1</sup>, J. Zitzow<sup>2</sup>, D. J. Ehresman<sup>2</sup>, S. Chang<sup>2</sup>, J. L. Butenhoff<sup>2</sup> and B. Hagenbuch<sup>1</sup>. <sup>1</sup>Pharmacology, Toxicology and Therapeutics, Kansas University Medical Center, Kansas City, KS; <sup>2</sup>Medical Department, 3M Center, St. Paul, MN.

Perfluoroalkyl sulfonates (PFSA) are a group of persistent environmental contaminants that have been detected in wildlife and human serum. Based on estimations from retired fluorocarbon production workers, the elimination half-lives of certain PFSA, such as perfluorohexanesulfonate (PFHxS) and perfluorooctanesulfonate (PFOS), are very long (several years). Pharmacokinetic studies in animal models indicate that the long half-lives of these compounds are due to slow renal clearance and strong hepatic accumulation. In previous studies we have demonstrated certain organic anion transporters expressed in the kidney and the liver are involved in the disposition of another family of perfluoroalkyl substances, perfluoroalkyl carboxylates (PFCAs), in rats. However, so far it is unknown whether PFSA are also substrates for the same drug transporters. Therefore, we wanted to test whether the organic anion transporters involved in the disposition of PFCAs are also responsible for the disposition of PFSA. We used HEK293 cells overexpressing rat OAT1, OAT3 and OATP1A1 and measured the uptake of model substrates in the absence and presence of PFSA with different carbon chain-lengths, namely perfluorobutanesulfonate (PFBS), PFHxS and PFOS. PFHxS showed the strongest inhibition for both rat OAT1 and OAT3, while rat OATP1A1 was only inhibited by PFOS. Direct uptake determination of these PFSA demonstrated that rat OAT1 and OAT3 can transport PFBS and PFHxS while rat OAT3 and OATP1A1 might transport PFOS. In conclusion, these results suggest that the same families of transporters in the rat that are involved in the disposition of PFCAs are also involved in the disposition of PFBS, PFHxS and PFOS.

**PS 493 Toxicokinetics of Inhalation, Metabolism and Elimination of 6:2 FTOH and 8:2 FTOH in Rats.**

M. W. Himmelstein, T. L. Serex, R. C. Buck and M. H. Russell. *E.I. DuPont de Nemours & Co Inc., Wilmington, DE.*

This study compares the in vivo metabolism of two fluorotelomer alcohols (6:2 FTOH and 8:2 FTOH). Single 6-h inhalation exposures were conducted in Crl:CD(SD) rats followed by analysis of per- and poly-fluorinated acid metabolites in plasma. Both substances were readily absorbed and rapidly eliminated via conjugation and oxidative metabolism. Following exposure to either 0.5 or 5.0 ppm 6:2 FTOH, the terminal metabolites included perfluorobutanoic acid (PFBA), perfluorohexanoic acid (PFHxA), perfluoroheptanoic acid (PFHpA) and 5:3 Acid (C<sub>5</sub>F<sub>11</sub>CH<sub>2</sub>CH<sub>2</sub>COOH). 5:3 Acid was the dominant acid metabolite in plasma which, based on toxicokinetic modeling, represented 0.2-3.8 mol% and 1.2-2.8 mol% of the inhaled dose of 6:2 FTOH in male and female rats, respectively. Corresponding yields of PFHxA were 0.1-2.8 mol% and 0.5-1.7 mol% in male and female rats, respectively. The sum of all modeled acid analytes ranged between 0.5 and 7.1 mol% with higher yields of all analytes observed at lower inhaled 6:2 FTOH doses. After 6:2 FTOH exposure cessation, the fluorinated acids observed in plasma were rapidly eliminated with typical elimination half-lives of a few hours. A single 8:2 FTOH 6-h exposure of rats to 0.16 or 1.6 ppm resulted in dose proportional formation of perfluorooctanoic acid (PFOA) and 7:3 Acid (C<sub>7</sub>F<sub>15</sub>CH<sub>2</sub>CH<sub>2</sub>COOH) as the major fluorinated acid metabolites. In male and female rats, toxicokinetic calculations of 7:3 Acid in plasma resulted in yields of 0.9-2.1 mol% in male and female rats while PFOA yields ranged between 0.3 and 1.1

mol%. 7:3 Acid was eliminated with calculated half-lives of 1-7 hrs in male and female rats while the elimination of PFOA showed distinct gender differences with half-lives of 6-8 hrs in female rats and no measurable decline in male rats over the 18-h period of depuration. For both fluorotelomer alcohols, the major terminal acids formed metabolically in rats were 5:3 Acid and PFHxA from 6:2 FTOH and 7:3 Acid and PFOA from 8:2 FTOH. This study demonstrates rapid bioelimination of inhaled fluorotelomer alcohols from plasma.

#### PS 494 Absorption, Distribution, Metabolism, and Elimination of [<sup>14</sup>C] 6:2 Fluorotelomer Alcohol in the Rat.

R. T. Mingoia<sup>1</sup>, S. C. Carpenter<sup>1</sup>, T. L. Whyte<sup>1</sup>, M. W. Himmelstein<sup>1</sup>, T. A. Snow<sup>1</sup>, L. Cox<sup>1</sup>, S. A. Gannon<sup>1</sup> and R. C. Buck<sup>2</sup>. <sup>1</sup>DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE; <sup>2</sup>E. I. duPont de Nemours and Company, Inc., Chemicals and Fluoroproducts, Wilmington, DE.

Fluorotelomer alcohols (FTOHs; F(CF<sub>2</sub>)<sub>x</sub>C<sub>2</sub>H<sub>4</sub>OH, x=6, 8, or 10) are used in the manufacture of specialty fluorinated surfactants and polymers. Fluorotelomer manufacturers are moving away from raw materials that are potential precursors to perfluorooctanoic acid (PFOA), such as the higher fluorotelomer alcohol homologues, to products based on 6:2 FTOH as a raw material. To better understand 6:2 FTOH biological fate, the absorption, distribution, metabolism, and elimination of [1,2-<sup>14</sup>C] 6:2 FTOH was investigated following a single oral dose administration of 5 and 125 mg/kg to male and female rats. The maximum concentration of total radioactivity in plasma following oral dosing at 5 and 125 mg/kg occurred by 2 h post dose in both male and female rats. The plasma terminal elimination half-life values for total radioactivity were approximately 79 h in male rats at both dose levels and 78 and 63 h in female rats following a 5 and 125 mg/kg dose, respectively. Terminal elimination half-life values in red blood cells were approximately twice that in plasma, ranging from 121 h to 160 h. The internal dose as measured by area under the concentration-time curve to infinity (AUC<sub>inf</sub>) was similar for both male and female rats. The increase in AUC<sub>inf</sub> was slightly less than dose proportional from 5 mg/kg to 125 mg/kg. Preliminary material balance and tissue distribution data following an oral 5 mg/kg dose suggests that at 7 days postdose, less than 5% of the administered radioactivity was present in tissues with the highest concentrations occurring in fat, adrenals, and thyroid. The majority of the [1,2-<sup>14</sup>C] 6:2 FTOH dose was excreted in feces with 65% and 50% excreted in male and female rats, respectively. Renal excretion was also a significant elimination pathway with 10% and 18% excreted in urine in male and female rats, respectively.

#### PS 495 Analysis of tris(2-Chloroisopropyl)phosphate Metabolites in Rat Plasma for Toxicology Studies.

B. Collins<sup>2</sup>, S. Waidyanatha<sup>2</sup>, M. Stout<sup>2</sup>, A. Gutierrez<sup>1</sup>, R. Mathias<sup>1</sup>, C. Dillon<sup>1</sup>, D. Slade<sup>1</sup>, C. Crouch<sup>1</sup>, K. Aillon<sup>1</sup>, J. Algaier<sup>1</sup> and R. Harris<sup>1</sup>. <sup>1</sup>MRI Global, Kansas City, MO; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

Tris(2-Chloroisopropyl)phosphate, TCP, is an organophosphate compound used as a flame retardant and plasticizer especially in polyurethane foam in furniture and in home insulation. Due to its environmental prevalence and resulting human exposure, TCP is under study by the NTP. In support of NTP toxicological studies, MRI Global developed methods to analyze TCP and two major metabolites, Mono (MCPP, 2 isomers) and Bis 2-chloroisopropyl phosphate (BCPP, 3 isomers) in rodent plasma and blood. Because of its similarity to Tris(2-chloroethyl)phosphate, BCPP was expected to be the major TCP metabolite. During the analytical method development, multiple isomers of MCPP were observed and hence were included in the method. The 5 isomers of the two metabolites were characterized using synthetic standards following derivatization with BSTFA/pyridine prior to analysis by GC/MS without using an internal standard. The ions monitored in the selected ion monitoring mode were for MCPP, m/z 211, 227, 283 and for BCPP, m/z 155, 171, 197.

The quantitation of MCPP and BCPP was achieved without derivatization using LC/MS/MS following extraction of 100 µL of plasma with 200 µL acetonitrile, removing acetonitrile by evaporation, and reconstituting the residue in 100 µL of 2% MeOH in water containing 50 mM tributylamine, TrBA (pH 5 with formic acid) with internal standard dibenzylphosphate. The LC/MS analysis used a phenylhexyl column, which resulted in good linearity with a preliminary limit of detection value of 5 to 10 ng/mL of plasma ranging to over 500 ng/mL. Multiple MCPP and BCPP isomers were quantified as one MCPP and one BCPP peak.

Plasma samples from rats and mice from single and multiple exposures to TCP were analyzed to show the applicability of this method. The data show the presence of MCPP and BCPP at levels significantly higher than the parent TCP.

#### PS 496 In Vitro-In Vivo Extrapolation of 7-Ethoxycoumarin Metabolism Using 3D-Organotypic Liver Bioreactor.

K. Choi<sup>1</sup>, J. Campbell<sup>1</sup>, W. P. Pfund<sup>2</sup>, J. McKim<sup>3</sup>, E. L. LeCluyse<sup>1</sup> and H. J. Clewell<sup>1</sup>. <sup>1</sup>The Hamner Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>RealBio Technology, Inc., Kalamazoo, MI; <sup>3</sup>CeeTox Corp., Kalamazoo, MI.

A liver bioreactor system was developed to simulate the metabolism and clearance of compounds similar to the liver in vivo to provide better prediction of in vivo clearance and metabolite profiles of compounds from in vitro data. Primary rat and cryopreserved human hepatocytes were maintained in a RealBio D4™ Culture System for approximately a month. General metabolic and liver-specific functions and cellular damage of rat/human hepatocytes inside liver bioreactor were monitored. Stable levels of biomarkers and related functional endpoints were achieved after a 7-10 day period for both rat and human liver bioreactors, respectively (glucose 64.6 – 86.6/152 – 182 mg/dL; lactate 0.6 – 1.9/0.1 – 3.7 mmol/L; pH 7.4 – 8.0/7.4 – 7.5; albumin 0.8 – 1.0/1.0 – 1.1 mg/mL; total protein 7.5 – 8.8/1.8 – 20 mg/mL; ALT 4.9 – 13.6/6.0 – 9.9 U/L; AST 6.8 – 25.4/18.9 – 53.1 U/L). The activities of rat CYP2B, CYP2C11 and CYP3A were monitored by the production of 16β-OH testosterone, 16α-OH testosterone and 6β-OH testosterone, respectively. Rat hepatocytes at 28 days in a liver bioreactor and treated with 5 µM dexamethasone for 24hr showed 3-fold increase in CYP3A activity. Metabolism of 7-ethoxycoumarin (7-EC) was characterized in the rat liver bioreactor. 7-Hydroxycoumarin was the predominant metabolite produced, which was further metabolized to the glucuronide and sulfate conjugates. The depletion of 7-EC showed mono-exponential decay with an estimated intrinsic clearance of 113.3 µL/min/106 cells. Scaling of the in vitro CL<sub>int</sub> to in vivo CL<sub>int</sub> yielded in vivo prediction of 135.98 mL/min/rat body weight (250g). In conclusion, hepatocytes maintained in a 3D organotypic liver bioreactor showed stable liver functional capacity and intrinsic clearance over an extended period. This system may help resolve current limitations in assessing the clearance mechanisms and long-term effects of compounds and their major metabolites on chemical-induced liver toxicity.

#### PS 497 Enhanced Intranasal Delivery of Gemcitabine to the Central Nervous System.

M. Krishan<sup>1</sup>, G. Gudelsky<sup>2</sup>, P. Desai<sup>2</sup> and M. Genter<sup>1</sup>. <sup>1</sup>Environmental Health, University of Cincinnati, Cincinnati, OH; <sup>2</sup>College of Pharmacy, University of Cincinnati, Cincinnati, OH.

Delivery of therapeutics to the brain to treat neurological diseases is a challenge due to impenetrable nature of the blood brain barrier (BBB). Intranasal (IN) drug administration is a non-invasive approach for rapid direct drug delivery from the nose to the central nervous system (CNS), thereby minimizing systemic exposure. The current study focuses on a strategy to enhance the delivery of the nucleoside drug gemcitabine (GEM) to the CNS via IN administration. Our approach takes advantage of the fact that the BBB and olfactory epithelial (OE) tight junctions (TJs) share many proteins in common. We hypothesized that by transiently increasing the permeability of nasal epithelial tight junctions using the BBB permeabilizer piperazine (PV), we will increase the concentration of GEM reaching the brain extracellular fluid (BECF) following IN delivery, with the goal of delivering therapeutic concentrations of nucleoside drugs to the CNS. Experimental methods included IN administration of fluorescein isothiocyanate-dextran beads (FD4), in-vitro GEM recovery, in vivo brain microdialysis for BECF collection, HPLC analysis to measure GEM in BECF, histopathology, and western blot analysis. Distribution studies with FD4 showed significant deposition in the ethmoid turbinates, suggesting drug uptake through OE. Clinically-relevant doses of PV (up to 1.4% IN) did not cause histological evidence of cytotoxicity or inflammation in nasal epithelia, lung, liver, spleen, or kidney. Pharmacokinetics of GEM in BECF showed area under the curve (AUC) = 5.55±0.84 µg.h/mL for PV (1.4%) + GEM (50mg/kg) treated animals, compared to 1.5±0.29 µg.h/mL for GEM without PV treatment. Western blot analysis suggested that IN PV treatment increased permeability through OE TJs by transiently decreasing the levels of TJ protein occludin. Thus, it appears that transient permeabilization of nasal epithelial TJs provides a non-invasive means to enhance delivery of nucleoside drugs to the CNS.

#### PS 498 Altered Irinotecan Pharmacokinetics in Diet-Induced Obesity.

P. Shah, A. Gandhi and R. Ghose. *Pharmaceutical and Pharmacological Sciences, University of Houston, Houston, TX*. Sponsor: R. Ghose.

Purpose: Irinotecan (CPT-11) is a topoisomerase I inhibitor that has been shown to be highly effective in treatment of variety of cancers. It has recently been shown that CPT-11 administration is associated with liver toxicity and this effect is compounded by baseline obesity. It was found that patients with a BMI index of >25

were twice as much susceptible to developing liver toxicity than patients with BMI index of <25. CPT-11 metabolizes to SN-38, which then undergoes glucuronidation by uridine glucuronosyl transferase (UGT) 1A1 to form SN-38 glucuronide (SN-38G). Excess accumulation of the toxic metabolite SN-38 is known to cause fatal diarrhea in cancer patients. We hypothesize that accumulation of SN-38 is associated with increased liver toxicity of CPT-11 in obesity.

Methods: For metabolism studies, liver S9 fractions were prepared from diet-induced obese (DIO, 60% fat) and lean mice (10% fat). UGT1A-mediated metabolism of SN-38 was determined in liver S9 fractions. For pharmacokinetic studies, mice were injected with a single oral dose of 10 mg/kg CPT-11 and blood and feces samples were collected from 0-8hr. Samples were analyzed for CPT-11 and SN-38 concentrations using LC-MS/MS. Liver tissues were harvested for real-time PCR studies. The mRNA and serum TNF $\alpha$  levels were measured in liver and plasma samples, respectively.

Results: We found that the rate of formation of SN-38G was 2 fold lower in the DIO mice compared to the lean controls. This corresponded with reduced expression of UGT1A1 in DIO mice livers. We did not observe significant changes in the area under the curve (AUC) or clearance of CPT-11 between the DIO and lean mice. However, plasma and fecal exposure of SN-38 was increased by 2 folds in the DIO mice compared to the lean controls. We also observed significantly higher mRNA and serum levels of TNF $\alpha$  in the DIO mice as compared to the lean mice. Higher TNF $\alpha$  levels are known to be associated with liver toxicity.

Conclusion: CPT-11 dosage should be closely monitored for effective and safe chemotherapy in obese patients who are at a higher risk of developing liver toxicity.

#### PS 499 Interaction of Immunosuppressants with Human Organic Anion Transporters 1 and 3 and Multidrug Resistance Proteins 2 and 4.

R. Greupink<sup>1</sup>, A. A. El-Sheikh<sup>2</sup>, H. Wortelboer<sup>3</sup>, J. J. Van den Heuvel<sup>1</sup>, M. Schreurs<sup>1</sup>, J. B. Koenderink<sup>1</sup>, R. Masereeuw<sup>1</sup> and F. G. Russel<sup>1</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; <sup>2</sup>Department of Pharmacology, Faculty of Medicine, Minia University, Minya, Egypt; <sup>3</sup>TNO, Zeist, Netherlands.

Renal proximal tubule transporters can play a key role in excretion, pharmacokinetic interactions and toxicity of immunosuppressant drugs. Basolateral organic anion transporters (OATs) and apical multidrug resistance proteins (MRPs) contribute to active tubular uptake and urinary efflux, respectively. Combining immunosuppressants during therapy may lead to drug-drug interactions occurring at the transporter level, resulting in toxicity. We studied the effect of different immunosuppressants on OAT1- and OAT3-mediated uptake of [3H]-methotrexate ([3H]MTX) in cells, and on ATP-dependent [3H]MTX transport in membrane vesicles isolated from HEK293 cells over-expressing human MRP2 and MRP4. For the uptake transporters, we found that cyclosporine, dexamethasone, azathioprine and 6-mercaptopurine did not affect either transporter. Cytarabine, vinblastine, vincristine, hydrocortisone and mitoxantrone significantly inhibited OAT1 ( $p < 0.05$  at 10  $\mu$ M), whereas these compounds did not inhibit OAT3. In contrast to other compounds, mycophenolic acid (10  $\mu$ M) inhibited OAT3 more effectively than OAT1, reducing [3H]MTX uptake by  $86 \pm 4\%$  and  $52 \pm 5\%$  of control, for OAT3 and OAT1 respectively. Subsequent studies showed that the IC<sub>50</sub> of mycophenolic acid for OAT3 was 4.3  $\mu$ M (95% CI: 2.7-6.9  $\mu$ M), which is close to its reported C<sub>max</sub>, unbound ( $\sim 1$   $\mu$ M). With regard to the apical transporters, cyclophosphamide, hydrocortisone, tacrolimus and mycophenolic acid inhibited both MRP2 and 4. Cyclosporine, vincristine and vinblastine only inhibited MRP2, while 6-mercaptopurine only inhibited MRP4. In conclusion, immunosuppressants may alter renal transport activity. From a drug safety perspective, the observed differences in transporter inhibition profiles may provide a selection criterion when combining immunosuppressive drugs.

#### PS 500 Accumulation of $\beta$ -N-methylamino-L-Alanine in Tissues following Repeat Oral Administration to Harlan Sprague-Dawley Rats.

C. Garner<sup>1</sup>, C. J. Wegerski<sup>1</sup>, M. Doyle-Eisele<sup>1</sup>, J. Lucak<sup>1</sup>, S. Waidyanatha<sup>2</sup>, J. D. McDonald<sup>1</sup> and J. M. Sanders<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

$\beta$ -N-methylamino-L-alanine (L-BMAA) was nominated to the National Toxicology Program for toxicological assessment based on widespread environmental distribution and evidence that the potentially neurotoxic compound may accumulate in CNS tissue. Data describing metabolism and disposition of L-BMAA are needed to support planned NTP toxicity studies. Male Harlan Sprague-Dawley rats were dosed by gavage with [1,2-<sup>14</sup>C]-L-BMAA (1 mg/kg/d) for 1, 5, and 10 consecutive days. Excreta and tissues were collected for up to 72 hours after the final

dose. The majority of <sup>14</sup>C was recovered as <sup>14</sup>CO<sub>2</sub> (50-60%) across 10 days of dosing and <10% of dose was excreted in urine. HPLC profiles of urine showed multiple polar metabolites and L-BMAA was not detected. Over 10 days of dosing <sup>14</sup>C continued to accumulate in tissues including the brain. After single and up to 10 day repeat doses the majority of the <sup>14</sup>C recovered in tissues was found in liver, adipose, muscle, and skin; < 0.01% dose was recovered in the brain. Accumulation rate of brain <sup>14</sup>C over 10 days exceeded elimination by >3 fold. On days 1, 5, and 10 a majority of <sup>14</sup>C in brain tissue 24 h following the final dose was recovered in the protein after exhaustive extraction. The nature of BMAA associated with brain protein was investigated in vitro. Incubation of [1,2-<sup>14</sup>C]-L-BMAA in vitro with rat brain homogenates released <sup>14</sup>CO<sub>2</sub> and <sup>14</sup>C was incorporated into protein. HPLC analysis of in vitro protein hydrolysates showed that [<sup>14</sup>C]-L-BMAA itself and other <sup>14</sup>C-equivalents made up the radioactive components. Thus accumulation of L-BMAA and its equivalents in brain tissue may be due in part to incorporation into protein. Brain tissue from repeat dose administration in rats is currently being analyzed to investigate the nature of the radiolabel associated with the protein. This work was conducted for the NTP under NIEHS Contract N01-ES-75562.

#### PS 501 Comparative Nonclinical Ocular Tissue Distribution of the Visual Cycle Modulator (VCM) Emixustat in Rats, Beagle Dogs, and Cynomolgus Monkeys.

T. Podoll<sup>1</sup>, R. J. Eyre<sup>1</sup>, S. Al-Fayoumi<sup>1</sup>, E. Austin<sup>1</sup>, E. Prescott<sup>2</sup>, G. Sun<sup>2</sup>, M. Orme<sup>1</sup> and R. Kubota<sup>1</sup>. <sup>1</sup>Acucela Inc., Seattle, WA; <sup>2</sup>Covance, Madison, WI.

Emixustat HCl is a novel, non-retinoid VCM that inhibits a key step in regeneration of 11-cis-retinal by retinyl ester isomerase RPE65. Emixustat is currently in late Phase 2 clinical development as an orally administered treatment for geographic atrophy associated with dry age-related macular degeneration (AMD). In ADME studies, very low plasma concentrations of emixustat are seen as it is extensively metabolized, producing pharmacologically inactive metabolites. Interestingly, the pharmacological activity of emixustat has been shown to be prolonged beyond the time at which its plasma concentrations are no longer measurable. Ocular distribution studies using <sup>14</sup>C emixustat were undertaken in rat, dog, and monkey to better understand the time course of emixustat ocular tissue exposure in relation to observed pharmacology activity in animal models.

Pigmented and albino rats received single oral doses of 1 mg/kg, and were prepared for QWBA, or a repeated oral dose (QD for 7 days) and were prepared for ocular dissection. Dogs received 0.3 mg/kg as a single or a repeated oral dose (QD for 7 days). Monkeys received 0.9 mg/kg/day as a single or a repeated oral dose (TID for 7 days). Eye levels were observed for up to six weeks postdose.

The mean recovery of radioactivity was >95% in rat and dog, and >90% in monkey. The half life of removal of radioactivity from eye tissues was longer in all species than that observed in plasma. Consistent among the three species, emixustat parent molecule was the major component found in eye tissues. In all three species, the retina C<sub>max</sub> of emixustat were >50 fold higher than respective plasma C<sub>max</sub> on a ng $\cdot$ equiv/g basis. Although high levels of the major metabolites were observed in plasma, they were not observed in eye tissues. Preclinical ocular distribution results indicated emixustat parent is the predominant molecule in the eye responsible for pharmacological activity.

#### PS 502 Development of Sustained Release Buprenorphine for Use As an Improved Analgesic in Toxicology Studies: Assessment of Formulation Pharmacokinetics.

L. Koetznar<sup>1</sup>, W. Stokes<sup>2</sup>, W. Lance<sup>3</sup>, G. Wnorowski<sup>1</sup>, N. South<sup>4</sup> and J. Boulet<sup>1</sup>. <sup>1</sup>Product Safety Labs, Dayton, NJ; <sup>2</sup>NICEATM, NIEHS, Research Triangle Park, NC; <sup>3</sup>Wildlife Pharmaceuticals, Fort Collins, CO; <sup>4</sup>Battelle, Columbus, OH.

Acute toxicology safety testing procedures can involve animal pain and distress. U.S. regulatory agencies and the OECD recently adopted and updated procedures that incorporate the routine use of systemic analgesics to avoid or reduce pain and distress for eye irritation testing procedures. Buprenorphine is recommended as a useful analgesic for such toxicology studies. However, buprenorphine requires a minimum of twice-daily dosing at 12 hour intervals to maintain effective analgesia. A study was therefore conducted to evaluate sustained release formulations to determine their usefulness for once-per-day or less frequent dosing. The pharmacokinetics of two sustained release formulations of buprenorphine were compared to buprenorphine in saline using male 2-2.5 kg New Zealand White rabbits. Sustained release formulations were prepared using N-methyl-pyrrolidone (NMP) or Triacetin as the vehicle. Following subcutaneous dosing, blood samples were collected at intervals to four days; plasma buprenorphine was determined using liquid chromatography with mass spectrometry. Both the NMP and Triacetin formulations produced higher plasma buprenorphine concentrations than the saline formulation at time points from 12 hours on. The Triacetin formulation also resulted in higher concentrations at earlier time points, as well as concentrations near or

above 0.1 ng/mL—a concentration previously associated with analgesic activity in other species—to 96 hours post-dosing. Body weight and food consumption were recorded, and did not show adverse effects of treatment with sustained release formulations. No abnormal clinical signs or local lesions were observed. These results suggest that the Triacetin sustained release formulation of buprenorphine can significantly reduce the dosing interval required and can be a useful replacement for twice-daily treatments.

## **PS 503 Acute Rat Inhalation Pharmacokinetic Study of 10.9 kD Protein with or without Pegylation.**

J. Gould<sup>1</sup>, I. Carvajal<sup>1</sup>, T. Davidson<sup>1</sup>, A. Kozhich<sup>1</sup>, J. Laporte<sup>2</sup>, J. Li<sup>1</sup>, N. Mathias<sup>1</sup>, L. Schneeweis<sup>1</sup>, S. Thompson-Iritani<sup>1</sup>, J. Valentine<sup>1</sup>, B. Wang<sup>1</sup> and H. H. Haggerty<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb, New Brunswick, NJ; <sup>2</sup>Charles River Laboratories Preclinical Services Montréal Inc, Senneville, QC, Canada.

Biologics are an evolving protein-based therapeutic approach in the pharmaceutical industry. As part of assessing hazards, an Occupational Exposure Limit (OEL) is developed internally for proprietary biologics to support worker safety. Biologics are considered to be less hazardous than small molecules due to suspected lower systemic bioavailability (BA) from the lung and degradation in the GI tract. To investigate fate after inhalation (Inh), SD rats were exposed to RGE (10.9 kD protein), RGE-PEG (40 kD PEG+10.9 kD protein) or saline by nose-only Inh for 1 hr. The pharmacokinetic (PK) profile was investigated in blood and bronchial alveolar lavage fluid (BAL). The measured experimental exposures were 42 and 48 mg/m<sup>3</sup>, corresponding to a calculated dose of 1.8 and 2.1 mg/kg, and a mean mass aerodynamic diameter of 1.8 and 1.9  $\mu$ m for RGE and RGE-PEG, respectively. The systemic PK profile for RGE and RGE-PEG included AUC(INF) of 169 and 357 ng.h/mL; C<sub>max</sub> of 19.8 and 10.1 ng/mL; T<sub>max</sub> of 2 and 9 hrs; and t<sub>1/2</sub> of 5.5 and 21 hrs; respectively. When compared to an IV study, systemic BA was 1.4 and 0.05%, respectively. From BAL levels, the left lung lobe contained 4.2 and 3.2% of the calculated dose at end of exposure and the lung t<sub>1/2</sub> was 4.5 and 7.2 hrs, respectively. These results indicate that after Inh exposure, systemic BA was low, with the PEG-RGE being markedly less than the unmodified RGE. However, the overall AUC(INF) for both proteins was similar. Compared to systemic results, the lung PK for the two proteins were similar with respect to t<sub>1/2</sub> and reduced percent of dose delivered to the lung. These PK results suggest that compared to small molecule drugs, there may be a decreased hazard for proteins, which would be demonstrated by applying these data-derived PK factors to the OEL calculation. Further studies on additional biologics would be needed to generalize across proteins.

## **PS 504 Simulation of Perfluoroacid Accumulation in Humans Exposed to Perfluorotelomer Alcohol Products.**

W. Roth and P. Rice. *Office of Food Additive Safety, US FDA, College Park, MD.*

Perfluorochemical grease-proofing agents derived from perfluorotelomer alcohols are commonly used in fast-food packaging, and have been of concern because of the toxicity and potential for biopersistence of components of these products, such as the surfactant perfluorooctanoic acid (PFOA) and related perfluoroalkyl carboxylic acids (PFCAs). Although the predominant products of perfluoroalkyl-ethanol (PFAE) metabolism are usually conjugates such as PFAE-O-glucuronide or PFAE-S-glutathiones, studies in the rat indicated that small amounts of PFCAs are also formed, and might lead to accumulation in other species (especially humans) under the appropriate kinetic conditions. We have previously conducted pharmacokinetic modeling of the metabolism of PFOE based on the rat experiments of Fasano et al. (2006), and were able to explain the metabolic appearance of PFOA with fitted kinetic coefficients. Since that time, additional in vitro data from human, rat, and mouse hepatocyte incubations has become available (Naab et al., 2007; Fasano et al., 2009), allowing us to extend our PK model to predict accumulation of PFCAs derived from PFAE products in the mouse and humans. Although neither the PK model prediction nor the in vitro data are definitive, this combination of alternative methods provides insight into PFAE exposures and consequent levels of PFCAs.

## **PS 505 Uptake and Disposition in Humans of Hydrofluorocarbons (HFCs) Used As Refrigerants.**

L. Ernstgård, B. Sjögren and G. Johanson. *Work Environmental Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

A variety of hydrofluorocarbons (HFCs) have replaced the ozone-depleting chlorofluorocarbons (CFC) and hydrochlorofluorocarbons (HCFC) during the last decades. There are few data on uptake and disposition of HFCs in humans. In a se-

ries of experiments, we therefore exposed healthy volunteers to vapors of four commonly used HFCs, namely difluoroethane (HFC152a; 0, 200 and 1000 ppm), trifluoroethane (HFC143a; 500 ppm), tetrafluoroethane (HFC134a; 500 ppm) and pentafluoropropane (HFC245fa; 0, 100 and 300 ppm). In parallel, blood:air, saline:air and olive oil:air partition coefficients (PCs) were determined in vitro. The inhalation exposures were performed for 2 h during light physical exercise (50 W) in an exposure chamber. Capillary blood, urine and exhaled air were sampled until next day and analyzed for the parent substance by head-space gas chromatography. Fluoride and other potential metabolites were analyzed in urine using an ion selective electrode and 19F-NMR analysis, respectively. All HFCs had similar toxicokinetic profiles in blood with a rapid initial increase of HFC and an apparent steady-state reached within a few minutes. The area under the concentration-time curves (AUC) of HFC152a and HFC245fa in blood was proportional to the exposure level, suggesting first-order kinetics. For all four HFCs, the inhalation uptake was low (less than 4%) and only minor amounts were excreted unchanged in breath and urine after exposure. No signs of metabolism were detected except a slightly increased urinary excretion of fluoride after exposure to 1000 ppm HFC152a. No other urinary metabolites were detected. The observed time courses in blood and breath could be well described with a physiologically-based pharmacokinetic (PBPK) model. In conclusion, the uptake and disposition of the four HFCs are consistent with the PCs determined in vitro and with zero or insignificant biotransformation.

## **PS 506 Ethanol Toxicokinetics Resulting from Inhalation Exposure in Human Volunteers and Toxicokinetic Modeling.**

J. Dumas-Campagna, G. Charest-Tardif, R. Tardif and S. Haddad. *Environmental and Occupational Health, IRSPUM, Université de Montréal, Montréal, QC, Canada.*

There is a lack of information and increased interest on the risks associated with chronic inhalation exposures to low levels of ethanol (< 1000 ppm). A physiologically based pharmacokinetic model (PBPK) for inhaled ethanol was previously developed based on exposed volunteers but only for levels above 5000 ppm. Uncertainty still remains about the validity of this model to predict the blood levels of ethanol (BE) for lower level exposures. This project aims to determine the BE resulting from exposure to low concentrations (<1000 ppm) in order to adjust/validate the PBPK model. Ten volunteers (5 men and 5 women) were exposed for 4 h to vapors of ethanol (125, 250, 500, 750 and 1000 ppm) in resting conditions in an inhalation chamber. An additional exposure to 750 ppm that included 4 periods of 12 minutes of exercise at 50W was performed. Blood samples and alveolar air were collected during and after the exposure. Results show that there is a linear relationship between the ethanol inhaled air concentrations and (i) BE (women: r<sup>2</sup> = 0.98/men: r<sup>2</sup> = 0.99), as well as (ii) ethanol concentrations in the alveolar air at end of exposure period (men: r<sup>2</sup> = 0.99/women: r<sup>2</sup> = 0.99). Furthermore, exercise resulted in a significant increase (2 to 3 times) in BE after each period of 12 min of exercise. Overall, the model predictions were overestimated at exposure levels < 2616 ppm for men and < 2300 ppm for women. At lower exposure concentrations, limiting the clearance to the liver compartment was insufficient to account for total ethanol clearance. Adjusting the model by adding extra-hepatic biotransformation of high affinity and low capacity associated with the richly perfused tissues allowed the model to fit adequately the low and high exposure level toxicokinetic data. These new toxicokinetic data and improved PBPK model for ethanol will facilitate the refinement of risk assessment for chronic inhalation exposure to low levels of ethanol. (Project funded by ANSES, France).

## **PS 507 Physiologically-Based Pharmacokinetic (PBPK) Modeling: Extrapolation from In Vitro to In Vivo, a Case Study Using a Novel Dermal Compartment.**

M. V. Evans<sup>1</sup>, C. A. Wilson<sup>2</sup>, L. J. Beesley<sup>2</sup>, L. S. Leon<sup>2</sup>, R. A. Pegram<sup>1</sup>, E. L. Croom<sup>1</sup>, C. R. Eklund<sup>1</sup> and M. E. Sawyer<sup>2</sup>. <sup>1</sup>PB, US EPA, Research Triangle Park, NC; <sup>2</sup>REU 2012, North Carolina State University, Raleigh, NC.

PBPK models are useful extrapolation tools requiring time course data for calibration. A unique data set for rodents and humans was used with an existing PBPK model for species extrapolation. This same data set also enabled an in vitro to in vivo extrapolation, an emerging application tool for PBPK modeling. By adding a dermal compartment, a refined rodent PBPK model for orally administered lindane was developed and optimized using time-course tissue concentration data for Wistar rats. This refined PBPK model also provided blood and skin partition coefficients (P<sub>blood</sub> = 1.72 and P<sub>skin</sub> = 26.2); other partition coefficients were obtained from the literature. Next, a human in vivo model was extrapolated from the rodent model using physiological values from the literature. In addition, a novel in vitro model of human skin containing a follicular compartment was developed to

improve the fit to the available in vitro absorption data. In vitro dermal permeability coefficients were estimated using two different methods: 1) a permeability coefficient of 0.013 cm/hr was derived with the Potts-Guy equation; simulations generated with this coefficient matched the upper error results from the in vivo data; and 2) a permeability coefficient of 0.0043 cm/hr resulted from the dermal in vitro model; simulations generated with this coefficient matched the lower error results from the same in vivo data. The permeability value obtained using the in vivo PBPK model was 0.0060 cm/hr, which provided the best fit to the data. This result is between the in vitro and the Potts-Guy estimates, and PBPK simulations generated with this in vivo permeability fit through the averaged data points. In summary, PBPK modeling was found to be a powerful in vitro to in vivo extrapolation tool, particularly when time course datasets are available. (This abstract does not reflect EPA policy).

**PS 508 Evaluation of Toxicity Adjustment Factors Used for the Risk Assessment of Chlorpyrifos Oxon in Drinking Water.**

M. Bartels<sup>1</sup>, S. Marty<sup>2</sup>, J. E. Chambers<sup>3</sup>, J. J. Galligan<sup>4</sup>, D. W. Lickfeldt<sup>5</sup> and D. R. Juberg<sup>5</sup>. <sup>1</sup>Toxicology, Dow Chemical, Midland, MI; <sup>2</sup>Toxicology, Dow Chemical, Midland, MI; <sup>3</sup>College of Veterinary Medicine, Mississippi State University, Mississippi State, MS; <sup>4</sup>Neuroscience Program, Michigan State University, East Lansing, MI; <sup>5</sup>Regulatory Laboratory, Dow AgroSciences LLC, Indianapolis, IN.

In the Preliminary Human Health Risk Assessment for chlorpyrifos (CPF), EPA has derived toxicity adjustment factors (TAF) for chlorpyrifos oxon (Oxon), for both acute and chronic dietary scenarios, of 12 and 18, respectively, based on relative inhibition of RBC acetylcholinesterase (AChE) by Oxon, relative to CPF. However, a comprehensive evaluation of the biological effects of Oxon, following oral exposure, has shown that this test material undergoes complete first-pass metabolism, via chemical and/or enzymatic processes in the GI tract, GI tissue, portal vein blood and liver. As a result, no test material is systemically available at  $\leq 10$  mg/kg, as shown by non-detectable levels of Oxon in blood and no inhibition of brain ChE activity at doses up to 10 mg/kg in adult rats. Numerous datasets on tissue sensitivity to Oxon show that effects in brain are predictive and conservative for ChE inhibition, relative to other target tissues. Minor effects seen in the GI tract, at dose levels  $\geq 5$  mg/kg, are limited to the portal of entry (i.e., do not directly affect other tissues), are not considered to have long-term clinical consequences, and would not be expected given the predicted, low level exposures to Oxon in drinking water. As a result of these analyses, it is proposed that the potency of Oxon be based on a relevant toxicity endpoint (e.g., brain effects seen at  $> 10$  mg/kg) and not on RBC ChE inhibition, which is an indicator of low levels of Oxon that are not systemically available.

**PS 509 Effects of Leucine Administration on Plasma and Brain Levels of Other Amino Acids.**

K. Yu, L. Narayanan, J. Gearhart, J. J. Schlager, F. Lobo-Menendez, D. A. Mahle and P. Robinson. *AFRL, Wright-Patterson AFB, Dayton, OH.*

Leucine (leu), one of the essential branch-chained amino acids (AAs), has been shown to activate mTOR to increase protein synthesis, and for the brain, may provide enhanced cognitive memory deposition. However, little is known regarding leu kinetics. Investigations into the leu kinetics revealed that it was eliminated very fast from the blood after dosing, and leu levels in brain were higher than blood, indicating active transport of leu across the blood brain barrier (BBB). The objective of this work was to investigate the effects of leu administration on blood and brain levels of 20 AAs, and the BBB role (if any) to leu kinetics. A rodent model was dosed leu via iv (5 & 12.9 mg/kg) for dose-response and time-course studies, and orally (319 mg/kg) for time-course analysis. Tissue leu levels were measured at various time points (5m–6h, iv and 30m–4h, orally). Interestingly, more than 65% of all AAs were increased in brain. At the 5 mg/kg dose, valine, lysine and proline in brain were increased, while aspartic acid and isoleucine levels decreased. At the 12.9 mg/kg dose, serine, tryptophan, lysine and proline in brain were increased, while threonine and methionine decreased (all relative to control,  $p < 0.05$ ). With oral dosing, 16 AAs in brain were increased at the 1h time point. Isoleucine (time point 1 & 4h), lysine (0.5 & 1h), histidine (0.5 & 1h) and proline (all time points: 0.5, 1, 2, and 4h) in brain were increased significantly from control at  $p < 0.05$  or less. Brains to plasma AA ratios were increased following dosing for lysine, methionine and valine at 5 mg/kg, proline at 12.9 mg/kg and isoleucine and proline for oral dosing groups. Our results indicate that leucine administration initiate complex time- and dose- dependent responses in both plasma and brain levels of the other AAs. These preliminary data show that neither the specific BBB transport system for AAs (most AAs use the L1 large neutral AA transporter for crossing the BBB), nor obvious general chemical or biological AA properties determine the brain levels and uptake behavior observed in these studies.

**PS 510 Screening for Substrates of the P-Glycoprotein Transporter.**

R. A. Pegram<sup>1</sup>, E. L. Croom<sup>1</sup> and J. A. Campbell<sup>2</sup>. <sup>1</sup>NHEERL/ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>NCBA/SEE Program, Washington DC.

P-glycoprotein (Pgp) is an ATP-dependent efflux transporter of xenobiotic compounds with broad substrate specificity. Pgp is an important component of the blood-brain barrier and frequently mediates resistance of tumors to chemotherapeutic agents. Attempts to predict the in vivo toxicity of environmental chemicals based upon in vitro screening test results can be erroneous if transporter effects are not considered. In this study, a multi-tiered in silico/in vitro testing approach was used to predict Pgp substrates within a set of ToxCast chemicals. An in silico analysis using a support vector machine predicted 45 of the 280 chemicals to be Pgp substrates; these predictions matched the results of a separate in silico docking analysis. Only 5% of the chemicals with MW  $< 400$  (and none with MW  $< 300$ ) were predicted as substrates, while 87% with MW  $> 400$  were predicted substrates. In vitro cell-based assays were used to further screen for Pgp substrates among chemicals with MW  $> 300$ . Dye efflux experiments were conducted with NIH 3T3 MDR1 cells that stably express human Pgp. A number of potential substrates were identified by this assay (including ivermectin and abamectin), as shown by their capability to interfere with efflux of Hoechst 33342 dye from the cells. A more definitive assay was used to test chemicals with known cytotoxicity by comparing toxicity in the MDR1 cells and wild type 3T3 cells. Pgp substrates (i.e., chemicals that were less toxic to MDR1 cells) included captan, naled, pyriproxyfen, thiophanate, thiodicarb, abamectin, niclosamide, and rotenone. These results demonstrate that a systematic approach involving a combination of in silico and cell-based in vitro assays can successfully predict Pgp substrates within large chemical test sets. In vitro toxicants that are identified as Pgp substrates will require additional toxicokinetic assessment to correctly predict their potential in vivo toxicity. (This abstract does not reflect EPA policy.)

**PS 511 Transport Mediated Mechanism for Nucleoside Penetration of the Blood-Testis Barrier.**

D. M. Klein<sup>1</sup>, R. N. Hardwick<sup>1</sup>, K. K. Evans<sup>2</sup>, W. H. Dantzler<sup>2</sup>, S. H. Wright<sup>2</sup> and N. J. Cherrington<sup>1</sup>. <sup>1</sup>Pharmacology/Toxicology, University of Arizona, Tucson, AZ; <sup>2</sup>Physiology, University of Arizona, Tucson, AZ.

The blood-testis barrier (BTB) is formed by tight junctions between Sertoli cells and prevents the entry of many therapeutics into the lumen of the seminiferous tubules (STs) shielding developing germ cells from chemical exposure. One drug class of HIV therapeutics, nucleoside reverse transcriptase inhibitors (NRTIs), can penetrate the BTB and be detected in human seminal plasma at concentrations higher than that of blood plasma. The purpose of this study is to determine the mechanisms by which NRTI drugs are transported across the BTB. Transport studies in isolated rodent seminiferous tubules using H3uridine (Kt 89.72uM) as a model nucleoside substrate indicate that seminiferous tubules take up nucleosides almost exclusively via equilibrative nucleoside transporter 1 (ENT1). The IC50 for NBMPR, an ENT inhibitor, is 12.9 nM. Trans-epithelial transport of uridine by primary rat Sertoli cells can also be blocked by ENT1 inhibition. Blocking ENT1 function on the basolateral membrane also prevents uridine uptake into cells. These data correspond with immunohistochemical staining of rat testes showing ENT1 on the basolateral membrane, whereas ENT2 is on the apical membrane of Sertoli cells. This localization suggests that ENT1 acts as an uptake transporter and ENT2 may facilitate the efflux of nucleosides and NRTI drugs into the lumen of STs. Uridine transport can also be inhibited by NRTI drugs. We also demonstrate transepithelial transport of radiolabeled NRTIs zidovudine (AZT) and didanosine (ddI) through primary Sertoli cells is partially blocked by ENT1 inhibition (88% and 67% for AZT and ddI respectively). These data indicate a novel ENT dominant mechanism for the transepithelial transport of nucleosides and NRTI drugs across the BTB.

**PS 512 Pharmacokinetics and Bioavailability Testing of Levofloxacin in Rats.**

K. K. Kabirov, A. Banerjee, E. Onua, M. Hautmann and A. Lyubimov. *Toxicology Research Laboratory/UIC, Chicago, IL.*

Drug exposure of the antibiotic levofloxacin was examined in male and female Sprague Dawley rats following oral and intravenous administration. Pharmacokinetic modeling and determination of bioavailability were conducted following single dose treatment and subsequent measurements of levofloxacin levels in plasma. Dose levels studied were 50 mg/kg oral (PO) and 25 mg/kg intravenous

(IV). There were no abnormal clinical signs observed following dosing, which might have otherwise affected the pharmacokinetic modeling. The systemic bioavailability of levofloxacin in rats after PO administration ranges between 33.7–42.7%, and appears to be lower in males. The volume of distribution ( $V_z$ ) appeared to be higher in female than in male rats following IV administration. Other pharmacokinetic parameters appeared to be similar in both male and female rats for both routes of administration. Levofloxacin appears to distribute widely in rat tissues and possibly exhibits a large affinity for tissue proteins. The half-life of the drug is short (4.33 hr and 4.96 hr in males and females, respectively, following PO administration; 1.38 hr and 1.55 hr in males and females, respectively, following IV administration), probably due to a high systemic clearance. Levofloxacin single IV (25 mg/kg) and PO (50 mg/kg) doses were well tolerated by male and female rats. Mean ( $\pm$ SD) AUC<sub>0-inf</sub> values following IV administration were  $11339.0 \pm 572.3$  hr\*ng/mL and  $9422.7 \pm 1169.4$  hr\*ng/mL, in males and females, respectively, and following PO administration were  $8051.4$  hr\*ng/mL and  $10211.6$  hr\*ng/mL in males and females, respectively. Based on mean  $T_{max}$  and terminal elimination half-life values, levofloxacin is rapidly absorbed and eliminated.

**PS 513 Comparative Disposition and Metabolism of 2, 2'-Dithiobisbenzanilide following Dermal, Oral, and Intravenous Administration to Harlan Sprague-Dawley Rats and B6C3F1/N Mice.**

J. Lucak<sup>1</sup>, C. Garner<sup>1</sup>, C. J. Wegerski<sup>1</sup>, J. M. Sanders<sup>2</sup>, M. Doyle-Eisele<sup>1</sup>, J. D. McDonald<sup>1</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

2, 2'-Dithiobisbenzanilide (DTBBA) is used as a peptizing agent in tires and rubber products and occupational exposure to DTBBA may occur mainly through dermal contact. Potential systemic exposure via the dermal route was investigated in rodents and compared to intravenous and oral routes. A single dermal dose of [<sup>14</sup>C]DTBBA (4 mg/kg, in acetone) were applied (protected from oral grooming) to male Harlan Sprague-Dawley rats and B6C3F1/N mice and its disposition and metabolism 72 h after was compared to 4 mg/kg intravenous and gavage doses. Following a dermal dose of [<sup>14</sup>C]-DTBBA in rats and mice,  $10.9 \pm 2.9\%$  and  $10.6 \pm 2.9\%$  of the dose was absorbed, respectively. Excretion of absorbed dose was via urine ( $18.4 \pm 3.3\%$ ;  $34.7 \pm 7.7\%$ ) and feces ( $32.6 \pm 10.7\%$ ;  $49.5 \pm 10.8\%$ ) for rats and mice, respectively. Following gavage administration in both species, the absorption was complete. Excretion of [<sup>14</sup>C] after rat intravenous doses was mostly via urine ( $73.1 \pm 7\%$ ). After mouse intravenous, mouse or rat dermal or gavage doses ~30% to ~40% was recovered in urine and feces. The percent dose in tissues after dermal dosing was  $4.58 \pm 1.92\%$  for the rat and  $0.98 \pm 1.13\%$  for mouse and in both species non dose site skin had the highest [<sup>14</sup>C] levels. Radioactivity remaining in tissues followed the trend of dermal  $\geq$  intravenous > gavage in rat and intravenous > gavage  $\approx$  dermal in mouse. DTBBA was not detected in urine. Urine metabolite profiles were qualitatively similar between species but the levels of some metabolites varied between dose routes. The structure of the predominant urinary metabolite was identified as thiobisbenzanilide-S-glucuronide by LC/MS/MS and <sup>1</sup>H and <sup>13</sup>C-NMR. This work was conducted for the NTP under NIEHS Contract N01-ES-75562.

**PS 514 Effect of Vehicle on the Dermal Absorption of 2-Hydroxy-4-Methoxybenzophenone Harlan Sprague-Dawley Rats and B6C3F1/N Mice.**

C. J. Wegerski<sup>1</sup>, C. Garner<sup>1</sup>, M. Doyle-Eisele<sup>1</sup>, J. M. Sanders<sup>2</sup>, J. D. McDonald<sup>1</sup>, S. S. Auerbach<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

2-Hydroxy-4-methoxybenzophenone (HMB) is used as sunscreen agent with significant human exposure. To support a vehicle selection for potential dermal studies in rodents, the effect of different dermal vehicles on absorption and disposition of 0.1 or 10 mg/kg [<sup>14</sup>C]HMB was investigated in male and female Harlan Sprague Dawley Rats and B6C3F1/N Mice 72 h following application. The vehicles investigated were ethanol, ethanol:coconut oil (1:1), coconut oil, light paraffin oil, or a lotion (olive oil:emulsifying wax:water, 15:15:70). In rats, the greatest absorption was observed with paraffin oil ( $79.8 \pm 6.9\%$ ). Absorption across all vehicles followed the trend of paraffin oil > ethanol:coconut oil > ethanol > coconut oil > lotion. Dose did not have an impact on absorption in rats at 10 and 0.1 mg/kg when paraffin oil was used as the vehicle ( $79.8 \pm 6.9$  and  $72.5 \pm 8.5\%$  dose, respectively

( $p > 0.05$ ). Ethanol gave a large difference in absorbed dose between rats ( $67.8 \pm 3.2\%$  dose) and mice ( $43.7 \pm 3.7\%$  dose) ( $p < 0.001$ ). The absorbed dose was similar between rats ( $34.6 \pm 8.5\%$  dose) and mice ( $36.8 \pm 8.2\%$  dose) when using the lotion vehicle. There was also no significant difference in the absorbed dose between male and female mice using the lotion ( $36.8 \pm 8.2\%$  and  $46.2 \pm 7.3\%$  dose, respectively) ( $p > 0.05$ ). In rats, the percent dose recovered in tissues ranged from 2.8–8.3 for all dosing vehicles, which was higher than the percent recovered in tissues for mice (0.6–1.2). Non-dose site skin was the site of greatest tissue burden in both species. In conclusion, these studies indicate use of paraffin oil as the vehicle provides the highest systemic absorption of HMB and there is a difference in absorption between rats and mice. This work was conducted for the NTP under NIEHS Contract N01-ES-75562.

**PS 515 Lipophilicity and Membrane Affinity of Munitions Constituents Using Biolipid Beads.**

A. B. Goins<sup>1</sup>, D. R. Johnson<sup>2</sup>, C. Y. Ang<sup>1</sup>, A. M. Scott<sup>2</sup>, A. J. Bednar<sup>2</sup>, T. M. Reese<sup>3</sup> and F. C. Hill<sup>2</sup>. <sup>1</sup>Environmental Laboratory, US Army Engineer Research & Development Center, Vicksburg, MS; <sup>2</sup>Badger Technical Services, Vicksburg, MS; <sup>3</sup>Jackson State University, Jackson, MS.

Bioaccumulation of organic molecules into fat can be predicted by chemical lipophilicity which is measured by the octanol:water partition coefficient (Kow). Newly developed methods use the liposome:water partition coefficient (Klipw) with phosphatidylcholine (PC) instead of octanol to more accurately represent the capacity of membrane lipids to accumulate neutral organic chemicals. In this study, a new technique for measuring Klipw using solid-supported PC liposomes attached to silica beads (TRANSIL® Sovicell, Leipzig, Germany) was used to assess the membrane affinity (i.e., Klipw) of 10 munitions compounds (MCs) and 5 environmental breakdown products (BPs). Nitroaromatic compounds studied were 2,4,6-trinitrotoluene [TNT], 2,4-dinitrotoluene [2,4-DNT], 2,6-dinitrotoluene [2,6-DNT], 1,3,5-trinitrobenzene [TNB], 2,4-dinitroanisole [DNAN]; cyclic nitramine compounds studied were hexahydro-1,3,5-trinitro-1,3,5-triazine [RDX], octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine [HMX], hexanitrohexaazaisowurtzitan [CL-20]; and other nitrogenous compounds studied were 5-nitro-2,4-dihydro-3H-1,2,4-triazol-3-one [NTO] and 2,2-dinitro-1,1-ethenediamine [FOX-7]. Results indicate that nitroaromatic and cyclic nitramine compounds have lipophilicities with log Klipw ranging from 1.55–3.22, with TNT and RDX log Klipw 2.18 and 2.26, respectively. RDX-like compounds and the TNT BP 4-aminodinitrotoluene (4-ADNT) have Klipw >1 log units higher than computational and literature-based log Kow. NTO and FOX-7 were found to have very low lipophilicity (log Klipw < 1, below biolipid assay detection limit). In conclusion, use of Klipw from biolipid beads rather than Kow from literature or computational sources may allow scientists and risk assessors to avoid underestimating chemical bioconcentration.

**PS 516 Less Is More: Better Toxicity Data from Fewer Rodents Using Plasma Microsampling.**

G. Schmitt, A. Eichinger-Chapelon, D. Zaugg and T. Singer. *Toxicology, F. Hoffmann-La Roche, Basel, Switzerland.*

The standard design of drug development rodent toxicity studies today involves numerous large volume blood samplings to characterize the toxicokinetics of a drug candidate. Due to the large volume and generally required anesthesia, standard practice is to use additional satellite animals. Using the plasma microsampling technique developed by Ove Jonsson et al. (Bioanalysis (2012), 4(6), 661–674) would change this. With this technique, satellite animals for kinetic bleedings are no longer required (3R-Reduce), anesthesia is no longer required for small (i.e.,  $\mu$ L) blood volume sampling from the tail vein (3R-Refine), and lastly less animals means less test compound is needed. Ultimately, plasma microsampling would be used for toxicokinetic blood collection in all types of rodent toxicology studies performed at or under sponsorship of F. Hoffmann-La Roche. To reach this goal, a method validation study has been initiated using acetaminophen and an anti-CD20 monoclonal antibody as model compounds. These compounds were selected to investigate the different analytical methods needed for small versus large molecule, i.e., liquid chromatography coupled to mass spectrometry versus an enzyme-linked immunosorbent assay, respectively. For each compound, one low and one high dose were selected to check for dose exposure dependence. The validation study design would use both the microsampling and conventional large volume sampling in the same animals in an authentic 14-day rat toxicity study and compare the exposure data obtained from each technique. If successful (i.e., comparable exposure data), the use of the microsampling technique in rodent toxicity studies will

lead to i) a significant reduction in animal use (e.g., 32 instead of 48 rats in a 14-day dose-range finding study), ii) the abandonment of anesthesia for toxicokinetic blood sampling, and iii) better data as effect and exposure are gathered in the same animal leading to better assessments of drug-related effects.

**PS 517 Using PBPK Modeling to Address Diurnal Variation and Age Differences in Hexavalent Chromium Toxicokinetics in Humans.**

C. R. Kirman<sup>1</sup>, C. M. Thompson<sup>2</sup>, D. M. Proctor<sup>3</sup>, M. Suh<sup>3</sup>, L. C. Haws<sup>4</sup>, M. A. Harris<sup>2</sup> and S. M. Hays<sup>5</sup>. <sup>1</sup>Summit Toxicology LLP, Orange, OH; <sup>2</sup>ToxStrategies, Katy, TX; <sup>3</sup>ToxStrategies, Rancho Santa Margarita, CA; <sup>4</sup>ToxStrategies, Austin, TX; <sup>5</sup>Summit Toxicology LLP, Allenspark, CO.

A physiologically based pharmacokinetic (PBPK) model has been developed to describe the toxicokinetics of hexavalent chromium [Cr(VI)] in mice, rats, and humans. The PBPK model was used to support a human health risk assessment (HHRA) based upon mouse small intestinal (SI) tumors. Key factors contributing to the delivery of Cr(VI) to the SI were identified by sensitivity analyses, and include gastric pH, gastric transit time, and gastric reducing equivalents. These factors affect the rate of Cr(VI) reduction in gastric contents, with a higher delivery of Cr(VI) resulting from higher pH values (which causes slower rates of Cr(VI) reduction), shorter stomach transit times, and lower reducing equivalent concentrations. The PBPK model was used to address 4 important sources of variation. First, the model was used to account for normal diurnal variation in gastric lumen factors (e.g., in normal individuals, baseline gastric pH is typically between 1-3 between meals, but rises rapidly to levels of 5-7 at the start of a meal, then returning to baseline levels within a 2-3 hours). Second, the model was used to simulate exposures to different age groups, including infants, children, youths, adults, and elderly, since some age groups (e.g., infants) normally exhibit higher pH values than adults. Age-specific differences in the key factors were incorporated in the modeling to estimate human equivalent lifetime average daily dose corresponding to point of departures determined for mouse SI lesions. Third, the model was used to assess risk to specific populations (proton-pump inhibitor users) that may be sensitive to Cr(VI) due to alterations in gastric pH. Lastly, the model was used to assess the impact of the timing of Cr(VI) exposure events on delivery of Cr(VI) to the SI with respect to their occurrence during or between meals. The implications to HHRA are quantified and discussed.

**PS 518 Advantages of Using Quadrupole Time-of-Flight (QTOF) in the Bioanalysis of Large Therapeutic Peptides.**

F. Garofolo. *Bioanalytical Services, Algorithme Pharma, Laval, QC, Canada.*  
Sponsor: K. Draper.

**Purpose.**

MUC5AC13, hepcidin, and calcitonin were selected as model compounds to demonstrate the advantages of QTOF in large therapeutic peptides bioanalysis for toxicokinetic (TK) and pharmacokinetic (PK) studies.

**Methods.**

Samples were prepared by spiking MUC5AC13, hepcidin or calcitonin in plasma. They were extracted using protein precipitation followed by solid phase extraction. UPLC was used for chromatography. MUC5AC13 and Calcitonin were analyzed on TripleTOF5600 with DuoSpray. A KinetexC18 column and 0.6mL/min flow rate in gradient conditions were used. For hepcidin, electrospray Chip emitters TriVersaNanoMate on TripleTOF5600 with AtlantisT3 column at 0.5mL/min flow rate in gradient conditions were used.

**Results.**

MUC5AC13 showed multiple charge states +2 and +3 as the most abundant ions in QTOF full scan. Summing +2 and +3 charge states with a 10mDa extraction window was used for quantification, over 3.5 orders of linear range (0.4-2000ng/mL), a precision of <9.3% and an accuracy between 86-113% were obtained. In hepcidin quantification, full scan and parent ion quantification showed interferences even with narrow extraction window (2-5mDa). The interference peaks might be in source fragments and thus eliminated by the first quadrupole (Q1). Hence, quantification of hepcidin was performed in QTOF tandem mass spectrometry and summing +4 charge state isotopomers of parent ion at a 10mDa extraction window and it showed 3 orders of linear dynamic range (2-2048ng/mL) a precision of <9% and an accuracy between 80-112%. Calcitonin quantification showed +3, +4 and +5 charge states as the most abundant ions. QTOF full scan and summing +3, +4 and +5 charge states of parent ion at a 10mDa extraction window were used for quantification. The observed LLOQ was 50pg/mL with 4 orders of linear dynamic range. The precision was better than 15% and the accuracy between 83-118%.

**Conclusion.**

The benefits of QTOF bioanalytical quantification for large therapeutic peptides (minimum drug optimization; generic method and non-targeted quantification) were confirmed and it can be used for TK & PK studies.

**PS 519 A New Strategy to Effectively Reduce Matrix Effect Caused by Phospholipids in Plasma Samples under Hydrophilic Interaction Liquid Chromatography (HILIC).**

M. Raigneau and F. Garofolo. *Bioanalytical Services, Algorithme Pharma Inc., Laval, QC, Canada.* Sponsor: K. Draper.

**Purpose.**

Significant reduction of matrix effect due to phospholipids (PL) in plasma sample by using aprotic solvent to improve the performance of bioanalytical methods used for drug quantification in toxicokinetic and pharmacokinetic studies.

**Methods.**

Rivastigmine was extracted using liquid-liquid extraction and injected using HILIC column with ammonium acetate / Acetonitrile (ACN) with a flow rate=0.8mL/min. Analysis was performed on ABSciexAPI3000 with electrospray(+). Lower limit of quantification=10pg/mL. PL were monitored at m/z 184. The PL extractability was evaluated by samples evaporated in polypropylene (PP) instead of glass tubes and reconstituted with ACN.

**Results.**

Extracted plasma samples were reconstituted in mobile phase (MP blank) or in ACN blank and injected with post-column infusion of rivastigmine. The post-column infusion of MP and ACN blanks showed no suppression at the drug retention time. However, the baseline from the post-column infusion of MP blank dropped by 35% after seven injections. However, ion-suppression was not observed for the ACN blank. These results suggest that the late eluting suppressors are not reconstituted in ACN. PL peak was observed after seven MP blank injections suggesting that the late eluting suppressors in the MP blank are phospholipids. This peak was not observed in ACN blank. These results suggest that PL are reconstituted in mobile phase and elute as late eluting suppressors under the chromatographic conditions. However, PL are not reconstituted using ACN. The extracted blank plasma samples were reconstituted in PP tubes with ACN and compared to MP and ACN blanks reconstituted in glass tubes to determine if the PL are insoluble in ACN or if adsorption occurred on the glass tube surface. The PP ACN & MP blanks chromatograms were identical thus demonstrating that PL are soluble in ACN but were adsorbed on silica surface.

**Conclusion.**

The reconstitution of extracted samples in glass test tube using 100% ACN successfully eliminates the matrix effect caused by phospholipids.

**PS 520 Impact of Organic Solvent Additive on the Integrity of Plasma Samples over Time in Bioanalysis by LC-MS/MS.**

C. Dicaire and F. Garofolo. *Bioanalytical Services, Algorithme Pharma Inc., Laval, QC, Canada.* Sponsor: K. Draper.

**Purpose.**

Evaluation of plasma integrity over time due to addition of organic solvent in quality control samples (QCs) for morphine-6-glucuronide (M6G) bioanalytical method that was validated to be used in pharmacokinetic studies.

**Methods.**

The samples were extracted using solid phase cartridges. The injection of the samples was performed on XBridge Phenyl column (2.1x50mm, 5µ) in gradient conditions on Agilent1100 coupled with ABSciex API5000 in electrospray(+). The QCs were prepared with M6G alone and M6G + naltrexone (Co-Administered Drug - CAD) at 1.0% organic content vs. 1.5% respectively. M6G and M6G-D3 (IS) were monitored at m/z 462/201 and 465/289 respectively. Full scans and post-columns infusion were performed to evaluate the presence and determine the impact of interfering compounds.

**Results.**

A significant decrease in signal (~35%) was observed for M6G/IS over time for the QC containing naltrexone. A post-column infusion profile of these QCs showed the presence of suppressors which co-eluted with M6G/IS. Chromatographic separation was achieved between naltrexone and M6G/IS thus eliminating any possible suppression from naltrexone. Full scan experiments enabled the detection of two specific masses co-eluting with M6G/IS only in the QCs stored over time and containing naltrexone. QCs containing only the analyte and others containing the analyte with naltrexone were prepared in different plasma matrices. Some blank matrices were tested alongside with blank matrix containing different organic solvent percentage. The freshly prepared QCs did not show ion suppression; either in the presence of naltrexone or of the extra organic solvent. The long-term evaluation of the matrices in the presence of organic solvent (1.5%), showed two unknown compounds to appear over time and elute at the retention time of M6G thus creating a suppression zone.

## Conclusion.

The amount of organic solvent added impacted the integrity of the plasma samples over time. The ion suppression observed in plasma was not due to the addition of the CAD (naltrexone) but due to the amount of organic.

## PS 521 Dried Blood Spots (DBS) On-Card Derivatization: An Easy & Alternative Form for Sample Handling to Overcome the Biological Matrix Instability of Thiorphan.

R. Sabelli and F. Garofolo. *Bioanalytical Services, Algorithm Pharma Inc., Laval, QC, Canada.* Sponsor: K. Draper.

**Purpose:** Use of in-house pre-treatment of DBS cards to overcome stability challenges of thiorphan in toxicokinetic and pharmacokinetic studies.

### Methods.

Thiorphan was spiked in whole blood (range of 5-600ng/mL) and 40uL of whole blood were applied on untreated or in-house pretreated cards with 2-bromo-3'-methoxyacetophenone FTA DMPK-A, B and C cards. Disks (6mm) were punched from the blood spots, transferred into tubes and 200uL of internal standard (thiorphan-D5) in methanol was added. Samples were vortexed and left on bench for one hour. 100uL of the supernatant was transferred into 96wellplate already containing 100uL of water prior to injection on a Zorbax BonusRP column eluted using a gradient. Analysis was performed on an ABSciex API3000 in electrospray(+).

### Results.

The instability of thiorphan in biological matrix was demonstrated and minimized by derivatization to thiorphan-MP with 2-bromo-3'-methoxyacetophenone (BMP). In order to simplify sample handling process, on-card derivatization using DBS was investigated. The instability of thiorphan on-card, without derivatization, was demonstrated on all DBS cards used. Therefore, on-card derivatization technique was investigated. BMP could be added directly to the card for at least 2 days prior to blood spotting without compromising thiorphan derivatization. Although the on-card derivatization of thiorphan was successful on the A and C cards, the derivatization reaction seemed to be inhibited on the B card. Linearity of a calibration curve for a range of 5-600ng/mL was demonstrated using A and C cards pretreated with 0.5M BMP. Precision was 2-8% and the accuracy was 97-104%. Results showed on-card stability of thiorphan-MP for at least 2 days.

### Conclusion.

It was clearly demonstrated that DBS on-card derivatization offers a practical alternative for the bioanalysis of thiorphan in TK & PK studies since it requires less manipulation than the regular sample handling process.

## PS 522 Superparamagnetic Iron Oxide Loaded Cross-Linked Nanoassemblies Improve Tumor Accumulation and Magnetic Resonance Imaging *In Vivo*.

M. Dan<sup>1,2</sup>, M. T. Dickerson<sup>1</sup>, P. A. Hardy<sup>3</sup>, Y. Bae<sup>1</sup> and R. A. Yokel<sup>1,2</sup>.  
<sup>1</sup>Pharmaceutical Sciences, University of Kentucky, Lexington, KY; <sup>2</sup>Toxicology, University of Kentucky, Lexington, KY; <sup>3</sup>Anatomy and Neurobiology, University of Kentucky, Lexington, KY.

**Purpose:** To improve accumulation and contrast-enhanced magnetic resonance imaging of glioma using cross-linked nanoassemblies loaded with superparamagnetic iron oxide nanoparticles (CNA-IONPs) for potential glioma theranostic applications.

**Methods:** CNA-IONPs were synthesized and characterized. Gd-DTPA was used to monitor glioma tumor growth as a T1 contrast agent. CNA-IONPs were injected via the tail vein of a glioma xenograft rat model. T2 weighted MR images were taken 10 min and 2 h after the injection. T2\* was used to predict CNA-IONPs concentration increases. Glioma tumor, contralateral brain tissue, blood, and peripheral organs were collected at 2 or 6 h and iron concentrations analyzed by inductively coupled plasma mass spectrometry (ICP-MS).

**Results:** CNA-IONPs had a neutral zeta potential, hydrodynamic size ~ 30 nm, and were highly stable in medium containing serum at 37 °C over 30 h. CNA-IONPs showed significant T2 and T2\* contrast enhancement 2 h after injection. Gd-DTPA (0.3 mmol/kg) enhanced the tumor on T1 images acquired immediately after injection. T1 images acquired 2 h after injection showed Gd-DTPA was almost entirely cleared. In certain regions of the tumor, R2\* (1/T2\*), which is proportional to iron concentration, increased 48% from 10 min to 2 h after CNA-IONP injection. ICP-MS iron concentration in glioma tissue was 3 to 9 times higher than in contralateral brain tissue at 2 h. The iron concentrations in blood and peripheral organs did not significantly change from 2 to 6 h.

**Conclusions:** CNA-IONPs had desirable physicochemical properties for in vivo application. They preferentially accumulated in glioma and the concentration increased with time consistent with their long blood circulation time. CNA-IONPs have the potential to improve MRI diagnosis and provide a platform for incorporating glioma therapeutics.

Support: NCI Cancer Nanotechnology Training Center grant R25CA153954.

## PS 523 Age-Dependent Capability of Drug Metabolism in Commercially Available Human Hepatocytes.

M. Sunouchi<sup>1</sup>, K. Nakazawa<sup>1</sup>, R. Kikura-Hanajiri<sup>2</sup>, K. Kobayashi<sup>3</sup>, H. Kojima<sup>1</sup> and M. Usami<sup>1</sup>. <sup>1</sup>Pharmacology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Pharmacognosy and Phytochemistry, National Institute of Health Sciences, Tokyo, Japan; <sup>3</sup>Shizuoka Prefectural Agriculture and Forestry College, Iwata, Japan. Sponsor: H. Kojima.

Primary human hepatocytes have been worldwide used as a good tool to evaluate the safety of chemicals containing environmental pollutants, pesticides and drugs. On the other hand, it is known that the drug-metabolizing enzyme activities of hepatocytes are changing with aging. There, however, are large interindividual variations in the levels of CYP enzyme activities and the response to inducers among hepatocyte donors. Therefore, in this study we analyze the relation between the enzyme activities and the induction levels of the enzymes.

We analyzed the enzyme activities of CYP1A1, CYP2B6, CYP3A4, CYP2C8, CYP2C9, CYP2C19, CYP2D6 and UGT and their responses to CYP inducers by comparing the data of cryopreserved human hepatic cell suspension and plateable hepatocytes regarding the enzyme activities and the levels of mRNA's encoding the enzymes presented from multiple suppliers. Total samples used in this study were obtained from more than 100 donors (3 months - 82 years old).

CYP1A2 activities in hepatocytes from young donors (< 4 years old) tended to be reduced in cell suspension and were largely induced both in the activity and the mRNA levels in plateable hepatocytes by beta-naphthoflavone. The enzyme activities and the mRNA levels of CYP3A4 and CYP2B6 in the young donors were positively induced by rifampicin. There was large variability in CYP activities and the abilities of the inducers. The utility of these cryopreserved human hepatocytes as an evaluation system for the safety of chemicals will be discussed.

## PS 524 AHR-Mediated Epigenetic Modulation of CYP19 and BCRP in Human Breast Adipose Fibroblasts and MCF-7 Cells.

M. B. van Duursen, S. M. Nijmeijer, M. de Dreu and M. van den Berg. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

The epithelial-stromal microenvironment in breast cancer largely determines chances of therapeutic success, due to modulation of tumor cell gene expression and drug resistance. In breast adipose fibroblasts (BAFs) surrounding a tumor, expression of aromatase (CYP19), the enzyme responsible for local estrogen production, is elevated. In breast cancer cells, over-expression of breast cancer resistance protein (BCRP) is one of the major causes of multi-drug resistance and chemotherapy failure. Both BCRP and CYP19 over-expression have been related to hypomethylation of the promoter regions by DNA methyltransferases (DNMTs). Earlier studies have suggested that the aryl hydrocarbon receptor (AHR) can function as an epigenetic regulator. Here, the effect of the non-toxic AHR agonist tranilast on CYP19 and BCRP expression was investigated in BAFs and MCF-7 cells. In BAFs, tranilast caused a significant 70% reduction of CYP19 expression, which concurred with a 1.3/pI to 1.4-promoter switch. In MCF-7 cells, tranilast induced expression of the AHR-responsive gene CYP1A1 (15-fold) and breast cancer resistance protein (BCRP, 2-fold), but had no effect on the expression of DNMT1, 3a and 3b. CYP19 expression in MCF-7 cells was too low to be detected. Inhibition of DNA methylation by 5-aza-2'-deoxycytidine (5-aza-dC, 10 µM) significantly up-regulated expression of CYP19, BCRP (28-fold) and DNMTs (2 to 5-fold) in vehicle control-treated MCF-7 cells. In combination with tranilast, the induction of gene expression by 5-aza-dC was attenuated, except for CYP1A1 expression. Changes in EROD (CYP1A1) and aromatase activity in MCF-7 cells concurred with the gene expression profiles. These data show that AHR activation by tranilast leads to epigenetic modulation. This results in downregulation of CYP19 possibly through alternate promoter use and potential abrogation of multidrug resistance as result of BCRP overexpression. Our results indicate that the AHR might provide a multimodal target in the emerging field of epigenetic therapeutics.

## PS 525 The Ah Receptor Recruits Protein Kinases to Phosphorylate Ser10 in Histone H3 of the CYP1A1 Promoter Chromatin.

H. Kurita and A. Puga. *Department of Environmental Health, University of Cincinnati, Cincinnati, OH.*

Halogenated aromatic hydrocarbons such as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) cause many types of toxicity via the aryl hydrocarbon receptor (AHR). One of the best known proteins induced by TCDD is the cytochrome P450 1A1

(CYP1A1). Induction of this enzyme requires AHR ligand-dependent activation followed by the activated AHR binding to xenobiotic responsive elements (XRE) in the promoter region of the *Cyp1a1* gene. Histone modifications are well-known epigenetic markers modulating the activity of transcription factors by alteration of chromatin states. Among histone modifications, phosphorylation of serine-10 in histone H3 (H3S10ph) by various kinases has been reported to play a role in mitosis. Prior work from this lab had shown that the level of H3S10ph in the XRE enhancer region of the *Cyp1a1* promoter was elevated by AHR activation, which led us to search for responsible kinases that would be recruited by the ligand-activated AHR. To search for candidate kinases that phosphorylate H3S10 in an AHR dependent manner, we performed chromatin immunoprecipitation (ChIP) assays for the enhancer region of *Cyp1a1* in TCDD-treated Hepa-1 cells by using antibodies for AHR, H3S10ph and various kinases previously reported to phosphorylate this site. We found that binding of a subset of these kinase, including IKK $\alpha$ , MSK1, MSK2 and SRK, to the *Cyp1a1* enhancer region was absent in control cells and significantly increased by TCDD treatment. Given the known role of the AHR in cell cycle and differentiation, these data suggest that H3S10ph might be an activated AHR-dependent marker that signals cellular proliferation and mitosis. *Supported by NIH grant R01 ES 06273*

## PS 526 Epigenetics of Arsenic Carcinogenesis and Location of Methylated DNA Sites Underlying Gene Expression Changes.

B. A. Merrick<sup>1</sup>, E. J. Tokar<sup>1</sup>, D. P. Phadke<sup>2</sup>, R. R. Shah<sup>2</sup>, M. Wang<sup>3</sup>, O. Gordon<sup>3</sup>, G. M. Wright<sup>3</sup>, M. Burke<sup>3</sup>, S. A. Baxter<sup>3</sup>, K. E. Pelch<sup>1</sup>, R. R. Tice<sup>1</sup> and M. P. Waalkes<sup>1</sup>. <sup>1</sup>DNTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>Bioinformatics, SRA, Durham, NC; <sup>3</sup>Genomics, DHMRI, Kannapolis, NC.

Inorganic arsenic (As) is an environmental human carcinogen and the prostate gland is among its many target organs. CAsE-PE transformed cells, developed after prolonged As exposure of normal human RWPE-1 prostate cells, have aberrant methylated DNA (MeDNA) patterns. We hypothesized that MeDNA changes might influence gene expression in As transformation. MeDNA changes were studied on a genome-wide level after affinity enrichment followed by bisulfite reduction and Illumina deep sequencing. Gene expression was determined by RNA-Seq. Analysis of RNA-Seq data showed 1,068 genes increased and 1,046 decreased at >2X fold change,  $p < 0.05$ . Key upregulated genes included vesicular trafficking protein, Syn3 (594X), the gluconeogenic enzyme FBP1 (321X), the peptidase, GGT5 (414X), and the oncogene, K-Ras (146X); downregulated genes at <100X fold control included high mobility group HMGA1, fibronectin-1, filamin B and the glycolytic enzyme, PKM2. Alignment of bisulfite sequencing data showed 1000's of cytosine methylations throughout the genomes of these cells. However, the number of methylation sites either nearby or within gene coding regions that might influence expression was a much smaller proportion of total. Several genes had notable decreases in expression and increased methylation. For example, nestin is an intermediate filament protein and progenitor marker, which was reduced 14X fold in CAsE-PE transformed cells vs RWPE-1 controls and that had a concurrent average increase in methylation of cytosines at 27X fold above control within a CpG island in the 5' region. Similarly, neurotrimin is an adhesion molecule whose expression in CAsE-PE cells was reduced by >100 fold vs controls and had a 25X fold increase in methylation of the promoter region. These data suggest deep sequencing of MeDNA enrichments can provide new insight into effects of environmental carcinogens on the epigenetic landscape leading to a malignant phenotype.

## PS 527 Age- and Sex-Related Alterations in Renal Global DNA Methylation during the Life Cycle of Rats.

T. Han, C. L. Moland, J. C. Kwekel, V. Desai and J. C. Fuscoe. *Division of Systems Biology, National Center for Toxicological Research, US FDA, Jefferson, AR.*

Epigenetic modifications of DNA, such as methylation of cytosine, are critical to regulating gene and miRNA expression, cellular differentiation, and X-chromosome inactivation, and have been shown to be involved in human diseases including cancer. The role of epigenetic changes in renal development and diseases has been noted. However, comprehensive study is needed to understand the epigenetic effects on renal disease susceptibility and progression at different life stages and between the sexes. Recent advances in high throughput technologies such as high density methylation array and next generation sequencing make it possible to monitor the methylation status at the whole genome level. In this study, kidney tissues from Fischer 344 rats at 2, 5, 6, 8, 15, 21, 78, and 104wk of age for both sexes were examined for sex- and age-specific alterations in DNA methylation using Roche 385k rat promoter methylation microarrays, which cover 15,398 CpG island regions. The raw image data were analyzed by DEVA (v1.2.1) to compute the methylation changes in these samples. Biweight mean centering normalization was applied before downstream analysis. Hierarchical clustering analysis indicated that the

overall methylation patterns are similar between the age groups, but there are distinct methylation patterns between male and female rats. The results indicate that there are slightly more methylated sites at 2wk of age compared to later ages. A higher number of methylated sites were found on the X chromosome in females than males, suggesting involvement in repression of X-inactivated genes. These results provide a comprehensive global view of the DNA methylation status in the kidney over the entire rat life cycle. These age- and sex-related differences in DNA methylation may provide insights in susceptibility to kidney disease and its progression.

## PS 528 Phylogenetic Identification of Variably Methylated Transposons As Biomarkers for Early Environmental Exposures.

C. Faulk, A. K. Barks and D. Dolinoy. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

A small number of retrotransposons in the long terminal repeat (LTR) class are known to exhibit environmental sensitivity in DNA methylation status, and are termed "metastable epialleles". Two of the sequenced examples, the agouti viable yellow (Avy) and the CDK5 activator-binding protein (CabpIAP) result from a recently inserted LTR, an intracisternal A particle (IAP) element. These insertions are from the same family, and show high sequence identity (98.5%). Additionally, both act as biomarkers of early exposure. Until now, neither the full extent of variability at these metastable epialleles, nor the phylogenetic relationship underlying variable elements was well understood. Using a computational approach, we identified 10,802 IAP LTRs in mice, and filtered by subtype to yield 1,388 IAP LTRs in the family that includes Avy and CabpIAP. Phylogenetic analysis revealed duplication and divergence events subdividing this family into three clades. To characterize variation across clades, DNA from isogenic mice was subjected to combined bisulfite and restriction analysis (CoBRA) at 21 LTR transposons (7 per clade). To validate our candidate IAP LTRs for interindividual variation, we assayed 17 isogenic mice for shifts in liver DNA methylation patterns. Methylation levels at individual LTRs varied widely with mean methylation ranging from a low of 59% to a high of 89%. Among mice, average methylation across all LTRs was not significantly different (71%-74%,  $p > 0.99$ ). Finally we determined that the clade with the most conserved elements had significantly higher average methylation across LTRs than either diverged clade. Thus, we increase the number of known epigenetically modifiable loci and provide evidence that sequence identity is predictive of methylation level. Since repetitive elements comprise nearly half of mammalian genomes, they are likely targets for toxicological disruption, especially during early development. The characterization of murine metastable epialleles is crucial for the development of treatments for environmentally-induced disease.

## PS 529 Chromatin Context Modulates Genome-Wide p53 Sequence-Specific Occupancy and Exposure-Induced Gene Expression.

D. A. Bell, D. Su, M. R. Campbell and X. Wang. *NIEHS, Research Triangle Park, NC. Sponsor: B. McIntyre.*

DNA damaging agents activate p53 to bind to DNA response elements leading to transactivation of p53 pathway genes and directing cells toward arrest or apoptosis. To understand the determinants of treatment-specific and tissue-specific responses to DNA damage we have carried out treatments using ENCODE cells in an exposure model and generated genome-wide data (p53 ChIPseq, H3K4me3 ChIPseq, sequence specificity, evolutionary conservation and gene expression). Effects of doxorubicin and nutlin-3 treatments in lymphoid cells have been compared with other cell types and analyzed in relation to chromatin context based on the ENCODE chromatin hidden Markov model (ChromHMM). We identified novel chromatin interactions that modulate the transcriptional response to p53 activation following DNA damage. Highly induced p53 genes typically display both low H3K4me3 marks and low baseline expression. Among the 2568 high confidence p53-occupied genes detected by p53 ChIP-seq, 45% have active promoter marks (H3K4me2, H3K4me3, H3k27ac, H3K9ac) prior to treatment. Surprisingly, based on ChromHMM categorization, ~22% of p53 genes displayed repressive chromatin states; including many highly-induced p53 response genes. Many p53 peaks were located in genomic regions with preexisting states classified as promoters (16%) or enhancers. However, notably a large percentage (31%) of all p53 binding peaks were found in repressed or heterochromatin regions far distant from a transcription start site. Thus p53 binding occurs in regions of both accessible and inaccessible chromatin although induced expression was most commonly associated with inaccessible chromatin. We identified p53 DNA binding motifs in 95% of p53 ChIPseq peaks and used a position weight matrix model (PWM) to score similarity to the consensus p53 motif. PWM strength and spacer length have distinctive distribution patterns between different chromatin states. Thus both epigenetic and sequence-based factors modulate the DNA damage response regulated by p53.

**PS 530 Mercury Exposure and DNA Methylation among Dental Professionals.**

J. Goodrich, N. Basu, A. Franzblau and D. Dolinoy. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Epigenetic alteration may be a key mechanism linking chemical exposures to toxicity and disease. Recent, yet limited, animal and human data suggest that mercury (Hg) modifies the epigenome, specifically DNA methylation. This study hypothesizes that methylmercury and inorganic Hg exposures from fish consumption and dental amalgams, respectively, alter DNA methylation patterns at multi-copy repeats and candidate genes. Dental professionals were recruited at meetings of both the Michigan and American Dental Associations (MDA, ADA). Subjects provided survey data (e.g. exposure sources, demographics) and samples for Hg measurement and epigenetic analysis. Total Hg was quantified via atomic absorption spectrophotometry in hair and urine, indicative of methylmercury and inorganic Hg exposures, respectively. Methylation was assayed globally by pyrosequencing of long interspersed elements (LINE-1) and site-specifically at *DNMT1*, *SEPW1*, and *SEPP1* in bisulfite converted DNA (isolated from buccal mucosa or saliva in the MDA; blood leukocytes and saliva in the ADA). In the MDA cohort (n=158), hair Hg (mean  $\pm$ SD:  $0.55 \pm 0.54$   $\mu$ g/g) and urine Hg ( $1.05 \pm 1.08$   $\mu$ g/L) overlapped with levels of the general US population. Multivariate linear regression displayed a trend of hypomethylation at LINE-1 and three candidate genes with increasing hair Hg levels. Only in males, this trend was significant ( $p < 0.05$ ) in models of mean *SEPP1* methylation, methylation of each *SEPP1* CpG site, and of one LINE-1 site. Relationships between urine Hg and DNA methylation were not significant. Associations between Hg biomarker levels and DNA methylation will be further explored using samples from the ADA cohort (n>500). This work suggests that methylmercury modifies DNA methylation at labile regions in males. Epigenetic modification by Hg should be further investigated to elucidate this pathway as a mechanism of toxicity.

**PS 531 Alteration of Gene Methylation in the Testis of Rats and Mice Chronically Exposed to Low-Dose Cadmium.**

B. Wang<sup>1,2,3</sup>, L. Yang<sup>2</sup>, Y. Tan<sup>3</sup> and C. Lu<sup>3</sup>. <sup>1</sup>Department of Pathology, Inner Mongolia Forestry General Hospital, Hulunbuir, China; <sup>2</sup>Department of Pathophysiology, Jilin University, Changchun, China; <sup>3</sup>Department of Pediatrics, University of Louisville School of Medicine, Louisville, KY.

Testicular cancer has a unique epigenetic phenotype and Cadmium is known to be human carcinogens. To further evaluate gene methylation alterations of testis by Cadmium (Cd) treatment, this study was designed to aim at genome-wide screening of the altered methylation genes in the testis of rats chronically exposed to low-dose Cd. First, rats were exposed to Cd at 20 nmol/kg every other day for 4 weeks and gene methylation was analyzed at the 52nd week with methylated DNA immunoprecipitation-CpG island (CGI) microarray. Among the 490 altered genes, there were 134 genes whose promoter CGIs were all hypermethylated, 346 genes whose promoter CGIs were hypomethylated, and 10 genes whose promoter CGIs were some hypermethylated and some hypomethylated. Furthermore, *Rassf1* gene promoter CGI hypermethylation was detected and confirmed in Cd treated mice at the 60th week by mouse tumor suppressor gene array. In mice model, mice were given chronic exposure of Cd with and without methylation inhibitor (5-aza-2'-deoxycytidine, 5-aza) for 6 weeks and at the 60th week *Rassf1* promoter CGI hypermethylation was prevented. Results showed that testis of mice previously exposed to chronic Cd displayed an increased *Rassf1* CGI methylation, which was prevented by 5-aza treatment. These results suggest that DNA methylation of *Rassf1* gene promoter down-regulated its activity, leading to a reduction of testicular apoptosis, and may be a potential cause of Cd-induced testis cancer.

**PS 532 Epigenetic Modifications from Lead Exposure: Influences of Sex, Exposure Level, and Developmental Timing of Exposure on DNA Methyltransferases and Methyl Cytosine-Binding Proteins.**

S. Kidd, D. Anderson and J. Schneider. *Thomas Jefferson University, Philadelphia, PA.*

Maintaining normal DNA methylation levels is critical during development and in adults, DNA methylation may maintain a subtle balance of global gene expression pattern, crucial for normal neuronal function. DNA methylation is catalyzed by a family of DNA methyltransferases (Dnmts) that include the maintenance enzyme *Dnmt1* and the de novo methyltransferase *Dnmt3a*. DNA methyltransferase (*Dnmt*) expression is subject to active regulation under both physiologic or pathologic conditions and is critical to the regulation of synaptic plasticity in the mature brain. Dysregulation of *Dnmts* has been associated with a variety of cognitive disorders. Likewise, methyl cytosine-binding proteins such as MeCP2 and MBD1

play important roles in transcriptional regulation. The present study investigated the extent to which these enzymes are affected by developmental Pb exposure. Long Evans dams were fed Pb-containing food (RMH 1000 with or without added Pb acetate: 0, 150, 375, 750 ppm) prior to breeding and stayed on the same diet through weaning at postnatal day 25 (perinatal exposure group (Peri)). Other animals were exposed to the same doses of lead but exposure started on postnatal day 1 and continued through postnatal day 25 (early postnatal exposure group (EPN)). A third group had Pb exposure from postnatal day 1 through day 45 (long postnatal exposure (LPE)). All animals were euthanized on day 45 and hippocampi were removed, frozen and stored until processed. Analyses showed significant effects on *Dnmt1* and MeCP2 in particular, lesser effects on *Dnmt3a* and MBD1, with effects modified by sex, developmental window of exposure and level of Pb exposure. Interestingly, the degree of modulation appeared to be more related to when the exposure occurred developmentally than to the absolute duration of the exposure. These data suggest epigenetic effects of developmental Pb exposure on DNA methylation that depend on sex, level of exposure and developmental period of exposure. Supported by NIH RO1-ES015295.

**PS 533 A Clinical Study to Clarify Effect of Blueberry (*Vaccinium spp.*) on Oxidative Stress and Global Methylation.**

M. Kim and M. Yang. *Sookmyung Women's University, Seoul, Republic of Korea.*

Blueberry (*Vaccinium spp.*) has shown a broad spectrum of biomedical functions including anti-oxidative and anti-inflammatory effects through in vitro or animal studies. However, its human studies are relatively few. In addition, food-born epigenetic modulators, e.g. folate, genistein, etc., can recover environmental exposure-related epigenetic alterations. Therefore, epigenetics can be a useful screening method to find a new functional food. We performed a two weeks- intervention study to evaluate anti-oxidative and epigenetic effects of blueberry in young women (N=8, age= 22.6 $\pm$ 0.7 yrs, BMI=20.2 $\pm$ 1.97 kg/m<sup>2</sup>). Among the subjects, two persons took vt C (1 g/day) as positive controls and the others took blueberry juice [240 ml (total polyphenol 300mg, anthocyanin 76mg)/day]. From genomic DNA of their peripheral blood, we analyzed global methylation-status with MethylationFlashTM methylated DNA quantification kit (Epigentek). We also analyzed urinary malondialdehyde (MDA), a biomarker of oxidative stress with HPLC/UVD. As a result, we found that blueberry did not reduce urinary MDA levels as much as vt C did. In addition, both blueberry and vt C treatment somewhat increased global DNA methylation. There were no significant differences in the global DNA methylation between the two treatments ( $p=0.89$ ). Therefore, anti-oxidative activity of blueberry was not found in this trial, compared to vt C. However, its epigenetic effects can be similar to vt C's. In conclusion, the present study provides that a medicinal function of blueberry can be induced by global hypermethylation rather than anti-oxidative effects.

**PS 534 The Role of microRNAs in the Pathogenesis of MMPi-Induced Skin Fibrodysplasia.**

D. P. Tonge<sup>1</sup>, J. D. Tugwood<sup>2</sup> and T. W. Gant<sup>1</sup>. <sup>1</sup>CRCE, Health Protection Agency, Oxford, United Kingdom; <sup>2</sup>Global Safety Assessment, AstraZeneca, Cheshire, United Kingdom.

This study sought to investigate the role of microRNAs (miRNAs) in the pathogenesis of matrix metalloproteinase inhibitor (MMPi) induced skin fibrodysplasia (FD) in the dog.

MicroRNAs are short non-protein-coding RNAs that modulate protein translation from specific mRNAs. Certain miRNAs exhibit tissue specificity, and are dysregulated in response to specific pathologies. MicroRNAs are detectable in biological fluids, paving the way for their use as biomarkers. Matrix metalloproteinases (MMPs) are a family of proteolytic enzymes and have been an attractive pharmacological target for a number of indications. However, development has been hampered by the propensity of these compounds to cause connective tissue pathologies. The broad-spectrum MMPi AZM551248 has been shown to induce such effects in the dog, characterised by fibroblast proliferation and collagen deposition in subcutaneous tissues.

Thirty 12-month old female beagle dogs were assigned to six groups. Animals were dosed orally once daily with vehicle, or with vehicle plus 20mg/kg/day AZM551248 for between 4 and 17 days. miRNA expression profiles in subcutaneous skin were determined by high-throughput sequencing (SOLiD 4.0).

Following 4 days MMPi administration, 13 miRNAs were differentially expressed in the skin compared with vehicle treated animals. Several of these were members of the miR-200 family and were attenuated in response to MMPi. As the severity of FD increased at the later time-points, miRNAs associated with TGF $\beta$  synthesis were modulated. Evidence of epithelial to mesenchymal transition was present at all study time points. Receiver operator curve analysis revealed that miR-21 expression in the cervical subcutaneous tissue was a sensitive and specific biomarker of FD incidence.

We have described a role for miRNAs in processes relevant to the key histopathological events associated with MMPi-induced FD. Furthermore, we have identified key miRNAs with the potential to be used as informative biomarkers of FD.

### PS 535 Exposure of Pregnant Mice to Chlorpyrifos-Methyl Alters Embryonic H19 Gene Methylation Patterns.

H. Kang<sup>1</sup>, H. Shin<sup>1</sup>, J. Seo<sup>1</sup>, S. Park<sup>1</sup>, Y. Park<sup>1</sup>, S. Son<sup>1</sup>, S. Jeong<sup>3</sup> and J. Kim<sup>2</sup>.  
<sup>1</sup>Veterinary Toxicology and Chemistry, National Veterinary Research and Quarantine Service, Anyang, Republic of Korea; <sup>2</sup>Toxicology Laboratory, College of Veterinary Medicine, Konkuk University, Seoul, Republic of Korea; <sup>3</sup>GLP Research Center, College of Natural Science, Hoseo University, Asan, Republic of Korea.

The aim of this study was to identify whether chlorpyrifos methyl (CPM) exposure during pregnancy leads to changes in the methylation patterns of H19 gene. CPM 4, 20, 100mg/kg bw/day was administered to 4 pregnant mice per group between 7 and 12 days post coitum (d.p.c.). Pregnant mice were killed at 13 d.p.c. and genomic methylation in primordial germ cells (PGCs) and fetal organs (the liver, intestine, and placenta) was examined. Four polymorphism sites in the H19 alleles of maternal (C57BL/6) and paternal (CAST/Ei) alleles were identified at nucleotide position 1407, 1485, 1566 and 1654 and the methylation patterns of 17 CpG sites were analyzed. The methylation level in male and female PGCs was not altered by CPM treatment in the maternal allele H19. The methylation level of the paternal H19 allele was altered in only male PGCs in response to the CPM treatment. The methylation level at a binding site for the transcriptional regulator CTCF2 was higher than that at the CTCF1 binding site in all CPM-treated groups. In the placenta, the aggregate methylation level of H19 was 56.89% (control) and ranged from 47.7% to 49.89% after treatment with increasing doses of CPM. H19 gene from theliver and intestine of 13 d.p.c. fetuses treated with CPM was hypomethylated compared with controls, although H19 mRNA expression was unaltered. In the placenta, H19 expression was slightly increased in the CPM-treated group, although not significantly. IGF2 expression levels were not significantly changed in the placenta. In conclusion, CPM exposure during pregnancy alters the methylation status of the H19 gene in PGCs and embryonic tissues. We infer that these alterations are likely related to changes in DNA demethylase activity.

### PS 536 Autoimmune Disease Triggered by Trichloroethylene Is Associated with Epigenetic Alterations in Cd4<sup>+</sup> T Cells.

K. Gilbert<sup>1</sup>, S. Blossom<sup>1</sup> and C. Cooney<sup>2</sup>. <sup>1</sup>University of Arkansas for Medical Sciences/Arkansas Children's Hospital Research Institute, Little Rock, AR; <sup>2</sup>Central Arkansas Veterans Healthcare System, Little Rock, AR.

Previous studies have shown that chronic (32-week) exposure to occupationally-relevant concentrations of trichloroethylene (TCE) in the drinking water of female MRL+/+ mice promoted autoimmune hepatitis. This was accompanied by the expansion of CD4<sup>+</sup> T cells that secreted increased levels of IFN- $\gamma$  and expressed an activated (CD44<sup>hi</sup>CD62L<sup>lo</sup>) phenotype. The current study was initiated to determine the mechanism by which TCE altered CD4<sup>+</sup> T cell function. The study constituted a longitudinal evaluation of mouse TCE exposure over 40 weeks. Alterations in IFN- $\gamma$  production corresponded to changes in the expression of markers used to assess DNA methylation, namely retrotransposons Iap (Intracisternal A Particle) and Muerv (murine endogenous retrovirus). In addition, global DNA methylation was significantly altered in CD4<sup>+</sup> T cells from TCE-treated mice. Most recently, bisulfite sequencing revealed that DNA methylation of CpG sites associated with the Ifng promoter was significantly, and time-dependently altered by TCE exposure. Thus, for the first time, a toxicant known to promote autoimmune disease has been shown to alter epigenetic processes (DNA methylation) in the cell type that mediates pathology, namely CD4<sup>+</sup> T cells.

### PS 537 Is the Current Product Safety Assessment Paradigm Protective for Transgenerational Epigenetic Effects?

R. A. Alyea<sup>1</sup>, M. J. LeBaron<sup>1</sup>, R. Sura<sup>1</sup>, J. A. Murray<sup>1</sup>, I. P. Pogribny<sup>2</sup>, J. K. Passage<sup>1</sup>, R. G. Ellis-Hutchings<sup>1</sup>, N. P. Moore<sup>3</sup>, E. W. Carney<sup>1</sup>, B. Gollapudi<sup>1</sup> and R. J. Rasoulpour<sup>1</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Division of Biochemical Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR; <sup>3</sup>Dow Europe GmbH, Horgen, Switzerland.

Placement of epigenetic effects appropriately into the product safety paradigm is challenging due to an incomplete understanding of causal associations between epigenetics and apical adverse effects. To begin to understand this relationship, groups of 25 pregnant F0 CD-1 mice were administered ~10  $\mu$ g/kg/day diethylstilbestrol (DES) or ~30  $\mu$ g/kg/day 17 $\beta$ -estradiol (E2) via the diet or by subcutaneous injection (SC) from gestation day 9 – lactation day 20. F1 offspring were mated for two

additional generations, with F1-F3 offspring evaluated for uterotrophic effects on postnatal day (PND) 21 and 18 months. F1 generation weanlings in the DES and E2 diet groups had a 3-4-fold increase in relative uterine weights, which corresponded to hyperplasia and hypertrophy of the endometrial epithelium and hypertrophy of the myometrium. Gene array analysis of these groups showed an increase in cancer and reproductive associated biofunctional and canonical pathways. The F1 18 month DES SC and diet group had an increase in squamous metaplasia of the endometrium and squamous cell carcinoma in the DES diet group, but no histopathological effects in either E2 group at 18 months. When comparing gene lists in the PND 21 E2 and DES diet groups, ~1500 known genes were unique for DES, of which 24 remained significantly altered up to 18 months. These gene sets provided candidates for further epigenetic analysis. The F2 generation DES diet group had a marginal increase in mean PND 21 uterine weights and a treatment-related increase in leiomyoma/leiomyosarcoma at 18 months. In the F3 generation, there was no effect on uterine weight or histopathology at PND 21 or 18 months. Under the conditions of this study, there were no transgenerational effects associated with DES or E2, which would suggest that a typical margin of exposure risk assessment would be protective.

### PS 538 Genome-Wide Methylation Profiling in Rat Tissues for Nongenotoxic Carcinogens Using Medip-Chip.

S. Ozden<sup>1</sup>, N. Turgut Kara<sup>2</sup>, T. Chen<sup>3</sup>, B. Alpertunga<sup>1</sup>, K. Chipman<sup>4</sup> and A. Mally<sup>2</sup>. <sup>1</sup>Department of Pharmaceutical Toxicology, Faculty of Pharmacy, Istanbul University, Istanbul, Turkey; <sup>2</sup>Division of Molecular Biology and Genetics, Faculty of Science, Istanbul University, Istanbul, Turkey; <sup>3</sup>School of Public Health, Soochow University, Suzhou, China; <sup>4</sup>School of Biosciences, University of Birmingham, Birmingham, United Kingdom; <sup>5</sup>Department of Toxicology, University of Würzburg, Würzburg, Germany.

DNA methylation is an epigenetic mark that has a crucial role in chemical carcinogenesis. The aim of the study was to perform a genome-wide analysis of DNA methylation profile of non-genotoxic hepatocarcinogens including tetrachlorodibenzo-p-dioxin (TCDD), hexachlorobenzene (HCB), methapyrilene (MPY) and the male rat kidney carcinogens, d-limonene, p-dichlorobenzene (DCB), chloroform and ochratoxin A (OTA) in their respective target tissues in rats dosed under bioassay conditions. Methylated DNA immunoprecipitation (MeDIP) was used in conjunction with a NimbleGen promoter plus CpG island array to identify differentially methylated DNA regions (DMRs) on a genome-wide basis. We first identified a total of 76 candidate DMRs for OTA, 1 DMR for MPY and 4 DMRs for chloroform by the MeDIP-Chip method. No change was observed in rats treated by TCDD, HCB, DCB and d-limonene. It is expected that results from this study will contribute to a better understanding of the key molecular events which occur during early stages of chemical carcinogenesis and aid in identification of mechanism-based biomarkers for early detection of non-genotoxic carcinogens.

### PS 539 Modulation of DNA (Cytosine-5)- Methylation in the Mouse Embryonic Stem Es-D3 Cell- and in the Human Intestinal CaCo2-Cells by Okadaic Acid.

E. E. Creppy, S. Moukha, E. Renault and B. Sangare-Tigori. *Toxicology, University Bordeaux Segalen, Bordeaux, France.*

Okadaic acid (OA) a polyether fatty acid produced by marine plankton (dinoflagellates) accumulates in the black sponge and in mussels and oysters and causes shellfish diarrhetic syndrome in consumers. It is also suspected of causing gut tumours in humans. It is a tumour promoter in mouse skin, inhibitor of protein phosphatase 1 and 2A (IC50=x109M<sup>-1</sup>) and a potent and specific inhibitor of protein synthesis in cell-free system (IC50=33.7x1011M<sup>-1</sup>). The cell death induced by OA occurs by both apoptosis and necrosis. OA induces hypermethylation and/or hypomethylation of deoxycytidine residues in the DNA concentration-dependently. We have investigated the effects of okadaic acid on the methylation of [poly(dIdC-dIdC)] by DNAMtase of ES-D3 cells in the presence of [3Hmethyl]-SAM, and 3H-labelled OA. The methylation rate was evaluated by the determination of the total [3H]-label in the trichloroacetate precipitated material after incubation (37°C for 60 min. in initial velocity conditions) and then by the radioactive counts of the peak corresponding to the [3H]m5dC by HPLC and Flo-one Packard coupled to UV detection. m5dC was also quantified by ELISA. In parallel, parameters such as lipoperoxidation, DNA-oxidized bases related to oxidative stress, ILs production, NF-kB, 8OH-dG, caspase-3, bax and bcl2 activation were determined. The results of three independent experiments showed hypermethylation for low concentrations of OA (maximum + 90% at 15nM) and hypomethylation for cytotoxic concentrations. Altogether these data point at an epigenetic mechanism of action of OA in the pathway for its tumour promotion. Since the epigenetic effects are already induced by low concentration of OA (hypermethylation-mitogenic activity) it should be taken into account when assessing the risk for human.

**PS 540 Methylation Profiles of CpG Islands Localized in the Upstream Regions of the Human Microsomal Epoxide Hydrolase Gene Promoters.**

C. J. Omiecinski, X. Cai, S. Su and W. D. Hedrich. *Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.*

Previous studies from our laboratory demonstrated that expression of the human epoxide hydrolase gene (EPHX1) is driven by a far upstream E1-b promoter in most human tissues, whereas the proximal E1 promoter selectively drives hepatic EPHX1 expression. The molecular mechanisms underlying the differential promoter usage are not well elucidated. CpG islands are short stretches of DNA harboring relatively higher frequencies of the cytosine/guanine repeat sequence, potentially reflective of higher gene methylation modifications. In-silico analysis of the human EPHX1 gene indicated that the upstream regions of E1 and E1b promoters of human EPHX1 gene are both rich in CpG islands. As methylation status of CpG islands around gene promoter regions is often associated with transcriptional repression of genes, we investigated the methylation status of CpG islands proximal to the upstream regions of the E1b and E1 promoters in several human cell lines and in primary human hepatocytes. Our data demonstrate that the methylation status of all the CpG islands in upstream regions of the E1b promoter from different cell lines is essentially the same and only sparsely methylated (<10%). In contrast, the CpG islands located at regions close to the E1 promoter are highly methylated (>60%) in cell lines originating from lung and kidney. In contrast, in hepatocellular carcinoma HepG2/C3A cells, the CpG islands localized at -128bp, -89bp, -48bp and +8bp of the E1 promoter are 0%, 0%, 0%, 0% and 25% methylated, respectively. Similarly, the CpG islands located at -724bp, -602bp, -128bp, -89bp, -48bp and +8bp of the E1 promoter in human primary hepatocytes are all unmethylated. The methylation status of these promoters from human hepatic and non-hepatic tissues are also consistent with our results from different cell lines and primary hepatocytes. These findings suggest that differential methylation status determines tissue selective promoter usage for EPHX1 expression in humans.

**PS 541 Identification of Arsenic-Responsive microRNAs in Rats by Genome-Wide High-Throughput Sequencing.**

Y. Ge<sup>1</sup>, J. R. Olson<sup>1</sup>, H. Wu<sup>2</sup> and X. Ren<sup>1</sup>. <sup>1</sup>*Social and Preventive Medicine & Pharmacology and Toxicology, The State University of New York at Buffalo, Buffalo, NY;* <sup>2</sup>*School of Environment and Public Health, Wenzhou Medical College, Wenzhou, China.*

Consumption of drinking water contaminated with arsenic, a naturally occurring carcinogenic metalloid, constitutes a major public health problem. Although the relationship between exposure and carcinogenesis is well documented, the mechanisms by which arsenic participates in tumorigenesis are not fully elucidated. Epigenetic modifications are often dysregulated in cancer and occur following exposure to a number of carcinogenic chemicals and are suggested to play a key role in arsenic-induced carcinogenesis. Beyond DNA methylation, other epigenetic mechanisms, in particular miRNA expression, that play a critical role in regulation of gene expression, have yet to be adequately investigated for arsenic. In the current study, male rats were exposed to sodium arsenite (As(3+)) up to 150ppm in drinking water for 60 days. miRNAs was extracted from rat liver, the primary tissue for arsenic metabolism and potential target of arsenic carcinogenesis, following As(3+) treatment. Genome-wide profiling of miRNA in rat livers was generated to identify As(3+)-responsive miRNAs by next generation high-throughput sequencing technology. The preliminary results indicate that exposure to environmentally-relevant levels of As(3+) lead to aberrant expression of multiple miRNAs in rat liver. Additional analysis will identify miRNAs whose levels are most differentially expressed in rats due to arsenic treatment, and potentially identify early pre-disease epigenetic biomarkers of arsenic exposure. The results may also provide insights into the role of miRNAs in arsenic carcinogenesis (This work was supported by Zhejiang Natural Science Foundation, China (H.W.); and Startup fund (to X.R.) provide by SUNY at Buffalo).

**PS 542 Benzo(a)pyrene Enhances Line-1 Reactivation in the Absence of Retinoblastoma Proteins: Implications for Global Epigenetic Silencing and Heterochromatin Regulation.**

D. E. Montoya-Durango and K. S. Ramos. *Biochemistry and Molecular Biology, University of Louisville, Louisville, KY.*

Benzo(a)pyrene (BaP) is a ubiquitous environmental pollutant that induces DNA mutations and disease. At the molecular level, BaP induces the reactivation of LINE-1 (or L1), a parasitic DNA element that normally remains silent in differentiated cells. L1 epigenetic silencing involves promoter DNA hypermethylation, recruitment of transcriptional repressors such as retinoblastoma (RB), and small

RNAs. Since RB proteins control the cell cycle and help recruit transcriptional corepressors to chromatin, we hypothesized that i) L1 expression may follow cell cycle progression, and ii) absence of RB is associated with derepression of L1. In the present studies, ES-D3 mouse embryonic stem cells were stained live and sorted for different phases of the cell cycle, followed by measurements of L1 message by quantitative PCR. L1 message was most abundant in the G1 phase of the cell cycle, coinciding with the stage where RB becomes inactivated by hyperphosphorylation. In separate experiments, isolates of mouse embryo fibroblast (MEFs) deficient for the RB family of proteins (TKO MEFs) were exposed to BaP for 12 hours and real time PCR used to quantify changes in the abundance of L1 transcripts. Compared to wild type counterparts, RB null cells dramatically overexpressed L1 in the presence of BaP. Cytochrome P450 genes involved in BaP metabolism also showed an enhanced inducibility in mutant cells, suggesting increased chromatin accessibility to transcription factors. Collectively, these data indicate that L1 is regulated in a cell-cycle dependent manner and that mutation or loss of RB proteins in humans in the face of environmental stress may contribute to the deregulation of L1 in somatic cells. Such deregulation may compromise differentiation programs and induce acquisition of neoplastic phenotypes.

**PS 543 DNA Methylation Patterns Represent "Environmental Footprints" of Transcription Factor Occupancy.**

D. Rojas<sup>1,2</sup>, K. Bailey<sup>2</sup>, A. Sanders<sup>2</sup>, L. Smeester<sup>2</sup>, B. Ahir<sup>2</sup>, J. E. Rager<sup>2</sup>, Z. Drobná<sup>3</sup> and R. C. Fry<sup>1,2</sup>. <sup>1</sup>*Curriculum in Toxicology, UNC School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Department of Environmental Sciences and Engineering, UNC Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>3</sup>*Department of Nutrition, UNC Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Previous research has demonstrated that binding of transcription factors (TFs) to promoters can alter the DNA methylation patterns within these regions. While previous research was conducted in the context of stem cell differentiation, the impact of environmental toxicants on TF binding and subsequent effects on DNA methylation has not been examined. Our group recently identified genes in human leukocyte DNA and mouse livers that exhibit differential CpG island methylation following exposure to metals/metalloids including cadmium and arsenic. Among these genes, we have identified enrichment for transcription factor binding sites that we postulate represent "environmental footprints" of transcription factor occupancy. For example, we identified enrichment of the Metal-Responsive Transcription Factor-1 (MTF-1) binding site in the promoter regions of genes in which DNA methylation status of white blood cells was associated with cadmium or arsenic exposure in two different human populations. Based on these results, we hypothesize that in response to environmental stimuli, selective occupancy of DNA regions by transcription factors can alter the access of epigenetic modifiers to DNA, resulting in gene-specific DNA methylation patterns. To support our hypothesis, we utilized in vitro culture of human cells to study changes in genome-wide promoter DNA methylation patterns associated with specific changes in transcription factor binding induced by cadmium and arsenic. These results provide crucial information relating to the mechanism by which specific genes display toxicant induced patterns of DNA methylation.

**PS 544 Increased Growth Inhibition of Human Breast Cancer Cells by Co-Treatment with EGCG and 5-aza-2'-deoxycytidine Is Modulated through Epigenetic Mechanisms.**

T. Tyagi, J. Treas and K. P. Singh. *Environmental Toxicology, Texas Tech University, Lubbock, TX.*

Breast cancer is the leading cause of cancer deaths in women. Both genetic and epigenetic processes are implicated in breast carcinogenesis. Aberrations in DNA methylation pattern contribute to cancer development. Studies show that half of all the tumor suppressor genes are inactivated more often by epigenetic, rather than genetic mechanisms in all types of cancer. As epigenetic changes like DNA methylation are reversible, demethylating drugs, such as, 5-aza-2'-deoxycytidine (5-aza) are being clinically used as cancer chemotherapeutics. However, there are cytotoxic effects associated with high doses of these drugs. Alternative dietary compounds like EGCG, a green tea polyphenol are known to possess anticancer properties with minimal or no toxic effects on normal cells. EGCG is also reported to have DNA demethylation and histone modification activity. Therefore, the purpose of this study was to investigate the efficacy of co-treatment of EGCG and 5-aza, at low doses in inhibiting growth of MCF-7 breast cancer cells. MCF-7 cells were treated with either 5-aza, (5µM), EGCG (50µM, 100µM) or their combination. MTT assay showed that co-treatment significantly decreased cell viability as compared to

individual treatment. Both compounds arrest separate phases of cell cycle, but co-treatment eventually increased the percentage of growth arrested and apoptotic cells. Increased hypomethylation due to co-treatment was also observed in global genomic methylation analysis. Downregulation of DNMT1 expression was significantly greater in co-treatment than individually treated cells. These data suggest that co-treatment with EGCG and 5-aza, at low doses can synergistically reverse hypermethylation induced gene silencing and hence can be used for inhibition of breast cancer growth while minimizing cytotoxicity on normal cells.

**PS 545 Differential Expression of Long Intervening Noncoding RNAs in the Livers of Female B6C3F1 Mice Exposed to the Carcinogen Furan.**

L. Recio<sup>1</sup>, S. Phillips<sup>1</sup>, T. Maynor<sup>1</sup>, M. D. Waters<sup>1</sup>, F. Jackson<sup>2,3</sup> and C. Yauk<sup>2</sup>. <sup>1</sup>ILS, Research Triangle Park, NC; <sup>2</sup>Environmental Health Science and Research Bureau, Healthy Environments and Consumer Safety Branch, Health Canada, Ottawa, ON, Canada; <sup>3</sup>Department of Biology, Carleton University, Ottawa, ON, Canada.

The mammalian genome is transcribed into mRNAs that code for protein as well as a broad spectrum of other noncoding (nc) RNA products. Long ncRNAs (lncRNA), defined as noncoding RNA species > 200 nucleotides long, are emerging as important epigenetic regulators of gene expression and are involved in a spectrum of biological processes of relevance to toxicology. We have conducted a gene expression profiling study in liver using female B6C3F1 mice exposed to the carcinogen furan at 0.0, 1.0, 2.0, 4.0, and 8.0 mg/kg for 3 weeks. LncRNAs showed a non-linear dose response with no lncRNAs differentially expressed at 1.0 or 2.0 mg/kg and two lncRNAs differentially expressed at 4.0 mg/kg furan. At 8.0 mg/kg furan, 13.3% (83/632) of the differentially expressed transcriptome was comprised of lncRNAs. Among the lncRNAs observed, a number showed transcriptional clustering with nearby protein coding genes. For example, in furan-exposed mouse liver there was increased expression of lncRNA-p21. LncRNA-p21 is an anti-sense transcript that is 15 kb downstream from Cdkn1a locus and is known to be induced by p53 in human cells. LncRNA-p21 appeared to be co-transcribed with the protein coding gene Cdkn1a in response to 8.0 mg/kg furan. These data suggest that lncRNAs are transcriptional targets of furan-induced cytotoxicity and cell proliferation. We hypothesize that lncRNAs have potential as epigenomic biomarkers of carcinogenic exposures and we are currently examining lncRNA expression in the liver of mice exposed to a number of other carcinogens.

**PS 546 ROS-Generation Leads to 5-Hydroxymethylcytosine Formation and DNA Demethylation.**

J. B. Coulter<sup>1,2</sup>, C. M. O'Driscoll<sup>1,2</sup> and J. P. Bressler<sup>1,2</sup>. <sup>1</sup>Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; <sup>2</sup>Neurology, Hugo Moser Research Institute at Kennedy Krieger, Baltimore, MD.

DNA methylation is a chemical modification at the 5' position on cytosine residues involved in gene repression. Notably, DNA methylation plays a vital role in stem cell differentiation. A better understanding of the dynamic processes controlling methylation and demethylation is critical to identifying chemicals with potential to disrupt programming of the methylome and may uncover targets in diseases such as neurodegenerative disease and cancer. While enzymes which methylate cytosines neighboring guanines (CpG's) have been identified, no demethylase has been discovered in mammalian cells. Inhibition of DNA methyltransferases leads to demethylation, though these mechanisms depend on cell division and may not explain active demethylation in post-mitotic cells such as neurons. Recent work has uncovered the role of Tet proteins in converting 5-methylcytosine to 5-hydroxymethylcytosine (5-hmC). Subsequent deamination by cytidine deaminases followed by base excision repair results in unmethylated cytosine. Here, we show that sub-lethal exposures of the benzene metabolite hydroquinone (HQ) led to formation of 5-hmC in HEK293 cells and a human neural progenitor cell line. In HEK293 cells, HQ exposure led to increases in reactive oxygen species (ROS), reactivation of a methylation-silenced reporter plasmid, and demethylation of CpG's within its promoter. Both 5-hmC formation and plasmid reactivation were inhibited by the antioxidants  $\alpha$ -tocopherol and N-acetyl-L-cysteine, indicating ROS formation was involved. Moreover, reactivation of the silenced plasmid by HQ was enhanced in cells overexpressing cytidine deaminase APOBEC2. These effects were observed with no detectable changes in Tet gene expression, though activity may have changed. Our data indicate toxicant-induced ROS leads to CpG demethylation in a manner consistent with oxidation-deamination mechanisms catalyzed by Tet proteins and suggest a link between cellular redox status and maintenance of the epigenome.

**PS 547 A Critical Review of Epigenetic Transgenerational Inheritance following Environmental Exposures.**

J. Heilman, E. Freeman and B. Polakoff. *Exponent, Inc, Washington DC.*

Epigenetic transgenerational effects are phenotypic traits passed down from generation to generation via heritable modifications in the epigenetic landscape. There are several accounts in the literature investigating the effects of environmental factors on the transgenerational inheritance of purportedly epigenetic traits. Epigenetic transgenerational effects have been suggested through animal models to lead to such conditions as polycystic ovarian disease, prostate disease phenotype, abnormal sperm parameters, altered discrete brain nuclei, fetal abnormalities, increased tumor frequency, altered immune function, and indications of kidney disease. Certain compounds have received particular attention with respect to transgenerational epigenetic changes, with some publications claiming to demonstrate transgenerational epigenetic effects and others refuting the existence of these effects. Recently, increasingly more diverse compounds have been tested for the ability to induce transgenerational epigenetic changes either alone or in mixtures, including pesticides, plastics components, and hydrocarbons. Although many publications claim to demonstrate clear evidence of transgenerational epigenetic effects, an equally clear mechanism explaining how the effect is conveyed is often lacking. Additionally, it remains to be explained how any particular chemical, that is not, for example, a methyl donor, could impact such a diverse collection of phenotypic outcomes. While the possibility of epigenetic transgenerational inheritance is not questioned, it is suggested that a clear or strong mechanistic link has not been established between many of the compounds purported to effect epigenetic transgenerational inheritance, and the subsequently observed phenotypes. A critical analysis of a selection of the evidence assessing epigenetic transgenerational inheritance following exposure to environmental agents and chemicals will be presented with particular focus on mechanisms of epigenetic inheritance, discrepancies in the literature, study quality, reproducibility and transparency.

**PS 548 Effect of Increased Reactive Oxygen Species on microRNA Expression in First Trimester Placental Trophoblasts.**

C. E. Cross, C. M. Rondelli, M. Xu and S. Z. Abdel-Rahman. *Obstetrics & Gynecology, UTMB, Galveston, TX.*

In early pregnancy, the conceptus is highly sensitive to reactive oxygen species (ROS). Expression of superoxide dismutase, catalase, glutathione peroxidase and high levels of glutathione, taurine, and vitamins A and D protect the conceptus by 5 weeks. During implantation, maternal spiral artery remodeling and trophoblast invasion serves as the beginning of placental development and would result in increased protection of the fetus to normal ROS signaling. However, improper invasion and remodeling can result in disease development. Although debated, the current proposed model for preeclampsia, which manifest as abnormally high blood pressure (>140/80) after 20 weeks gestation in a previously normotensive woman, is aberrant maternal spiral artery remodeling, subsequent altered angiogenesis and localized ischemia/reperfusion due to continued muscularization of the spiral arteries. Preeclampsia is associated with low birth weight, preterm labor, small gestational age, and intrauterine growth restriction as well as altered gene expression in the placenta as a result of increased ROS production. Epidemiological screening studies for preeclampsia indicate alterations in placental microRNA (miRNA) expression as a result of increased trophoblast apoptosis. The goal of this project is to determine the effect of increased ROS during early placental development on miRNA expression to better understand the time frame of gene expression alteration. The villous 3A first trimester cell line was exposed to varying concentrations of H<sub>2</sub>O<sub>2</sub> over 24 hours to determine the amount of intracellular ROS generated from this model. Using an optimal exposure of 50  $\mu$ M, we then determined the effect of increased ROS exposure on the expression of 1008 miRNAs using the human miRNome PCR array (Qiagen). The miRNAs shown to be altered from increased ROS production are being selected for pathway analysis and further study using miRNA mimics and inhibitors (Supported by T32-07454; P30-006676).

**PS 549 Identification of Mode-of-Action Specific Toxicity Transcript Profiles In Vitro Using a Connectivity Mapping Approach.**

J. M. Naciff<sup>1</sup>, N. DeAbrew<sup>1</sup>, G. Overmann<sup>1</sup>, R. Adams<sup>1</sup>, G. Carr<sup>1</sup>, R. Settivari<sup>2</sup>, J. Tiesman<sup>1</sup>, C. Edward<sup>2</sup> and G. Daston<sup>1</sup>. <sup>1</sup>Procter & Gamble, Cincinnati, OH; <sup>2</sup>Dow Chemical Company, Midland, MI.

We hypothesize that it is possible to predict toxicity by assessing changes in gene expression in a small number of cell types enriched in toxicologically relevant pathways. We have evaluated the transcriptional profile elicited by 34 chemicals in HepG2, Ishikawa and MCF7 cells, using microarrays (U219, Affymetrix). These chemicals act via a number of modes of toxicity and do not involve direct chemical

reactivity, as this can be adequately detected by a number of simple in vitro methods. Each of the 34 chemicals was tested at 3 doses and at 3 different time points; however, data presented here are for only one dose and one time point (6h). The relatedness of each transcript profile to each other was analyzed using the cMAP platform (Broad Institute). The results indicate that not all cell lines responded to all chemicals. For example the response of the Ishikawa cells to methotrexate is minimal (16 genes significantly affected), while the MCF7 and HepG2 cells have a robust response to this chemical (>3000 genes significantly affected). A comparison of responses to chemicals that share similar modes of action (MOA) exhibited very high correlation, even among different cell lines. These correlations held true for both agonists (cMAP score  $\leq 1$ ) and antagonists (score  $\leq -1$ ) and extended to MOAs mediated through receptors (AR, ER, FX, PR, etc.) and enzyme inhibition (histone deacetylase, DHFR, etc.). For example, using the signature from valproic acid (VA) treated cells to query the cMAP database yield high positive connectivity scores for VA in all three cell lines tested, as well as with other HDAC inhibitors (vorinostat, trichostatin, bufexama, depudecin and HC toxin), regardless of cell lines or concentrations. The transcript profile elicited by chemicals with various MOAs in selected cell types, coupled with a cMAP approach for the analysis of the response, offers relevant biological data to predict biological activity and MOA, and thus toxicity, in a defined in vitro system.

## PS 550 Analysis of Longitudinal Metabolomic Data from Endocrine Disruption Studies: The A-SCA Method.

C. Canler<sup>1,2</sup>, M. Tremblay-Franco<sup>1,2</sup>, N. J. Cabaton<sup>1,2</sup>, R. Gautier<sup>1,2</sup>, L. Debrauwer<sup>1,2</sup>, A. M. Soto<sup>3</sup> and D. Zalko<sup>1,2</sup>. <sup>1</sup>INRA, UMR 1331 TOXALIM Research Center in Food Toxicology, Toulouse, France; <sup>2</sup>Université de Toulouse, INP, UMR1331, TOXALIM, F-31000, Toulouse, France; <sup>3</sup>Department of Anatomy and Cellular Biology, Tufts University School of Medicine, Boston, MA.

Metabolomics are increasingly being used in the field of toxicology. Experimental designs involving the study of dynamic changes in the metabolome raise new methodological challenges in the field of data analysis, regarding long term and perinatal in vivo studies. Multivariate analysis of variance (MANOVA), often used to analyze experimental data, is not always appropriate for metabolomics, especially when sample size is much smaller than the total number of variables, which prevents the testing of underlying hypotheses (normality, homoscedasticity). Multivariate methods, such as Principal Component Analysis (PCA) or Partial Least Squares-Discriminant Analysis (PLS-DA), often used to analyze metabolomic data, do not take into account data's temporal structure, resulting in a loss of information when used alone. In this study, we applied a method combining ANOVA and PCA: A-SCA (Anova-Simultaneous Component Analysis; SCA is a generalization of PCA) taking into account the experimental design, as well as the relationship between variables, to allow data modelisation. Data were first separated into blocks corresponding to the different sources of variation (experimental design factors). Then SCA was independently applied on each block, and permutations test was used to evaluate the significance of model parameters. This method was applied to the study of the effects of low doses of bisphenol A (BPA) on global metabolism in SD rats exposed in the perinatal period, (NIEHS project #5RC2ES018822). Pregnant rats were exposed to DMSO (vehicle-control), 0.25, 2.5, 25 or 250 ng BPA/kg BW/day. Serum samples of the F1 generation were collected on days 21, 50, 90, 140 and 200 of the experiment, and submitted to 1H NMR spectroscopy. Using the A-SCA method, time effects were demonstrated.

## PS 551 A Systems Chemical Biology Approach to Predict Effects from Chemical Cocktail Exposure.

K. Kongsbak<sup>1,2</sup>, N. Hadrup<sup>1</sup>, A. Vinggaard<sup>1</sup> and K. Audouze<sup>2</sup>. <sup>1</sup>National Food Institute, Technical University of Denmark, Søborg, Denmark; <sup>2</sup>Center for Biological Sequence Analysis, Department of Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark.

Purpose: In its report, Toxicity Testing in the 21st Century, the National Research Council called for the development of new approaches to human health risk assessment that would rely, in part, on computer-based models rather than animal testing and epidemiology (National Research Council 2007).

Using a systems chemical biology approach, we have studied the five commonly used pesticides epoxiconazole, mancozeb, prochloraz, procymidone, and tebuconazole that are all known to have effects on male reproductive development. The purpose of this study was to apply a method previously described by Audouze and Grandjean (Audouze & Grandjean, 2011) to generate hypotheses on the mechanisms linking relevant human outcomes to specific compounds.

Methods: An integrative systems biology approach was adapted to investigate similar or shared modes of action for the chemicals in the mixture of the five pesticides. Human chemical-protein/gene associations were collected from the databases ChemProt, STITCH, and CTD. These associations were then enriched using

known protein-protein interactions (PPIs) to yield associations between the chemicals and PPI networks. Subsequently, data integration was performed using in-house tools to extrapolate data to human diseases and pathways affected by the selected chemicals.

Results: The applied method on these chemicals is capable of identifying known effects on male reproductivity and of predicting novel effects on human health.

With the successful identification of known effects, a thorough data analysis is likely to help the linkage between the investigated compounds and their potential effects on other aspects of human health.

Perspectives: As the systems chemical biology approach relies on existing data it serves as an important tool in the efforts to apply alternative methods to animal testing. Furthermore, the method integrates data from many sources, which allows for unraveling of previously unidentified pathways of toxicity.

## PS 552 Modeling Species-Specific Metabolic Responses to TCDD in Mice and Rats Using a Reconstructed Metabolic Network.

R. Nault<sup>1,4</sup>, M. Wu<sup>3</sup>, C. Chan<sup>2,3,4</sup> and T. R. Zacharewski<sup>1,4</sup>. <sup>1</sup>Center for Integrative Toxicology, MSU, East Lansing, MI; <sup>2</sup>Chemical Engineering & Material Science, MSU, East Lansing, MI; <sup>3</sup>Computer Science & Engineering, MSU, East Lansing, MI; <sup>4</sup>Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI.

2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) elicits species-specific transcriptomic and metabolomics responses. Using a reconstructed metabolic network and published microarray datasets, we examined the ability of the network to predict hepatic metabolomic responses based on TCDD-elicited differential gene expression profiles. Previously published temporal whole-genome microarray datasets (2-168h) for TCDD-treated female C57BL/6 mice (30 µg/kg) and female Sprague-Dawley rats (10 µg/kg) were used. Context-specific metabolic networks were generated using the Gene Inactivity Moderated by Metabolism and Expression (GIMME) method by including induced genes (fold change  $\geq 1.5$ , P1(t)  $\geq 0.99$ ) and reactions necessary to maintain a steady-state flux. The mouse context-specific metabolic network revealed more reactions involved in fatty acid (FA) activation and triglyceride synthesis suggesting an increased flux towards lipid synthesis relative to the rat. Meanwhile, mice had fewer reactions involved in FA oxidation, carnitine shuttling, and glycerophospholipid metabolism suggesting FA catabolism is induced in rats exposed to TCDD. Moreover, the predicted induction of glycerophospholipid metabolism is consistent with reported changes in phosphoethanolamine in mice, and phosphocholine and phosphatidylserine in rats. In summary, we show that context-specific metabolic networks based on transcriptomic data are consistent with observed species-specific metabolomic changes elicited by TCDD including hepatic lipid accumulation observed in mice and species-specific glycerophospholipid metabolism effects. Moreover, the reconstructed metabolic network facilitated differential gene expression interpretation by providing valuable insights into the species-specific disruption of metabolic responses. Funded by SRP P42ES04911.

## PS 553 Multiscale Modeling for Individualized Spatiotemporal Prediction of Drug Effects.

J. G. Diaz Ochoa, J. Bucher, J. Niklas and K. Mauch. *InSilico Biotechnology AG, Stuttgart, Germany*. Sponsor: C. Yang.

Recently, in silico models for biokinetics have become a relevant way to test the distribution and metabolism of substances in single cells and in organisms. Its relevance is accentuated by the fact that in the next future an animal free toxicity assessment must be implemented in the European Union. Inside the COSMOS project (HEALTH-F5-2010-266835), which is funded by the European Union and a consortium of cosmetic industries (Cosmetics Europe), the central aim is to develop computational methods and in silico models for the prediction of long term toxicity upon repeated exposure to compounds. The power of such methods is (i) to derive quantitative predictions and (ii) to extrapolate results from in vitro measurements into in vivo predictions.

In this contribution, we present a case study that addresses acetaminophen induced hepatotoxicity. Based on a metabolic network model assigned to individual cells, which includes transport, drug metabolism, and intracellular mechanisms leading to toxicity, we were able to predict the metabolism of acetaminophen and production of toxic substances in the liver lobules in different time periods. Depending on the accumulation of these substances, the cell integrity in the liver was estimated. Such estimation is relevant not only for the prediction of physical changes in the organ but also for the prediction of changes in the clearance of the liver under high or repeated drug dosage. Our model also predicted variations of drug toxicity depending on alterations in metabolic enzyme activities. Variations in enzyme activities reflect genetic characteristics or diseases of individuals, thus allowing stratified or even personalized predictions of drug toxicity as well as drug efficacy.

**PS 554 Toxicogenomic Analysis of Environmental PAH Mixtures in a Model of Transplacental Carcinogenesis.**

S. C. Tilton<sup>1</sup>, L. K. Siddens<sup>2</sup>, A. J. Larkin<sup>2</sup>, B. N. Do<sup>2</sup>, K. C. Dunn<sup>2</sup>, E. P. Maden<sup>2</sup>, S. K. Krueger<sup>2</sup>, K. M. Waters<sup>1</sup>, W. M. Baird<sup>2</sup> and D. E. Williams<sup>2</sup>. <sup>1</sup>Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Oregon State University, Corvallis, OR.

Several polycyclic aromatic hydrocarbons (PAHs) are bioavailable to the fetus *in utero*, can generate DNA damage after transplacental exposure and result in increased incidence of carcinogenesis in offspring in an arylhydrocarbon (Ahr)-dependent manner. However, little is known about the effects of environmental PAH mixtures or mechanisms of carcinogenesis. Therefore, we utilized a mouse model of transplacental carcinogenesis to investigate the effect of PAH mixtures collected from environmental samples compared to the known carcinogen, dibenzo[def,p]chrysene (DBC). *Ahr*<sup>b-1/d</sup> (responsive) females were bred with *Ahr*<sup>d/d</sup> (non-responsive) male mice at eight weeks of age. Females were gavaged on gestation day 17 with DBC, an artificial atmospheric PAH mixture or PAH extract collected from Portland Harbor Superfund Site. Subsamples from each treatment (n=4) were euthanized 24 hrs post-treatment to collect fetal thymus, lung and liver for microarrays. At 3-6 months of age, 79% of the offspring from DBC-treated dams were euthanized due to severe T-cell lymphoma, as expected, which was not detected in the other treatment groups. Exposure of mice to both DBC and the artificial atmospheric mixture resulted in significant (p<0.05) increase in the overall incidence of lung nodules, 100% and 46%, respectively, in offspring at 10 months of age compared to controls. Global transcriptional analysis of fetal tissues 24 hrs post-treatment results in treatment-dependent, tissue-dependent and genotype-dependent gene signatures. A pathway-based approach was utilized to identify mechanisms of exposure and link gene signatures to tumor outcome. Network and transcription factor analysis of the gene clusters further resulted in identification of upstream regulators associated with PAH-induced carcinogenesis. These data describe potential mechanisms for DBC and PAH mixtures *in utero* that may be linked to downstream carcinogenesis in offspring. Supported by P42\_ES016465.

**PS 555 Functional Profiling to Reveal Toxicity Pathways.**

C. Vulpe<sup>1</sup>, W. Varsally<sup>3</sup>, R. Thomas<sup>2</sup>, I. Gerlovina<sup>2</sup>, B. Gaytan<sup>1</sup>, Y. De La Rosa<sup>1</sup>, M. North<sup>1</sup>, A. E. Hubbard<sup>2</sup>, P. Antczak<sup>3</sup> and F. Falciani<sup>3</sup>. <sup>1</sup>Nutritional Science and Toxicology, University of California Berkeley, Berkeley, CA; <sup>2</sup>Biostatistics, School of Public Health, University of California Berkeley, Berkeley, CA; <sup>3</sup>University of Liverpool, Liverpool, United Kingdom.

We contend that functionally conserved toxicity pathways underlie adverse cellular responses to toxicants. Therefore, we are using functional profiling in *Saccharomyces cerevisiae*, to identify the pathways involved in cellular toxicity. In this approach, the ~4500 viable deletion strains are pooled, grown for multiple generations in the presence of a toxicant, and sensitivity of each strain is individually quantified. If a deletion strain is significantly sensitive/resistant, then it provides evidence that the gene product absent in that strain plays a functional role in toxicity. We utilized this approach to identify key susceptibility genes to a wide variety of toxicants. We then applied reverse engineering to infer functional relationships between gene products and assemble functional networks. We used the network inference ARACNE algorithm (using a mutual information threshold of 0.35 (equating to a p-value of 10E-16) to infer a network containing 2604 nodes and 33593 edges representing functional linkage between non-essential genes. We identified key network modules enriched in different functional properties (e.g. mitochondrial function) that may represent common toxicity "hubs" and/or endpoints. We evaluated the relationship between these functional hubs and individual toxicants. We found enrichment of strains affected by individual toxicants in different hubs, perhaps indicative of the functional components associated with toxicity for each toxicant. We suggest that this functional approach in yeast and development of functional networks provides a unique insight into both the shared and unique molecular responses to toxicant exposure.

**PS 556 Prenatal Exposure to Transition Metals in Ambient PM2.5 Up-Regulates Nitrotyrosine in Human Cord Blood.**

C. Barros Veguilla<sup>1</sup>, J. Niu<sup>2</sup>, B. Yan<sup>2</sup>, N. Li<sup>2</sup>, Q. Qu<sup>1</sup> and L. Chen<sup>1</sup>. <sup>1</sup>Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY; <sup>2</sup>School of Public Health, Lanzhou University, Lanzhou, China.

Objective: Our previous study indicated that the ambient levels of nickel (Ni), copper (Cu), arsenic (As), and selenium (Se) in Jinchang were 76, 25, 17, and 7 fold higher than Zhangye, respectively. This pilot study was conducted in both cities to

assess potential adverse effects of prenatal exposures to these high levels of pollutants on the fetus. Methods: A total of 60 healthy nonsmoking pregnant women were recruited in Jinchang and Zhangye for collection of paired maternal and cord blood samples. ICP-MS was used to measure the concentrations of Ni, Cu, As, Se, and Co in blood samples. ELISA kits were used to measure human C-reactive protein (CRP), interleukin 6 (IL-6), nitrotyrosine, and cotinine. Results: All metals measured were elevated in both maternal and cord blood collected from Jinchang as compared to those from Zhangye, while significant differences were only detected for As, Co, and Se. In addition, Ni and As in cord blood were significantly higher than those in maternal blood with cord/maternal ratios of 1.56 ± 0.13 and 1.41 ± 0.25, respectively. Surprisingly, the levels of Cu in cord blood were significantly lower than paired maternal blood (cord/maternal ratios of 0.41 ± 0.04). The cord blood level of nitrotyrosine in Jinchang was significantly higher than that in Zhangye (p<0.0001). The other inflammatory biomarkers were not significantly different between these two groups. In contrast, CRP in maternal blood was 9 fold higher than cord blood (p<0.0001). The levels of IL-6 and nitrotyrosine were higher in cord blood compared with maternal blood although the differences were not statistically significant. Conclusion: The results suggest that the blood-placenta barrier may effectively prevent transportation of Cu from mother to fetus. On the other hand, Ni and As may easily penetrate placenta barrier and accumulated in cord blood, which may be responsible for the up-regulation of nitrotyrosine.

**PS 557 A Global Genomic Screening Strategy Reveals Genetic and Chemical Activators of Peroxisome Proliferator-Activated Receptor Alpha (PPARalpha).**

C. Corton<sup>1</sup>, N. Vasani<sup>1</sup>, M. B. Rosen<sup>1</sup>, B. D. Abbott<sup>1</sup>, C. Lau<sup>1</sup>, W. Ward<sup>1</sup>, R. S. Thomas<sup>2</sup>, D. Applegate<sup>3</sup> and K. Oshida<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>3</sup>Regenomed, San Diego, CA.

A comprehensive survey of chemical, diet and genetic perturbations that activate PPARalpha in the mouse liver has not been carried out but would be useful to identify factors that may contribute to PPARalpha-dependent liver tumors. A gene signature dependent on PPARalpha activation was identified by comparing the transcript profiles after exposure to three PPARalpha activators (Wy-14,643, fenofibrate, perfluorooctanoic acid) in wild-type and PPARalpha-null mice. In independent experiments using transcript profiles from the livers of chemically-exposed male or female mice, the signature correctly predicted activation by 2 known PPARalpha activators but not 10 activators of other pathways. Individual genes in the signature (i.e., Cyp4a10, Pdk4) were used in RT-PCR experiments to show the specificity of the response to PPARalpha activators compared to chemical-induced activation of other xenobiotic-activated transcription factors. The signature was used with standard classification methods to identify perturbations in which PPARalpha was activated in an Affymetrix compendium of ~750 mouse liver transcript comparisons encompassing a broad range of chemical, dietary and genetic perturbations. We found that PPARalpha is activated by a number of novel chemicals, dietary regimens and genetic mutations. Specific findings include activation by 1) chemicals that cause steatosis (e.g., TCDD, BaP), 2) dietary regimens of triglycerides, "fast food" and "cafeteria" diets, and fish oil, and 3) nullizygous mutations in a number of genes (Mfp2, Erc1, Por, Hnf1a, Fah/p21, Udf2, Hif1a, Hif2a) that could be secondary to steatosis. The findings increase our understanding of the factors that impact PPARalpha activation and that could contribute to increases in PPARalpha-dependent liver tumors. (This abstract does not represent EPA policy.)

**PS 558 Proteomic Analysis of Biological Responses from Exposures to Chemical Mixtures.**

M. E. Bruno<sup>1</sup>, W. Winnik<sup>2</sup>, A. Swank<sup>2</sup>, K. Wallace<sup>1</sup>, S. Leavitt<sup>1</sup> and Y. Ge<sup>1</sup>. <sup>1</sup>ISTD, US EPA, Research Triangle Park, NC, NC; <sup>2</sup>US EPA, Research Triangle Park, NC. Sponsor: K. Kitchin.

Nickel (Ni), cadmium (Cd) and chromium (Cr) are human lung carcinogens but the key events leading to their toxic effects are not fully elucidated. In addition, little is known about the molecular basis and the underlying toxic mechanisms of co-exposure of these carcinogenic metals which are frequently observed in environmental exposures. In this study, we investigated the biological responses and effects of the exposures of three metals, individually and in combinations, in BEAS-2B human lung epithelial cells. Utilizing two dimensional gel electrophoresis and mass spectrometry, we identified 455 differentially expressed proteins in BEAS-2B cells exposed to the metals and their mixtures at different doses. The identified protein changes were validated using Western blot and protein functional assays. These altered proteins were mapped to protein interaction networks, toxicity lists, and

canonical pathways using Ingenuity Pathway Analysis. The number of pathways affected in cells exposed to single metals or metal mixtures were: Ni (4 up and 5 down), Cd (1 up and 7 down), Cr (6 up and 0 down), Cd-Cr binary (12 up and 9 down) and Cd-Cr-Ni ternary (11 up and 5 down). The proteins and pathways that were unique or common to the specific metals and their mixtures were also identified. For instance, ubiquitin conjugated enzyme E2 protein was present only in mixtures. At the pathway level, Rho A signaling was changed only in mixtures. Specific effects of a metal in a binary mixture was also ascertained. Exposure to Cr (1.8  $\mu\text{m}$ ) resulted in upregulation of the protein ubiquitination pathway. In contrast, coexposure to a Cd (7.5  $\mu\text{M}$ ) and Cr (1.8 $\mu\text{m}$ ) binary mixture had the opposite effect on this pathway. In summary, this study enabled us to (1) distinguish single metals from metal mixtures at both the protein and pathway level and (2) determine the contribution of a metal in a metal mixture.

This abstract does not necessarily reflect EPA policy

**PS 559 Environmentally Relevant Concentrations of the Flame Retardant BDE-209 in Sediment Linked to Potential Developmental and Neurotoxic Effects on Zebrafish Embryos.**

N. G. Reyero Vinas<sup>1</sup>, L. Escalon<sup>2</sup>, E. Prats<sup>3</sup>, J. Stanley<sup>2</sup>, B. Thienpot<sup>3</sup>, N. Melby<sup>2</sup>, P. Babin<sup>4</sup>, E. J. Perkins<sup>2</sup> and D. Raldua<sup>3</sup>. <sup>1</sup>Mississippi State University, Vicksburg, MS; <sup>2</sup>US Army, Vicksburg, MS; <sup>3</sup>CSIC, Barcelona, Spain; <sup>4</sup>University of Bordeaux, Bordeaux, France.

Decabromodiphenyl ether (BDE-209) is a fully brominated diphenyl ether compound used as a flame retardant in polystyrene applications such as casings for computers, upholstery textile and televisions. It is highly lipophilic and persistent and as such it is prone to bioaccumulation and biomagnifications in the food chain. Increasing concentrations of polybrominated diphenyl ethers in wildlife have been documented since the mid 1990s. BDE-209 is a very large molecule, and the general thought was that due to its size it was not bioavailable, and therefore could not bioaccumulate in wildlife. Several studies now have proven this concept wrong, as BDE-209 has been found in many aquatic and terrestrial organisms. Exposure to BDE-209 has been linked to decreased learning and memory in mice, behavioral changes in mice and inhibition of neural stem cells into neurons in culture. As many of the toxic effects of BDE-209 have been found on laboratory exposures, here we analyze the potential effects of an environmentally relevant dose of BDE-209 on zebrafish (*Danio rerio*) embryo. Zebrafish embryos were exposed to sediments that contained 12,500  $\mu\text{g/kg}$  BDE-209 for eight days. We analyzed gene expression changes, thyroid function, and morphometric parameters. Gene expression analysis highlighted the potential effects of BDE-209 on development, neurotoxicity, and liver toxicity. We then analyzed the effects of BDE-209 on zebrafish behavior. BDE-209 affected zebrafish response to light as well as movement. Our results show that environmentally relevant doses of BDE-209 are not only bioavailable but can have adverse effects on organisms.

**PS 560 The Induction of Oxidative Stress by Mixtures of Dichloroacetate and Trichloroacetate in the Livers of Mice after Subchronic Exposure.**

E. Hassoun and J. Cearfoss. *Pharmacology, University of Toledo, Toledo, OH.*

Dichloroacetate (DCA) and trichloroacetate (TCA) are drinking water chlorination byproducts and were previously found to induce oxidative stress (OS) in the hepatic tissues of B6C3F1 male mice after subacute and subchronic exposures. In order to determine the effects of mixtures of DCA and TCA on OS induction in the hepatic tissues, groups of male B6C3F1 mice were treated daily, by gavage, with 3 different mixtures (Mix I, Mix II and Mix III) of the compounds for 13 weeks. The concentrations of the compounds in Mix I, II and III, respectively corresponded to those producing approximately 15%, 25% and 35% of maximal induction of OS by the individual compounds in the subchronic studies. The mice were euthanized at the end of the treatment period and livers were assayed for the biomarkers of OS that included production of superoxide anion, lipid peroxidation and DNA single strand breaks. While the effects on all of the biomarkers in response to Mix. I and II were additive, they were greater than additive in response to Mix III. The induction of OS in the livers of B6C3F1 mice after long term exposure to DCA and TCA was previously suggested as an important mechanism in the long term hepatotoxicity/hepatocarcinogenicity of the compounds, hence exposure to mixtures of the two compounds are expected to significantly increase the risk of exposure to the individual compounds. (Supported by NIH/NIEHS grant # R15ES013706-01A2)

**PS 561 Ultrafine Particles Are Not Major Carriers of Carcinogenic PAHs and Their Genotoxicity in Size-Segregated Aerosols.**

J. Topinka<sup>1</sup>, A. Milcova<sup>1</sup>, J. Schmuczerova<sup>1</sup>, J. Krouzek<sup>2</sup> and J. Hovorka<sup>2</sup>. <sup>1</sup>Genetic Ecotoxicology, Institute of Experimental Medicine AS CR, Prague, Czech Republic; <sup>2</sup>Institute for Environmental Studies, Faculty of Science, Charles University in Prague, Prague, Czech Republic.

Some studies suggest that genotoxic effects of the combustion related aerosol are induced by carcinogenic polycyclic aromatic hydrocarbons (c-PAHs) and their derivatives forming organic fraction of the ambient air particulate matter (PM). The proportion of the organic fraction in PM is known to vary with particle size. The ultrafine fraction is hypothesized to be the most important carrier of c-PAHs, since it possesses the highest specific surface area of PM. To test this hypothesis, the distribution of c-PAHs in the organic extracts (EOMs) was compared from 4 size fractions of ambient-air aerosols: coarse ( $1 < d_{ae} < 10 \mu\text{m}$ ), upper ( $0.5 < d_{ae} < 1 \mu\text{m}$ ), and lower ( $0.17 < d_{ae} < 0.5 \mu\text{m}$ ) accumulation, and ultrafine ( $d_{ae} < 0.17 \mu\text{m}$ ). High-volume aerosol samples were collected consecutively in 4 localities differing in the extent of environmental pollution. The genotoxicity of EOMs was measured by the analysis of DNA adducts induced in the acellular assay consisting of calf thymus DNA with/without rat liver microsomal S9 fraction coupled with <sup>32</sup>P-postlabelling. The upper accumulation fraction was the major size fraction in all 4 localities forming 37-46 % of the total PM mass. As per  $\text{m}^3$  of sampled air, this fraction also binds the highest amount of c-PAHs. Correspondingly, the upper accumulation fraction induced highest DNA adduct levels. As per PM mass itself, the lower accumulation fraction is seen to be the most efficient at binding DNA-reactive organic compounds. Interestingly, the results suggest that the fraction of ultrafine particles of various ambient air samples is neither a major carrier of c-PAHs nor a major inducer of their genotoxicity, which is an important finding for the extensively discussed toxicity and health effects of ultrafine particles. Support: Grant Agency of the Czech Republic (CZ: P503/12/G147).

**PS 562 Acute, Five- and Ten-Day Inhalation Study of Hydroprocessed Esters and Fatty Acids-Mixed Fats (HEFA-F) Jet Fuel.**

D. R. Mattie<sup>1</sup>, A. L. Carter<sup>1</sup>, P. Eden<sup>1</sup>, J. Z. Hezel<sup>1</sup>, T. R. Sterner<sup>2</sup>, D. A. Dodd<sup>3</sup>, G. A. Wilson<sup>4</sup>, K. L. Mumy<sup>5</sup> and B. A. Wong<sup>5</sup>. <sup>1</sup>711 HPW/RHDJ, Wright-Patterson AFB, OH; <sup>2</sup>HJF, Wright-Patterson AFB, OH; <sup>3</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>4</sup>EPL, Research Triangle Park, NC; <sup>5</sup>NAMRU-D, Wright-Patterson AFB, OH.

The U.S. Air Force is pursuing development of alternative fuels to augment or replace JP-8 jet fuel. Hydroprocessed Esters and Fatty Acids from Mixed Fats (HEFA-F) jet fuel was administered as an aerosol and vapor mixture to 5 male and 5 female Fischer-344 rats per group. Inhalation exposures lasted 6 hours per day for 1 day (with and without an 11-day recovery period), 5 days or 10 days (5 days per week for 2 weeks). Concentrations for each exposure were 0, 200, 700 and 2000  $\text{mg/m}^3$ ; mean aerosol percents were 0, 7, 22 and 28%, respectively. There were no significant changes in male or female body weights due to HEFA-F exposure at any time point. Food and water consumption, urinalysis, clinical pathology, lung cytokine/chemokine and blood cytokines were measured at 10 days. Decreased mean food consumption in male rats was significant at 2000  $\text{mg/m}^3$ . A 10% decrease in mean water consumption was observed in all HEFA-F exposed female rats. Urinalysis changes included a slight decrease in pH in all exposed rats, as well as a small elevation in ketones and the presence of leukocytes and hemoglobin in the 2000  $\text{mg/m}^3$  males. There were no changes in standard clinical chemistry or hematology parameters. Caudal lung tissue was analyzed for cytokines, chemokines and receptors using a PCR array for rat inflammatory cytokines and receptors kit; no significant changes were seen. Proinflammatory blood cytokines showed no significant differences, although a trend for increasing MCP-1 with increasing dose was seen. Male kidney weight increases were likely related to hyaline droplet formation, relevant only to male rats. Nasal cavity changes included olfactory epithelial degeneration at 2000  $\text{mg/m}^3$ . Alveolus inflammation was seen in the 2 higher doses at 10 days. To examine sensory irritation, male Swiss-Webster mice were exposed nose-only to 2000  $\text{mg/m}^3$  HEFA-F for 30 minutes, resulting in 23% respiratory depression.

**PS 563 Global Gene Expression Changes Induced by Organic Extracts of Air Pollutants in Human Lung Cells.**

H. Libalova<sup>1</sup>, K. Uhlirova<sup>1</sup>, J. Klema<sup>2</sup>, M. Machala<sup>3</sup>, M. Ciganek<sup>3</sup>, J. Topinka<sup>1</sup> and R. J. Sram<sup>1</sup>. <sup>1</sup>*Institute of Experimental Medicine AS CR, Prague, Czech Republic*; <sup>2</sup>*Czech Technical University, Prague, Czech Republic*; <sup>3</sup>*Veterinary Research Institute, Brno, Czech Republic*.

Many adverse effects of the ambient air pollution have been linked to polycyclic aromatic hydrocarbons (PAHs) occurring in the complex mixture adsorbed onto airborne particles. Besides their genotoxic effect, some of them are known to act via aryl hydrocarbon receptor (AhR)-mediated nongenotoxic and tumor promoting mechanism. This study employed human lung adenocarcinoma cells (A549) to investigate the effect of complex mixture of the air pollutants on the global gene expression changes. We determined whole-genome gene expression profiles (Illumina platform) of cells treated with organic extracts (EOMs) from particulate matter (<2.5 µm) collected in four localities in the Czech Republic differing in the level of the air pollution. Simultaneously, detailed chemical analysis of EOMs from each locality was performed. Despite various sources, EOMs exhibited equal qualitative composition although the absolute level of PAHs and other pollutants in the most polluted locality was much higher comparing to other localities. Gene expression profiles of cells treated with equal amounts of EOM from each locality showed similar patterns. No significant diversity among localities was found. Goeman's global test and KEGG pathway database were applied to identify the most deregulated pathways and contributing genes. We observed significantly deregulated processes and genes common for all localities including metabolism of amino acids such as glycine, serine and threonine (SHMT2, PSAT1), xenobiotic metabolism (CYP1B1, ALDH3A1), vitamin B6 metabolism (PDXK), TGF-beta signaling (SMAD3), immune system and infectious diseases (IL8, PTGS2) or cell cycle (E2F2, CCND3). It has been proposed that most of them are modulated by activated Ah-receptor. Our results suggest the prominent role of activated Ah-receptor and other events possibly leading to the metabolic reprogramming and tumor promotion in A549 cells. Support: Grant Agency of the Czech Republic (CZ:P503/11/0142).

**PS 564 Evaluation of Additivity of Binary Mixtures of Perfluoroalkyl Acids (PFAAs) on Peroxisome Proliferator-Activated Receptor-Alpha (PPARα) Activation *In Vitro*.**

C. J. Wolf<sup>1</sup>, C. Rider<sup>2</sup>, C. Lau<sup>1</sup> and B. D. Abbott<sup>1</sup>. <sup>1</sup>*Toxicity Assessment Division, US EPA, ORD, NHEERL, Research Triangle Park, NC*; <sup>2</sup>*National Toxicology Program, NIEHS, Research Triangle Park, NC*.

Perfluoroalkyl acids (PFAAs) are found globally in the environment and in animal tissues, and are present as mixtures of PFAA congeners. Mechanistic studies have found that *in vivo* effects of PFAAs are mediated by PPARα. Our previous studies showed that individual PFAAs activate PPARα transfected into COS-1 cells. Here we evaluated whether binary combinations of perfluorooctanoic acid (PFOA, C8) and other PFAAs interact in an additive fashion to activate PPARα. COS-1 cells in 96 well plates were transiently transfected with mouse PPARα luciferase reporter plasmid. After 24 hours, cells were exposed to either vehicle control (0.1 % DMSO or water), PPARα agonist (WY14643, 10 µM), C8 or perfluorononanoic acid (C9) at 1 - 128 µM, perfluorohexanoic acid (C6) at 8 - 1024 µM, or perfluorooctane sulfonate (C8S) at 4 - 384 µM to generate sigmoidal dose-response curves. In addition, cells in the same plate were exposed to binary combinations of C8 + either C6, C9, or C8S, in an 8x8 factorial design. After 24 hours of exposure, cells were lysed and luciferase activity was measured. Data were transformed on a fold-induction and % maximal response basis. The dose-response data for individual chemicals were fit to sigmoidal curves and analyzed with nonlinear regression to generate EC50s and Hill slopes, which were used in response-addition and dose-addition models to calculate predicted responses for mixtures. All PFOA+PFAA combinations produced dose-response curves that were closely aligned with the predicted curves for both response addition and dose addition. However, at higher concentrations of all chemicals, the observed response curves deviated upward from the predicted models of additivity, although with more variability. We conclude that at the lower concentration ranges, binary combinations of PFAAs behave additively in activating PPARα in the COS-1 cell system. This abstract does not necessarily reflect USEPA policy.

**PS 565 Reference Dose (RfD)-Based Chronic Human Health Hazard Ranking System for Complex Mixtures—Assessment of Polar Nonhydrocarbons in Groundwater at Biodegrading Petroleum Sites.**

A. K. Tiwary<sup>1</sup>, R. I. Magaw<sup>1</sup>, D. A. Zemo<sup>2</sup>, K. T. O'Reilly<sup>3</sup>, R. E. Mohler<sup>1</sup> and K. A. Synowicz<sup>1</sup>. <sup>1</sup>*CETC, San Ramon, CA*; <sup>2</sup>*Zemo & Associates LLC, Incline Village, NV*; <sup>3</sup>*Exponent, Inc., Bellevue, WA*.

Chronic human health hazard evaluations of chemical mixtures are challenging and generally rely on similarities in toxicity mechanisms and dose-additivity of chemicals in the mixture. However, such assessments are inadequate for highly complex mixtures such as those present in groundwater at biodegrading petroleum sites where thousands of compounds representing many distinct structural classes of chemicals may be present. A hazard ranking system based on USEPA Reference Doses (RfDs) was developed to evaluate the potential chronic human health hazards presented by complex mixtures of polar petroleum biodegradation products in water. Equivalent risk-based drinking water concentrations for the range of identified RfDs were derived using the USEPA Regional Screening Level (RSL) equation for Tap Water Screening Levels (SLwater-nc-ing).

Based on the RfDs of representative chemicals for each structural class of potential biodegradation products, overall summary hazard rankings of "Low", "Low to Moderate", and "Moderate", were assigned. Classes constituting chemicals with RfDs ≥ 0.1 mg/kg/day were defined as being of "Low" hazard; "Low to Moderate" if 0.1 > RfD ≥ 0.01 mg/kg/day, and "Moderate" if 0.01 > RfD ≥ 0.001 mg/kg/day. These three groups included essentially all of the potential polar biodegradation products for which RfDs were available. This RfD based system is consistent with similar systems developed by USEPA OPPTS and UN GHS programs and was validated by review of USEPA summary documents.

The ranking system was applied to groundwater samples collected from biodegrading petroleum sites and the results show that the vast majority of the polar biodegradation products are in structural classes that may present "Low" hazard to humans. Overall, the polar mixtures are unlikely to present a significant risk to human health if consumed as drinking water.

**PS 566 Repeat-Dose and Developmental Toxicity Assessment of Crude Oil.**

R. H. McKee<sup>1</sup>, M. J. Nicolich<sup>2</sup>, T. Roy<sup>3,4</sup>, R. White<sup>5</sup> and W. Daughtrey<sup>1</sup>. <sup>1</sup>*Toxicology and Environmental Sciences, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ*; <sup>2</sup>*COGIMET, Lambertville, NJ*; <sup>3</sup>*Port Royal Research, Hilton Head, SC*; <sup>4</sup>*University of South Carolina, Beaufort, SC*; <sup>5</sup>*American Petroleum Institute, Washington DC*.

**Abstract**

Petroleum (commonly called crude oil), CAS number 8002-05-9, is a complex substance of variable composition, primarily composed of hydrocarbon constituents. The principal acute toxicological hazards are those associated with exposure to volatile hydrocarbon constituents and hydrogen sulfide, and chronic hazards are associated with exposure to benzene and polycyclic aromatic compounds (PAC). To further characterize the potential for repeated dose and/or developmental effects from dermal contact, the PAC content of 46 crude oils was measured using a method based on DMSO extraction followed by GC separation and quantitation of the aromatic ring classes (ARC). Statistical models were then used to predict the potential for target organ and developmental toxicity of the 46 crude oils based on their ARC profiles. We compared model predictions to empirical data from previously tested crude oils, showing that one of the previously tested oils approximated a "worst case" situation. Thus, this modeling exercise demonstrated that data from previously tested crude oils could be used to form a reasonable basis for characterizing the repeated dose and developmental toxicological hazards of crude oils in general.

**PS 567 Insights from Initial Analysis for Harmful and Potentially Harmful Constituents (HPHC) in Tobacco Products.**

M. Oldham, D. DeSoi, K. A. Wagner and M. J. Morton. *Altria Client Services, Richmond, VA*.

A total of 20 commercial cigarette and 16 commercial smokeless tobacco products were initially assayed for 96 HPHC (Draft HPHC list, Federal Register, August 12, 2011) prior to draft guidance by FDA (March 30, 2012). The FDA Draft Guidance specified a reduced list of HPHC with more replicates than initially tested. Three contract laboratories were used to complete all testing. The same lots of commercial product were used for all testing. Cigarettes were tested using both the ISO and Canadian intense smoking regimens. In general, the levels of HPHC

constituents in the commercial products tested were consistent with levels previously reported in the literature. Approximately 12% of HPHC measured for cigarettes and smokeless tobacco products were not found or were below the limit of quantification. Comparison of initial HPHC results with results from additional replicates demonstrated statistically significant differences for most HPHC (i.e. temporal variability). Therefore, simple conventional comparisons, such as two-sample t-tests are inappropriate for comparing products tested at different points in time from the same laboratory or from different laboratories. Additionally, all of the HPHC in mainstream cigarette smoke were correlated to tar yield as previously reported in the literature.

Although each analytical assay was validated within a laboratory, some HPHC results were quite different between laboratories. These differences demonstrate the need for standardized methods between laboratories with defined repeatability and reproducibility determined by inter-laboratory collaborative testing for each HPHC using certified reference standards. Since no one-to-one relationship of tobacco constituent to human disease exists, the biological relevance of these HPHC results to human disease is unknown.

## PS 568 Different Toxicity Outcomes in Rats Correlated with EPR and NMR Spectra of Crude Oil from Various Sources.

S. A. Meyer<sup>1</sup>, S. Jaligama<sup>1</sup>, K. A. El Sayed<sup>2</sup> and T. R. Dugas<sup>3</sup>. <sup>1</sup>Toxicology, University LA-Monroe, Monroe, LA; <sup>2</sup>Basic Pharmaceutical Sciences, University LA-Monroe, Monroe, LA; <sup>3</sup>Pharmacology, Toxicology & Neurosciences, LSU Health Sciences Center, Shreveport, LA.

Crude oil varies with source in its relative composition of alkanes, simple and polycyclic aromatics, nitrogen, sulfur, asphaltene and porphyrin nickel and vanadium. Here, we identify several toxicological effects upon acute exposure of rats to crude oil from several sources and correlate these with peaks of select constituents from spectra of the crude oils obtained with EPR and <sup>1</sup>H- and <sup>13</sup>C-NMR. Sources of oil were Louisiana sweet crude, Nigerian (Qua Iboe) sweet crude and Iraqi high sulfur (ONTA, Inc., Toronto, Canada). Female Sprague-Dawley rats were given 2 daily doses of 2.5 and 5 ml/kg of oil or vehicle (0.5% DMSO in corn oil) by oral gavage. Rats were euthanized after 48 h and blood was taken for hematology, clinical chemistry and immunoassay for cytokines and vasoactive agents. Femur bone marrow cells were assayed for CFU-GM myeloid progenitors. All oils elevated serum alkaline phosphatase (ALP) with LA oil being least active, in agreement with liver pathology. Liver weight increased 25-75% and CYP1A1 protein was elevated with all, Iraqi oil being most effective. Granulocytes increased ~2-fold by high dose of LA and Iraqi oil. Spleen weights decreased 30% with high dose of Iraqi and Nigerian oil. CFU-GMs decreased only with high dose of LA oil (40%). Vasoconstrictor endothelin-1 increased 2-fold in serum from rats treated with Iraqi and Nigerian oils. <sup>1</sup>H- and <sup>13</sup>C-NMR spectra gave qualitatively similar alkane peaks for all oils, but differing aromatic peaks, e.g., benzene (<sup>1</sup>H-NMR 7.38 ppm) of Iraqi oil was least intense. EPR spectra of all oils exhibited asphaltene free radical peak with intensity greatest for Iraqi oil. Vanadium porphyrin was detected in Iraqi oil only. Summarizing, LA sweet crude oil was uniquely myelosuppressive and with lesser effect on spleen and liver weights and ALP. Iraqi oil, richest in asphaltene free radical and vanadium porphyrin and lowest in benzene, most affected liver weight and CYP1A1 (LA Board of Regents)

## PS 569 Complex Mixtures of PAHs Are More Potent Than Benzo[a]pyrene at Inducing Cellular Inflammatory and DNA-Damage Response.

K. Dreijl<sup>1</sup>, I. W. Jarvis<sup>1</sup>, C. Bergvall<sup>2</sup>, M. Bottai<sup>1</sup>, G. A. Umbuzeiro<sup>3</sup>, R. Westerholm<sup>2</sup> and U. Stenius<sup>1</sup>. <sup>1</sup>Institute Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Department Analytical Chemistry, Stockholm University, Stockholm, Sweden; <sup>3</sup>Faculty of Technology, State University of Campinas, Limeira, Brazil. Sponsor: G. Johanson.

Complex mixtures of polycyclic aromatic hydrocarbons (PAHs) are present in air particulate matter (PM) and have been associated with many adverse health effects including cancer and cardiovascular disease. We hypothesize that interactions between different PAHs stand for a major biological effect. We have previously showed that soil PAH extracts induce persistent DNA damage including prolonged activation of DNA damage markers H2AX and Chk1. To further study the effects of mixtures of PAHs biological testing of air PM extracts were performed using human HepG2 and H1395 cells and sensitive cellular endpoints relevant for carcinogenesis (DNA damage response) and cardiovascular pathogenesis (inflammatory signaling). The cellular response was compared to benzo[a]pyrene (BP) and dibenzo[a,l]pyrene (DBP). The results showed a more than additive response for binary mixtures of BP and DBP on activation of Chk1. Persistent activation of DNA damage signaling was observed at significantly lower concentrations of air PM extracts than BP alone. Activation of DNA damage signaling was more persistent in

air PM fractions containing PAHs with more than four aromatic rings suggesting larger PAHs contribute more to the genotoxicity of PAHs in air PM. Furthermore, we observed significant up-regulation of pro-inflammatory stress responsive genes including several cytokines in response to air PM extracts corresponding to 1 nM BP. Employing specific inhibitors showed that the activation of inflammatory signaling was mediated through the Ah-receptor and MAPK signaling. Taken together, our data indicate synergistic effects on important cellular signaling events due to PAH interactions. This suggests that human health risk assessment based on additivity such as toxicity equivalency factor scales may significantly underestimate the risk of exposure to complex mixtures of PAHs.

## PS 570 Individual and Cumulative Health Risk Assessment of 17 PFASs in the Swedish Population.

D. Borg<sup>1</sup>, B. Lund<sup>2</sup>, N. Lindquist<sup>2</sup> and H. Håkansson<sup>1</sup>. <sup>1</sup>Institute of Environmental Medicine (IMM), Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Swedish Chemicals Agency (KemI), Stockholm, Sweden.

Perfluoroalkylated and polyfluoroalkylated substances (PFASs) are a large class of chemicals that have emerged as global environmental contaminants. This study, carried out in accordance with the European chemicals legislation (REACH) guidelines for risk assessment, evaluated possible health risks of 17 PFAS congeners in the Swedish population. The exposure assessment was based on blood and serum levels from biomonitoring studies in the Swedish population. Population groups considered were the general population and occupationally exposed professional ski waxers. The hazard assessment primarily considered hepatotoxicity and reproductive toxicity which were endpoints shared by the selected congeners. Read-across was performed to the closest most potent congener for 12/17 congeners lacking toxicological data and/or internal dose levels. The result of the risk characterization showed no cause for concern for hepatotoxicity or reproductive toxicity in the general population, except for hepatotoxicity in a subpopulation eating PFOS-contaminated fish. However, a cause for concern was identified for the non-conventional endpoints disrupted mammary gland development and immunotoxicity. For the occupationally exposed professional ski waxers safe use could not be shown based on concern for liver toxicity by PFOA and by all congeners in combination, for reproductive toxicity by all congeners in combination as well as for disrupted mammary gland development and immunotoxicity. This is the first attempt to assess the health risks to a combination of a large number of PFASs.

## PS 571 Mixtures of Benzo(A)Pyrene with Direct or Indirect Acting Mutagens Have a Nonmonotonic Mutation Profile.

R. David and N. J. Gooderham. Imperial College, London, United Kingdom.

Genotoxic carcinogens are present in the human diet, and Benzo(a)pyrene (BaP), 2-Amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP) and acrylamide (AC) represent three important examples. BaP is a polycyclic aromatic hydrocarbon generated by incomplete combustion of organic substances such as lipids, thus contaminating numerous foodstuffs, PhIP is a heterocyclic amine formed when meat is cooked, and AC forms when foods, such as potatoes and cereals, are cooked at temperatures exceeding 100°C. Individually these have been shown to be genotoxic but the biological consequences of exposure to mixtures of these chemicals have not been systematically examined.

The aim of the current study was to examine the biological response of MCL-5 cells (metabolically competent human lymphoblastoid cell line) to mixtures of these genotoxins at concentrations relevant to human exposure (µM to sub-nM). Cells were exposed to the chemicals individually or in mixtures for 24h and mutagenicity was assessed through resistance to trifluorothymidine at the thymidine kinase (TK) locus and 6-thioguanine at the hypoxanthine-guanine phosphoribosyltransferase (HPRT) locus.

At the TK locus the mixtures produced non-monotonic mutation responses; 100nM BaP combined with some low, non-mutagenic concentrations of other mutagens showed synergism, while antagonism was observed for 10µM BaP in mixtures with higher concentrations of other genotoxins. Responses differed between the two loci, with a higher than anticipated mutation frequency (MF) observed for high concentration combinations at HPRT compared to TK. Combining 10µM BaP with 100µM PhIP reduced the number of cells in S phase with a corresponding increase in sub-G1 and G1. Moreover, ethoxoresorufin-O-deethylase (EROD; CYP1A) activity and CYP1A1 mRNA levels significantly correlated with each other and with the MF at TK emphasising the involvement of the CYP1A family in this mutation response. This non-monotonic MF is of significance when considering risk assessment, especially at low concentration combinations where the individual chemicals are not measurably mutagenic.

**PS 572 Preliminary Steps in a Whole Mixture Strategy for Risk Evaluation.**

K. Joshi and C. Gennings. *Virginia Commonwealth University, Richmond, VA.*

When assessing risks posed by environmental chemical mixtures, whole mixture approaches are preferred to component approaches. When toxicological data on whole mixtures as they occur in the environment are not available, EPA guidance states that toxicity data from one or more mixtures considered "sufficiently similar" to the environmental mixture(s) can serve as surrogates. However, the selection process of which mixtures to experimentally evaluate is an open line of inquiry. The objective of our study was to demonstrate a proof-of-concept strategy for the selection process using a mixture of 17 polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and polychlorinated biphenyls (PCBs) based on (i) human biomonitoring data from the National Health and Nutrition Examination Survey (NHANES); and (ii) single chemical dose response models from the literature. Principal component (PC) analysis was conducted to identify patterns of chemicals present in humans as measured in serum concentrations in the US population using NHANES data. Five different concentration patterns were found to represent 82% of the variation in the mixture concentrations for these 17 chemicals. Population-based median concentration estimates for the chemicals identified by large absolute values in the PCs were used to define mixing proportions for the five mixtures. Robust optimal designs, using a maximin optimization criterion which is robust to model misspecification, were determined for the mixtures using published dose-response models in Crofton et al (2005, EHP). The approach provides design information for conducting mixtures studies in support of a whole mixtures risk assessment. Next steps include estimating the dose values required to approximate the blood concentrations in the mixtures. Determining how representative these mixtures are to the population concentrations while testing for sufficient similarity is a long-range research goal. (The authors gratefully acknowledge the support from #R01ES015276, #T32 ES007334, and #UL1TR000058.)

**PS 573 Coexposure to Low-Dose Model Testicular Toxicants Induces Gene Alterations.**

N. Catlin, S. M. Huse and K. Boekelheide. *Brown University, Providence, RI.*

Testicular effects of chemical mixtures may differ from those of the individual chemical constituents. This study assesses the co-exposure effects of the model germ cell- and Sertoli cell-specific toxicants, X-radiation (x-ray) and 2,5-hexanedione (HD), respectively. X-ray induces germ cell apoptosis and HD has been shown to attenuate the x-ray effect on germ cells. Adult rats were exposed to different levels of x-ray (0.5Gy, 1Gy, 2Gy), HD in the drinking water for 18 days (0.33%, 1%), alone or in combination. Custom PCR arrays were generated based on a panel of genes identified through microarray studies; hierarchical clustering of these PCR arrays identified dose-dependent treatment effects on the apoptosis-related genes Fas, Aen, and Casp3. The 5Gy + 1% HD co-exposure induced Aen and Casp3 expression, with a maximum fold induction of 3.1 and 2.6, respectively. Also, Fas was significantly induced 2.6-fold at this co-exposure dose, despite no induction of Casp3, Fas, or Aen expression by x-ray or HD alone. In order to assess cell type-specific attenuation of HD effects with x-ray co-exposure, we used laser capture microdissection (LCM) to examine a panel of apoptosis-related transcripts using PCR arrays. Several pro-apoptotic genes were identified, which increase with a fold change greater than 1.4 after 2Gy x-ray exposure, including Traf3, Tnfrsf10 and Fas. We also identified an anti-apoptotic gene, Bcl2a1d, which increases in fold change across the different exposures (0.33% HD, 1.3 fold; 2Gy x-ray, 1.6 fold; 0.33% HD + 2Gy, 3.1 fold). Ingenuity Pathway Analysis of the gene expression data produced two over-represented pathways across all treatment groups examined with LCM: Induction of Apoptosis by HIV1 and Death Receptor Signaling. We amplified LCM RNA and examined the same apoptosis transcripts. When compared to our unamplified RNA, we found a Pearson correlation coefficient of 0.64, indicating that use of amplified LCM RNA may introduce significant bias. These results provide insight into environmentally relevant low-dose co-exposures of model testicular toxicants.

**PS 574 Development of a Portable In Vitro System for Lab. and Field Aerosol Exposure Studies.**

J. Zavala, K. Lichtveld, S. Ebersviller, G. W. Walters, H. E. Jeffries, K. G. Sexton, W. Vizuete, I. Rusyn and I. Jaspers. *Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

There is a growing interest in studying the toxicity of multi-pollutant mixtures found in ambient air, and the U.S. Environmental Protection Agency (EPA) is moving towards setting standards for these types of mixtures. Conventional in vitro

exposure methods do not properly emulate human exposures and are not adequate to meet the EPA's strategic plan to demonstrate a direct link between air quality and health effects. Exposure of cells at the air-liquid interface (ALI) is the most realistic approach to emulate in vivo exposures. A new portable in vitro system that uses electrostatics to deposit particles onto the cells has been developed and this study demonstrates the efficacy of this device. The portable system provides a viable environment within its electric field for cultured human lung cells grown on permeable membrane supports. This method provides an efficient and effective way to expose cells to particles without prior collection and subsequent resuspension in a liquid medium. Cell viability testing included maintaining normal cell culture conditions for exposures across the ALI for periods of up to 4 hours outside of a tissue culture incubator. Results from all cell viability testing with A549 human lung cells show that no parts, components, materials or operating characteristics of the portable sampler induce any cytotoxicity, as measured by lactate dehydrogenase (LDH), or inflammatory response, as measured by interleukin-8 (IL-8). A549 cells were then exposed to photochemically-aged diesel exhaust (DE) using the UNC rooftop smog chamber. An exposure dose of 3.6 µg of DE particles in air was delivered to the cells and a 3-fold increase in LDH and IL-8 was observed when compared to controls. This new device can serve as a stepping-stone for researchers and engineers to develop new and improved in vitro exposure technology suitable for field use.

**PS 575 Chemical Dispersants Used in the Gulf of Mexico Are Cytotoxic to Human Lung and Skin Fibroblasts.**

J. Wise<sup>1,2</sup>, S. Wise<sup>1,2,3</sup>, H. Xie<sup>1,2,3</sup>, J. Griffith<sup>4</sup> and J. Wise<sup>1,2,3</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME; <sup>2</sup>Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME; <sup>3</sup>Department of Applied Medical Science, University of Southern Maine, Portland, ME; <sup>4</sup>Department of Coastal Sciences, University of Southern Mississippi, Ocean Springs, MS.

Chemical dispersants are chemicals compounds that can be used to aid in the cleanup of crude oil spills. In 2010, they became a significant public health concern due to the BP Deepwater Horizon Oil Crisis; when millions of gallons of chemical dispersants specifically Corexit® 9527 and 9500 were applied via aerial spray and deepwater injection to break up the crude oil. Toxicity of Corexit® to humans is unknown, and the primary routes of exposure to these chemical dispersants are inhalation, direct dermal contact and ingestion. The objective of this study is to determine the cytotoxicity and genotoxicity of these two dispersants in human lung (WTHBF-6) and skin (BJhTERT) fibroblasts. Cells were treated with and without S9 fractions with cofactors, because fibroblast cells may not readily express cytochrome P450 enzymes necessary to metabolize chemicals. Corexit® 9500 was cytotoxic to lung and skin cells. Specifically in skin, 50, 250, 350 and 500 ppm, it induced 95, 89, 52, and 3 percent relative survival, respectively. S9-mediated metabolism increased toxicity inducing 78, 84, 39 and 2 percent relative survival, respectively. Corexit® 9527 was cytotoxic to lung and skin cells. Specifically in skin, 500, 650, 850 and 1000 ppm, it induced 89, 56, 73, and 24 percent relative survival, respectively. S9-mediated metabolism increased toxicity inducing 65, 60, 22 and 0 percent relative survival, respectively. Our genotoxicity data is less clear. Corexit® 9527 induced 8 aberrations per 100 metaphases at 850 ppm, but caused cell cycle arrest at 875 ppm. Similarly Corexit® 9500 induced 14 aberrations per 100 metaphases at 350 ppm, but caused cell cycle arrest at 425 ppm. Ongoing and future work will consider the effects of dispersed oil.

**PS 576 Micronanoparticle Suspension Formulation Development for Medical Chemical Countermeasures.**

L. Cabell<sup>1</sup>, J. McDonough<sup>1</sup>, A. Clark<sup>1</sup>, T. Belski<sup>2</sup> and L. Mobley<sup>2</sup>. <sup>1</sup>SWRI, San Antonio, TX; <sup>2</sup>CBMS/IMTS, Frederick, MD. Sponsor: J. Johnson.

Current U.S. medical chemical countermeasures require battlefield stability and an effective shelf life. One example is bis-pyridinium oximes that are used for the treatment of Organophosphate (OP) intoxication to counter the effects of AChE inhibition. This class of oximes possesses poor thermal stability in an aqueous formulation due to hydrolytic cleavage. CBMS and SwRI have developed non-Newtonian suspension formulations of oximes in cottonseed oil (CSO) vehicles that impart oxime solid stability characteristics to oxime/CSO liquid suspension formulations. MMB4 DMS and HI-6 DMS have shown superior thermal stability in these liquid suspension formulations compared to aqueous formulations and equal thermal stability compared to solid formulations. These types of formulations have shown bioavailability comparable to parent active pharmaceutical ingredients (API) in aqueous formulations. C<sub>max</sub> and T<sub>max</sub> for these APIs are relatively the same with absorption and elimination not substantially affected. In principle, these types of

suspension formulations can be used to stabilize any drug that is prone to hydrolytic cleavage. In addition, the nature of these suspensions inhibits drug-drug interaction in the formulations as well as promotes differential drug controlled release if designed appropriately. We have designed these suspensions with high zero-shear viscosity, which allows it to resist sedimentation and non-Newtonian behavior that causes shear thinning, such that the viscosity decreases and the product flows easily under a shear force, such as injection through a needle. Furthermore, the viscosity and sedimentation behavior are controlled by formulation parameters such as particle size and concentration. DISTRIBUTION STATEMENT A. Approved for public release; distribution is unlimited.

**PS 577 Application of Generalized Concentration Addition to Receptors That Dimerize.**

T. Webster, *Department Environmental Health, Boston University School of Public Health, Boston, MA.*

Concentration addition is a standard toxicological method for analyzing mixtures of similarly acting compounds. A significant limitation of concentration addition is that it cannot be used to describe the effect of mixtures containing partial agonists at response levels above that for the compound with lowest efficacy. Unfortunately, partial agonism is a common phenomenon, limiting the application of concentration addition. We previously proposed generalized concentration addition (GCA) as a solution to this issue and successfully used this method to describe data from experiments involving mixtures of full and partial agonists of the AhR receptor. GCA requires the use of dose-response functions that are invertible over the relevant range. This posed no problem for the AhR-ligand systems described by a Hill function with a Hill coefficient of one. Receptors that dimerize (or receptors that bind two ligands) are often modeled using Hill functions with Hill coefficients of two, but these functions are not appropriately invertible. We used mathematical models based on equilibrium kinetics and mass balance to describe a simple pharmacodynamic model of binding of ligands to receptors followed by dimerization: e.g.,  $A + R_{AR, AR+AR} \rightleftharpoons ARRA$ , where A is a ligand, R is a receptor, AR is a ligand-receptor complex, and ARRA is the dimerized complex. This leads to theoretical dose-response functions that are invertible and different from Hill functions but approximated by them at low doses. Such models may be applicable to examining mixtures of full and partial agonists of several systems of receptors that dimerize including the androgen and estrogen receptors.

**PS 578 Generalized Concentration Addition Models Some but Not All Interactions of Mixtures of Androgen- and Estrogen-Receptor Active Compounds in High-Throughput Screening Assays.**

F. Parham<sup>1</sup>, M. DeVito<sup>1</sup>, R. Huang<sup>2</sup>, M. Xia<sup>2</sup>, B. Collins<sup>1</sup>, C. Rider<sup>1</sup> and R. R. Tice<sup>1</sup>. <sup>1</sup>NTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>NCATS, NIH, Bethesda, MD.

As part of the U.S. Tox21 collaboration, 69 mixtures of compounds previously found to be active in estrogen or androgen receptor (ER or AR) reporter assays were tested in ER and AR high throughput screening assays in agonist and antagonist mode. ER-active compounds used were acetochlor, alachlor, bisphenol A, butyl benzyl phthalate, chlordecone, DDT, dicumyl peroxide, ethylenediamine, p-n-nonylphenol, and zearalenone. AR-active compounds were androstenedione, dexamethazone, flouxymestron, hydroxyflutamide, medroxyprogesterone acetate, o-methoxyphenol, oxymetholone, and progesterone. Of the 69 mixtures, 32 were AR-active compounds only, 23 were ER-active compounds only, and 14 were both groups of compounds. Mixtures contained between 2 and 18 chemicals and were equipotent mixtures, mixtures of equal concentration and mixtures that varied potency of the individual chemicals. The 18 compounds were also tested individually. A generalized concentration addition model for partial agonism and antagonism was used to model the concentration-response of the mixtures as a function of the parameters of the response for the mixture components. The parameters were derived using two optimization methods. In the first method, the parameters for the mixtures components were derived by fitting the model to the single-component data, and then the model was used to predict the mixture effects. In the second method, the parameters were obtained by fitting the model to all the data (both single-component and mixture) simultaneously. The second method generally accurately models both the single-component and mixture data, although there were several mixtures that were not accurately represented by the model. The first method was inaccurate for many more mixtures. The experiment demonstrates that high-throughput assays can be used to evaluate dose addition theory for large numbers of individual chemicals and mixing ratios.

**PS 579 Cumulative Risk Assessment of Radon and Confounder Mixtures.**

M. Mumtaz<sup>1</sup>, L. Keith<sup>1</sup>, D. Wohlers<sup>2</sup> and E. Murray<sup>1</sup>. <sup>1</sup>Division of Toxicology and Human Health Sciences, CDC ATSDR, Atlanta, GA; <sup>2</sup>SRG, Inc., North Syracuse, NY.

Cumulative risk assessment is a challenging proposition because it involves integration and collective distillation of all available data capturing the essence of the potential risks of multiple stressors, chemical and nonchemical. The conclusions of such assessments must also integrate the inherent disparities, the constraints of the data gaps, and address data uncertainties. More recently communities and stakeholders have also voiced concerns about health effects beyond the single stressor-specific critical effects and the role of interactions in the overall toxicity of real life exposures. Most often the focus has been on chemical toxicity; here we present a case of chemical plus radiological effects. The Agency for Toxic Substances and Disease Registry (ATSDR) has updated the Toxicological Profile for Radon to comprehensively evaluate its systemic toxicity and carcinogenicity. It features information from individual and pooled epidemiological studies of miner and residential cohorts to assess radon carcinogenicity. These studies largely accounted for smoking and arsenic as confounders. Crystalline silica and diesel exhaust carcinogenicity was not integrated into the miner assessments. Thus, radon carcinogenicity may have been overestimated in miners. Residential epidemiological studies of radon have assessed cancer risk addressing smoking as a confounder and suggested that lung cancer mortality in radon-exposed populations may be 25 times higher among smokers than never-smokers. It is not possible to avoid exposure to radon and its progeny since they are ubiquitous. For this reason, to limit potential health effects, EPA recommends keeping radon air level <4 pCi/L in residential settings. Diesel exhaust and other indoor chemicals/non-chemical stressors, including biologics, might enhance the health effects of residential radon and should be considered as part of any risk assessment. (The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of ATSDR.)

**PS 580 90-Day Inhalation Toxicity Study with Hydroprocessed Esters and Fatty Acids Jet Fuel from Camelina (HEFA-C) in Rats.**

K. L. Mumy<sup>1</sup>, W. R. Howard<sup>1</sup>, B. A. Wong<sup>1</sup> and D. R. Mattie<sup>2</sup>. <sup>1</sup>Naval Medical Research Unit - Dayton, Wright Patterson Air Force Base, OH; <sup>2</sup>711 HPWIRHDJ, Wright Patterson Air Force Base, OH.

The Department of Defense is actively pursuing the development of alternative fuels to augment or replace petroleum-based jet fuels. Towards these efforts, numerous synthetic and biologically-based fuels are currently under consideration for military use. Given the widespread use of fuels within the military, the health effects associated with occupational exposure to fuels remains a concern. Toxicity studies are being performed with the fuels in order to assess any possible health effects related to fuel exposure. Hydroprocessed Esters and Fatty Acids jet fuel (HEFA) is a type of hydrotreated renewable jet fuel currently under consideration. One specific type of HEFA is generated from oils extracted from the camelina plant (*Camelina sativa*; HEFA-C). In order to evaluate potential toxicity of HEFA-C, an *in vivo* 90-day whole body inhalation study was performed with the fuel (concentrations of 0, 200, 700 and 2000 mg/m<sup>3</sup> for 6h/day, 5 days/wk) using male and female Fischer 344 rats. Following exposure, a series of toxicity endpoints was evaluated, including food consumption and body weight, genotoxicity by micronucleus (MN) test, neurotoxicity and histopathology. There was no change in food consumption attributed to fuel exposure and the average body weight was found to slightly decrease (not statistically significant) in animals exposed to the high concentration. MN test was negative for evidence of genotoxicity. No significant effects were observed on clinical chemistry or hematology evaluations and no significant neurobehavioral effects were observed based on functional observational battery and motor activity tests. Minimal effects attributable to exposure to HEFA-C were observed with histopathology. These effects included goblet cell hyperplasia and olfactory epithelium degeneration at the highest concentration of exposure. These data will help guide the establishment of an occupational exposure limit for this alternative jet fuel.

**PS 581 Chemical Characterization of Complex Aromatic Flame Retardants for Toxicological Studies.**

R. Harris<sup>1</sup>, M. Kroenke<sup>1</sup>, J. Van Scoy<sup>1</sup>, Q. Lawrence<sup>1</sup>, B. O'Brien<sup>1</sup>, A. Ammenhauser<sup>1</sup>, L. Siemann<sup>1</sup>, K. Aillon<sup>1</sup>, J. Algaier<sup>1</sup>, B. Collins<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>MRIGlobal, Kansas City, MO; <sup>2</sup>National Toxicology Program NIEHS, Research Triangle Park, NC.

Aromatic phosphates (APs), which are replacing polybrominated diphenyl ethers as flame retardants, contain multiple isomeric forms and are formulated with other flame retardants in commercial products. Manufacturer and lot-to-lot variation add to the complex nature of AP products, making toxicity data interpretation difficult with respect to individual product components.

Six APs [triphenyl phosphate (TPP), tert-butylphenyl diphenyl phosphate (BPDP), tricresyl phosphate (TCP), 2-ethylhexyl diphenyl phosphate (EHDP), isodecyl diphenyl phosphate (IDDP), and phenol, isopropylated phenol phosphate (3:1) (IPP)] were nominated to the National Toxicology Program (NTP) for toxicity testing. MRIGlobal supported the NTP by performing chemical identity and purity studies on the selected chemicals.

GC/FID was used to separate components of each AP and GC/MS or NMR was used to identify components. TPP and EHDP were of low complexity. TPP contained a single component with chromatographic purity of 99.8% and no variation between 2 lots of a supplier. EHDP from 2 suppliers contained 3 components and had chromatographic purities of 98.5 and 97.4%. Both lots contained TPP at similar concentrations (1.5 vs. 2.5%). BPDP and TCP were considered to be moderately complex. A lot of BPDP contained 6 major components, identified as BPDP isomers and TPP. A lot of TCP contained 10 major components identified as TCP isomers and TPP. IDDP and IPP were considered highly complex with over 20 major components. Seven lots of IPP, from 5 vendors, contained TPP and 14 other major components identified as IPP isomers. Three IDDP lots from 3 vendors contained TPP and more than 30 components, identified as IDDP isomers or structurally similar analogs. Both IPP and IDDP demonstrated a high degree of lot-to-lot variability and large supplier differences.

**PS 582 Preparation of Toxicological Studies: Principal Component Analysis of Isopropylated Phenol Phosphate.**

J. Algaier<sup>1</sup>, M. Kroenke<sup>1</sup>, L. Lucas<sup>1</sup>, K. Bauer<sup>1</sup>, K. Aillon<sup>1</sup>, L. Siemann<sup>1</sup>, R. Harris<sup>1</sup>, B. Collins<sup>2</sup> and S. Waidyanatha<sup>2</sup>. <sup>1</sup>MRIGlobal, Kansas City, MO; <sup>2</sup>National Toxicology Program, NIEHS, Research Triangle Park, NC.

Phenol, isopropylated Phosphate (3:1), IPP, is one of many multi-component aryl phosphate flame retardants also used as plasticizers in products such as polyurethanes, textile coatings, and paints. Due to potential consumer exposure and the lack of adequate toxicity data, IPP has been selected for evaluation by the National Toxicology Program (NTP). MRIGlobal supported the NTP by procuring seven different IPP lots from five suppliers and chemically characterizing the material. IPP characterization will not only inform the NTP of the material's complexity, but may allow for source identification of IPP used in product mixtures.

Each IPP lot was analyzed and chromatographically fingerprinted following the development of a gas chromatographic/flame ionization detection method. Each lot contained 25 to 30 components pointing towards the existence of mono- bis- or tris-isopropylated phenyl groups and multiple positional isomers. With this many component peaks, simple chromatographic overlays do not allow for complex data evaluation and understanding of the dynamic nature of these lots.

To achieve a better understanding of IPP component complexity Principal Component Analysis (PCA) was performed. PCA, a common multivariate statistical technique for finding patterns in data of high dimension, was used to find potential groupings with respect to suppliers in the dataset generated for 11 key IPP chromatographic components in 48 sample runs of 7 lots from 5 suppliers. Of the 11 possible principal components, the first 2 explained 56% and the first 3 explained 75% of the total variance in the data. A 3-D plot of the data clearly demonstrated supplier grouping, enabling identification of specific suppliers. Commercial products may now be compared to these fingerprints for possible source identification.

**PS 583 The Effects of Atrazine Exposure on Genome Wide Expression Levels in Male *Drosophila melanogaster*.**

M. Xie<sup>1</sup>, J. Walters<sup>2</sup> and A. C. Fiumera<sup>1</sup>. <sup>1</sup>Biological Sciences, Binghamton University, Binghamton, NY; <sup>2</sup>Ecology and Evolutionary Biology, University of Kansas, Lawrence, KS. Sponsor: A. Fiumera.

Atrazine (2-chloro-4-ethylamino-6-isopropylamino-1,3,5-triazine) is one of the most commonly applied herbicides in the United States to control broad leaf and grassy weeds. Although beneficial in agriculture, atrazine can also be a potential environmental toxicant. It has been detected at low concentrations in surface water,

ground water and precipitation. In addition, many studies demonstrate that atrazine is a potent endocrine disruptor and affects a variety of reproductive traits in vertebrates, such as sperm number and motility, as well as, sperm capacitation. We are studying the effects of atrazine exposure on genome wide expression levels (RNA-seq) in the model genetic system, *Drosophila melanogaster*. Male flies were reared throughout their entire life cycle on either control food or food containing 20 ppm atrazine and flash frozen at 4 to 6 days old. Two biological replicates, each consisting of a pool of 40 flies, were prepared for each condition and were multiplexed in a single lane of an Illumina HiSeq2000, yielding at least 10 million reads per replicate. We used different combinations of read-counting procedures (HTseq, RSEM) and testing statistics (DEseq, baySeq) in all 4 possible combinations to determine differentially expressed genes. Twenty six genes that showed consistent expression differences (i.e. ranked in the top 50 significant genes of the different analyses) were analyzed using qRT-PCR (20 control and exposed replicates). Eleven of these 26 genes were significantly changed after 20 ppm atrazine exposure. Most of these genes are currently uncharacterized and have not been previously shown to be affected by environmental stressors. Future work will investigate how polymorphisms in these genes impact susceptibility.

**PS 584 Effects of Atrazine Exposure on Male Reproductive Performance in *Drosophila melanogaster*.**

A. R. Vogel and A. C. Fiumera. *Biological Sciences, Binghamton University, Vestal, NY.* Sponsor: A. Fiumera.

Atrazine is the one of the most commonly applied herbicides in the United States. In a variety of vertebrate classes, atrazine can feminize males and reduce their reproductive performance, likely through its effects on aromatase. Much less is known, however, about the effects of atrazine on invertebrates. In this study, we investigate the effects of larval atrazine exposure (4 ecologically relevant concentrations and unexposed controls) on reproductive performance of adult male *Drosophila melanogaster*. We scored male mating rate when mating to virgins (mating rate) and previously mated females (remating rate), as well as, a male's ability to prevent the female from remating (refractoriness). We also scored measures of male induced female fertility, including egg laying rate and total progeny production. Atrazine exposure significantly negatively affected male mating rate ( $p = 0.010$ ), male induced egg laying rate ( $p = 0.001$ ) and total progeny production ( $p = 0.012$ ). It had no effect on refractoriness. In general, we observed non-monotonic responses such that the intermediate exposure levels showed the largest reduction in male reproductive performance. For example, male remating rate was reduced between the unexposed controls and individuals reared on food with 2 ppM atrazine ( $p < 0.05$ ) but not for flies reared on 20 ppM food. Ongoing work is investigating sperm sperm transfer, storage and utilization rates.

**PS 585 Effects of the Herbicide Trifluralin in HepG2 Cell Culture.**

M. F. Franco<sup>1</sup> and D. J. Dorta<sup>2</sup>. <sup>1</sup>Universidade de São Paulo (USP). Faculdade de Ciências Farmacêuticas de Ribeirão Preto (FCFRP), Ribeirão Preto, Brazil; <sup>2</sup>Departamento de Química, Universidade de São Paulo (USP). Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto (FFCLR), Ribeirão Preto, Brazil.

The emerging contaminants are a new category of xenobiotics widely distributed in the environment. These contaminants include pesticides, within them are the herbicides, a heterogeneous category of chemical products, designed to control weeds. Trifluralin ( $\alpha, \alpha, \alpha$  - trifluoro - 2,6 - dinitro - N,N - dipropyl - p - toluidine) is a herbicide used on many agronomic crops. The present study aimed to evaluate the cytotoxic effects of the Trifluralin in HepG2 cell culture through the assays of cell proliferation, cell viability and mitochondrial membrane potential. It was used concentrations of 1, 5, 10, 20, 50 and 100  $\mu$ M of trifluralin dissolved in dimethyl-sulfoxide. The time of exposure was 24, 48 and 72 hours. The assessment of cell proliferation was performed with the dye sulforhodamine B (SRB Assay), the test of cell viability was done using the dye bromide 3 - (4,5-dimethylthiazol-2-yl) -2,5 diphenyl tetrazolium (MTT Assay), and for the analysis of the mitochondrial membrane potential, cells were incubated with a solution tetramethylrhodamine methyl ester. All experiments were performed in triplicate. The ANOVA test was applied followed by Dunnett. The results of SRB assay at 24, 48 and 72 hours of exposure showed a significant difference from the control at concentrations of 50 and 100  $\mu$ M of trifluralin. Effects on the MTT assay and mitochondrial membrane potential showed a similar pattern, being significant from the control at the concentrations of 50 and 100  $\mu$ M of trifluralin. We can conclude that trifluralin affects the HepG2 cells by inhibiting cell proliferation and/or inducing cell death and disrupting mitochondrial membrane potential at concentrations of 50  $\mu$ M and higher. Further studies will be performed to better understand the effects of trifluralin on HepG2 cells.

**PS 586 Effect of p, p'-DDE on Adipogenesis and Macrophage Activation.**

L. Mangum<sup>1</sup>, G. E. Howell<sup>1,2</sup>, S. B. Pruett<sup>1</sup>, M. K. Ross<sup>1</sup> and J. E. Chambers<sup>1</sup>.  
<sup>1</sup>Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS; <sup>2</sup>Biological Sciences, Mississippi College, Clinton, MS.

There is evidence that exposure to organochlorine compounds, such as DDE, may contribute to dyslipidemia, obesity, and insulin resistance, a cluster of signs that comprise the metabolic syndrome. Obesity results from adipocyte hyperplasia and hypertrophy which leads to recruitment of immune cells to adipose tissue and eventually contributes to localized chronic low-grade inflammation and adipocyte dysfunction. This study investigated a potential COX-2 dependent mechanism by which DDE could modulate normal physiological function and facilitate an increased risk of developing metabolic syndrome following exposure. Murine (J774a.1) and human (THP-1) macrophage cell lines and murine preadipocytes (3T3-L1) were used to investigate the effects of DDE on inflammation and adipogenesis. Macrophage cell lines were exposed to DDE or a known COX inhibitor for 18 hr before treatment with an inflammatory challenge of lipopolysaccharide (LPS) or palmitic acid (PA). Cell culture supernatants were analyzed for the presence of prostaglandins PGE<sub>2</sub>, PGD<sub>2</sub>, PGF<sub>2α</sub>, arachidonic acid (AA), and thromboxane (TBX) and for proinflammatory cytokines, including tumor necrosis factor (TNFα). 3T3 preadipocytes were induced to differentiate to adipocytes using a sub-optimal differentiation cocktail in the presence of DDE or a COX-2 inhibitor, with or without TNFα, a known COX inducer and suppressor of adipogenesis. Mature adipocytes were analyzed for intracellular lipid accumulation by Oil Red O staining. Both DDE and COX inhibitors increased adipogenesis in a dose-dependent manner in all treatments. In macrophages, DDE exposure followed by LPS or PA challenge reduced secretion PGE<sub>2</sub>, PGF<sub>2α</sub>, and PGD<sub>2</sub> and caused a slight increase in secretion of TNFα over vehicle. COX enzymes have a complex role in both inflammation and adipogenesis, and these results suggest that DDE exposure may contribute to altered adipogenesis and increased inflammation, potentially through a COX-2 dependent mechanism.

**PS 587 Organophosphorus Pesticides Activate Mast Cells Ex Vivo and In Vivo.**

A. C. Grodzki and P. J. Lein. *Molecular Biosciences, University of California Davis, Davis, CA.*

Mast cells are immune cells involved in diverse inflammatory diseases and are best known for their critical role in allergic reactions and asthma. In asthma, mast cells are activated by the cross-linking of FcεRI (the high affinity IgE receptor) with antigen-specific IgE, but these cells can be activated via several additional mechanisms. We hypothesized that organophosphorus pesticides (OPs) can activate mast cells in an IgE-independent manner. OPs are known to modulate immune function at levels that do not cause significant inhibition of cholinesterases, and previous studies of total peritoneal cells exposed to the OP malathion *in vivo* suggested that at least this OP modulates primary macrophage functions as an indirect consequence of mast cell degranulation. To determine whether OPs can target mast cells directly, we evaluated cellular degranulation using morphologic criteria, and release of β-hexosaminidase, a marker for mast cell degranulation, in percoll gradient-purified and non-purified rat peritoneal and mesentery mast cells following exposure to OPs. Preliminary experiments indicated that *ex vivo* exposure to paraoxon induced significant mast cell degranulation within 1 h and increased release of β-hexosaminidase in a concentration dependent manner. *In vivo* treatment with parathion caused mast cell degranulation with increased β-hexosaminidase release in the peritoneal cavity. Therefore, the data suggests that parathion and paraoxon affect mast cell stability, provoking degranulation and consequent release of inflammatory mediators. Ongoing studies are exploring the action of other OPs, carbamates and pyrethrins on mast cells and evaluating the mechanism by which these pesticides affect mast cell integrity. This work was supported by funding from the National Institutes of Health (grant R01 ES017592 to P.JL) and a postdoctoral fellowship to ACGG (T32 HL007013).

**PS 588 Detection of Dichlorvos Targets in Hepatocytes.**

T. Bui-Nguyen<sup>1</sup>, W. Dennis<sup>2</sup>, J. A. Lewis<sup>2</sup> and D. A. Jackson<sup>2</sup>. <sup>1</sup>Oak Ridge Institute for Science and Education (ORISE), Frederick, MD; <sup>2</sup>US Army Center for Environmental Health Research, Frederick, MD.

Toxicity of dichlorvos (DDVP), an organophosphate (OP) pesticide, classically results from modification of the serine in the active sites of cholinesterases. However, DDVP also forms adducts on unrelated targets such as transferrin and albumin,

suggesting that DDVP causes cellular perturbation by modifying non-cholinesterase targets. Here, we identify novel DDVP-modified targets in lysates of a human hepatocyte-like cell line (HepaRG) in competitive pull-down experiments using DDVP and a biotin-linked organophosphorus compound (10-fluoroethoxyphosphinyl-N-biotinamidopentyldecanamide; FP-biotin), which competes with DDVP for similar binding sites. Using the competition assay and mass spectrometry, we show that DDVP forms adducts to six new target proteins, including Glyceraldehyde-3-Phosphate Dehydrogenase (GAPDH). We validated the results using purified GAPDH incubated with DDVP and found that GAPDH Tyr-314, a residue in the known active site, is modified by DDVP. GAPDH activity is inhibited in a concentration dependent manner in DDVP-treated HepaRG cells, suggesting that the modification directly inhibits the enzyme. These results may help explain the chronic metabolic effects of DDVP exposure.

Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the U.S. Army. The research described herein was sponsored by the USAMRMC and Military Operational Medicine Research Program. This research was supported in part by an appointment to the Postgraduate Research Participation Program at the U.S. Army Center for Environmental Health Research (USACEHR) administered by the Oak Ridge Institute for Science and Education through an interagency agreement between the U.S. Department of Energy and USACEHR.

**PS 589 Neonicotinoid Insecticides: Formaldehyde Generation As a Proposed Mechanism of Mouse-Specific Hepatotoxicity and Hepatocarcinogenicity of Thiamethoxam.**

T. Swenson and J. Casida. *Graduate Group in Molecular Toxicology, University of California Berkeley, Berkeley, CA.*

Thiamethoxam (TMX), one of the most important insecticides, is carcinogenic and hepatotoxic in mice but not in rats. Green *et al.* (*Toxicol. Sci.* **86**, 36-47, 2005) established that TMX is a much better substrate for mouse liver cytochrome P450s than the corresponding rat or human enzymes in forming desmethyl-TMX (dm-TMX), which is also hepatotoxic, and clothianidin (CLO), which is not hepatotoxic or carcinogenic. The present investigation examines the hypothesis that liberation of formaldehyde (HCHO) or an N-methylol intermediate during TMX and dm-TMX metabolism to CLO and dm-CLO, respectively, provides a molecular explanation for the mouse-specific toxicity. Mouse liver microsomes were compared to rat and human liver microsomes in the metabolism of the seven commercial neonicotinoids and dm-TMX in the presence or absence of the cofactor, NADPH. HCHO production was determined by derivatization with 2,4-dinitrophenylhydrazine and monitoring by HPLC while other TMX metabolites (dm-TMX, CLO and dm-CLO) were quantitated by LC/MS. TMX and dm-TMX yielded more HCHO than any of the six other commercial neonicotinoids and mouse microsomes gave much higher conversion than rat or human microsomes. HCHO or an N-methylol intermediate in TMX and dm-TMX metabolism is therefore the candidate reactive hepatotoxicant. The N-methylol intermediates are difficult to analyze because of their chemical instability. These results provide HCHO liberation as an alternative to the earlier explanation of TMX hepatotoxicity in which dm-TMX is the proposed reactive metabolite and its toxicity is exacerbated by dm-CLO inhibition of inducible nitric oxide synthase (iNOS) (Green *et al.*, 2005). Although the HCHO generation proposal versus the dm-TMX/iNOS inhibition hypothesis for TMX toxicity is not fully resolved, the mouse vs. rat vs. human comparison of TMX metabolism reconfirms that the rat (showing no carcinogenic effects) is the best risk assessment model for humans.

**PS 590 Chiral Pesticide Pharmacokinetics: A Range of Values.**

J. F. Kenneke<sup>1</sup>, S. A. Marchitti<sup>1</sup>, S. Rawat<sup>2</sup>, D. T. Chang<sup>3</sup>, C. M. Grulke<sup>3</sup>, C. S. Mazur<sup>1</sup> and M. R. Goldsmith<sup>3</sup>. <sup>1</sup>US EPA, Athens, GA; <sup>2</sup>Student Services Authority, Athens, GA; <sup>3</sup>US EPA, Research Triangle Park, NC.

Approximately 30% of pesticides are chiral and used as mixtures of two or more stereoisomers. In biological systems, these stereoisomers can exhibit significantly different pharmacokinetics (absorption, distribution, metabolism, and elimination). In spite of these differences, these "mixtures" are often treated as a single compound in exposure and hazard assessment. To evaluate the impact of pharmacokinetic differences on internal exposure (dose) estimates, we studied the stereoisomer-specific metabolism of twenty chiral 1,2,4-triazole fungicides in hepatic microsomes, hepatocytes, and purified cytochrome P450s (P450). Additionally, we measured the metabolism of the pure stereoisomers for three of the

fungicides. Studies indicated that CYP3A4 was a major metabolizing enzyme for a majority of the fungicides. In general, the stereoisomers of each fungicide (pure and in the fungicide mixture) exhibited significantly different clearance rates. With some compounds, one or more stereoisomers inhibited the clearance of the other stereoisomers. Results were consistent across genders. In an effort to explain the observed stereoisomer clearance rates, we utilized a directed ligand-based pharmacophore analysis to identify key ligand features. Triadimefon was the only fungicide that preferentially underwent stereoselective carbonyl reduction rather than P450-mediated oxidation. Reduction of the prochiral carbonyl produced four stereoisomers of triadimenol. Relative formation of the triadimenol stereoisomers varied among 16 vertebrate species; the individual triadimenol stereoisomers differentially inhibited CYP3A4 metabolism. These results suggest that treating a chiral pesticide as a single chemical rather than a mixture could introduce errors in risk assessment. Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

**PS 591 Alpha-Cypermethrin Metabolism and Exposure Assessment in Egyptian Agricultural Workers.**

S. T. Singleton<sup>1</sup>, J. B. Knaak<sup>1</sup>, L. Chi<sup>1</sup>, B. P. McGarrigle<sup>1</sup>, F. M. Farahat<sup>2</sup> and J. R. Olson<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, University at Buffalo, Buffalo, NY; <sup>2</sup>Menoufia University, Shibin el Kom, Egypt.

Pyrethroids are neurotoxic insecticides that exert their effects by prolonging the opening time of sodium channels and increase the duration of neuronal excitation. Alpha-cypermethrin (aCM) is derived from the 8-stereoisomer containing pyrethroid cypermethrin, and is one of the most common pyrethroids being used in agriculture throughout the world. Pyrethroids are extensively metabolized in the liver by both esterases and oxidative enzymes. In vitro metabolism assays with human liver microsomes and cytosol demonstrate that aCM undergoes metabolism to the detoxified metabolites, 3-phenoxybenzoic acid (3-PBA) and cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (cis-DCCA) in both liver fractions. Previous studies suggest that 3-PBA may be a general biomarker of human exposure to pyrethroids, while cis-DCCA is a specific biomarker of aCM. A sensitive GC-MS NCI method was developed and daily urinary cis-DCCA and 3-PBA concentrations were quantitated for Egyptian agriculture workers who were applying alpha-cypermethrin to cotton fields for up to 10 consecutive days. Both cis-DCCA and 3-PBA were detected in the urine of all workers and ranged from 0.07-17.7 µg/g creatinine and 0.5-19.7 µg/g creatinine, respectively. This study is the first to use these biomarkers to quantify occupational exposures to alpha-cypermethrin. The in vivo biomarker data and in vitro metabolism kinetic data will be useful in future efforts to model human exposures to alpha-cypermethrin. (This research was supported in part by U.S.EPA STAR grant R833454 and NIEHS R01 ES016308)

**PS 592 4'-OH-Deltamethrin Metabolite-Induced Changes in Oxidative Stress Biomarkers in SH-SY5Y Cells and Alleviation Effect of Melatonin.**

M. R. Martinez-Larrañaga, A. Romero, E. Ramos, V. Castellano, M. A. Martinez, I. Ares, M. Martinez and A. Anadon. *Toxicology & Pharmacology, Complutense University, Madrid, Spain.*

Oxidative damage has been recognized as one of the primary causes of subcellular toxicity pesticides. Studies on pyrethroid insecticides have also suggested a putative role for free radicals in the lipid peroxidation and other oxidative stress-mediated injuries. Although initially it was thought that metabolites of deltamethrin, a  $\alpha$ -cyano pyrethroid insecticide, should be less toxic than the parent compound, we studied the oxidative stress-inducing effect of both the oxidative metabolite 4'-OH-deltamethrin and the parent compound in SH-SY5Y neuroblastoma cells. Cell line SH-SY5Y was used by their vulnerability to the oxidative damage. Lipid peroxidation induced by deltamethrin and 4'-OH-deltamethrin with or without melatonin was evaluated. Intracellular malondialdehyde (MDA) production was quantified using a thiobarbituric acid reactive substance assay. Changes in nitric oxide (NO) production were measured indirectly as the accumulation of nitrites (the end-product of NO metabolism) in the medium using Griess assay. In the present study, the levels of both NO and lipid peroxides measured as MDA, which can lead to a loss of membrane structure and function, were found to be significantly increased in deltamethrin and 4'-OH-deltamethrin treated cells. Both deltamethrin (10 µM) and 4'-OH-deltamethrin (10 µM) induced a significant increase in MDA levels (3- and 3.5-fold above basal,  $p < 0.001$  respectively) as well as increased by 3.5- and 5-fold,  $p < 0.001$ , NO production. Our results also demonstrated that melatonin (1 µM) significantly reversed the effects of deltamethrin and 4'-OH-deltamethrin.

In the present in vitro study, it is demonstrated that the metabolite 4'-OH-deltamethrin, is more cytotoxic than the parent compound deltamethrin. This work was supported by projects Refs. GR35/10-A UCM-BSCH, S2009/AGR-1469 and Consolider-Ingenio CSD/2007/00063 (FUN-C-FOOD), Madrid, Spain.

**PS 593 Effect of Age on Plasma Protein Binding of Deltamethrin, Cis-Permethrin, and Trans-Permethrin in Rats.**

P. Sethi<sup>1</sup>, S. Muralidhara<sup>1</sup>, M. Amaraneni<sup>1</sup>, T. Mortuza<sup>1</sup>, C. Chen<sup>1</sup>, B. S. Cummings<sup>1</sup>, J. V. Bruckner<sup>1</sup>, N. Assaf<sup>2</sup>, D. Minnema<sup>3</sup> and C. A. White<sup>1</sup>. <sup>1</sup>Department of Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA; <sup>2</sup>Valent BioSciences, Libertyville, IL; <sup>3</sup>Syngenta Crop Protection, Greensboro, NC.

Plasma protein binding (PPB) can influence the toxicokinetics of highly-bound chemicals, by limiting the amount of compound free to reach target organs and sites of elimination. Because the influence of age on PPB of common pyrethroids is unclear, this study was undertaken to determine if binding of deltamethrin (DLM), cis-permethrin (CIS) or trans-permethrin (TRANS) changes during maturation. The PPB of DLM, CIS and TRANS was studied in plasma of 10-, 15-, 21- and 90-day-old (adult) rats. A solvent extraction method was developed to quantify the binding of these highly hydrophobic compounds to rat plasma (RP) proteins and lipoproteins. A 10-µl aliquot of 14C-DLM, -CIS or TRANS was mixed with 90 µl of plasma and cold compound yielding concentrations of 250-100,000 nM. Samples were incubated and shaken at 37°C for 3 hr. The unbound fraction was extracted with 200 µl of isooctane, the lipoprotein-bound fraction with 200 µl of octanol, and the albumin-bound fraction with 200 µl of acetonitrile. Samples were treated with 10 µl of a 0.64 M solution of sodium fluoride to inhibit carboxylesterases. The free fractions of DLM, CIS and TRANS were higher in 10-day-old RP ( $27.1 \pm 6.1$  to  $29.9 \pm 6.4$  %) than adult RP ( $19.2 \pm 1.5$  to  $21.3 \pm 2.1$  %). The fractions of DLM, CIS and TRANS bound to lipoproteins were slightly higher in the pre-weanlings, however the fractions bound to protein were substantially lower. In 15-day-old rats the free fraction and lipoprotein-bound fraction of DLM, CIS and TRANS decreased somewhat. At day 21, PPB reached adult levels. The lower PPB in pre-weanlings is consistent with lower total plasma protein levels. Their lower albumin levels appear to account for the relatively low protein binding of DLM, CIS and TRANS. (Supported by the Council for Advancement of Pyrethroid Human Risk Assessment)

**PS 594 Assessment of an In Vitro Human Dermal Absorption Database for Pesticide Formulations to Establish Scientifically-Based Default Dermal Absorption Values.**

M. Aggarwal<sup>1</sup>, A. Hueser<sup>2</sup>, C. Strupp<sup>3</sup>, C. Wiemann<sup>4</sup>, P. Fisher<sup>5</sup>, B. Parr-Dobrzanski<sup>6</sup>, M. Soufi<sup>7</sup> and R. Billington<sup>1</sup>. <sup>1</sup>Dow AgroSciences, Abingdon, United Kingdom; <sup>2</sup>Dr Knoll Consult GmbH, Leverkusen, Germany; <sup>3</sup>Feinchemie Schwebda GmbH, Kleines Wiesental, Germany; <sup>4</sup>BASF Oesterreich GmbH, Vienna, Austria; <sup>5</sup>Bayer CropScience, Sophia-Antipolis, France; <sup>6</sup>Syngenta, Bracknell, United Kingdom; <sup>7</sup>DuPont de Nemours (Deutschland) GmbH, New-Isenburg, Germany.

Dermal absorption (DA) values for plant protection products (PPP) are required as inputs to risk assessment models used in the EU for assessing non-dietary risk for sprayers, workers, residents and bystanders. DA values are generated using undiluted PPP and representative field spray dilutions. The European Food Safety Authority (EFSA) published guidance on dermal absorption for PPP that includes highly conservative default DA values of 25% and 75% for undiluted PPP and field spray dilutions, respectively. Moreover, a default DA value of 75% applies to the undiluted PPP if it contains  $\leq 5\%$  active substance. To determine the validity of these default values, data from over 300 in vitro DA studies using human skin have been collected, collated and evaluated to establish the scientific validity of the default values and other endpoints. All studies that complied with the principles of OECD test guideline #428 were chosen for this analysis. These studies were performed on a wide range of formulation types and concentrations. The analysis was carried out considering two definitions of DA: (i) radioactivity present in receptor fluid and receptor chamber wash, plus skin minus the first two tape strips (i.e., worse-case definition) and (ii) radioactivity present in receptor fluid and receptor chamber wash plus skin minus stratum corneum (best-case definition). The analysis suggests that the default DA values for concentrate and spray dilution should not be more than 5% and 40%, respectively, considering the worse-case DA definition. Preliminary ranking for influence of formulation type on DA for undiluted PPP is EC = EW > SL = SE = SC > CS = solid formulations = FS. Data will also be presented on the influence of formulation types on DA for field spray dilutions.

**PS 595** **Determination of Pyrethroids in Rat Blood and Tissues Using Gas Chromatography (GC) Negative Chemical Ionization Mass Spectrometry.**

D. Gullick<sup>1</sup>, X. Wang<sup>1</sup>, J. V. Bruckner<sup>1</sup>, B. S. Cummings<sup>1</sup>, D. Minema<sup>2</sup>, M. Krolski<sup>3</sup> and M. G. Bartlett<sup>1</sup>. <sup>1</sup>PBS, University of Georgia, Athens, GA; <sup>2</sup>Syngenta Crop Protection, Greensboro, NC; <sup>3</sup>Bayer Crop Science, Research Triangle Park, NC.

Pyrethroids are the more stable synthetic structural analogues of naturally occurring pyrethrins, which are potent insecticides that exhibit low mammalian toxicity. A reproducible and sensitive bioanalytical method was developed to monitor the uptake and elimination of pyrethroids in plasma and tissues following oral dosing of rats as part of an approach to assess their risk to human health by physiologically based pharmacokinetic (PBPK) models. Blood and tissue homogenates (100 µL) were spiked with Deltamethrin, cis- or trans-permethrin. 1% phosphoric acid (100 µL) was added (to reduce binding of pyrethroids to proteins) and mixed. Internal standard (another pyrethroid) and 400 µL acetonitrile were added and mixed (to precipitate the proteins and extract the pyrethroids) and centrifuged. Supernatant (500 µL) was evaporated to dryness, reconstituted with toluene (300 µL), filtered (0.2 µm PTFE syringe filter), evaporated, and reconstituted with toluene (50 µL) for analysis. Samples were injected into an Agilent 6890 gas chromatograph using pulsed splitless injection onto a Zebtron® ZB5-MS capillary column eluting into a 5973 quadrupole mass analyzer in negative chemical ionization mode. Fragment ions were monitored using selected-ion monitoring for quantitation and verification of the analyte. The method was linear from 1 ng/mL to 1 µg/mL from tissues and blood. The limit of detection was 0.5 ng/mL, the limit of quantitation was 1 ng/mL, and the intraday precision and accuracy of the method were better than 15% across the linear range. Absolute recovery from blood and tissues was greater than 50%. The method was successfully used to monitor the uptake and elimination of pyrethroids in blood and tissues following oral dosing of rats. (Supported by the Council for the Advancement of Pyrethroid Human Risk Assessment).

**PS 596** **Toxicokinetics of Low Doses of the Pyrethroid, Deltamethrin (DLM), in Rats.**

C. Chen<sup>1</sup>, S. Muralidhara<sup>1</sup>, D. Gullick<sup>1</sup>, T. Mortuza<sup>1</sup>, M. Amaraneni<sup>1</sup>, P. Sethi<sup>1</sup>, D. W. Gammon<sup>2</sup>, S. S. Anand<sup>3</sup>, T. G. Osimitz<sup>4</sup>, C. A. White<sup>1</sup>, B. S. Cummings<sup>1</sup> and J. V. Bruckner<sup>1</sup>. <sup>1</sup>PBS, University of Georgia, Athens, GA; <sup>2</sup>FMC, Ewing, NJ; <sup>3</sup>DuPont Haskell, Newark, DE; <sup>4</sup>Science Strategies LLC, Charlottesville, VA.

Pyrethroid insecticides are the widely used to control a wide variety of pests in and around homes, in food handling establishments, in mosquito control, and in agriculture. Pre-weanling and weanling rats are much more sensitive to lethality from a single high dose of the Type II pyrethroids deltamethrin (DLM) and cypermethrin than are adult rats. The hypothesis is that this is due to the incomplete development of the detoxification enzymes in the young rats. No age-related sensitivity to lethality or acoustic startle response has been noted at low doses of DLM. Our hypothesis is that, despite immature detoxification enzymes, sufficient metabolic capability is present to readily eliminate low doses. The current work was conducted to generate low-dose DLM blood and tissue time-course data to test this hypothesis and to provide input to a physiologically based pharmacokinetic model. Time-courses for 0.1, 1 and 5 mg DLM/kg have been delineated in adult rats dosed orally with DLM in 1 or 5 ml corn oil/kg or in 1 ml glycerol formal/kg. Serial sacrifices of groups of 3–5 rats have been conducted at intervals from 15 min to 96 hr post-dosing to obtain blood, brain, and other tissue samples for GC-MS analysis. Dose-dependent increases in peak DLM blood and non-adipose tissue levels were manifest from 2 to 6 hr. The larger volume of corn oil resulted in a relatively broad peak or plateau in blood levels and a more gradual decrease over the monitoring period than with the low volume. Brain levels at comparable times were significantly lower with the larger dosing volume. A significant portion of each dose of DLM was sequestered in fat, with slow release resulting in prolonged elevation of blood levels and thus availability to other tissues. (Supported by the Council for the Advancement of Pyrethroid Human Risk Assessment)

**PS 597** **Dislodgeable Foliar Metabolites of Malathion and Fenpropathrin May Contribute to Aggregate Harvester Exposure Estimates Using Urine Biomonitoring.**

Y. Liu<sup>2</sup>, G. Sankaran<sup>1,2</sup>, L. T. Tang<sup>2</sup>, L. Chen<sup>2</sup>, A. Krieger<sup>2</sup>, J. H. Ross<sup>3</sup>, H. Vega<sup>2</sup> and R. Krieger<sup>1,2</sup>. <sup>1</sup>University of California Riverside, Riverside, CA; <sup>2</sup>University of California Riverside, Riverside, CA; <sup>3</sup>Gem Quality Risk, Inc., Carmichael, CA.

Parent insecticide residues dissipate on sprayed leaf surfaces and may yield derivatives used as biomarkers of exposure to the pesticide on foliar surfaces. It is imperative to determine if surface derivatives actually contribute to the apparent aggregate exposure of harvesters based upon urine biomonitoring. If pesticide derivatives that are potential urine biomarkers persist longer than the parent insecticide on treated plants and they are bioavailable, their absorption and excretion may confound harvester exposure reconstruction for risk assessment. Strawberry harvester exposures to malathion and fenpropathrin use were studied during July 2012 at Santa Maria, CA. Quantitative measurements of parent residues and corresponding biomarker residues on leaf surfaces determined using nitrile gloves worn by workers and 24 hr urine samples from harvesters (and matched controls with no occupational exposure) were conducted at specified intervals post malathion and fenpropathrin application on strawberry fields. Urine biomonitoring allows reconstruction of absorbed dose/day from all possible routes of pesticide and biomarker exposure using rapidly excreted urine biomarkers. Preliminary data show that when foliar malathion residue transferred to cotton cloths (µg/cm<sup>2</sup>; 0.238 to 0.027) and harvester gloves (µg/pair; 13944 to 3435) declined by 90% and 75% respectively in the 3d between the first picking and the second picking; corresponding malathion transferred foliar biomarkers dropped only by 16% and 11%, respectively. These data suggest surface derivatives last longer than parent residues on foliar surfaces. Structurally similar derivatives are dermally absorbed and this may explain why biomonitoring historically has indicated exposure to parent long after the parent has dissipated.

**PS 598** **Soil Concentrations and Human Exposures to Contaminated Soil in the Remote First Nation Community of Fort Albany, Ontario, Canada.**

E. N. Liberda<sup>1</sup>, E. S. Reyes<sup>1</sup> and L. J. Tsuji<sup>2</sup>. <sup>1</sup>School of Occupational and Public Health, Ryerson University, Toronto, ON, Canada; <sup>2</sup>Department of Environment and Resource Studies, University of Waterloo, Waterloo, ON, Canada.

A study was conducted in the James Bay Region of Ontario, Canada to examine the concentration of dichlorodiphenyltrichloroethane and metabolites (o,p'-DDE, p,p'-DDE, o,p'-DDD, p,p'-DDD, o,p'-DDT, p,p'-DDT, and ΣDDT) in potentially contaminated soil sites, and to assess the exposure pathways to ΣDDT by comparing the estimated daily intake (EDI) to acceptable daily intake (ADI) values. The contaminated soil plots were analyzed by a gas chromatograph equipped with a 63Ni electron capture detector (GC/ECD) or by gas chromatography with a mass spectrometer as a detector (GC/MS). The samples were first extracted using a Soxhlet apparatus with dichloromethane as the solvent and sample cleanup was applied using a Florisil extraction column. The mean ΣDDT found in the soil plots were distributed irregularly with values ranging from not detected to 4.19 mg/kg. From the soil plots analyzed, Plot A had the highest ΣDDT concentration of 1.12 mg/kg, followed by Plot B and Plot C which were 0.09 mg/kg and 0.01 mg/kg, respectively. The exposure analysis showed that the risks to humans was below governmental guidelines, even though the DDT concentration in the soil was above Canada's soil guidelines of 0.7 mg/kg as set by the Canadian Council of Ministers of the Environment. The DDT concentration in Plot A breached maximum levels, therefore this land cannot not be used for agricultural as planned nor for recreational purposes. However, both Plots B and C were below maximum threshold limits, and this land may be used to grow safe food resources.

**PS 599** **Effect of Soil Fumigation with Methyl Bromide against Earthworm, *Aporrectodea caliginosa*.**

N. S. Ahmed, S. S. Desouky, A. H. Elsebae and S. S. Soliman. *Pesticide Chemistry, Alexandria University, Alexandria, Egypt.*

Methyl bromide, MBr, is a soil and food commodity fumigant that is used to control most kind of pests that born from or affect them, respectively. Earthworms, *Aporrectodea caliginosa*, are very important for healthy and productive soil. Although, MBr has been added to the list of chemicals that deplete the ozone layer (Montreal Protocol), its use still allowed under several condition worldwide. Effect of MBr against earthworm was investigated in this study. Worms were exposed to one fumigation level of 30 gm/m<sup>2</sup> where worms were distributed in several depths

of the used soil. Mortality and some biochemical effects in the exposed worms compared to control were measured at 24, 48, and 72 hours after exposure. MBr at the tested level caused 100% mortality in worms crawling at 10 and 30 cm depth in all tested intervals. At the 50 cm depth, mortality rates were 80, 90, and 90 percent at the 24, 48, and 72 hours after exposure, respectively. The effect of MBr against protein content of earthworm crawling at the 50 cm depth was measured. Results showed that, after 24, 48 hours, the protein content increased significantly. There was no significant difference after 72 h of exposure in protein content between exposed worms and the control. Effect of MBr at the tested level on the activities of earthworms glutathione-S-transferases, GS-T; acetylcholinesterase, AChE; and cellulase were also determined in worms crawling at the 50 cm depth. Results showed only slight significant increase in AChE activity at 24 and 48 hours after exposure relative to control. MBr at the tested level caused significant increase in GS-T activity of the exposed earthworm at all tested exposure intervals. On the other hand, there was a significant increase in cellulase activity after 24 h as compared to control. However, this difference disappeared at 48 and 72 hours following exposure. These results indicate that MBr is a very potent soil fumigants that also kill the beneficiary earthworms in soil and protection of earthworms must be taken into consideration while searching for alternative to MBr.

## PS 600 Mechanism of Paraquat-Induced Pulmonary Fibrosis and Intervention of Pyrrolidine Dithiocarbamate.

M. Huang<sup>1,2</sup>, P. Zhang<sup>3</sup>, X. Chang<sup>2</sup>, Q. Wu<sup>2</sup> and Z. Zhou<sup>2</sup>. <sup>1</sup>Occupational Health Science, Ningxia Medical University, Yinchuan, China; <sup>2</sup>Occupational Health Science and Toxicology, Fudan University, Shanghai, China; <sup>3</sup>Occupational Health, Centers for Disease Control and Prevention of Jiading, Shanghai, China.

The mechanism of Paraquat-induced pulmonary fibrosis and potential therapeutic effect of pyrrolidine dithiocarbamate (PDTC) were studied. Male SD rats were divided into control group (0.9% NaCl, gavage), PDTC group (100mg/kg, ip), PQ (80mg/kg, gavage) group and PQ+PDTC (100mg/kg, ip) group. On the 1st, 3rd, 7th, 14th, 28th and 56th day after treatment, The expressions of connective tissue growth factor (CTGF) and  $\alpha$  smooth muscle actin ( $\alpha$ -SMA) in lung tissues were measured. The mRNA levels of CTGF, Fn, Col I, Col III and integrin  $\alpha 5$  were analyzed with quantitative RT-PCR. Meanwhile, the lung pathological changes were observed and the content of Hydroxyproline (Hyp) was measured. The expression of CTGF in PQ group increased gradually compared with control group ( $P < 0.05$ ). CTGF mRNA level significantly increased from the 1 st to the 14 th day compared with control group ( $P < 0.05$ ). PQ significantly increased Fn mRNA level on all time points and integrin  $\alpha 5$  mRNA level from the 3 rd to 56 th day compared with control group ( $P < 0.05$ ). Col I mRNA level significantly increased from the 7 th to the 56 th day and Col III mRNA level appears to be decreased from the 14 th to the 56 th day. PDTC treatment significantly decreased the levels of those factors compared with PQ group in corresponding time points ( $P < 0.05$ ). Noteworthy, PDTC strongly attenuated histopathological changes and decreased the content of Hyp. These results suggested that CTGF plays a key role in paraquat-induced pulmonary fibrosis, which is characterized by increased Fn, integrin  $\alpha 5$ , Col I and Col III mRNA levels. PDTC may inhibit NF- $\kappa$ B activity and further significantly decrease expressions of CTGF leading to drastically attenuated pulmonary fibrosis. However, the mechanisms of PDTC intervention still remain to be explored.

## PS 601 Testicular Toxicity of Fluorochloridone in Adult Sprague-Dawley Rats.

L. Xu<sup>2,1</sup>, Z. Zhou<sup>2</sup>, Q. Zhao<sup>2</sup>, D. Lou<sup>2</sup>, X. Chang<sup>2</sup>, P. Xiao<sup>3</sup>, X. Hong<sup>3</sup> and X. Yu<sup>1</sup>. <sup>1</sup>Department of Environmental Health Science, University of Georgia, Athens, GA; <sup>2</sup>School of Public Health, Fudan University, Shanghai, China; <sup>3</sup>Shanghai Municipal Center for Disease Control & Prevention, Shanghai, China.

Fluorochloridone (FC) a widely used herbicide in Europe and the US, has been recognized as a potential reproductive and developmental toxicant. However, there is little data available concerning its male reproductive toxicity. In this study, we examined the testicular toxicity of FC in SD male rats. Adult rats were treated by gavage with FC at doses of 0, 30, 150, 750 mg/kg/d for four weeks. FC exposure resulted in a decrease in the absolute and relative weight of testes and a decrease in the absolute weight of epididymides as compared with the control. Cauda epididymal sperm count decreased dramatically in a dose-dependent manner. In addition, histological lesions were also found in the testes of the treated animals. A dose-effect (response) relationship analysis suggested that changes in cauda epididymal sperm count and testicular histological structure could be the most sensitive indicators for FC induced testicular toxicity.

## PS 602 Carbofuran Is Not an Endocrine Disruptor—Weight-of-Evidence of US EPA's Tier 1 Endocrine Disruptor Screening Program Assays and Higher Tier Studies.

D. W. Gammon, B. Sharma, S. Longacre, G. Mitchell, S. Mukhi, M. Oh and Z. Liu. APG, FMC Corp, Ewing, NJ.

Carbofuran, the active ingredient in FMC Corporation's FURADAN® Insecticide/ Nematicide products, underwent testing in EPA's Tier I endocrine disruption screening program (EDSP), as required for all US registered pesticide active ingredients, to assess whether carbofuran had the potential to interact with endocrine systems. Nine of the eleven carbofuran Tier 1 EDSP assays showed no potential to interact with endocrine systems. The slight increase in estradiol in the in vitro steroidogenesis assay, and the mild to moderate thyroid hypertrophy and mild thyroid hyperplasia in the amphibian metamorphosis assay observed with relatively high carbofuran concentrations were not corroborated by any of the other assays. Only the highest concentration (100  $\mu$ M) was positive in the steroidogenesis assay, several orders higher than the concentration required for AChE inhibition. Previously conducted higher tier in vivo carbofuran developmental, reproductive and chronic toxicity studies showed no endocrine-mediated effects. The overall lack of effects in the carbofuran Tier 1 EDSP assays is consistent with the lack of endocrine-mediated effects in the previously conducted carbofuran higher tier in vivo studies. The collective results of the carbofuran Tier 1 EDSP assays and previously conducted higher tier in vivo studies indicate carbofuran is not an endocrine disruptor, and that there is no concern for endocrine effects resulting from the use of FURADAN® products according to label instructions.

## PS 603 Reproductive Outcomes in Women Para-Occupationally Exposed to Pesticides in an Agricultural Community in Southern Mexico.

G. López-Manzanero<sup>1</sup>, N. Pérez-Herrera<sup>1</sup>, L. Dzib-Cocom<sup>1,2</sup>, P. García-Molina<sup>1,2</sup>, M. Vera-Avilés<sup>1</sup>, T. Castillo-Burguete<sup>3</sup>, L. González-Navarrete<sup>1</sup>, J. Alvarado-Mejía<sup>1</sup>, B. Jiménez-Delgadillo<sup>1</sup>, J. Arias-León<sup>1</sup>, V. Suárez-Solis<sup>1</sup>, M. Cárdenas-Marrufo<sup>1</sup>, I. Vado-Solis<sup>1</sup>, C. Pérez-Osorio<sup>1</sup>, I. Hernández-Ochoa<sup>4</sup> and B. Quintanilla-Vega<sup>4</sup>. <sup>1</sup>Faculty of Medicine, Autonomous University of Yucatán, Mérida, Mexico; <sup>2</sup>Faculty of Chemistry, Autonomous University of Yucatán, Mérida, Mexico; <sup>3</sup>Human Ecology Department, CINVESTAV, Mérida, Mexico; <sup>4</sup>Toxicology Department, CINVESTAV, Mexico City, Mexico.

Epidemiological studies have shown that farmers are at high risk of developing adverse effects including reproductive problems. However, reproductive outcomes by para-occupational exposure to pesticides in wives of farmers are poorly documented. We reported reproductive alterations such as poor semen quality in farmers and spontaneous abortions and preterm birth in wives of agricultural workers mostly exposed to organophosphate pesticides (OP). Thus we evaluated the scenery of para-occupational pesticide exposure and its associated reproductive outcomes in wives of farmers. A transversal study was conducted in Yucatán, Mexico in wives of farmers exposed to pesticides (n=28) and wives of workers without pesticide exposure (n=45). Women donated a blood sample and responded a questionnaire. The TORCH profile was determined as potential confounders. General characteristic and TORCH profile were similar between two groups. Age at menarche was marginally lower in wives of farmers (11.5 $\pm$ 1.06 vs. 12.13 $\pm$ 1.56 years, p=0.07). Difficulty getting pregnant was more prevalent in wives of farmers (63 vs 13%, p=0.0003), preterm births were marginally more frequent in these women (7 vs 0%, p=0.07), and the birth weight of the first child was slightly lower in couples of farmers (2.94 $\pm$ 0.55 vs 3.16 $\pm$ 0.48 Kg, p=0.09). A complex scenery of pesticides exposure was observed, paraquat, glyphosate, 2,4-D amine, methamidophos and chlorpyrifos were among the most used pesticides. Results show that pesticide para-occupational exposure in wives of farmers may be involved with reproductive outcomes. Supported by PROMEP-SEP-México.

## PS 604 Extension of a Nasal Dosimetry Model for Acetaldehyde to Account for Vasodilation.

P. M. Schlosser<sup>1</sup>, M. H. Lumpkin<sup>2</sup> and J. B. Morris<sup>3</sup>. <sup>1</sup>NCEA, US EPA, Research Triangle Park, NC; <sup>2</sup>ENVIRON International Corporation, Atlanta, GA; <sup>3</sup>School of Pharmacy, University of Connecticut, Storrs, CT.

Acetaldehyde (AAld) is an important industrial chemical, used in manufacturing a wide range of products, but sources also include volcanoes, forest fires, biological waste degradation, and respiration by plants. Subchronic inhalation causes olfactory and nasal respiratory tissue degeneration in rats at  $\geq$  150 ppm and nasal tumors in both regions at  $\geq$  750 ppm. The toxicity of AAld is likely due to its metabolism to acetic acid in nasal tissues. A series of physiologically-based

pharmacokinetic (PBPK) models have been published which use results from computational fluid dynamics to specify regional airflow and air-phase transport resistance in the nose. Most recently, Teeguarden et al. (Inhal. Toxicol., 20:375-390, 2008) developed a version which included polymorphisms in human high-affinity acetaldehyde dehydrogenase (ALDH2). However, Stanek et al. (Inhal. Toxicol., 13:807-822, 2001) showed that AALD causes vasodilation, increasing uptake of acetone with co-exposure of the two. Vasodilation will also increase uptake of AALD. If this is not included in the model, the extent of metabolism estimated by fitting a PBPK model to nasal AALD uptake data could be over-predicted at concentrations where dilation is significant. Therefore we revised the PBPK model of Teeguarden et al. to include vasodilation (increases in nasal blood flow), with the amount of dilation estimated from the data of Stanek et al. using a parallel acetone PBPK model. An error in model code calculation of tissue phase mass transfer resistance was also corrected. The net result is an increase in the estimated  $V_{max}$  for ALDH2 and a dose-dependent change in total metabolism in rats: increased at lower concentrations where ALDH2 is not saturated, but decreased at 1500 ppm where vasodilation is significant. Quantifying the impact of this revision requires integration of model results with dose-response (i.e., benchmark dose) modeling. (Views expressed here are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.)

## PS 605 An In Silico Model of Spermatogenesis for Use in Predictive Toxicology.

A. M. Frame, M. C. Leung, T. B. Knudsen and R. Judson. *US EPA, Research Triangle Park, NC.*

EPA's toxicity reference database (ToxRefDB), covering 963 compounds tested in 4209 animal studies, indicated testicular atrophy as an adverse outcome for 278 (28.9 %) chemicals and reduced sperm quality or quantity for 72 (9.8 %) chemicals tested in chronic and subchronic rodent toxicity studies. The sensitivity of the male reproductive system, coupled with the biological complexity of testicular function and the large number of untested chemicals, motivates the need for predictive computational models of male reproductive function based on high-throughput screening (HTS) and in vitro data. Toward this end, we are building a virtual tissue model of the hypothalamic-pituitary-gonadal system (vHPG) that integrates computational approaches for kinetic modeling and dynamic simulation. As a proof of concept, we have constructed a multicellular agent-based model of the rat seminiferous tubule using CompuCell3D. The model integrates cell signaling networks for hormonal effects (FSH, testosterone), growth factor and cytokine stimulation (GDNF, TNF $\alpha$ , TGF $\beta$ , IL1 $\alpha$ ) and transcription factors (e.g. ERM, RhoX5, SOX8, WT1) responsible for regulating key events in the spermatogenic cycle. It also enables Sertoli cell interactions including cytoskeletal restructuring and protein secretion. To test our model, over 1900 chemicals associated with toxic effects on sperm were characterized for effects on spermatogenesis and mechanisms of action. We then identified chemicals targeting specific key aspects of spermatogenesis: cellular division (bleomycin, cisplatin, doxorubicin), cell/cell adhesion (adjudin, indenopyridines, indazole-3-carboxylic acid), and Sertoli cell death ( $\beta$ -benzene hexachloride), as well as putative endocrine disruptors (e.g. atrazine, bisphenol A, ketoconazole). Preliminary results indicate that the model responds appropriately, in terms of sperm production, to the disruption of key signaling events. This abstract does not necessarily reflect Agency policy.

## PS 606 Development of PBPK Models for Gasoline in Adult and Pregnant Rats and Their Fetuses.

S. A. Martin<sup>1</sup>, W. M. Oshiro<sup>1</sup>, P. A. Evansky<sup>1</sup>, J. Ford<sup>1</sup>, L. L. Degen<sup>1</sup>, H. A. El-Masri<sup>1</sup>, W. R. LeFevre<sup>1</sup>, E. D. McLanahan<sup>2</sup>, D. MacMillan<sup>1</sup>, W. K. Boyes<sup>1</sup> and P. J. Bushnell<sup>1</sup>. <sup>1</sup>National Health and Environmental Effects Research Laboratory, US EPA, Durham, NC; <sup>2</sup>National Center for Environmental Assessment, US EPA, Durham, NC.

Concern for potential developmental effects of exposure to gasoline-ethanol blends has grown along with their increased use in the US fuel supply. Physiologically-based pharmacokinetic (PBPK) models for these complex mixtures were developed to address dosimetric issues related to selection of exposure concentrations for in vivo toxicity studies. Sub-models for individual hydrocarbon (HC) constituents were first developed and calibrated with published literature or QSAR-derived data where available. Successfully calibrated sub-models for individual HCs were combined, assuming competitive metabolic inhibition in the liver, and a priori simulations of mixture interactions were performed. Blood HC concentration data were collected from exposed adult non-pregnant (NP) rats (9K ppm total HC vapor, 6h/day) to evaluate performance of the NP mixture model. This model was then converted to a pregnant (PG) rat mixture model using gestational growth equations that enabled a priori estimation of life-stage specific kinetic differences. To address the impact of changing relevant physiological parameters from NP to PG, the PG

mixture model was first calibrated using the NP data. The PG mixture model was then evaluated against data from PG rats that were subsequently exposed (9K ppm/6.33h gestation days (GD) 9-20). Overall, the mixture models adequately simulated concentrations of HCs in blood from single (NP) or repeated (PG) exposures (within ~2-3 fold of measured values of most HCs), indicating that the blood data from PG rats were not highly sensitive to PG-specific physiological parameters. This PG model will be used to estimate internal HC concentrations in the total fetus during in utero exposure to HC vapors. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

## PS 607 Strategy to Support Clearance Model of Inhaled Libby Amphibole Asbestos Fibers in Rat and Human Respiratory Tract.

B. Asgharian<sup>2</sup>, O. T. Price<sup>2</sup>, S. H. Gavett<sup>1</sup> and A. M. Jarabek<sup>1</sup>. <sup>1</sup>US EPA, Research Triangle Park, NC; <sup>2</sup>ARA, Inc., Raleigh, NC.

To characterize inhaled Libby amphibole (LA) asbestos fibers as retained dose (RD), we developed a strategy to integrate experimental data with compartmental modeling. Compartments extend our model structure for inhalability and deposition (Asgharian, 2012) to estimate RD in major respiratory tract (RT) regions (upper respiratory tract, URT; tracheobronchial, TB; and pulmonary, PU), pleural lining (PL), and lymph nodes (LN). The strategy provides data to derive 3 clearance mechanisms in the respiratory tract (RT): mucociliary (MC), translocation (TR), and dissolution (DS). Initial mass in each region is calculated using the deposition model verified with fiber burden data in the URT, trachea/larynx, 5 lung lobes and pleural casts in F344 rats from a 6-hr exposure of LA at 0, 3.5, or 25 mg/m<sup>3</sup>. MC rates of the URT and TB regions are estimated by refining published rate constants with fitting mass burdens measured in URT, TB, LN and PL compartments of a 5-d study in rats at those 3 concentrations with post-exposure time course (0-, 6-, 12-, and 24-hr). Burden data in rats from a 13-wk study at 0, 3.3, 1, and 10 mg/m<sup>3</sup> with post-exposure time course (1-d and 1-, 3- and 18-mo) refine TR rates from PU to TB, PL and LN compartments and evaluate overload. The initial DS rate is based on burden data from the URT coupled with in vitro data on DS of LA incubated with synthetic lung lining fluid. Data from in vitro incubation of LA with acid refine DS rate for TB and PU regions. This integrated strategy is the first to derive characterization of MC, TR and DS rates in the rat RT. For humans, DS rates were not scaled, published human MC rates are adjusted based on mass conservation (Asgharian et al., 2001), TR rates to PL and LN compartments are scaled on MC, and PU TR is scaled from the rat by an approach described for particles (Jarabek et al., 2005) based on regional surface area. (The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.)

## PS 608 A Modified PBPK Model for RDX (hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine) to Improve Rat to Human Toxicokinetic Extrapolation.

A. E. Loccisano<sup>1,3</sup>, R. S. DeWoskin<sup>2</sup>, P. M. Schlosser<sup>2</sup>, A. F. Sasso<sup>3</sup> and L. J. D'Amico<sup>3</sup>. <sup>1</sup>Oak Ridge Institute for Science & Education, Oak Ridge, TN; <sup>2</sup>ORD/NCEA, US EPA, Research Triangle Park, NC; <sup>3</sup>ORD/NCEA-IRIS, US EPA, Washington DC.

RDX is a military explosive that has been detected in air, soil, and ground water at or near military bases and munitions plants and storage facilities. Studies in rats provide evidence of mortality, reproductive toxicity, and neurotoxicity associated with RDX exposure. Physiologically-based pharmacokinetic (PBPK) models can aid in interpreting toxicological data and extrapolations across dose, species and exposure routes. Presented here is the further development and application of an RDX PBPK model for rats and humans originally published by Sweeney et al. (Regul. Toxicol. Pharmacol., 2012 v. 72, p. 107-114). The differences in the GI tract submodel and absorption parameters for different formulations of RDX in the Sweeney model are problematic for risk assessment because there is no rationale or predictability to the changes. Modifications to the model include a consistent submodel for the GI tract, a consistent set of absorption parameters to simulate oral exposures to RDX, and oral absorption rate constants keyed to different formulations of administered RDX per the kinetic data in the literature. Model code was also added to simulate drinking water and inhalation exposures relevant to human chronic exposures. The resulting model simulations are consistent with observed differences in the time course blood level data from a variety of PK studies, RDX formulations, and dosing regimens. Blood concentrations of RDX did not differ considerably when simulating inhalation exposure as compared to oral exposure. Model fits to rat data resulting from a subchronic drinking water exposure demonstrated achievement of steady state levels, lack of metabolic induction over time

from repeated doses, and the utility of the modified RDX model for use in estimating and extrapolating blood levels following repeated exposure. [The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.]

**PS 609** **Developing New Methods to Measure Reactive Oxygen Species Related to Aerosol Components.**

W. Huynh<sup>1</sup>, E. Browne<sup>2</sup> and R. E. Peltier<sup>1</sup>. <sup>1</sup>Public Health - Environmental Health Sciences, University of Massachusetts Amherst, Amherst, MA; <sup>2</sup>Veterinary & Animal Sciences, University of Massachusetts Amherst, Amherst, MA.

Reactive oxygen species (ROS) have been shown to be an important indicator of adverse toxicological effects and has been widely studied in the context of ambient air pollution exposure research. ROS is formed *in vivo* as a result of exposure to ambient air pollutants and is thought to be a convenient approach to understanding responses arising from air pollution exposures. Current methods of measurement for ROS typically follow a labor-intensive and time-consuming method of collection and extraction of particles from the field, which are then introduced (often at very high concentrations) *in vitro*. The objectives of this research are to streamline these approaches by developing and characterizing a new instrument capable of automated, semi continuous quantification of ROS. The work presented here attempts to fill this gap by repeatedly inducing reactive oxygen on plated immortalized pulmonary epithelial cells (BEAS-2B) which have been loaded with 2',7'-dichlorofluorescein diacetate (DCFH-DA). The data presented here are based on a method using 96-well plates and standard fluorescent spectrometry methods. These results are compared with similar approaches using a system of horseradish peroxidase and DCFH-DA. Tested elements include micromolar concentrations of hydrogen peroxide, solutions of ammonium sulfate and nitric acid, and quinones. We show that, with notable limitations, plated cells can respond to repeated dosing of simulated air pollution, suggesting that this method is suitable for further instrument method development.

**PS 610** **Designing Quantitative Structure Activity Relationships (QSAR) to Predict Specific Toxic Endpoints for Polybrominated Diphenyl Ethers (PBDE) in Mammalian Cell Culture Systems.**

S. Rawat<sup>1,2</sup> and E. D. Bruce<sup>2,3</sup>. <sup>1</sup>US EPA, Athens, GA; <sup>2</sup>Department of Environmental Science, Baylor University, WACO, TX; <sup>3</sup>Department of Civil Engineering, Texas A&M University, College Station, TX.

Polybrominated diphenyl ethers (PBDEs) are flame retardants that have had vast industrial application in consumer products, such as plastics, building materials, electronics and textiles. They are structurally similar to thyroid hormones that are responsible for regulating metabolism in the body. Therefore, PBDEs compete for the thyroid hormone binding receptors and this can adversely affect thyroid hormone transport and metabolism. Due to their potential threat to human health, this study aimed to design Quantitative Structure Activity Relationship (QSAR) models for predicting specific toxic endpoints, namely, cell viability and apoptosis. Human hepatocarcinoma (Hep G2) cells were exposed to PBDEs and were used as a model system to evaluate cell viability using Janus Green dye and apoptosis using a caspase assay. Data collected from the experiments were used to create QSAR models using the Genetic Function Approximation (GFA) method of generating predictive models. Cell viability and apoptosis responses elicited by the PBDEs were successfully modeled with an  $r^2$  of 0.97 and 0.94 respectively. Van der Waal's surface area and Gasteiger charges were found to be the important properties that characterize cell viability. Molar refractivity, Kappa-3, and VSA\_PartialCharge figured as the most appropriate descriptors to characterize apoptosis.

**PS 611** **A Preliminary Physiologically-Based Pharmacokinetic (PBPK) Model of Squalene in Vaccines.**

M. A. Tegenge and R. J. Mirkus. CBER, US FDA, Rockville, MD.

Adjuvants are often added to vaccine formulations to potentiate the immune response to antigen. Aluminum salts are the oldest and most widely used adjuvants; however, in recent years, oil-in-water emulsion adjuvants have emerged as alternative adjuvant systems. Two emulsion adjuvants, MF59® and ASO3®, for example, have been developed commercially using the triterpene oil, squalene. Although

squalene is a natural component of the diet and an endogenous precursor of cholesterol, its fate following intramuscular (IM) injection as a vaccine adjuvant constituent is not fully understood. In the absence of experimental pharmacokinetic data in humans, we constructed a whole body physiologically based pharmacokinetic (PBPK) model for intramuscularly injected squalene-in-water emulsion in adults. Based on published information, we assumed a mean diameter of 160 nm for the emulsion and stabilization by nonionic surfactants. Hence, preferential uptake into the lymphatics, rather than the blood, would be expected following IM injection. Tissue-blood partition coefficients for squalene were estimated by an algorithm approach that considered its binding potential to neutral lipids and lipoproteins. Physiological and biochemical parameters were obtained from standard sources in the published literature. The results of our modeling indicate that intramuscular squalene emulsion will transfer from the site of injection into the lymphatics rapidly and will be essentially cleared from the deltoid muscle in two days. The major proportion of the injected squalene was predicted to distribute to the draining lymph nodes and accumulate in distal adipose tissues. Our model indicated slow clearance from the latter compartment most likely because of partitioning into neutral lipids and a low rate of squalene biotransformation there. However, the predicted contribution of administered squalene was still only ~0.1% of the endogenous pool of squalene in adipose tissue. In conclusion, our results provide important pharmacokinetic information that may help to explain the pharmacodynamic activity of a new class of vaccine adjuvants that contain squalene.

**PS 612** **A Model for Elucidating the Role of the Aryl Hydrocarbon Receptor in TCDD-Mediated IgM Suppression in Human B Cells.**

N. Kovalova<sup>1,2</sup>, M. Manzan<sup>2</sup>, R. B. Crawford<sup>2</sup> and N. E. Kaminski<sup>1,2</sup>. <sup>1</sup>Pharmacology/Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

The aryl hydrocarbon receptor (AHR) is a transcription factor mediating toxic effects of 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). The objective of the present study was to establish a human B cell model for elucidating the role of the AHR in TCDD-induced suppression of the IgM production by B cells. The SKW6.4 cell line used here is an Epstein-Barr virus-transformed, IgM-secreting human B cell line. Wild-type SKW 6.4 cells are AHR null. We have used a lentiviral transduction system to establish a SKW 6.4 cell line that stably expresses the human AHR cloned from hepatoma HepG2 (SKW E8). An expression vector was designed to produce an AHR-GFP fusion protein under the control of a doxycycline-inducible promoter. SKW E8 and HepG2 cells express similar levels of AHR mRNA, as determined by qRT-PCR. TCDD treatment significantly induced Cyp1B1 mRNA expression in SKW E8 but not in SKW 6.4 cells, indicating that the transduced AHR retained its transactivational activity. To assess the effects of TCDD on IgM secretion, increasing concentrations of TCDD were added to pokeweed mitogen (PWM) or lipopolysaccharide (LPS) activated SKW cell lines, induced IgM was measured by ELISA. IgM secretion by PWM- or LPS-stimulated SKW E8 but not SKW6.4 cells was suppressed by TCDD in a concentration-dependent manner. Further analysis of the TCDD-induced suppression of the IgM response in SKW E8 cells revealed that to suppress IgM production, TCDD must be added within the first 12 h post-LPS activation. A similar window of sensitivity for the TCDD-induced suppression of the IgM response was previously described in primary mouse B lymphocytes. We demonstrate that the introduced AHR is functional and induction of IgM production is suppressed by TCDD-treatment as shown in primary B cells. These results suggest that human SKW6.4 E8 cells represent a model for elucidation of the molecular mechanisms involving AHR signaling in IgM suppression.

**PS 613** **The Impact of Variation in Scaling Factors on the Estimation of Internal Dose Metrics: A Case Study Using Bromodichloromethane.**

E. M. Kenyon<sup>1</sup>, R. A. Pegram<sup>1</sup>, C. R. Eklund<sup>1</sup> and J. C. Lipscomb<sup>2</sup>. <sup>1</sup>ORD/NHEERL, US EPA, Durham, NC; <sup>2</sup>ORD/NCEA, US EPA, Cincinnati, OH.

Physiologically based pharmacokinetic (PBPK) models can include values for metabolic parameters extrapolated from *in vitro* metabolism studies using scaling factors such as mg of microsomal protein per gram of liver (MMPGL) and liver weight (LW). Variation in scaling factor values impacts metabolic rate parameter estimates ( $V_{max}$ ) and hence estimates of internal dose used in dose response analysis. The impact of variation in MMPGL and LW on estimates of internal dose was assessed using a human PBPK model for bromodichloromethane (BDCM). Internal dose metrics evaluated were area under the curve for blood BDCM (AUC), maximum concentration of BDCM in blood ( $C_{max}$ ) and amount metabolized in liver per

hour (AML) - for two exposure scenarios (single 0.25 liter drink of water or 10 minute shower) under typical (10 ppb) and plausible high level (50 ppb) water concentrations. MMPGL and LW (as a fraction of body weight) values used in the analysis reflect the range of values reported for adult humans. For each concentration, each dose metric was changed less than 5% for the showering scenario (inhalation and dermal exposure) because  $V_{max}$  for hepatic metabolism is not a very influential parameter for dose metrics related to blood concentration following low level exposures. In contrast, an 8-fold difference in  $C_{max}$  and AUC was observed for each oral exposure concentration, but AML was relatively unchanged. Sensitivity analysis for AUC for the oral exposure scenario revealed that MMPGL was the most influential parameter, followed closely by LW, with blood flow to the liver being moderately influential. This analysis demonstrates that variability in the scaling factors used for in vitro to in vivo extrapolation (IVIVE) of metabolic rate parameters can have a significant impact on estimates of internal dose metrics under environmentally relevant exposure scenarios. This indicates the need to evaluate both uncertainty and variability for scaling factors used for IVIVE. (This abstract does not necessarily reflect USEPA policy).

**PS 614 Kinetic Modeling Reveals the Roles of ROS Scavenging and DNA-Repair Processes in Shaping the Dose-Response Curve of  $KBrO_3$ -Induced-DNA Damage.**

D. J. Miller and M. A. Spassova. *National Center for Environmental Assessment, US EPA, Washington DC.* Sponsor: S. Vulimiri.

We have used kinetic modeling to investigate how DNA repair processes and scavengers of reactive oxygen species (ROS) can affect the dose-response shape of pro-oxidant induced DNA damage. We used as an example chemical  $KBrO_3$ , a water ozonation by-product and environmentally present pro-oxidant with genotoxic and carcinogenic effects. In our model,  $KBrO_3$  is activated via interaction with glutathione and forms reactive intermediates that directly interact with DNA to form 8-hydroxy-2-deoxyguanosine DNA adducts (8-OH-dG) – an effect convincingly established in literature. The single strand breaks (SSB) that can result from failed base-excision repair of these adducts were considered in the model as an effect downstream from 8-OH-dG. We previously demonstrated that in the presence of effective base-excision repair, 8-OH-dG can exhibit threshold-like dose-response dependence, while the downstream SSB can still exhibit a linear dose-response. We now further demonstrate that this result holds for a variety of model variants. In particular, we investigated how the presence of a scavenger of the bromate reactive intermediates affects the dose-response shape of 8-OH-dG and SSB. It has been shown that melatonin, a terminal antioxidant, inhibits  $KBrO_3$ -caused oxidative damage. Our modeling revealed that a single pulse exposure to  $KBrO_3$  in the presence of such a terminal scavenger can lead to a sublinear/threshold-like dependence of the response for both 8-OH-dG and SSB. However, sustained exposure to  $KBrO_3$  can lead to fast scavenger exhaustion, in which case the dose-response shapes for both endpoints are not substantially affected. The results are important to consider when forming conclusions on a chemical's toxicity based on the dose-response of early genotoxic events.

**PS 615 A Compartmental Pharmacokinetic (PK) Model for Bromate in F344 Rats.**

N. Kolisetty<sup>1</sup>, C. A. White<sup>1</sup>, R. J. Bull<sup>2</sup>, J. A. Cotruvo<sup>3</sup>, J. W. Fisher<sup>4</sup> and B. S. Cummings<sup>1</sup>. <sup>1</sup>Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA; <sup>2</sup>Mo Bull Consulting, Richland, WA; <sup>3</sup>Joseph Cotruvo & Assoc. LLC, Washington DC; <sup>4</sup>National Center for Toxicological Research, US FDA, Jefferson, AR.

Bromate ( $BrO_3^-$ ) is a toxic water disinfection by-product formed during ozonation of source water containing bromide ( $Br^-$ ). It is a proven animal and probable human carcinogen (group 2B). However,  $BrO_3^-$  pharmacokinetics (ADME) at low doses is not fully understood. To better understand  $BrO_3^-$  ADME, we developed a pharmacokinetic (PK) model based on the raw data from our recent publication (Bull et al. 2012). Based on goodness of fit, and the model diagnostics, a pharmacokinetic model fitted with individual animal data and weight-2 (1/Y<sup>2</sup>) weight scheme was chosen as a model of choice to describe  $BrO_3^-$  disposition in female F344 rats.  $BrO_3^-$  disposition after IV bolus was best described using a 1-compartmental pharmacokinetic model for doses up to 0.5 mg/kg; and by using a 2-compartmental pharmacokinetic model for doses of 1-2.5 mg/kg potassium bromate ( $KBrO_3$ ).  $BrO_3^-$  disposition was best described using a 1-compartmental model following its oral administration (0.5 to 20 mg/kg  $KBrO_3$ ) in female F344 rats. Analysis of  $BrO_3^-$  PK parameters following oral administration, suggested that  $BrO_3^-$  absorption occurs in a first order manner with a rate constant ( $K_a$ ) of ~0.16 min<sup>-1</sup>.  $BrO_3^-$  appears to undergo extensive first pass reduction, resulting in

bioavailability of ~19-25%. Approximately 90% of orally administered  $BrO_3^-$  is reduced to  $Br^-$  in the body, and the remaining  $BrO_3^-$  appears to be excreted from the body as  $BrO_3^-$  in the urine at 0.002 L/min/kg. In conclusion,  $BrO_3^-$  undergoes extensive reduction to  $Br^-$  in liver and blood following its oral administration in female F344 rats, which limits  $BrO_3^-$  distribution to the peripheral tissues to exert its toxic effects.

**PS 616 A Strategy for Developing a PBPK Model to Describe the Kinetics of Silver Nanoparticles.**

M. Yoon<sup>1</sup>, S. Sumner<sup>2</sup>, R. Snyder<sup>2</sup>, T. Fennell<sup>2</sup> and H. J. Clewell<sup>1</sup>. <sup>1</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>RTI International, Research Triangle Park, NC.

Our previous model for C60 was proposed as a general platform for PBPK modeling of engineered nanoparticles (NPs). Since the structure was based on biological mechanisms that govern NP disposition, the platform can be applied to other NPs by changing parameters to account for particle-to-particle variance in biological processes. In this study, the model was parameterized for silver (Ag) NPs using tissue concentration data collected in adult female SD rats after a single intravenous (IV) dose (1 mg/kg) of Ag NPs (20 or 110 nm) in water stabilized with polyvinyl pyrrolidone (PVP) or Ag acetate in PVP. Parameterization was based on size-dependent dissolution potential of Ag NPs under physiological conditions as well as generally applicable size-dependent endocytosis efficiency for particles. Due to the dissolution potential, a combination of two kinetic models, one for Ag NPs and the other for ionic forms of Ag was used. The model successfully simulated observed concentrations of total Ag in various tissues as well as in urine and feces after a single IV dose of Ag NPs. The model was then extrapolated to Ag NPs with other coating agents. The published data for tissue concentrations of total Ag in adult male Wistar rats after single or multiple (~0.1 mg/kg/day) IV administration of Ag NPs in phosphate buffer (20 or 110 nm) was simulated. For this evaluation, the impact of different coatings on Ag NPs stability in size, shape and surface properties was also considered in the parameterization. The current model captured the time courses of total Ag concentration in blood, liver, lung, spleen, and heart both for single and multiple exposures from this study. The overall success in extending the C60 model to Ag NPs demonstrated the applicability of our model structure, as a general platform, to other NPs when combined with nanoparticle-specific properties for the given material (This work was supported by NIEHS Award #U19ES019525, but solely expresses the view of the authors).

**PS 617 A Physiologically-Based Pharmacokinetic Model to Describe the Pharmacokinetic Disposition for Hexamethyldisiloxane, a Linear Volatile Methyl Siloxane, following Inhalation Exposures in the Rat.**

T. McMullin, J. Y. Domoradzki, D. A. McNett, J. Durham and K. P. Plorazke. *Health and Environmental Sciences, Dow Corning Corporation, Midland, MI.*

The purpose of this work was to expand a previously developed physiologically based pharmacokinetic (PBPK) model for hexamethyldisiloxane (HMDS) (Dobrev et al., 2003) with additional kinetic data to further examine the processes regulating the pharmacokinetic disposition of HMDS. Time-course concentrations of parent HMDS and total metabolites in multiple tissues, blood and exhaled breath in male and female F344 rats during and following nose only vapor inhalation exposure to 5000ppm 14C-HMDS were used to extend the model. A 15 day inhalation study was also conducted to understand impacts, if any, following repeated exposures. Based on similarities in physicochemical properties, the HMDS model structure was adapted from another volatile methylsiloxane (VMS) octamethylcyclotetrasiloxane (D4) model structure (Andersen et al., 2001). This updated model now includes saturable metabolism in the liver, a diffusion-limited uptake of HMDS in the fat compartment and a blood lipid pool where a fraction of HMDS is sequestered and unavailable for exchange into blood and exhalation from the lung. HMDS and its metabolites in blood, liver, lung, fat and exhaled breath following both single and multiple exposures are well described with this model using a single set of parameters. Consistent with D4 kinetic behavior, low blood:air partitioning and extensive metabolism lead to rapid clearance of free HMDS from the body following both single and repeated exposures. Despite retention of bound HMDS in tissues at the extended time points following exposure, the extensive and rapid clearance mechanisms of HMDS lead to tissue and exhaled breath concentrations of HMDS that are similar following both multiple day exposures and single exposures. This PBPK model is a starting point from which the pharmacokinetic disposition of HMDS and, upon extension, other linear VMSs, can be evaluated for risk assessment.

**PS 618 Use of a Physiologically-Based Pharmacokinetic Model to Simulate the Time Course of 3-Hydroxybenzo(a)Pyrene Metabolite in Workers Exposed to Polycyclic Aromatic Hydrocarbons and Predict Most Plausible Exposure Scenarios.**

R. Heredia-Ortiz<sup>1</sup>, A. Maitre<sup>2</sup> and M. Bouchard<sup>1</sup>. <sup>1</sup>Department Environmental and Occupational Health, University of Montréal, Montréal, QC, Canada; <sup>2</sup>CHU de Grenoble, Université Joseph Fourier, Grenoble, France.

Mathematical modeling has become an important tool to assess xenobiotic exposure in humans. In the present study, we have used a human physiologically-based pharmacokinetic (PBPK) model to reproduce the time-course of 3-hydroxybenzo(a)pyrene (3-OHBP) in the urine of industrially exposed workers and in turn predict most plausible exposure scenarios. Urinary voids from a dozen workers highly exposed to polycyclic aromatic hydrocarbons (PAHs) in the Rhone-Alpes region in France have been collected during a typical workweek (beginning and end-of-shift) and subsequent days off; urinary concentrations of 3-OHBP were then determined. Based on the information obtained for each worker (airborne BP concentration, daily shift hours, tasks, protective equipment), the time courses of 3-OHBP in the urine of the different workers have been simulated using the PBPK model, considering the various possible exposure routes, oral, dermal and inhalation, as well as combined exposure. The model was constructed from *in vivo* experimental data in rats and then extrapolated from animals to humans after assessing and adjusting most sensitive model parameters as well as species specific physiological parameters. The model was able to closely reproduce the observed time course of 3-OHBP and establish most plausible exposure route depending on the worker. It appears as a useful tool to better interpret biomonitoring data of PAH exposure on the basis of 3-OHBP biomarker levels.

**PS 619 Computational Modeling of the Pathway Linking Oxidant Exposure with a Fluorescent Reporter Protein in Human Airway Epithelial Cells.**

W. Cheng<sup>1</sup>, J. M. Samet<sup>2</sup> and R. B. Conolly<sup>3</sup>. <sup>1</sup>Environmental Science and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>EPHD, US EPA, Chapel Hill, NC; <sup>3</sup>ISTD, US EPA, Chapel Hill, NC.

Air pollution is one of the most common environmental exposures imposed on humans in urban areas on a daily basis. Mixtures of gaseous and particle pollutants contain hundreds of thousands of compounds with the potential for numerous interactions. Many pollutants operate through modes of action involving oxidative stress. We use the genetically engineered fluorescent reporter roGFP to assess oxidative stress in transformed human airway epithelial cells. The specific goal of current study was to develop a computational model of the biochemical pathway linking oxidant exposure with oxidation of roGFP. Models of this type can provide insights into the structure and kinetics of these pathways that complement the information obtained directly from the laboratory studies. As our initial effort at model development, we used live cell imaging to monitor roGFP oxidation by micromolar H<sub>2</sub>O<sub>2</sub>. roGFP was fully oxidized within 20 min and recovery to its reduced state took several hours. These kinetics were well described by the model. Furthermore, the model-based quantitative analysis has shown that the observed response for oxidation of roGFP is nonlinear with dose and consistent with Michaelis-Menten kinetics. These latter results reflect the underlying sequence of enzymatic reactions, e.g., glutathione peroxidase, glutaredoxin and glutathione reductase, through which the oxidizing effect of H<sub>2</sub>O<sub>2</sub> is transmitted to roGFP. These results illustrate how computational modeling of modes of action of oxidants can provide insights that complement laboratory observations and that will be needed as we seek to understand the health risks associated with air pollution exposures. This presentation reflects the views of the authors and does not necessarily reflect EPA policy.

**PS 620 Comparative Toxicokinetic and Toxicodynamic Study of Trichloroethylene and Tetrachloroethylene in the Mouse.**

V. Soldatow<sup>1</sup>, H. Yoo<sup>1</sup>, B. Wanda<sup>1</sup>, L. B. Collins<sup>1</sup>, S. Kim<sup>2</sup>, K. Xia<sup>1</sup>, W. Sun<sup>1</sup>, E. Wright<sup>1</sup>, W. A. Chiu<sup>1</sup>, K. Guyton<sup>3</sup> and I. Rusyn<sup>3</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>Seoul National University, Seoul, Republic of Korea; <sup>3</sup>NCEA, US EPA, Washington DC.

Trichloroethylene (TCE) and tetrachloroethylene (PCE) are ubiquitous environmental and occupational agents hazardous to human health. Several important gaps in our understanding of their potential toxicity have been identified: 1) extent of inter-individual variability in toxicity, 2) complexities associated with linking metabolites to specific organ toxicity, and 3) comparative analysis of toxicokinetics (TK) and toxicodynamics (TD) of these closely related agents. This project aimed

to fill these gaps by providing TK and TD data using a panel of mouse strains as a model for inter-individual variability. We focus on key metabolites of TCE and PCE: trichloroacetic acid (TCA), dichloroacetic acid (DCA), trichloroethanol (TCOH), S-(1,2,2-trichlorovinyl)-L-cysteine (TCVC), S-(1,2-dichlorovinyl)-L-cysteine (DCVC), and S-(1,2,2-trichlorovinyl)glutathione (TCVG), and S-(1,2-dichlorovinyl)glutathione (DCVG). In the TK and TD studies, a single oral dose of TCE or PCE (24-800 mg/kg or 30-1,000 mg/kg, respectively, in 5% Alkamuls EL-620 in saline) was administered to male mice from three strains (C57BL/6J, NZW/LacJ and B6C3F1/J). Quantification of metabolites (up to 36 hours post dosing) was performed in serum, liver, kidney, spleen, brain, lung, and bone marrow. In addition, RNA Sequencing was used to identify dose-response changes in gene expression in liver. These data are relevant for human health assessments of TCE and PCE as they provide data for kinetic modeling, dose-response analysis of the toxicity mechanisms, and evaluation of inter-individual differences in susceptibility to these chemicals. **PS 621 A Mechanistic Model of GABAA-Receptor Trafficking during Status Epilepticus.**

E. Merrill<sup>1</sup>, J. Gearhart<sup>1</sup>, C. Ruark<sup>1</sup>, D. A. Mahle<sup>2</sup> and P. Robinson<sup>1</sup>. <sup>1</sup>AFRL/RHDJ, Henry M. Jackson Foundation, Wright Patterson Air Force Base, OH; <sup>2</sup>Human Performance, AFRL/RHDJ, Wright Patterson Air Force Base, OH.

The efficacy of benzodiazepines (BZ) to abolish seizures diminishes rapidly with time after onset of status epilepticus (SE). This progressive loss of efficacy is associated with the rapid internalization of BZ-sensitive GABAA receptors, together with a slight increase in localization of BZ-insensitive GABAA receptors to the synaptic membrane. We developed a compartmental model of receptor localization and movement in the dendritic spine that includes surface receptors within the post-synaptic density (PSD), including those bound to gephyrin scaffold proteins, and the extrasynaptic membrane (ESM), as well as internalized receptors. The model includes movement of receptors between these compartments as well as receptor synthesis and degradation. The model was used to simulate receptor trafficking under normal (non-seizure) and status epilepticus conditions. Data from *in vitro* studies using various neuronal cell cultures as well as HEK cells modified to express GABAA receptors were used to parameterize and validate the model. Increases in receptor endocytosis rate and lateral movement from PSD to ESM (or a decrease in gephyrin binding) were found to be sufficient to simulate SE conditions. By integrating the current GABAA receptor trafficking model with a physiologically-based pharmacokinetic (PBPK) model for diazepam, a time-dependant therapeutic dose can be predicted. The model suggests that approximately 55% occupancy of the original receptor number is required to reverse ongoing seizures. This is up from a reported 37% occupancy required to prevent the initiation of seizures in the rat, when diazepam is administered as a prophylaxis.

**PS 622 Multichemical Bayesian Calibration of a Generic Physiologically-Based Pharmacokinetic (PBPK) Model to Calculate Biological Limit Values for Lipophilic Volatile Organic Compounds.**

R. McDougall<sup>1</sup>, M. Verner<sup>2,3</sup>, G. Charest-Tardif<sup>4</sup>, R. Tardif<sup>4</sup> and G. Johanson<sup>2</sup>. <sup>1</sup>Faculty of Engineering and Applied Science, University of Ontario Institute of Technology, Oshawa, ON, Canada; <sup>2</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; <sup>4</sup>Département de santé environnementale et santé au travail, Université de Montréal, Montréal, QC, Canada.

Biomonitoring provides an integrative measure of internal exposures in workers exposed to contaminants in the occupational setting. PBPK models validated against empirical data can be used to estimate the variability in biological levels following specific exposure conditions. Given the large array of contaminants in the workplace, the calibration of a generic PBPK model could be useful to generate biological limit values for chemical with little or no available human data. We aimed to develop a generic PBPK model for lipophilic volatile organic compounds (VOCs) in end-exhaled air, which can be obtained non-invasively, and to calibrate it using Markov Chain Monte Carlo (MCMC) techniques and human data from controlled exposures. We built a simple 3-compartment PBPK model (liver, adipose tissue and rest of the body) that runs on three chemical-specific parameters: intrinsic clearance and octanol:water and blood:air partition coefficients. Global sensitivity analysis was used to identify the most influential parameters on end-exhaled air

levels. MCMC analysis was employed to infer population and individual distributions for these significant parameters based on levels measured in 12 individuals exposed to styrene, n-hexane or toluene. The generic VOC PBPK model calibrated by MCMC analysis was able to predict end-exhaled air levels for the 12 individuals and 3 compounds. The chains from the converged MCMC runs will be used to derive distributions of end-exhaled air for given exposure scenarios. Our next steps will be to include more individuals, compounds and exposures scenarios with variable workloads to better describe variability in the population.

## PS 623 Development of a New 3D Human Small Intestinal Tissue Model.

S. Aychunie, Z. Stevens, T. Landry, P. Hayden and M. Klausner. *MatTek Corporation, Ashland, MA.*

The epithelial lining of the gastrointestinal (GI) tract is a gatekeeper for entry of orally ingested nutrients and xenobiotics including medications. The intestinal lining has a well organized structure containing proliferative cells which migrate along the crypt-villi axis and differentiate into functional mature epithelial cells. Currently, the most common in vitro model utilized for study of drug absorption at the intestinal mucosa is based on a 2-D cell culture model of the colon carcinoma cell line, Caco-2. These cells differentiate into monolayers of polarized enterocytes that are connected by tight junctions, but lack mucus-secreting goblet cells and show inter-passage inconsistency. Others have developed small intestinal organoids which are not suitable for apical application of test articles. Here, we report the reconstruction of a human organotypic small intestinal tissue (SI) generated from primary human SI epithelial cells that grow in tissue culture inserts using serum free medium. Human SI epithelial cells and myofibroblasts were expanded in monolayer culture and seeded on a microporous membrane containing a fibroblast-collagen-gel substrate to reconstruct three dimensional organotypic SI tissues. Tissue morphology and biomarker expression of the SI model were characterized by H&E staining and immunohistochemistry, respectively. Basal cell proliferation markers, cytokeratins (CK) and mucin were monitored over an 11-day culture period. Analysis of the SI tissue model revealed: 1) wall-to-wall growth of the epithelial layer, 2) columnar epithelial cell morphology similar to that of native SI tissue, 3) expression of muc-2, CK19, and villin at the surface of the epithelium, and 4) Lgr5+ (crypt stem cell marker) positive cells. In conclusion, the new human cell based 3D SI tissue model will likely serve as a valuable tool to evaluate pre-clinical therapeutic drug candidates intended for oral administration and study microbiomes and microbial infection of the GI tract.

## PS 624 Evaluating Dose-Response Parameters of an *In Vitro* DNA-Chemical Interaction Using a Mechanistic Biological Model.

A. Nong, K. Lyon, J. M. Gavina and Y. Feng. *Environmental Health Science and Research Bureau, Health Canada, Ottawa, ON, Canada.*

Benchmark dose modeling of genomic data is a trending approach in toxicity testing, and system biology modeling attempts to understand quantitative data in light of what we expect from more complex biological systems. Biological modeling approaches can incorporate different forms of kinetic and dynamic data of a chemical interaction in vitro. The objective of this effort was to interpret a biological model mechanism and parameters describing a chemical doubled stranded oligonucleotide interaction assay for a series of chemicals (tetrachlorohydroquinone, styrene-7,8-oxide, methyl methane sulfonate, phenyl glycidyl ether, and benzo(a)pyrene diol epoxide), with both time series and dose-ranged measurements. The chemicals have been analyzed with time series, dose-response and inhibition mixture response analysis. A model using mixed Michaelis-Menten kinetic and multiple binding was determined to be best suited with the data coherency between the biological and mathematical expectations. This was based on the results of the model, as well as the poorer results of other considered models (e.g. constant rate constants, linear rate constants, multi-step reactions, Hill functions). Correlations between coefficients and various chemicals, as well as sensitivity analysis, gave evidence of a deeper mechanism underlying nucleotide perturbations (e.g. relations amongst the half-life, dose and the curvature of the reactions). Two model parameters, molecular binding coefficient (range from 0.1 to 2.6) and nonlinear affinity rate constant (ranging from 30 to 5300  $\mu\text{M}$ ), were dose dependant and specific to each chemical. These kinetic parameters are suitable candidates for a quantitative structure-activity analysis with chemical descriptors for nucleotide binding sites and interaction efficacy as indicators of adduct formation. These biological models fit the biological expectations for the governing mechanisms, giving further evidence of the effectiveness of statistical and benchmark dose modeling in toxicity testing.

## PS 625 Developing Predictive Approaches to Characterize Adaptive Responses of the Reproductive Endocrine Axis to Aromatase Inhibition: Computational Modeling.

M. Breen<sup>1,2</sup>, D. L. Villeneuve<sup>3</sup>, G. T. Ankley<sup>3</sup>, D. Bencic<sup>4</sup>, M. S. Breen<sup>5</sup>, K. H. Watanabe<sup>6</sup>, A. L. Lloyd<sup>2</sup> and R. B. Conolly<sup>1</sup>. <sup>1</sup>ISTD, NHEERL, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Biomathematics Program, Department of Mathematics, NCSU, Raleigh, NC; <sup>3</sup>Mid-Continent Ecology Division, US EPA, Duluth, MN; <sup>4</sup>Ecological Exposure Research Division, US EPA, Cincinnati, OH; <sup>5</sup>NERL, US EPA, Research Triangle Park, NC; <sup>6</sup>Environmental and Biomolecular Systems, Oregon Health & Science University, Beaverton, OR.

Exposure to endocrine disrupting chemicals can affect reproduction and development in both humans and wildlife. We developed a mechanistic mathematical model of the hypothalamic-pituitary-gonadal (HPG) axis in female fathead minnows to predict dose-response and time-course (DRTC) behaviors for endocrine effects of a well-defined aromatase inhibitor, fadrozole (FAD). The model includes a regulatory feedback that mediates adaptive responses to endocrine stress by controlling the secretion of a generic gonadotropin (LH/FSH) from the hypothalamic-pituitary complex. Plasma 17 $\beta$ -estradiol (E2) and ovarian cytochrome P450 (CYP) 19A aromatase mRNA data from two time-course experiments, each of which included both an exposure and a depuration phase, and plasma E2 data from 4 days exposure experiment were used to develop and evaluate the model. Model parameters were estimated using E2 concentrations for 0, 0.5, and 3  $\mu\text{g/L}$  FAD concentrations, and good fits to these data were obtained. The model accurately predicted CYP19A mRNA fold changes for controls and three FAD doses (0, 0.5, or 3  $\mu\text{g/L}$ ), and venous E2 dose-response during FAD exposure on day 4. Comparing the model-predicted DRTC with experimental data provided insight into how the feedback control mechanisms embedded in the HPG axis mediate these changes: adaptive changes in plasma E2 levels occurring during exposure and "overshoot" occurring post-exposure. This study demonstrates the value of mechanistic computational modeling to examine and predict the possible dynamic behaviors. This abstract does not necessarily reflect US Environmental Protection Agency policy.

## PS 626 Mitochondrial Dysfunction-Induced by Sertraline, an Antidepressant Agent.

L. Couch<sup>1</sup>, Y. Li<sup>1</sup>, J. Fang<sup>1</sup>, M. Higuchi<sup>2</sup> and L. Guo<sup>1</sup>. <sup>1</sup>NCTR, US FDA, Jefferson, AR; <sup>2</sup>Department of Biochemistry and Molecular Biology, University of Arkansas for Medical Sciences, Little Rock, AR.

Sertraline, a selective serotonin reuptake inhibitor (SSRI), has been used for the treatment of depression. Although it is generally considered safe, cases of sertraline-associated liver injury have been documented; however, the possible mechanism of sertraline-associated hepatotoxicity is entirely unknown. Here we report that mitochondrial impairment may play an important role in liver injury induced by sertraline. In mitochondria isolated from rat liver, sertraline uncoupled mitochondrial oxidative phosphorylation and inhibited the activities of oxidative phosphorylation Complexes I and V. Additionally, sertraline induced Ca<sup>2+</sup>-mediated mitochondrial permeability transition (MPT), and the induction was prevented by bongkrekic acid, a specific MPT inhibitor targeting adenine nucleotide translocator (ANT), implying that the MPT induction is mediated by ANT. In freshly isolated rat primary hepatocytes, sertraline rapidly depleted cellular ATP and subsequently induced lactate dehydrogenase (LDH) leakage; both were attenuated by bongkrekic acid. Our results, including ATP depletion, induction of MPT, inhibition of mitochondrial respiration complexes, and uncoupling oxidative phosphorylation, indicate that sertraline-associated liver toxicity is possibly via mitochondrial dysfunction.

## PS 627 Mouse Liver Protein Sulfhydryl Depletion Induced by Acetaminophen Exposure.

X. Yang<sup>1</sup>, J. Greenhaw<sup>1</sup>, Q. Shi<sup>1</sup> and W. F. Salminen<sup>2</sup>. <sup>1</sup>Division of Systems Biology, US FDA, National Center for Toxicological Research, Jefferson, AR; <sup>2</sup>PAREXEL, Benton, AR.

Since Acetaminophen (APAP) remains the leading cause of acute liver failure in the western world, a large body of research has been conducted to understand the mechanisms behind the pathogenesis. The role of protein sulfhydryl depletion in APAP-induced liver injury was investigated in this study and compared to protein adducts and classical measures of toxicity. A single oral gavage dose of 150 or 300 mg/kg APAP in B6C3F1 mice produced increased serum alanine aminotransferase levels, liver necrosis, and glutathione depletion in a dose-dependent manner. The levels of global free protein sulfhydryls were significantly decreased at 1 hour and

remained as such through 24 hours postdose. Histochemical detection of free protein sulfhydryls showed a zonal pattern of sulfhydryl depletion within the liver lobule. The centrilobular areas exhibited dramatic decreases in protein free sulfhydryls while the periportal regions were essentially spared. Oxidation of the free protein sulfhydryls occurred in the same regions of cells that contained APAP-protein adducts and developed necrotic changes. Interestingly, the majority of free protein sulfhydryl depletion was due to reversible oxidation since the global and lobule-specific effects were essentially reversed with TCEP, a sulfhydryl reducing agent, prior to maleimide labeling. The changes in protein sulfhydryl oxidation may act as the sensor for oxidants, such as ROS and RNS. Therefore, investigating the protein sulfhydryl depletion may have important clinical ramifications in understanding the pathogenesis of APAP-induced hepatocellular injury.

**PS 628 Purinergic Receptor Antagonist A438079 Protects against Acetaminophen-Induced Liver Injury by Inhibiting P450 Isoenzymes Not Inflammasome Activation.**

Y. Xie, C. Williams, M. R. McGill, M. Leborfsky, A. Ramachandran and H. Jaeschke. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Acetaminophen (APAP) overdose is the most frequent cause of acute liver failure in the western world. Controversy exists regarding the hypothesis that the hepatocyte injury is amplified by a sterile inflammatory response, rather than being the result of intracellular mechanisms alone. A recent study suggested that the purinergic receptor antagonist A438079 protects against APAP-induced liver injury by preventing the activation of the Nalp3 inflammasome in Kupffer cells and thereby preventing inflammatory injury. To test the hypothesis that A438079 actually affects the intracellular signaling events in hepatocytes, C57BL/6 mice were treated with APAP (300 mg/kg) and A438079 (80 mg/kg) or saline and GSH depletion, protein adduct formation, c-Jun-N-terminal kinase (JNK) activation, oxidant stress and liver cell necrosis was determined between 0-6h after APAP administration. APAP caused rapid GSH depletion, extensive protein adduct formation in liver homogenates and in mitochondria, JNK phosphorylation and mitochondrial translocation of phosphor-JNK within 2h, oxidant stress, and extensive centrilobular necrosis at 6h. A438079 significantly attenuated GSH depletion, which resulted in a 50% reduction of total liver and mitochondrial protein adducts and substantial reduction of JNK activation, mitochondrial P-JNK translocation, oxidant stress and liver injury. The same results were obtained using primary mouse hepatocytes. A438079 did not directly affect JNK activation induced by tert-butyl hydroperoxide and GSH depletion. However, A438079 dose-dependently inhibited hepatic P450 enzyme activity. Thus, the protective effect of A438079 against APAP hepatotoxicity in vivo can be explained by its effect on metabolic activation and cell death pathways in hepatocytes without involvement of the Nalp3 inflammasome.

**PS 629 The Role of Choline Depletion in Perfluorooctanesulfonate-Induced Hepatic Steatosis.**

P. Krishnan<sup>1</sup>, A. D. Patterson<sup>1</sup>, D. J. Ehresman<sup>2</sup>, P. B. Smith<sup>1</sup>, M. K. Scavell<sup>1</sup>, S. Chang<sup>2</sup>, J. L. Burenhoff<sup>2</sup> and J. M. Peters<sup>1</sup>. <sup>1</sup> Pennsylvania State University, University Park, PA; <sup>2</sup>3M Company, St. Paul, MN.

In toxicological studies, perfluorooctanesulfonate (PFOS) exposure has resulted in hepatic steatosis and hypolipidemia, believed to be the result of decreased production and secretion of VLDL and HDL and increased uptake of VLDL-triglyceride. The hypothesis that PFOS produces hepatic steatosis via ionic sequestration of available choline necessary for the production of VLDL was examined. Plausibility was supported by identification of an ion-triad between two molecules of choline and one molecule of PFOS in vitro. We fed male C57BL/6 mice either a control diet or a marginal methionine/choline-deficient (mMCD) diet, both with and without PFOS. After a two-week run-in period on diets without PFOS, control or mMCD diets containing 0, 30, 60, or 120 mg K+PFOS/kg diet were fed for three weeks. There was a dose-dependent increase in the relative liver weight in both control and mMCD fed mice. Dietary PFOS was also associated with dose-dependent decreases in body weight, increases in hepatic triglyceride concentration, and increases in serum ALT, ALP, and bile acids, all with larger effects observed in mice fed mMCD compared to those fed the control diet. Serum and liver concentrations of PFOS were increased in a dose-dependent manner on both diets; however, serum PFOS concentrations were higher and liver concentrations lower in mMCD-fed mice compared to corresponding control-fed mice. This is surprising because the evidence suggested that PFOS-induced hepatotoxicity was exacerbated in the mMCD diet fed mice. Metabolomic analysis demonstrated that PFOS caused a significant decrease in the hepatic concentration of many phosphatidylcholines in the PFOS-fed mice compared to controls. Further, the average serum concentration of choline was reduced by dietary PFOS. These studies are the first to provide evidence that PFOS may cause hepatic steatosis through depletion of choline required for hepatic VLDL production and export.

**PS 630 Platelet Depletion Reduces Acetaminophen Hepatotoxicity in Mice.**

K. Miyakawa<sup>1,2</sup>, R. Albee<sup>3</sup>, M. Scott<sup>1</sup>, P. E. Ganey<sup>2,3</sup>, J. Luyendyk<sup>1,2</sup> and R. Roth<sup>2,3</sup>. <sup>1</sup>Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Acetaminophen (APAP) overdose is the major cause of acute liver failure in the U.S. Previous studies identified decreases in blood platelet concentration in patients with APAP toxicity, but the role of platelets in APAP-induced liver injury is unclear. We tested the hypothesis that platelets contribute to liver injury in a mouse model of APAP hepatotoxicity. Blood platelet concentration was reduced 6-36 h after administration of APAP (300 mg/kg, ip) to mice, and immunofluorescent labeling showed increased platelets within livers at 2-6 h. Pretreatment of mice with anti-CD41 IgG to reduce circulating platelet concentrations to 1/10th of control reduced liver injury at 6, 12 and 24 hr after APAP administration, as evaluated by plasma alanine aminotransferase activity and the area of hepatic necrosis. The erythrocyte-to-hepatocyte volume ratio in the livers of APAP-treated mice was also reduced by anti-CD41 IgG pretreatment, suggesting a reduction in congestion or hemorrhage. The early (30 min) APAP-mediated consumption of reduced glutathione (GSH) was unaffected by platelet depletion, suggesting that the reduction in injury was not a consequence of diminished APAP bioactivation. Activated platelets provide a thrombogenic surface for amplification of thrombin generation; indeed, platelet depletion significantly reduced the increase in plasma concentration of thrombin-antithrombin complexes, a biomarker of thrombin generation, at 3h. Addition of thrombin to cultures of primary hepatocytes in vitro did not affect APAP-induced cytotoxicity, suggesting that thrombin does not contribute to toxicity through a direct action on hepatocytes. Taken together, the results suggest that platelets support thrombin generation and contribute to congestion or hemorrhage and hepatocellular injury after APAP overdose. (Supported by NIH grant R01 DK087886.)

**PS 631 Acute Biliary Hyperplasia in F344 Rats Administered the Indole-3-Carbinol Analog, NSC 743380.**

M. Davis<sup>1</sup>, S. Eldridge<sup>1</sup>, K. Elsass<sup>2</sup>, T. Horn<sup>3</sup> and J. Morris<sup>1</sup>. <sup>1</sup>DCTD, NCI, Bethesda, MD; <sup>2</sup>Battelle, Columbus, OH; <sup>3</sup>IITRI, Chicago, IL.

Biliary hyperplasia discovered in preclinical safety assessment represents a severe finding due to being unmanageable and non-monitorable in the clinical setting. NSC-743380 (1-[(3-chlorophenyl) methyl]-1H-indole-3-methanol) is in early stages of development as an anticancer agent at the NCI. In an exploratory toxicity study in rats, acute hepatotoxicity, characterized by biliary hyperplasia and inflammatory hepatic necrosis, was observed 5 days after dosing orally at 100 mg/kg/day. The hepatotoxicity noted was also apparent from the clinical chemistry results that showed marked increases in alkaline phosphatase, alanine aminotransferase and aspartate aminotransferase levels by day 2 dosing relative to controls. In contrast, IV dosing with NSC-743380 (6.25 – 25 mg/kg/day), produced no microscopic lesions or clinical chemistry changes relative to controls either on day 2 or after day 5 of dosing. Plasma levels of NSC-743380 and its aldehyde and acid metabolites obtained for IV administration were higher than that achieved from oral administration; however, liver toxicity, as determined by clinical chemistry and histopathology, was observed only after administration of the parent compound and not the aldehyde or acid metabolite. In addition, the toxicity profiles of a structurally similar inactive molecule and a structurally diverse molecule (with the same efficacy profile) were compared to NSC-743380 to explore scaffold versus target-mediated toxicity. Following 2 days of oral dosing at 100 mg/kg/day, the structurally different compound produced a similar toxicity profile, although less severe, than NSC-743380. Taken together, the hepatotoxicity associated with NSC-743380 appears to be related to the parent molecule rather than its major metabolites and related to target-modulation representing on-target toxicity. Furthermore, this molecule offers a unique opportunity to explore biomarkers for biliary hyperplasia using a short-duration toxicology study design. N01CM201100019/N01CM201100027

**PS 632 Identifying Proregenerative Signaling after Acetaminophen-Induced Acute Liver Failure in Mice Using Incremental Dose Model.**

B. Bhushan, C. Walesky, P. Borude, G. Edwards and U. Apte. *Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Overdose of acetaminophen (APAP) is the major cause of acute liver failure (ALF) in the US with very limited treatment options. Recent studies suggest that liver regeneration is a critical determinant of overall survival following APAP overdose and

has highlighted the potential of regenerative therapies for ALF. However, the mechanisms of liver regeneration following APAP-induced ALF are not completely clear. In the present study, we studied the major signaling pathways involved in liver regeneration following APAP-induced ALF using an incremental APAP dose model. Two-month-old male C57BL/6 mice were treated with either 300 mg/kg (APAP300) or 600 mg/kg (APAP600) APAP and liver injury and regeneration was studied over a time course of 0 to 48 hr. Mice treated with APAP300 developed extensive liver injury followed by significant liver regeneration resulting in resolution of APAP-induced injury by 48 hr. In contrast, mice treated with APAP600 exhibited significant injury but substantial decrease in liver regeneration. The inhibition of liver regeneration in APAP600 group was associated with decreased Cyclin D1 mRNA and protein expression, decreased phosphorylation of Rb protein and sustained expression of p21. Further analysis of several signaling pathways revealed differences in pro-mitogenic signaling between APAP300 and APAP600. EGFR, c-Met, and downstream activation of MAPK pathways were highly activated in APAP600, where regeneration was inhibited. However, canonical Wnt/ $\beta$ -catenin pathway and NF- $\kappa$ B signaling were activated in APAP300 where liver regeneration was stimulated and inhibited in APAP600 group where regeneration was decreased. Finally, a TaqMan-based PCR array of 15 growth factor genes revealed rapid induction of several growth factors including HGF, VEGF, Kit-L, and PDGF $\alpha$  specifically in APAP300 group. Taken together, our study has identified Wnt and NF- $\kappa$ B signaling as potential pathways that regulate liver regeneration after APAP overdose.

**PS 633 Potential Hepatoprotective Effects of Licorice Root (*Radix glycyrrhizae*) Extract against Carbon Tetrachloride-Induced Hepatotoxicity in Isolated Rat Hepatocytes.**

O. S. El-Tawil<sup>1</sup>, A. A. Shalaby<sup>2</sup> and E. A. Mohamed<sup>3</sup>. <sup>1</sup>Department of Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Cairo University, Cairo, Egypt; <sup>2</sup>Department of Biochemistry, Faculty of Veterinary Medicine, Suez Canal University, Ismailia, Egypt; <sup>3</sup>Department of Pharmacology and Toxicology, Faculty of Pharmacy, Al-Azhar University, Cairo, Egypt. Sponsor: A. Kadry.

*Radix glycyrrhizae* is one of the native Mediterranean plants. Licorice root is a popular soft drink in Egypt. Literatures cited therapeutic effects of licorice. The present work is to evaluate the potential hepatoprotective effects of aqueous licorice root extract against the cytotoxic effects and the oxidative stress induced by carbon tetrachloride (CCl<sub>4</sub>) in isolated primary rat hepatocytes. Hepatocytes were isolated by collagenase perfusion technique. Cytotoxicity was determined by assessing cell viability and leakage of cytosolic enzymes, such as lactate dehydrogenase (LDH), alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Oxidative stress was assessed by determining reduced glutathione (GSH) level and lipid peroxidation as indicated by thiobarbituric acid reactive substances (TBARS) production. Exposure of isolated rat hepatocytes to CCl<sub>4</sub> (5mM) caused cytotoxicity and oxidative injury, manifested by loss of cell viability and significant increase in LDH, ALT and AST leakages. As well as, CCl<sub>4</sub> caused progressive depletion of intracellular GSH content and significant enhancement of TBARS accumulation. Preincubation of hepatocytes with either licorice (25  $\mu$ M/ml) or silymarin (0.5mM) which is a known hepatoprotective agent, ameliorated the hepatotoxicity and oxidative stress induced by CCl<sub>4</sub>, as indicated by significant improvement in cell viability, significant decrease in LDH, ALT and AST leakages, significant prevention of GSH depletion and significant decrease in TBARS formation as compared to CCl<sub>4</sub> alone-treated cells. The present results indicate that CCl<sub>4</sub> has a potential cytotoxic effect in isolated rat hepatocytes; and licorice extract possess a highly promising hepatoprotective effects against CCl<sub>4</sub> - induced hepatotoxicity.

**PS 634 Lack of Human Health Relevance of Increased Hepatocellular Adenoma in Male Cd1 Mouse Treated with Cyproconazole or Propiconazole.**

D. Cowie<sup>1</sup>, R. Green<sup>1</sup>, E. Barnes<sup>1</sup>, R. Currie<sup>1</sup> and R. Peffer<sup>2</sup>. <sup>1</sup>Syngenta, Bracknell, United Kingdom; <sup>2</sup>Syngenta, Greensboro, NC.

In 18- to 24-month carcinogenicity studies, treatment with cyproconazole (CCZ) or propiconazole (PPZ) with high levels (100 to 200ppm and 2500ppm, respectively) in the diet resulted in increased incidences of hepatocellular adenoma in male CD1 mice. The proposed non-genotoxic mode of action (MOA) for induction of these tumours involves a number of common key events that define a common toxicity pathway. The first key event is activation of the constitutive androstane receptor (CAR). This stimulates increased DNA replication and hepatocellular proliferation along with differential expression of genes that result in

a suppression of apoptosis. Following prolonged exposure, this pro-proliferative milieu along with suppression of apoptosis promotes the growth and progression of spontaneously transformed cells eventually producing hepatocellular adenoma. The ability of CCZ and PPZ to elicit these key events *in vivo* was confirmed by measuring Cyp2b and Cyp3a induction as a surrogate for CAR activation and replicative DNA synthesis to assess hepatocellular proliferation. In addition, the requirement for CAR activation for increased hepatocellular proliferation was demonstrated for CCZ using CAR knock-out mice. Furthermore, reporter gene assays demonstrated that PPZ is a direct activator of both mouse (potent) and human (weak) CAR. Following experimental demonstration of the proposed MOA for mice, the lack of human relevance was assessed by comparing the effects of PPZ or CCZ on primary cultures of mouse and human hepatocytes. Consistent with the *in vivo* observations, treatment of mouse hepatocytes with CCZ or PPZ resulted in increases in Cyp2b, Cyp3a and replicative DNA synthesis. In contrast, treatment of human hepatocytes with these compounds resulted in increased Cyp2b and Cyp3a, but not replicative DNA synthesis. These data demonstrate a qualitative species difference in response to CAR activation. The lack of proliferative response in human hepatocytes means it is reasonable to conclude that neither CCZ nor PPZ are hepatotumorigenic in humans.

**PS 635 In Vivo Lead Hepatotoxicity in Mice Is Reversed by a Molluscan C-Reactive Protein Purified from *Achatina fulica* (Bowdich).**

S. Mukherjee, S. Sarkar, S. Chatterjee and S. Bhattacharya. Zoology, Visva Bharati University, Santiniketan, India.

Vertebrate liver is affected by several heavy metals among which lead (Pb) occupies a significant position. Lead induced prooxidant/ anti-oxidant balance contributes to tissue injury via oxidative damage to critical biomolecules (lipids, proteins, and DNA). We have earlier reported amelioration of lead induced toxicity by the application of C-reactive protein (CRP) isolated from a mollusc *Achatina fulica* in rat hepatocytes *in vitro* (SOT, 51st Annual Meeting, 2012), however, the mechanism of anti-stress property of ACRP has not been clarified. We evaluated *in vivo* hepatoprotective role of ACRP against Pb(NO<sub>3</sub>)<sub>2</sub> induced toxicity in mice, where CRP is not an acute phase protein (Du Clos, 2003). Adult male albino mice weighing 20 $\pm$ 2 g were segregated in 3 groups of 5 animals each. Group I served as control and received intraperitoneal (ip) normal saline. Group II received ip 14.8 mg/kg body weight Pb(NO<sub>3</sub>)<sub>2</sub> (1/10 LD<sub>50</sub>) for 7 consecutive days. Group III received ip Pb(NO<sub>3</sub>)<sub>2</sub> once daily for 7 days and from day 5 onwards ACRP (100  $\mu$ g/mouse) was co-administered ip with Pb(NO<sub>3</sub>)<sub>2</sub> until day 7. Generation of superoxides in liver was routinely assessed by TBARS assay (Buege and Aust, 1978) and the level of endogenous anti-oxidant GSH was determined (Sedlak and Lindsay, 1968). Administration of Pb(NO<sub>3</sub>)<sub>2</sub> significantly depleted liver glutathione and enhanced lipid peroxidation by 2 fold against control. Interestingly, ACRP co-treatment significantly reversed glutathione level and lipid peroxidation towards control while enhanced expression of Nrf2 and MAPKs (ERK, JNK and p38) indicated expression of several antioxidant genes. Protective role of ACRP against lead toxicity is further evidenced by profound induction of HSP70. It is concluded that ACRP reduces metal toxicity by triggering the survival pathway and inducing several anti oxidant genes in lead treated mice.

**PS 636 Eosinophils Not Neutrophils Mediate Halothane-Induced Liver Injury in Mice.**

W. R. Proctor, M. Chakraborty, J. C. Morrison, L. S. Chea, J. D. Berkson, K. Semple, M. Bourdi and L. R. Pohl. Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, National Heart, Lung and Blood Institute, Bethesda, MD.

Liver eosinophilia has often been associated with drug induced liver injury, though its role in the etiology of this disease remains unclear. We decided to investigate this problem in a murine model of halothane-induced liver injury, where neutrophils have been reported to play a pathogenic role. When female Balb/c mice were administered halothane, eosinophils were detected by flow cytometry in the liver within 12 hours and increased thereafter proportionally to liver damage. Infiltrating neutrophils did not increase significantly until 18 hours after halothane administration. Chemokines CCL11 and CCL24, which are known to attract eosinophils, increased in response to halothane-treatment. Immunohistochemical staining for the cytotoxic eosinophil granule protein, major basic protein, revealed that eosinophils accumulated exclusively around areas of hepatocellular necrosis. The severity of HILI was decreased significantly when the study was repeated in wild-type mice partially depleted of eosinophils by pretreatment with Siglec-F antibody, while the

number of hepatic neutrophils remained unchanged. Conversely, selective depletion of neutrophils by pretreatment with low concentrations of Gr-1 antibody failed to reduce the extent of HILI when levels of eosinophils remained unchanged. The pathologic role of eosinophils was confirmed when halothane induced hepatotoxicity was significantly reduced in the eosinophil lineage ablated  $\Delta\text{dblGata}^{-/-}$  mice, which are neutrophil competent. Our findings indicate that eosinophils, not neutrophils, have a pathologic role in HILI in mice and suggest that they may contribute similarly in many clinical cases of DILI.

### PS 637 Effect of Ligand Activation of PPAR $\beta/\delta$ in Kupffer Cells.

G. Balandaram<sup>1</sup>, J. M. Peters<sup>1</sup> and E. J. Gonzalez<sup>2</sup>. <sup>1</sup>Veterinary and Biomedical Sciences, Pennsylvania State University, University Park, PA; <sup>2</sup>Laboratory of Metabolism, NCI, Bethesda, MD.

Peroxisome proliferator-activated receptor  $\beta/\delta$  (PPAR $\beta/\delta$ ) can inhibit pro-inflammatory activities in the liver. Since activated Kupffer cells can modulate hepatic inflammation, the role of PPAR $\beta/\delta$  in modulating Kupffer cell activities was examined. Kupffer cells were isolated from wild-type, Ppar $\beta/\delta$ -null or Ppar $\beta/\delta$ -null mice expressing a DNA binding mutant form of PPAR $\beta/\delta$  in the Kupffer cells (PPAR $\beta/\delta$  DBM). Cultured Kupffer cells from the three genotypes phagocytized latex beads demonstrating relative purity. Ligand activation of PPAR $\beta/\delta$  in Kupffer cells increased expression of the PPAR $\beta/\delta$  target gene, adipocyte differentiation-related protein (Adip) in wild-type but not in Ppar $\beta/\delta$ -null or PPAR $\beta/\delta$  DBM Kupffer cells. Ligand activation of PPAR $\beta/\delta$  attenuated lipopolysaccharide (LPS)-induced expression of the pro-inflammatory gene, tumor necrosis factor- $\alpha$  (Tnf $\alpha$ ) mRNA in Kupffer cell cultures from wild-type and PPAR $\beta/\delta$  DBM mice but not from Ppar $\beta/\delta$ -null mice. Wild-type Kupffer cells treated with LPS to induce an M1 phenotype exhibited increased expression of the pro-inflammatory macrophage markers Tnf $\alpha$ , interleukin-6 (IL-6), interleukin-1 $\beta$  (IL-1 $\beta$ ) and chemokine ligand-4 (Ccl4) and ligand activation of PPAR $\beta/\delta$  attenuated these responses. Wild-type Kupffer cells treated with IL-4 to induce an M2 phenotype exhibited increased expression of the anti-inflammatory markers arginase type-1 (Arg-1), macrophage galactose N-acetyl-galactosamine specific lectin-1 (Mgl-1), c-type lectin domain family 7, member A (Clec7A) and interleukin-10 (IL-10), but ligand activation of PPAR $\beta/\delta$  did not influence these responses. Combined, results from these studies suggest that PPAR $\beta/\delta$  inhibits hepatic inflammation, at least in part, via transrepression of pro-inflammatory signaling in Kupffer cells. Since this effect can be found with a DNA binding mutant form of PPAR $\beta/\delta$ , this suggests that the attenuation of pro-inflammatory signaling could be due to direct protein-protein interaction of PPAR $\beta/\delta$  with other inflammatory signaling molecules such as NF- $\kappa$ B.

### PS 638 Hepatocyte Tissue Factor Triggers the Procoagulant Response Associated with Acetaminophen-Induced Liver Injury and Hepatocyte Transplantation.

J. Luyendyk<sup>1</sup>, A. K. Kopec<sup>1</sup>, N. Joshi<sup>1</sup>, H. Cline<sup>1</sup>, S. Bishop<sup>1</sup>, K. M. Kassel<sup>1</sup>, C. E. Rockwell<sup>2</sup>, N. Mackman<sup>3</sup> and B. P. Sullivan<sup>1</sup>. <sup>1</sup>Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>3</sup>Department of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.

The localization and regulation of tissue factor (TF) activity in hepatocytes (HPCs) is poorly understood and a role for HPC TF in vivo has not been established. We characterized the expression of TF by mouse HPCs and evaluated the role of HPC TF in mouse models of HPC transplantation and acetaminophen (APAP) overdose. TF mRNA, protein, and total procoagulant activity (PCA) were significantly reduced in isolated HPCs and in liver homogenates from TF<sup>flox/flox</sup>/albumin-Cre mice (HPC<sup>ΔTF</sup> mice) compared to TF<sup>flox/flox</sup> mice (control mice). TF protein on the surface of intact HPCs had PCA that was reduced by cell-impermeable lysine conjugating reagents, but was unaffected by an inhibitory TF antibody that competes for factor VII binding. Intact mouse HPCs clotted factor VII-deficient human plasma and TF-dependent factor Xa generation by HPCs occurred without exogenous factor VIIa. Thrombin generation in a model of HPC transplantation was dependent on donor HPC TF expression. Thrombin generation was also dramatically reduced in APAP-treated HPC<sup>ΔTF</sup> mice compared to APAP-treated control mice. The results indicate that TF expressed on the surface of mouse HPCs is preloaded with VII/VIIa, and that HPC TF is essential for coagulation induced by hepatocellular injury in vivo. Moreover, the expression of TF by HPCs implies that most hepatotoxic responses are likely accompanied by activation of the extrinsic pathway of blood coagulation.

### PS 639 Hepatoprotective Effects of Fibrin(ogen) in Chronic Xenobiotic-Induced Cholestatic Liver Injury: Potential Involvement of Platelets.

N. Joshi<sup>2</sup>, K. M. O'Brien<sup>2</sup>, B. L. Copple<sup>2</sup>, K. J. Williams<sup>1</sup> and J. Luyendyk<sup>1</sup>. <sup>1</sup>Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI; <sup>2</sup>Pharmacology & Toxicology, Michigan State University, East Lansing, MI.

Coagulation cascade activation and hepatic fibrin(ogen) deposition are evident in a model of chronic alpha-naphthylisothiocyanate (ANIT)-induced cholestatic liver injury. We have shown previously that complete fibrin(ogen) deficiency increases liver necrosis in mice fed a diet containing ANIT. The mechanism whereby fibrin(ogen) deficiency worsens injury in this model is not known, nor is it clear whether stabilizing hepatic fibrin would be hepatoprotective. One possibility is that fibrin(ogen)-dependent platelet activation protects the liver from chronic ANIT diet-induced injury. We tested the hypothesis that stabilizing hepatic fibrin(ogen) inhibits ANIT-induced chronic cholestatic liver injury by supporting hepatic platelet accumulation/activation. Mice fed a diet containing 0.025% ANIT for 2 weeks developed liver injury consisting of multifocal acute hepatocellular necrosis and inflammation, peribiliary fibrosis, lymphocytic inflammation and bile duct epithelial hyperplasia. Immunofluorescent CD41 (alpha<sub>IIb</sub> integrin) staining revealed a marked increase in platelets in livers of mice fed the ANIT diet compared to mice fed control diet. Administration of the anti-fibrinolytic drug tranexamic acid (1200 mg/kg, ip, bid) significantly reduced liver injury in mice fed the ANIT diet, but did not affect platelet accumulation. Administration of the platelet inhibitor clopidogrel significantly increased serum alanine aminotransferase (ALT) levels and liver necrosis in mice fed the ANIT diet. Moreover, serum ALT activity was increased in mice deficient in protease activated receptor-4 (PAR-4), a primary thrombin receptor on mouse platelets. The results indicate that stabilization of hepatic fibrin with antifibrinolytic therapy significantly reduces liver injury in mice fed ANIT diet. Moreover, the results suggest that platelets are also hepatoprotective in mice fed the ANIT diet.

### PS 640 Effects of Acetaminophen and Oxidative Stress on Primary Human Hepatocytes Derived from a Steatotic Liver.

M. J. Liguori, D. J. Cugier, R. Ciurlionis, A. C. Ditewig, J. Lai-Zhang, G. D. Gagne and E. A. Blomme. Department of Cellular and Molecular Toxicology, AbbVie, Abbott Park, IL.

Primary human hepatocytes are a favored in vitro system for characterization of some types of hepatotoxicity. Donor demographics, disease states, and lifestyles result in significant donor to donor variability and can have a strong influence on the sensitivity of primary hepatocytes to hepatotoxins. Here, we describe a unique primary human hepatocyte system originating from the liver of a female donor (SMK) with severe metabolic syndrome and pre-conditioned steatosis. The cells had a lipid-rich phenotype that was clearly visible both using standard light microscopy and lipid fluorescent stain, which showed a 400% increase in signal intensity compared to a standard lot of hepatocytes. In general, steatotic cells have enhanced sensitivity to the presence of reactive oxidative stress (ROS). To test whether SMK cells were more susceptible to ROS, SMK and cells from a normal donor were exposed to acetaminophen, a drug with a well characterized ROS-mediated mechanism of toxicity, at a dose range of 0.5 to 20 mM for 72h using standard culture conditions. SMK hepatocytes were 2.7-fold more susceptible to APAP induced cytotoxicity compared to their normal counterparts. The lipid signal was slightly reduced upon high levels of APAP. Total RNA was isolated from SMK both from naïve and APAP treated cells and subjected to whole genome transcriptomic profiling. When compared to a pool of non-diseased hepatocyte donors, naïve SMK cells showed extensive gene expression changes that were largely associated with bioenergetic pathways with marked downregulation of lipid processing control and synthesis genes (e.g. SREBP). Agglomerative hierarchical cluster analysis revealed a clear distinction between SMK and its normal counterparts of the global expression profiles induced after treatment with APAP. In summary, this study demonstrates that hepatocytes with marked steatosis can serve as interesting molecular models for ROS-mediated hepatotoxic injury.

**PS 641 Meso-Dihydroguaiaretic Acid Inhibits Alcoholic and Nonalcoholic Fatty Liver by Antagonizing LXR $\alpha$  Activity.**

W. Sim<sup>1</sup>, S. Park<sup>1</sup>, K. Lee<sup>1</sup>, Y. Jye<sup>1</sup>, H. Yin<sup>1,4</sup>, Y. Choi<sup>1</sup>, S. Sung<sup>1</sup>, S. Park<sup>2</sup>, H. Park<sup>2</sup>, K. Shin<sup>3</sup> and B. Lee<sup>1</sup>. <sup>1</sup>College of Pharmacy, Seoul National University, Seoul, Republic of Korea; <sup>2</sup>School of Pharmacy, Sungkyunkwan University, Suwon, Republic of Korea; <sup>3</sup>College of Pharmacy, The Catholic University, Bucheon, Republic of Korea; <sup>4</sup>Molecular Pharmacology and Physiology, University of South Florida Health Sciences Center, Tampa, FL.

Collaborative regulation of liver X receptor (LXR) and sterol regulatory element binding protein (SREBP)-1 are main determinants in hepatic steatosis. Recent studies indicate that selective intervention of overly functional LXR $\alpha$  in the liver shows promise in treatment of fatty liver. In the present study, we evaluated the effects of meso-dihydroguaiaretic acid (MDGA) on LXR $\alpha$  activation and its ability to reverse fatty liver in mice. An LXR $\alpha$  co-activator recruitment assay and molecular docking analysis were performed to evaluate the binding of MDGA to the ligand-binding domain (LBD) of LXR $\alpha$ . The ability of MDGA to inhibit LXR $\alpha$ -dependent steatosis was investigated in an ethanol- or high-fat-diet (HFD)-induced steatosis model. MDGA inhibited activation of the LXR $\alpha$ -LBD by competitively binding to the pocket for agonist T0901317 and decreased the luciferase activity in LXRE-tk-Luc-transfected cells. MDGA attenuated the expression of LXR $\alpha$  and hepatic neutral lipid accumulation in ethanol- and HFD-induced fatty liver. MDGA reduced the expression of LXR $\alpha$  co-activator protein RIP140 in HFD-fed mice. While MDGA decreased the expression of LXR $\alpha$ , SREBP-1, SCD-1, and FAS proteins, genes associated with reverse cholesterol transport such as ABCA1 and ABCG1 were not affected. These results demonstrate that MDGA has the potential to reverse alcoholic and nonalcoholic steatosis mediated by selective inhibition of LXR $\alpha$  in the liver.

**PS 642 Toxicity of Diethylnitrosamine (DEN) in the Liver of Constitutive Androstane Receptor (CAR)-Knockout (KO) Mice.**

K. Inoue<sup>1</sup>, M. Takahashi<sup>1</sup>, Y. Sakamoto<sup>1</sup>, K. Tamura<sup>1</sup>, S. Matsuo<sup>1</sup>, Y. Kodama<sup>2</sup> and M. Yoshida<sup>1</sup>. <sup>1</sup>Division of Pathology, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Division of Toxicology, National Institute of Health Sciences, Tokyo, Japan.

CARKO mice showed high mortality after injection of DEN. To clarify the cause of high susceptibility in CARKO mice to the toxicity of DEN, 6-week old male CARKO and C3H mice were intraperitoneally injected 90 mg/kg body weight of DEN, and their livers were collected at days 1, 3, 7 and 14 after DEN treatment. Relative weight, pathological changes, mRNA expression and enzyme activity levels of CYP2B10 and CYP2E1 in the liver of CARKO mice were compared with controls injected saline or with wild mice. DEN significantly reduced relative liver weights in both genotypes and the decreased liver weights in CARKO mice were significantly lower than wild mice at days 7 and 14. Microscopically, pale cytoplasm of the hepatocytes in the centrilobular area was observed by DEN treatment at day 1, and the area of this change was larger in CARKO than in wild mice. DEN treatment also increased slight to mild single necrosis of hepatocytes and mononuclear cell infiltration in the centrilobular area from day 1 and from day 3, respectively. The intensities of single necrosis and mononuclear cell infiltration in CARKO mice were comparable to wild mice. While the expression level of Cyp2b10 in the liver of wild mice increased by DEN with or without significance, compared with their controls, the level in CARKO mice remarkably diminished in both control and DEN groups at all time points. As for testosterone hydroxylase activity (CYP2B10), there were no difference between controls and DEN groups or both genotypes at days 1 and 7. DEN treatment significantly decreased Cyp2e1 and aniline hydroxylase activity (CYP2E1) level in both genotypes at day 1, compared with each control, and the decreased level of aniline hydroxylase activity was significantly lower in CARKO than in wild mice. Judging from these results, high susceptibility in CARKO mice to the toxicity of DEN might be caused by immediate decrease of CYP2E1 activity after DEN treatment.

**PS 643 Leptin Modulates Toxicity Associated Steatohepatitis through Peroxynitrite in Kupffer Cells.**

S. Das<sup>1</sup>, A. Kumar<sup>2</sup>, D. Ganini<sup>2</sup>, E. J. Tokar<sup>3</sup>, J. Corbett<sup>2</sup>, M. Kadiiska<sup>2</sup>, M. P. Waalkes<sup>3</sup>, A. Diehl<sup>4</sup>, R. P. Mason<sup>2</sup> and S. Chatterjee<sup>1,2</sup>. <sup>1</sup>Environmental Health Sciences, University of South Carolina, Columbia, SC; <sup>2</sup>Laboratory of Toxicology and Pharmacology, NIEHS, Research Triangle Park, NC; <sup>3</sup>Inorganic Toxicology, NIEHS, Research Triangle Park, NC; <sup>4</sup>Gastroenterology, Duke University, Durham, NC.

Progression from steatosis to toxin-mediated steatohepatitis (TASH) lesions is hypothesized to require a second hit. These lesions have been associated with increased oxidative stress, often ascribed to high levels of leptin and other proinflam-

matory mediators. Here we have examined the role of leptin in inducing oxidative stress and Kupffer cell activation in toxin-mediated steatohepatic lesions of obese mice. Male C57BL/6 mice fed with a high fat diet (60%kcal) at 16 weeks were administered CCl<sub>4</sub> to induce steatohepatic lesions. Approaches included use of immuno-spin trapping for measuring free radical stress, gene-deficient mice for leptin, p47 phox, iNOS and adoptive transfer of leptin primed macrophages in vivo. Diet-induced obese (DIO) mice, treated with CCl<sub>4</sub> increased serum leptin levels and leptin receptor expression. Oxidative stress was significantly elevated in DIO mice liver but not in OB/OB mice, or in DIO mice treated with leptin antibody. In OB/OB mice, leptin supplementation restored markers of free radical generation. Markers of free radical formation were significantly decreased by the peroxynitrite decomposition catalyst FeTPPS, the iNOS inhibitor 1400W, the NADPH oxidase inhibitor apocynin, or in iNOS or p47 phox-deficient mice. These results correlated with the decreased expression of TNF-alpha and MCP-1 and decreased leptin receptor expression. Kupffer cell depletion eliminated oxidative stress and inflammation, whereas in macrophage-depleted mice, the adoptive transfer of leptin-primed macrophages significantly restored inflammation. These results, for the first time, suggest that leptin action in macrophages of steatotic liver through induction of iNOS and NADPH oxidase caused peroxynitrite-mediated oxidative stress thus activating Kupffer cells and modulating leptin receptor expression in the liver. (NIH-4-R00-ES19875)

**PS 644 Occupational Vinyl Chloride Exposures Are Associated with Significant Changes to the Plasma Metabolome: Implications for Toxicant Associated Steatohepatitis.**

B. Wheeler<sup>1</sup>, M. Cave<sup>1,2</sup>, K. Falkner<sup>1</sup> and C. McClain<sup>1,2</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY.

Occupational vinyl chloride (VC) exposure has been associated with steatohepatitis (TASH) and liver cancer, although the modes of action are unknown. Metabolomics has recently been utilized for the evaluation of drug-induced liver injury, but has not previously been performed for occupational VC exposures. Plasma samples from 17 highly-exposed VC workers without liver cancer and 27 unexposed healthy volunteers were obtained from a specimen bank. GC/MS (Thermo-Finnigan Trace DSQ fast-scanning single-quadrupole mass spectrometer) and LC/MS2 (Waters ACQUITY UPLC, Thermo-Finnigan LTQ mass spectrometer) were performed. Software was used to match ions to a library of standards for metabolite identification and quantitation by peak area integration. Statistical significance was determined using Welch's t-tests. 613 unique named metabolites were identified. Of these, 189 metabolites were significantly increased in the VC exposure group while 94 metabolites were significantly decreased. The most striking differences occurred in lipid metabolites. Essential (7 of 7) and long chain free fatty acids (19 of 19, including arachidonic acid, 6 fold) were significantly increased with VC exposure. Lipid peroxidation products were likewise increased by VC exposure: monohydroxy fatty acids (8 of 9, including 13-HODE, 211 fold); fatty acid dicarboxylates (8 of 13); oxidized arachidonic acid products (7 of 7, including 5-HETE, 9-HETE, and 15-HETE, up to 616 fold). Other arachidonic acid products including leukotriene B<sub>4</sub> (52 fold) were also up-regulated with VC exposure. Abnormalities were also noted in amino acid metabolism, and particularly the transmethylation and transsulfuration pathways. VC exposure was associated with increased plasma free fatty acids and lipid peroxidation products. Lipotoxicity, pro-inflammatory lipid peroxidation products, and impaired transmethylation/transsulfuration pathways represent novel modes of action for VC hepatotoxicity.

**PS 645 Pregnancy-Related Lactogenic Hormones Alter the Expression of Uptake and Efflux Transporters in Primary Human Hepatocytes.**

J. E. Moscovitz<sup>1</sup>, C. J. Gibson<sup>1</sup>, H. J. Chung<sup>2</sup>, H. Y. Jeong<sup>3</sup> and L. M. Aleksunes<sup>1,4</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ; <sup>2</sup>College of Pharmacy, Gyeongsang National University, Jinju, Republic of Korea; <sup>3</sup>Department of Pharmacy Practice, University of Illinois, Chicago, IL; <sup>4</sup>Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ.

The secretion of lactogenic hormones prolactin (PRL) and placental lactogen (PL) increases steadily throughout pregnancy and reaches the highest levels just prior to parturition. The effects of lactogenic hormones on the expression of hepatic transporters critical for the excretion of endogenous chemicals, drugs, and toxicants have not been characterized. To investigate the regulation of transporters by lactogenic hormones, sandwich-cultured, freshly isolated human hepatocytes from three adult female donors were treated for 72 hours with vehicle (carbonate-buffered saline),

human PRL (150 ng/ml) or human PL (6 µg/ml), and total RNA was isolated. Gene expression was quantified by microarray analysis and validated with quantitative real-time PCR (qPCR). qPCR analysis shows PRL and PL have differential effects on the gene expression of hepatic transporters. PRL caused the up-regulation of mRNA for the uptake transporter OAT2 by 60%, and down-regulation of the efflux transporters MRP3, MRP6, and BCRP between 15 and 20%. PL decreased mRNA expression for all uptake transporters tested, significantly for NTCB, OCT1, OATP1B1, and OATP1B3. In addition, PL increased efflux transporter gene expression for ABCA1 and BSEP by 100%, but reduced MDR1, MRP2, MRP3, MRP5, MRP6, and BCRP mRNAs. Taken together, these data suggest hormones secreted during pregnancy may globally suppress the maternal gene expression of many uptake and efflux transporters crucial for chemical excretion by the liver. Supported by ES020522, DK080774, ES007148, ES005022, HD065532.

**PS 646 Acrolein Cytotoxicity in Hepatocytes Involves Endoplasmic Reticulum Stress, Mitochondrial Dysfunction, and Oxidative Stress.**

M. Mohammad<sup>1</sup>, D. Avila<sup>1</sup>, J. Zhang<sup>1</sup>, S. Barve<sup>1</sup>, G. Arteel<sup>3</sup>, C. McClain<sup>1,2</sup> and S. Joshi-Barve<sup>1</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY; <sup>3</sup>Pharmacology and Toxicology, University of Louisville, Louisville, KY.

Acrolein is a common environmental, food and water pollutant and a major component of cigarette smoke. Also, it is produced endogenously via lipid peroxidation and cellular metabolism of certain amino acids and drugs. Acrolein is cytotoxic to many cell types including hepatocytes; however the mechanisms are not fully understood. We examined the molecular mechanisms underlying acrolein hepatotoxicity in primary human hepatocytes and hepatoma cells. Acrolein, at pathophysiological concentrations, caused a dose-dependent loss of viability of hepatocytes. The death was apoptotic at moderate and necrotic at high concentrations of acrolein. Acrolein exposure rapidly and dramatically decreased intracellular glutathione and overall antioxidant capacity, and activated the stress-signaling MAP-kinases JNK, p42/44 and p38. Our data demonstrate for the first time in human hepatocytes, that acrolein triggered endoplasmic reticulum (ER) stress and activated eIF2 $\alpha$ , ATF-3 and -4, and Gadd153/CHOP, resulting in cell death. Notably, the protective/adaptive component of ER stress was not activated, and acrolein failed to up-regulate the protective ER-chaperones, GRP78 and GRP94. Additionally, exposure to acrolein disrupted mitochondrial integrity/function, and led to the release of pro-apoptotic proteins and ATP depletion. Acrolein-induced cell death was attenuated by N-acetyl cysteine, phenyl-butyric acid, and caspase and JNK inhibitors. Our data demonstrate that exposure to acrolein induces a variety of stress responses in hepatocytes, including GSH depletion, oxidative stress, mitochondrial dysfunction and ER stress (without ER- protective responses) which together contribute to acrolein toxicity. Our study defines basic mechanisms underlying liver injury caused by reactive aldehyde pollutants such as acrolein.

**PS 647 Interstrain Differences in Progression from Simple Liver Steatosis to Fibrosis Are Associated with Altered Hepatic Iron Metabolism in Mice.**

S. Shpileva<sup>1</sup>, L. Muskhelishvili<sup>2</sup>, M. Pogribna<sup>1</sup>, C. Cozart<sup>1</sup>, M. Bryant<sup>1</sup>, F. A. Beland<sup>1</sup> and I. P. Pogribny<sup>1</sup>. <sup>1</sup>Division of Biochemical Toxicology, NCTR, US FDA, Jefferson, AR; <sup>2</sup>Toxicologic Pathology Associates, NCTR, US FDA, Jefferson, AR.

Nonalcoholic fatty liver disease (NAFLD) is a major health problem and a leading cause of chronic liver disease in the United States and other developed countries. The pathogenesis of NAFLD is often conceptualized as a two-step process that consists of hepatic triglyceride accumulation leading to steatosis as a first step, followed by a second step that includes oxidative stress, inflammation, and fibrogenesis. However, there is a lack of consensus on the significance of these events and the underlying mechanisms responsible for the disease progression and, more importantly, for differences in inter-individual disease severity and sensitivity. In a previous study we demonstrated that the inter-strain variability in severity of NAFLD was associated with dysregulation of lipid metabolism (first step). Emerging evidence indicates the importance of altered iron metabolism in the mechanism of the second step leading to progression from simple hepatic steatosis to fibrosis. The goal of this study was to investigate whether or not inter-individual differences in the intracellular iron metabolism are associated with development and severity of fibrosis induced by methyl-donor-deficiency among individual inbred strains of mice. Feeding male A/J, 129S1/SvImJ, and WSB/Eij mice a choline- and folate-deficient (CFD) diet for 12 weeks caused liver injury similar to NAFLD, with the magnitude being A/J < 129S1/SvImJ < WSB/Eij. The inter-strain variability in severity of

NAFLD and its further progression to fibrosis, which was characterized by hepatic stellate cell activation and up-regulation of fibrosis markers, was associated with the extent of hepatic iron metabolism deregulation. This was evidenced by strain-dependent alterations in the expression of iron-regulatory genes (Tfr, Fth1, Slc40a1, and Hfe2), which was correlated tightly with the degree of hepatic fibrotic changes in the livers of the mice fed the CFD diet.

**PS 648 Dose-Dependent Hepatic Physiological, Histopathological, and Gene Expression Responses in C57BL/6 Mice following Repeated TCDD Exposure.**

T. R. Zacharewski<sup>1,3</sup>, K. A. Fader<sup>1,3</sup>, J. Harkema<sup>2,3</sup> and R. Nault<sup>1,3</sup>. <sup>1</sup>Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI; <sup>2</sup>Pathobiology and Diagnostic Investigations, Michigan State University, East Lansing, MI; <sup>3</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a potent aryl hydrocarbon receptor (AhR) agonist. We have previously reported that exposure to a single oral dose of 1 µg/kg TCDD induces hepatic steatosis in mice. A complementary 28 day repeated-dose dose-response study was performed to further investigate the effects of TCDD on steatosis and its progression to steatohepatitis and cirrhosis. C57BL/6 mice were gavaged every 4 days with sesame oil vehicle control or 0.001 - 30 µg/kg TCDD. Although repeated dosing did not significantly affect body weight gain, gonadal white adipose tissue (gWAT) weight was 50% lower at 30 µg/kg while relative liver weight was increased at 3, 10, and 30 µg/kg TCDD. Histopathology revealed dose dependent alterations with minimal centrilobular microvesicular lipid accumulation (hepatic steatosis) at 3 µg/kg, mild to moderate hepatic lipid accumulation with mild inflammation at 10 µg/kg (steatohepatitis), and widespread micro- and macro-vesicular lipid accumulation in the centrilobular, mid-zonal, and periportal regions of the liver, inflammation, and perivascular fibrosis suggesting early cirrhosis at 30 µg/kg. QRT-PCR revealed dose-dependent induction of *Cyp1a1*, *Cyp1a2*, *Cyp1b1*, *Dysf*, *Gstp2*, *Notch1*, *Nqo1*, *Pla2g12a*, *Serpina6a*, *Srxn1*, *Tiparp*, and *Tnfrsf2*, as well as down-regulation of *Got1* and *Pck1*. Dose-response modeling (ToxResponse modeler) revealed similar ED50's to 24h single dose TCDD studies. These results suggest that simple steatosis can progress to steatohepatitis with fibrosis following repeated TCDD exposure, due to persistent AhR-mediated differential gene expression associated with lipid transport, processing, and metabolism. Funded by SRP P42ES04911.

**PS 649 Impaired Glycosylation and Membrane Localization of Uptake and Efflux Transporters in Human Nonalcoholic Fatty Liver Disease.**

J. Clarke<sup>1</sup>, P. Novak<sup>2</sup>, A. D. Lake<sup>1</sup>, R. N. Hardwick<sup>1</sup> and N. J. Cherrington<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, University of Arizona, Tucson, AZ; <sup>2</sup>Biology Centre ASCR, Institute of Plant Molecular Biology, Ceske Budejovice, Czech Republic.

The prevalence of non-alcoholic fatty liver disease (NAFLD) and the more severe non-alcoholic steatohepatitis (NASH) is estimated to be 30-40% and 5-17%, respectively. We have previously demonstrated a loss of N-linked glycosylation and decreased membrane localization of the efflux transporter ABCG2 in rodent and human NASH resulting in the altered disposition of drugs. N-linked glycosylation of proteins has been shown to be critical for proper protein folding and trafficking to the plasma membrane. The purpose of this study was to assess the transcriptomic expression of genes involved in protein glycosylation and processing through the endoplasmic reticulum (ER), and to determine the effect of altered glycosylation on key drug transporters during the progression of human NAFLD. For this study, human liver samples diagnosed as healthy, steatosis, NASH with fat, and NASH without fat were analyzed. Using bioinformatics methods we discovered that genes involved in protein processing in the ER and biosynthesis of N-glycans were significantly enriched for downregulation in NAFLD progression. Included in the N-glycan biosynthesis category were genes involved in the oligosaccharyltransferase complex, N-glycan quality control, N-glycan precursor biosynthesis, N-glycan trimming to the core, and N-glycan extension from the core. In contrast to down-regulation of these genes, N-glycan degradation genes were unaltered in the progression to NASH. Immunoblot analysis of the uptake transporters OATP1B1 and OATP1B3 and the efflux transporters ABCG2 and BCRP demonstrated a significant loss of glycosylation, while immunohistochemical analysis revealed impaired membrane localization of ABCG2. We propose that the loss of glycosylation and impaired membrane localization of key uptake and efflux transporters in human NASH is a potential mechanism for the occurrence of altered drug disposition in NASH.

**PS 650 High Dietary Fructose Induced Copper Deficiency Contributes to Alcoholic Liver Disease Progression.**

M. Song<sup>1</sup>, T. Chen<sup>3</sup> and C. McClain<sup>1,2,3</sup>. <sup>1</sup>Department of Medicine/GI, University of Louisville, Louisville, KY; <sup>2</sup>Louisville VAMC, Louisville, KY; <sup>3</sup>Pharmacology and Toxicology, University of Louisville, Louisville, KY.

**Background/Aims:** The increased consumption of fructose parallels the increased prevalence of obesity and the metabolic syndrome in the United States and worldwide. Noteworthy is that obesity potentiates the severity of alcohol-induced liver injury. High fructose feeding impairs intestinal copper absorption and leads to copper deficiency in rodents. Moreover, Copper deficiency is associated with the decreased antioxidant defenses and mitochondrial dysfunction. In this study, we investigated whether high fructose diet induced obesity potentiates chronic alcohol drinking induced liver injury.

**Methods:** Six-week-old male C57BL/6J mice were fed either control diet or high fructose diet (60%, w/w) for 18 weeks. 20% (w/v) ethanol was given ad libitum after 8-weeks high fructose feeding until the end of the experiment. Copper status, hepatic injury and steatosis were assessed.

**Results:** High fructose diet feeding led to copper deficiency as indicated by decreased plasma ceruloplasmin, Cu, Zinc superoxide dismutase (SOD1) and increased copper chaperone for SOD1 (CCS). Liver injury was significantly induced in mice fed with high fructose diet followed by chronic alcohol drinking as evidenced by robust increased plasma ALT, AST, chemokine (mouse KC) and liver histology. Both liver triglyceride and plasma triglyceride were significantly increased with chronic alcohol drinking, however, neither additive nor synergistic effects was observed in mice fed with high fructose diet followed by chronic alcohol.

**Conclusion:** Our data suggest that high fructose diet-induced obesity may potentiate chronic alcohol drinking induced liver injury. High fructose feeding induced copper deficiency might be a priming factor to chronic alcohol drinking induced liver injury. The potential mechanism might relate to the decreased antioxidant defense caused by copper deficiency.

**PS 651 Steroid Sulfatase Enhances Hepatic Estrogen Activity and Protects Mice from Obesity and Type 2 Diabetes.**

W. Xie and M. Jiang. University of Pittsburgh, Pittsburgh, PA.

The enzyme steroid sulfatase (STS) is responsible for the formation of biologically active estrogens by the hydrolysis of estrogen sulfates and regulates estrogen homeostasis. In this report, we showed that hepatic over-expression of STS in female STS transgenic mice elicited metabolic benefits that protected mice from high fat diet (HFD) induced obesity and type 2 diabetes. STS transgenic mice subjected to HFD challenge displayed significant decrease in fat mass and body weight, and increased energy expenditure without alterations in food intake compared with their wild-type counterparts. Moreover, STS transgenic mice had improved glucose tolerance. The metabolic benefit was associated with inhibition of hepatic gluconeogenic genes and inflammation related genes. Silencing the transgene expression through tet-off regulatory system abolished the metabolic benefit, indicating that the protection is caused by transgene itself rather than non-specific effects from random transgene insertion sites. The hepatic estrogen signaling was enhanced in STS transgenic mice, whereas elimination of the primary source of estrogens by ovariectomy abolished the protective metabolic phenotype, suggesting the metabolic action is mediated by increased estrogenic activity in STS transgenic mice liver. In summary, our results have revealed an important metabolic function of STS and may establish it as a novel therapeutic target for the prevention and treatment of obesity and type 2 diabetes.

**PS 652 Effect of Diallyl Disulfide on the Cytokines Expression in Cadmium Chloride-Treated Liver Cells.**

S. Smith, C. Odewumi, V. Badisa, A. Abdulla and L. M. Latinwo. *Biology, Florida A&M University, Tallahassee, FL.* Sponsor: A. Becker.

Cadmium is one of the most hazardous metals in the environment. Studies have shown that exposure to cadmium causes damage to many organs that may alter biological activities of the cells and may lead to cancer in mammalian systems. In the presence of toxicants, cells produce various cytokines in the body to reduce the toxic effect of the toxicants. Diallyl disulfide (DADS), an organosulfur compound in the garlic extract has been used in many countries as a preventive compound for various diseases. DADS can act as chelator and/or as an antioxidant. This project was designed to study the preventive effect of DADS on the cytokines expression in cadmium chloride (CdCl<sub>2</sub>) treated normal rat liver CRL1439 cells. For the viability assay, the cells were treated with CdCl<sub>2</sub> alone (0, 50 and 150  $\mu$ M), DADS alone (150 and 300  $\mu$ M) or co-treated with 2 h pre-treatment of DADS (150 and 300  $\mu$ M) prior to CdCl<sub>2</sub> (150  $\mu$ M) for 24 h and the cells viability was measured by the

crystal violet assay. For the cytokine array analysis, the cells were treated with CdCl<sub>2</sub> alone (0, and 150  $\mu$ M), DADS alone (150  $\mu$ M) or co-treated with 2 h pre-treatment of DADS (150  $\mu$ M) prior to CdCl<sub>2</sub> (150  $\mu$ M) for 6 h and the cytokines expression was measured using the Ray Biotech human cytokine array 7 kit. Viability results revealed that 150  $\mu$ M of DADS showed the greatest protection against CdCl<sub>2</sub> toxicity. In the cells treated with CdCl<sub>2</sub> alone, 22 cytokines were up-regulated and 2 cytokines were down-regulated. However, in the co-treated cells, the pattern of cytokines expression observed was reversed, indicating the protective effect of DADS against CdCl<sub>2</sub> toxicity. Cytokines that were up-regulated in CdCl<sub>2</sub> alone are involved in the alterations of cell cycle control system and cell mediated immunity. The present study clearly shows the preventive effect of DADS on the cytokines expression in the CdCl<sub>2</sub> treated liver cells and suggests that DADS can be used as preventative agent for cadmium toxicity.

**PS 653 The Effect of Fenugreek Leaf Extract on Gene Expression Profile of Cadmium Chloride Treated Normal Rat Liver Cells.**

R. L. Lyles, C. Odewumi, V. Badisa and L. M. Latinwo. *Biology, Florida A&M University, Tallahassee, FL.* Sponsor: A. Becker.

**Rationale and Scope of the Study:** Cadmium is a toxic and carcinogenic metal pollutant that has been known to cause DNA damage. It targets many human organs, mainly lungs, liver, and kidneys. Many chemo-preventive agents have been used against the toxic effect of many heavy metals. Fenugreek belongs to the family Leguminosae and well known for its medicinal value. In our study, the effect of Fenugreek Leaf Extract (FLE) on the viability and total gene expression profile in cadmium treated rat liver cells was evaluated. **Experimental Procedure:** The cells were treated with CdCl<sub>2</sub> (0, 25  $\mu$ M) alone or pretreated with FLE (0.005  $\mu$ g/ml) for 4 h followed by CdCl<sub>2</sub> (25  $\mu$ M) for 36 h or 48 h at 37°C in a 5% CO<sub>2</sub> incubator. The viability was measured by crystal violet dye staining method. The total gene profiles were determined using RG230 PM whole genome microarray which was processed by Affymetrix Gene Atlas system. The Partek Express software analyzes the genes up or down regulated in the treated samples. The Partek pathway software identifies the pathways affected by the treatment. **Results:** In CdCl<sub>2</sub> alone treated cells, the viability was reduced to 37.1%, while in the cells pretreated (4 h) with FLE followed by CdCl<sub>2</sub>, the viability was increased to 102% respectively, in comparison to the control cells (100%). In CdCl<sub>2</sub> alone treated cells, out of 31,139 genes on the array 61 were up regulated (>2 fold) and 124 were down regulated ( $\leq$  2 fold) respectively in comparison to control cells. In the cells pretreated with FLE followed by CdCl<sub>2</sub>, 181 genes were up regulated (>2 fold) and 161 genes were down regulated ( $\leq$  2 fold). The main pathways affected in above treatment groups were ribosome, TCA cycle and DNA replication. **Conclusion:** Our results indicate that pretreatment with FLE for 4 h affects gene expression profile in the cadmium treated cells. The alteration in the genes expression in the FLE pretreated cells may be responsible for the protective effect against cadmium toxicity. Therefore, our study suggests that fenugreek leaves can be used to reduce cadmium toxicity.

**PS 654 Evidence for a Functional Keap1-Nrf2 Cell Defence Pathway in Human Liver.**

I. M. Copple<sup>1</sup>, C. Rowe<sup>1</sup>, R. P. Jones<sup>2,1</sup>, S. W. Fenwick<sup>2</sup>, H. Z. Malik<sup>2</sup>, C. Goldring<sup>1</sup>, N. R. Kitteringham<sup>1</sup> and B. Park<sup>1</sup>. <sup>1</sup>MRC Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom; <sup>2</sup>Department of Hepatobiliary Surgery, Aintree University Hospital NHS Foundation Trust, Liverpool, United Kingdom. Sponsor: D. Mendrick.

The transcription factor Nrf2 regulates a battery of cell defence processes that protect against drug-induced liver injury in rodents, yet very little is known regarding the role of Nrf2 in regulating resistance to drug-induced stress in man. Utilising hepatocytes isolated from surgically resected healthy liver tissue (n=6), we provide the first comprehensive delineation of the Nrf2 pathway in human liver. Hepatocytes were isolated using a standard collagenase perfusion protocol, seeded onto Type I collagen-coated culture plates and reverse-transfected with 20 nM of an siRNA duplex targeted against Nrf2, Keap1 or a scrambled non-targeting control siRNA duplex. siRNA depletion of Nrf2 was associated with a decrease in the mRNA and protein levels of the established Nrf2 target genes GCLC, NQO1 and SRXN1. Furthermore, following siRNA depletion of Keap1, the cytosolic repressor of Nrf2, the total cellular abundance of Nrf2 protein was increased, as was the mRNA and protein levels of GCLC, NQO1 and SRXN1. The potent Nrf2 activator CDDO-Me induced a robust stabilisation of Nrf2 in human hepatocytes, and this was associated with a time and Nrf2-dependent increase in the mRNA and protein levels of GCLC, NQO1 and SRXN1. Under the same conditions, CDDO-Me provoked a

time and Nrf2 -dependent increase in total glutathione levels. Therefore, the Keap1-Nrf2 pathway regulates the basal and inducible activity of key cell defence processes in human hepatocytes, and may therefore be a novel marker of chemical stress and/or a promising therapeutic target in man. Notably, there was marked (up to 5-fold) inter-individual variation in the basal and inducible level of Nrf2 protein across hepatocytes isolated from patients. Such inter-individual variation in the activity of Nrf2 may have important consequences for susceptibility to disease and drug-induced toxicity in man.

## PS 655 Dibenzofuran and Mitochondrial Function: Interaction with Adenine Nucleotide Translocator.

C. M. Palmeira<sup>1,2</sup>, F. V. Duarte<sup>1,2</sup>, A. P. Gomes<sup>1,2</sup>, J. S. Teodoro<sup>1,2</sup>, A. T. Varela<sup>1,2</sup>, A. J. Moreno<sup>1</sup> and A. P. Rolo<sup>2,3</sup>. <sup>1</sup>Department of Life Sciences, University of Coimbra, Coimbra, Portugal; <sup>2</sup>Center for Neurosciences and Cell Biology, University of Coimbra, Coimbra, Portugal; <sup>3</sup>Department of Biology, University of Aveiro, Aveiro, Portugal.

Dioxins and furans are very toxic and exposure to these environmental pollutants, such as fuel constituents, is linked to several diseases. Dibenzofuran is listed as a pollutant of concern due to its persistence in the environment, bioaccumulation and toxicity to humans and the environment.

Mitochondrial function is very important in cellular homeostasis and keeping a proper energy supply for eukaryotic cells is essential in the fulfillment of the tissues energy-demand. The main objectives of this work concerned Dibenzofuran effects on mitochondrial function. We isolated mitochondria from rat liver and incubated them with Dibenzofuran to analyze the effects of this pollutant at the level of mitochondrial function.

The effects of Dibenzofuran exposure include a markedly increase in the lag phase that follows depolarization induced by ADP, indicating an effect in the phosphorylative system. Experiments performed using carboxyatractyloside (CAT) suggested an interaction of Dibenzofuran with the ANT carrier. Dibenzofuran exposure also produces an inhibition of mitochondrial permeability transition and an increase in calcium retention capacity, which may also be explained by a putative interaction of Dibenzofuran with ANT.

Clarifying the role of pollutants in some mechanisms of toxicity, such as unbalance of bioenergetics status and mitochondrial function, may help to explain the progressive and chronic evolution of diseases derived from exposure to environmental pollutants.

Duarte FV (SFRH/BD/38372/2007), Teodoro JS (SFRH/BD/38467/2007), Gomes AP (SFRH/BD/44674/2008) and Varela AT (SFRH/BD/44796/2008) are recipients of a Fundação para a Ciência e a Tecnologia (Portugal) scholarship.

## PS 656 Trovafloxacin-Induced TNF Expression in Raw Cells Is ATR-Dependent.

K. L. Poulsen<sup>1,2</sup>, P. E. Gancay<sup>1,2</sup> and R. A. Roth<sup>1,2</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Trovafloxacin (TVX) is a fluoroquinolone antibiotic associated with idiosyncratic drug-induced liver injury (IDILI) in humans. The mechanism underlying this toxicity remains unknown. An animal model of IDILI in mice revealed that TVX synergizes with a concurrent inflammatory stress from bacterial lipopolysaccharide (LPS) to result in liver injury. This hepatotoxic interaction depended upon prolongation of the LPS-induced appearance of tumor necrosis factor- $\alpha$  (TNF) in the plasma of animals coexposed to TVX. We established a model in vitro in RAW 264.7 murine macrophages (RAW cells) in which exposure to TVX alone or in combination with LPS increases both cellular TNF mRNA and TNF protein released into the culture medium. TVX is a bacterial topoisomerase inhibitor, and in a cell-free assay it inhibited mammalian topoisomerase II- $\alpha$  as well. Interestingly, TVX also caused a concentration-dependent increase in DNA double-strand breaks (DSBs) in RAW cells. Inasmuch as DSBs can activate kinases such as ataxia telangiectasia mutated (ATM) and Rad3-related (ATR), kinase inhibitors were tested for their ability to diminish TVX-induced synthesis and release of TNF from RAW cells. A selective ATM inhibitor (KU55933) had no effect on TNF mRNA or TNF release from TVX-exposed RAW cells. In contrast, a novel ATR inhibitor (NU6027) significantly attenuated the TVX-induced increase in TNF mRNA. NU6027 also eliminated the interaction between TVX and LPS, significantly decreasing TNF release in cells treated with TVX-LPS to the level induced by LPS alone. These findings suggest that ATR plays an important role in TNF expression in response to TVX exposure. (Supported by NIH grant R01 DK061315 and T32 ES007255)

## PS 657 3, 3'-Diindolylmethane Attenuates Lipopolysaccharide/D-Galactosamine-Induced Fulminant Hepatic Failure by Inducing Changes in microRNA Expression in the Liver-Infiltrating Mononuclear Cells.

S. Tomar, P. Nagarkatti and M. Nagarkatti. Pathology, Microbiology and Immunology, School of Medicine, University of South Carolina, Columbia, SC.

Lipopolysaccharide/D-Galactosamine (LPS/D-GalN) induced acute liver injury is a widely used animal model of human fulminant hepatic failure. Our studies demonstrate that pretreatment with 3,3'-Diindolylmethane (DIM), a plant derived compound and a ligand for Aryl hydrocarbon receptor (AhR) reduces LPS/D-GalN induced acute liver injury in BALB/c mice. This was demonstrated by decreased mortality, serum levels of pro-inflammatory cytokines such as TNF $\alpha$  and IL-6, serum Alanine Transaminase (ALT) enzyme, liver damage by histology, liver infiltration of mononuclear cells and the myeloperoxidase (MPO) activity in the liver tissues of mice treated with DIM prior to induction of liver injury. DIM treatment also suppressed Caspase 3 activity, nuclear NF- $\kappa$ B translocation and activation of ERK MAP kinase in the liver tissues. DIM treatment also causes a reduction in absolute numbers of activated macrophages that infiltrate the liver. In vitro studies showed that DIM causes suppression in the expression of activation markers, CD69, CD86 and MHCII, and increased apoptosis of B cells after LPS treatment. Interestingly, AhR antagonist CH223191 was able to cause a reversal of these DIM-mediated in vitro effects, indicating that the effects of DIM were mediated through the AhR. miRNA expression microarray revealed that DIM causes a differential change in the expression of several miRNAs that regulate multiple pathways of immune cell responses including MAP kinases, STAT proteins, TNF $\alpha$ , IL-6 and NF- $\kappa$ B signaling within the liver infiltrating mononuclear cells. Our results indicate that DIM suppresses acute liver injury by regulating miRNA expression within the liver infiltrating mononuclear cells and that DIM could be a potential therapeutic strategy for acute liver injury. (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

## PS 658 Multiple Mechanisms for the Appearance of Acetaminophen-Protein Adducts in Plasma: Basic Science and Clinical Implications.

M. R. McGill, Y. Xie, M. Bajt, M. Yang, C. Williams and H. Jaeschke. Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.

Acetaminophen (APAP) overdose is a major cause of acute liver failure. The drug is metabolized to an intermediate (NAPQI) which binds to proteins. Protein binding in the liver initiates a cascade of intracellular signaling events leading to necrosis. Interestingly, APAP-protein adducts can also be detected in plasma. Initially, this was thought to be due to release of hepatocyte contents during cell death. However, it has been shown that plasma adducts can appear without injury. Here, we have confirmed this by showing that plasma adducts increase before ALT at toxic doses, are detectable after non-toxic doses, and are detectable in APAP-resistant rats. How this occurs is not yet known. To explore this further, primary mouse hepatocytes were treated with APAP in medium with or without serum. In serum-free medium we could measure extracellular proteins within 3 h (Coomassie), demonstrating active protein secretion. Adducts were detected in both regular and serum-free medium at this time point ( $0.77 \pm 0.08$  and  $0.31 \pm 0.01$  nmol/mL, respectively), suggesting that secretion is one mechanism by which extracellular adducts appear. The difference may be due to diffusion of NAPQI and direct serum-protein binding. Cell adducts were higher in cultures without serum ( $0.42 \pm 0.02$  vs.  $0.24 \pm 0.02$  nmol/mg protein), indicating that serum absence did not reduce metabolism. To test if necrosis can increase serum adducts, we treated mice with doses of APAP that did not cause injury and induced necrosis with ischemia-reperfusion. A significant increase in serum APAP-protein was observed. This could have implications for the clinical use of this parameter in patients with non-APAP liver injury and incidental APAP ingestion. Conclusions: Multiple mechanisms are involved in appearance of serum APAP-protein adducts, including secretion and passive release during necrosis. Caution should be used in the clinical interpretation of APAP-protein adducts.

## PS 659 Insulin-Mimetic Effects of Arsenic: Modulation of FoxO Signaling to Affect Selenoprotein P Expression.

I. Hamann and L. Klotz. Faculty of Pharmacy and Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada.

Epidemiological studies have indicated a dose-response relationship between the prevalence of diabetes mellitus and arsenic exposure from drinking water. Mechanisms by which arsenic may cause this diabetogenic effect are largely unknown. Recent studies indicate that arsenic may impair insulin-stimulated glucose

uptake. The phosphoinositide 3'-kinase (PI3K)/Akt signaling pathway plays an important role in glucose metabolism, in part by regulating the activity of forkhead box/class O (FoxO) transcription factors. The present study aimed at investigating the effect of As<sup>3+</sup> (arsenite) on FoxO activity in human hepatoma cells, the role of PI3K/Akt signaling therein and the modulation of the expression of FoxO target genes, such as that of selenoprotein P (SeP), a hepatokine causing insulin resistance. We analyzed changes in phosphorylation of Akt and FoxO1a/3a in HepG2 human hepatoma cells in response to As<sup>3+</sup> by Western blotting and found a concentration-dependent increase in phosphorylation of Akt at S473, with arsenite being effective already at low micromolar concentrations. Arsenite exposure caused phosphorylation of FoxO1a and FoxO3a at sites known to be phosphorylated by Akt, T32 and T24, respectively. Phosphorylation of FoxOs was prevented by wortmannin, pointing to the involvement of PI3K. The functional inactivation of FoxOs by As<sup>3+</sup> was observed in an ELISA-based DNA binding assay and at the level of FoxO target gene expression: SeP and glucose-6-phosphatase mRNA levels were clearly downregulated after 24h exposure to nanomolar As<sup>3+</sup> concentrations, as demonstrated by real-time RT-PCR. Curiously, As<sup>3+</sup> showed a biphasic effect on SeP protein levels, inducing a small increase in the nanomolar and a distinct decrease in the micromolar concentration range. In conclusion, As<sup>3+</sup> may perturb cellular signaling pathways involved in fuel metabolism: it stimulates insulin-like signaling in HepG2 cells and affects the expression of FoxO target genes and the release of the hepatokine SeP, which is known to modulate insulin sensitivity.

## PS 660 The Role of Multidrug Resistance Protein 4 (Mrp4, Abcc4) in Protecting against Acetaminophen (APAP)-Induced Hepatotoxicity.

A. M. Bataille and J. E. Manautou. *Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Mrp4 is a member of the ABC family of membrane transport proteins that functions as an efflux transporter for a wide variety of substrates. Previous studies in our laboratory have shown that Mrp4 is the most significantly induced hepatic transporter by toxic acetaminophen (APAP) treatment. The basal expression of Mrp4 in normal human and naïve C57BL/6J mouse liver is very low. However, Mrp4 expression is greatly induced by exposure to hepatotoxins that cause oxidative stress, suggesting that this transporter is up-regulated to assist in defending against cellular stress. Additional studies in our laboratory demonstrated that a low hepatotoxic dose of APAP protects against subsequent administration of a higher dose of APAP. This phenomenon is referred to as APAP autoprotection and liver Mrp4 induction is even more pronounced in this mouse model. Despite these findings, the precise role that enhanced Mrp4 expression plays in protecting against APAP hepatotoxicity remains unclear. To study this, we analyzed the responsiveness of Mrp4 heterozygous mice (Mrp4<sup>+/-</sup>) to APAP hepatotoxicity and the ability of these mice to exhibit resistance to APAP upon toxicant re-exposure. The results showed that APAP hepatotoxicity in Mrp4<sup>+/-</sup> mice is significantly higher than in wild-type mice. However, the ability of these mice to develop tolerance to APAP liver injury is unchanged. Analysis of potential differences in gene expression of other hepatic membrane transporters, oxidative stress-related genes and drug detoxification enzymes revealed that there are no significant changes that could account for the differential susceptibility of Mrp4<sup>+/-</sup> mice to APAP toxicity. Based on these results, we conclude that Mrp4 plays a critical role in preventing APAP-induced hepatotoxicity but that its role in APAP autoprotection may be less substantial.

## PS 661 Dual Role of Macrophages in Injury and Repair in Acetaminophen-Induced Hepatotoxicity.

C. R. Gardner<sup>1</sup>, H. M. Choi<sup>1</sup>, J. D. Laskin<sup>2</sup> and D. L. Laskin<sup>1</sup>. <sup>1</sup>Rutgers University, Piscataway, NJ; <sup>2</sup>UMDNJ-RWJ Medical School, Piscataway, NJ.

Activated macrophages and the mediators that they release play a key role in acetaminophen (APAP)-induced hepatotoxicity; however, their role is dependent on their phenotype and timing of appearance in the liver. Whereas classically activated M1 macrophages contribute to tissue injury, alternatively activated M2 macrophages are involved in tissue repair. To assess the role of these macrophage subpopulations in APAP hepatotoxicity, we used gadolinium chloride (GdCl<sub>3</sub>) and clodronate liposomes (CL), which block M1 and M2 macrophages, respectively. Male Long Evans hooded rats were treated with GdCl<sub>3</sub> (7 mg/kg, iv) or CL (0.4 ml/100 g body weight), 24 and 48 h prior to APAP (600 mg/kg, ip). Cells were isolated 24 h later. Treatment of rats with APAP resulted in a decrease in CD163<sup>+</sup> resident repair macrophages in the liver after 24 h, with no significant effect on infiltrating CD11b/CD68<sup>+</sup> M2 repair macrophages. Pretreatment of rats with GdCl<sub>3</sub>, which protects against APAP hepatotoxicity, resulted in a decrease in macrophage expression of inducible nitric oxide synthase, a prototypical marker of classical activation. This was associated with an increase in CD163<sup>+</sup> resident and

CD11b/CD68<sup>+</sup> infiltrating repair macrophages in the liver. Conversely, CL pretreatment, which exacerbates APAP hepatotoxicity, markedly decreased both of these repair macrophage populations. Expression of markers of alternative M2 macrophage activation including STK, macrophage stimulating protein, and arginase-1, as well as the anti-inflammatory cytokine IL-10 were also reduced in CL treated rats. Taken together these data support the concept that macrophages play distinct role in APAP hepatotoxicity depending on their functional capacity. Supported by NIH GM034310, ES004738, CA132624, AR055073 and ES005022.

## PS 662 Induction of Hepatic Bcrp Transporter Expression in Mice Treated with Perfluorooctanoic Acid.

M. Little<sup>1,2</sup>, L. Eldasher<sup>2</sup>, X. Wen<sup>2</sup>, K. M. Bircsak<sup>2</sup>, L. L. Yacovino<sup>2</sup> and L. M. Aleksunes<sup>2,3</sup>. <sup>1</sup>Department of Chemistry and Biochemistry, Montclair University, Montclair, NJ; <sup>2</sup>Department of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ; <sup>3</sup>Toxicology Division, Environmental and Occupational Health Sciences Institute, Rutgers University, Piscataway, NJ.

Perfluorooctanoic acid (PFOA) is an industrial chemical that has been associated with negative health outcomes. The purpose of this study was to determine whether PFOA alters the expression of the breast cancer resistance protein (BCRP/ABCG2), an efflux transporter found in hepatocytes and renal proximal tubule cells, in mice and to determine whether PFOA interferes with BCRP transport in vitro. To test this, Bcrp mRNA and protein expression were measured in the kidneys and livers of male C57BL/6 mice treated with PFOA (1 or 3 mg/kg/d po) for 7 days. In addition, ATPase and membrane vesicle experiments were used to assess whether PFOA alters human BCRP activity. As expected, PFOA treatment increased liver weights as well as the mRNA and protein expression of the known target, cytochrome P450 4a14, in the liver and kidneys of mice. Compared to vehicle-treated control mice, PFOA treatment increased hepatic, but not kidney, Bcrp mRNA and protein between 2- and 3-fold. Immunofluorescent staining revealed enhanced canalicular Bcrp staining in liver sections from PFOA-treated mice. In the ATPase assay, PFOA decreased transporter activity in sulfasalazine-activated BCRP membranes. In addition, PFOA inhibited BCRP-mediated transport in membrane vesicles between 47 and 69% at high concentrations (>25 µM). In conclusion, PFOA induces hepatic Bcrp expression in mice and may inhibit human BCRP function at high concentrations. Supported by DK080774, ES020522, ES020721, ES005022 and ASPET SURF.

## PS 663 Xenosensors Mediated Regulation of ATP Binding Cassette Transporter B6 (ABCB6).

H. D. Chavan and P. Krishnamurthy. *Pharmacology, Toxicology & Therapeutics, Kansas University Medical Center, Kansas City, KS.*

Cytochromes P450 (P450s) are induced in response to therapeutic drugs and environmental contaminants, leading to increased detoxification and elimination of the xenobiotics. Xenosensors like PXR, CAR and AhR play a major role in drug and environmental contaminant induced expression of P450s. Each P450 is composed of an apoprotein moiety and a heme prosthetic group, which is required for P450 activity. Thus, under conditions of P450 induction, there is a coordinate increase in heme biosynthesis to compensate for the increased expression of P450s. ABCB6, a mitochondrial ABC transporter, is shown to regulate heme biosynthesis by modulating coproporphyrinogen transport from the cytoplasm into the mitochondria. However, it is not known if exposure to xenobiotics induces ABCB6 expression, to assure an adequate and apparently coordinated supply of heme for the functional P450. In the present study, we evaluated the role of xenosensors PXR, CAR and AhR in the regulation of Abcb6. Our results demonstrate that AhR and CAR but not PXR regulate ABCB6 expression. AhR mediated regulation of Abcb6 expression was observed both in mice and in human cell lines, while CAR mediated regulation of Abcb6 expression was seen only in mice and not in human cell lines. Further, promoter activation studies demonstrate that both AhR and CAR induce Abcb6 expression by interacting with their respective response elements in the 5' flanking region of the Abcb6. These studies are the first to describe direct transcriptional activation of both mouse and human ABCB6 by xenobiotics similar to those found in inducible P450s. The results presented in this work have both pharmacological and toxicological significance. AhR ligands have the ability to precipitate porphyria and both AhR and CAR ligands have been shown to promote cell growth and proliferation. We have previously shown that ABCB6 expression promotes cell growth and proliferation during carcinogenesis. Thus, ABCB6 induction by xenosensors AhR and CAR could be a potential contributing factor in drug induced porphyria and carcinogenesis.

**PS 664** **Hepatic Flavin-Containing Monooxygenase-3 (FMO3) Protein Is Inducible by Acetaminophen Treatment.**

S. Rudraiah and J. E. Manautou. *University of Connecticut, Storrs, CT.*

Flavin-containing monooxygenase 3 (FMO3) is a drug-metabolizing enzyme with functions similar to CYP450. Hepatic expression of human FMO3 gene is highly variable and is important in the detoxification of xenobiotics. Fmo3 was thought to be non-inducible but recent data showed that activation of the Ah receptor induces Fmo3 mRNA in mice. Recent microarray work by our group also showed a drastic induction of liver Fmo3 mRNA expression in a mouse model of resistance to acetaminophen (APAP) hepatotoxicity (autoprotection). In addition to APAP, alpha-naphthyl isothiocyanate treatment and bile duct ligation in mice markedly increase Fmo3 gene expression. The purpose of this study was to evaluate the Fmo3 gene regulation and protein expression during APAP hepatotoxicity. Among all Fmo isoforms analyzed for mRNA expression, Fmo3 was most significantly induced following a single dose of APAP (400mg/kg). Although Fmo3 mRNA levels increased significantly by APAP, its protein expression was marginally changed. Consistent with this, the catalytic activity of Fmo3 measured by oxygenation of methimazole did not change significantly either. By contrast, both Fmo3 mRNA and protein expression are significantly higher in mice pretreated and re-exposed to APAP (autoprotection model). In agreement with greater Fmo3 protein expression in livers of autoprotected mice, its catalytic activity was also significantly higher. In summary, the dramatic changes in Fmo3 gene expression produced by a single dose APAP are not accompanied by concomitant changes in protein and enzyme function, whereas livers from mice pretreated and re-exposed to APAP exhibit induction of both Fmo3 protein expression and catalytic function. Additional work is currently underway to determine the functional significance of enhanced Fmo3 protein function and which factors and signaling pathways mediate Fmo3 gene and protein expression during APAP toxicity. Taken together, these findings establish for the first time induction of not only Fmo3 gene expression, but also significant protein levels and function. Supported by NIH DK069557.

**PS 665** **Vanin-1 Knockout Mice Exhibit Alterations in Compensatory Immune Infiltration and Hepatocyte Proliferation following Acetaminophen Toxicity.**

D. Ferreira<sup>1</sup>, F. Galland<sup>2</sup>, P. Naquet<sup>2</sup> and J. E. Manautou<sup>1</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT; <sup>2</sup>Centre d'Immunologie de Marseille-Luminy CNRS-INSERM, Université de la Méditerranée, Marseille, France.

Previously we have shown that Vanin-1 (Vnn1) knockout mice are more susceptible to APAP hepatotoxicity (400mg/kg, i.p.) despite no differences in hepatic glutathione (GSH) content or gene expression of APAP metabolizing enzymes or transporters. Here we show that in vitro, livers from both genotypes showed similar capacities to bioactivate APAP to its reactive metabolite (~1.8 nmol APAP-NAC/min/mg protein) and to detoxify the parent compound by glucuronidation (~1.7 nmol APAP-Gluc/min/mg protein) and sulfation (~15.6 pmol APAP-Sulf/min/mg protein). Together, these data strongly suggest that the enhanced susceptibility of Vnn1 knockout mice to APAP toxicity is not due to differences in APAP metabolism. Immunohistochemistry of formalin-fixed liver sections following APAP treatment revealed a lack of PCNA positive hepatocytes and F4/80 positive macrophages in and around areas of centrilobular necrosis in Vnn1 knockouts at 48 hours after APAP. qRT-PCR from total RNA isolated from whole livers indicated that inducible nitric oxide synthase (iNos) and interleukin-4 were reduced by 2.9 and 4.3 fold, respectively, in control treated Vnn1 knockout mice relative to wild-types. Additionally, interferon  $\gamma$  was 2.7 fold lower in Vnn1 knockout mice at 48 hours after APAP treatment in comparison to wild-types. Myeloperoxidase and iNos exhibited a trend of decreased expression in Vnn1 knockouts at 48 hours, but these differences were not statistically significant. Together, these results indicate that a lack of Vnn1 expression may alter the normal compensatory repair and immune responses following toxic APAP exposure although it is unknown to what extent these mechanisms contribute to the enhanced susceptibility of Vnn1 knockout mice to APAP hepatotoxicity.

**PS 666** **Transcription Regulation by Novel Interaction of Kruppel-Like Factor 6 with Aryl Hydrocarbon Receptor at the NC-XRE.**

A. D. Joshi, D. P. Jackson, S. R. Wilson and C. Elferink. *Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX.*

The Aryl Hydrocarbon Receptor (AhR) is a ubiquitous, ligand mediated basic helix-loop-helix transcription factor of Per/ARNT/Sim family that regulates adaptive and toxic responses to variety of chemical pollutants such as polycyclic aromatic hydrocarbons (PAH) and halogenated aromatic hydrocarbons, most notably

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Upon ligand activation, the AhR translocates into the nucleus and binds to DNA at the XRE along with aryl receptor nuclear translocator (ARNT) and facilitates transcription of cytochrome P450 family members. In addition, AhR-regulated gene expression is known to regulate G1 phase cell cycle progression. Recent DNA microarray experiments by our group showed that plasminogen activator inhibitor 1 (PAI-1) is a TCDD responsive gene lacking the XRE. Subsequent characterization identified a novel non-consensus XRE (NC-XRE) located within the PAI-1 promoter that supports direct binding of AhR independent of ARNT. While the XRE and NC-XRE are distinct entities, the NC-XRE shares marked homology with the DNA binding sequence of the Kruppel-like Factor (KLF) family of transcription factors. The KLF superfamily of proteins are related to Sp1 and characterized by three zinc finger domains in their C-termini that confer binding to a GC-box linked to diverse target genes. Our results indicate that AhR interacts directly with KLF6 at the NC-XRE in a dioxin-dependent manner. Furthermore, sequential deletion studies demonstrate the importance of the AhR C-terminal and KLF6 N-terminal domains in this interaction. Since KLF6 is a liver specific tumor suppressor that has been shown to induce transcription of the G1 cyclin-dependent kinase inhibitor p21Cip1, the potential exists for overlapping or common roles involving both proteins in cell cycle regulation. Our further studies will focus on mapping the AhR complex at NC-XRE and understanding the role of this complex in transcription regulation. This work was supported by R01ES007800 and P30ES006676.

**PS 667** **Mild Endoplasmic Reticulum Stress Preconditioning Attenuates Methylmercury-Induced Cellular Damage by Inducing Favorable Stress Responses.**

F. Usuki<sup>1</sup>, M. Fujimura<sup>2</sup> and A. Yamashita<sup>3</sup>. <sup>1</sup>Clinical Medicine, National Institute for Minamata Disease, Minamata, Japan; <sup>2</sup>Basic Medical Sciences, National Institute for Minamata Disease, Minamata, Japan; <sup>3</sup>Molecular Biology, Yokohama City University School of Medicine, Yokohama, Japan. Sponsor: A. Naganuma.

Methylmercury (MeHg) toxicity is a continuous environmental problem to human health. Failure to protect cells against MeHg-induced early oxidative stress triggers subsequent endoplasmic reticulum (ER) stress and apoptosis. Here, we demonstrate the protective effects of mild ER stress preconditioning against MeHg toxicity on a MeHg-susceptible cell line. Cells preconditioned with low concentrations (0.1-0.3  $\mu$ g/ml) of an inhibitor of ER  $\text{Ca}^{2+}$ -ATPase, thapsigargin (TPG), showed resistance to MeHg cytotoxicity through several favorable stress responses, which included phosphorylation of eukaryotic initiation factor 2 alpha (Eif2 $\alpha$ ), accumulation of activating transcription factor 4 (Atf4), and upregulation of stress-related proteins (glucose regulated protein of 78 kDa (Grp78) and metallothionein 1 (Mt1)). Atf4 accumulation was mediated by translation inhibition of its upstream open reading frame (uORF) and translation facilitation of its protein-coding ORF by the phospho-Eif2 $\alpha$ . Nonsense-mediated mRNA decay (NMD) activity was suppressed by the combined effects of decreased expression of several NMD components besides the phospho-Eif2 $\alpha$ -mediated general suppression of translation initiation, resulting in accumulated Atf4 mRNA but not protein. Integrated stress responses led to a delay of MeHg-induced oxidative stress and the activation of extracellular signal-regulated kinase pathways to promote cell survival in preconditioned cells exposed to MeHg. Finally knockdown experiments demonstrated that Grp78 plays a crucial role in protecting preconditioned cells against MeHg cytotoxicity. These results suggested that mild ER stress preconditioning is a useful therapeutic intervention against MeHg toxicity, the underlying mechanism being the induction of integrated stress responses.

**PS 668** **Differences in Regulation of Gene Expression Profiles of the Bone Marrow between C57BL/6 and C3H/He Mice after Benzene Treatment.**

Y. Hirabayashi<sup>1</sup>, B. Yoon<sup>2</sup>, K. Igarashi<sup>1</sup>, J. Kanno<sup>1</sup> and T. Inoue<sup>3,4</sup>. <sup>1</sup>Cell & Molecular Toxicology Division, Biology Safety & Research Center, National Institute of Health Sciences, Tokyo, Japan; <sup>2</sup>Histology & Molecular Pathogenesis Laboratory, School of Veterinary Medicine, Kangwon National University, Chuncheon, Republic of Korea; <sup>3</sup>Function & Structural Medicine Department, Nihon University School of Medicine, Tokyo, Japan; <sup>4</sup>National Institute of Health Sciences, Tokyo, Japan.

We focused on the differences in the regulation in gene expression profiles of the bone marrow, which predict benzene-specific early responses related to plausible leukemogenic changes, between C57BL/6 (B6), a lymphoid-neoplastic-prone mouse strain, and C3H/He (C3H), a myelogenous-leukemia-prone mouse strain. Previously, we showed a latent potential of induction of myelogenous leukemias by benzene in both strains, but with different mechanistic propensities. Consequently, reciprocal differences between B6 and C3H mice in gene expression profiles related

to leukemogenesis were found by gene chip analyses 28 days after benzene treatment. Because leukemia did not develop in all mice even under the optimal condition, we further analyzed the data, focusing on not only strain differences but also individual differences. Two types of gene expression profile were recognized: one, corresponding to common gene profiles obtained by one-way analysis of variance or Welch's t-test, which were commonly shared by all mice in the same group each; and the other, corresponding to stochastic gene-expression profiles obtained by principal component analysis, which were unique genes in each individual mouse. The results clearly elucidated that the predicted gene expression profiles in the regulation of transcription factors (TFs) for proliferation were essentially different in each strain. The selected TFs, i.e., 20 for B6 and 11 for C3H, were less overlapped among each mouse in the same strain, and their regulation showed the coexistence of both suppression and activation signals in B6, whereas suppressive signals were generally predominant in C3H. These differences in regulatory gene-expression profiles may be essentially related to the strain differences in the incidence and spectrum of the leukemogenesis after benzene treatment.

## PS 669 Biphase Influence of Arsenic, Cadmium, Mercury, and Nickel on Aryl Hydrocarbon Receptor (AhR) Signaling.

A. Rannug<sup>1</sup>, A. Mohammadi-Bardbori<sup>1</sup>, L. Vikström Bergander<sup>1</sup> and U. Rannug<sup>2</sup>. <sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Department of Genetics, Microbiology and Toxicology, Stockholm University, Stockholm, Sweden.

Interaction of oxidants with the metabolic turnover of the endogenous AHR ligand 6-formylindolo[3,2-b]carbazole (FICZ) seems to play critical roles in downstream AHR-mediated signaling. Production of superoxide leading to increased proliferation was observed after exposure of immortalized human keratinocytes (HaCaT) to low levels of As<sup>3+</sup>, Cd<sup>2+</sup>, Hg<sup>2+</sup> and Ni<sup>2+</sup>. Higher concentrations lowered the intracellular GSH levels and led to temporal inhibition of FICZ-stimulated cytochrome P4501A1 (CYP1A1) activity and increased adaptive antioxidant responses as measured by expression of antioxidant genes. After addition of FICZ (150 pM) together with the metals a temporal inhibition of the metabolic degradation of FICZ occurred, as determined by HPLC analyses. At these inhibitory concentrations, the metals themselves activated CYP1A1 at late time points. Transcriptional activation of CYP1A1 was estimated with a luciferase reporter assay in human hepatoma HepG2-XRE-Luc cells and the ability of the metals to activate the AHR only in the presence of the natural ligand FICZ was established by comparing AHR activation in commercial DMEM medium and in DMEM medium free from background levels of FICZ. NADPH oxidase (NOX) activity was critical for the stimulation of proliferation by the metals as determined by lack of proliferative responses in human X-CGD myeloid cells carrying a mutated gp91phox gene. In addition, influence of NOX on CYP1A1 gene expression was indicated by lower metal-stimulated luciferase activity in HepG2 cells treated with the NOX inhibitor diphenyliodonium. Pretreatment with the metals led 24 h later to elevated GSH levels and increased sensitivity of the AHR to low levels of FICZ (superinduction). We propose that the AHR/CYP1-dependent auto-regulatory feed-back mechanism, which ensures low steady-state levels of FICZ, works in close concert with the NADPH oxidase system.

## PS 670 Differential Gene Expression Responses by Hepatic Lobe in Fischer Rats Treated with Carcinogens Phenobarbital and Diethylnitrosamine.

B. Li<sup>1</sup>, M. W. Trimble<sup>2</sup>, D. Henderson<sup>1</sup>, S. Stepanians<sup>1</sup>, M. L. Parrish<sup>1</sup>, B. Kevin<sup>2</sup>, A. Sharma<sup>2</sup>, G. A. Boorman<sup>3</sup> and S. Williams<sup>2</sup>. <sup>1</sup>Covance Genomics Laboratories, Inc., Seattle, WA; <sup>2</sup>Covance Laboratories, Inc., Madison, WI; <sup>3</sup>Covance Laboratories, Inc., Chantilly, VA.

Rodent liver is a primary organ for assessing compound toxicity. Non-genotoxic carcinogens such as phenobarbital (PB) and genotoxic carcinogens such as diethylnitrosamine (DEN) induce morphological and physiological changes in the liver that may vary by lobe. For example, DEN induces more tumors in the right liver lobe than in the left and median lobes. To elucidate the molecular mechanisms underlying the differential compound responses, as well as the differences among the three liver lobes, groups of male Fischer rats were treated with 0 or 7.5 mg/kg/day of DEN, or 0 or 65 mg/kg/day of PB, by daily oral gavage for two and four weeks. Samples of the right lateral (RL), right median (RM), and left lateral (LL) hepatic lobes were obtained for gene expression analysis and pathological assessment. DEN induced slight apoptosis/necrosis of individual hepatocytes in all lobes, while administration of PB was associated with centrilobular hypertrophy that was much less prominent in the left lateral lobe compared with the other lobes. Gene expression profiles were assessed for three animals/group/interval using whole genome

microarrays. The data showed that PB and DEN both induced robust, yet quite distinct, transcriptional changes in the animals, which could partially explain the differential morphological/physiological outcomes. In both groups of vehicle-treated rats, the transcriptional profile of the LL lobe was much different from those of the RL and RM lobes, whereas the latter two were quite similar to each other. In animals given DEN or PB, such lobe difference was much reduced, slightly more so in the rats given DEN than in those given PB. Overall, the gene expression profile may provide clues to the mechanism of PB- and DEN-induced liver tumors, and possible molecular biomarkers for predicting liver toxicity.

## PS 671 In Vitro Effects of Aldehydes Present in Tobacco Smoke on Gene Expression in Human Lung Alveolar Epithelial Cells.

N. Cheah<sup>1,2,4</sup>, J. Pennings<sup>2</sup>, J. Vermeulen<sup>2</sup>, F. J. van Schooten<sup>1</sup> and A. Opperhuizen<sup>1,3</sup>. <sup>1</sup>Toxicology, Maastricht University, Maastricht, Netherlands; <sup>2</sup>Laboratory for Health Protection Research, National Institute for Public Health and the Environment, Bilthoven, Netherlands; <sup>3</sup>Risk Assessment, Netherlands Food and Consumer Product Safety Authority, Utrecht, Netherlands; <sup>4</sup>Cigarette Testing Laboratory, Health Sciences Authority, Singapore, Singapore. Sponsor: H. van Loveren.

Tobacco smoke consists of thousands of harmful components. A major class of chemicals found in tobacco smoke is formed by aldehydes, in particular formaldehyde, acetaldehyde and acrolein. The present study investigates the gene expression changes in human lung alveolar epithelial cells upon exposure to formaldehyde, acrolein and acetaldehyde at sub-cytotoxic levels. We exposed A549 cells in vitro to aldehydes and non-aldehyde chemicals (nicotine, hydroquinone and 2,5-dimethylfuran) present in tobacco smoke and used microarrays to obtain a global view of the transcriptomic responses. We compared responses of aldehydes with that of the non-aldehydes. Formaldehyde gave the strongest response; a total of 66 genes was greater than 1.5-fold differentially expressed mostly involved in apoptosis and DNA damage related processes, followed by acetaldehyde (57 genes), hydroquinone (55 genes) and nicotine (8 genes). Acrolein and mixture gave effects to oxidative stress genes, no gene expression effect found on the exposure to 2,5-dimethylfuran. Overall, aldehyde responses are primarily indicative for genotoxicity and oxidative stress. These two toxicity mechanisms are linked to respiratory diseases such as cancer and COPD, respectively. The present findings could be important in providing further understanding of the role of aldehydes emitted from cigarette smoke in the onset of pulmonary diseases.

## PS 672 Regulation of the Metabolic Switch between Ductal Carcinoma In Situ (DCIS) and Invasive Breast Cancer (IBC).

K. C. Scribner<sup>1</sup>, Y. Fan<sup>2</sup>, M. Ragavan<sup>3</sup>, R. Chapkin<sup>2</sup>, C. Hilty<sup>3</sup>, H. Payne<sup>4</sup>, R. Mounieime<sup>4</sup>, F. Behbod<sup>5</sup> and W. Porter<sup>1</sup>. <sup>1</sup>Integrative Biosciences, Texas A&M University, College Station, TX; <sup>2</sup>Integrative Nutrition and Complex Diseases, Texas A&M University, College Station, TX; <sup>3</sup>Chemistry, Texas A&M University, College Station, TX; <sup>4</sup>Image Analysis Laboratory, Texas A&M University, College Station, TX; <sup>5</sup>Pathology and Laboratory Medicine, University of Kansas Medical Center, Kansas City, KS.

Ductal carcinoma in situ (DCIS) accounts for 15-25% of breast cancers. However, there is a gap in our understanding of the factors that regulate the progression of DCIS to invasive breast cancer (IBC). Deregulation of cell metabolism is a defining feature of tumor cells, which utilize glycolysis instead of oxidative phosphorylation. Since altered metabolism promotes invasion and metastasis, the mechanisms regulating this switch could be critical in mediating the transition from DCIS to IBC.

Single-minded-2s (Sim2s) is present in early stage DCIS lesions and lost in IBC. Re-establishment of SIM2s in the MCF10DCIS.com model inhibits tumor growth, invasion, and metastasis. We hypothesize that SIM2s plays a key role in mediating the switch between DCIS and IBC.

To determine the effect of SIM2s on metabolism in DCIS progression, we analyzed SIM2s over and under-expressing MCF10DCIS.com cells for energy dependent differences in growth, autophagy, and metabolism. Live cell imaging and TEM were used to determine SIM2s' effect on mitochondria and autophagy. Nuclear Magnetic Resonance and Seahorse analysis was employed to compare differences in metabolic signatures and measure oxidative phosphorylation and glycolytic capacity.

Re-establishment of SIM2s induced oxidative phosphorylation and adaptation to metabolic stress through increased oxygen consumption, whereas loss of SIM2s promoted glycolysis by elevating glucose uptake and lactate production.

These results suggest that SIM2s plays a critical role in DCIS progression and loss of SIM2s is required for the switch from oxidative phosphorylation to glycolysis.

**PS 673 Hypoxia Perturbs PCB-Induced Aryl Hydrocarbon Receptor Signaling and CYP1A1 Induction in Human Cells.**

S. U. Vorrink and F. E. Domann. *Human Toxicology, The University of Iowa, Iowa City, IA.*

The aryl hydrocarbon receptor (AhR) pathway controls cellular responses to exposure of foreign substances by activating genes that aid in xenobiotic metabolism. The ligand-activated AhR forms a heterodimer with its binding partner aryl hydrocarbon receptor nuclear translocator (ARNT) and subsequently induces the transcription of genes such as CYP1A1, a member of the cytochrome P450 family and a phase I detoxifying enzyme. Notably, ARNT proteins also dimerize with hypoxia-inducible factors (HIF $\alpha$ ) which mediate the cellular response to low oxygen (hypoxia). During hypoxia, HIF $\alpha$ :ARNT heterodimers form and activate the transcription of genes that promote cell survival in low oxygen environments. Since HIF $\alpha$  and AhR share a common subunit, ARNT, the possibility for signaling crosstalk exists at this axis. We hypothesized that hypoxic conditions cause HIF $\alpha$  to sequester ARNT and thus inhibit the activation of a robust AhR transcriptional response in response to a polychlorinated biphenyl (PCB) AhR ligand. To test this hypothesis we queried several human cell lines for their responses to PCBs. Our results indicate that CYP1A1 mRNA expression was induced by 3,3',4,4',5-pentachlorobiphenyl (PCB 126) in an AhR-specific manner. Exposure of the cells to hypoxia (1% oxygen for 8 hours) significantly inhibited the induction of CYP1A1 mRNA by up to 74%. EMSA and CYP1A1 promoter:Luciferase reporter assays to measure DNA binding and transcriptional activities of AhR complexes further showed an inhibitory effect of hypoxia treatment on PCB-induced AhR signaling. Growth curve and MTT assays demonstrated significant growth inhibition following PCB 126 treatment. Taken together, these findings indicate that hypoxia significantly interferes with AhR-mediated responses to PCBs. Our future studies will investigate whether the observed effects also occur at the protein level and whether hypoxia can prevent the growth inhibitory effect of PCB treatment. (Supported by grant NIEHS P42 ES 013661.)

**PS 674 Characterizing Chronic Nicotine Exposure-Induced Behaviors and Gene Regulations in *Caenorhabditis elegans*.**

J. R. Polli, F. A. Taki, M. A. Smith and X. Pan. *Biology, East Carolina University, Greenville, NC.* Sponsor: J. DeWitt.

Nicotine is one of the most abused substances. Nicotine binds nicotinic acetylcholine receptors (nAChRs), stimulates the mesolimbic dopamine system, and leads to addiction. With chronic exposures to low concentrations of nicotine are a common scenario, this study aims to characterize chronic nicotine exposure-induced behaviors and explore affected gene pathways in the model organism, *Caenorhabditis elegans* (*C. elegans*). *C. elegans* were treated with control, 6.17  $\mu$ M, and 61.7  $\mu$ M of nicotine for 24-hour and locomotion behaviors were characterized using a worm tracking system. Our preliminary data has determined several additive behavioral patterns following chronic low range micromolar nicotine exposures, including stimulation, withdrawal, and tolerance. Locomotive behaviors were stimulated in control worms that were exposed to nicotine. Withdrawal behaviors were observed as increased locomotion speeds when nicotine dosages were disrupted in nicotine-dependent worms. We also detected the expressions of 39 functional genes implicated in cholinergic signaling, locomotion, egg-laying, and stress-response. Findings showed that gene expressions are most active in low but not in high concentration dosages. The expression profiles of all the tested protein-coding genes were affected with a range from 12.5 fold down-regulation (old-1) to 138.1 fold up regulation (hlh-14). Nicotine exposure also affected the expression of microRNAs, an extensive class of a small regulatory RNAs.

**PS 675 TNIP1 Regulates the Cell Stress Response through Repression of Heat Shock Proteins A6 and A1A.**

V. P. Ramirez<sup>1</sup>, M. Stamatis<sup>2</sup>, A. Shmukler<sup>2</sup>, C. Zhang<sup>3</sup> and B. J. Aneskievich<sup>3</sup>.

<sup>1</sup>Pharmacology & Toxicology Program, University of Connecticut, Storrs, CT;

<sup>2</sup>PharmD Program, University of Connecticut, Storrs, CT; <sup>3</sup>Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT.

TNIP1 protein represses gene expression otherwise activated by NF- $\kappa$ B, RAR, and PPAR. Additionally, TNIP1 expression is increased in several cutaneous inflammatory diseases and wound healing. Thus, while some transcription factor targets and pathologies have been recognized, the spectrum of genes possibly affected by TNIP1 is unknown. To identify additional gene expression changes due to increased TNIP1 levels, we conducted a microarray analysis from keratinocytes transiently overexpressing TNIP1.

In addition to repression of genes known to be activated by NF- $\kappa$ B, RAR, and PPAR, a surprising result of decreased HSP gene family expression was observed (ex. 20x and 3.2x for HSPA6 and A1A, resp.). This reduction was confirmed by

qPCR and western blot. Both HSPA6 and A1A have similar functions in cell protection where knockdown of either HSP reduced cell viability post-cell stress. Since HSPA6 basal and induced expression was decreased by TNIP1, it was chosen for further studies.

To guide analysis of how HSPA6 may be regulated by TNIP1, we isolated and performed in silico analyses on the HSPA6 3-kb promoter. Putative PPAR, RAR and NF- $\kappa$ B sites were found. PPAR $\alpha$  and RAR ligands had no effect, but PPAR  $\beta/\delta$  and  $\gamma$  ligands increased HSPA6 expression ~4x. To search for TNIP1-responsive region(s), we cloned 5'-HSPA6 promoter deletions into a reporter construct. Intriguingly, the most repressed region lacks PPREs, RAREs, and NF- $\kappa$ B sites. These results suggest that although PPAR can regulate HSPA6 and TNIP1 may be repressing HSPA6 through this transcription factor, there is an additional TNIP1-sensitive region independent of its previously identified PPAR, RAR and NF- $\kappa$ B targets. Moreover, our data suggests TNIP1-mediated HSPA6 repression is independent of PPAR, RAR or NF- $\kappa$ B, suggesting there may be additional, as yet unrecognized, targets where interaction with TNIP1 results in reduced transcriptional activity.

**PS 676 Erk1/2 Pathway Inhibition Attenuates BoNT/A-Induced Neurite Outgrowth in Motor Neurons.**

L. Liu and J. A. Coffield. *University of Georgia, Athens, GA.*

Botulinum neurotoxin A (BoNT/A) is known to be neurotoxic due to its paralytic effect at cholinergic synapses with extremely high potency. Independent of that, BoNT/A has been found to stimulate neurite outgrowth of motor neurons both in vivo and in vitro, which may account at least in part for the initiation of recovery from botulism. The signaling pathways regulating the BoNT/A-induced neurite outgrowth process have not been identified. In the current study, we used pharmacologic kinase inhibition to investigate the more relevant outgrowth pathways. GFP positive motor neurons were directly differentiated from HBG3 mouse embryonic stem cells, and treated with a MEK1/2 inhibitor in the presence of 1nM BoNT/A. Following 6 and 24h post BoNT/A exposures, single motor neurons were image-captured. The total neurite length and number of branches of primary and secondary neurites were measured and counted. Significant differences were determined using one-way or two-way ANOVA with post hoc tests. Preliminary results showed that 10  $\mu$ M of the MEK1/2 inhibitor specifically blocked BoNT/A's stimulatory effect on secondary branching at 6h compared to toxin only treated controls, suggesting an early, transient role in BoNT/A-induced signal transduction. In addition, there was no effect of MEK1/2 inhibition on the toxin's enzymatic action to cleave SNAP-25. Collectively, these data suggest that ERK1/2 pathway may play an important role in the early phases of BoNT/A-induced neurite outgrowth.

**PS 677 Inhibition of TGF $\beta$ -Induced Integrin- Growth Receptor Cooperative Signaling by Cucurbitacin B, Causes Breast Cancer Growth Suppression.**

P. Gupta and S. K. Srivastava. *TTUHSC, Amarillo, TX.*

Integrins have recently been shown to play an important role in promotion of cell motility and survival in various cancers through cooperative signaling with EGFRs. Integrins transmit cell survival signals through ILK-Paxillin complex and further play role in activating AKT signaling. Cucurbitacin B (CuB) is a steroidal class of chemical present in the plants belonging to cucurbitaceae family. CuB has shown cytotoxic potential in several cancers by causing G2/M cell cycle arrest and inhibition of JAK/STAT3 pathway. However, the exact mechanism of CuB and its role in metastasis and cell survival is not known. Our results show that CuB significantly suppressed the growth of MDA-MB-231, SKBR3, MCF-7, MDA-MB-231 (HER2) and MCF-7 (HER2), five different breast cancer cells in a concentration and time-dependent manner. CuB also induced apoptosis and down-regulated ILK1 expression. In addition, CuB down-regulated ITGB4 and ITGA6 protein expression and suppressed the phosphorylation of AKT at Ser473, paxillin at Tyr118. Previous studies have shown that TGF $\beta$  mediates physical association of ITGB4 and HER2, through Src kinase to enhance cell survival and motility. Interestingly we observed significant downregulation of Src, EGFR and HER2 in different breast cancer cells, suggesting that CuB suppresses cooperative signaling of Integrins and HER2. We also observed that TGF $\beta$  pretreatment imparted protection from CuB's cytotoxic effects, indicating that CuB modulates TGF $\beta$  mediated Integrin signaling. Taken together our results indicate the anti-cancer effects of CuB in breast cancer cells by targeting ITGB4/ITGA6, Src, ILK and TGF $\beta$ . Further detailed mechanistic work is in progress. [Supported in part by R01 grants CA106953 and CA129038 (to S.K.S.) awarded by the National Cancer Institute].

Key: ITGB4 – Integrin  $\beta$ 4, ITGA6 – Integrin  $\alpha$ 6, TGF $\beta$  – Transforming growth factor  $\beta$ , ILK- Integrin linked kinase, EGFR – Epidermal growth factor receptor, CuB – Cucurbitacin B

**PS 678 High Content Live-Cell Imaging of Nrf2 and NF- $\kappa$ B Signaling Reporters As Predictive Tools to Classify Drug-Induced Liver Injury Responses.**

B. Herpers, L. Fredriksson, Z. Di, H. de Bont and B. van de Water. *Toxicology, Leiden University, Leiden, Netherlands.*

Drug-induced liver injury (DILI) is an important clinical problem and predicting human DILI for novel candidate drugs is difficult. Current models indicate that in many cases DILI is linked to reactive metabolite formation and involves activation of innate immune systems. Here we systematically evaluated the combined application of high content live cell imaging-based analysis of 1) NRF2 activation as a measure for reactive metabolite stress, 2) perturbations of the normal NF- $\kappa$ B activation mediated by TNF $\alpha$ ; and 3) synergistic induction of apoptosis by DILI compounds and TNF $\alpha$ . Fifteen drugs associated with DILI were evaluated. Most DILI compounds induced NRF2 stabilization-dependent activation of the downstream target SRXN1 (11 out of 15). Various DILI compounds affected the TNF $\alpha$ -induced activation of NF- $\kappa$ B (6 out of 15), which strongly correlated to the strength of NRF2 activation. In particular for those compounds that show strong NRF2 activation and perturbation of NF- $\kappa$ B signaling, a significant drug-cytokine synergy for apoptosis was observed, which included carbamazepine, diclofenac, ketoconazole, clozapine, nefazodone and amiodarone. Together, our data support that mechanism-based high content imaging strategies involving combined analyses of cellular stress responses contribute to DILI hazard identification.

**PS 679 Translation Initiation Factor EIF4A1 Determines TNF $\alpha$ -Mediated Apoptosis in Drug-Induced Liver Injury through the Stress Protein Chop.**

L. Fredriksson, B. Herpers, S. Wink, J. Meerman and B. van de Water. *Toxicology, Leiden University, Leiden, Netherlands.*

Drug-induced liver injury (DILI) is an important clinical problem and to minimize it a more detailed knowledge about the mechanism is essential. Here we used a functional genomics approach to establish the critical drug-induced toxicity pathways that act in synergy with the pro-inflammatory cytokine tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) to cause apoptosis of liver HepG2 cells. Transcriptomics-based analysis of the toxicity response pathways activated by hepatotoxicants diclofenac (DCF) and carbamazepine (CBZ) revealed significant activation of the nuclear factor-erythroid 2 (NF-E2)-related factor 2 (Nrf2) oxidative stress response, and endoplasmic reticulum (ER) stress/translational initiation signaling. Importantly, significant activation of these pathways after drug exposure could be confirmed by transcriptomics of primary hepatocyte cultures as well as *in vivo*. Systematic siRNA-mediated knockdown of the individual toxicity pathway determinants established the critical roles of these pathways for the drug/TNF $\alpha$ -induced apoptosis in the HepG2 cell system. Pre-induction of the cytoprotective Nrf2 pathway by knockdown of its negative regulator Kelch-like ECH-associated protein 1 (Keap1) suppressed the drug/TNF $\alpha$  synergy. Furthermore, ER stress signaling by selective protein kinase R-like ER kinase (PERK) activation and subsequent expression of C/EBP-homologous protein (CHOP) was crucial in the onset of drug/TNF $\alpha$ -induced apoptosis independent of drug-induced oxidative stress. Interestingly, CBZ and DCF caused an enhanced expression of the translational initiation factor EIF4A1. Importantly, depletion of EIF4A1 almost completely inhibited CHOP expression in association with protection against the drug/TNF $\alpha$ -mediated cell killing. We propose a model in which enhanced drug-induced translation initiates PERK-mediated CHOP signaling thereby sensitizing towards caspase-8-dependent TNF $\alpha$ -induced apoptosis.

**PS 680 The Effect of Thermal Stress on *Drosophila melanogaster* Gene Expression.**

K. Silkaitis<sup>1,2</sup>, A. Branco<sup>1</sup> and B. Lemos<sup>1</sup>. <sup>1</sup>Molecular and Integrative Physiological Sciences, Department of Environmental Health, Harvard School of Public Health, Boston, MA; <sup>2</sup>Temple University, Philadelphia, PA. Sponsor: V. Vaidya.

Genetic tools can be used to dissect the biological pathways mediating stress response. Studying *Drosophila melanogaster* responses to environmental stress is informative because prior studies have shown that resistance to one type of environmental stress often confers resistance to additional stresses. In particular, temperature stress can alter thermal homeostasis, which can affect the biological dosage of an environmental toxicant. In *D. melanogaster*, thermal stress has been shown to affect males differently than females, demonstrated not only by male sterility but also in autosomal and X-linked gene expression. Gene expression is further controlled by the geographic origin of the Y chromosome. We investigated the effect of cold stress on two genotypes of *D. melanogaster* that contained a Y chro-

mosome from a natural population in either Massachusetts (Ymass) or Democratic Republic of the Congo (Ycongo), temperate and tropical climates, respectively. Newly emerged male flies were collected and reared at 25°C or 16°C. The flies were then flash frozen, total RNA was extracted and hybridized to a microarray, and differential expression (DE) of genes was assessed with Bioconductor/Limma. We identified more than 1,000 DE genes ( $p < 0.001$ ) in common between the comparisons of Ymass 16°C to 25°C and Ycongo 16°C to 25°C. Gene expression in the testes was most affected by temperature among the 27 tissues examined, while genes relating to calcium binding, metabolism, and cell proliferation showed high levels of DE. In tandem, we examined the effects of parental growth temperature on gene expression in male F1 progeny. We found that maternal exposure to cold stress differentially affected the expression of genes in progeny involved in cell death, metabolism, and responses to sodium. Together, these results suggest that responses to environmental stressors, including toxicants, may depend on both temperature and Y chromosome genotype.

**PS 681 Dual Mechanisms for Controlling Chk1 Protein Levels.**

F. Zhang, S. S. Lau and T. J. Monks. *Department of Pharmacology and Toxicology, College of Pharmacy, University of Arizona Health Sciences Center, Tucson, AZ.*

2,3,5-tris(glutathion-S-yl)hydroquinone (TGHQ), a metabolite of benzene, catalyzes the generation of reactive oxygen species (ROS), and caspase-dependent apoptosis in HL-60 cells. We now report that TGHQ induced severe DNA damage, as evidenced by DNA ladder formation and histone H2AX phosphorylation, and the subsequent engagement of checkpoint response pathways. Thus, TGHQ induced the activation of both ATR and ATM, which initiate the mammalian DNA damage response via the phosphorylation of the effector proteins Chk1 and Chk2. Perturbation of Chk1 signaling abrogates the TGHQ-induced S-phase arrest, indicating an important role for Chk1 in the S-phase checkpoint following TGHQ-induced DNA damage. Moreover, Cdc25A, which is required for the intra-S phase checkpoint, was degraded in HL-60 cells treated with TGHQ. TGHQ also substantially decreased Chk1 levels, primarily by decreasing the Chk1 gene transcription. Consistent with these findings, MG-132, a proteasome inhibitor, failed to restore Chk1 protein levels. Interestingly, MG-132 itself ( $> 0.1 \mu\text{M}$ ) decreased Chk1 expression, whilst simultaneously inducing Ser-345 Chk1 phosphorylation. RT-PCR data revealed that MG-132 down-regulates Chk1 gene expression. Finally, following S-phase cell synchronization with aphidicolin, TGHQ strikingly attenuated the S-phase arrest, which may drive HL-60 cells into premature mitosis in the presence of un-repaired DNA damage. In summary, TGHQ-induced DNA damage triggers the ATM/ATR-Chk1/Chk2-Cdc25 pathway and induces Chk1-dependent S-phase arrest in the p53-deficient HL-60 cells. The results are consistent with the view that targeting of Chk1 is an effective chemotherapeutic strategy. However, the data also reveal that in addition to the established mechanism of Chk1 protein degradation engaged by the majority of anti-cancer agents, a novel mechanism to modulate Chk1 protein expression can be engaged at the transcriptional level.

**PS 682 Atrazine-Elicited Differential Gene Expression in BLTK1 Leydig Cells.**

A. L. Forgacs<sup>1,2</sup> and T. R. Zacharewski<sup>1,2</sup>. <sup>1</sup>Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI; <sup>2</sup>Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Atrazine (ATR) is a widely used triazine herbicide associated with impaired reproductive development and function. We have previously demonstrated that ATR affects basal and recombinant human chorionic gonadotropin (rhCG)-induced steroidogenic activity in BLTK1 murine Leydig cells as early as 2 hrs. ATR elicited dose-dependent induction of Star, Hsd3b6 and Hsd17b3 mRNA levels while repressing Hsd3b1, Cyp17a1 and Srd5a1 expression at 24 hrs. The current study evaluates the temporal gene expression effects (1-48 hrs) of 300  $\mu\text{M}$  ATR on Agilent 4 X 44K oligonucleotide microarrays using a dye-swap independent reference design. ATR differentially regulated the expression of 797 unique genes (fold change  $> 1.5$ ,  $P(t) > 0.999$ ), with 389 up-regulated and 416 down-regulated at a minimum of one time point. Most changes were observed at later time points (12-48 hrs) suggesting early ATR induction of testosterone (T) levels in media are independent of gene expression. However, sustained T levels coincide with the induction of Star mRNA. Database for Annotation, Visualization and Integrated Discovery (DAVID) and Ingenuity Pathway Analysis (IPA) identified over-represented gene functions associated with reproductive system development and function, tissue morphology, and regulation of hormone metabolism, consistent with ATR effects on BLTK1 cell morphology and steroidogenesis. The IPA transcription

factor tool predicted the activation of SREBF1 and SREBF2 comprising the induction of cholesterol uptake (Ldlr), cholesterol biosynthesis (Hmgcr, Hmgcs1, Lss, Sqle, Cyp51) and cholesterol transporter (Star) gene expression. Additionally, the predicted activation of CREB1, CREB2, CEBPA and CEBPB suggest increased cAMP-mediated gene expression such as the induction of Vegfa, Gadd45a, and Bcat1 involved in cell morphology and growth. Collectively, these results suggest the later effects of ATR on BLTK1 murine Leydig cell steroidogenesis are mediated by SREBF- and CREB-mediated changes in gene expression.

## PS 683 Hepatic Gene Expression Analysis of 2-Aminoanthracene-Exposed Fisher-344 Rats Reveal Patterns Indicative of Liver Carcinoma and Type 2 Diabetes.

W. E. Gato<sup>1</sup>, B. D. Hales<sup>2</sup> and J. C. Means<sup>3</sup>. <sup>1</sup>Chemistry, Augustana College, Rock Island, IL; <sup>2</sup>Physiology, Southern Illinois University Carbondale, Carbondale, IL; <sup>3</sup>Environmental Science & Management, University of California Santa Barbara, Santa Barbara, CA.

The goal of the present study was to examine hepatic differential gene expression patterns in Fisher-344 rats in response to dietary 2-aminoanthracene (2AA) ingestion for 14 and 28 days. Twenty four post-weaning 3-4 week old F-344 male rats were exposed to 0 mg/kg-1-diet (control), 50 mg/kg-1-diet (low dose), 75 mg/kg-1-diet (medium dose) and 100 mg/kg-1-diet (high dose) 2AA for 14 and 28 days. This was followed by analysis of the liver for global gene expression changes. In both time points, the numbers of genes affected seem to correlate with the dose of 2AA. Sixteen mRNAs were differentially expressed in all treatment groups for the short-term exposure group. Similarly, 51 genes were commonly expressed in all 28-day exposure group. Almost all the genes seem to have higher expression relative to the controls. In contrast, cytochrome P450 family 4, subfamily a, polypeptide 8 (Cyp4a8), and monocyte to macrophage differentiation-associated (Mmd2) were down-regulated relative to controls. Differentially expressed mRNAs were further analyzed for associations via DAVID. GO categories show the effect of 2AA to be linked with genes responsible for carbohydrate utilization and transport, lipid metabolic processes, stress responses such as inflammation and apoptosis processes, immune system response, DNA damage response, cancer processes and circadian rhythm. The data from the current study identified altered hepatic gene expression profiles that may be associated with carcinoma, autoimmune response, and/or type 2 diabetes. Possible biomarkers due to 2AA toxicity in the liver for future study include Abcb1a, Nhej1, Adam8, Cdkn1a, Mgmt, and Nrcam

## PS 684 Utilizing RNA Sequencing and the DNA-Damage Response to Model Chemical Toxicity: How PKC-Activating Tumor Promoters Create a Path of Their Own.

K. P. Glover<sup>1</sup>, L. K. Markell<sup>1</sup>, E. Donner<sup>1</sup>, Z. Chen<sup>2</sup> and X. Han<sup>1</sup>. <sup>1</sup>DuPont Haskell, Newark, DE; <sup>2</sup>DuPont Information & Computing Technologies, Wilmington, DE.

The DNA damage response (DDR) is an essential cellular pathway for maintaining genomic integrity and preventing neoplastic transformation. Although tumor promoting compounds do not directly cause fixed mutations, they have been previously shown to alter many different cellular processes that also impact normal DDR signaling. Therefore, the purpose of this study was to profile PKC activating tumor promoting chemicals by their respective alterations to normal DDR signaling induced by short-wavelength ultraviolet light (UVC). Human lymphoblastoid TK6 cells were exposed to 1 nM 12-O-tetradecanoyl-phorbol-13-acetate (TPA) for 72 hours which caused a reduction in cell growth and changes in cellular morphology. Following UVC exposure (10 J/m<sup>2</sup>), TPA treated cells displayed a synergistic increase in apoptosis and a significant delay in  $\gamma$ H2AX clearance. Other PKC activating tumor promoters including other phorbol esters, mezerein, sapintoxin D, (-)-indolactam V, and resiniferonol 9,13,14-ortho-phenylacetate caused similar changes in cell morphology and a synergistic increase in apoptosis following UVC exposure. RNA sequencing was used to capture the global transcriptomic profile 8 hours after UVC-induced DNA damage following TPA pretreatment. Principle component analysis of UVC treated cells revealed a relationship between gene expression patterns and the concentration of TPA (0.2, 0.5 and 1 nM). These findings indicate a deviation from the normal DDR response. TPA pretreatment at 1 nM caused greater than 300 of the UVC-regulated genes to be downregulated and greater than 80 UVC-regulated genes to be upregulated compared to the normal UVC expression profile. These results show that the tumor promoter TPA has a unique gene expression profile following DNA damage that can be potentially used to profile this class of chemical.

## PS 685 Reactive Nitrogen Species Regulate Autophagy through ATM-AMPK-TSC2-Mediated Suppression of mTORC1.

D. N. Tripathi<sup>1</sup>, R. Chowdhury<sup>2</sup>, L. J. Trudel<sup>2</sup>, G. N. Wogan<sup>2</sup> and C. L. Walker<sup>1</sup>. <sup>1</sup>Center for Translational Cancer Research, IBI, Texas A&M HSC, Houston, TX; <sup>2</sup>Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA.

Reactive intermediates such as reactive oxygen species (ROS) and reactive nitrogen species (RNS) play essential roles in the cell as signaling molecules, but in excess, constitute a major source of cellular damage in both physiological (i.e. mitochondrial respiration) and pathophysiological (i.e. inflammation) settings. Recently, ROS were shown to induce autophagy via a novel ATM signaling pathway in the cytoplasm. Activation of cytoplasmic ATM by ROS engages LKB1 and AMPK kinases to activate the TSC2 tumor suppressor, which represses mTORC1 (a negative regulator of autophagy) to induce autophagy. However, whether RNS engage this or similar signaling pathway(s) to regulate mTORC1 and induce autophagy is unclear. We found under conditions of steady-state nitric oxide (NO) exposure, rapid activation of ATM and downstream signaling by this stress kinase to LKB1-AMPK and the TSC2 tumor suppressor. As a result, mTORC1 was repressed as evidenced by decreased phosphorylation of the direct mTORC1 targets S6K, 4EBP1, and ULK-1, the target for mTORC1 repression of autophagy. Induction of autophagy concordant with decreased ULK-1 phosphorylation by mTORC1 at S757 and increased phosphorylation at S317 by AMPK was demonstrated by increased ratio of LC3-II/LC3-I, formation of GFP-LC3 puncta, increase in acidic vesicles and decreased p62 levels, indicative of increased autophagic flux. While autophagy has been shown to have pro-death and pro-survival functions, induction of autophagy by NO caused loss of cell viability, suggesting it functions primarily as a cytotoxic response to excess nitrosative stress. These data indicate that nitrosative stress, like oxidative stress, regulates autophagy. As cancer cells are particularly sensitive to nitrosative stress, these data open new therapeutic avenues capitalizing on the ability of NO and RNS to induce autophagic cell death.

## PS 686 CYP2S1 Expression Influences Cytotoxicity of the Anticancer Prodrug, AQ4N, in Human Bronchial Epithelial Cells.

N. M. Singh and A. M. Rowland. Chemistry and Biochemistry, NMSU, Las Cruces, NM.

Cytochrome P450 2S1 (CYP2S1) is one of the most upregulated P450s identified in human cancers and correlates with poor prognosis. The underlying cause of elevated CYP2S1 expression and the consequence of elevated expression is not known. The only recognized substrate for CYP2S1 is AQ4N (Baxanthrone). AQ4N is a bioreductive prodrug under clinical investigations for hypoxic tumors. AQ4N is metabolically reduced in hypoxic environments to the topoisomerase II inhibitor, AQ4. CYP2S1 is recognized as one of the most efficient enzymes to catalyze this reduction. The objective of this study was to determine: i) whether human CYP2S1, like the mouse CYP2s1, is elevated in response to hypoxia and ii) whether changes in CYP2S1 expression influence CYP2S1-mediated metabolism of AQ4N. To determine whether CYP2S1 was induced in response to hypoxia we evaluated mRNA expression in the presence of 1% oxygen as well as the hypoxia mimetics cobalt chloride and o-phenanthroline. CYP2S1 mRNA was significantly increased by approximately 8-, 3-, and 50-fold in response to 1% oxygen, cobalt chloride, and o-phenanthroline. These results suggest that human CYP2S1 mRNA is elevated in response to hypoxia. To determine whether changes in CYP2S1 expression influence AQ4N metabolism we examined the effects of AQ4N and AQ4 on cell viability in bronchial epithelial cells (BEAS-2B) cells differentially expressing CYP2S1. Cytotoxicity was estimated using alamar blue reduction in cells expressing high (CYP2S1-flag), medium (control plasmids: pcDNA3.1 and scrambled shRNA), and low CYP2S1 expression (CYP2S1 shRNA). Preliminary results demonstrate that elevated CYP2S1 expression does enhance cytotoxicity under hypoxic conditions (0.2%-1% O<sub>2</sub>). Interestingly, our results also suggest a protective role for CYP2S1 in normoxic conditions (21% O<sub>2</sub>). These data suggest that elevated CYP2S1 expression may have a dual role in protecting normal cells while promoting AQ4N-mediated cytotoxicity in hypoxic cells.

**PS 687 Transcriptome Analysis Reveals Novel Pathway Regulation in Response to Differential Expression of CYP2S1 in Human Lung Cells.**

T. W. Madanayake<sup>1</sup>, A. M. Rowland<sup>1</sup>, N. Devitt<sup>2</sup> and I. Lindquist<sup>2</sup>. <sup>1</sup>Chemistry and Biochemistry, NMSU, Las Cruces, NM; <sup>2</sup>National Center for Genomics Research, Santa Fe, NM.

Cytochrome P450 2S1 (CYP2S1) is considered an orphan P450s with an unknown biological function. Data from our laboratory and others suggests that CYP2S1 may have an important physiological role in modulating the synthesis and metabolism of bioactive lipids, including prostaglandins and retinoids, respectively. CYP2S1 expression is elevated in epithelial-derived cancers. Whether increased CYP2S1 expression in proliferative disease is protective, detrimental, or fails to impact disease progression remains to be determined. To elucidate its role, we need to understand the physiological significance of CYP2S1. We reasoned that transcriptome analysis of human bronchial epithelial cells (BEAS-2B) differentially expressing CYP2S1 would reveal metabolic shifts in key regulatory pathways linked to CYP2S1-mediated metabolism. To test this idea, we established four stable BEAS-2B cell lines expressing high (CYP2S1-Flag), medium (pcDNA3.1 and scrambled shRNA), and low (CYP2S1 shRNA) CYP2S1 expression. Expression levels confirmed using qRT-PCR and western analysis. Alterations in the transcriptome were determined using RNA-sequencing (RNA-seq) analysis. RNA was isolated from three biological replicates from each of the four experimental conditions (CYP2S1-Flag vs pcDNA3.1 and CYP2S1 shRNA vs SCRAM shRNA). Eight to fourteen million sequencing reads were generated from each of the 12 samples. Four distinct population clusters were identified using principal component analysis, representing each of the transformed cell lines. Approximately 1000 genes were differentially expressed in response to CYP2S1. Among these were key regulatory enzymes involved in prostaglandin synthesis. RNA-seq also identified novel changes in the mTOR pathway, which regulates cell size. Significant differences in cell size was in lung cells differentially expressing CYP2S1, revealing a potentially novel role for CYP2S1 in cell size regulation.

**PS 688 In-Depth Examination of How Exposure to Long-Term Low-Dose Chromium Alters the Transcriptional Response to BaP.**

J. Ovesen, Y. Fan and A. Puga. University of Cincinnati, Cincinnati, OH.

Complex mixtures and their toxicity are a significant and growing problem that must be addressed by applied toxicology. Techniques for the assessment of similar compounds in a mixture based on relative toxicity are inadequate for the assessment of complex mixtures with different types of components. In complex mixtures, multiple exposures generate specific changes in gene expression that cannot be attributed to any single mechanism. Data on the responses to these kinds of mixtures are rare and often contradictory. Our previous work demonstrated that epigenetic regulation of gene transcription plays an important role in chromium's toxic response, and that Cr is capable of altering the transcriptional regulation of known BaP responsive genes, like Cyp1a1. Here we use RNA-seq after long-term low-concentration exposure to chromium to examine the extent to which chromium exposure can alter BaP induced transcriptional responses throughout the transcriptome. We find that mouse hepatoma cells exposed to long-term low concentrations of sodium chromate, in the range of 0.1 – 0.5  $\mu$ M, accumulate double-strand DNA breaks, and that the percentage of cells undergoing apoptosis increases concurrently with either increased concentration or longer period of exposure to Cr. Using RNA-seq we determined that the transcription of genes critical to several important processes are regulated differently by BaP if the cells were previously chronically exposed to a low concentration of Cr. In cells grown normally genes related to critical functions like cell cycle and tissue development are down-regulated but cells treated with low concentration Cr for a long period of time do not down-regulate these functions in response to acute BaP treatment. These findings can serve as a guide for studies to determine what biological functions normally regulated by BaP may be abnormally regulated when there are previous exposures to chromium. Supported by NIH grant ES010807.

**PS 689 Expression of the Nuclear Receptor Corepressor Tnfr1 in Mouse Tissues.**

N. Francis, C. Zhang and B. J. Aneskievich. University of Connecticut, Willimantic, CT.

Tnfr1 regulates multiple signaling pathways (NF- $\kappa$ B, ERK2, PPAR and RAR) involved in either executing or responding to toxic insults. Altered Tnfr1 expression levels are associated with certain human inflammatory diseases. These cell signaling and pathology studies revealed some molecular targets and potential organ end-

points. Additionally, body-wide data on expression of Tnfr1 is incomplete. To gain a better understanding of Tnfr1's expression pattern and functional role, we developed a Tnfr1 gene trap knock out (KO) mouse to identify possible new signaling and organ targets.

The Tnfr1 gene trap KO mouse was created via a  $\beta$ -Geo cassette ( $\beta$ -galactosidase and neomycin resistance genes) insertion into the Tnfr1 first intron. Expression from the cassette allowed for evaluation of Tnfr1 promoter activity in different tissues qualitatively via X-gal staining, immunofluorescent (IF) staining for  $\beta$ -Galactosidase ( $\beta$ -Gal), and quantitatively via Q-PCR. With WT tissues as a control, all heterozygote (Tnfr1 +/-) tissues turned blue with X-gal staining. Results of IF  $\beta$ -Gal staining in Tnfr1 +/- mouse tissues were similar to that of X-gal whole organ staining and paralleled the Tnfr1 antibody staining. For most organs, both  $\beta$ -Gal and Tnfr1 were homogeneously expressed across the tissue. However, for kidney, both  $\beta$ -Gal and Tnfr1 glomerular staining was significantly reduced compared to convoluted tubules suggesting distinct expression levels and fidelity of the  $\beta$ -Gal marker for the endogenous Tnfr1 expression. Q-PCR results revealed that the Tnfr1 promoter activity, determined by steady state levels of  $\beta$ -Gal mRNA, varied among different tissues and mirrored the Tnfr1 mRNA levels. These results suggest Tnfr1 is expressed at varying levels in different mouse tissues. Recent studies report a high rate of lethality in Tnfr1 KO mouse embryos due to fetal liver apoptosis (Oshima et al, 2009, Zhou et al, 2011). By contrast, we demonstrate there are tissues other than liver expressing Tnfr1 and that biological function of these organs may be impacted by changes in levels of Tnfr1 protein.

**PS 690 Evaluating the Role of Kinase Activation Involved in Chemical-Dependent p53 Response to DNA Damage.**

B. Reidel<sup>1</sup>, B. Sun<sup>1</sup>, A. Scott<sup>2</sup>, Y. Adeleye<sup>2</sup>, M. E. Andersen<sup>1</sup> and R. A. Clewell<sup>1</sup>. <sup>1</sup>The Hammer Institutes, Durham, NC; <sup>2</sup>Unilever, PLC, London, United Kingdom.

Post-translational modifications (PTMs) of p53, individually and in combination, help determine the function of p53 in DNA damage response, e.g. cell cycle arrest, apoptosis and DNA repair. The dose-response for p53 activation, cell cycle, apoptosis and mutation (micronuclei) were studied for etoposide (ETP), methylmethane sulfonate (MMS) and quercetin (QUE). Cellular response was chemical specific, despite similar induction of DNA damage (double strand breaks) and p53. Here, we investigated activation of mitogen-activated protein kinases (MAPKs) and phosphoinositide 3-kinases (PI3Ks) in response to MMS, ETP, and QUE across doses and time (1 – 24 hrs) in human fibrosarcoma cells (HT1080). The MAPKs were studied by measuring p-p38, p-ERK1/2, p-JNK1/2, and p-MEK1 using immunoblot and Luminex assays, and the PI3Ks: p-ATM, p-ATR, p-DNA-PK and p-Chk 2 by immunoblot and flow cytometry. MAPKs and ATM were activated by all three chemicals. Although p-ATM, p-p38, p-ERK and p-JNK increased at 1, 3 and 24 hrs, they showed different patterns of activation that may lead to observed differences in cell fate. While ETP and MMS showed maximal p-ERK1/2 and p-ATM at 24 hr, QUE displayed a much stronger p-ERK and p-ATM response at 1 hr, which may indicate more efficient repair, and is in agreement with less micronuclei observed with QUE vs. ETP or MMS. p-p38 - associated with p-p53 (ser46) leading to apoptosis - was induced quickly with ETP (1 hr), but more slowly with QUE, an observation consistent with observed apoptosis by ETP, but not QUE in HT1080 cells. ETP showed a much stronger induction of p-ATR than either MMS or QUE, and only QUE inhibited p-ATR. Our results indicate that, types and timings of the activated kinases are chemical specific and likely to determine the downstream actions of p53. Currently, we are evaluating treatment dependent PTMs of p53 by proteomics, as well as kinase specific inhibitors to further confirm the relationship between kinase modification of p53 and cell fate.

**PS 691 Global Transcriptional Analysis of Zebrafish Embryos following Acute Exposure to Cadmium.**

M. J. Jenny<sup>1</sup>, E. E. Linney<sup>2</sup>, B. O'Shields<sup>1</sup>, A. Holowiecki<sup>1</sup> and A. McArthur<sup>1</sup>.

<sup>1</sup>Department of Biological Sciences, University of Alabama, Tuscaloosa, AL;

<sup>2</sup>Department of Molecular Genetics and Microbiology, Duke University Medical Center, Durham, NC.

Although cadmium (Cd) exerts its toxic effects through the generation of oxidative stress, many of the cellular mechanisms involved in Cd toxicity are not fully established. Utilizing zebrafish embryos as a model, we undertook a transcriptomic-based approach to investigate the role of Cd as a developmental toxicant and assist in the identification of novel mechanisms of cellular dysfunction. Zebrafish embryos (24, 48, 72 and 96 hpf) were continuously exposed to Cd (25, 50, 100, 150  $\mu$ M) for 24 hours prior to mortality assessment. No significant mortality was observed prior to 72 hpf. However, at 96 and 120 hpf the 50  $\mu$ M Cd dose resulted in 20% and 40% mortality, respectively, while the 100 and 150  $\mu$ M Cd doses resulted in an average of 75% and >95% mortality, respectively. To investigate global changes in gene expression, zebrafish embryos (72, 96 and 120 hpf) were exposed

to 50  $\mu\text{M}$  Cd for 4 or 8 hours. Global gene expression profiling was performed using the Agilent 4x44K Zebrafish Oligo Microarray. Overall, 788 probes were significantly upregulated, while 679 probes were downregulated in one or more treatments. Principle component analysis was employed to find trends among the various treatments. The first principle component separated out the 96 and 120 hpf Cd-treated embryos, consistent with the mortality curves suggesting that zebrafish embryos become most sensitive to Cd toxicity around 96 hpf. The majority of genes altered by Cd exposure resulted in the upregulation of a large subset of genes responsive to oxidative stress, genes involved in glutathione synthesis and heme/iron homeostasis, mitochondrial uncoupling proteins, and various solute carriers with roles in zinc transport/homeostasis or mitochondrial oxidative phosphorylation. The majority of genes downregulated by Cd were involved in cell cycle control and DNA replication. A thorough analysis of genes differentially regulated by Cd during zebrafish development will be presented. [R00ES017044]

## PS 692 Role of Chromatin Structural Changes in Regulating Human CYP3A Ontogeny.

N. L. Giebel<sup>1</sup>, J. D. Shadley<sup>1</sup>, K. Dorko<sup>2</sup>, S. C. Strom<sup>3</sup>, P. M. Simpson<sup>1</sup>, K. Yan<sup>1</sup> and R. N. Hines<sup>1</sup>. <sup>1</sup>Pediatrics, Medical College of Wisconsin, Milwaukee, WI; <sup>2</sup>Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS; <sup>3</sup>Laboratory Medicine, Karolinska University Hospital, Stockholm, Sweden.

Variability in drug metabolizing enzyme (DME) developmental trajectories contributes to differential susceptibility to chemical toxicity and adverse drug reactions, particularly in the first years of life. Factors linked to variability are largely unknown and molecular mechanisms regulating ontogeny are likely involved. To evaluate chromatin structure dynamics as a contributing mechanism, age-dependent changes in histone marks were evaluated within known *CYP3A4*, *CYP3A7*, *FMO1*, and *FMO3* regulatory domains. Chromatin immunoprecipitation with fetal and adult primary human hepatocyte chromatin pools followed by qPCR was used to determine relative histone mark occupancy. Histone mark occupancy is consistent with many regions of bivalent chromatin (i.e., exhibiting histone marks associated with active and repressive transcription) in adult and fetal hepatocytes with the exception of the *CYP3A7* XREM and C/EBP $\beta$  domains in adult hepatocytes. For *CYP3A4*, the bivalent regulatory domains are consistent with a low level of fetal liver expression. Differential histone mark occupancy indicates adult histone mark and transcription factor occupancy have a developmental trajectory towards an active transcriptional state. In contrast, the bivalent *CYP3A7* regions in fetal hepatocytes do not correspond with high expression and surprisingly, adult hepatocytes had less histone mark occupancy, particularly the repressive mark H3K27me3. These findings for *CYP3A7* suggest mechanisms other than chromatin structural changes involved in regulating ontogeny. Chromatin structural change is an important mechanism controlling DME ontogeny, particularly for those whose specific activity increases substantially after birth. Supported in part by NIH grant GM081344

## PS 693 6-Formylindolo(3, 2-b)carbazole (FICZ) Positively Regulates the Signosome Responsible for Retinoic Acid (RA)-Induced Differentiation of Leukemic Blast Model HL-60.

R. Bunaciu and A. Yen. Cornell University, Ithaca, NY.

Tryptophan is an essential amino acid that absorbs strongly in UV (extinction coefficient: 5,050 M<sup>-1</sup>cm<sup>-1</sup> for 280 nm). Both in cell free conditions (such as cell culture media exposed to light) and in the cells (such as skin keratinocytes exposed to sunlight), tryptophan yields a multitude of photoproducts. One such photoproduct is 6-Formylindolo(3,2-b)carbazole (FICZ). FICZ has a high affinity for AhR (K<sub>d</sub>=7x10<sup>-11</sup> M). It is proposed to be an endogenous AhR agonist and also a cytochrome P450 family 1 substrate. FICZ and a multitude of its metabolites have been shown to be present in human fluids. Currently all the complete parenteral nutrition formulations contain tryptophan. The bags for total parenteral nutrition are made of clear plastic. Since many cancer patients receive both parenteral nutrition and chemotherapy (generally enhancing AhR expression and activity), it is of significant interest to assess potential effects of FICZ on cell differentiation and in particular on RA-induced leukemic cell differentiation. HL-60 leukemic cells were untreated or treated with RA alone or RA in combination with FICZ for 48 h. To assess the involvement of AhR, other cells were treated either with  $\alpha$ -naphthoflavone and RA or  $\beta$ -naphthoflavone and RA. Expression of cell surface differentiation markers, cell cycle distribution and respiratory burst response were quantified by flow cytometry. Western blots were performed to assess the proteins known to be part of the signosome driving the RA-induced differentiation. FICZ augments the RA-induced differentiation as evidenced by CD38 and CD11b receptors, inducible respiratory burst, G0 cell cycle arrest and growth curves.

Signaling molecules previously shown to be upregulated by RA and to drive RA induced differentiation were enhanced by FICZ: MAPK signaling axis, Src family kinases, Cbl, VAV, SLP-76, PI3K, and IRF-1. Moreover, AhR is associated with the c-CBL adaptor in the signosome, as shown by IP. In conclusion, FICZ modulates RA induced differentiation.

## PS 694 Nrf2 Gene Regulation during Oxidative Stress in Embryonic Development.

A. R. Timme-Laragy<sup>1,2</sup>, S. I. Karchner<sup>1</sup>, R. C. Harbeitner<sup>1</sup>, A. G. MacArthur<sup>3</sup> and M. E. Hahn<sup>1</sup>. <sup>1</sup>Biology, Woods Hole Oceanographic Institution, Woods Hole, MA; <sup>2</sup>Public Health, University of Massachusetts, Amherst, MA; <sup>3</sup>AGM Consulting, Hamilton, ON, Canada.

Nrf2 is a transcription factor that regulates antioxidant defenses in response to oxidative stress. Embryonic development is highly susceptible to disruption by exposure to chemicals, including those that alter redox balance. The role of Nrf2 in the oxidative stress response (OSR) during embryonic development remains unclear. Our previous work identified a novel Nrf2 paralog, *nrf2b*, in zebrafish (*Danio rerio*). This study builds upon that work to elucidate the roles of *nrf2a* and *nrf2b* in regulating the OSR during vertebrate embryonic development. Zebrafish embryos were micro-injected with antisense morpholino oligonucleotides (MO) to knock down translation of either *nrf2a* or *nrf2b*, or a standard morpholino control (co-MO). At 48 hours post fertilization, embryos were exposed to the pro-oxidant and Nrf2 activator, *tert*-butylhydroquinone (tBHQ) or vehicle (DMSO) for 4 hours, and preserved for RNA isolation. Microarrays were conducted using Agilent's V3 44k array, and selected genes validated by QPCR. In response to tBHQ, 71 probes were up-regulated in the co-MO group, including *gstp1*, *gclc*, *ferritin*, *peroxiredoxin1*, *hsp70*, *sod1*, and other genes typically found as part of the OSR. Interestingly, we found that an important and often overlooked part of the OSR is the down-regulation of genes, including *cathepsin*, various complement components, and *apolipoprotein Ea*. Knockdown of Nrf2a or Nrf2b blocked some but not all of the tBHQ-induced changes in OSR gene expression and the effects of Nrf2a-MO and Nrf2b-MO were distinct. The results show that Nrf2 paralogs primarily regulate distinct gene sets, with some overlapping targets, in response to oxidative stress in embryos. This study also highlights the importance of gene down-regulation as a component of the OSR during embryonic development. [F32ES017585, R01ES016366].

## PS 695 On Breast Cancer Treatment, Synergistic Effects of Akt1 shRNA and Paclitaxel-Incorporated Conjugated Linoleic Acid-Coupled Poloxamer Thermosensitive Hydrogel.

S. Hong<sup>1</sup>, C. Cho<sup>2</sup> and M. Cho<sup>1</sup>. <sup>1</sup>Laboratory of Toxicology, Seoul National University, Seoul, Republic of Korea; <sup>2</sup>Agricultural Biotechnology, Seoul National University, Seoul, Republic of Korea.

The phosphoinositide 3-kinase (PI3K)/Akt1 signaling pathway has emerged as a target for treatment of cancer therapy. In this study, we develop a strategy to enhance Akt-targeted therapy. We thought that combination of Akt1-targeted therapy with conventional chemotherapy using paclitaxel-incorporated conjugated linoleic acid-coupled poloxamer (CLA-CP) thermosensitive hydrogel may have synergistic effects in cancer therapeutic efficiency compared with chemotherapy alone. MDA-MB-231 cell, the human breast cancer cell line, was inoculated into 6-week-old female BALB/C nu/nu athymic mice. After 2 weeks of inoculation, shAkt1 and CLA-CP treatments were subcutaneously injected into the tumor. We found that the combination of shAkt1 with paclitaxel showed synergistic anti-cancer effects, thus, inhibiting the growth of human breast cancer cells, and breast cancer xenografts in mice as well. The combination therapy showed enhanced anti-cancer effects through inhibiting Akt1 signaling, inducing apoptosis. In addition, it suppressed angiogenesis and proliferation, also. It suggests that the presented strategy of combination of shAkt1 with paclitaxel may have a potential for the treatment of breast cancer.

## PS 696 TBX5 As Targets for Treatment of Chronic Obstructive Pulmonary Disease.

J. Lee and G. Acquah-Mensah. Massachusetts College of Pharmacy Health and Sciences, Worcester, MA.

Chronic Obstructive Pulmonary Disease (COPD) is a progressive disease of the respiratory system which is characterized by destruction of the epithelium cells of lungs. Current therapies alleviate symptoms of COPD but do not treat the under-

lying causes. It has been recognized in the literature that the T-box transcriptional factor TBX5 is suppressed in patients with COPD. The purpose of the study was to identify regulatory target genes of TBX5 and their significance in future treatment of COPD. A compendium of lung epithelium microarray datasets was created using GSE 19027 and GSE 994 from the Gene Expression Omnibus database. Probe IDs for TBX5 and genes that have known interactions with the TBX5 transcription factor were used to generate an initial network. Bayesian Network Inference with Java Objects was then used to generate a new regulatory network, given the gene expression data. Cytoscape was used to visualize the difference between the initial and predicted networks. In addition, analysis of GSE 1650, which compared lung tissue from smokers with severe emphysema and smokers with mild or no emphysema, was done. The resulting network indicates that STAT3 regulates TBX5, NKX2-5, GATA4, ID2 and TAZ. The regulatory relationships between STAT3 and TBX5, NKX2-5, GATA4, ID2 have been validated in the published literature. However, a relationship between STAT3 and TAZ has not been established. It is known that TAZ regulates TBX5. This presents with a possible feed-forward relationship among TBX5, STAT3 and TAZ. STAT3 is known to be involved in cell growth, apoptosis, and regulation of anti-inflammatory response by controlling genes involved in the inflammatory response. This result suggests a potential inhibitory relationship between STAT3 and TBX5 since STAT3 was up-regulated in smokers with severe emphysema and TBX5 was suppressed in patients with COPD. The result suggests that future therapies targeting STAT3 or TBX5 can regulate inflammatory response involved in COPD. Further research is warranted to investigate how TBX5, STAT3 and TAZ play a role in the inflammatory response of COPD.

**PS 697** **Suppressive Effect of HES1 (*Drosophila* Hair and Enhancer of Split-1) on Human Hepatic Multidrug Resistance-Associated Protein 4 (MRP4) Gene Expression and Induction of HES1 by Oxidative Stress.**

X. Gu and J. E. Manautou. *Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT.*

Previous in silico studies in our laboratory identified a total of 107 canonical HES1-binding N-boxes (CANNAG) in a 10kb DNA fragment upstream to the translation start site of the multidrug resistance-associated protein 4 (MRP4/ABCC4). In this study, we investigated the role of HES1 in regulating MRP4 gene expression. We have identified a 16-bp DNA fragment in the MRP4 promoter-proximal region containing a non-canonical N-box (GGCGTG) for HES1 that accounts for a profound suppression of MRP4 promoter transcription activity in HepG2 cells. A point mutation in this cis-element (GGCGTC) resulted in the loss of this suppressive effect of HES1. Furthermore, suppression of MRP4 reporter genes containing 230 bp, 5 kb or 7 kb of 5' flanking regulatory sequences was observed by over-expression of HES1 but not by a dominant negative mutant form of HES1 which is unable to bind to DNA. From these findings we hypothesized that the MRP4 induction we have previously reported under conditions of oxidative stress might be due in part to down-regulation of HES-1 expression. To our surprise, HES1 mRNA levels are significantly increased in the human liver cell line HC04 treated with the pro-oxidant chemicals tert-butylhydroperoxide or tert-butylhydroquinone (100-300µM). We also detected HES1 protein accumulation in nuclei of HC04 treated with these chemicals in a dose- and time- dependent manner. Similarly, treatment of mice with toxic doses of APAP increases liver HES1 mRNA levels. These increases in expression and function of the repressive factor HES1 by oxidative stress seem inconsistent with the induction of MRP4 that also occurs under oxidative stress conditions. Studies are currently underway to investigate whether HES1 directly regulates MRP4 gene expression in vivo by oxidative stress and to determine the interplay of HES1 with other activating and repressive transcription factors known to regulate MRP4. Supported by NIH Grant DK069557.

**PS 698** **Exposure to Metals Mixtures: Genomic Alterations of Infectious Disease Response Pathways in Children Exposed to Environmental Metals.**

J. Gruber<sup>1,2</sup>, R. D. Patel<sup>1</sup>, J. E. Rager<sup>1</sup>, A. P. Sanders<sup>1</sup>, S. Edwards<sup>3</sup>, J. E. Gallagher<sup>3</sup> and R. C. Fry<sup>1</sup>. <sup>1</sup>*Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>3</sup>*National Health and Environmental Effects Research Laboratory, US EPA, Research Triangle Park, NC.*

Exposure to toxic metals can have harmful health effects, particularly in children. Although studies have investigated the individual effects toxic metals have on gene expression and health outcomes, there are no studies assessing the effect of metal mixtures on gene expression profiles. Here, we assessed the mixture effect of six

toxic metals (arsenic, beryllium, cadmium, chromium, mercury, and lead) on gene expression profiles in children in Detroit, Michigan. As part of the Mechanistic Indicators of Childhood Asthma (MICA) cross sectional study, we assessed metal exposure in 131 children in Detroit using fingernail metals levels. A metals mixture score was calculated and compared to gene expression profiles across the population adjusting for age and race. There were 145 unique genes that were significantly differentially expressed when comparing children exposed to low and high levels of the metals mixture. Of the genes differentially expressed, 107 (74%) had increased expression while 38 (26%) had decreased expression. The main biological function associated with multiple metals was infectious disease. Within that group, genes were associated with infection of respiratory tract ( $P < 10^{-6}$ ) severe acute respiratory syndrome ( $P < 10^{-5}$ ), and sepsis ( $P < 10^{-3}$ ). Taken together, these data demonstrate that exposure to metals mixtures may activate gene networks related to infectious disease response. This abstract does not necessarily reflect the views or policies of the EPA.

**PS 699** **Transcriptomics Analysis of Lung Tissues of Brown Norway Rats Exposed to the Sensitizers Trimellitic Anhydride (TMA), Oxazolone (OXA) or Dinitrochlorobenzene (DNCB).**

F. Kuper<sup>2</sup>, M. Radonjic<sup>2</sup>, J. van Triel<sup>1</sup>, Y. Staal<sup>1</sup>, R. Woutersen<sup>2</sup> and R. Stierum<sup>2</sup>. <sup>1</sup>*TNO Triskelion, Zeist, Netherlands;* <sup>2</sup>*The Netherlands Organisation for Applied Scientific Research, TNO, Zeist, Netherlands.*

TMA is a respiratory allergen, OXA is a potent contact allergen in man, but elevates serum IgE levels and Thelper2 cytokines in test animals, suggesting that it has also respiratory allergenic potential. DNCB is a contact allergen. Brown Norway rats (BN) were sensitized by two dermal applications of TMA, OXA or DNCB. The animals were provoked by inhalation on day 21. TMA and OXA both induced elevation of serum IgE, breathing pattern changes and the same type of allergic laryngeal inflammation. However, microarray analysis of the lung (sampled 24 hrs after provocation) indicated that OXA may act through different mechanisms than TMA, despite a certain overlap in activated genes. TMA upregulated strongly Th2-associated genes and genes associated with lung remodeling, whereas OXA activated predominantly Th1-associated genes. The variability in balance between Th1- and Th2-associated genes may reflect different subtypes of respiratory allergies. DNCB induced a very mild inflammation in the larynx, which resembled DNCB-induced inflammation in the skin; only a few Th1-associated genes were differentially expressed in the lung. The transcriptomics analysis supports the idea that classification of allergens based on single genes is unreliable. Omics data contribute to our understanding of respiratory allergy and may help in the design of a predictive toxicity test for sensitization.

**PS 700** **In Vivo Expression of p16INK4a in Response to Toxicological Exposures.**

J. Sorrentino<sup>1,3</sup>, N. Sharpless<sup>1,2,3</sup> and C. Burd<sup>4</sup>. <sup>1</sup>*Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>2</sup>*Departments of Medicine and Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>3</sup>*Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC;* <sup>4</sup>*Molecular Genetics, Ohio State University, Columbus, OH.*

In mammals, expression of p16INK4a is highly regulated. Excess expression can lead to cellular senescence and aging, while impaired activation is associated with cancer. The precise mechanism of p16INK4a regulation in vivo is poorly understood. In vitro systems have limited utility since proliferation in culture induces p16INK4a. Both extrinsic (chemotherapy and ionizing radiation) and intrinsic (telomere shortening and improper DNA damage repair) stimuli can induce p16INK4a, but the kinetics of and cellular responses to these genomic insults have not been examined in vivo. To address this question, we developed a murine strain with firefly luciferase 'knocked-in' to the endogenous p16INK4a locus and under control of the p16INK4a promoter (p16-LUC). We exposed p16-LUC mice to 50ppm arsenic, 42% fat diet, 350 J/m<sup>2</sup> UVB light, or cigarette smoke for a minimum of 6 months. Every other month, p16-LUC mice were imaged to measure luciferase induction. At 30 weeks of exposure, mice exposed to cigarette smoke displayed 2 times higher levels of whole body luciferase activity than no-smoke controls. Additionally, mice exposed to UVB exhibited 1.5 times higher levels of luciferase activity by 6 weeks of exposure that reached 8 times over control mice by 24 weeks. In arsenic exposed mice, there was only a slight induction of p16INK4a by 24 weeks (not statistically significant). We observed no differences in p16INK4a expression in mice on high fat diet (42% fat) compared to normal fat diet (4%) after 78 weeks. Currently, we are correlating luciferase expression in different organs with tissue damage and mRNA expression of p16INK4a. The data generated from these experiments will demonstrate how environmental exposures are associated with expression of p16INK4a, a mediator of tumor suppression and aging. (Supported by T32 ES07126, HHMI Translational Medicine Program, and UO1-CA141576)

**PS 701 Reprogramming of the HepG2 Genome by Long Interspersed Nuclear Element-1: Regulatory Control of Epithelial to Mesenchymal Transition Is Independent of Reverse Transcriptase.**

P. Bojang<sup>1</sup>, M. Anderton<sup>2</sup>, R. Roberts<sup>2</sup> and K. S. Ramos<sup>1,3</sup>. <sup>1</sup>Biochemistry and Molecular Biology, University of Louisville, Louisville, KY; <sup>2</sup>General Toxicology Sciences, AstraZeneca, Manchester, United Kingdom; <sup>3</sup>Center for Environmental Genomics and Integrative Biology, University of Louisville, Louisville, KY.

Long Interspersed Nuclear Element-1 (LINE-1 or L1) is an autonomous, mobile element within the human genome that transposes via a "copy and paste" mechanism and relies upon L1-encoded endonuclease and reverse transcriptase (RT) activities to compromise genome integrity. Because the complexity of L1 biology is not understood, studies were conducted to evaluate the impact of L1 on epithelial to mesenchymal transition (EMT) in HepG2 cells. Forced expression of synthetic wild type or mutant (D702Y) L1 deficient in RT activity was associated with formation of cytoplasmic foci and minor association with the nuclear compartment. Random de novo L1 retrotransposition was identified in cells expressing wild type L1, but not the D702Y mutant. Both synthetic wild type and mutant L1 induced marked reductions in the expression of epithelial markers and overexpression of mesenchymal markers. These data establish L1 as a key regulator of genome plasticity in HepG2 cells via RT-dependent and RT-independent mechanisms which do not couple to intrinsic retrotransposition activity.

**PS 702 Interoperability Case Study: Connecting Models across Exposure and Dose-Response Arenas for Characterization of Vinyl Chloride Hepatotoxicity.**

D. S. Womack<sup>1</sup>, S. M. Beaulieu<sup>1</sup>, A. B. Parks<sup>1</sup>, M. Mumtaz<sup>2</sup>, P. Ruiz<sup>2</sup>, J. Babendreier<sup>3</sup> and A. M. Jarabek<sup>4</sup>. <sup>1</sup>RTI, Research Triangle Park, NC; <sup>2</sup>ATSDR, Atlanta, GA; <sup>3</sup>US EPA, Athens, GA; <sup>4</sup>US EPA, Research Triangle Park, NC.

The 2012 SOT workshop "Building for Better Decisions: Multi-scale Integration of Human Health and Environmental Data" advanced seamless data and model integration for support of sustainability and improved risk characterizations. It highlighted the need for interoperability of models across the source/exposure/dose-response/cost/benefit continuum. We conducted a case study to illustrate interoperability issues for characterizing aggregate risk of liver cancer or hepatotoxicity for inhaled and ingested vinyl chloride (VC). Exposure models used were the EPA's Assessment System for Population Exposure Nationwide (ASPEN) using data of the National-scale Air Toxics Assessment (NATA) for inhalation, and the Human and Ecological Exposure and Risk in Multimedia Environmental System (HE<sup>2</sup>RMES) domain within the Framework for Risk Analysis in Multimedia Environmental Systems (FRAMES) with Data for Environmental Modeling (D4EM) of the Agency's integrated exposure modeling (iem) technologies. The dose-response was characterized by data on the Integrated Risk Information System (IRIS) and the physiologically-based pharmacokinetic (PBPK) model for VC available in the ATSDR PBPK toolkit. Output from ASPEN and HE<sup>2</sup>RMES for inhaled VC exposure illustrates the value to efficient model comparison if plug-and-play capability is provided by interoperability. Conflicting assumptions regarding key parameters between exposure and dose-response arenas were highlighted when computing aggregate risk from oral and inhalation routes; these conflicts must be rectified prior to proper model integration. This exercise readily shows how the ability to transparently integrate such models impacts current approaches and enhances understanding of each discipline. (The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency or the Agency for Toxic Substances and Disease Registry.)

**PS 703 Modeling Acute Exposure Guideline Levels (AEGs).**

M. T. Chu, C. M. Nordberg, R. Manimaran, Y. Tie and E. Demchuk. ATSDR, Atlanta, GA.

Acute Exposure Guideline Levels (AEGs) are comprehensively peer-reviewed health guidance values for assessing the risk of acute once-in-a-lifetime or rare exposures to hazardous inhalation chemicals. Each AEG is a concentration designed to prevent health effects of a certain type (AEG-1: reversible, AEG-2: disabling, AEG-3: life-threatening) at one of the five exposure durations (1/6, 1/2, 1, 4, 8h). Currently only 272 compounds have published AEGs and among them 114 have unassigned AEGs-1. The objective of present work was to develop a novel *in silico* approach for rapid estimation of provisional AEG-1 thresholds, specifically at 8h (AEG-1<sub>8h</sub>). Correlation and multivariate linear regression analyses were employed

to assess significant predictors for AEG-1. AEGs-2 and -3 were identified as perspective explanatory variables, controlled for physiochemical properties and chemical-specific qualitative data used to extrapolate AEGs (e.g. species, target health endpoint, uncertainty factors).  $\chi^2$ - and *t*-tests were used to assess the homogeneity of covariates in the training and test sets. Variable selection involved multicollinearity, interaction, and confounding assessments. An exhaustive all-possible-subset selection was employed to determine the best information-entropy model. Available toxicological LOAEL or NOAEL data were used to validate the model. The final model was developed for AEG-1<sub>8h</sub>. It relied on AEG-2<sub>8h</sub> values as the main explanatory variable, controlled for chemical volatility, testing species, and uncertainty factors. For the chemicals without the AEG-1<sub>8h</sub> assigned, approximately 70% of model-predicted concentration thresholds were within a 10-factor of their extrapolated LOAEL or NOAEL values. The proposed 1D-QSAR model provides a meaningful and statistically-valid method to derive provisional AEG-1 thresholds that is consistent with available toxicological data. Such *in silico* methods offer a complementary approach when biological or toxicological evidence is insufficient, budget is limited, and/or rapid assessment is necessary, as in an emergency response.

**PS 704 Concentration-Time Relationships for Short-Term Inhalation Exposures to Hazardous Substances.**

R. Manimaran and E. Demchuk. Agency for Toxic Substances and Disease Registry, Atlanta, GA. Sponsor: P. Ruiz.

Acute Exposure Guideline Levels (AEGs) are developed by the USEPA AEG committee for controlling acute exposures to airborne chemical hazards. AEGs are the threshold exposure limits for once-in-a-lifetime or rare chemical exposures at five exposure durations (1/6, 1/2, 1, 4, 8h). AEGs are derived from various published and unpublished experimental studies described in Technical Support Documents prepared by the committee. An AEG concentration (C) for a specific duration (t) is extrapolated from available experimental data. Extrapolations are carried out using the exponential function,  $Cn \cdot t = k$ , where n, the temporal scaling factor (TSF), is chemical-specific. Preferably, it is derived experimentally, but thus far experimental TSFs for few chemicals have been derived. For most of 272 chemicals on the AEG list, TSFs are unknown. For these chemicals, the AEG committee has adopted a rule by which n = 1 when extrapolating from short- to long-term durations, and n = 3, when extrapolating from long- to short-term durations. However, for many chemicals with unknown TSFs, this rule has been abandoned in favor of chemical-specific information deemed appropriate by the committee. Thus, the AEG database contains rich expert-validated chemical-specific information about temporal extrapolation. The objective of the present study was to extract this information. Using regression analysis for each chemical in the database, a surrogate TSF was derived. In addition to being chemical-specific, TSFs were found to be health-effects-specific. The relationship between median TSFs for mild/reversible ( $n_1=2.9$ , AEG-1 tier), disabling/irreversible ( $n_2=2.0$ , AEG-2), and life-threatening effects ( $n_3=1.8$ , AEG-3) was  $n_1 > n_2 > n_3$ . A geometric mean TSF for the AEG-3 tier,  $n_3 = 1.88$  [95% CI: 1.77, 1.99], was closest to n = 1 in Haber's rule, which applies to combat exposures to chemical warfare agents. This observed agreement indicates that model-derived TSFs may be appropriate for temporal extrapolation of AEG concentrations to durations of exposure for which experimental durations are not available.

**PS 705 Refined Animal Toxicity Testing Using Unequally Sized Dose Groups and Benchmark Dose Analysis.**

M. Öberg, J. Ringblom, F. Kalantari and G. Johanson. Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Benchmark dose (BMD) analysis has been recommended as a more robust alternative to the No Observed Adverse Effect Level (NOAEL) as it makes use of all the data from the study to derive the point of departure. In this study, we used simulations to examine the possibility to optimize the study design for BMD analysis by introducing unequally sized dose groups. In addition, this BMD-aligned design of experiment was evaluated regarding animal distress. Experimental data were generated by Monte Carlo simulations for fixed doses and equally sized groups. We started with the OECD standard of 4 dose groups (logarithmic dose spacing: 0-1-3-10 mg/animal) with 20 animals per group and assumed a sigmoidal dose-effect curve. The distribution of animals between dose groups was then altered before performing the next set of simulations. The quality of the simulated BMD was evaluated against the "true" dose-effect curve and the standard 4x20 design. The procedure was repeated for scenarios with different effect variability and dose placements on the dose-effect curve. The designs with more animals in the low dose groups generally showed significantly better quality than the standard design with equally sized dose groups. With these designs it was also possible to reduce animal distress with 45%, under the assumption that the distress is proportional to dose. To reduce

the number of animals in the high dose group would be an important refinement of animal testing since the primary parameter for setting the high dose is the tolerability determined by clinical signs of moderate severity, e.g. weight loss of up to 20%, hunched intermittently, intermittent convulsions or transient prostration. In conclusion, our simulations suggest that toxicological studies can be improved by unequally sized dose groups, which also results in substantially reduced distress. The study illustrates how regulatory testing may be refined (one of the R's in 3R – Reduce, Refine, Replace) by use of BMD-aligned experimental design.

## PS 706 A Novel Screening System for Classifying Potential Health and Environmental Impacts Associated with Hydraulic Fracturing Fluids.

C. N. McFarland and D. B. Davies. *Intrinsic Environmental Inc., Calgary, AB, Canada.*

Public opposition to hydraulic fracturing or “fracking” is being witnessed across many communities in the U.S.A., Canada and elsewhere. Concerns over this practice include the potential impacts of fracking on groundwater and surface water quality, air quality, human health, and terrestrial and aquatic ecosystems. These concerns have prompted some jurisdictions to place temporary moratoriums on the practice until a better understanding of these potential impacts is gained. Numerous initiatives are now underway to heighten this understanding, including measures aimed at increasing awareness of the chemical additives that are used during the process. Many jurisdictions are now mandating public disclosure of these additives, and chemical registries that list the additives delivered down-hole on a well-by-well basis have emerged. Although these registries identify the chemicals used, they provide no indication of the potential health and environmental risks that the additives could present. To help fill this void, a novel risk-based screening system was developed to improve the understanding of the potential health and environmental impacts of the chemical additives used in hydraulic fracturing. The system relies on the results of toxicity and environmental fate studies for a number of key endpoints to assess the potential risks involved. The endpoints include acute and chronic oral toxicity, reproductive and developmental toxicity, mutagenicity, carcinogenicity, aquatic toxicity, environmental persistence and bioaccumulation potential. The outcomes of the screening process are used to assign the chemical additive products to one of several categories depending upon the potential risks involved. This categorization process allows the product users to take appropriate steps to manage the potential hazards. The screening system has been used to classify more than 1,500 products to date, has proven to be reliable and effective, and is currently being adopted on an industry-wide basis in Canada.

## PS 707 Analysis of the Validated Epiderm Skin Corrosion Test (EpiDerm SCT) and a Prediction Model for Sub-Categorization According to the UN GHS and EU CLP.

S. Letasiova<sup>2</sup>, H. Kandarova<sup>2</sup>, T. Milasova<sup>2</sup> and M. Klausner<sup>1</sup>. <sup>1</sup>MatTek Corp, Ashland, MA; <sup>2</sup>MatTek IVLSL, Bratislava, Slovakia. Sponsor: P. Hayden.

Skin corrosion refers to the production of irreversible damage to the skin manifested as visible necrosis through the epidermis and into the dermis. In 2004, OECD adopted two ECVAM-validated reconstructed human skin model assays (EpiDerm and EPIKIN) for testing skin corrosion (OECD TG 431). However, OECD TG 431 does not satisfy international labeling guidelines for transport of dangerous goods since none of the methods were validated for sub-categorization. The UN-GHS utilizes 3 corrosion sub-categories (1A-very dangerous, 1B-medium danger and 1C-minor danger). Labeling a chemical as 1A has important consequences for transport, including very small volume package limits for air transport, prohibition from passenger aircraft, protective storage conditions, costly containers, and low market acceptance. Animal tests are still utilized for assessing the packaging subclasses. An in vitro method that discriminates between the 1A and 1B/1C classes will therefore have a substantial impact on reducing animal tests for this purpose.

The current study evaluates whether the EpiDerm SCT can discriminate between UN-GHS classes 1A, 1B/1C and non-corrosives (NC) based on the MTT viability assay. Data obtained during the ECVAM validation study (Liebsch et al, 2000) indicated sensitivity of 100% for class 1A. In the current study (> 80 chemicals), sensitivity for class 1A was obtained in a range of 77 – 87% depending on cutoff chosen following a 3 min exposure. None of 1A chemicals was under-predicted as NC. Specificity for NC chemicals was 80%.

As demonstrated by results of this study, EpiDerm SCT allows a partial sub-classification of corrosives into sub-category 1A, 1B/1C, and NC. Adoption of the new prediction model based on a 3 min endpoint into the validated EpiDerm SCT design would allow identification of severely corrosive substances and would lead to significant reduction in animal use for corrosion sub-group package labeling.

## PS 708 Physiologically-Based Pharmacokinetic (PBPK) Modeling for the Development of Provisional Advisory Levels (PALs): A Case Study with Fentanyl.

H. Shankaran<sup>1</sup>, F. Adeshina<sup>3</sup> and J. G. Teeguarden<sup>2</sup>. <sup>1</sup>Computational Biology and Bioinformatics, Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA; <sup>3</sup>National Homeland Security Research Center, US EPA, Washington DC.

Provisional advisory levels (PALs) are tiered exposure limits for toxic chemicals in air and drinking water that are developed to assist in emergency responses. Physiologically-based pharmacokinetic (PBPK) modeling can support this process by enabling extrapolations across doses, and exposure routes, thereby addressing gaps in the available toxicity data. Here, we describe the development of a PBPK model for Fentanyl – a synthetic opioid used clinically for pain management – to support the establishment of PALs. Starting from an existing model for intravenous Fentanyl, we first optimized distribution and clearance parameters using several additional IV datasets. We then calibrated the model for oral and inhalation exposures using pharmacokinetic datasets for various Fentanyl formulations. Predictions of the calibrated model were in good agreement with the >50 datasets considered here. For aerosolized pulmonary Fentanyl,  $F=1$  and  $t_{90}<1$ min indicating complete and rapid absorption. The  $F$  value ranged from 0.35 to 0.74 for oral and various trans-mucosal routes. Oral Fentanyl was absorbed the slowest ( $t_{90} \sim 300$ mins); the absorption of intranasal Fentanyl was relatively rapid ( $t_{90} \sim 20$ -40mins); and the various oral trans-mucosal routes had intermediate absorption rates ( $t_{90} \sim 160$ -300mins). Based on these results, for inhalation exposures, we assumed that all of the Fentanyl inhaled from the air during each breath directly, and instantaneously enters the arterial circulation. We present model predictions of Fentanyl blood concentrations in oral and inhalation scenarios relevant for PAL development, and provide an analytical expression that can be used to extrapolate between oral and inhalation routes for the derivation of PALs.

## PS 709 Pooled Analysis for Chronic Dietary Studies of Di-Isononyl Phthalate.

C. M. North<sup>1</sup>, M. J. Nicolich<sup>2</sup>, K. M. Kransler<sup>3</sup> and R. A. Barter<sup>1</sup>. <sup>1</sup>ExxonMobil Biomedical Sciences, Amundale, NJ; <sup>2</sup>Cogimet, Lambertville, NJ; <sup>3</sup>ExxonMobil Chemical Company, Houston, TX.

Point of departure selection for risk assessment can be complicated when more than one study is available for evaluation. Differences in dose spacing and post-mortem evaluation can result in differing conclusions, leading to uncertainty and additional conservatism in the overall assessment. Here, several analysis methods were utilized to estimate the point of departure using the pooled data from two rat chronic toxicity studies on di-isononyl phthalate (DINP), a general purpose plasticizer used in flexible vinyl applications. Two chronic dietary administration studies (two year) were conducted in DINP-exposed F344 rats. Dietary administration in the two studies were different, with doses of approximately 0, 15, 152, and 307 (Study I) or 0, 29, 88, 359, and 733 (Study II) mg/kg/day. In addition, the number of liver sections evaluated between the two studies differed, impacting the overall incidence of observed liver effects. In both studies, a dose-related increase in the incidence of spongiosis hepatitis was observed in male rats. Separate NOAELs of 15 (Study I) or 88 (Study II) mg/kg/day were determined from the two studies; separate Benchmark Doses (BMDs) were estimated at 38 and 203 mg/kg/day, respectively. A pooled data approach, rather than a combining of the NOAEL or BMDs from the individual studies was utilized to derive a rational, data-based NOAEL or BMD. A generalized linear model with a logistic link function was used to determine a NOAEL for the pooled analysis. The NOAEL was the lowest dose group whose model coefficient was not statistically significantly different from the control group coefficient at the 5% significance level. The calculated NOAEL using the pooled data was 152 mg/kg/day. A BMD10 of 72.4 mg/kg/day with a 95% BMDL10 of 61.0 mg/kg/day were calculated with the pooled data. Pooled analysis, combined with robust statistical analysis, is a useful and rigorous method for deriving a point of departure that considers data from multiple, compatible studies.

## PS 710 A Systematic Approach for Identifying, Evaluating, and Presenting Mode-of-Action Evidence in IRIS Toxicological Reviews.

M. E. Kushman<sup>1,3</sup>, A. D. Kraft<sup>2</sup>, K. Guyton<sup>2</sup>, B. Sonawane<sup>2</sup>, W. A. Chiu<sup>2</sup>, S. Makris<sup>2</sup> and I. Rusyn<sup>3</sup>. <sup>1</sup>ORISE/US EPA, Washington DC; <sup>2</sup>NCEA, US EPA, Washington DC; <sup>3</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC.

Recent National Research Council recommendations on the process of hazard assessment include improving transparency and standardization of evidence collection, selection, presentation, and evaluation. Per this recommendation, we designed

a process that was tested using di(2-ethylhexyl)phthalate (DEHP) liver tumorigenesis as a case study. We identified relevant modes of action (MOAs) from published reviews and devised an overall search strategy. Literature search strings containing relevant synonyms and wildcards for DEHP and its metabolites, MOAs, and species of interest were tested in PubMed. Specific tiered assessment criteria for exclusion/inclusion into the search were also defined and literature was searched and screened according to these tiered criteria. For MOAs with large databases, additional screening criteria were applied through manual curation of the articles. The evidence gathering process was documented as a literature tree, clearly describing each step of the search, inclusion/exclusion, and curation. Studies satisfying the assessment criteria were summarized into evidence tables. Narratives for each liver cancer related MOA were composed. Literature was organized in the EPA's Health and Environmental Research Online (HERO) database using tags in accordance with assessment criteria. This approach streamlines and exemplifies transparent mechanistic evidence capture and reporting for DEHP liver carcinogenicity. Large amounts of information are effectively managed and appraised, and enabled for analysis of concordance across studies and species in MOA determinations for hazard assessment. This research was supported in part by an appointment to the Research Participation Program for the U.S. EPA, Office of Research and Development, administered by ORISE through an interagency agreement between the U.S. Department of Energy and EPA. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the US EPA.

**PS 711 A Nonparametric Bayesian Approach for Benchmark Dose Estimation from Continuous Data.**

K. Shao<sup>1</sup>, J. S. Gift<sup>2</sup>, L. Kopylov<sup>3</sup> and W. A. Chiu<sup>3</sup>. <sup>1</sup>NCEA-ORISE, US EPA, Research Triangle Park, NC; <sup>2</sup>NCEA, US EPA, Research Triangle Park, NC; <sup>3</sup>NCEA, US EPA, Washington DC.

The current approach for benchmark dose (BMD) estimation from continuous data (e.g., body weight, relative liver weight), proposed by Crump (1984) and used in EPA's BMD software (BMDs), models the responses at each dose level as a population described by mean and variance. Then, various dose-response models (e.g. Hill, Exponential, Power and Polynomial) and variance models are fit to the means, and the model parameters, as well as the variance, are estimated using the maximum likelihood estimation (MLE) approach for BMD calculation. Due to limited data, a common situation in risk assessment, the selection of a particular model and modeling assumptions such as the distribution of the responses (i.e., normal or log-normal distribution) is usually based on limited biological and toxicological information and empirical fit. Consequently, the selection of appropriate BMD and BMDL estimates from the results of a set of acceptable dose-response models is often criticized as being somewhat arbitrary. The non-parametric Bayesian (NPB) approach proposed in the present study models endpoints as a single-point mean response at each dose level without assuming the format of dose-response models or the distribution of responses. The NPB is a data-driven approach and the only assumption employed is that the curve is monotonically increasing or decreasing. The methodology is illustrated through both existing and simulated dose-response datasets, and compared with prevailing parametric methods available in the standard BMDs. The results of these analyses suggest that the NPB method can adequately fit the data and provide comparable BMD estimates (to the standardized models in BMDs). The NPB can provide flexibility in model fitting, and with further research, could be refined into a promising supplemental tool for BMD estimation.

**PS 712 Material Threat Assessment Chemical and Scenario Selection Process.**

J. Moser<sup>1,2</sup>, D. Howell<sup>1,2</sup> and R. Jablonski<sup>1,3</sup>. <sup>1</sup>Chemical Security Analysis Center, Department of Homeland Security, Gunpowder, MD; <sup>2</sup>Battelle Memorial Institute, Columbus, OH; <sup>3</sup>Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD.

The Department of Homeland Security (DHS) Chemical Security Analysis Center (CSAC) and the Department of Health and Human Services (DHHS) Biomedical Advanced Research and Development Authority Division of Analytic Decision Support (BARDA ADS) jointly assess public health hazards and consequences related to potential chemical agent attacks on the U.S. homeland. To provide a realistic appraisal of the type of threats chemical agents pose to the U.S. populace, the CSAC and BARDA ADS evaluate a broad range of chemicals to assess an adversary's potential to cause significant adverse consequences. This is accomplished through the development of Material Threat Assessments (MTAs), which examine the potential acquisition of a chemical and whether effective dissemination on a target can cause significant severe or lethal effects. Each MTA consists of an analysis of a single chemical or group of chemicals that have a similar mechanism of action,

while modeling these chemicals across a standard set of scenarios to enable comparison among chemicals and scenarios. MTAs include a comparison of public health consequences of a chemical attack with and without the use of consequence mitigating countermeasures. This presentation describes how the Chemical Terrorism Risk Assessment (CTRA) is used to inform the MTA process and describes the tools and assumptions employed to select high risk and high consequence chemicals and scenarios.

**PS 713 Use of REACH Registration Data for Improving Thresholds of Toxicological Concern (TTC).**

V. Mostert<sup>1</sup>, N. Wieneke<sup>1</sup>, C. Wiegand<sup>1</sup>, C. Jakupoglu<sup>1</sup>, M. Sica<sup>1</sup>, G. Werle-Schneider<sup>2</sup> and N. Jägemann<sup>2</sup>. <sup>1</sup>ICB EHS TOX-L, Dr. Knoell Consult GmbH, Leverkusen, Germany; <sup>2</sup>ICB TOX-C, Dr. Knoell Consult GmbH, Mannheim, Germany.

The Threshold of Toxicological Concern (TTC) concept is utilised to identify human exposures that are so low that in-depth toxicological investigations are expendable. This is called "exposure-based waiving".

Exposure-based waiving serves to focus available resources on substances with relevant human exposure potential.

Important work into establishing TTC values has been published by Munro et al. (1996). The initial report used a database of 613 organic substances compiled from publicly available sources. In total, 2941 NOELs were collected in this fashion. The Munro concept used the Cramer classification to categorise substances according to their hazard potential.

We broadened the TTC database by including NOAELs published on the EChA website as per 19 July 2012, containing data for more than 7600 substances. Only non-gaseous mono-constituent substances with oral NOAELs were included in the TTC database. Organophosphates and genotoxic substances were excluded from the database as well as NOAELs obtained for surrogate substances. NOAELs for all systemic endpoints (general toxicity, developmental toxicity, fertility, neoplasia) were taken into account. Where appropriate, default assessment factors of up to 6 were used to establish chronic NOAELs for each substance.

For every eligible substance, we collected the published CLP category for acute oral toxicity as a potential predictor of overall hazard potential. This gives rise to five categories of acute oral toxicity.

A TTC is calculated from the 5th percentile of NOAELs in each of these categories using the REACH rules for establishing DNELs for workers and the general population.

This poster presents the preliminary results for more than 1500 substances. The results indicate that the TTC concept becomes more robust when using the very broad EChA database. It also suggests that acute oral toxicity categories can be used as a predictor for the overall hazard potential of a substance.

**PS 714 Evaluation of the Toxrttool for Assessing Quality of Toxicological Studies for Risk Assessments.**

D. Segal<sup>1</sup>, S. Makris<sup>1</sup>, D. Bergfelt<sup>1</sup>, A. D. Kraft<sup>1</sup>, A. Bale<sup>1</sup>, K. Raffaele<sup>1</sup>, K. Crofton<sup>3</sup>, M. E. Gilbert<sup>3</sup>, M. Selgrade<sup>2</sup>, R. Blain<sup>2</sup> and K. Fedak<sup>2</sup>. <sup>1</sup>US EPA, Washington DC; <sup>2</sup>ICF International, Durham, NC; <sup>3</sup>US EPA, Research Triangle Park, NC.

In order to improve transparency and consistency, both the European Union and National Academy of Sciences have recommended the standardization and documentation of criteria used to evaluate the quality of studies considered in health risk assessments of xenobiotics. Although peer reviewed publication is an important criterion for judging scientific data, the quality of studies and reporting of results vary tremendously. To find a means to efficiently assess the quality of these studies, we evaluated a publicly available algorithm (Toxicological data Reliability assessment Tool, ToxRTTool) recently developed by the European Commission. The ToxRTTool builds on the Klimisch score, a method for categorizing the reliability of toxicological studies, but adds important criteria that should be present in a high-quality journal article used to support health risk assessments. To evaluate the ToxRTTool, 20 peer-reviewed studies on thyroid disrupting chemicals were selected, ranging in quality from excellent to poor as determined a priori by a thyroid expert on the team. Eight scientists with various levels of expertise then used the ToxRTTool to evaluate the papers, and the consistency and reliability of scores were compared across evaluators. Scores were most consistent for previously judged 'high-quality' papers with greater variability among scores as the quality of papers diminished. The basis for inconsistencies appeared to be related to the subjective nature and lack of clarity for responding to many criteria. In conclusion, by providing more objective criteria and better instructions for responding, the ToxRTTool would likely be extremely useful for systematic evaluations of peer reviewed studies being considered for health risk assessments.

(Disclaimer: The views in this abstract are those of the authors and do not necessarily reflect the views or policies of the EPA.)

**PS 715 GO-Quant Systems-Based Quantitative Analysis of Dynamic Signaling Pathways during Neurodevelopment and Implication for Risk Assessment.**

X. Yu and L. Xu. *Environmental Health Science, University of Georgia, Athens, GA.*

The most critical biological process during neurodevelopment is the timely controlled signaling pathways. Many reports provided qualitative data demonstrating the critical role of neuro-developmentally related pathways. However, only few have provided quantitative evaluation of the dynamic pathways during these processes. These differences in dynamic signaling pathways are believed to be tightly associated with the sensitivity of window of exposure to toxicants, but still have not been clearly examined. Genome-wide scale evaluation of gene expression has proven to be a powerful tool in understanding molecular mechanism during neurodevelopment. Thorough analysis of these genomic data during development will inevitably lead to a greater understanding of how changes in transcriptome relate to functional and structural changes in the neurodevelopment. However, the integration of these gene expression data into a description of dynamic signaling pathways within specific events of development has proven to be a difficult task. We constructed and established meta-database for neurodevelopment and applied systems-based GO-Quant program to quantitatively map the developmental stage-specific landmark of signaling pathways. Our GO-Quant analysis with rat gene expression array data demonstrated the dynamic changes of multiple signaling pathways during different stages of development. The mapping of the dynamic pathways greatly improves our understanding of time-dependent role of each signaling pathway during neurodevelopment. The systems-based identification of developmental stage-specific landmark signaling pathways helps to create sensitive, breakthrough early biomarkers for neurodevelopmental toxicity.

**PS 716 Safety Assessment of a Novel Antibiotic Using a Mouse Population-Based Approach Predicts Risk of DILI in Humans Where Classical Models Fail.**

M. Mosedale<sup>1</sup>, C. Kurtz<sup>1</sup>, J. Eaddy<sup>1</sup>, K. Adkins<sup>2</sup>, H. Wu<sup>2</sup>, P. B. Watkins<sup>1,3</sup> and A. H. Harrill<sup>1,3</sup>. <sup>1</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>Pfizer, Inc., Groton, CT; <sup>3</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC.

Development of the macrolide antibiotic PF-04287881 was suspended following elevations in liver function tests observed in a Phase I clinical trial. The potential for drug-induced liver injury (DILI) due to this compound was not predicted by standard nonclinical toxicology studies. We hypothesized that a mouse diversity panel (MDP), comprised of genetically diverse inbred strains, could predict the DILI potential of PF-04287881. Additionally, using the MDP offers the ability to identify genetic loci that underlie PF-04287881 DILI susceptibility. In this study, we collected serum and liver tissue from 34 mouse strains treated with PF-04287881 (600 mg/kg, i.g.) or vehicle once daily for 7 days. Significant elevations in serum alanine aminotransferase (ALT) levels in PF-04287881-treated animals relative to vehicle-treated controls were observed in 31 of the 34 strains ( $p < 0.05$ ). The average fold change in ALT varied greatly across strains (from 1.6 - 14.2). Microscopic findings of single cell necrosis, hepatocellular hypertrophy and Kupffer cell vacuolation were observed together or individually depending on strain. Genome wide association analysis conducted using ALT fold change identified 51 significantly associated single nucleotide polymorphisms, 12 of which occurred in known genes. These genes are involved in pathways important for transcriptional regulation, mitochondrial function, and cell structure and signaling. Taken together, these data support our hypothesis that the MDP can predict DILI liability for compounds without a clear hepatotoxicity signal in standard preclinical species. These findings also demonstrate the potential for this population-based approach to improve human risk assessment in drug-safety testing as well as yield mechanistic insights into the toxicity mechanisms via pharmacogenetic investigation.

**PS 717 An Investigation of Factors Associated with Mortality Patterns across the Midwestern United States.**

M. P. Chan. *Environmental Sciences Program, Southern Illinois University Edwardsville, Edwardsville, IL.*

Various studies have indicated that mortality rates are positively correlated with social inequalities, air pollution, elevated ambient temperature, age, availability of medical care and other factors. This study develops a model that uses indicators for multiple factors to predict the mortality rates for selected diseases by county across

the Midwestern United States. A total of 1,055 counties from 12 states in the Midwestern region were studied. Systematic random sampling was used to select a subset of counties from the 1,055 counties to validate the model. Appropriate statistical analyses were used to predict the relationship between environmental pollutants, socio-economic factors, risk factors, social capital, weather, crime, social and other factors to explain variations in county-specific mortality rates for the leading causes of death and lifespan in the US. It is anticipated that this study would suggest the complex inter-relationships of multiple factors that influence mortality and lifespan, and suggests the need for a better understanding of the pathways through which these factors, mortality, and lifespan are related at the community level, particularly in urban versus rural settings. The resulting findings might assist policy makers at local, state, and federal levels in developing effective prevention strategies in this region.

**PS 718 Establishment of the Cumulative Margin of Exposure for a Group of Polychlorinated Biphenyl (PCB) Congeners.**

F. Kalantari<sup>1</sup>, C. Bergkvist<sup>1</sup>, M. Berglund<sup>1</sup>, E. Fattore<sup>3</sup>, A. Glynn<sup>2</sup>, H. Håkansson<sup>1</sup> and S. Sand<sup>2</sup>. <sup>1</sup>Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>National Food Agency, Uppsala, Sweden; <sup>3</sup>Institute for Pharmacological Research, Milano, Italy.

Due to the fact that humans are exposed to mixtures of chemicals, the development of methods that can assess the combined risk resulting from cumulative exposure to a several chemicals is of high interest. The aims of this study were: (1) to estimate a cumulative margin of exposure (MOE) for a group of polychlorinated biphenyls (PCBs) using reduction of hepatic vitamin A as an example endpoint; (2) To compare a relative potency factor (RPF) based approach with a RPF-free approach for estimating the cumulative MOE.

The MOE was defined as the ratio between a reference dose, derived using the benchmark dose (BMD) approach (based on experimental dose-response data), and the estimated human dietary PCB exposure. A distribution for the cumulative MOE was established, taking into account inter- and intra-individual variability as well as uncertainty in data measurements. The cumulative MOE reflected mainly the MOE for PCB 126; other PCB congeners had little contribution to the cumulative exposure and MOE. The median of the 0.1st percentile for the cumulative MOE was about 20 for women; depending on the percentile, the cumulative MOE was 2 - 4 times higher for men compared to women. Furthermore, a relative potency factor (RPF) based approach was compared to an RPF-free approach for estimating the cumulative MOE. The RPF-free approach more completely accounts for variability and uncertainty on the other hand, the RPF-based approach is less data intensive and can be more easily implemented in practice, allowing for a use of existing data on RPFs. Consideration of the discussed approaches may contribute to improving cumulative health risk assessments.

**PS 719 A Prototype for Integrating Toxicokinetics into the Human Health Risk Assessment Process for Agrochemicals: Sulfoxaflor.**

C. Terry<sup>1</sup>, M. Aggarwal<sup>1</sup>, A. T. McCoy<sup>2</sup>, L. G. McFadden<sup>2</sup>, R. J. Rasoulpour<sup>2</sup>, M. Bartels<sup>2</sup> and R. Billington<sup>1</sup>. <sup>1</sup>Human Health, Dow AgroSciences, Oxfordshire, United Kingdom; <sup>2</sup>The Dow Chemical Company, Midland, MI.

Toxicokinetics (TK) has played a central role in the pharmaceutical industry for decades and this data can provide valuable information for human health risk assessment. However, historically, limited internal dose data have been routinely generated for agrochemicals. In recent years this trend has begun to change; the main drivers for this being: ILSI/HESI-ACSA principles, new EU Regulation (1107/2009 EC) and OECD guidelines.

Integrated TK in toxicity studies is now routine at Dow AgroSciences for all new active substances. This approach involves no additional animal usage.

This abstract describes the advantages of integrated TK to each stage of the risk assessment process and specific examples are provided from the toxicology programme of the new insecticide, sulfoxaflor, to show that integrated TK allows:

1. Hazard identification:
  - a. More relevant routes of administration for toxicity studies – comparison of systemic dose across different routes of exposure, for example in rat and rabbit developmental toxicity studies.
  - b. Kinetically-derived maximum dose approach – allowing more appropriate dose levels to be selected for the mouse carcinogenicity study, for example.
2. Dose-Response Assessment:
  - a. All life-stages of test species to be addressed – application of TK data in developmental and reproduction studies, for example.
3. Exposure Assessment:
  - a. Refinement of default 'external' (mg/kg bw/day) exposure assessments – for example, use of TK data from animals in 'TK Modeler', to predict systemic human exposure.
4. Risk Characterisation:

- a. Integrated Mode-of-Action (MoA) and human relevance investigations – for example, anchoring *in vitro* MoA test concentrations to the *in vivo* effect levels in animals.
- b. Setting of ‘internal’ Reference Doses (RfDs) – for example, proposing the corresponding blood concentration from critical *in vivo* studies used to set RfDs (such as the acceptable daily intake (ADI) or acute reference dose (ARfD), as an ‘internal’ RfD.

**PS 720 Refinement of the Exposure Component of the Human Health Risk Assessment Process for Agrochemicals: Development of a Simple Tool.**

A. T. McCoy<sup>1</sup>, C. Terry<sup>2</sup> and G. Drummond<sup>2</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI; <sup>2</sup>Dow AgroSciences, Milton Park, United Kingdom.

Traditional human health risk assessments include Uncertainty Factors (UFs) to account for toxicokinetic (TK) and toxicodynamic differences between animals and humans. Predictions of systemic exposure in humans, based on animal TK data or measured human biomarker levels, could allow for science-based refinements in the UFs related to interspecies differences in TK. These refinements could provide more realistic reference dose values, while predictions of human blood levels could help to inform calculations of biomonitoring equivalents.

The aims of this project were two-fold. The first was to develop a user-friendly modeling method that could accurately predict systemic bioavailability via parenteral exposure routes (i.e. dermal) in humans. Ideally, this model could predict exposure levels in both urine and blood. The second was to utilize animal TK data (measured or modeled from alternate exposure routes) to predict systemic exposure in humans from either occupational, bystander or residential exposures, using a simple TK modeling approach.

TK Modeler is an Excel-based program developed for prediction of blood levels of a test material and optimal sampling time selection for TK analysis. This program was successfully used to predict human blood levels, both, after exposure by parenteral routes (dermal), and using data derived only from animals. Three data-rich Dow AgroSciences molecules were used as case studies: haloxyfop, triclopyr and picloram. Attempts were made to achieve both of the above aims with each molecule, though this was not always possible due to limited available data. Overall, accurate predictions of human blood levels were achieved in most cases where adequate data were available. The only exceptions were due to large species differences between animal and human kinetics. A greater understanding of these animal/human systemic exposure comparisons will help to reduce interspecies uncertainty related to TK that are used in regulatory risk assessments.

**PS 721 An Approach for Characterizing Uncertainty in Relative Potency Factors.**

H. Carlson-Lynch<sup>1</sup>, J. Stickney<sup>1</sup>, A. Bacom<sup>1</sup>, G. Diamond<sup>1</sup>, B. Thayer<sup>1</sup>, P. McClure<sup>1</sup>, L. Flowers<sup>2</sup>, C. Chen<sup>2</sup>, M. Gehlhaus<sup>2</sup> and M. Pratt<sup>2</sup>. <sup>1</sup>SRC, Inc., East Syracuse, NY; <sup>2</sup>US EPA, Washington DC.

Relative potency factors (RPFs) for cancer may be calculated as the ratio of the slopes of two dose-response curves, each estimated by linear extrapolation from a benchmark dose (BMD) value. BMD values are subject to uncertainties stemming from study design features such as dosing interval and numbers of animals tested, as well as uncertainties pertaining to modeling, such as model choice, goodness-of-fit, and choice of benchmark response (BMR) relative to the observable data range. Quantitative characterization of the uncertainty in a RPF estimate is desirable both for comparing different estimates and for use in characterizing uncertainty in risk estimates obtained with a RPF. Because it is estimated as a ratio, a RPF poses certain challenges with respect to statistical approaches to characterizing uncertainty. Analytic approaches to calculating a confidence interval for a ratio (e.g., Hinkley 1969) were explored as a means of characterizing the uncertainty in a number of RPF estimates for benzo[b]fluoranthene (relative to benzo[a]pyrene). In addition, a Monte Carlo simulation method was investigated. For both approaches, the RPF estimate was simplified as a ratio of BMDs estimated at the same BMR (10% extra risk), and the standard error of the BMD was approximated using the upper and lower 90% confidence limits reported by the BMD software. For the Monte Carlo method, the benchmark dose was simulated as a lognormal distribution. Each iteration of the Monte Carlo simulation consisted of random samples from the probability distributions of BMDs for benzo[b]fluoranthene and benzo[a]pyrene, and calculation of an RPF for each random draw. The Monte Carlo simulation approach, unlike the analytic approach, provided plausible confidence limits and therefore, useful quantitative estimates of the uncertainty in the RPFs. (The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA).

**PS 722 The Chemical Terrorism Risk Assessment Medical Mitigation Model: Approach, Toxicology, and Medical Endpoints.**

D. Winkler<sup>1</sup>, M. T. Whitmire<sup>2</sup>, K. Good<sup>1</sup> and J. A. Cox<sup>2</sup>. <sup>1</sup>Battelle Memorial Institute, Columbus, OH; <sup>2</sup>DHS Chemical Security Analysis Center, Gunpowder, MD. Sponsor: H. Salem.

The Chemical Terrorism Risk Assessment (CTRA) is a probabilistic risk assessment that considers threat, vulnerability, consequences, and mitigation to yield a comprehensive estimate of chemical terrorist risk to the Nation. The Medical Mitigation (MedMit) model is a key component of the CTRA; it is a stock and flow model with parameters defined by toxicology and emergency medicine subject matter experts. The MedMit model estimates the number and type of injured victims according to dose, and determines the number of victims that may be saved or benefitted by the public health response. This presentation will discuss the approach to parameter quantification. It includes the definition of chemical-specific toxicity values for life-threatening, severe, and mild to moderate injury types, the desire and benefits of including these different victim types in the Medical Mitigation model, the segregation of more than 100 chemicals into toxidromes, and the data collection process. The application of toxicology to the CTRA enables a more realistic representation of event consequences and the public health response. Consequently, the model makes it possible to assess the effectiveness of the existing public health response system and examine improvement strategies. Such a capability permits policy makers to make informed decisions regarding resource allocation, and assists responders' understanding of chemical terrorist events and areas of potential improvement.

**PS 723 A Decision Tool for Assessing Polymers and Polymeric Substances with Potential Hazards to Human Health.**

B. K. Gadagbui<sup>1</sup>, A. Maier<sup>1</sup>, P. Nance<sup>1</sup>, M. Jayjock<sup>2</sup> and C. Franklin<sup>2</sup>. <sup>1</sup>Toxicology Excellence for Risk Assessment, Cincinnati, OH; <sup>2</sup>The LifeLine Group, Annandale, VA.

Polymers display a wide variety of characteristics – e.g., presence of non-bound residual monomers, polymerization chemicals, degradation products, and additives – that may pose a potential health hazard. There is a paucity of direct testing data on many polymers to adequately evaluate their toxicity, but several regulatory agencies have provided guidance for assessing polymer safety. We evaluated each of these approaches and identified the strengths and weaknesses of each. No single published model appears to cover all characteristics of interest. This suggests the need to develop a comprehensive decision tool to identify polymeric substances that may pose potential toxicological hazards to human health. We developed a decision tool that incorporates a weight of evidence approach integrating information for many individual hazard flags. Hazard flags were placed into four broad categories: (1) empirical hazard information on the polymer or residual monomer; (2) evidence of toxicity based on structural properties (i.e., based on polymer class, monomer components, or reactive functional groups); (3) potential for significant tissue dose (i.e., based on molecular weight distribution or systemic bioavailability); and (4) hazard based on foreseeable special use considerations. Some of these hazard flags have not been considered previously by the regulatory agencies. We tested this approach for a number of polymers to demonstrate how the new tool (integrates) incorporates all available regulatory approaches as well as the new features and provides a comprehensive decision framework for evaluating polymer safety.

**PS 724 The h-NAG-1 Transgenic Mouse Serves As an Animal Model for Obesity.**

G. J. Moser<sup>1</sup>, K. Chrysovergis<sup>2</sup>, J. Kosak<sup>2</sup>, J. Kim<sup>2</sup>, M. Nixon<sup>1</sup>, E. Gilas<sup>1</sup>, M. Streicker<sup>1</sup> and T. Eling<sup>2</sup>. <sup>1</sup>Investigative Toxicology, Integrated Laboratory Systems, Inc., Durham, NC; <sup>2</sup>NIEHS, Research Triangle Park, NC.

NSAIDS-activated gene-1 (h-NAG-1) transgenic mice (C57BL/6-Tg(CAG-GDF15)) over express human NAG-1/ Growth/differentiation factor-15 (GDF15). Hemizygous h-NAG-1 mice are significantly leaner than their wild-type littermates and have less abdominal white fat despite comparable food intake. To improve our understanding of the mechanisms of obesity development, h-NAG-1 mice and WT were put on a 10 or 60% diet for 12 weeks and blood was collected. Final body and abdominal white fat weights were increased in WT relative to h-NAG-1 mice. The h-NAG-1 mice on the high and low fat diet had lower circulating levels of the inflammatory adipokine leptin, although the difference on the high fat diet was much greater (3.5 +/- 1.1; h-NAG-1 and 55.4 +/- 8.7 ng/ml; WT) than on the low fat diet (2.3 +/- 0.7; h-NAG-1 and 15.8 +/- 6.8 ng/ml; WT). Similarly, serum insulin levels were significantly decreased in h-NAG-1 mice on both diets. Because obesity, via

higher leptin levels, can increase inflammatory responses, hNAG-1 mice and WT were injected with the inflammatory agent lipopolysaccharide (LPS) and serum inflammatory cytokine measured. The levels of KC, IL-6, MCP-1 and TNF $\alpha$  were lower in the leaner h-NAG-1 transgenic mouse. The data indicate the h-NAG-1 mouse may serve as a model for investigating obesity and how environmental exposures may be altered by obesity.

## PS 725 Extended Exenatide Treatment Causes Pancreatic Stress and Injury in a Rodent Model of Insulin Resistance.

R. L. Rouse, S. R. Stewart, B. A. Rosenzweig, K. L. Thompson, K. I. Shea, D. G. Goodwin and J. Zhang. *CDER, US FDA, Silver Spring, MD.*

A possible association between use of the anti-diabetic drug exenatide and acute pancreatitis has been suggested by the analysis of post-approval adverse event data but remains controversial. Studies were undertaken to determine whether an animal model could be developed to reveal potential safety signals consistent with pancreatitis following exposure to drug. Subcutaneous exenatide injection (3, 10, or 30  $\mu$ g/kg for 6 weeks) of Sprague-Dawley rats, caerulein-treated rats, and Zucker fatty diabetic rats demonstrated no consistent histopathologic pancreatic injury signal on standard chow or a high fat, high carbohydrate diet (HFD). However, C57BL/6 mice placed on HFD for 6 weeks exhibited a dose and time dependent pancreatic responses to single daily subcutaneous exenatide injections (3, 10, or 30  $\mu$ g/kg, for up to 12 weeks) that were exacerbated by the HFD. Focal areas of acinar cell necrosis progressing to edema, inflammation, and general tissue fibrosis and atrophy were identified in control mice but were much more prevalent in exenatide treated mice. Other findings included acinar cell hypertrophy and hyperplasia with increased incidence of autophagy and apoptosis in proportion to necrosis and inflammation. Regardless of exenatide exposure, mice on HFD had increased body weight and significantly elevated blood glucose and serum pro-inflammatory cytokines compared to mice on standard chow. The type of stress and injury produced in this study do not approximate the acute necrotizing pancreatitis described in adverse event reports but represent a reproducible pancreatic signal that might be useful for the preclinical safety evaluation of pancreatic injury induced by anti-diabetic drugs.

## PS 726 Adipose Deficiency of Nrf2 in Ob/Ob Mice Results in Severe Metabolic Syndrome.

P. Xue, Y. Hou, Y. Chen, B. Yang, J. Fu, H. Zheng, K. M. Yarbrough, C. G. Woods, Q. Zhang, M. E. Andersen and J. Pi. *The Hamner Institutes for Health Sciences, Durham, NC.*

Nuclear factor E2-related factor 2 (Nrf2) is a transcription factor that functions as a master regulator of the cellular adaptive response to oxidative stress. Our previous studies showed that Nrf2 plays a critical role in adipogenesis by regulating expression of CCAAT/enhancer-binding protein  $\beta$  and peroxisome proliferator-activated receptor  $\gamma$ . To determine the role of Nrf2 in the development of obesity and associated metabolic disorders, the incidence of metabolic syndrome was assessed in whole body or adipocyte-specific Nrf2-knockout mice on a leptin-deficient ob/ob background, a model with an extremely positive energy balance. On the ob/ob background, ablation of Nrf2, globally or specifically in adipocytes, led to reduced white adipose tissue (WAT) mass, but resulted in an even more severe metabolic syndrome with aggravated insulin resistance, hyperglycemia and hypertriglyceridemia. Compared to wild-type, WAT of ob/ob mice expressed substantially higher levels of many genes related to antioxidant response, inflammation, adipogenesis, lipogenesis, glucose uptake and lipid transport. Absence of Nrf2 in WAT resulted in reduced expression of most of these factors at mRNA and/or protein levels. Our findings support a novel role for Nrf2 in regulating adipose development and function, by which Nrf2 controls the capacity of WAT expansion and insulin sensitivity and maintains glucose and lipid homeostasis.

## PS 727 Effect of a Purified Openstandard Diet (OSD) on Body Weight (BW), Adiposity, and Glucose Tolerance (GT) in Male C57BL/6 Mice.

M. A. Pellizzon, M. R. Ricci and E. A. Ulman. *Research Diets, Inc., New Brunswick, NJ.* Sponsor: *P. Marone.*

Purified diets (PDs) offer biologists the ability to have fine control over diet composition compared to grain-based chows which often contain phytoestrogens and toxic heavy metals. However, common PDs such as the AIN-76A (76A) and AIN-93G (93G) may predispose rodents to moderate elevations in BW, blood and liver lipids, and reduced GT, vs. chows. The relatively higher levels of sucrose, lower total

fiber (~5% in PDs vs. ~20% in chow) and lack of soluble fiber in PDs (0 vs. ~2% in chows) may be responsible for these effects. Therefore, we tested two new PDs for their metabolic effects vs. chow (Purina 5002), 76A and 93G: 1) a PD with no sucrose and 9% fiber (7% insoluble, 2% soluble fiber; OSD) and 2) OSD with a fiber level and type similar to chow (18% insoluble, 2% soluble fiber; OSD+F). 75 weanling male C57BL/6N mice (n=15/grp) were fed ad-lib for 88 days. Other than BW (weekly) and an oral GT test (OGTT; day 83), all other measures (adiposity index [AI=adipose depot wt\*100/carcass wt]), liver triglycerides [TG], 6 hr fasted serum glucose, insulin and leptin were terminal. Baseline (17 $\pm$ 0.4 g) and terminal BW (31 $\pm$ 1 to 37 $\pm$ 1) were similar for all groups, but BW gain over time in OSD and 93G was higher (-2.3 g, p<0.05) vs. other groups. AI was similar in all groups but higher in OSD vs. 93G (13 $\pm$ 0.004% vs. 11 $\pm$ 0.01%, p<0.05). Serum leptin was higher in OSD (34 $\pm$ 1 ng/ml) and 93G (36 $\pm$ 2) vs. chow (22 $\pm$ 3) and OSD+F (23 $\pm$ 2, p<0.05). All groups had similar fasting glucose and insulin. Glucose area under the curve during OGTT was higher (p<0.05) for 76A (38,400 $\pm$ 2,500 mg/dl/120 min) and 93G (36,500 $\pm$ 3,000) vs. both chow (27,300 $\pm$ 1,400) and OSD (26,400 $\pm$ 1,600), while OSD+F (32,400 $\pm$ 1,800) was intermediate and not different from 76A and 93G or chow and OSD. Liver TG levels were no different between chow (4.5 $\pm$ 0.2 mg/g), OSD+F (8 $\pm$ 1) and 76A (6.5 $\pm$ 1) but were higher (p<0.001) for OSD (10 $\pm$ 1) and 93G (10 $\pm$ 1). These data suggest that PDs with no sucrose and higher fiber can improve GT over established PDs.

## PS 728 Development of an Oral Exposure Model to Predict Drug Hypersensitivity Using Brown Norway Rat.

A. Tamura, I. Miyawaki, T. Yamada, J. Kimura and H. Funabashi. *Safety Research Laboratories, Dainippon Sumitomo Pharma Co., Ltd., Osaka, Japan.*

**Background:** It is important in new drug development to evaluate the potential of drug hypersensitivity as well as the other adverse effects in non-clinical study, but validated methods are not available yet. Brown Norway (BN) rat is a strain that seems susceptible to substances that induce immune-mediated adverse reaction, and thus this particular strain has been used in studies on chemical-induced autoimmunity and food allergy. In the present study we examined whether it would be possible to develop a new predictive model of drug hypersensitivity using BN rat.

**Methods:** As representative drugs with the potential of drug hypersensitivity in humans, phenytoin (PHT), carbamazepine (CBZ), amoxicillin (AMX), and sulfamethoxazole (SMX) were orally administered to BN rats for 28 days to investigate their effects on these animals. The examinations included observation of clinical signs, hematology, determination of serum IgE levels, histology, and flow cytometric analysis of lymphocyte subsets.

**Results:** Skin rashes similar to what are often seen in humans were not observed in any animals treated with these drugs. Circulating inflammatory cells and serum IgE levels increased only in the animals treated with CBZ and SMX. Only germinal center hyperplasia was commonly noted in spleen and/or mesenteric lymph nodes in the animals treated with all the drugs. The changes of proportions of lymphocyte subsets were only noted in spleen of the animals treated with PHT and CBZ for 7 days and not for 28 days.

**Conclusion:** The potential of drug hypersensitivity was detected in BN rats by performing histological examination of secondary lymphoid organs/tissues. The present data suggested that BN rat could provide a useful animal model to evaluate the potential of drug hypersensitivity. Compared to existing models, the advantages of using this model are capable to evaluate 1) by oral administration, 2) not using reporter antigen, and 3) in easy method (general histological examination).

## PS 729 Behavioral, Neurochemical and Histological Characterization of a Novel MitoPark Mouse Model for Neurotoxicity and Neuroprotection Studies.

M. R. Langley, A. Ghosh, M. Ay, A. Kanthasamy, H. Jin, V. Anantharam and A. G. Kanthasamy. *Biomedical Sciences, Iowa Center for Advanced Neurotoxicology, Iowa State University, Ames, IA.*

Parkinson's disease is now recognized as a neurodegenerative condition caused by a complex interplay of genetic and environmental factors. The animal models presently available, created by neurotoxic insults or genetic defects, do not fully recapitulate the chronic and progressive nature of the nigrostriatal dopaminergic neurodegenerative process. Recently, the MitoPark mouse model was created by inactivation of mitochondrial transcription factor Tfam in the nigrostriatal pathway through the control of a DAT promoter. In this study, we tested the utility of MitoPark mice for neurotoxicological and neuroprotective studies using behavioral, neurochemical and histological analyses. Measurement of locomotor activity in MitoPark mice over 8-25 weeks revealed that motor function started to decline at 12 weeks of age and progressed over time, leading to severe deficits at 17-25 weeks.

MitoPark mice also showed a dramatic loss of striatal dopamine and its metabolites compared to wild type C57 mice. In order to determine the gene-environmental interaction, we exposed MitoPark mice to Mn (10 mg/kg, p.o) daily for 30 days. Motor deficits were significantly exacerbated in Mn-treated Mitopark mice beginning at week 10 compared to vehicle treated MitoPark mice. The depletion of striatal dopamine, DOPAC and HVA content in MitoPark mice was exacerbated in Mn-treated MitoPark mice. We also evaluated the neuroprotective efficacy of a novel mitochondrial-targeted antioxidant, mitoapocynin. Oral administration of mitoapocynin (10 mg/kg, p.o) three times a week to MitoPark mice through 13-24 weeks of age restored behavioral deficits, striatal dopamine depletion and TH neuronal cell loss in MitoPark mice. Our results demonstrate that the MitoPark mouse is an excellent model to study the gene-environmental interactions associated with mitochondrial defects in the nigral dopaminergic system as well as to evaluate the neuroprotective efficacy of novel neuroprotective agents.

### PS 730 Continuous Infusion in Genetically-Altered Down Syndrome Mice.

H. van Wijk. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: S. Kirk.

Performing femoral vein catheterisation surgery with tail cuff exteriorisation directly at the performing laboratory offers various advantages. Implanted mice avoid transport from a third party supplier post-surgery. This reduces the risks associated with post operative transport (expression of disease), requires a shorter total recovery time, and allows utilisation of unusual strains not surgically available.

In this study we investigated the feasibility of performing femoral vein catheterisation with tail cuff exteriorisation surgery in-house on B6EiC3Sn a/A-Ts(1716)65Dn (Ts65Dn) Euploid Ts65Dn mice (Jackson Laboratories, Bar Harbour, Maine, USA) to avoid tube restraint necessary for iv bolus administration and allow behavioural monitoring.

Ts65Dn is a widely accepted mutant strain model of Down's syndrome allowing assessment of medicines for potential unwanted side effects in disease patients. The chromosomal complement of the Ts65Dn mouse is incomplete relative to conventional mice; however the animals do not require special husbandry conditions, housing or maintenance and are considered to show normal behaviour in most respects. They are not affected by heart abnormalities common in humans affected by Down's Syndrome.

The mean bodyweight of the control euploid mice is greater than the Ts65Dn mice (~ 40g and 30g respectively). The mean body length for Ts65Dn mice is shorter (~ 1 cm nose - base of tail; 1.5 cm nose - tip of tail) presenting challenges in surgery and tail cuff attachment. To ensure tail size was not likely to impede exteriorisation of the catheter, a range of tail cuff sizes were used.

Of the 16 Ts65Dn and 16 wild type mice that were surgically prepared, only one Ts65Dn mouse failed to recover and was humanely killed three days post surgery. No unexpected clinical signs were seen after surgery and infusion and body weights started to regain six days post surgery, which is quicker than previously described by Arts et al 2012.

In conclusion, in-house catheterisation of Ts65Dn mice was shown to be more humane than obtaining and transporting surgically prepared mice from a third party, reducing the chance of disease expression.

### PS 731 Generation and Characterization of a Humanized *C. elegans* Transgenic Animal That Results in Early Onset, Age-Dependent Complete Loss of DA Neurons.

S. Jamadar, N. VanDuyn and R. M. Nass. *Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.*

Background: Parkinson's disease (PD) is a slowly progressive neurodegenerative disease characterized by the selective loss of dopamine (DA) neurons. Despite over 50 years of intensive research into the disorder, the origin of the pathogenesis and the molecular determinants involved in PD have not been elucidated. A significant hindrance in dissecting these molecular components is the lack of facile *in vivo* genetic models to explore the mechanisms involved in age-dependent cell death. Aims/Objectives: Our goal in this study was to develop and characterize a viable *C. elegans* animal that has early onset, age-dependent complete loss of DA neurons. Methods: We utilized transgenic *C. elegans*, reverse genetics, biochemical assays, immunofluorescence, mRNA and miRNA arrays, RT-PCR, Western analysis, and neuronal morphology analysis to characterize expression, localization and the role of human alpha-synuclein, parkin and mutant genes in DA neuron pathology. Results: We generated genetic crosses with *C. elegans* containing human A53T alpha-synuclein, an endogenous parkin mutation and other genetic modifications. One product of this study is the generation of a *C. elegans* transgenic animal that results in a robust DA neurodegeneration phenotype. Immediately after hatching, the animals have their full complement of DA neurons as determined by confocal analysis and DA levels by HPLC, yet animals approximately 8 days old exhibit a

complete loss of DA neurons. Our data suggests that post-translational modifications play significant roles in DA neuron vulnerability to PD-associated genes and toxicants. Conclusions: We have generated a novel transgenic, the first animal (vertebrate or invertebrate) that has a complete loss of DA neurons as a function of age. This animal is proving to be invaluable in determining molecular basis of gene- and toxicant-associated DA neuron vulnerability. Support: NIEHS ES014459 and ES003299 to RN, and EPA STAR Graduate Fellowship to NVD.

### PS 732 Development of Animal Models of Idiosyncratic Drug-Induced Liver Injury.

I. G. Metushi and J. Uetrecht. *Pharmacology and Toxicology, University of Toronto, Toronto, ON, Canada.*

Background: Idiosyncratic drug-induced liver injury (IDILI) remains a serious health problem and it also significantly increases the risk of drug development. Unfortunately, not much is known about the mechanism of IDILI and a main reason is because there are no good animal models. We set out to develop animal models of IDILI by focusing on two drugs: Isoniazid (INH) and Amodiaquine (AQ), both of which cause IDILI in humans. Results: INH was found to covalently bind to mouse and to a lesser extent rat liver macromolecules. Treatment of Balb C, C57BL/6 mice, Wistar or Brown Norway rats with INH did not result in significant liver injury. Treatment of Cbl-b<sup>-/-</sup>, PD1<sup>-/-</sup> and NAT 1/2<sup>-/-</sup> mice resulted in mild liver injury. One possible reason that these animals did not develop more extensive liver damage is immune tolerance. Immunization of C57BL/6 mice with S100 hepatic protein modified with INH produced a greater degree of autoimmune hepatitis than S100 alone, but when INH was subsequently given orally this prevented the autoimmune hepatitis. Treatment of female C57BL/6 mice with AQ resulted in a mild transaminase (ALT) increase at week 3 and this resolved by week 5. Immunohistochemical staining and flow cytometry showed that AQ-induced liver injury in C57BL/6 mice was associated with infiltration of immune cells such as F4/80, CD11b, CD4, CD8 and CD45R in the liver and spleen. Treatment of Cbl-b<sup>-/-</sup> and PD1<sup>-/-</sup> mice with AQ resulted in more severe liver injury, but ALT still resolved despite continued treatment. Treatment of Cbl-b<sup>-/-</sup> mice with FICZ and Anti-CD25 Ab to break immune tolerance was not effective. Treatment of RAG1<sup>-/-</sup> mice also resulted in a mild increase in ALT but the ALT did not appear to resolve as it did in the C57BL/6 mice. Conclusion: These data suggest that the dominant response to these drugs is immune tolerance. Treatment of female C57BL/6 mice with AQ results in delayed onset of mild liver injury which resolved despite continued treatment; this is similar to what happens in humans and this model is being further characterised. Supported by grants from CIHR.

### PS 733 Role of Myeloid-Derived Suppressor Cells in a Murine Model of Drug-Induced Liver Injury Mediated by the Adaptive Immune System.

M. Chakraborty, L. S. Chea, J. D. Berkson, W. R. Proctor, J. C. Morrison, K. Semple and L. R. Pohl. *Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, National Heart, Lung and Blood Institute, Bethesda, MD.*

Although clinical evidence suggests that many cases of serious idiosyncratic drug-induced liver injury (SIDILI) are mediated by hepatic protein adducts of drugs and the adaptive immune system, detailed experimental proof for this mechanism of toxicity has remained elusive due to the lack of animal models. We have hypothesized that SIDILI is as rare in animals as it is in humans due at least in part to the tolerogenic nature of the liver, which consists of multiple negative regulators of the adaptive immune system. This idea has now been tested in an established murine model of halothane-induced liver injury where the toxicity is initiated by the metabolism of halothane to form trifluoroacetylated liver proteins and enhanced by the innate immune system, which are prerequisites for activating the adaptive immune system. Twenty-four hours after female Balb/cj mice were treated with halothane, analysis of the liver revealed perivenous necrosis and an infiltration of CD11b<sup>+</sup> Gr-1<sup>High</sup> neutrophils, as reported by other researchers. Further study revealed that the neutrophils contained a subpopulation of myeloid-derived suppressor cells (MDSC) that inhibited the proliferation of both CD4<sup>+</sup> and CD8<sup>+</sup> T cells isolated from naïve mice. When MDSC were depleted from the liver with Gr-1 antibodies prior to two treatments with halothane, enhanced liver injury was observed nine days after the second exposure of halothane as compared to mice that were pretreated with isotype control antibodies before halothane treatments. Moreover, the liver injury was associated with elevated levels of hepatic T cells and serum antibodies that both reacted with trifluoroacetylated liver proteins isolated from halothane treated mice. Collectively, our data provides a rational approach for developing animal models of SIDILI mediated by the adaptive immune system and suggests that deficiencies in liver tolerance may predispose patients to SIDILI.

**PS 734 Defective Platelet Function in a Mouse Model of Progressive Cholestasis.**

Y. Zhang<sup>1</sup>, F. Li<sup>2</sup>, S. Cheepala<sup>1</sup>, Y. Wang<sup>1</sup>, E. J. Gonzalez<sup>2</sup> and J. D. Schuetz<sup>1</sup>.

<sup>1</sup>Pharmaceutical Sciences, St. Jude Children's Research Hospital, Memphis, TN;

<sup>2</sup>Laboratory of Metabolism, Center for Cancer Research, NCI, National Institutes of Health, Bethesda, MD.

We have recently demonstrated that Abcb11-deficient mice recapitulate the human genetic disease PFIC2 (progressive familial intrahepatic cholestasis type 2) attributed to loss of function of the ABC transporter, ABCB11 (1). Cholestatic liver diseases lead to coagulopathies, however it is unclear if these are due to defects in the liver's production of fibrinogen and procoagulant factors or defects in platelet function. By metabolomic analysis we demonstrated that lysophosphatidylcholine (lysoPC) (16:1 and 18:1) concentrations were elevated 2 to 5 times (vs. WT) in the liver and sera of Abcb11-null mice before evidence of frank liver damage. Because lysoPC inhibits platelet aggregation (2) we hypothesized that platelets of Abcb11-null mice might have aggregation defects due to elevated serum lysoPC. Platelet counts were comparable between the Abcb11-null mice and WT mice and platelet-rich plasma was used to test platelet aggregation. Agonist-induced aggregation of Abcb11-null platelets was impaired for agonists: ADP, collagen and thrombin. This ubiquitous defect is consistent with reduced expression of dense granule marker P-selectin and platelet receptor protein GPVI. As there are no changes in the downstream signaling genes *Plcγ1*, *Syk*, and *FcRγ1*, in platelets of Abcb11-null mice; our results suggest that defective aggregation of Abcb11-null platelets is the result of down-regulation of GPVI and P-selectin which may be secondary to lysoPC exposure.

**PS 735 Validation of ROS As a Toxicity Marker in Zebrafish.**

W. Seng, C. Li and P. McGrath. *Phylonix, Cambridge, MA.*

Oxidative stress, associated with an increased level of reactive oxygen species (ROS), is a key factor in both drug-induced toxicity and disease pathogenesis. However, conventional methods for assessing ROS damage are labor intensive and slow hampering widespread use as a toxicity marker. Because of their genetic and physiological similarity to humans, zebrafish have shown promise as an efficient and predictive animal model for assessing drug toxicity, safety and efficacy. Similar to effects in mammals, ROS levels have been shown to increase in zebrafish after drug treatment and irradiation. In this study, we developed a quantitative whole zebrafish microplate-based ROS assay format that relies on a commercially available fluorogenic dye (5-[and-6]-chloromethyl-2,7-dichlorodihydrofluorescein diacetate, acetyl ester, CM-H2DCFDA). We validated the assay using 7 characterized mammalian ROS inducers: TSA [Trichostatin A], PMA [4β-phorbol 12-myristate 13-acetate], Cisplatin, DCA [Dichloroacetate], Menadione, TBHP [tert-Butyl hydroperoxide] and Ethanol and 1 negative control compound, NAC [N-Acetyl-L-cysteine]. In order to optimize the assay, we assessed: ROS level by zebrafish developmental stage, linear relationship between number of animals per microwell and fluorescence intensity, signal to noise (S/N) ratio, effect of carrier DMSO, assay specificity, and assay reproducibility and robustness.

To confirm results using the whole animal microplate format, we also visually assessed site of ROS induction in transparent animals using fluorescent based morphometric image analysis. Using both the microplate format and whole mount morphometric image analysis, compared to mammals, the overall correct prediction rate in zebrafish was 100%, which according to the European Centre for the Validation of Alternative Methods (ECVAM), is considered "excellent". These results underscore the high conservation of toxicity pathways among species and support use of the whole zebrafish ROS assay as a rapid, predictive in vivo assay for compound screening.

**PS 736 The Effect of Fluoride on the Bones and Teeth of ICR-Derived Glomerulonephritis (ICGN) Mice by Subacute Exposure.**

M. Hosokawa<sup>1</sup>, C. Sugaya<sup>2</sup>, M. Tsunoda<sup>2</sup>, K. Itai<sup>3</sup>, Y. Kodama<sup>4</sup>, Y. Sugita-Konishi<sup>4</sup>, H. Ohta<sup>5</sup>, Y. Ito<sup>6</sup>, M. Shimahara<sup>6</sup>, K. Yokoyama<sup>1</sup> and Y. Aizawa<sup>7</sup>.

<sup>1</sup>Epidemiology and Environmental Health, Juntendo University, Tokyo, Japan;

<sup>2</sup>Preventive Medicine, Kitasato University, Sagami, Japan; <sup>3</sup>Iwate Medical University, Morioka, Japan; <sup>4</sup>National Institute of Health Sciences, Tokyo, Japan;

<sup>5</sup>Environmental, Occupational Health and Toxicology, School of Allied Health Science, Kitasato University, Tokyo, Japan; <sup>6</sup>Oral surgery, Osaka Medical College, Takatsuki, Japan; <sup>7</sup>Kitasato University, Tokyo, Japan.

Dental fluorosis and osteofluorosis by drinking water contaminated with fluoride (F) have been reported in China and India. Because fluoride is excreted from the kidney, the toxic effects of F may be affected more significantly by F in ICR-derived glomerulonephritis (ICGN) mice that have commonly been used as a model of renal failure. In this study, we administered F to ICGN and ICR mice to compare the effects of F on the teeth and bones between mice with and without renal failure. Both male and female ICGN and ICR mice were administered F at the concentrations of 0, 25, 50, 100, and 150 ppm in the drinking water for 4 weeks. The mice's femurs were sampled and photographed with a standard aluminum scale. The photographs were analyzed by microdensitometry, and the indexes calculated were: bone mineral content and bone density. The teeth were decalcified in EDTA solution and stained with HE. All the ICGN mice exposed to 150 ppm died. However, no ICR mice died. The mean bone density was significantly lower in the female ICGN mice exposed to 150 ppm compared to the control. The mean mineral content and bone density of the female 100 ppm ICGN group were significantly lower than those of the control. There were no significant differences in the bone indexes among the male ICGN groups. In ICR mice, the mean bone mineral content and bone density were higher in the 150-ppm group for both male and female. The heterogeneity of calcification in the tooth enamel was observed in the ICGN mice exposed to 150 ppm. The decrease in bone density in the mice exposed to F may be due to systemic effects of F. ICR mice exposed to F may be used as a model of osteofluorosis.

**PS 737 A Population-Level Mouse Model to Investigate the Genetic Determinants of Susceptibility to Environmental Toxicants.**

M. C. DeSimone<sup>1</sup>, S. H. Jennings<sup>2</sup>, A. B. Rogers<sup>3</sup> and D. Threadgill<sup>1</sup>. <sup>1</sup>Genetics, North Carolina State University, Raleigh, NC; <sup>2</sup>Veterinary Medicine, North Carolina State University, Raleigh, NC; <sup>3</sup>Pathology, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Carcinogenesis bioassays have lacked the genetic component critical for the evaluation of underlying disease susceptibility genes. Here we used a systems biology approach to model the genetic heterogeneity of exposed human populations, including the inter-individual variation in drug metabolism and transport. We developed a novel intercross population derived from FVB/N<sup>Abcb1a/1b/-/-</sup>, a multi-drug resistant p-glycoprotein knockout mouse model, and CAST/EiJ a wild-derived strain that is genetically distinct from the FVB/N background. Using this intercross to model human biology, including using a western diet, environmentally-relevant doses of trichloroethylene (TCE) and inorganic arsenic (iAs), were evaluated for their effects on toxicity susceptibility. A study cohort of 900 FVB/N<sup>Abcb1a/1b/-/-</sup> x CAST/EiJ F3 mice was divided into nine dose groups, each containing 50 female and 50 males, and was administered TCE and sodium arsenite via the drinking water and chow, respectively, at environmentally-relevant concentrations for 56 weeks using a dose-ratio approach. At harvest, biofluids and tissues were either formalin fixed for pathology, or flash frozen for molecular analysis. Mice co-exposed to TCE and iAs developed hepatocellular carcinoma, as well as renal cysts, clear cell foci and dilated renal tubules consistent with human renal disease pathogenesis. Whole genome expression analysis of kidney tissues revealed a distinct response signature for the combinatorial exposures, including overexpression of oncogenes implicated in the development of human renal cell carcinoma. Genome-wide allelotyping of each mouse using a 7,851 SNP genotyping array will reveal the genetic variants underlying toxicity response. This experimental paradigm has successfully modeled the population-level variability in disease response and has the potential to identify individuals sensitive to toxicity.

**PS 738 Human Antibodies Can Cross Guinea Pig Placenta and Bind Its Neonatal Fc Receptor: Implications for Evaluating Immune Therapy during Pregnancy.**

L. Ma<sup>1</sup>, L. Zhong<sup>1</sup>, D. M. Toibero<sup>3</sup>, A. Hoglund<sup>2</sup>, J. Beren<sup>4</sup>, M. G. Norton<sup>1</sup>, P. Zhang<sup>1</sup> and E. B. Struble<sup>1</sup>. <sup>1</sup>Laboratory of Plasma Derivatives, Division of Hematology, OBRR, CBER, US FDA, Bethesda, MD; <sup>2</sup>Division of Veterinary Services, CBER, US FDA, Bethesda, MD; <sup>3</sup>University of Maryland, College Park, MD; <sup>4</sup>OC TEC, CDER, US FDA, Silver Spring, MD.

Disclaimer: The findings and conclusions in this presentation have not been formally disseminated by the Food and Drug Administration and should not be construed to represent any Agency determination or policy.

Despite increased use of monoclonal and polyclonal antibody therapies, including during pregnancy, there is little data on appropriate animal models that could humanely be used to understand determinants of protection, and to evaluate safety of these biologics in the mother and the developing fetus. We have demonstrated that pregnant guinea pigs can transport human IgG transplacentally at the end of pregnancy. Using an intravenous anti-hepatitis B specific immune globulin preparation as an example, we show that IgG subclasses one, two and three are measurable in both the sows and their piglets. Given that IgG4 can be transferred transplacentally in the guinea pig, our observations indicate that all human IgG subclasses can pass guinea pig placenta during the last third of pregnancy. In addition, we found that all human IgG subclasses are capable of binding to a soluble form of the guinea pig neonatal Fc receptor *in vitro* in a manner similar to that demonstrated for the human variant. This result suggests that transplacental transport of human IgG subclasses in guinea pig mirrors the receptor-based mechanism seen in humans. Together, our studies lay the groundwork in introducing pregnant guinea pigs as an appropriate model for the evaluation of antibody therapies during pregnancy and advancing the health of women and neonates.

**PS 739 Gender and Perinatal Exposure to Bisphenol A Affect Markers of Inflammation in the Brain and Spleen of Young Rats.**

J. Rodriguez-Santiago<sup>1</sup>, Z. Varguaz-Villarrubia<sup>1</sup>, D. R. Mierke<sup>3</sup>, R. N. Sadowski<sup>2</sup>, L. M. Wise<sup>2</sup> and S. N. Laverne<sup>3</sup>. <sup>1</sup>Aguadilla, University of Puerto Rico, Aguadilla, Puerto Rico; <sup>2</sup>Psychology, University of Illinois, Urbana, IL; <sup>3</sup>Comparative Biosciences, University of Illinois, Urbana, IL.

Bisphenol A (BPA) is an environmental estrogen disruptor that has been extensively studied for its repro- and neurotoxicity. It has also been shown to activate the immune system and to induce inflammation. This study therefore evaluated markers of inflammation in the brain and spleen of young rats exposed perinatally to BPA. Pregnant rats were dosed with 400 ug/kg/day of BPA during pregnancy, and rat pups continued to be dosed during PND1-PND9; they were then weaned, and eventually humanely euthanized at PND23. The spleens and brains were collected and snap frozen straight away, and stored at -80°C. MHCII levels in the spleens were estimated semi-quantitatively using immunohistochemistry. Cytokine levels were measured in both the spleens and the brains, using a multibead kit. Female rats had higher MHCII levels in their spleen in the vehicle group; this gender effect was absent in the BPA exposed animals where both genders showed similarly high levels. Spleens showed higher levels of IL-1b than brains, but IL-6 and TNFa levels were similar in both organs. In the spleen, IL-1b and IL-6 were higher in females in the vehicle group, but they were higher in males in BPA exposed animals; TNFa levels were higher in females in the control group, but they were similar between genders in the BPA group. BPA decreased IL-1b, increased TNFa, but did not affect IL-6 in male brains. Work is underway to investigate the effect of BPA on inflammation status depending on the exposure timing during development.

**PS 740 Comparing Minimal Supportive Care Models of Hematopoietic Acute Radiation Syndrome in Nonhuman Primates.**

R. Guilmette, M. Doyle-Eisele, W. Weber and D. Melo. *LRRI, Albuquerque, NM.*

Currently male Rhesus Macaques are the standard non-human primate model for hematopoietic acute radiation syndrome however the availability of these animals may limit the drug development studies conducted with treatment candidates. As an alternative, LRRI recently performed a comparison study using male and female cynomolgus macaques. Animals were irradiated with a 6-MV Varian 600c linear accelerator using a two-dimensional irradiation scheme (bilateral) at a dose of 3.5 Gy. Blood was collected prior to irradiation (baseline) and at the following time points post irradiation: 1, 2, 3, 6, 8, 13, 15, and 20 days. Antibiotics, supplemental fluids,

and nutritional support were administered throughout the study. In accordance with the rhesus macaque published data, an initial spike in neutrophils was followed by neutropenia 24 hours following irradiation. By 7 days post irradiation, the platelet levels dropped. At Day 22, an LD100 for females was established. Males began recovering and survived to their scheduled necropsy at Day 30. Baseline measurements for c-reactive protein were consistent with literature values. A biphasic increase occurred between days 1-3 and days 20-27 post irradiation. In addition to CRP, Flt-2L (a hematopoietic growth factor) was also consistent with the literature which showed an increase around day 5 and 20-23 post irradiation. Based on the results, male cynomolgus macaques react similarly to rhesus macaque following external irradiation exposure at this dose level and may be a useful substitute based on their availability. In addition, these data suggest a sex sensitivity in this species.

**PS 741 Development of a Phosgene-Induced Acute Lung Injury in the Conscious Pig.**

S. Graham<sup>1</sup>, A. J. Smith<sup>1</sup>, R. L. Perrott<sup>1</sup>, S. J. Rutter<sup>1</sup>, P. Marshall<sup>1</sup>, T. Mann<sup>1</sup>, B. J. Jugg<sup>1</sup> and A. M. Sciuto<sup>2</sup>. <sup>1</sup>Biomedical Sciences, DSTL, Salisbury, United Kingdom; <sup>2</sup>Medical Toxicology, USAMRICD, Aberdeen Proving Ground, MD.

The toxic industrial chemical (TIC) phosgene (CG) is a reactive intermediate used in a range of industrial processes. Exposure to high concentrations of CG results in an asymptomatic period (2-6 h) before pulmonary oedema develops. There are no specific medical countermeasures for such poisoning, treatment being supportive in an intensive care setting. Evidence based treatment guidelines are needed for health care practitioners to guide treatment. Small animal models have been used to screen candidate therapies, extrapolation of therapeutic benefit to man requires verification in a larger animal model e.g. the pig. There is, therefore, a requirement to develop a conscious large animal model of CG-induced lung injury in which to verify efficacious treatments. If successful, this model will allow assessment of therapeutic interventions to CG-induced lung injury in a species closer to man.

After a period of socialisation, animals were surgically prepared to allow physiological measurements (arterial blood pressures, ECG, temperature and activity via telemetric implant) and blood samples (via exteriorised catheters) to be taken. After a 1 week recovery from surgery and baseline measurements (1 week) animals were exposed to either air or phosgene under anaesthesia, then recovered and monitored for 24 h.

Air-exposed and phosgene-exposed animals were successfully recovered and monitored to 24 h post exposure. The phosgene-exposed animals had a severe but non-lethal phosgene-induced lung injury at 24 h compared to air-exposed controls, demonstrated by changes in arterial blood gas measures, gross pathology and histopathology.

The feasibility of this unique model has been demonstrated. Further refinement of the telemetry technology may be required to add robustness and improve confidence in extrapolation to man. We intend to use the model to test therapeutic candidates proven efficacious in a small animal model.

**PS 742 Sex Differences in Inflammatory Response in a DAPM-Induced Rat Model of Pulmonary Hypertension.**

M. A. Carroll Turpin, V. Y. Hebert, H. Wensler, T. Chotibut, C. Robinson and T. R. Dugas. *Pharmacology, Toxicology and Neuroscience, LSUHSC-Shreveport, Shreveport, LA.*

Pulmonary Arterial Hypertension (PAH) is a cardiovascular disorder characterized by elevated pulmonary artery pressure as a result of arterial wall thickening. Patients survive, on average, 2.8 yr after diagnosis and are 3-4 times more likely to be women than men. There is no cure - the few therapies available can only slow progression. Our purpose was to develop a relevant animal model of PAH in order to identify sex differences that contribute to disease progression, and in doing so, identify potential new treatment strategies. 4,4'-Methylenedianiline (DAPM) is an aromatic amine used industrially in the synthesis of polyurethanes. Chronic, intermittent treatment of rats with DAPM results in medial hyperplasia of pulmonary arterioles, exclusively in females, coupled to increases in pulmonary arterial pressures. After 12 wk, significant increases in plasma levels of endothelin-1 (ET-1) and serotonin (5-HT), but decreases in nitrite (NO<sub>2</sub><sup>-</sup>), were observed in females (not males) treated with DAPM. A decrease was observed in the serum ratio of the estrogen metabolites 2-hydroxyestradiol (2-OHE)/16α-hydroxyestrogen (16α-OHE; p = .07). In females, ET-1, NO<sub>2</sub><sup>-</sup> and 2-OHE/16α-OHE were significantly correlated with peak pressure gradient, an indirect measure of pulmonary arterial pressure. In DAPM-treated females, serum IL-10 decreased 37% (p = .0129). INF-γ increased by 48% and IL-6 increased 3-fold (as determined by Bio-Plex cytokine assay). These changes were not significant. However, there were significant interactions between sex and treatment. Future studies will address the contributions of these inflammatory cytokines in PAH initiation and progression in females.

**PS 743 Cynomolgus Macaque (*Macaca fascicularis*) As a Potential Animal Model for Studying Bleomycin-Induced Pulmonary Fibrosis.**

M. Doyle-Eisele<sup>1</sup>, J. Villalba<sup>1</sup>, Y. Shi<sup>1</sup>, J. D. McDonald<sup>1</sup> and I. O. Rosas<sup>1,2</sup>.  
<sup>1</sup>LRRI, Albuquerque, NM; <sup>2</sup>Harvard Brigham and Women's Hospital, Boston, MA.

Bleomycin Sulfate-Induced Pulmonary Fibrosis has been extensively described in mice. However, to our knowledge few non-murine animal models have been implemented before. Here we investigated the pathogenic/inflammatory potential of Bleomycin administration in Cynomolgus Macaques (*Macaca fascicularis*), a surrogate model for human pulmonary fibrosis. Fifteen Cynomolgus Macaques (6 insulin resistant on high fat diet and 9 on standard primate chow) were challenged via a bolus insufflator with varying doses of Bleomycin Sulfate (0.1-1.9 mg/kg). Animals were followed during 10 weeks of study by twice daily cage-side clinical observations. Bronchoalveolar lavage (BAL) and pulmonary function tests (PFTs) were performed biweekly until necropsy. PFTs were completed for each animal (previously anesthetized) using a whole body plethysmograph. A subset of inflammatory potential markers was further analyzed in BAL cell mRNA. Macroscopic lung abnormalities were examined at necropsy. Increases in PYCARD and TXNIP were noted in all animals that received high fat diet compared to those on normal primate chow irrespective of the bleomycin dose. Interestingly, NLRP3, PYCARD, PR2X7, TXNIP, and IL-18 mRNA expression showed an inverse relationship with the bleomycin dose for both feed types. The development of fibrosis in monkeys mimics more of a chronic process as seen in humans. Though our animals presented structural/molecular changes, all of them were asymptomatic. Animals fed a high fat diet have increased inflammasome activation than those fed the standard diet however there is no significant association with the bleomycin dose and the inflammasome activation. These findings suggest that Cynomolgus Macaques may be a potential animal model for studies of Bleomycin-induced pulmonary fibrosis, and this might prove to be a prerequisite for translational research.

**PS 744 Cue-Induced vs Cocaine+Cue-Induced Reinstatement: Two Different Animal Models of Relapse.**

D. Pushett, G. Froget, D. Virley, V. Castagné and C. Froger-Colleaux. *Porsolt SAS, Le Genest-St-isle, France.*

Both environmental factors and abused drugs play a role in drug-seeking. The aim of this work was to compare two models of cocaine-induced reinstatement (i.e. cue- and cocaine+cue). Rats were subjected to daily sessions in operant chambers during which they could receive i.v. infusions of cocaine (0.35 mg/kg/infusion): when rats pressed the active lever, a cue light and a tone signal were turned on together with activation of the infusion pump. When cocaine self-administration was acquired, rats were moved to extinction sessions where active lever-presses no longer produced cocaine infusion, cue light/tone presentation or noise from the pump. Once rats had met extinction criteria, they were subjected to a single reinstatement session. Rats were pretreated with vehicle or raclopride (0.08 or 0.15 mg/kg s.c., -30 min). The cue-induced reinstatement session began with a tone and cue light. The remainder of the session was identical to the self-administration session except that no cocaine was delivered. For the cocaine+cue-induced reinstatement session, rats were administered with a non-contingent administration of cocaine (10 mg/kg i.p.) prior to being placed in the chamber. In rats treated with vehicle, a greater number of active lever presses were observed during the cocaine+cue-induced reinstatement session as compared with the cue-induced reinstatement session. A consistent inhibitory profile on cocaine-seeking behavior was demonstrated for raclopride at the higher dose (0.15 mg/kg s.c.) in both models. However the suppressing effect of raclopride at the lower dose (0.08 mg/kg s.c.) was only observed in the cue-induced reinstatement model. These data demonstrate that the cocaine+cue-induced reinstatement model induces a higher level of drug-seeking which is more difficult to reverse than the drug-seeking produced in the cue-induced reinstatement model. Conversely, the cue-reinstatement model may be more sensitive to detect relapse-facilitating effects of test substances.

**PS 745 Early Juvenile Exposure to High-Dose Acetaminophen Impacts Adult Murine Social Behavior in a Strain-Dependent Manner.**

G. G. Gould<sup>1</sup>, C. Smolik<sup>1,2</sup>, T. Gu<sup>1</sup>, M. Vitela<sup>1</sup>, M. F. Valdez<sup>2</sup>, J. Hensler<sup>2</sup>, A. Seillier<sup>2</sup>, A. Giuffrida<sup>2</sup> and S. T. Schultz<sup>3</sup>. <sup>1</sup>Physiology, UTHSCSA, San Antonio, TX; <sup>2</sup>Pharmacology, UTHSCSA, San Antonio, TX; <sup>3</sup>Family and Community Medicine, UTHSCSA, San Antonio, TX.

Pediatric acetaminophen use has increased since 1980, while baby aspirin use declined after its association with Reye Syndrome. It has been hypothesized that increased exposure of children under 5 years old to acetaminophen may be contributing to the rise in autism incidence. Cumulative acetaminophen doses < 75

mg/kg/day for 2 days are within recommended guidelines, but may be problematic for children in whom conjugative disposition pathways are impaired. Alternative metabolic pathways, either via deacetylation to promote endogenous cannabinoid neurotransmission or via oxidative pathways, may be harmful at vulnerable stages of brain development. We sought to model this scenario to clarify possible mechanisms using juvenile mice. We hypothesized that high-dose (>100 mg/kg/day) acetaminophen exposure in weanling (PD18-21) mice would produce impairments in the social behavior of C57BL/6J mice and would worsen them in BTBR mice. Male pups of each strain were exposed for 4 days to 4x daily injections of acetaminophen (100 mg/kg), WIN 55,212 (0.1 mg/kg) or vehicle (saline + 10% DMSO), and matured to adulthood (PD 80). Three chamber sociability tests of C57BL/6 mice revealed a significant (p<0.05) reduction in social interaction relative to vehicle controls that was comparable to prenatal treatment with valproic acid. However, the social behavior of BTBR mice was unaffected. Levels of 2-arachidonoylglycerol and serotonin transporter binding site density were also reduced in both strains. In contrast C57BL/6 mice exposed for 4 days to 1.5 mg/ml of acetaminophen were unaffected. Thus, exposure to supratherapeutic doses of acetaminophen or cannabinoid full agonists indicates a possible role for cannabinoid receptors in modulating social behavior, at least in juvenile mice. This research was supported by US Navy contracts and a sub-award from UTHSCSA Institute for Integration of Medicine and Science CTSA grant #UL1RR025767.

**PS 746 Interlaboratory Comparison of Clearance Rates of Xenobiotics by Cryopreserved Trout Hepatocytes for the Prediction of Bioaccumulation Potential.**

K. Fay<sup>1</sup>, R. T. Mingoia<sup>2</sup>, I. Goeritz<sup>3</sup>, D. L. Nabb<sup>2</sup>, A. D. Hoffman<sup>1</sup>, B. D. Ferrell<sup>2</sup>, H. M. Peterson<sup>2</sup>, J. W. Nichols<sup>1</sup>, H. Segner<sup>3</sup> and X. Han<sup>2</sup>. <sup>1</sup>US EPA, Duluth, MN; <sup>2</sup>DuPont Haskell Global Centers for Health & Environmental Sciences, Newark, DE; <sup>3</sup>University of Bern, Bern, Switzerland.

Hepatic biotransformation is an important determinant of chemical bioaccumulation in fish. Consequently, improvements to bioaccumulation models can be made using estimates of chemical biotransformation rates. Cryopreserved trout hepatocytes have previously been used to measure the clearance rates of some compounds. The use of this information within a regulatory context requires, however, that such results be reproducible across laboratories. In this study, three independent laboratories performed a round-robin study using cryopreserved rainbow trout (*Oncorhynchus mykiss*) hepatocytes. Six compounds were selected for testing: benzo[a]pyrene, 4-nonylphenol, di-tert butyl phenol, fenthion, methoxychlor and o-terphenyl. Pre-trial studies were performed to streamline the assay protocol, standardize hepatocyte counting procedures, and characterize potential sources of variability. The results confirmed first-order depletion kinetics for the selected compounds and highlighted the effects of assay temperature as well as lot variability. Each laboratory then conducted clearance assays for the six compounds using a substrate depletion approach. The analyses for each substrate were conducted at one institute to focus the comparison on the assay itself. Compounds determined to be poorly (o-terphenyl; <0.05 ml/h/106 cells) or rapidly metabolized (benzo[a]pyrene; >0.3 ml/h/106 cells) were similarly determined across laboratories. Coefficients of variation across the three laboratories were generally 30% or better, suggesting this method of determining intrinsic clearance is transferable and reproducible. This inter-laboratory comparison strongly supports the use of cryopreserved trout hepatocytes as a tool for estimating hepatic clearance for bioconcentration factor predictions.

**PS 747 Pharmacokinetics of Dichloroacetate in a Canine Model.**

H. W. Maisenbacher<sup>1</sup>, A. L. Shroads<sup>2</sup>, G. Zhong<sup>3</sup>, A. D. Daigle<sup>1</sup>, M. M. Abdelmalak<sup>2</sup>, I. Sosa Samper<sup>1</sup>, B. D. Mincey<sup>1</sup>, M. O. James<sup>3</sup> and P. W. Stacpoole<sup>2</sup>. <sup>1</sup>Small Animal Clinical Sciences, University of Florida, Gainesville, FL; <sup>2</sup>Medicine, University of Florida, Gainesville, FL; <sup>3</sup>Medicinal Chemistry, University of Florida, Gainesville, FL.

Dichloroacetate (DCA) is an investigational drug for mitochondrial diseases, pulmonary arterial hypertension (PAH), and cancer in humans. It is metabolized to glyoxylate by glutathione transferase zeta 1/maleylacetoacetate isomerase (GSTZ1/MAAI), which also catalyzes the penultimate step in tyrosine catabolism. DCA is a mechanism-based inhibitor of GSTZ1/MAAI, thereby inhibiting its metabolism and causing accumulation of reactive tyrosine intermediates, such as maleylacetone (MA). Human haplotype variation in GSTZ1 also confers variable rates of DCA biotransformation that may impact chronic safety. Dogs express GSTZ1/MAAI and develop PAH and cancer; thus, they may be a valuable model of human diseases in which DCA is used. Accordingly, we characterized the pharmacokinetics and dynamics of DCA in a canine model.

Based on an initial 2 day dose-response study, 3 dogs were orally administered 6.25mg/kg q12h DCA for 4 weeks. Between day 1 and 14, Cmax was significantly different ( $p < 0.01$ ) and clearance approached significance ( $p = 0.067$ ). The differences between day 1 and 28 approached significance for  $t_{1/2}$  ( $p = 0.058$ ) and clearance ( $p = 0.065$ ). Urinary levels of DCA ( $p = 0.074$ ) and MA ( $p = 0.056$ ) tended to increase during DCA exposure. There were no differences in packed cell volume, blood alanine aminotransferase, aspartate aminotransferase or glucose levels, or nerve conduction velocities between day 0 and 28. Liver biopsies on day 0 and 27 demonstrated complete inhibition of GSTZ1 protein expression and activity ( $0.305 \pm 0.030$  vs.  $0.012 \pm 0.009$  nmol glyoxylate formed/min/mg protein,  $p < 0.01$ ). Dogs demonstrate slower clearance and greater inhibition of DCA metabolism than rodents and most humans. The plasma kinetics of DCA in dogs is similar to humans with GSTZ1/MAAI polymorphisms that confer exceptionally slow plasma clearance. Thus, dogs may be a useful model to further investigate the toxicokinetics of DCA.

#### PS 748 Determination of Onset of Sexual Maturity in Female Göttingen Minipigs.

B. Peter<sup>1</sup>, H. Lorentsen<sup>2</sup>, E. van Duijnhoven<sup>1</sup>, M. van Tuyll<sup>1</sup>, B. van Rozendaal<sup>1</sup> and H. Emmen<sup>1</sup>. <sup>1</sup>Toxicology, WIL Research Europe B.V., 's-Hertogenbosch, Netherlands; <sup>2</sup>Ellegaard Göttingen Minipigs A/S, Dalmose, Denmark.

Minipigs are often used in safety assessment studies with pharmaceuticals. Based on breeding experience, female minipigs are considered to reach sexual maturity at 4-5 months of age. However, more exact scientific data on sexual maturity is lacking. This information is pivotal for the design and interpretation of toxicity studies during drug development.

First, a pilot study was initiated to find useful parameters for the detection of estrous cycle in adult female Göttingen minipigs. Three sows at 10-11 months of age housed adjacent to adult boars were monitored daily for signs of heat (specific behavior, changes of the vulva) for 29 days. In addition, rectal body temperature was recorded, vaginal smears were taken for estrous cycle determination and the reproductive hormones progesterone and  $17\beta$ -oestradiol were measured in serum. Progesterone analysis was the most valuable method, showing a cyclic pattern of release. The outcome of the examination of vulva and vaginal smears was less clear. Other external signs of heat did not reveal a cyclic pattern.

Subsequently, the approximate age at which female minipigs reach onset of sexual maturity was determined. For this, two gilts at 2 months of age, housed in the same room as adult boars, were used. Investigations included progesterone analysis, observations of the vulva, estrous cycle determination and recording of body weights. Progesterone levels increased first at approximately 5.5 and 6.5 months of age (body weight: 12.7 and 17.3 kg), respectively. The hormone release was indicative for a functional corpus luteum. For one female progesterone analysis was continued for nearly 3 months. The cycle duration was approximately 3 weeks which is in line with published data (18-21 days). However, the different stages of the cycle could not easily be distinguished by evaluation of vaginal smears. This information will be used in a following study to further investigate onset of sexual maturity in a female minipig population.

#### PS 749 Recording of the Full-Field Electroretinogram in the Göttingen Minipig.

R. Forster<sup>1</sup>, A. Augsburger<sup>2</sup>, V. Haag<sup>1</sup> and J. Legrand<sup>1</sup>. <sup>1</sup>CiToxLAB France, Evreux, France; <sup>2</sup>DMV Clinique Vétérinaire, Bois-Guillaume, France.

The purpose of this work was to evaluate a simple electroretinographic protocol on a representative sample of Göttingen minipigs. Electroretinogram recordings were conducted on 162 healthy minipigs (81 males and 81 females) aged 4-6 months. After a 1.5-h light adaptation period, the animals were placed under general anesthesia. First, binocular full-field photopic electroretinogram recordings were conducted under photopic conditions. Subsequently, scotopic electroretinogram recordings were conducted during dark adaptation every 4 min over a 20-min period. At the end of this period, the maximal combined rod-cone response was recorded by measuring the retinal response to a single high-intensity flash. We used sclerocorneal clips as active electrodes and needle electrodes for the reference and ground. The a-wave and b-wave peak times and amplitudes were measured and statistically analyzed. For each of the statistical comparisons, normality and homogeneity of variances were evaluated. No significant gender differences were observed, with the exception of a higher b-wave amplitude for the photopic ERG recordings in females ( $48.14 \pm 12.91$  IV vs.  $42.88 \pm 10.67$  IV;  $p < 0.005$ ). The process of dark adaptation was evaluated, and the maximal combined rod-cone response was measured (a- and b-wave amplitudes and peak time). In conclusion, photopic and scotopic electroretinogram recordings were performed in the minipig using a protocol based on light adaptation followed by dark adaptation. Sclerocorneal clip electrodes allowed a quick assembly and examination.

#### PS 750 Normal Physiological Ranges for Hanford Miniature Swine.

J. Liu<sup>1</sup>, L. D. Brown<sup>1,2</sup>, T. J. Madsen<sup>1</sup>, S. Schlink<sup>1</sup>, M. Freeman<sup>1</sup>, B. C. Hanks<sup>1,2</sup>, A. Stricker-Krongrad<sup>1</sup> and G. F. Bouchard<sup>1,2</sup>. <sup>1</sup>Sinclair Research Center, LLC, Columbia, MO; <sup>2</sup>Sinclair BioResources LLC, Auxvasse, MO.

The miniature swine have been increasingly recognized as a non-rodent model in regulatory toxicity. Members of the FDA have even published on the use of miniature swine as an alternative to canine and non-human primates in regulatory toxicity. The similarities between the cardiovascular, renal, and digestive systems make the miniature swine a suitable animal to model the human counterpart. The miniature swine are also the most recognized species for dermal toxicology. The Hanford miniature swine (HMS) has other attractive traits that make them a good substitute to model humans. They are omnivorous, easy to handle, prone to obesity, and will develop atherosclerosis and dyslipidemia if fed a high fat diet. With the advent of new techniques, all routes of compound administration can be used with miniature swine. The HMS should be considered as one of the non-rodent species in toxicity testing. In an effort to generate a database on baseline information about the normal physiological status of the Hanford miniature swine, we report expanded and updated physiological data from normal intact and naïve juvenile and young adult miniature swine of both genders. The normal physiological data gathered includes growth parameters, hematology, serum chemistry, coagulation profile, urinalysis, ECG rhythm and segment intervals, and organ weights.

#### PS 751 A Six-Month Feeding Study for WistarHannover gpt Delta Transgenic Rat.

H. Takagi<sup>1</sup>, Y. Nozaki<sup>1</sup>, A. Kawada<sup>1</sup>, M. Yamada<sup>2</sup>, K. Masumura<sup>2</sup> and T. Nohmi<sup>3</sup>. <sup>1</sup>Biotechnical Center, Japan SLC, Inc., Hamamatsu, Japan; <sup>2</sup>Division of Genetics and Mutagenesis, National Institute of Health Sciences, Tokyo, Japan; <sup>3</sup>Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan. Sponsor: A. Nishikawa.

Transgenic rodent gene mutation assays, recently adopted as OECD test guideline TG488, are useful methods to evaluate *in vivo* mutagenicity of chemicals in a target organ. The multiple copies of genetically neutral transgenes that contain reporter genes for mutation analysis are integrated in the chromosome of the transgenic rodents. However, biological identities between the transgenic and non-transgenic animals are not well demonstrated. To evaluate the characteristics of WistarHannover gpt delta transgenic (Tg) rat in general toxicity study, we investigated the clinical and pathological features of the gpt delta transgenic and non-transgenic WistarHannover rats in six months feeding study. The six week-old Slc:WistarHannover/Rcc (gpt delta) and Slc:WistarHannover/Rcc (40 animals/sex/strain) were employed for this assessment. Twenty animals in each sex were subjected to necropsy at 13 and 26 weeks after starting, then, clinical and pathological assessments were conducted. In Slc:WistarHannover/Rcc(gpt delta), the values of several parameters in hematology, clinical biochemistry and organ weights were different from those in Slc:WistarHannover/Rcc with statistical significance. These alterations, however, were within the range of historical control data of in housed Slc:WistarHannover/Rcc, and thus were considered to be incidental. In histopathology, spontaneous lesions in WistarHannover such as fibrosis in the heart, microgranuloma in the liver and so on were observed in both strains. These results suggested that there were no remarkable differences which indicate phenotypic modulation in Tg rats, and supported the conclusion that Slc:WistarHannover/Rcc(gpt delta) has similar characteristics to WistarHannover.

#### PS 752 A Medium-Term Animal Model Using gpt Delta Rats for Predicting Chemical Carcinogenicity and Related Mechanisms of Action.

K. Matsushita<sup>1</sup>, Y. Ishii<sup>1</sup>, S. Takasu<sup>1</sup>, K. Kuroda<sup>1</sup>, A. Kijima<sup>1</sup>, T. Nohmi<sup>2</sup>, K. Ogawa<sup>1</sup>, A. Nishikawa<sup>2</sup> and T. Umemura<sup>1</sup>. <sup>1</sup>Division Path., National Institute Health Science, Tokyo, Japan; <sup>2</sup>BSRC, National Institute Health Science, Tokyo, Japan.

In this study, an animal model (GPG46) capable of rapidly detecting chemical carcinogenicity with the underlying mechanisms of action was developed in gpt delta rats using a reporter gene assay to detect mutations and a medium-term rat liver bioassay to detect tumor promotion. The standard protocol for the GPG46 model was developed based on the results of dose-response exposure to diethylnitrosamine (DEN) and treatment with phenobarbital over time following DEN administration. Briefly, gpt delta rats were exposed to various chemicals for 4 weeks, followed by a partial hepatectomy (PH) to collect samples for the *in vivo* mutation assay. The mutant frequencies (MFs) of the reporter genes were examined as an indication of tumor initiation. A single i.p. injection of 10 mg/kg DEN was administered in rats 18 h after the PH to initiate hepatocytes. Tumor promoting activity was evaluated

based on the development of glutathione S-transferase placental form (GST-P) positive foci at week 10. The genotoxic carcinogens 2-acetylaminofluorene (2-AAF), 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) and safrole (SF), the non-genotoxic carcinogens piperonyl butoxide (PBO) and phenytoin (PHE), the non-carcinogen acetaminophen (APAP) and the genotoxic non-hepatocarcinogen aristolochic acid (AA) were tested to validate the GPG46 model. The MFs of the gpt genes were significantly increased in rats treated with 2-AAF, IQ, SF and AA. The number and area of GST-P positive foci were increased in the livers of rats treated with 2-AAF, IQ, SF, PBO and PHE. APAP treatment did not elevate the MFs of the gpt genes and inhibited the development of GST-P positive foci. The validation results indicate that the GPG46 model could be a powerful tool in understanding chemical carcinogenesis and provide valuable information regarding human risk hazards.

**PS 753 Age-Related Changes in Body Composition in Laboratory Rats: Strain and Gender Comparisons.**

R. C. MacPhail, P. M. Phillips, C. J. Gordon and K. A. Jarema. *NHEERL, US EPA, Research Triangle Park, NC.*

Long Evans (LE), Sprague Dawley (SD), Fischer 344 (F344), and Brown Norway (BN) rats are all commonly used as laboratory research subjects. These strains have been studied under many conditions, but few studies have measured changes in body composition as the animals age. Understanding strain differences with regard to body composition, age and growth are essential for understanding toxicity mechanisms, specifying deprivation regimens for studies on food-rewarded learning and performance, and developing accurate pharmacokinetic models of toxicity. This study used a Bruker body composition analyzer to compare the changes in body fat, lean tissue, and fluid for male (n=12/strain) and female (n=12/strain) LE, SD, F344 and BN rats. We found dramatic differences in body composition between the four rat strains. In both male and female rats, body weights were similar for the LE and SD strains, and much lower for the F344 and BN strains. In all cases, body weights for females were less than males. Lean mass for both genders followed a similar pattern as body weight, with the LE and SD rats differing from the BN and F344 rats, and males differing from females. Total fat content differed substantially between strains. The LE rats had the highest fat content, followed by SD, then F344, and finally BN, which had the lowest fat content. These strain differences were seen with both males and females. When body fat was calculated as a percentage of total body weight, the LE rats still had the highest values and the BN rats had the lowest values. However, the male SD and F344 rats appeared to be nearly identical in percent fat. Moreover, the female SD and F344 had similar percent fat values early in development, but these values diverged as they continued to age. These results show marked differences in body composition between four rat strains commonly used in toxicology research.

(This is an abstract of a proposed presentation and does not reflect US EPA policy.)

**PS 754 Assessment of Cardio-Respiratory Function in Conscious Rats: Use of Combined Telemetry and Plethysmography.**

E. Hayes, S. Rompion, E. Gascoin, M. Maujeul, M. Lepage and G. Froget. *Porsolt SAS, Le Genest-St-isle, France.*

In vivo safety pharmacology assessment of cardiovascular (CV) and respiratory function is a regulatory requirement during pre-clinical drug development. Combination of both assessments in a single model could be useful with respect to reducing animal use. We established a model of combined telemetry and plethysmography to evaluate the time-dependent effects of various reference compounds on CV and respiratory function in conscious rats. Male Sprague Dawley rats (n=5-6) were implanted with DSI telemetric devices and placed into plethysmographic chambers (EMKA) with receivers (DSI). Clonidine, verapamil and theophylline were examined for their effects on heart rate, HR; mean arterial blood pressure, MAP, minute volume, MV; tidal volume, TV; respiratory rate, ReR and enhanced pause, Penh before and for 360 min after drug administration. Data were compared by two-way ANOVA (group, time). In controls, a transient decrease in TV (-22%) and Penh (-21%) and a transient increase in ReR (+121%) and MV (+69%) were observed but returned to baseline values within 90 min and remained stable thereafter. No change in MAP or HR occurred in controls. Clonidine (1 mg/kg, i.p.) reduced HR (-55%), MV (-39%) and TV (-39%) but increased ReR (+95%) and Penh (+96%). Verapamil (30 mg/kg, p.o.) reduced MAP (-39%) but had no effect on ventilation. Theophylline (100 mg/kg, p.o.) exhibited respiratory stimulant and bronchodilatory properties (MV, +125%; ReR, +313%; TV, +40%; Penh, +28%) with concomitant tachycardia (HR, +63%). Overall the expected pharmacological actions of the reference compounds on cardio-respiratory function were adequately determined using a combined telemetry and plethysmography system in conscious rats. Combined use of telemetry-plethysmography in the same study may be useful for the development of new compounds that can be compared to established drugs. This model also allows for a reduction in animal use requirements for CV and respiratory safety pharmacology and fulfills the ethical rule of 3R.

**PS 755 Comparison of Ophthalmologic Findings in Young Adult CrI: CD SD and Wister Han Rats.**

H. Kuno<sup>1</sup>, S. McPherson<sup>2</sup>, Q. Kong<sup>2</sup>, S. Mason<sup>2</sup> and Q. He<sup>2</sup>. <sup>1</sup>NTOLLC, Abiko-shi, Japan; <sup>2</sup>WuXi AppTec Co. Ltd., Suzhou, China.

With more than one strain of rat now being used in toxicology studies, a study was instigated to see if there were differences in the incidence and nature of background lesions between the CrI: CD SD and the Wister Han rat.

The results of pretest ophthalmologic examinations of Wister Han (Charles River USA) and CrI:CD rats purchased from Charles River USA and BioLASCO Taiwan Co., Ltd respectively were analyzed. The percentage incidences (total number of lesion(finding)/total number of rats) of the findings were compared for evidence of any significant differences between the two strains and sexes to see if any particular finding was unique or predominately expressed in one of the two strains/sexes.

Corneal opacity along with the palpebral fissure is commonly observed in rats. Wister Han rats showed both a dense and higher incidence of this lesion when compared with CrI: CD rats. In addition, for Wister Han rats a higher incidence was observed for females as compared with males. This gender difference was not apparent for CrI: CD rats. Based on the differences of corneal opacity, the number eyes of CrI: CD rats that were considered normal was higher than that recorded for Wister Han rats. In addition, unilateral or bilateral posterior cortical multifocal pinpoint opacity was observed for Wister Han rats but not CrI: CD rats. In conclusion, there is a clear difference in the incidence of spontaneous ocular findings observed for both Wister Han and CrI:CD rats; with CrI:CD rats showing a lower incidence of corneal opacity along with interpalpebral fissure and no posterior cortical lens opacity.

**PS 756 Feasibility of 3-Month Intravenous Bolus Injections via the Femoral Vein and an External Access Port in Sprague-Dawley Rats.**

J. Perron<sup>1</sup>, R. Tavcar<sup>1</sup>, L. Armer<sup>1</sup> and R. Forster<sup>2</sup>. <sup>1</sup>CiToxLAB North America, Laval, QC, Canada; <sup>2</sup>CiToxLAB France, Evreux, France.

Long term intravenous (IV) dosing continues to be critical in non-clinical development of many drugs (e.g., anti-cancer agents, large molecules), or pharmaceuticals that cannot achieve high systemic exposure by other routes. The IV route is commonly used in Sprague-dawley rats and the most common injection site is the tail vein. Although daily tail vein injection is normally feasible in acute and sub-acute studies (1, 7 or 14-day duration), sub-chronic and chronic studies (28-days, ≥ 3-months duration), once, twice and even multiple daily administration may be technically challenging and require additional animals at each dose level to assure an adequate number of animals to complete the study. Vehicle selection can also influence the success of long term daily or multiple daily tail vein injections and the use of the vena cava allows for a greater pool of blood to minimize secondary effects caused by non-ideal formulations. In alignment with the 3Rs (Reduction, replacement, refinement), our laboratory has demonstrated that daily intravenous injection via the femoral vein in the rat and external access port was feasible over a period of up to 3 months, which helped minimizing the number of animals per dose level to the minimum required by regulations. A medical grade polyurethane-based catheter was surgically implanted in the vena cava via the femoral vein and connected to a Quick-connect harness with a Luer Valve. A heparin-based locking solution was used to fill the catheter and the injection cap. Sodium chloride for injection (0.9% Saline) was injected daily for up to 3 months via the injection cap, at a dose volume of 5 mL/kg. The experimental procedures were well-tolerated and no adverse effects were observed in clinical signs, body weight, and clinical pathology. Histopathological tissue changes were comparable to findings in catheterized animals. The IV bolus injection via the femoral vein and an external access port was shown to be a suitable alternative to tail vein injection for rat sub-chronic and chronic studies.

**PS 757 Noninvasive Airway Resistance Measurements in Large Animals by High-Frequency Airwave Oscillometry.**

T. F. Schuessler<sup>1</sup>, A. Robichaud<sup>1</sup>, R. Forster<sup>2</sup>, M. Pouliot<sup>2</sup>, A. Asch<sup>2</sup>, E. Troncy<sup>3</sup> and S. Authier<sup>2,3</sup>. <sup>1</sup>SCIREQ Scientific Respiratory Equipments, Montréal, QC, Canada; <sup>2</sup>CiToxLAB North America, Laval, QC, Canada; <sup>3</sup>Faculty of Veterinary Medicine, University of Montréal, St-Hyacinthe, QC, Canada.

Large animals are generally more sensitive than rodents to drug induced respiratory changes. Methodologies to measure airway resistance in large animals normally require an esophageal pressure probe placed under anesthesia or a surgically implanted pleural pressure catheter. Both approaches could alter experimental endpoints in toxicology studies, which limit their use in drug development. A

non-invasive methodology to measure airway resistance by high frequency airway oscillometry was evaluated in conscious Beagle dogs and cynomolgus monkeys. A forced oscillation system was used to assess airway resistance and obtain conventional respiratory parameters (tidal volume, respiratory rate) before and after an intravenous treatment with a bronchoactive agent. Respiratory mechanics measurements were performed using 16 second long single (19 Hz) or composite (6, 10, 14, 19, 26 and 31 Hz) high frequency waveforms, which were applied at each time point at the subject's airway opening via a face mask. During measurements, pressure and flow signals were recorded. After collection of baseline measurements, methacholine was administered to Beagle dogs (n=4) and cynomolgus monkeys (n=4) at 8 and 68 mcg/kg, respectively. A peak increase in airway resistance (+64% in Beagle dogs and +30% in cynomolgus monkeys) was observed after intravenous methacholine administration in both species with return to baseline comparable levels within 10 min. Airway resistance data analysis for individual animals revealed mean percent variations from baseline ranging from 9.5 to 18.6% for dogs and from 4.4% to 6.9% for cynomolgus monkeys, suggesting stable and reproducible assessment of lung function. Airway oscillometry appears to be suitable for non-invasive respiratory mechanics measurements in large animal toxicology studies.

**PS 758 Seizure Liability Models: Seizure Characterization and Automated Detection in Telemetered Nonhuman Primates.**

S. Authier<sup>1,2</sup>, S. Maghezzi<sup>1</sup>, M. Pouliot<sup>1</sup>, S. Bernasconi<sup>3</sup>, T. de Geyer d'Orth<sup>3</sup>, P. Zitoun<sup>3</sup> and R. Forster<sup>1</sup>. <sup>1</sup>CiToxLAB North America, Laval, QC, Canada; <sup>2</sup>Faculty of Veterinary Medicine, University of Montréal, St-Hyacinthe, QC, Canada; <sup>3</sup>NOTOCORD, Croissy-sur-Seine, France.

Seizure liability studies in non human primates generally aim to: 1) confirm drug-induced seizures are self-limiting, 2) determine plasma level at seizure onset 3) identify prodromal clinical signs which can be monitored in clinical trials 4) confirm that conventional drugs (e.g. diazepam) can treat drug-induced seizure and 5) confirm the no observed adverse effect level (NOAEL) by absence of paroxysmal activity. To achieve these goals, typical study designs include video-EEG monitoring. Continuous telemetry monitoring generates a considerable amount of data which translates into lengthy analysis when solely relying on manual EEG review. A new application for seizure detection was developed in non-human primates (NHP). The prototype evaluates temporal and spectral features and compares them to features extracted from a sliding reference window. Detected seizures are validated based on a decision tree and artifact rejection algorithms. The automated prototype was used to evaluate periods of up to 68h of continuous EEG data and all detections were subject to a visual review. All animals presented at least one epileptic event. A detection sensitivity of 86.4% with 2.3 false positives per hour of signal was achieved using the default parameters of the prototype. Detection sensitivity increases to 100% when selecting optimal settings for each individual. The processing time was approximately 5 minutes for a 24h EEG telemetry signal. These promising results reflect progress in an era computerized data analysis. Further improvements are investigated to maintain a detection sensitivity of 100% essential with the model, while keeping the number of false detections low to increase data analysis efficiency.

**PS 759 Comparing Data Obtained by Refined Restraint Methods to Traditional Methods in Nonhuman Primate Studies.**

N. Lalayeva<sup>1</sup>, N. Bailey<sup>1</sup>, J. Kenfield<sup>1</sup>, N. Makori<sup>1</sup>, P. Franklin<sup>1</sup>, T. Beck<sup>1</sup> and R. Nagata<sup>2</sup>. <sup>1</sup>Safety Assessment, SNBL USA, Ltd., Everett, WA; <sup>2</sup>Corporate, Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.

As nonhuman primates continue to be an important model in nonclinical toxicology/pharmacology studies, improving methods of animal handling during procedures is essential. The aim of this study is to present historical background data collected using a refinement in the restraint technique, the Procedure Cage (PC). Use of the PC has the potential to contribute to minimizing inter- and intra-animal data variability when compared to data collected using other restraint methods (e.g. Restraint Chair [RC]). Historical control pregnancy loss ratio of 16.3% (range 0–31.3%) obtained using the PC is relatively low when compared to published data (17.8%, Hendrie et al. 1996, Am J Primat 40:41; and 29.6%, Wehner et al. 2009, BDR [B] 86:144). Restraint-associated stress can also influence values of hemodynamic and cardiovascular measurements. In a telemetry study comparing cardiovascular parameters for restraint in the Restraint Chair (RC) vs. Procedure Cage (PC), six telemetry implanted animals were monitored and data analyzed for heart rate (HR) and mean arterial blood pressure (BP) using a validated Notocord Telemetry System. In a series of procedures performed, HR for RC animals was on average 1.2 times (range 147–198 bpm) that of PC animals (range 139–167 bpm). BP for RC animals was on average 1.1 times (range 102–109) that of PC animals (range 90–96). The RC animals returned to baseline HR and BP levels only 22 and 33% of the time, beginning at 15 and 30 min post procedure, respectively. In contrast, the

PC animals returned to baseline HR and BP levels 50 and 91% of the time beginning at 5 and 10 min post procedure, respectively. In summary, it is evident that use of the PC method has potential to contribute to obtaining more robust data and, thus, could eventually lead to use of fewer animals on study.

**PS 760 Comparative Analysis of Noninvasive Blood Pressure Data by High-Definition Oscillometry (HDO) in Cynomolgus Monkeys of Mauritian and Asian Origin.**

B. Niggemann and U. Zuehlke. Covance Laboratories GmbH, Muenster, Germany. Sponsor: G. Weinbauer.

Cardiovascular investigations - among other diagnostic parameters - are essential for the detection and interpretation of untoward findings in preclinical studies. As cardiovascular toxicity in general and blood pressure determination in particular is concerned with adverse effects of xenobiotics on the circulatory system, a representative analysis of non-invasive blood pressure data is mandatory for the right interpretation of apparent circulatory findings.

Cynomolgus monkeys are frequently used in toxicity studies and animals from various sources such as Mauritius and Asia are available from acknowledged breeders. The aim of the present work was to compare non-invasive blood pressure data from group housed, untreated and unsedated cynomolgus monkeys of Mauritian and Asian origin.

Individual data from 150 Mauritian and 92/128 Asian male and female animals, each were analysed for systolic, diastolic and mean arterial blood pressure.

Blood pressure data of male and female animals of either origin showed slight but significant differences ( $P \leq 0.05$  to  $P \leq 0.001$ ) and values for males were higher than for female animals. Comparison of blood pressure data from monkeys of Mauritian and Asian origin revealed that systolic pressure (+9.0 % M; +10.4 % F), diastolic pressure (+12.0 % M; +14.1 % F) and mean arterial pressure (+10.1 % M; +11.7 % F) were significantly ( $P \leq 0.01$  and  $P \leq 0.001$ ) elevated in monkeys from Mauritius when compared to monkeys from Asia.

**PS 761 Procedure Refinement and Reduced Restraint Enables Extended 6-Hour-Daily Inhalation Dosing in Beagle Dogs.**

A. Dumais<sup>1</sup>, M. Stoute<sup>1</sup>, R. Tavcar<sup>1</sup> and R. Forster<sup>2</sup>. <sup>1</sup>CiToxLAB North America, Laval, QC, Canada; <sup>2</sup>CiToxLAB France, Evreux, France.

Extended duration of dosing for preclinical assessment of inhaled pharmaceuticals is considered advantageous when testing products of expected low toxicity. Technical limitations have often determined the maximum time of exposure in non-rodents such as Beagle dogs. Increased exposure time can improve the chances and accuracy of determining the maximum tolerated dose rather than being limited to a maximum feasible dose. A study was undertaken to confirm whether reduced restraint (platform) combined with procedural refinements would enable routine 4 hr daily dosing (5 days) and even 6 hr daily dosing (3 days). Prior to delivery from the supplier, a number of dogs were presented to platform restraint and inhalation facemask for up to 15 min and those demonstrating acceptance were selected. Following receipt, the four dogs were gradually acclimated for increasing periods of time (up to 4 hrs) to the inhalation equipment over 13 consecutive days. During the acclimation period, the dogs were monitored for behavior changes (excessive salivation, trembling, vocalization, struggling and increases in respiratory rate). Reinforcement through positive behavior by voice and minimal animal contact during the sham dosing where emphasized. Verbal rewards, petting and treats were provided after completion of each session. All animals underwent the 4 hr daily sham dosing except one female for which the sham dosing had to be interrupted on Days 2 to 4. The 6 hr sham dosing was initiated and successfully conducted using the remaining 3 dogs. There were no changes in clinical signs, body weights or food consumption throughout the study. In conclusion, extended daily inhalation dosing in Beagle dogs is made possible by combining animal screening at the supplier, extensive acclimation, positive behavior re-enforcement and reduced restraint. This enables to more accurately determine the NOEL and improve the determination of a MTD while improving animal welfare by reducing the level of restraint and stress.

**PS 762 Reducing Blood Volume for Hematology and Clinical Chemistry Analysis in Mice.**

A. Prefontaine, C. Copeman, L. Huard, D. Lourdel, K. Petitclerc and F. Poirout. Charles River, Montréal, QC, Canada. Sponsor: M. Vézina.

Blood volume limitations are a challenge with mice when used as a preclinical model. Cohorts of mice are often needed, sampled terminally to meet requirements. This is a sub-optimal use of animals and implies more animals, test materials, technical personnel and costs. To permit interim sampling and reduce blood

volume for hematology and clinical chemistry, we investigated dilution of small blood volumes collected by jugular venipuncture. Whole blood (300 uL instead of 1.2 mL) collected from 46 mice was split; 150uL for hematology and 150 uL for clinical chemistry. For hematology, 2 blood and 2 reticulocyte smears were prepared prior to diluting 100 uL of blood with 200 uL of ADVIA sheath rinse solution®. The 1:3 dilution was analyzed on the ADVIA 120 hematology analyzer (Siemens). All flagged values were verified by microscopic blood smear evaluation. Serial blood dilutions yielded adequate precision up to 1:5 dilution. For clinical chemistry, 40 to 50 uL of serum was diluted 1:3 in saline. Samples were analyzed on the Modular Analytics biochemistry analyzer (Roche) with exception of electrolytes. Serial dilutions of all chemistry parameters evaluated had previously demonstrated acceptable precision up to 1:5 dilution in saline. Jugular vein versus abdominal aorta sample results, were compared using historical ranges. Twelve of 46 (hematology) and 8 of 46 (clinical chemistry) samples were inadequate for analysis, similar incidence to abdominal aorta sampling. Jugular vein samples had slightly higher RBC and platelet counts, while clinical chemistry parameters were comparable except for slight elevations in aspartate aminotransferase. These dilutions necessitated more technical sample processing, but allowed clinical pathology analysis with only 300 uL of blood (ie. 4X reduction), presenting clear advantages, including interim study sampling, reduction in animals, combination of endpoints for in a given mouse, improving correlations and interpretation.

**S 763 Human Health and Environmental Concerns around Natural Gas Production Using Hydraulic Fracturing.**

*Z. Naufal. Chevron Energy Technology Company, Houston, TX.*

Natural gas production from shale rock formations using hydraulic fracturing has expanded greatly over the last decade across the United States and other parts of the world. The expansion came as a result of advances in horizontal drilling technology which helped unlock large natural gas supplies in shale and other tight rock formations across the country. Calls to reduce greenhouse gas emissions, the high cost of energy, and other economic pressures also contributed to the rapid growth of shale gas drilling using hydraulic fracturing. As a result, natural gas production is the highest it has been in the United States in decades. However, with the expansion of hydraulic fracturing into rural communities and areas traditionally not familiar with oil and gas explorations, questions about public health and environmental impacts have been raised by some residents living in proximity to fracturing operations. Data gaps may exist since the growth of fracturing operations has outpaced the research efforts conducted by the broad scientific community around this issue. In general, recent research activities have focused on understanding the potential impacts of the chemical components of the fluids used to fracture rock formations. Other issues raised by the public include the increase in noise, air, and light pollution in hydraulic fracturing areas and the potential for accidental contamination of air or groundwater. This session will provide an overview of the current and projected extent of the use of hydraulic fracturing to meet energy needs, and a discussion of the questions surrounding the public health and environmental impacts of this technology.

**S 764 Current Status of Tight Oil and Gas Development Using Hydraulic Fracturing.**

*J. Imse. ENVIRON International Corporation, Denver, CO. Sponsor: Z. Naufal.*

The industry is rapidly evolving - as a result of the variations in world pricing, and greater public and regulatory scrutiny. The practices of only a few years ago have been replaced in this changing industry. As a result, there has been increasing scrutiny into the process of hydraulic fracturing and how current practices may result in potential exposure pathways that may pose risks to human health. Chemical additives used in this process - the disclosure of those chemicals is now required in states representing approximately 90% of the US production - have evolved at a rapid pace and have evolved from hazardous constituents to food grade substances. Furthermore, additives once viewed as benign (sand) are now receiving greater scrutiny when evaluated in a safety context - e.g. silica (sand). Monitoring and exposure evaluations implemented at sites where hydraulic fracturing occurs will need to evolve rapidly to match the evolving additives in use. Similarly, studies with an objective of evaluating historical exposures will require a major study component focused on determining the actual additives used and the concentrations used at each site.

**S 765 An Assessment of Exposure Pathways and Potential Impacts to Human Health Associated with Shale Gas Drilling and Production Operations.**

*A. Harris. ENVIRON International Corporation, Little Rock, AR.*

Shale gas drilling operations continue to expand in the US, leading to increasing focus on identifying and understanding potential impacts to human health. The primary concern is the potential contamination of air and groundwater in communities located near shale gas drilling sites. Air quality may be affected from drilling and fracturing activities as well as emissions from vehicles and equipment. Air quality studies have been conducted both at drilling sites and near community receptors. VOCs, when detected, have been at concentrations below health-based benchmarks. Multiple studies have also been conducted to evaluate potential impacts to groundwater by additives of fracturing fluid, petroleum constituents and methane. Migration of fracture fluids to groundwater aquifers have been proposed although there is currently little data indicating that groundwater has been impacted by fracture fluids. Other exposure pathways of concern include leaks or spills of undiluted additives to surface water and inadequate containment of flowback and produced wastewater.

**S 766 The Potential Toxicological Impacts of Shale Gas Drilling: An Overview.**

*B. Goldstein and J. Kriesky. University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA.*

The pace of development of hydraulic fracturing technology to extract natural gas from shale formations has outstripped that of the research necessary to ensure that we maximize the benefits and minimize the risk of this important activity. Issues of particular toxicological concern include the potential impact of the evolving list of chemical and physical agents which are used in hydrofracturing. Concerns also extend to upstream processes, such as the mining of silica and the delivery of chemical and physical agents to the site; the on-site drilling, hydrofracturing and long term extraction processes, including contamination of groundwater, and emissions and noise from diesel compressors; and downstream activities such as the distribution of the hydrocarbon products and the safe disposal of the literally millions of gallons of fluid that comes up from underground containing such agents as brine components, arsenic and radioactive agents. Of particular toxicological importance is the potential adverse consequences of the mixtures of hydrofracturing agents, hydrocarbons and natural agents brought to the surface. Air pollution also has been documented and there is concern about the nearby impacts of the release of hydrofracturing agents and volatile hydrocarbons, as well as regional ozone issues. The longer term legacy of site specific pollution is also an issue.

**S 767 Community Exposure and Risk Near Natural Gas Production Sites: Impacts and Research Needs.**

*J. Adgate. Colorado School of Public Health, University of Colorado, Aurora, CO. Sponsor: A. Harris.*

The current boom in domestic natural gas production has focused national attention on the environmental and health impacts of this process. Increased development of unconventional natural gas resources (i.e., from shales, coal beds and tight sands) using hydraulic fracturing ("fracking") has raised concerns about impacts on environmental quality and human health, especially as development has moved into populated areas. While public concerns tend to focus on potential water contamination, the well development process also results in emissions of multiple air toxics when injected water "flows back" to the surface with the natural gas, accompanying petroleum condensate and fracking chemicals. Studies in Colorado and elsewhere indicate that multiple air toxics and chemicals used in well production activities are emitted from gas development and production sites. Research on non-occupational exposure indicates that air pollution is a major concern because health-based risk estimates for nearby residents are greater than for individuals living further from well development sites. Human exposures and risks vary with proximity to wells, specific activities at well pads, topography/meteorology, and individual operator practices and controls. This talk explores our current understanding of exposure and health risks around well development sites, identifies major information gaps and uncertainties, and outlines research that will improve our understanding of the health risks associated with natural gas development.

## **S** 768 **Air Quality Impacts of Natural Gas Operations in Texas.**

M. Honeycutt, S. Ethridge and T. Bredfeldt. *Texas Commission on Environmental Quality, Toxicology Division, Austin, TX.*

Texas is home to the Barnett Shale, a shale-containing geological formation in a highly-populated area which is currently being actively drilled using hydraulic fracturing. The Texas Commission on Environmental Quality (TCEQ) is charged with regulating sources of air emissions from natural gas operations and has spent considerable resources examining emissions from these sources. The TCEQ has utilized flyovers of helicopters outfitted with infra-red (IR) cameras capable of visualizing volatile organic compound (VOC) emissions, conducted numerous mobile monitoring trips, and has installed an extensive ambient air fixed-site monitoring system in areas with intensive drilling. Between August 1, 2009, and June 30, 2012, the TCEQ has surveyed 2,307 sites in the Barnett Shale area using hand-held IR cameras, and at 2,263 of these sites, hand-held survey instruments were also used. These surveys included citizen complaint investigations, compliance investigations, mobile monitoring trips, and follow-up investigations based on helicopter flyovers. As a result of observations with the hand-held IR camera and measurements collected using the survey instruments, 1,167 short-term field canister samples have been collected and analyzed for VOCs. Less than 5% of VOC canister samples measured short-term levels of concern. Short-term samples have also been collected and analyzed for carbonyls, NO<sub>x</sub>, and sulfur compounds and none of the analyses have measured chemicals at short-term levels of concern. Six stationary VOC monitors were operational in the Barnett Shale area in 2009, thirteen are operational now. No VOCs have been detected to date at levels of long-term health concern.

## **S** 769 **Role of Metabolic Syndrome and Perivascular Adipose in Exposure-Induced Vascular Dysfunction.**

D. J. Conklin<sup>1</sup> and M. J. Campen<sup>2</sup>. <sup>1</sup>*Cardiovascular Medicine, University of Louisville, Louisville, KY;* <sup>2</sup>*Department of Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.*

Recent epidemiological studies indicate that ambient air pollution enhances the progression from metabolic syndrome to diabetes but not by increasing obesity. Because vascular dysfunction and vascular insulin resistance are two early events associated with metabolic syndrome and air pollution exposure, the mechanisms by which these alterations occur in the vasculature could be informative of changes in overall cardiovascular disease risk. Similarly and increasingly, there is a growing recognition that the perivascular adipose tissue (PVAT) is an important regulator of vascular tone under normal homeostatic conditions and PVAT is altered during disease states, including metabolic syndrome and diabetes. The perivascular adipose tissue structure and function are changed to a proinflammatory state both by disease, angiotensin II, and by exposure to environmental pollutants, implicating these alterations in subsequent endothelial and vascular dysfunction. This symposium will provide both an introduction to the role of perivascular adipose tissue in health and metabolic disease states and draw on evidence from environmental and experimental model studies to emphasize specific alterations in perivascular adipose tissue and how these changes contribute to subsequent vascular dysfunction and potentially increase the risk of cardiovascular disease.

## **S** 770 **Turning Vascular Disease Inside Out: Role of Perivascular Adipose Tissue in Coronary Artery Disease.**

N. Weintraub. *Division of Cardiovascular Diseases, University of Cincinnati, Cincinnati, OH.* Sponsor: D. Conklin.

Adipose tissue surrounding the great vessels [perivascular (PV) adipose tissue, or PVAT] expands during obesity and correlates with the extent of visceral fat and insulin resistance in humans. Moreover, both the amount of PVAT and the degree of PVAT inflammation correlate with the presence of atherosclerotic coronary artery disease. Studies in isolated perivascular adipocytes indicate that the cells display a reduced state of adipogenic differentiation, and enhanced pro-inflammatory cytokine expression, as compared with subcutaneous and visceral adipocytes. In response to just two weeks of high fat feeding in mice, adipogenic gene expression is markedly reduced, while pro-inflammatory cytokine expression is up-regulated, in PVAT. Using a novel model of PVAT transplantation to the mouse carotid artery in the setting of high fat feeding, we demonstrate that PVAT enhances atherosclerosis and wire injury-induced neointimal hyperplasia, triggering inflammatory cell infiltration and proliferation of vasa vasorum. Our data suggest that PVAT plays a pathogenic role in vascular disease, linking metabolic signals to inflammation and angiogenesis of the blood vessel wall.

## **S** 771 **Perivascular Adipose and Vascular Dysfunction in Mice after Combined High-Fat Diet and Concentrated Ambient Particulate Matter Exposure.**

D. J. Conklin and P. Haberzettl. *Cardiovascular Medicine, University of Louisville, Louisville, KY.*

Exposure to inhaled fine particulate matter induces endothelial dysfunction and increases the risk of cardiometabolic disease, insulin resistance and the risk of diabetes, however, the mechanisms by which PM<sub>2.5</sub> enhances this risk are unclear. Because diabetes and air pollution are worldwide health problems, we examined whether high fat diet (HFD) enhanced concentrated ambient particulate matter (CAP)-induced EPC suppression and insulin resistance to ascertain the relationship between these important changes. Mice (male; C57BL/6) maintained on low fat (LFD, 10% kcal fat) or high fat (HFD, 60% kcal fat) were exposed to HEPA-filtered air or urban Louisville CAP (80-100 µg/m<sup>3</sup>) for 9 or 30 consecutive days (6h/d). CAP exposure or HFD prevented insulin-induced Akt and eNOS phosphorylation in isolated aorta, and aortic contractility was progressively dysfunctional under CAP, HFD and combined HFD+CAP treatments. Moreover, only combined HFD+CAP treatment increased glucose intolerance without increasing obesity, and thus, worsened the metabolic syndrome and progression toward diabetes. These data implicate alterations in vascular structure such as increased perivascular adipose in the combined effects of HFD+CAP on vascular dysfunction and insulin resistance.

## **S** 772 **NADPH Oxidase and Perivascular Superoxide Production with Particulate Matter Exposure.**

Q. Sun. *Environmental Health Sciences, The Ohio State University, Columbus, OH.*

Reactive oxygen species from oxidant-releasing enzymes such as NAD(P)H oxidase are known to play a causal role in certain disease development, and air pollutants, such as PM<sub>2.5</sub>, are known to cause vascular dysfunction in major cardiovascular diseases. To evaluate the role of exposure to airborne fine particulate matter (diameter, <2.5 µm, PM<sub>2.5</sub>) pollution on metabolic parameters, inflammation, and adiposity, PM<sub>2.5</sub> inhalation exposure was performed in C57BL/6 mice and mice deficient in the cytosolic subunit of the nicotinamide adenine dinucleotide phosphate (NADPH) oxidase p47phox (p47phox<sup>-/-</sup>) with normal or high fat diet. We found that PM<sub>2.5</sub>-exposed C57BL/6 mice exhibited metabolic abnormalities consistent with insulin resistance. Ex vivo-labeled and infused monocytes demonstrated increased adherence in the microcirculation of normal diet- or high-fat diet-fed PM<sub>2.5</sub>-exposed mice. p47phox<sup>-/-</sup> mice exhibited an improvement in parameters of insulin resistance, vascular function, and visceral inflammation in response to PM<sub>2.5</sub>. We concluded that exposure to high levels of PM<sub>2.5</sub> is a risk factor for subsequent development of insulin resistance, adiposity, and inflammation, and reactive oxygen species generation by NADPH oxidase appears to mediate this risk. Other NAD(P)H oxidase subunits and their roles in PM<sub>2.5</sub> exposure-induced cardiovascular diseases will also be summarized.

## **S** 773 **Role of Perivascular Adipose in Regulation of Vascular Function by the Aryl Hydrocarbon Receptor.**

M. K. Walker. *Department of Pharmaceutical Sciences, University of New Mexico, Albuquerque, NM.*

The aryl hydrocarbon receptor (AHR) has been demonstrated to be required for normal blood pressure regulation as demonstrated by the hypotensive phenotype in the global AHR knockout mouse. Notably, conditional deletion of the AHR solely from endothelial cells results in a nearly identical blood pressure phenotype as observed in the global knockout. Thus, we hypothesized that AHR plays a critical role in the vascular regulation of blood pressure. We generated ECahr<sup>-/-</sup> mice by crossing AHR floxed mice (ahr<sup>flx/flx</sup>) to mice expressing Cre recombinase driven by an EC-specific promoter. BP was assessed by radiotelemetry prior to and following an acute injection of the potent vasoconstrictor, angiotensin (Ang) II, or chronic treatment with an inhibitor of Ang II formation, Ang converting enzyme inhibitor (ACEi). ECahr<sup>-/-</sup> mice exhibited significantly different responses to Ang II and ACEi. While Ang II increased BP in both genotypes, the increase was sustained in ECahr<sup>+/+</sup>, whereas the increase in ECahr<sup>-/-</sup> mice steadily declined. Area under the curve (AUC) analysis showed that Ang II-induced increase in diastolic BP (DBP) over 30 min was significantly lower in ECahr<sup>-/-</sup> mice (AUC: ECahr<sup>+/+</sup> 1297±223 mmHg/30 min; ECahr<sup>-/-</sup> 504±138 mmHg/30 min, p<0.05). In contrast, while ACEi decreased BP in both genotypes, the subsequent rise in DBP after treatment was significantly delayed in the ECahr<sup>-/-</sup> mice. ECahr<sup>-/-</sup> mice also exhibited reduced vascular and adipose Ang II type 1 receptor (AT1R) expression, and reduced aortic Ang II-dependent vasoconstriction in the presence of vascular

adipose. Taken together these data suggest that hypotension in ECahr-/- mice results from reduced vascular responsiveness to Ang II that is influenced by AT1R expression and perivascular adipose.

## **S** 774 **Role of Perivascular Adipose Tissue in Angiotensin II-Induced Vascular Diseases.**

L. A. Cassis. *Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY.* Sponsor: D. Conklin.

Adipocytes express all components of the renin-angiotensin system necessary to synthesize and respond to angiotensin II (AngII). We have previously demonstrated that infusion of AngII to hyperlipidemic male mice augments atherosclerosis and causes the formation of abdominal aortic aneurysms (AAAs). Mechanisms for AngII-induced AAAs include inflammation that extends to perivascular adipose tissue surrounding the abdominal aorta. Inflammation in perivascular adipose tissue was augmented by genetic or diet-induced obesity, and resulted in marked increases in susceptibility to AngII-induced AAAs. Moreover, weight loss in previously obese mice resulted in remodeling of AAAs. Vascular changes in mice experiencing weight loss included reduced adventitial neovascularization, with alterations in stem cell populations in perivascular adipose tissue. Current studies are examining effects of deficiency of components of the renin-angiotensin system in adipocytes on AngII-induced vascular diseases.

## **W** 775 **Environmental Factors in Neurodegenerative Diseases.**

E. Tiffany-Castiglioni<sup>1</sup> and A. G. Kanthasamy<sup>2</sup>. <sup>1</sup>*Veterinary Integrative Biosciences, Texas A&M University, College Station, TX;* <sup>2</sup>*Biomedical Sciences, Iowa State University, Ames, IA.*

Exposures to environmental pollutants are implicated in the development of neurodegenerative diseases and protein conformational diseases, including Parkinson's Disease (PD) and Alzheimer's Disease (AD). The purpose of this workshop is to bring together experts to discuss etiologic factors associated with PD and AD, particularly environmental pesticides, heavy metals, and other pollutants, and to discuss new directions for identifying suitable targets for therapeutic strategies. Two very promising lines of investigation into the mechanisms of dopaminergic cell death in PD will be discussed, as well as the interaction of senescence-related, genetic, and environmental factors likely contributes to the etiology of late-onset neurodegenerative diseases such as PD and AD. The interactions of heavy metals with chaperone proteins that regulate protein folding and cell death as related to protein conformational diseases will also be discussed. The workshop will address six questions: 1) Despite equivocal results, why are genetic factors still considered the primary etiologic factor in late-onset neurodegenerative disease?; 2) How can existing models of neuronal cell death in neurodegenerative diseases be integrated?; 3) How can cell culture models be integrated into a better understanding neurodegenerative disease processes?; 4) Are there common pathways or mechanisms that are relevant to environmental exposures in protein folding diseases, including PD and AD?; 5) How do chemicals in a similar class of compounds elicit very different effects on the neurodegenerative processes?; 6) What is the evidence that early exposures to environmental factors predispose to neurodegenerative diseases?

## **W** 776 **ER Chaperone-Metal Interactions: Links to Protein Folding Disorders.**

E. Tiffany-Castiglioni and Y. Qian. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

Chaperones in the endoplasmic reticulum play vital roles in the folding, assembly, and post-translational modification of secretory proteins and also recycle, refold, or initiate degradation of misfolded proteins. Chaperone deficiencies are implicated in protein folding disorders of the CNS. We present evidence that the master chaperone 78 kD glucose regulated protein (GRP78) becomes pathologic through deleterious interactions with Pb and Cu. The key points of this presentation are that metals, including Cu and Pb, are implicated in the etiology of protein folding disorders, Cu and Pb induce the expression GRP78, Cu and Pb bind to GRP78, and metals impair GRP78 function when they bind to GRP78. Recent data from our lab demonstrate that GRP78 is involved in Cu homeostasis in primary astrocyte and C6 rat glioma cultures. Astrocytes cultured in medium containing 0.3 micromolar Cu accumulated Cu and expressed increased levels of GRP78 but not metallothionein (MT1/2). Cu isotope radiography and Cu affinity column analysis with cytosolic fractions of C6 cells showed that GRP78 bound to Cu. However, the level of GRP78 expression was not proportional to Cu accumulation in astrocytes and C6

cells: astrocytes expressed low protein levels of GRP78 compared to C6 cells but accumulated significantly more Cu. Furthermore, GRP78 depletion by RNA interference increased Cu accumulation by C6 cells. Whereas our findings implicated GRP78 in Cu homeostasis but not storage, we examined the possibility that GRP78 affected Cu accumulation through its role as a protein chaperone. We found that antibody to the Cu-extrusion pump Atp7a precipitated GRP78, but antibody to GRP78 did not precipitate Atp7a. We postulate that GRP78 may chaperone Atp7a as a client protein in cytosolic trafficking for the removal of Cu from the cell. Specific questions to be addressed include: Are there common pathways or mechanisms that are relevant to environmental exposures in protein folding disorders? How can cell culture models be integrated into a better understanding of neurodegenerative disease processes?

## **W** 777 **Novel Oxidative Cell-Death Signaling in Neurotoxicity Models of Parkinson's Disease.**

A. G. Kanthasamy. *Department of Biomedical Sciences, Iowa State University, Ames, IA.*

Although oxidative stress and apoptosis are known to be important in the degenerative process in dopaminergic neurons in PD, the apoptotic signaling mechanisms downstream of caspase-3 that contribute to the degeneration of dopaminergic neurons are poorly understood. We have identified that protein kinase C-delta (PKCδ), a member of the novel PKC isoform family, is highly expressed in nigral dopaminergic neurons, and that the kinase is persistently activated via a novel mechanism by which caspase-3 proteolytically cleaves to permanently dissociate the catalytic subunit from the regulatory subunit of PKCδ. We demonstrated that PKCδ proteolytic activation contributes to apoptotic cell death of dopaminergic neurons during oxidative damage induced by Parkinsonian toxicants such as 6-OHDA, MPTP and other dopaminergic neurotoxins. We also unexpectedly identified that protein kinase D1 (PKD1) is activated by a PKCδ dependent mechanism to protect dopaminergic neurons from the early stages of neurotoxic insult. The current status of our systematic characterization of PKCδ-PKD1 oxidative signaling in nigral degenerative processes using cell culture and animal models of PD as well as human postmortem PD brains will be presented. Potential therapeutic strategies targeting the signaling pathway will be discussed. The proposed PKCδ-PKD1 signaling will provide comprehensive information about signaling pathways associated with protective responses at the early stages of neurotoxicant-induced oxidative stress, as well as the cell signaling mechanisms that override them during prolonged oxidative insult in nigral dopaminergic neurons. Specific questions to be addressed will include: How can existing models of dopaminergic cell death in PD be integrated in relation to PKCδ-PKD1 signaling? Are there common pathways or mechanisms that are relevant to environmental exposures in PD and other neurodegenerative diseases? What are major interplay/interactions between genetic and environmental risk factors associated with neurodegenerative diseases? (supported by NIH grants ES10586, NS 074443, ES19267).

## **W** 778 **Industrial Toxicants and Parkinson's Disease.**

G. W. Miller. *Environmental Health, Emory University, Atlanta, GA.*

The exposure of the human population to environmental contaminants is recognized as a significant contributing factor for the development of Parkinson's disease (PD) and other forms of parkinsonism. While pesticides have repeatedly been identified as risk factors for PD, these compounds represent only a subset of environmental toxicants that we are exposed to on a regular basis. Non-pesticide contaminants, such as metals, solvents, and other organohalogen compounds (polychlorinated biphenyls (PCBs), polybrominated diphenyl ethers, trichloroethylene), have also been implicated in the clinical and pathological manifestations of these movement disorders. Here we report a relationship between PCBs and PD pathology. Post-mortem brain samples from control and PD patients were obtained from the Emory University Brain Bank and from the Nun Study. Concentrations of eight prevalent PCB congeners were extracted from post-mortem brain tissue and analyzed using gas chromatography-mass spectrometry. PCB congeners 153 and 180 were significantly elevated in the brains of Parkinson's disease patients. When stratified by sex, the female Parkinson's disease group demonstrated significantly elevated concentrations of total PCBs and specifically congeners 138, 153, and 180 compared to controls, whereas PCB concentrations in males were not significantly different between control and Parkinson's disease groups. In a separate population of women (Nun Study) who had no clinical signs or symptoms of PD, elevated concentrations total PCB and congeners 138, 153 and 180 were also observed in post-mortem brain tissue exhibiting moderate nigral depigmentation compared to subjects with mild or no depigmentation. These quantitative data demonstrate an association between brain PCB levels and Parkinson's disease-related pathology. Recent evidence from cellular and animal studies suggests that PCBs may induce

pathology by disrupting the normal storage and release of dopamine and related neurotransmitters. Dr. Miller will also present novel high throughput approaches that will be used to further study this association. Supported by NIEHS P01ES016731.

## **W 779 Integrating Epidemiological and Basic Research to Assess the Role of Pesticide Exposure in Neurodegenerative Disease.**

**J. Richardson.** *Robert Wood Johnson Medical School, Piscataway, NJ.*

Although a significant amount of research effort and resources have been focused on determining genetic contributors to Parkinson's disease (PD) and Alzheimer's disease (AD), purely genetic contributions account for only a fraction of the cases. Our laboratory has been specifically interested in the potential role of pesticides in the etiology and pathogenesis of both PD and AD. Recently, we have found that serum levels of a long-lasting residue of the organochlorine pesticide hexachlorocyclohexane ( $\beta$ -HCH) was significantly higher in the serum of PD patients, while the DDT metabolite, p,p'DDE, was significantly higher in patients with AD. DDE levels were 3.8-fold higher in serum of AD patients ( $2.61 \pm 0.35$  ng/mg cholesterol;  $n = 86$ ) when compared to controls ( $0.69 \pm 0.10$  ng/mg cholesterol;  $n = 79$ ;  $p < 0.001$ ). After controlling for age, sex, education, race, and sample collection site, the OR for increased risk of AD in the highest tertile of DDE levels was 4.26 (95% CI: 3.41-5.32;  $p < 0.001$ ). To determine whether DDT exposure alters the expression of AD-related genes in vivo, male C57BL6 mice were dosed with 3 mg/kg DDT every 3 days for 30 days. DDT significantly increased the mRNA levels of APP (25%), NEP (77%), and ApoE (150%) in the hippocampus. These data suggest that DDT selectively alters the expression of AD-related genes in a brain-region specific manner with the hippocampus being more sensitive than the frontal cortex. Specific Questions to be addressed will include: Despite equivocal results, why are genetic factors still considered the primary etiological factor in late-onset neurodegenerative disease? Are there common pathways or mechanisms that are relevant to environmental exposures in both PD and AD? How do chemicals in a similar class of compounds elicit very different effects on the neurodegenerative processes?

## **W 780 Life-Course Models for Ensuring Children's Health Protection.**

**S. P. Darney<sup>1</sup> and E. M. Faustman<sup>2</sup>.** <sup>1</sup>ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>Environmental & Occupational Health Sciences, University of Washington, Seattle, WA.

New knowledge about environmental risks to human reproduction and development directly relevant to children's health protection derives from the fields of developmental and reproductive toxicology, exposure science, epidemiology, risk assessment, and public health. Together, this information highlights the importance of the intrauterine environment in setting the stage for lifelong health, along with the complexities of the physical, chemical, and social factors that operate during critical windows of development to impact health and wellbeing. For example, breakthroughs in genetic polymorphisms and epigenetics are extending our understanding of inherent and acquired susceptibility to effects of environmental contaminants and showing how various intrauterine stressors such as nutrition, toxicants, and social stress may alter developmental programming at the start and throughout life. These scientific advances point to the need for innovative cumulative risk assessment methods and public health intervention approaches in order to account for risks that accrue across the developmental continuum from cradle to cradle. This workshop brings together the interdisciplinary expertise needed to begin integrating new knowledge into life-course models for children's health and wellbeing. Topics include research findings from toxicity testing and epidemiology studies specific to critical windows of exposure during pre-conception, pregnancy, and early childhood life stages to stimulate discussion on the broad challenge of optimizing testing and risk assessment models and enabling analyses across the whole life course. The workshop also features an innovative approach for evaluating and communicating complex scientific information about reproductive risks and interventions to diverse audiences including health care providers, parents (present and future), and regulators.

## **W 781 Today's Challenge for Protecting Children's Environmental Health for a Lifetime.**

**E. M. Faustman.** *University of Washington, Seattle, WA.*

Evidence continues to build for the increasing importance of early life experiences in defining not only childhood development and normal health trajectories but also the potential for chronic disease risk throughout later life. Thus, a critical need for

protecting children's health is recognition that our models require a dynamic context, a lifecourse framework in order to address the key differences in developmental landmarks, functionality and the windows of susceptibility to environmental impact. Such a framework is also needed to provide the context for incorporation of the multitude of research findings across lifespan and discipline and to develop effective public health interventions. To set the stage for the workshop this talk will identify the emerging issues and most pressing questions for reproductive and developmental toxicologists, epidemiologists, and risk and health assessors in lifecourse study. Research from contemporary science, including community-based cohort studies, coupled with research to elucidate molecular toxicity pathways and genetic polymorphisms will be presented to illustrate these important lifestages. Critical questions and research will be discussed within the framework and will include: What does this research tell us about critical windows of exposure, susceptibility and impact across lifecourse? What sorts of statistical models are needed to account for multiple stressors over time? How can this new science be used to build a case for developing a lifecourse approach to risk assessment and children's health protection? How can research in this arena be informed by the parents who live in communities which are highly impacted by environmental stressors? Research by developmental and reproductive biologists, toxicologists, epidemiologists and exposure and risk scientists are required and hence determination of how this multidisciplinary science can be integrated within the lifecourse models is essential. Presentation of both evidence and modeling approaches will be the basis for describing the lifecourse framework for risk assessment.

## **W 782 Periconception Parental Metal Exposures, Couple Fecundity, and Child Health: Delineating the Chicken and Egg Question.**

**G. M. Buck Louis, R. Sundaram and J. Maisog.** *Division of Epidemiology, NICHD, Bethesda, MD.* Sponsor: **S. Darney.**

Growing evidence suggests that human fecundity and fertility may be informative about the subsequent health and well-being of couples' offspring. This avenue of study is in keeping with the early origin for health and disease hypothesis (DOHAD), and the need for a life course approach for assessing health across the lifespan. Early evidence suggests that gynecologic and urologic disorders may be associated with adverse pregnancy outcomes such as genital-urinary malformations or diabetes in affected children. Similarly, couples experiencing conception delays are reported to be at higher risk of delivering infants of diminished gestation and birth size, outcomes associated with developmental disabilities and other childhood morbidities. This evolving body of evidence underscores the importance of exposure assessments in both partners in keeping with the couple-dependent nature of human reproduction and development. For illustrative purposes, this talk utilizes data from the recently completed Longitudinal Investigation of Fertility and the Environment (LIFE) Study to demonstrate the relation between couples' exposures to persistent environmental chemicals (i.e., cadmium, lead and mercury) and fecundity as measured by time-to-pregnancy (in menstrual cycles), and infant health outcomes such as gestation and birth weight. Blood cadmium concentrations in female partners (range 0.02-2.87  $\mu\text{g/L}$ ) and blood lead in male partners (range 0.34, 6.91  $\mu\text{g/dL}$ ) were significantly associated with a longer time to pregnancy as measured by fecundity odds ratio (FORs) below one (FOR=0.78; 95% CI 0.63, 0.97 and FOR=0.85, 95% CI 0.73, 0.98, respectively). When jointly modeling both partners' metal exposures as a continuous exposure, female lead and male cadmium exposures were associated with reductions in gestation and birth weight. Further analysis is underway to determine if the reduction in gestation and birth weight is mediated indirectly through reduced couple fecundity or directly on fetal growth and development.

## **W 783 Prenatal Pesticide Exposures and Children's Neurodevelopment across the Life-Course Continuum—Lessons from the Fields.**

**B. Eskenazi, A. Bradman, K. Harley and N. Holland.** *Center for Environmental Research and Children's Health, University of California Berkeley, Berkeley, CA.* Sponsor: **S. Darney.**

A growing body of evidence suggests that prenatal pesticide exposure may be related to adverse effects on neurodevelopment of children. In 2000-2001, we initiated CHAMACOS (Center for the Health Assessment of Mothers and Children of Salinas), a longitudinal birth cohort study, with the primary aim to investigate the association of prenatal and postnatal exposure to agricultural chemicals and health and development of children. We enrolled 601 pregnant women into this community-based participatory research project. The participants were primarily low-income Latinas from the agricultural community in the Salinas Valley, Monterey,

California. We conducted detailed neurodevelopmental assessment of the CHAMACOS children at multiple time points and currently the children are reaching their 12th birthday. During these years, we have monitored their exposures to a number of chemicals including pesticides such as organophosphates, organochlorines and fungicides. We have also examined potential genetic susceptibility to exposure with analyses of the PON1 polymorphisms and enzyme activity and we are now beginning analyses of epigenetic endpoints. These studies highlight the advantages of longitudinal cohort studies for evaluating the long-term impact of prenatal and early life exposures on children's health and development. Results of the CHAMACOS study to date, coupled with those of other longitudinal studies demonstrate how in utero exposure to certain pesticides can impact neurodevelopment. Furthermore, our results suggest that certain children by virtue of their genetic make-up may be more susceptible. Lastly, we have identified limitations in assessing exposures to pesticides that challenge our ability to determine "causal" relationships. Primary funders: Children's Center grant from NIEHS, NIH and US EPA

## **W 784** New Strategies for Addressing Toxicity Testing across the Lifespan.

P. M. Foster. *National Toxicology Program (NTP), NIEHS, Research Triangle Park, NC.*

A previous NTP workshop evaluating the utility of the cancer bioassay for detecting hormonally-related cancers (particularly breast, prostate, ovary and testis), concluded that the standard approach, commencing exposure as young adults (~ 6 weeks of age) is likely missing important windows during early development that could be critical for cancer outcomes and therefore assessment of lifetime risk. NTP used the workshop results to adopt a new default for rat cancer bioassays to incorporate early life exposures into the assay. NTP had previously conducted perinatal bioassays, but required specific justification; now, such studies are conducted routinely, unless there is a scientific rationale not to do so. This study begins exposure at implantation and continues until the offspring reach 2 years of age. Embarking on a cancer study requires preliminary dose setting information. For a cancer bioassay, this is normally a 90 d study, but would now require exposure from implantation thru weaning prior to the 90d component to evaluate target organ toxicity. Such an approach, would also lend itself easily to evaluations of multiple other end points from the same exposure paradigm, including developmental neurotoxicity and immunotoxicity and, if one bred the F1 offspring at adulthood, both fertility/fecundity and pre-natal developmental toxicity (teratology) - the NTP modified one-generation study. Each of these end points could be considered interchangeable "cassettes" depending on the type of toxicity that NTP was required to assess. Compared to the individual, stand alone studies, this would have considerable savings in time, cost and animal usage, yet generate high quality developmental and reproductive toxicity information for risk assessment. This is a similar approach to the OECD extended one-generation study, but has several major advantages, most importantly is a significantly improved ability to detect potential effects on fertility and fecundity in the same animals on which structural changes are evaluated, together with a pre-breed exposure that is consistent with the length of rat spermatogenesis.

## **W 785** Advancing Risk Communication and Decision Tools for Children's Health Protection.

T. J. Woodruff and P. Sutton. *Program on Reproductive Health and the Environment, UCSF, San Francisco, CA.* Sponsor: S. Darney.

Parents and physicians who take care of them and their children read and hear a plethora of information, some contradictory, about environmental and chemical risks to children's health. Better tools are needed to evaluate and synthesize this information and translate it into meaningful prevention strategies for health professionals, the public and policy-makers. Methods to synthesize the science into evidence-based decisions have been developed and validated in clinical arenas. But because of differences in approaches, the evidence-base and decision-context of clinical health sciences methods are not seamlessly applicable to environmental exposures. To meet this need, UCSF's Program on Reproductive Health and the Environment undertook an interdisciplinary collaboration to craft a systematic and transparent methodology to evaluate environmental contaminants and their potential effects on reproductive and developmental health. The result is the Navigation Guide, the product of a yearlong collaboration of 22 clinical and environmental health scientists and/or practitioners, from governmental and non-governmental organizations in the U.S. and Europe. Government agencies can use the Navigation Guide methodology to craft evidence-based statements regarding the relationship

between an environmental exposure and health. Government agencies called on to make risk management decisions can also apply the Navigation Guide to grade the strength of recommendations for prevention. Professional societies, healthcare organizations, and other potential guideline developers working with toxicologists can use the Navigation Guide to craft consistent and timely recommendations to improve patient, and ultimately population, health outcomes. Development of the first case studies applying the Navigation Guide methodology is extremely timely as it coincides with growing recognition of the need for updated methods in risk assessment, and related calls for government agencies such as the U.S. Environmental Protection Agency to incorporate systematic approaches into decision-making.

## **W 786** Nanoinformatics: Computational Challenges for Nanomaterial Hazard Assessment.

K. M. Waters<sup>1</sup> and S. Harper<sup>2</sup>. <sup>1</sup>*Systems Toxicology, Pacific Northwest National Lab, Richland, WA;* <sup>2</sup>*Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR.*

Hazard evaluation of the growing number of nanomaterials can be expedited and enhanced through the identification of underlying quantitative relationships between their structural, chemical, and physical properties and responses in key biological systems. The Toxicity in the 21st century testing paradigm holds particular promise for nanoparticles because whole animal testing is not economically practical or feasible for every new material introduced to the marketplace. Important advancements have been made in this emerging but critical field, yet many challenges remain. Distillation of the large amount of phenotypic data regarding *in vitro* cytotoxicity and inflammation down to *in vivo*-relevant adverse events is a daunting task, given the vast differences in microenvironment, temporal dynamics, and exposure. The use of systems biology approaches will enable the identification of relevant target organs/cell types, the development of mechanism-based assays for hazard assessment and computational modeling for predicting potential toxicity from human relevant exposures. This session will address computational challenges in data standards, data integration, and modeling of dose response and structure-activity relationships, including talks by experts in the areas of informatics, *in vitro* screening, *in vivo* exposures and PB/PK modeling. Included is an opening by the co-chair of the US-EU Nanoinformatics Community of Research, which seeks to facilitate intercommunication between researchers, regulators, and granting agencies on environmental health and safety issues for manufactured nanomaterials. Speakers will include current experimental and computational approaches as well as future research needs to identify relevant *in vitro* assays that are predictive for nanomaterial hazard assessment based on *in vivo* mode of action and realistic human exposures.

## **W 787** US-EU Nanotechnology Databases and Ontology Community of Research.

N. A. Baker<sup>1</sup> and H. Rauscher<sup>2</sup>. <sup>1</sup>*Pacific Northwest National Laboratory, Richland, WA;* <sup>2</sup>*DG Joint Research Centre Unit Nanobiosciences/TP 202, European Commission, Ispra, Italy.* Sponsor: K. Waters.

This talk will provide an overview on the work of a new US-EU Nanotechnology Safety Community of Research (CoR) focused on nanotechnology databases and ontology with specific examples and highlights from our own research. CoRs are groups of people who share a significant interest in nano safety, work together to develop a shared repertoire of resources, and have regular contact to address key global research challenges. Interconnected information systems are urgently needed for collating nanoscale material descriptions; their intrinsic and context-dependent properties and their interactions; and their interactions with biological entities. One goal of the CoR is to enable the sharing, searching, and analysis of nanoscale material characterization data across a wide range of experimental sources and guide the structuring of these data to enable their widest possible use. Achievement of this goal will deliver important new capabilities to allow integration of risk assessment data among labs throughout the world, to provide situational awareness of data coverage across nanomaterial categories, and to enable predictive computational models for bridging physical properties and biological outcomes with exposure, dispersal and fate. In order to realize this goal, the CoR will initially focus on the following three areas of investigation: Identification of the data elements necessary to establish common data-sharing models for this domain; specification of requirements for sharing data between research groups and repositories in human- and machine-interpretable forms; definition of concepts necessary to support the above activities and representation of those concepts in an ontological framework. This will include descriptors for the material itself as well as for its interaction with the environment and elements to characterize intermediate effects in adverse outcome

pathways. Through these activities the CoR will provide tools for improving the overall quality of experimental data being generated in EU and US research communities.

**W 788 High-Throughput Screening of Nanomaterial Bioactivity/Toxicity: The Computational Side Is Just As Important As the Testing Assays and Characterization.**

A. Wang. *US EPA, Research Triangle Park, NC.*

High-throughput screening (HTS) of bioactivity/toxicity is currently the only cost-efficient and rapid tool to screen the numerous nanomaterials (NMs) in use and under development. In the EPA ToxCast program, diverse classes of NMs and their micro-particle and ionic salt counterparts are tested in HTS assays to help prioritize NMs for further targeted testing. While the measured HTS endpoints are the same as those tested for traditional soluble chemicals, specific challenges arise for NMs for both experimental procedures and computational analysis. Challenges include no standard nomenclature, comparison of potency between different classes of NMs each tested at a different concentration range, linking NM physicochemical (pchem) characterization data into the analysis, and assay interference by NMs. With no standard nomenclature, we identified NMs by combining information on group (nano, micro, ion), chemical composition of the core and coating, primary particle size, and source. CAS numbers were purposely not used for NMs to avoid data being aggregated with bulk counterparts. We accounted NM exposure potential and tested NM at various concentrations, while all soluble chemicals were tested at the same concentrations in ToxCast and their sigmoidal AC50s were compared. NM bioactivity data is being analyzed using various dose metrics (e.g., either NM mass or surface area per medium volume or cell surface area) and potency estimates (LEC, sigmoidal AC50, etc.) for NM toxicity ranking. To link NM pchem properties into the bioactivity data, we choose to build a distinct database of NM pchem characterization results, instead of modifying the existing ToxCast database of bioactivity results. While HTS assays we used have successfully screened hundreds of soluble chemicals, inspecting the NM bioactivity results carefully resulted in discontinuing the use of one of the testing platforms because NMs interfere with the assay. Future research needs include developing computational models using NM pchem properties and/or in vitro data to predict in vivo effects.

**W 789 Computational Dosimetry for Nanomaterial Risk Assessment from Transcriptomic and HTP Data.**

J. G. Teeguarden<sup>1</sup>, V. Mikheev<sup>2</sup>, J. G. Pounds<sup>1</sup> and B. D. Thrall<sup>1</sup>. <sup>1</sup>*Systems Toxicology, Pacific Northwest National Lab, Richland, WA;* <sup>2</sup>*Battelle Memorial Institute, Columbus, OH.*

The convergence of evolutionary changes to the field of toxicology and the rapid emergence of an immense new class of toxicologically untested nanoscale materials has led to development of new genomic and high-throughput in vitro screening tools for toxicological assessment of nanomaterials. These advancements and refinements in the measurement and analysis of response have not however, been followed by equally important advancements nanoparticle kinetics and in the measurement of cellular or tissue exposure to test materials. The absence of adequate dosimetry data for nanomaterial toxicity studies is one of the largest sources of uncertainty in current testing paradigms. We present an integrated computational dosimetry framework for placing the results of in vitro genomics and high throughput (HTP) toxicity data in the context of in vivo animal and human exposures and improving the basis for hazard rankings. The framework is applied in three case studies to demonstrate the impact of an evolution from "exposure" to target cell dose based nanotoxicity assessments: 1) the disruption of macrophage pathogen clearance by macrophages in vitro; 2) in vitro cytotoxicity screening and hazard ranking of 25 metal oxides; and 3) in vitro screening and hazard ranking of nanomaterials from the U.S. EPA's ToxCast program.

**W 790 Integrative Nanotoxicology: Linking Rapid Assays and Informatics to Predict Nanomaterial-Biological Interactions.**

S. Harper<sup>1,2</sup>. <sup>1</sup>*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR;* <sup>2</sup>*Chemical, Biological and Environmental Engineering, Oregon State University, Corvallis, OR.*

While numerous nanotechnology and nanomaterial-based applications promise benefit to human health or the environment, the potential health and environmental risks associated with the unique properties of nanoscale materials are unknown and may lead to unintended health and safety consequences. The current gap in

nanoparticle toxicological data dictates the need to develop rapid, relevant and efficient testing strategies to assess these emerging materials of concern prior to large-scale exposures. Among these are informatics approaches to speed the rate at which we can gain information on the fundamental relationships between specific nanomaterial features and their behavior in the environment as well as their interactions with living systems. Data compiled using a dynamic whole animal (in vivo) assay to reveal whether a nanomaterial produces adverse responses have been made available through the Nanomaterial-Biological Interactions (NBI) knowledgebase (nbi.oregonstate.edu). Endpoints such as mortality, development, malformations and behavior were assessed in the embryonic zebrafish model. Data compression of the 23 individual endpoints provided the numerical representation of overall mortality and morbidity elicited by a particular nanomaterial at a given concentration. Computational analysis performed on 82 nanomaterial datasets has revealed the importance of surface chemistry as a driver for nanomaterial toxicity across material classes. Furthermore, data mining techniques to model the biological effects of nanomaterials were applied to this case study. Results illustrate that individual endpoints have different predictability given the same set of algorithms and cumulatively the combined values can provide significant insight into the potential toxicity associated with nanomaterials for use in hazard ranking.

**W 791 Usefulness of In Vivo Genomics for In Vitro Screening in Nanotoxicity.**

A. Erdely and P. C. Zeidler-Erdely. *NIOSH, Morgantown, WV.*

Literature-based network analysis of in vivo microarray data, which yields biologically relevant molecular networks from the dataset, is becoming an increasingly useful tool to identify nanoparticle-induced signaling. This approach can be used to discover molecules that contribute to endpoint health effects and otherwise unknown mechanisms of action. While animal inhalation exposures may be the most relevant for predicting human health effects of nanomaterials, it is not always feasible because of the vast number of particles being manufactured. Therefore, in vitro high-throughput screening (HTS) is being used to predict their potential toxicity. While HTS may be necessary, in vivo genomic studies still provide useful information for screening broad classes of nanomaterials. Similar to physiological experiments in which three results are expected—increased, decreased, and no change—the question of whether network-based genomics from in vivo studies is useful for in vitro screening can be answered yes, no, and maybe. The output from these studies provides significant molecular detail of an exposure. Advanced analysis can indicate specific transcription factors involved in the response, upstream, and downstream signaling, and also which cell type may be the most affected by a particular nanomaterial. However, there are challenges to converting genomic data from in vivo exposures to in vitro screening. These include responsiveness of the cell type in vitro vs observed in vivo changes, distinguishing temporal effects, and an isolated single cell response in vitro that lacks regulatory effects occurring in vivo. The in vivo genomic findings also have limitations including whether altered molecular networks from studies in rodents are applicable to the human, and therefore applicable to studies utilizing human cell lines. In addition, experimental design (e.g., dosing relevant to human exposure levels) should be evaluated when interpreting genomic analysis from in vivo studies. In summary, genomic analysis from in vivo studies, although not without limitations, can offer insight for HTS.

**W 792 Scientific and Regulatory Advances in Genetic Toxicology Safety Assessment.**

M. Aardema<sup>1</sup> and B. Mahadevan<sup>2</sup>. <sup>1</sup>*Toxicology, BioReliance, Rockville, MD;* <sup>2</sup>*Medical Safety & Surveillance, Abbott Laboratories, Columbus, OH.*

Recent reviews of genotoxicity assay performance, the use of these data in the safety evaluation process, and the development of new assays have led to important advancements in regulatory and scientific recommendations in the area of genetic toxicology. For instance, the International Conference on Harmonization (ICH) has recently finalized guidelines on genetic toxicology testing for drugs. The OECD is updating 15 year-old guidelines for genetic toxicology assays. International validation of new assays like the Comet assay have been completed. Workshops held by international expert groups on new approaches for genetic toxicology assessments highlight the importance of incorporating new approaches in drug safety evaluations. In recent years, significant progress has been made in incorporating quantitative approaches to genotoxicity dose response in order to identify a point of departure for application in risk assessment process. These important initiatives impact the science and practice of genetic toxicology safety assessments globally and across all sectors including drugs, chemicals, and consumer products. This workshop brings together international experts representing key geographies involved in leading these efforts. In an effort to discuss scientific and regulatory advances in genetic toxicology safety assessment, the following key aspects will be addressed in this workshop: (1) US FDA implementation of ICHS2 (R1) guidelines, (2) Latest updates and new approaches in international guidelines for genetic toxicology assays,

(3) Outcomes on the JACVAM Comet validation and OECD guideline development, and (4) New approaches for genotoxicity assessments and guidance on dealing with positive results. In addition, this workshop will provide a forum to discuss the scientific advances that have led to the latest regulatory guideline changes, and their implementation.

### **W 793 US FDA Implementation of the ICH S2(R1) Guideline.**

M. W. Powley. *CDER, US FDA, Silver Spring, MD.*

The genetic toxicology testing paradigm to support drug development was recently updated in ICH S2(R1) "Guidance on Genotoxicity Testing and Data Interpretation for Pharmaceuticals Intended for Human Use". Although the guideline contained a variety of revisions, the most substantial impact was on the selection and conduct of genetic toxicology assays. Historically, *in vitro* and *in vivo* assays were performed to detect gene mutations as well as structural and numerical chromosome damage. While the revised ICH testing battery addresses these same endpoints, the guideline provides options weighted toward *in vitro* or *in vivo* assessments. Another update was the inclusion of the *in vitro* micronucleus assay and *in vivo* comet assay as potential components of the primary evaluation. Additional changes included a reduced limit dose for *in vitro* mammalian cell assays (i.e., the lower of 1 mM or 0.5 mg/mL) and an emphasis on designing studies to evaluate multiple endpoints. Ultimately, the revisions were intended to improve performance characteristics of the genetic toxicology testing battery, provide options to Sponsors of drug development, and maintain patient safety while preventing unnecessary delays in developing drugs.

As ICH S2(R1) was adopted in November 2011, regulatory agencies and Sponsors are just beginning to gain experience with the guideline. This presentation will briefly review the guideline and discuss implementation by the U.S. Food and Drug Administration's Center for Drug Evaluation and Research. Emphasis will be placed on key factors considered in regulatory decision making and highlighted by a discussion of case studies where appropriate.

### **W 794 New Approaches in International Guidelines for Genetic Toxicology Assays: Latest Updates on OECD Guidelines.**

V. Thybaud<sup>1</sup>, J. van Benthem<sup>2</sup>, N. Delrue<sup>3</sup>, G. Douglas<sup>4</sup>, E. Lorge<sup>5</sup>, M. M. Moore<sup>6</sup>, R. Schoeny<sup>7</sup> and T. Singer<sup>4</sup>. <sup>1</sup>*Drug Disposition, Preclinical Safety and Animal Research, Sanofi, Vitry-sur-Seine, France;* <sup>2</sup>*National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands;* <sup>3</sup>*Organization for Economic Co-operation and Development (OECD), Paris, France;* <sup>4</sup>*Health Canada, Ottawa, ON, Canada;* <sup>5</sup>*Servier Group, Orleans-Gidy, France;* <sup>6</sup>*National Center for Toxicological Research, US FDA, Jefferson, AZ;* <sup>7</sup>*Office of Research and Development, US EPA, Washington DC.*

In March 2010, the 22nd meeting of the Working Group of National Coordinators of the OECD Test Guidelines Programme (WNT) approved a project for updating the Test Guidelines on genotoxicity, with Canada, the Netherlands, France and the USA identified as lead countries for this work. An Expert Working Group (EWG) comprised of international experts was established and has since met twice. The EWG has recommended the deletion of several Test Guidelines, including the assays conducted in yeast and *Drosophila*. The EWG is currently working on revisions to the *in vitro* Test Guidelines for the micronucleus test (TG487), chromosomal aberration test (TG473) and gene mutation test (TG476), as well as the *in vivo* assays for the mammalian erythrocyte micronucleus test (TG474), the mammalian bone marrow chromosomal aberration test (TG475), the dominant lethal test (TG478) and the spermatogonial chromosomal aberration assay (TG483). A new guideline dedicated to the thymidine kinase locus is also under development. In addition, an update has been initiated of the Introduction Document to the genetic toxicology test guidelines, which is intended to provide succinct and useful guidance to guideline users. The purpose of the presentation at the SOT meeting will be to provide information on the status of the revision process and its main accomplishments to date. The opinions in this abstract are those of the authors and do not represent the policies of the U.S. EPA and FDA.

### **W 795 JACVAM Comet Validation and OECD Guideline.**

M. Hayashi. *Public Interest Incorporated Foundation, BioSafety Research Center, Shiobinden, Iwata, Japan.*

The *in vivo* rodent alkaline comet assay is used world-wide to detect genotoxicity of chemicals. The assay, however, has not been formally evaluated for its reliability and relevance. Thus, the Japanese Center for the Validation of Alternative Methods

(JACVAM) has organized with ECVAM, ICCVAM and NICEATM. This validation study has been also supported by JEMS/MMS and the consultation team including statisticians and specialists for the comet assay. We had the kick-off meeting for this trial in 2006. We have studied on the protocol optimization, intra- and inter-laboratory reproducibility before starting the predictive capability as the 4th phase. In the 4th phase- 1st step validation study, the purpose was to examine the extent of reproducibility and variability of assay results among labs using coded test chemicals and the positive control EMS, when experiments were conducted in accordance with the Comet assay protocol-version 14. In review of the data, Validation Management Team (VMT) confirmed the reproducibility and variability of assay results among laboratories. Thus the VMT decided to move on to the 4th phase- 2nd step validation study with an expanded set of test chemicals in accordance with the Comet assay protocol-version 14.2. The purpose of the 2nd step is to investigate the predictive capability of the assay against carcinogenicity of test chemicals. In the 2nd step, we selected 40 test chemicals, which include different characteristics in chemical classes including: Genotoxic carcinogen, Genotoxic non-carcinogen, Non-genotoxic carcinogen, and Non-carcinogen. Each test chemical was examined in one lab, because reproducibility was robustly confirmed in the 1st step validation study. We will disclose all data shortly but up to now VMT satisfied the outcomes. We are finalizing the validation report of our whole trial and we are also preparing the Comet Assay Atlas to guide how to select nuclei to be analyzed. Now, we are on the line of OECD TG through the peer review of our validation report and we have started to draft test guideline on *in vivo* comet assay.

### **W 796 New Approaches for Genotoxicity Assessment and Guidance on Dealing with Positive Results.**

B. Gollapudi, V. Thybaud and J. Kim. *ILSI-HESI IVGT Project Committee, Washington DC.*

Exposure to mutagens can lead to adverse health consequences such as cancer and genetic diseases. A battery of short-term tests has been in use for decades to identify potential mutagenic agents. However, the relevance of findings from these assays in predicting human risk continues to be a subject of discussion, centering around three major topics on how to 1) improve the existing assays, 2) integrate emerging technologies, and 3) deal with positive findings. An international initiative consisting of experts from academia, industry and the government has been addressing these issues to enable more accurate assessment of human risk from exposure to mutagenic agents. In the area of improving the existing *in vitro* assays, the experts have been examining the choice of cell lines (e.g., human vs. rodents; p53 deficient vs. competent) and the metabolic activation systems (human vs. rodent) in order to make recommendations for future testing protocols. New technologies being considered as potential replacements and/or complements of the standard testing battery include the application of stem cells, 3-D skin/ liver tissues, humanized animal models, high throughput assays (Tox21), incorporation of biomarkers of epigenetic changes with potential transgenerational significance, and the utilization of non-invasive imaging technologies to probe into time/age-related changes in the same animal with parallel anatomical and functional assessments. Results from the genotoxicity assays have traditionally been interpreted in a qualitative manner without analysis of the dose-response relationships. An expert group examined several quantitative approaches to the analysis of the dose-response data to identify a point of departure (POD) that could be combined with mode of action analysis to determine whether exposure(s) below a particular level (i.e., POD corrected by safety and uncertainty factors) constitute a significant risk for humans. These, along with other ongoing national and international initiatives are paving the way for a paradigm shift in the field of genetic toxicology.

### **PL 797 Early Markers for Screening Workers Exposed to Nephrotoxic Chemicals.**

F. M. Merwally and A. ElSafty. *Environmental & Occupational Medicine Department, National Research Center, Giza, Egypt.*

Routine renal function tests are insensitive for detection of subclinical renal impairment. A marker of early renal affection is needed to be used for screening of workers at risk. In this study the activity of the urinary N—acetyl-B-D-glucosaminidase (NAG) was measured to detect early renal changes in workers exposed to nephrotoxic chemicals. The efficacy of NAG was also compared with that of urinary B2-microglobulin. The studied groups included 50 chemical laboratory workers exposed to aliphatic hydrocarbon solvents, 40 car painters exposed to aromatic hydrocarbon solvents, 36 plumbers exposed mostly to lead fumes and a control group of 36 clerks, matched the exposed groups in age, sex, smoking habits and socioeconomic status.

Approval of the Medical Research Ethics Committee at the National Research Center and Consent of all participants in the study were obtained. Exposure indices included lifetime hydrocarbon exposure score (HES), Lead in blood (Ug/dL), and lifetime exposure score for lead (LES-Pb).

Levels of urinary NAG differed significantly in all groups compared to controls. Unlike B2-microglobulin, NAG levels also expressed a strong and consistent correlation with cumulative exposure indices (HES&LES-Pb). Furthermore, an exposure-effect relationship existed between NAG and HES in solvent-exposed normotensive subjects. Values of NAG were higher in solvent-exposed hypertensives than normotensives. These results support the use of urinary NAG in the periodic screening of workers at risk, especially hypertensives and those with renal disease.

## PL 798 Is Indoor Exposure to DEHP a Health Risk?

A. Gotti<sup>1</sup>, D. A. Sarigiannis<sup>1,2</sup> and S. P. Karakitsios<sup>1,2</sup>. <sup>1</sup>Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece; <sup>2</sup>Chemical Process and Energy Resources Institute, Centre for Research and Technology Hellas, Thessaloniki, Greece.

The study describes a mechanistic approach for assessing the timecourse of the source-to-dose exposure to DEHP. The overall modelling framework was built on asclxtreme and consists of:

- Multiphase indoor air quality model, for estimating DEHP concentrations in the gas, particle and dust phase starting from gaseous emissions of products containing DEHP.

- Exposure assessment model that incorporates all possible exposure pathways and routes (inhalation of DEHP, skin exposure through dust rubbing off, non-dietary oral exposure through dust ingestion).

- Internal dose model, for the assessment of DEHP and its 3 major metabolites (MEHP, 5-OH MEHP and 5oxo-MEHP) in human tissues and urine through a multi-compartmental PBPK model.

- Uncertainty/variability analysis tool across all stages of the assessment.

Under a typical scenario in a common residential dwelling (surface area of 270 m<sup>2</sup> and air exchange rate of 0.5hr<sup>-1</sup>) characterized by DEHP gaseous emissions of 200 µg/h (vinyl flooring and other plastic materials), the concentrations of DEHP in the gaseous, particles and dust phase are equal to 1.5 µg/m<sup>3</sup>, 21 µg/m<sup>3</sup> and 4400 µg/g settled dust. Overall daily intake varies between 0.2 to 10 µg/kg-bw, depending on the exposure scenarios considered. The latter are age-dependent: adults are exposed mostly through inhalation and infants through non-dietary ingestion. For a common repeated aggregate exposure scenario of 2 µg/kg-bw, the DEHP internal dose in venous blood and in adipose tissue (where bioaccumulation is clearly observed) reach a quasi-state equilibrium of 0.07 and 0.4 µg/L respectively. The expected urinary concentrations of MEHP, 5-OH MEHP and 5oxo-MEHP are 3.1, 16 and 8 µg/gCr respectively. These findings are in good accordance to existing biomonitoring data from NHANES. They are also one order of magnitude below the Biomonitoring Equivalent value of 660 µg/gCr for the sum of all DEHP metabolites measured in urine showing that DEHP concentrations in dwellings does not pose any significant risk.

## PL 799 Identifying the Sources of Uncertainty in the Process of Reconstructing Exposures to Carbaryl Using Exposure-to-Dose Modeling.

K. Holm<sup>1</sup>, R. McDougall<sup>2</sup>, M. Yoon<sup>3</sup>, B. Young<sup>4</sup>, H. J. Clewell<sup>3</sup>, R. Tornero-Velez<sup>1</sup>, R. Goldsmith<sup>1</sup>, D. T. Chang<sup>1</sup>, C. M. Grulke<sup>1</sup>, M. B. Phillips<sup>1</sup>, C. C. Dary<sup>5</sup> and C. Tan<sup>1</sup>. <sup>1</sup>US EPA ORD NERL, Research Triangle Park, NC; <sup>2</sup>The AEgis Technologies Group, Oshawa, ON, Canada; <sup>3</sup>The Hamner Institute, Research Triangle Park, NC; <sup>4</sup>Bayer CropScience, Research Triangle Park, NC; <sup>5</sup>US EPA ORD NERL, Las Vegas, NV.

"Exposure reconstruction" is a process for estimating distributions of exposures that are consistent with observed biomarker levels, and comparable to risk-based guidance values. The research identified uncertainties in reconstructed carbaryl exposure estimates stemming from data gaps. Sources of uncertainty were identified by evaluating exposure reconstruction results in a simulated population for which we know the exposure level. The "Cumulative and Aggregate Risk Evaluation System" (CARES) exposure model was used to generate time-concentration profiles for 500 virtual individuals exposed to carbaryl in food and drinking water for 365 days. Time-concentrations profiles were the inputs for a human physiologically based pharmacokinetic (PBPK) model for carbaryl, and biomarker (metabolite 1-naphthol) concentrations in spot urine sample were simulated. Three mathematical techniques (namely, Exposure Conversion Factor, Discretized Bayesian, and Markov Chain Monte Carlo (MCMC)) were used to reconstruct mean daily carbaryl intake for the virtual population given the distribution of spot biomarker levels. We found that MCMC was the most precise method. Using MCMC for exposure reconstruction, we found that MCMC iterations did not converge to an

exposure distribution if either the PBPK parameters or the urine flow rate were varied. Variation in the time between exposure events and spot sampling also contributed to the uncertainty in the reconstructed exposure. We recommend measuring urine flow rate, obtaining accurate estimates of PBPK model parameters, and monitoring time between exposure events and sample collection for improving reconstructed exposure estimates for rapidly metabolized compounds such as carbaryl.

## PL 800 A Novel Design of Experiments Approach to Assess Biomarker Usage with Experiments Involving PBPK Models.

J. Ivy, M. A. Lyons, A. N. Mayeno and B. Reisfeld. Department of Chemical and Biological Engineering, Colorado State University, Fort Collins, CO.

In exposure assessment, samples from the environment and population are collected and analyzed to estimate the magnitude, frequency, and duration of exposure to an agent. In this and other applications, an appropriate design of experiments is critical to assure the optimal usage of resources and the efficient gathering of data necessary to answer important public health questions. To aid in such designs, physiologically based pharmacokinetic (PBPK) models are increasingly used to help elucidate chemical disposition, identify key biomarkers, and characterize the effects of uncertainty and variability. Although a number of approaches have been used to help optimize the design of experiments based on PBPK models, significant gaps remain in the efficiency and utility of these methods.

Here we describe a new approach in experimental design that can be used to identify quantities useful in exposure assessment experiments, such as maximally-informative biomarkers, types of biospecimen, and sampling times. This method involves the integration of an efficient sampling algorithm and metrics to assess information loss within a Bayesian inference framework containing a PBPK model. These features expand upon the capabilities of existing tools to include hierarchical statistical models and design comparison without random error.

To test the methodology, several models relevant to toxicology were evaluated, including those for styrene, methylmercury, dichloromethane, and chlorpyrifos. Results from these studies showed that the use of information loss as a design metric lead to precise and accurate reconstructions of simulated exposure data. These results also included a characterization and ranking of various biomarker- and exposure-related quantities in terms of their utility in conducting both forward and reverse dosimetry.

We expect that the proposed methodology will be useful in the design of exposure assessment experiments and related studies and will expand the field of Bayesian inference in environmental and human toxicology.

## PL 801 Antioxidants and Oxidative Modification of Biomolecules: Can They Identify a Biomarker of Ozone Oxidative Stress?

M. Kadiiska. NIEHS/NIH, Research Triangle Park, NC.

The effect of ozone exposure on antioxidants and oxidation products of lipids, proteins and DNA in the plasma and urine of rats was studied by the international biomarker of oxidative stress study sponsored by NIEHS/NIH. The goal of this multi-laboratory study was to identify a biomarker of ozone oxidative stress and to assess whether inconsistent results often found in the field of ozone oxidative stress might be due to a lack of comparability of the available methods where various oxidative products are measured as biomarkers. The time and dose-dependent effects of ozone exposure of rats on plasma and urine lipid hydroperoxides, TBARS, malondialdehyde, isoprostanes, protein carbonyls, methionine sulfoxidation, various tyrosine oxidation products, and DNA changes were investigated with different techniques. Effects of ozone on ascorbic acid, tocopherols, coenzyme Q, glutathione and uric acid were measured to determine if the oxidative effects of ozone would result in decreases of antioxidants in blood plasma and bronchoalveolar lavage fluid as expected. Generally, antioxidants were not changed or showed only high-dose and/or single time point. Ozone exposure did not cause statistically significant differences in plasma concentration products of lipid peroxidation or protein and DNA oxidation in a time- and dose-dependent pattern. However, urinary concentrations of isoprostanes measured with an immunoassay were increased by two different doses of ozone 8 h, 56 h and 70 h post-exposure. Since elevation of isoprostanes in urine was consistent at three time points studied, it is concluded that it fulfilled the oxidative stress biomarker criterion of significant effects measured in biological fluid and seen at both doses at more than one time point. Measurements of low molecular weight antioxidants in plasma are not sensitive biomarkers for oxidative damage induced by the ozone and may not be the tool of choice for the assessment of oxidative damage by ozone in vivo.

**PL 802 Enhancing PM Epidemiological Concentration-Response Functions by Incorporating Lung Deposition and Oxidative Potential.**

S. P. Karakitsios<sup>1</sup>, D. A. Sarigiannis<sup>1,2</sup>, V. Kalaitzis<sup>1</sup> and M. Kermenidou<sup>1</sup>.

<sup>1</sup>Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece;

<sup>2</sup>Chemical Process and Energy Resources Institute, Centre for Research and Technology Hellas, Thessaloniki, Greece.

Despite the fact that well documented associations have been established between urban air PM and mortality/morbidity, incorporating internal exposure and toxicity metrics would be expected to significantly improve risk assessment and management.

Thus, existing concentration response functions were modified taking into account the fraction of particles deposited across the respiratory tract (using the MPPD lung deposition model) and the relevance to the corresponding health endpoint. The latter also depends on the actual size distribution for a given PM mass concentration, which is better described by the particle number count (PNC). Finally, the oxidative potential of particles of different size was also taken into account to derive revised exposure-response functions.

To investigate the feasibility of using this approach an extensive measurement campaign was carried out in a large Metropolitan area. PM size and number distributions were recorded in four sites. PM<sub>10</sub>, PM<sub>2.5</sub> and PM<sub>1</sub> samples were analyzed for oxidative potential by measuring Reactive Oxygen Species (ROS) using the DTT protocol. The results showed that the fraction of ultra-fine and fine particles is higher in the city center than in the suburbs. The same is true for oxidative potential especially for the smaller particles. Thus, the actual exposure for endpoints related to lower respiratory tract deposition and possibly translocation within the systemic circulation (e.g. cardiovascular disease, adverse pregnancy outcomes) might rise to up to 4 times higher to the one estimated by the respective differences in mass concentration. Besides their implications for spatial epidemiology, our results show that future epidemiological studies would be greatly improved by incorporating evidence based on toxicity metrics, resulting in more robust associations between ambient air PM exposure and ill-health.

**PL 803 Continuous, Near Real-Time Toxicological Screening Using an Autonomously Bioluminescent Human Cell Line: A Transitory Preclinical Imaging Approach.**

D. Close<sup>1</sup>, T. Xu<sup>2</sup>, J. Webb<sup>2</sup>, S. Ripp<sup>1</sup> and G. Saylor<sup>1</sup>. <sup>1</sup>490 BioTech Inc., Knoxville, TN; <sup>2</sup>The University of Tennessee, Knoxville, TN.

Continuous toxicity monitoring using human cell-based bioreporters can report on the bioavailability and efficacy of toxic substances but is logistically challenging because of the cells' relatively high autofluorescent background or the expense and/or sample destruction required to perform bioluminescent substrate (i.e., luciferin) addition. To facilitate this process, we have synthetically optimized the bacterial luciferase gene cassette to function autonomously in human cells without the need for external substrate addition. A proof-in-principle demonstration using human kidney cells (HEK293) revealed that bioluminescent output declined in response to challenge with the DNA damaging antibiotic Zeocin in a dose response fashion. This response was similar to that displayed using commercially available firefly luciferase reporter assays, but allowed for repeated monitoring of the same samples, leading to a lower overall cost and increased data acquisition potential. Similarly, autobioluminescent reporter cells were designed using a tetracycline activated promoter and were demonstrated to be capable of autonomously initiating a bioluminescent response in reaction to treatment with the antibiotic doxycycline within 2.5 hours at a concentration of 100 ng/ml. The resultant bioluminescent signal was comparable to existing firefly luciferase-based reporter systems at  $1.33 (\pm 0.1) \times 10^7$  photons/second and was significantly greater than uninduced background ( $p < 0.01$ ). Additionally, we have validated the imaging capabilities of these autobioluminescent cells in a mouse model, demonstrating that the same system can be utilized for both high throughput culture based testing and low throughput animal studies. This approach therefore provides a route for the direct comparison of results as toxicological investigations transition across multiple levels of complexity.

**PL 804 Provisional Biomonitoring Equivalents for a Screening Level Evaluation of Urinary 3-Phenoxybenzoic Acid Concentrations in a Risk Assessment Context.**

L. Aylward<sup>1</sup>, S. M. Hays<sup>2</sup>, K. Irwin<sup>3</sup>, A. St-Amand<sup>3</sup> and A. Nong<sup>3</sup>. <sup>1</sup>Summit Toxicology, LLP, Falls Church, VA; <sup>2</sup>Summit Toxicology, LLP, Allenspark, CO; <sup>3</sup>Health Canada, Ottawa, ON, Canada.

3-phenoxybenzoic acid (3-PBA) is a common metabolite of a number of commonly-used pyrethroid pesticides of differing structures and relative potency and also exists as a residue in foods resulting from environmental degradation of parent

pyrethroid compounds. Thus, 3-PBA in urine cannot be used as a specific biomarker of exposure to specific pyrethroid compounds. However, an approach derived from the use of Biomonitoring Equivalents (BE), which are estimates of steady-state biomarker concentrations consistent with exposure guidance values, can be used in an assessment of nine pyrethroid compounds in order to estimate a conservative initial screening value for a tiered assessment of population data on 3-PBA in urine. The most recent USEPA reference doses (RfDs) for these pyrethroids were identified. An average urinary excretion fraction (FUE) for 3-PBA was estimated from four pyrethroid compounds with human excretion fraction data and then applied to all nine parent compounds. Estimated steady-state urinary 3-PBA concentrations associated with the RfD for each of the nine compounds ranged from 6 ug/L for cyhalothrin to 1,875 ug/L for permethrin. The lower end of this range can be used as a highly conservative screening value for assessment of population urinary 3-PBA data through an implicit assumption that all exposures leading to the observed 3-PBA were to the most potent parent compound and no direct exposure to 3-PBA has occurred. If population data do not exceed this level, it is unlikely that cumulative exposures to multiple pyrethroids are exceeding the RfD equivalent for the mixture. If population data do exceed this level, more detailed assessment and weighting of individual pyrethroid provisional BE values can be considered.

**PL 805 Beyond Biological Equivalents to Biologically Effective Dose.**

D. A. Sarigiannis<sup>1,2</sup>, S. P. Karakitsios<sup>1,2</sup> and A. Gotti<sup>1</sup>. <sup>1</sup>Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece; <sup>2</sup>Chemical Process and Energy Resources Institute, Centre for Research and Technology Hellas, Thessaloniki, Greece.

This paper deals with the refinement of the Risk Characterization Ratio (RCR) calculation by employing the enhanced Biomonitoring Equivalences (BEs) – Biologically Effective Dose (BED) concept, using a generic PBTK model. The overall methodology was demonstrated for Bisphenol-A and DEHP.

A generic multi-compartmental two generations (mother-fetus) PBTK model was developed so that it could be adaptable for humans, mice and rat. The model incorporates route and intra-species extrapolations, allowing the direct translation of animal NOAELs into human BEDs and BEs. The model was parameterized for BPA and DEHP based on existing human and rodents toxicokinetic data.

To estimate the BEs values, we estimated the BED for rodents corresponding to the steady-state concentration of orally administered doses as described in the respective guideline studies (5 mg/kg\_bw/day in mice for BPA and 592 mg/kg\_bw/day in Sprague-Dawley Rat for DEHP) from where the respective NOAELs were derived. The corresponding BED derived for mice (BPA) and rat (DEHP) respectively, were then translated by reverse modeling into human external exposure doses. Lastly, the corresponding BEs were derived by running the human parameterized PBTK models.

The direct extrapolation of observed NOAELs into human urine BEs through BEDs, resulted in higher values than the ones derived based on using human equivalent NOAELs and simple pharmacokinetic considerations. This comes as result of physiology-dependent differences in clearance and entero-hepatic recirculation between rodents and humans. In addition inter-individual variability is explicitly addressed via this approach. Thus, translating in vivo testing results into equivalent human exposure regimes and expected biomonitoring values is facilitated; uncertainties are minimized and unnecessary conservatism in population exposure/risk characterization is avoided.

**PL 806 Liver Effects in CD1 Mice Prenatally-Exposed to Low Doses of Perfluorooctanoic Acid (PFOA): Novel Modes of Action.**

S. E. Fenton<sup>1</sup>, A. J. Filgo<sup>1,4</sup>, C. A. Cummings<sup>5</sup>, M. Hoenerhoff<sup>2</sup>, D. Malarkey<sup>2</sup> and E. M. Quist<sup>1,2,3</sup>. <sup>1</sup>NTP Labs, DNTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>Cellular and Molecular Pathology Branch, NIEHS, Research Triangle Park, NC; <sup>3</sup>Comparative Biomedical Sciences, College of Veterinary Medicine, North Carolina State University Raleigh, NC; <sup>4</sup>Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>5</sup>Experimental Pathology Labs, Inc, Research Triangle Park, NC.

Perfluorooctanoic acid (PFOA) is a perfluoroalkyl acid primarily used as an industrial surfactant. It persists in the environment and has been linked to potentially toxic and/or carcinogenic effects in animals and people. As a known activator of peroxisome proliferator-activated receptors (PPAR), PFOA can cause alterations that lead to defects in fatty acid oxidation, lipid transport, and inflammation. Here, CD1 mice were orally gavaged with 0, 0.01, 0.1, 0.3 and 1 mg PFOA/kg body weight from gestation days (GD) 0 through 17. On postnatal day (PND) 21, histopathologic changes in the liver of offspring included hepatocellular hypertrophy and periportal inflammation that increased in severity by PND91 in an apparent dose-dependant response. In an earlier study, similarly exposed wildtype and PPARα KO SV129 and CD1 mice also developed significant hepatocellular hypertrophy by 72 weeks (high-dose groups). A significant dose dependent increase in

bile duct hyperplasia and hepatocellular hypertrophy in the PPAR $\alpha$  KO mice suggest a mechanism of hypertrophy independent of that previously reported for PPAR $\alpha$ -induced peroxisome proliferation in the current literature. Transmission electron microscopy (TEM) of selected liver sections from PND91 mice revealed PFOA-induced cellular damage and mitochondrial abnormalities with no evidence of peroxisome proliferation. These mitochondrial changes may represent PFOA-induced alterations in the beta-oxidation pathway regulated by PPAR $\alpha$  and/or may represent an earlier change that proceeds, or is independent of, PPAR $\alpha$ -induced peroxisome proliferation. This abstract does not necessarily reflect NIEHS policy.

## PL 807 Dose-Dependent Incidence of Murine Hepatic Tumors following Perinatal Bisphenol A Exposure.

C. Weinhouse<sup>1</sup>, O. S. Anderson<sup>1</sup>, I. L. Bergin<sup>2</sup> and D. Dolinoy<sup>1</sup>. <sup>1</sup>*Environmental Health Sciences, University of Michigan, Ann Arbor, MI*; <sup>2</sup>*Unit for Laboratory Animal Medicine, University of Michigan, Ann Arbor, MI*.

Epidemiological and animal studies have now critically established that environmental exposures during early embryonic development have the ability to influence adverse health outcomes in adulthood. This study evaluated adult health outcomes of perinatal exposure to the endocrine disruptor bisphenol A (BPA) in a mouse model. Prior studies have linked BPA exposure with precancerous lesions in mammary and prostate glands, and uterus, as well as with hepatic dysfunction. We exposed isogenic mice (n=69) perinatally through the maternal diet to 3 physiologically relevant doses of BPA (50 ng, 50  $\mu$ g, or 50 mg of BPA per kg diet) or a control diet. 23% (16/69) of 10-month offspring presented with hepatic tumors (hepatocellular carcinoma or hepatic adenoma), with a risk ratio of 7.15 for the 50 mg group (p=0.0280) and significant dose-response on Cochran-Armitage test of trend (p=0.0295). Importantly, observed early disease onset and lack of characteristic sexual dimorphism in tumor incidence support a non-classical etiology. Notably, the 1982 National Toxicology Program chronic feed study finding of multinucleated hepatocytes (MH) was replicated here. MH were present in 7 animals, exclusively in low-dose groups (n=4 in 50 ng group, n=3 in 50  $\mu$ g group); these abnormal cells may be associated with increased hepatocyte proliferation. The significance of this study includes: (1) these data represent the first report of frank tumors, in addition to precancerous lesions, in any organ following perinatal or adult BPA exposure; (2) these data represent the first report of neoplasms in a non-reproductive estrogen-target organ; (3) this study underscores the critical importance of exposure timing; and (4) this study implicates an environmentally ubiquitous chemical in development of hepatocellular carcinoma in mice, with potential implications for human disease. Funding: ES017524 and DK089503.

## PL 808 Liver Hypertrophy Is Not a Key Event in Constitutive Androstane Receptor (CAR)-Mediated Liver Tumor Development in Mice Treated with Triazoles.

K. Tamura<sup>1</sup>, K. Inoue<sup>1</sup>, M. Takahashi<sup>1</sup>, S. Matsuo<sup>1</sup>, K. Irie<sup>1</sup>, Y. Kodama<sup>2</sup>, S. Ozawa<sup>3</sup> and M. Yoshida<sup>1</sup>. <sup>1</sup>*Division Pathology, National Institute Health Sciences, Setagaya-ku, Tokyo, Japan*; <sup>2</sup>*Division Toxicology National Institute Health Sciences, Setagaya-ku, Tokyo, Japan*; <sup>3</sup>*School Pharmacology, Iwate Medicine University, Morioka, Iwate, Japan*.

Liver hypertrophy is accepted to be a key event in CAR-mediated liver tumor development in rodents. Many triazoles (TRIs) have been reported to induce hypertrophy and tumors in the livers of rodents. In this study, we clarified the involvement of CAR in TRI-induced liver hypertrophy and tumor development using CAR knockout mice (CARKO). Seven-week-old male CARKO and wild-type mice (WT) were treated with cyproconazole (Cypro), tebuconazole (Teb), or fluconazole (Flu) for 27 weeks at 200, 1500, or 200 ppm, respectively, in the diet. Tumors were initiated by a single i.p. injection of diethylnitrosamine (DEN) before the treatment. At interim kills at 4 (without DEN) and 13 weeks (with DEN), increases in liver weight and severe centrilobular/diffuse hepatocellular hypertrophy were detected in WT treated with TRIs. In CARKO, Teb induced severe liver hypertrophy, whereas Cypro and Flu induced very mild hypertrophy compared to that in corresponding WT. After 27 weeks of treatment, Cypro significantly increased eosinophilic altered foci/adenomas in WT. In CARKO, both types of lesions were clearly reduced compared to WT, but the multiplicity of foci was marginally higher than in the control. Teb increased eosinophilic foci in WT, but significantly depressed formation of these foci in CARKO. Flu and Teb had similar profiles in both genotypes. Basophilic foci/adenomas were also reduced in CARKO compared to WT for all TRI groups, but the effects were weak compared to changes in eosinophilic ones. Our present study indicated that CAR was the major mediator involved in liver hypertrophy for Cypro and Flu, but another pathway also existed. In particular, CAR was not involved in Teb-induced hypertrophy. Meanwhile, the involvement of CAR was crucial for TRI-induced tumors. These results suggested that liver hypertrophy was not a key event in CAR-mediated liver tumor development in mice.

## PL 809 Fluopyram: Mechanistic Investigations to Elucidate the MoA for Liver Tumor Formation in the Rat.

H. Tinwell<sup>1</sup>, D. Rouquié<sup>1</sup>, O. Blanck<sup>1</sup>, P. Maliver<sup>1</sup>, F. Schorsch<sup>1</sup>, S. Wason<sup>1</sup>, D. Geter<sup>2</sup> and R. Bars<sup>1</sup>. <sup>1</sup>*Bayer CropScience, Sophia Antipolis, France*; <sup>2</sup>*Bayer CropScience, Research Triangle Park, NC*.

Fluopyram, a broad spectrum fungicide, caused hepatomegaly, liver hypertrophy and resulted in an increased incidence of hepatocellular carcinomas and adenomas in female Wistar rats following chronic exposure (24 months) at the highest dose evaluated (1500 ppm equating to 89 mg/kg/d) in the guideline carcinogenicity study. Mechanistic studies were subsequently conducted in the female rat to identify the initial key events responsible for the tumor formation and to establish thresholds for each of the early hepatic changes. Studies showed increased expression of constitutive androstane receptor (CAR) and pregnane X receptor (PXR) inducible genes from as early as 3 days of treatment. Further confirmation of CAR/PXR activation was provided by increased activity of specific Phase I enzymes (PROD and BROD respectively). Increased hepatocellular proliferation (measured by Ki67) was observed, particularly in the centrilobular region, starting from 3 days of treatment. Cell proliferation was also increased after 7 and 28 days of treatment but to a lesser extent than that following a 3 day exposure. In these studies, dose responses and clear thresholds were established for gene expression, enzyme activity and cell proliferation. Furthermore, these early hepatic changes were shown to be reversible following compound withdrawal. Other modes of action (MoAs) for liver tumor formation such as genotoxicity or peroxisome proliferation were not observed. In conclusion, fluopyram is a threshold carcinogen and the resultant hepatocellular carcinomas in the female rat are due to hepatocellular proliferation mediated by CAR/PXR activation. It is unlikely that fluopyram would induce liver tumors in humans as the CAR/PXR induced hyperplastic response has been shown to be absent in human hepatocytes exposed to other known rodent hepatocarcinogens with the same MoA.

## PL 810 Mechanistic Investigation of Technical Toxaphene (TT)-Induced Mouse Liver Tumors.

Z. Wang<sup>1</sup>, B. H. Neal<sup>2</sup>, J. C. Lamb<sup>2</sup> and J. E. Klaunig<sup>1</sup>. <sup>1</sup>*Indiana University, Bloomington, IN*; <sup>2</sup>*Exponent Inc, Alexandria, VA*.

Chronic exposure to technical toxaphene (TT) resulted in an increase in liver tumors in B6C3F1 mice, with male mice showing higher response. TT appears to act on the tumor promotion process. The current study was performed to further investigate the mode of action (MOA) of TT inducing mouse liver tumors. In a preliminary dose range-finding study, mice were given TT (0, 10, 40, 80, 160 and 320 ppm) in diet continuously for two weeks. A decrease in body weight gain compared to control was observed in mice treated with 320 ppm TT in diet (3.27 g vs. -1.22 g). Body weight gains were also significantly decreased in the 80 ppm and 160 ppm treatment groups. A significant dose dependent increase in relative liver weight was observed in mice treated with 0, 40, 80, 160 and 320 ppm TT diet (4.81, 5.32, 6.05, 6.55 and 7.43 g respectively). A similar trend was observed in the liver weight. A dose dependent increase in liver centrilobular hypertrophy was seen in mice treated with 80, 160 and 320 ppm TT; this was not observed at the 10 and 40 ppm doses. Similarly, a significant dose dependent increase in hepatocyte DNA synthesis (BrdU incorporation) was seen in mice treated with 40 ppm, 80 ppm, 160 ppm and 320 ppm, compared with the untreated controls with labeling indices of 3.28, 6.34, 11.10, and 15.61 respectively, compared with 1.06 in the control group). The increase in labeling index showed agreement with the absolute and relative liver weight results. Based on findings of the range-finding study, a second study using 0, 3, 32 and 320 ppm TT diet was initiated to define the MOA for the TT mouse liver tumorigenic effects. Using phenobarbital as a positive control, the well-established hepatic tumor modes of action are being investigated including: cytotoxicity; receptor activation (PPAR $\alpha$ , CAR, estrogen, and AhR) and oxidative stress in TT treated B6C3F1 mice.

## PL 811 In Vitro Cross-Species Comparative Analysis of Pharmacokinetic and Molecular Responses Mediated by a Labile AhR Activator.

L. A. Murphy<sup>1</sup>, D. L. Rick<sup>1</sup>, L. McClymont<sup>1</sup>, J. McFadden<sup>1</sup>, M. Bartels<sup>1</sup>, N. J. Stagg<sup>2</sup>, R. Billington<sup>2</sup>, R. J. Rasoulpour<sup>1</sup> and D. L. Eisenbrandt<sup>2</sup>. <sup>1</sup>*The Dow Chemical Company, Midland, MI*; <sup>2</sup>*Dow AgroSciences, LLC, Indianapolis, IN*.

A novel herbicide in development, XDE-729 methyl, induces rodent liver effects through an aryl hydrocarbon receptor (AhR)-mediated mode-of-action (MoA). To further characterize species differences in these effects, mouse, rat, and human *in vitro* assays were used to elucidate differences in 1) AhR activation, 2) hydrolysis

rates to non-AhR activator metabolites, and 3) systemic exposure as predicted by a physiologically based pharmacokinetic (PBPK) model. AhR transactivation and binding assays indicated that XDE-729 methyl exhibits weak AhR agonism in mouse cells, no AhR agonism in human cells, and binds weakly to the rat AhR ligand and binding domain. Fresh hepatocytes from CD-1 mouse, Sprague Dawley rat, and human (6 donor livers) were used to compare XDE-729 methyl mediated CYP1A1 induction, a sensitive biomarker for AhR activation. Gene expression analysis indicated that rats are the most sensitive species with regards to XDE-729 methyl mediated CYP1A1 induction with maximal induction at 100  $\mu$ M of 147.7-fold in rat, versus 37.8-fold in mouse, and 2.9, 4.5, 6.2, 8.7, 10.3, and 34-fold in the six human livers. An *in vitro* study to determine hydrolysis rates of XDE-729 methyl to the major metabolite, XDE-729 acid, which does not activate AhR, indicated that: 1) the hydrolysis rate in human liver S9 is faster than rodents; 2) hydrolysis in human synthetic gastric fluid is faster than rodents 3) hydrolysis of XDE-729 methyl is slowest in human whole blood versus rat or mouse. A PBPK model using the *in vitro* hydrolysis rates predicted similar blood and liver levels of XDE-729 methyl in rat and human after XDE-729 methyl dietary exposure. However, the *in vitro* mechanistic data indicate that humans are less sensitive than rats based on faster liver hydrolysis rates of XDE-729 methyl and limited AhR activation; therefore, a margin of exposure risk assessment using the *in vivo* rat toxicity studies is protective of human health.

**PL 812 Developmental Exposure to 2, 3, 7, 8 Tetrachlorodibenzo-*p*-dioxin (TCDD) Affects Leukemogenesis in Adult Tumor Prone Mice by Interacting with the Thymus Expressed Notch1.**

M. D. Laiosa, L. Ahrenhoerster, D. Almagro and P. A. Lakatos. *Zilber School of Public Health, UW-Milwaukee, Milwaukee, WI.*

Reprogramming of progenitor cells during development can have profound impacts on later life disease susceptibility and is dependent on the interaction between genetic susceptibility of the child, the maternal intrauterine environment, and the timing of exposure to potential insults. In particular, developmental exposure to the persistent contaminant TCDD, acting through the aryl hydrocarbon receptor (AHR), is known to cause immunosuppression and is associated with hematological malignancies later in life. For example, at least 50% of all T-cell leukemias are associated with activating mutations in Notch1. Notch1 is a transmembrane receptor required for T-cell lineage commitment in the thymus. Moreover, preliminary data suggest a potential interaction between AHR and Notch1 signal transduction. To test for a possible gene-environment interaction between the AHR and Notch1, we hypothesized that leukemia prone Notch1 transgenic mice would have a more severe disease if exposed to TCDD during development. To test this hypothesis, timed pregnant dams were exposed to 0 to 3  $\mu$ g/Kg TCDD throughout pregnancy. We found that while there was no difference in disease onset, severity or incidence, there was a significant difference in the cell-type of T-cell thymomas that developed in these mice and this difference was observed only in males. Specifically, whereas Notch-TG control mice developed CD4<sup>+</sup> tumors, Notch-TG mice exposed to TCDD in utero developed CD8<sup>+</sup> tumors. This lineage switch in disease phenotype suggests a reprogramming of a hematopoietic precursor or tumor stem cell during development leading to a reversal in the T-lineage choice in the adult life. These data suggest that early life AHR activation has a long-term effect on Notch1-mediated thymocyte lineage choice throughout the life-course. These data have implications for disease susceptibility in vulnerable populations that may possess genetic instability in the Notch locus and/or have been exposed to AHR agonists developmentally.

**PL 813 Critical Evaluation of the Mode of Action of Carcinogenicity for Acrylonitrile.**

J. M. Fritz and A. M. Luke. *ORD/NCEA/IRIS, US EPA, Washington DC.*

Acrylonitrile (AN) is an aliphatic nitrile used as a reagent in industrial processes, and is polymerized into injection-molded plastics used to create pipes, automobile dashboards and children's building blocks. Annually, over 1.5 million tons are produced in the U.S. alone, where AN is regulated by EPA as a hazardous air pollutant. Industrial cohort studies suggest a potential association between AN exposure and increased risk of cancer mortality and experimental evidence demonstrates that acrylonitrile induces tumor formation at multiple sites in rodent species following oral and inhalation exposure. A comprehensive cancer mode of action (MOA) analysis has been conducted and may inform the correspondence between the human and animal datasets. The AN literature was reviewed for evidence pertaining to genotoxicity and other potential MOAs; data were sorted by species, endpoint, and study design, and effects were critically evaluated for consistency, magnitude, specificity, plausibility and coherence. Early effects in relevant adverse

outcome pathways were further assessed for causality, to determine if effects could indicate key events in AN-induced carcinogenesis. Critical analysis of the AN dataset supports potential contributions from multiple MOAs, including genotoxicity. Brain region-specific increases in lipid peroxidation and dose-dependent accumulation of 8-oxodG could support genotoxicity concurrent with oxidative stress *in vivo*, while covalent-binding to proteins and nucleic acids, liver DNA alkylation, leukocyte cell micronuclei formation and dose-dependent induction of forward mutations all support genotoxicity occurring prior to other cellular effects. While data-rich in some areas, other endpoints evaluated in the course of this analysis were data-poor. Some of these data gaps include a comprehensive evaluation of DNA repair and adducts, fixed mutations, and source of AN-induced oxidative species in rodent cancer target tissues. The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.

**PL 814 Long-Term Inhalation Study with Nanomaterials: Pulmonary Effects of Nanoscale CeO<sub>2</sub> and BaSO<sub>4</sub> in a Rat 28-Day Range Finding Study.**

J. Keller<sup>1</sup>, S. Gröters<sup>1</sup>, L. Ma-Hock<sup>1</sup>, V. Strauss<sup>1</sup>, K. Wiench<sup>2</sup>, B. van Ravenzwaay<sup>1</sup> and R. Landsiedel<sup>1</sup>. <sup>1</sup>*Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany;* <sup>2</sup>*Product Safety, BASF SE, Ludwigshafen am Rhein, Germany.*

Inhalation exposure has been considered as the major route of concern for nanomaterials. Recent published literature reveals a distinct gap of long-term inhalation studies, especially on industrial relevant poorly soluble bio-persistent particles (PSP), including their carcinogenic potential. Nanoscale CeO<sub>2</sub> and BaSO<sub>4</sub> will be accurately examined in a combined chronic and carcinogenicity inhalation study. Emphasis is placed on the relationship of inflammatory reactions, particle overload and lung tumor formation.

For this purpose, a 28 day range finding study according to the OECD Guideline 412 was performed. Groups of female Wistar rats (5 rats/ group) were whole body exposed to 0.5, 5, 25 mg/m<sup>3</sup> CeO<sub>2</sub> and 50 mg/m<sup>3</sup> BaSO<sub>4</sub> for 28 days. A concurrent control group was exposed to clean air. The exposure concentrations for CeO<sub>2</sub> were selected to achieve lung burden below and above particle overload.

Biological effects were examined immediately after last exposure and in a post-exposure period. Examined endpoints considered bronchoalveolar lavage, hematology and clinical chemistry, gross necropsy, histological examination of the respiratory tract and cell proliferation of the lung as well as systemic genotoxicity in peripheral blood cells.

Increased lung weights in the high dose test group of CeO<sub>2</sub> (25 mg/m<sup>3</sup>) and significant changes in lung lavage parameters (cell cytology, protein and enzyme levels) in the mid (5 mg/m<sup>3</sup>) and high dose test group of CeO<sub>2</sub> are indicative for early treatment-related findings. Subsequent results of particle related biological effects associated with an appropriate particle lung burden of the range finding study will be presented here. The outcome of the 28 day study will serve as basis for concentration selection for the upcoming long-term inhalation study.

**PL 815 Pulmonary Responses in Rats after Inhalation Exposure to Cerium Oxide Nanoparticles Generated by the Harvard Versatile Engineered Nanomaterial Generating System (Venges).**

V. Castranova<sup>1</sup>, M. Barger<sup>1</sup>, W. Goldsmith<sup>1</sup>, D. Frazer<sup>1</sup>, B. Hines<sup>1</sup>, W. McKinney<sup>1</sup>, G. Pyrgiotakis<sup>2</sup>, S. Gass<sup>2</sup>, P. Demokritou<sup>2</sup> and J. Ma<sup>1</sup>. <sup>1</sup>*HELD, NIOSH, Morgantown, WV;* <sup>2</sup>*Harvard University, Boston, MA.*

Recently cerium compounds have been used in a variety of consumer products including semiconductors, UV shields and diesel fuel additives to increase fuel combustion efficiency and decrease diesel soot emissions. Our previous studies have shown that exposure of rats to CeO<sub>2</sub> by intratracheal instillation not only induces sustained pulmonary inflammation, but also lung fibrosis. In the present study, the aerosols of CeO<sub>2</sub> or CeO<sub>2</sub> coated with a nanothin layer of amorphous SiO<sub>2</sub> (aSiO<sub>2</sub>-CeO<sub>2</sub>) were generated by the Harvard VENGES. The aerosols were diluted with air and delivered to a whole body exposure chamber. Male Sprague Dawley rats were exposed to CeO<sub>2</sub> or aSiO<sub>2</sub>-CeO<sub>2</sub> at 2.7 mg/m<sup>3</sup>, 2h/day for 4 days along with air controls. Animals were sacrificed at 1 or 84 days post exposure. Morphometric analysis of the CeO<sub>2</sub> and aSiO<sub>2</sub>-CeO<sub>2</sub> particle cores showed diameters of 12.8 and 19.2 nm, respectively. Mobility diameter modes of 82 and 96 nm were measured for the CeO<sub>2</sub> and aSiO<sub>2</sub>-CeO<sub>2</sub> aerosols aggregates in the breathing zone of the animals. Alveolar macrophages (AM) were obtained by bronchoalveolar lavage (BAL), and alveolar BAL fluids (BALF) were saved for further analysis. At 1 day after CeO<sub>2</sub> exposure, but not aSiO<sub>2</sub>-CeO<sub>2</sub>, significantly induced PMN infiltration and lactate dehydrogenase activity in the BALF. CeO<sub>2</sub> significantly increased collagen

degradation enzymes, matrix metalloproteinases (MMPs)-2 and tissue inhibitor of MMP-1 in the BALF, which may be involved in the modification of extracellular matrix. At 84 days post exposure, none of the particle treatment groups induced lung inflammation, cellular injury or alteration of hydroxyproline content in lung tissues. These results demonstrated that a thin coating of aSiO<sub>2</sub> on CeO<sub>2</sub> protected lungs from CeO<sub>2</sub>-induced acute lung toxicity, suggesting that a thin coating of aSiO<sub>2</sub> may potentially be used to modify other nanoparticle-induced lung toxicity.

## PL 816 Gene Expression Profiling of Human Lung Epithelial Cell Lines Exposed to Manufactured CoO and CeO<sub>2</sub> Nanoparticles.

I. Nelissen<sup>1</sup>, S. Verstraelen<sup>1</sup>, E. Casals<sup>2</sup>, S. Remy<sup>1</sup>, P. De Boever<sup>1</sup>, H. Witters<sup>1</sup> and V. Punters<sup>2</sup>. <sup>1</sup>Flemish Institute for Technological Research (VITO NV), Mol, Belgium; <sup>2</sup>Institut Català de Nanotecnologia (ICN), Barcelona, Spain. Sponsor: P. Hoet.

Exposure to manufactured nanoparticles (NPs) via inhalation can cause adverse human health effects. A transcriptomics study was performed to identify molecules and cellular pathways that are specifically triggered by in vitro exposure of the human bronchial BEAS-2B and alveolar A549 epithelial cell lines to 7-nm CoO and 4-nm CeO<sub>2</sub> NPs. We aimed to investigate whether 1) the same lung cell type responds similarly to the NPs, 2) alveolar vs. bronchial epithelial cells respond differently to the same NP, and 3) immunological processes are influenced. Non-cytotoxic exposure concentrations of monodispersed NPs were used. Statistically significant changes in gene expression as compared to solvent-treated cells (median |fold-change| > 1.5, p < 0.05) were evaluated after 3, 6, 10, and 24 hours.

The kinetics of the cell responses induced by the 2 NPs were similar within, but different between the 2 cell models. BEAS-2B cells were found to be more sensitive for NP toxicity, as they showed a higher total number of differentially expressed transcripts (DET) at a 10-fold lower NP-concentration than A549 cells. Hierarchical biclustering of all DET indicated that the transcriptional responses were quite heterogeneous among the 2 cell types and 2 NPs. Between 1% and 14% DET encoding markers involved in immune system processes were observed in the BEAS-2B and A549 cell lines, resp., with the highest fractions observed in BEAS-2B cells. Most of these genes, i.e. ITGB2, TLR6, PAG1, HLA-DRB3, TIRAP, and HLA-A, are involved in immune signalling or yet unassigned pathways. Nanoparticle exposure mainly induced suppression of immune gene transcription, rather than immune stimulation. The AKT1 gene was identified as a possible generic marker of lung epithelial cell-NP interaction.

Our data suggest that CoO- and CeO<sub>2</sub>-NP give rise to a distinct immunological response in bronchial and alveolar epithelial cells.

## PL 817 Mechanistic Insights into the Toxicity of Multiwalled Carbon Nanotubes and Cerium Dioxide Nanoparticles in Primary Human Bronchial Epithelial Cells.

S. Hussain<sup>1</sup>, R. Snyder<sup>1</sup>, S. M. Anderson<sup>1</sup>, J. D. Marshburn<sup>1</sup>, A. B. Rice<sup>1</sup>, N. J. Walker<sup>2</sup> and S. Garantziotis<sup>1</sup>. <sup>1</sup>Clinical Research Program, NIEHS (NIEHS)/National Institute of Health (NIH), Durham, NC; <sup>2</sup>DNTP, NIEHS, Research Triangle Park, NC.

Cerium dioxide nanoparticles (CeO<sub>2</sub> NPs) and multi-walled carbon nanotubes (MWCNT) are priority materials for urgent risk assessment due to wide spread industrial, consumer product and environmental utilizations. We aimed at deciphering the impact of CeO<sub>2</sub> NPs and MWCNTs on primary human bronchial epithelial cells (BEC) following an ex-vivo exposure. CeO<sub>2</sub> NPs and MWCNT suspensions were thoroughly characterized, including using transmission electron microscopy (TEM), dynamic light scattering (DLS), and zeta potential analysis. Cells were then exposed to nanomaterials for 18 - 24 hours and mechanisms of cell injury were studied. TEM revealed that both CeO<sub>2</sub> NPs and MWCNTs are internalized by bronchial epithelial cells and are found either in vesicles or free in the cytoplasm. CeO<sub>2</sub> NPs fail to elicit a toxic response in BECs at environmentally relevant doses. However, diesel exhaust particles and CeO<sub>2</sub> NPs co-exposure leads to significant increase in cytotoxicity. MWCNT exposure in bronchial epithelial cells leads to a time-dependent decrease in viability, increased reactive oxygen species production, NF-κB (p65)/Rel A phosphorylation and nuclear translocation. Moreover, we observed caspase-1 activation and increased numbers of autophagic vesicles in MWCNT-treated cells as compared to control cells. An increase in p62 levels indicated a blockage of autophagic turnover rather than autophagy induction in these cells which was associated with cytoskeletal alterations induced by MWCNT. In conclusion we demonstrate that nanomaterials exposure leads to

toxic events in primary human bronchial cells. Moreover, we show that doses of CeO<sub>2</sub> NPs and diesel exhaust particles that are innocuous in themselves can result in toxicity when given as a co-exposure.

## PL 818 Inflammatory and Free Radical Generation Characteristics of Nano-Cerium Dioxide.

V. C. Minarchick<sup>1</sup>, D. W. Porter<sup>2</sup>, N. R. Fix<sup>2</sup>, S. S. Leonard<sup>2</sup>, E. M. Sabolsky<sup>3</sup> and T. R. Nurkiewicz<sup>1</sup>. <sup>1</sup>Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV; <sup>2</sup>National Institute for Occupational Safety and Health, Morgantown, WV; <sup>3</sup>Mechanical Engineering, West Virginia University, Morgantown, WV.

Nano-cerium dioxide (CeO<sub>2</sub>) possesses the potential for use in human health by protecting against the deleterious effects of ischemia and radiation. However, the literature is polarized about the effects this compound has *in vivo*. Our laboratory has shown that pulmonary nano-CeO<sub>2</sub> impairs arteriolar reactivity 24 hrs post-exposure. The mechanisms of this impairment are currently unknown but may be linked to the free radical scavenging or inflammatory properties of this nanoparticle. The aims of this study were to: 1) thoroughly assess the physical and chemical characteristics of the nano-CeO<sub>2</sub>, 2) examine the antioxidant potential of nano-CeO<sub>2</sub> via electron spin resonance (ESR), and 3) assess the pulmonary inflammation in Sprague-Dawley rats 24 hrs post-intratracheal nano-CeO<sub>2</sub> instillation. The primary particle size of the nano-CeO<sub>2</sub> was calculated to ~3 nm (via transmission electron microscopy and surface area measurements). Dynamic light scattering determined the agglomerate size (~80 nm) and x-ray photoelectron spectroscopy determined the valence state of the nano-CeO<sub>2</sub>. The ESR measurements indicated that nano-CeO<sub>2</sub> alone did not generate free radicals and in the presence of cells (Raw264.7), nano-CeO<sub>2</sub> quenched the free radicals generated by these cells. Finally, bronchial alveolar lavage from rats instilled with 0, 10, 100 or 400 µg of nano-CeO<sub>2</sub> revealed an increase in polymorphonuclear leukocytes (0.6±0.2, 0.8±0.3, 7.1±0.9, and 10.3±0.9 per 106 cells), and lactate dehydrogenase (90±12, 100±9, 453±33, and 602±32 units/L) but there was no change in albumin. These findings provide evidence that pulmonary inflammation is present after exposure but does not damage to the epithelial/endothelial cellular barrier. Additionally, these nanoparticles are capable of quenching free radicals there by exerting a systemic effect.

NIH-RO1-ES015022 and RC1-ES018274 (TRN), and NSF-1003907 (VCM)

## PL 819 Nanoceria Distribution and Biopersistence in Rats Is Not Consistently Affected by Particle Size, Shape, Dose, or Dosing Schedule.

R. A. Yokel<sup>1,2</sup>, R. C. MacPhail<sup>5</sup>, J. M. Unrine<sup>3</sup>, P. Wu<sup>4</sup> and E. A. Grulke<sup>4</sup>. <sup>1</sup>Pharmaceutical Sciences, University of Kentucky, Lexington, KY; <sup>2</sup>Graduate Center for Toxicology, University of Kentucky, Lexington, KY; <sup>3</sup>Plant and Soil Sciences, University of Kentucky, Lexington, KY; <sup>4</sup>Chemical and Materials Engineering, University of Kentucky, Lexington, KY; <sup>5</sup>Toxicology Assessment Division, US EPA, Research Triangle Park, NC.

Background: Nanoceria is a diesel fuel additive, an abrasive in integrated circuit fabrication, and is being developed as an antioxidant therapeutic. Objectives: Determine the influence of nanoceria size, shape, dose, and dosing schedule on its distribution and biopersistence. Methods: Aqueous dispersions of citrate-stabilized cubic or polyhedral ceria and a ceria nanorod (10 x 40 to 600 nm), synthesized and characterized in-house, were iv infused into rats (single infusion of 5 nm @ 11, 56 or 85 mg/kg, 15 nm @ 70 mg/kg, 30 nm @ 6 or 85 mg/kg, 55 nm @ 50 mg/kg, nanorod @ 20 or 50 mg/kg; and 5 nm @ 11 mg/kg for 5 consecutive days). They were terminated 1 h to 90 days later. Controls received vehicle. Multiple organs were weighed and samples collected from multiple sites and blood for cerium determination. Results: The greatest % of the dose was in the liver, spleen and bone marrow; these levels decreased over time only in liver for the 30 nm ceria @ 6 mg/kg, and increased in spleen and bone marrow over time in several cases. There were no consistently significant differences in the % of the dose in the liver or spleen for the different sizes, shapes, doses, or dosing schedules other than tendencies for more nanorod accumulation in the spleen than the 5 nm polyhedral ceria and more nanorod accumulation in the bone marrow than the 5 or 30 nm ceria. Brain nanoceria was low; little to none was in brain parenchyma. Conclusions: Nanoceria, an insoluble metal oxide, was cleared into mononuclear phagocyte system organs in which it persisted for 90 days. Size, shape, dose, and dosing schedule had little effect on its distribution or persistence, suggesting repeated exposure will likely produce accumulation, perhaps reaching a level shown to be toxic after single high-dose administration. Support: US EPA STAR Grant RD-833772.

**PL 820 Metal Oxide Nanoparticles Alter Spontaneous Activity and Pharmacological Responses in Neuronal Networks Grown on Microelectrode Arrays.**

J. D. Strickland<sup>3,2</sup>, W. R. LeFev<sup>1</sup>, K. Dreher<sup>2</sup> and T. J. Shafer<sup>1</sup>. <sup>1</sup>IISTD, ORD, US EPA, Research Triangle Park, NC; <sup>2</sup>EPHD, ORD, US EPA, Research Triangle Park, NC; <sup>3</sup>North Carolina State University, Raleigh, NC.

The widespread use of engineered nanoparticles (NP) has increased their exposure potential and made it necessary to assess potential impacts on human health. Previous studies indicate that NPs can enter the brain via the olfactory nerve or by crossing the blood-brain barrier; thus, it is essential that their effects on neuronal function be examined. In the present study, 5 CeO<sub>2</sub> (7 to 1288 nm), and 4 TiO<sub>2</sub> (6 to 200 nm) NPs were examined to determine their ability to alter network function in primary cultures of cortical neurons grown on 12 well microelectrode array (MEAs) plates. NPs were dispersed in Neurobasal A medium containing 20% FBS (dispersant). Between days 14 to 21 in vitro, 1 hr of baseline activity was recorded prior to exposure to NPs. Changes in spontaneous mean firing rate (MFR) relative to the dispersant control were assessed 1, 24, and 48 hrs after exposure to NPs (3–50 µg/ml). Following the 48 hr recording, the response to a pharmacological challenge with the GABA<sub>A</sub> antagonist bicuculline (BIC; 25 µM) was assessed. In all, 3 of 5 CeO<sub>2</sub>, and 2 of 4 TiO<sub>2</sub> NPs decreased MFR below threshold following 1 hr exposure. All 4 TiO<sub>2</sub> NPs altered MFR beyond threshold at 24 hrs. At 48 hr, the MFR for all 9 NPs deviated from minimum threshold. BIC increased MFR in dispersant treated networks; of the 9 NPs tested, 3 TiO<sub>2</sub> particles and 1288 nm CeO<sub>2</sub> increased the BIC response in MFR, while <7 nm CeO<sub>2</sub> suppressed the BIC-induced change in MFR relative to control. Most notably, the results show that changes in network function occur in the absence of cytotoxicity and were observed at all time points regardless of particle type. The results indicate that metal oxide NPs can disrupt both spontaneous and GABA<sub>A</sub> receptor-mediated neuronal activity in vitro. Additional studies are necessary to investigate the mechanisms underlying these observations and understand the implications of NP exposure to neuronal function in vivo. (This abstract does not reflect Agency Policy.)

**S 821 Systems and Computational Biology As Foundations for Toxicology Research.**

L. D. Lehman-McKeeman. Bristol-Myers Squibb Company, Princeton, NJ.

Systems and computational approaches are holistic methods to elucidate and understand the complex interactions among components of a biologic response network and are central to the comprehensive understanding of all biological processes. The field requires the integration of concepts from biology and physiology, computer science and applied mathematics, as well as physics and engineering. Toxicology is also a multidisciplinary science and application of systems and computational approaches can aid in unraveling the dynamic and complex nature of toxic responses. In light of the broad utility of systems biology approaches to toxicology and risk assessment, the goal of this session is to feature eminent scientists who have made seminal contributions and advances in systems and computational biology. The broad areas to be addressed include:

- general concepts of systems biology tools including network mapping and statistical challenges in assuring the validity of network analyses along with the newest tools and approaches for gaining insight into the regulation and function of complex systems;
- applications of systems biology approaches to studying fundamental biological responses such as cell signaling and kinase networks;
- perspectives on the application of systems networks to biomedical research and particularly for studying disease etiology and prevention;
- computational strategies that inform the prediction of pharmacologic and toxicologic responses including the prediction of adverse drug reactions; and,
- novel applications of machine learning and cell imaging to evaluate subcellular organization and function that inform hypothesis testing and translational details that may be useful in drug development.

**S 822 Turning Protein Networks into Gene Ontologies.**

T. Ideker. Department of Medicine, University of California San Diego, La Jolla, CA. Sponsor: L. Lehman-McKeeman.

Ontologies have been very useful for capturing knowledge as a hierarchy of concepts and their interrelationships. In biology, a prime challenge has been to develop ontologies of gene function given only partial biological knowledge and inconsistency in how this knowledge is curated by experts. I will present a method by which large networks of gene and protein interaction, as are being mapped systematically for many species, can be transformed to assemble an ontology with equivalent cov-

erage and power to the manually-curated Gene Ontology (GO). The network-extracted ontology contains 4,123 biological concepts and 5,766 relations, capturing the majority of known cellular components as well as many additional concepts, triggering subsequent updates to GO. Using genetic interaction profiling we provide further support for novel concepts related to protein trafficking, including a link between Nnf2 and YEL043W. This work enables a shift from using ontologies to evaluate data to using data to construct and evaluate ontologies.

**S 823 Network2Canvas: Network Visualization on a Canvas with Enrichment Analysis.**

A. Ma'ayan. Department of Pharmacology and Systems Therapeutics, Mount Sinai School of Medicine, New York, NY. Sponsor: L. Lehman-McKeeman.

Networks are vital to computational systems biology research, but visualizing them can be a challenge. For networks larger than ~100 nodes and ~200 links, ball-and-stick diagrams fail to convey much information. To address this, we developed Network2Canvas (N2C), a web application that provides an alternative way to view networks. N2C visualizes network nodes by placing them on a square toroidal grid. These nodes are then clustered together on the grid using simulated annealing to maximize local connections. For visualizing the canvas, a node's brightness is made proportional to its local fitness; the brighter a node is, the stronger its connections to its neighbors. The grid is interactive, implemented in HTML5 and the Java Script library D3. We applied N2C to create canvases for 25 gene-gene functional association networks connecting human and mouse genes, and six drug-drug networks connecting FDA approved drugs based on their shared properties. N2C also has functions to perform enrichment analysis. Given lists of genes or drugs, N2C highlights enriched terms on the grid as well as computes the degree of clustering for these enriched nodes. We applied N2C to analyze nine cancer cell lines by comparing their enrichment signatures to enrichment signatures of matched normal tissues. Such analysis provides a global visualization of critical differences between normal tissues and cancer cell lines. In particular, we observed a common pattern of up regulation of the polycomb group and enrichment for the histone mark H3K27me3 in many of cancer cell lines. In summary, N2C provides a new flexible method to visualize large networks and to perform and visualize enrichment analysis on functional drug and gene networks. N2C is freely available at <http://www.maayanlab.net/N2C>

**S 824 Computational Approaches to Predicting Adverse Drug Reactions and Mitigating Off-Target Liabilities in Early-Stage Drug Discovery.**

L. Urban<sup>1</sup>, S. Whitebread<sup>1</sup>, E. Lounkine<sup>1</sup> and P. Müller<sup>2</sup>. <sup>1</sup>Center for Proteomic Chemistry, Novartis Institutes for Biomedical Research, Cambridge, MA; <sup>2</sup>Preclinical Safety, Novartis Institutes for Biomedical Research, Cambridge, MA.

Identifying unintended off-targets associated with adverse drug reactions (ADRs) is daunting by empirical methods alone. Many of these are unrelated to the therapeutic target and it would need hundreds of assays to reveal their involvement in clinical side effects. However, latest development in *in vitro* assay technologies, tools for pharmacovigilance, and establishment of clinical data warehouses laid the foundation for the development of computational strategies to predict side-effect targets and even their associations with pathways and complex biological systems. However, many of the early methods focused on cheminformatic aspects of lead optimization with little attention for translational value, not to mention the safety aspects of the chemical structures and individual molecules. Introduction of several theoretical methods to explore drug-target-adverse reactions changed the landscape of safety assessment and the translational value of these new methods has been increasing significantly. The methods could be characterized as statistical models, expert or rule-based systems, quantum mechanics calculations, and structure based approaches. Data used by these models are largely generated in *in vitro* assays and obtained from clinical observations. Novartis, in collaboration with UCSF and SeaChange has conducted a large-scale experimental test of the SEA method to predict drug activities on targets linked to ADRs, and a guilt-by-association method to associate that activity with side-effects and provided evidence that a drug-target-ADR network approach could have wide application to de-risking toxicological liabilities in drug discovery. In this presentation, we will highlight the various methods and applications developed for early risk assessment, and provide insight of their practical applications.

## **S** 825 **Image-Derived Models of Subcellular Organization and Perturbation.**

R. F. Murphy. *Biological Sciences, Carnegie Mellon University, Pittsburgh, PA.*  
Sponsor: L. Lehman-McKeeman.

Because of their complexity, cutting-edge machine-learning methods will be critical for building systems models of cell and tissue behavior and for future drug development. Such models require accurate information about the subcellular distributions of proteins, RNAs and other macromolecules in order to be able to capture and simulate their spatiotemporal dynamics. Unfortunately, information with sufficient resolution and for different cell and tissue types is currently very limited. Microscope images provide the best source of this information, and new tools are being developed to build models of cell organization directly from such images. The number of possible experiments needed is prohibitive, but active machine learning methods can be used to help choose which experiments are needed in order to construct sufficient models of how cell organization changes with cell type and with disease. In order to use these models for drug development, information on how thousands of cell components respond to millions of potential therapeutics is also needed in order to minimize toxicity. Active-learning methods can also guide experimentation to overcome the dimensionality of this problem.

## **S** 826 **From Inhaled Particles to Cardiovascular Disease and Toxicity: Evidence from Studies in Volunteers, Experimental Animals, and Cell-Based Systems.**

F. R. Cassee<sup>1</sup> and H. Kipen<sup>2</sup>. <sup>1</sup>*Centre for Environmental Health Research (MGO), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands;* <sup>2</sup>*Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

The adverse effects of air pollution on cardiovascular health have been established in a series of major observational studies. Even brief exposures to air pollution have been associated with marked increases in cardiovascular morbidity and deaths from myocardial ischemia, arrhythmia, and heart failure. The breadth, strength, and consistency of the evidence provide a compelling argument that air pollution, especially traffic-derived pollution, causes cardiovascular disease. However, these observational data are limited by imprecision in the measurement of pollution exposure, and the potential for environmental and social factors to confound these apparent associations. For a causal association to have scientific credence, a clear mechanism must be defined. What are the potential pathways through which air pollution mediates these adverse cardiovascular effects and diseases? And are the effects caused by the nano-sized particles? This session will focus on the underlying biological mechanisms of complex particle mixtures.

## **S** 827 **Acute Increases in Exhaled Breath Condensate No Metabolites Suggests Oxidative Stress As a Mechanism for the Health Effects of Traffic-Related Pollutants.**

H. Kipen<sup>1</sup>, R. J. Laumbach<sup>1</sup> and A. J. Gow<sup>2</sup>. <sup>1</sup>*Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ;* <sup>2</sup>*School of Pharmacy, Rutgers University, Newark, NJ.*

Explication of a mechanism lends substantial scientific credence to epidemiologic associations. For example, there are strong epidemiologic associations between increases in air pollution, specifically traffic-related air pollution, and adverse cardiopulmonary outcomes, but our understanding of explanatory mechanistic pathways is incomplete. What are the potential pathways through which air pollution mediates these adverse cardiopulmonary effects? This presentation will focus on some of the underlying biological mechanisms. One specifically hypothesized mechanism is acutely increased oxidative stress/inflammation in the airways, as reflected in exhaled breath condensate (EBC) nitrite and nitrate in human subjects. Nitric oxide (NO) is formed in the lung epithelium from activities of all three NO synthases, and may then diffuse into the airway lining fluid where it is subject to oxidation to nitrite and nitrate by multiple pathways. Data showing an increase in exhaled breath condensate nitrite and nitrate following either controlled diesel exhaust inhalation or acute highway traffic exposure will be reviewed. Multiple oxidative pathways for the acute increases in EBC nitrite will be discussed, along with implications for generation of cardiopulmonary effects.

## **S** 828 **Health Effects from Traffic Particles and Noise in Road Workers.**

M. Riediker<sup>1</sup>, R. Meier<sup>1</sup>, A. Ghio<sup>4</sup>, F. R. Cassee<sup>2</sup> and W. Cascio<sup>3</sup>. <sup>1</sup>*Department Workers' Health, Institute for Occupational Health Sciences, Lausanne, Switzerland;* <sup>2</sup>*Centre for Environmental Health Research (MGO), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands;* <sup>3</sup>*Environmental Public Health Division, US EPA, Research Triangle Park, NC;* <sup>4</sup>*Human Studies Division, US EPA, Research Triangle Park, NC.*

Fine particulate matter (PM<sub>2.5</sub>), gaseous co-pollutant, and noise exposure were assessed in panels of workers that spend most of their professional activities on or near roads. To quantify workers' exposure and related short term health effects, up until now, we observed 13 road maintenance workers, each over 5 non-consecutive work days. We used a methodology based on personal and work site measurements to assess the workers' exposure to particles, noise and co-pollutants. For examination of personal exposures during and after work, the workers were equipped with a personal particulate monitor (PM<sub>2.5</sub>) and a noise dosimeter. Additional exposure parameters measured at the work site provided a detailed evaluation of exposure during work. These included ultrafine particle counts, measurement of carbon monoxide, nitrogen dioxide and ozone as well as PM sampling for compositional analysis. Cardiovascular health endpoints were assessed before, during and 15 hours post work shift. These included a continuous ECG from before until 15 hours post work, measurement of blood pressure and lung function before and 15 hours post work as well as measurement of exhaled nitric oxide and blood markers 15 hours post work shift. Noise levels are generally high with extreme levels during certain activities. Mean work shift PM<sub>2.5</sub> Mass concentrations ranged from 17.0 µg/m<sup>3</sup> to 321.0 µg/m<sup>3</sup> (mean 56.8 µg/m<sup>3</sup>) and UFP counts were between 15,538 particles/cm<sup>3</sup> and 408,518 particles/cm<sup>3</sup> (70,721 particles/cm<sup>3</sup>). Results suggest that PM<sub>2.5</sub> induces cardiovascular effects and inflammation. PM<sub>2.5</sub> and noise were only weakly correlated, allowing further assessment of these associations.

## **S** 829 **Air Pollution Is Associated with Chronic Progression of Cardiovascular Disease.**

A. K. Lund. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Traffic-generated pollutant-exposures appear to have a strong correlation to these adverse vascular outcomes, as shown through roadway proximity studies. Controlled toxicological studies highlight potential interactions between vehicle-source emissions and upregulation of signaling molecules associated with progression of atherosclerosis. Mechanistically, a role for both innate and adaptive immune responses is emerging, with important recent findings demonstrating that receptors such as the lectin-like oxidized LDL receptor (LOX)-1 may play a role in communicating airway exposures to cardiovascular outcomes. Using a mixed vehicle emission (MVE: gasoline and diesel engine, 100 PM µg/m<sup>3</sup>) model we show that atherosclerotic Apolipoprotein E null (ApoE<sup>-/-</sup>) exhibit increased oxidized LDL, associated with proinflammatory responses and lipid accumulation, as well increased vascular LOX-1 expression, when exposed by inhalation 6 h/d for 7 days, compared to filtered air-exposed controls. Furthermore, we observe a significant upregulation of vascular factors downstream of the LOX-1 receptor that are associated with atherogenic plaque growth and rupture, including reactive oxygen species, endothelin (ET)-1 and matrix metalloproteinase (MMP)-9 in MVE-exposed Apo E<sup>-/-</sup> mice, expression of which are attenuated with anti-LOX-1 antibody treatment. These data indicate that vascular effects of inhalation exposure to traffic-generated pollutants, resulting in progression of atherosclerosis and onset of clinical cardiovascular events, may be mediated through scavenger receptor ligand binding, internalization, and downstream signaling pathways.

## **S** 830 **Effects on the Vascular System of Source-Specific Particles.**

M. E. Gerlofs-Nijland<sup>1</sup>, F. R. Cassee<sup>1,2</sup>, M. Steenhof<sup>1,2</sup>, M. Strak<sup>1,2</sup> and N. A. Janssen<sup>1</sup>. <sup>1</sup>*Centre for Environmental Health Research (MGO), National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands;* <sup>2</sup>*Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands.*

Oxidative potential as a metric to predict source specific cardiovascular toxicity? Presentation Description: Much attention has been paid to the role of tail pipe emissions on pulmonary and cardiovascular toxicity. Although the focus in the past few years has been on diesel engine exhaust, PM is emitted from other non-exhaust sources like brakes as well. Some sources have shown to have a much higher oxidative potential compared to diesel soot. Oxidative stress has been suggested as a key aspect leading to cardiovascular toxicity and worsening of diseases. It is therefore very important to measure oxidative stress to check on the health status. A simple

metric for oxidative stress in vivo could be the oxidative potential of particles indicating the possibility of PM to produce oxygen radicals and cause damage in vivo. The focus of this presentation will be on the oxidative potential of PM from different sources as a measure to predict source specific cardiovascular toxicity in vivo. Systemic effects in rats exposed for 4-weeks to diesel engine exhaust occurred including decreased numbers of white blood cells and reduced von Willebrand factor protein in the circulation. In addition, lung tissue factor activity is reduced in conjunction with reduced lung tissue thrombin generation. We have also shown in studies in which volunteers were exposed to air pollution at various locations dominated by different sources of emission that organic carbon, nitrate and sulfate to be most consistently linked with different biomarkers (e.g. high-sensitivity C-reactive protein, fibrinogen, von Willebrand factor and plasminogen activator inhibitor-1) of acute cardiovascular risk. Associations for PM mass concentrations and OP were less consistent, while other measured components of the air pollution

### **S 831 Diesel Exhaust: The Many Ways That Nanoparticles Can Impair Cardiovascular Health.**

M. Miller, J. P. Langrish, N. L. Mills, K. Donaldson, P. W. Hadoke and D. E. Newby. *Centre for Cardiovascular Sciences, University of Edinburgh, Edinburgh, United Kingdom.* Sponsor: F. Cassee.

The detrimental effects of air pollution on the cardiovascular system are now well established, however, the mechanisms underlying these effects remain to be determined. Using diesel exhaust as an example of a common air pollutant, rich in combustion-derived nanoparticles, this presentation will give an overview of the multiple ways urban air pollution can alter cardiovascular function. Studies in both animals and man have demonstrated that this pollutant impairs vascular function, promotes thrombosis, exacerbates cardiac ischemia and accelerates the development of atherosclerosis. The presentation will focus on preclinical experiments with diesel exhaust particulate (DEP) that provide insight into potential mechanisms for these effects, including oxidative stress, endothelial dysfunction, inflammation, particle translocation, as well as considering with constituents of DEP may be responsible for these harmful effects.

### **S 832 The Dynamics of Neuroinflammation and Inflammatory Cell Responses in Neurologic Disease.**

G. J. Harry<sup>1</sup> and C. P. Curran<sup>2</sup>. <sup>1</sup>*NTP Laboratory, NIEHS, Research Triangle Park, NC;* <sup>2</sup>*Northern Kentucky University, Highland Heights, KY.*

An increasing body of evidence indicates that neuroinflammation and activation of immune cells within the nervous system are associated with neurodegenerative disease, neurodevelopmental disorders, and potentially in reaction to environmental exposures. However, it is also increasingly obvious that these responses may be beneficial or detrimental, and discriminating between these has only recently been addressed. Understanding the process by which these responses are triggered and the spatiotemporal dynamics of the response is critical to developing a strategy for translating neuroinflammatory and immune response to effective prevention or treatment of neurologic disease/injury. Three well-known neurotoxins: trimethyltin, manganese, and mercury will be used as chemical probes to explore differences in the timing of inflammatory effects and consequences in the brain. We will conclude by discussing approaches to manipulate the lesion microenvironment and/or brain macrophage such that inflammation favors tissue repair in the spinal cord.

### **S 833 Microglia Heterogeneity in Neuroinflammation and Neurotoxicity.**

G. J. Harry. *NTP Laboratory, NIEHS, Research Triangle Park, NC.* Sponsor: C. Curran.

Microglia cells are the resident immune cells of the brain; however, they are also critical neural specific cells with multiple roles. The response of microglia has been associated with environmental exposures and is present in diagnosed neurodegenerative disease. In many cases, what is considered a microglia response is often a brain macrophage response that can be derived from both resident microglia and infiltrating blood-borne monocytes. In order to better understand the resident microglia response, data will be presented from a delayed neuronal death model following trimethyltin intoxication. This compound induces death of the dentate granule neurons across multiple species and is accompanied by a robust microglia response and elevation in pro-inflammatory cytokines. The process is tightly regulated and with the phagocytic clearance of the neuronal debris, the system actively

undertakes repair. Using this model of resident microglia activation, the dynamic sequence of events will be described that characterize the microglia response within areas of neuronal death, synaptic loss, and neuronal activity. Using this model we are able to identify the various functions of microglia and potentially identify a profile of molecular and morphological responses that will identify the different functions of the microglia. This will serve to identify those processes of microglia that need to be fostered and those that need to be mitigated by therapeutic intervention.

### **S 834 Neuroinflammation and Developmental Vulnerability to Manganese.**

R. B. Tjalkens<sup>1,2</sup>. <sup>1</sup>*Center for Environmental Medicine, Colorado State University, Fort Collins, CO;* <sup>2</sup>*Toxicology Section, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.*

There is increasing evidence that activation of microglia and astrocytes during development can influence susceptibility to neurodegeneration later in life. Environmental insults such as infectious agents, pesticides, and heavy metals have all been implicated in neuronal injury leading to increased activation of glial cells and development of chronic neuroinflammation. Exposure to elevated levels of the essential element manganese (Mn) causes a spectrum of neurochemical and neuropathologic changes that can culminate in irreversible neuronal injury in subcortical and cortical structures. Children are more vulnerable to Mn than adults and recent epidemiological evidence links high Mn in drinking water to cognitive and behavioral impairment. Mn neurotoxicity is associated with astrogliosis in the basal ganglia and studies conducted in our laboratory and others suggests that glial-derived inflammatory cytokines and nitric oxide (NO) influence the progression of neuronal injury. Increased expression of iNOS/NOS2 by activated glial cells in response to Mn results in nitrosative stress throughout the basal ganglia and enhanced apoptosis within selected populations of neurons in the globus pallidus and striatum. NOS2 is exclusively expressed in glia and produces high levels of NO, which forms highly reactive peroxynitrite anion (ONOO-) upon combining with superoxide, resulting in electrophilic nitration of cellular proteins that damages neurons. Peroxynitrite-mediated nitrosative stress is also implicated in a number of neurological disorders, including Alzheimer's and Parkinson's diseases. Inflammatory changes in glial cells may therefore be an important link between neurotoxic injury and persistent neurological dysfunction during aging.

### **S 835 Spontaneous and Mercury-Induced Antibodies to Brain Antigens Affect Fetal Brain Development.**

D. A. Lawrence<sup>1</sup>, Y. Zhang<sup>1</sup>, Y. Heo<sup>2</sup> and D. Gao<sup>1</sup>. <sup>1</sup>*Immunology, Wadsworth Center, Albany, NY;* <sup>2</sup>*Occupational Health, Catholic University of Daegu, Daegu, Republic of Korea.*

BTBR mice spontaneously develop a high level of serum IgG of which a proportion are antibodies (Abs) to brain antigens. These Abs enter the brain and are associated with expression of inflammatory cytokines, which are suggested to be related to presence of activated microglia and mast cells. The neurodevelopmental effects of BTBR mice are posited to be autoimmune due to elevated presence of activated CD4+ T cells driving Ab production, and the offspring have behaviors that resemble autism. IgG from BTBR mice intravenously injected into B6 pregnant dams caused offspring to have lowered social interactions; likewise, B6 embryos that are born from BTBR dams have lowered sociability. Changes in mitochondrial functions can alter these behavioral outcomes of BTBR mice, but the mechanisms remain unknown. Abs causing behavioral deficits is not a new finding, in that Abs induce neuropsychiatric syndromes in lupus-prone mice. Additionally, certain strains such as A.SW, which are sensitive to Hg-induced autoimmune responses, generate autoantibodies to brain antigens upon developmental exposure to HgCl<sub>2</sub> and have behavioral deficits as adults, and inflammatory cytokines in multiple brain regions are associated with the behavior changes; however, the HgCl<sub>2</sub>-induced effects are dependent on the genetics of the strain and sex of the developmentally exposed mice.

### **S 836 Manipulating Microglia and Macrophages to Promote Repair of Injured Spinal Cord.**

P. G. Popovich. *Department of Neuroscience, The Ohio State University, Columbus, OH.* Sponsor: C. Curran.

Following traumatic or ischemic/reperfusion injury to spinal cord or brain, macrophages derived from resident microglia and infiltrating blood monocytes accumulate in the affected area. Collectively, these cells exert diverse and conflicting effects on neurons and glia. Indeed, microglia/macrophages can cause neuronal cell death, axonal injury and demyelination but can also promote neuron survival, axon regeneration, remyelination and revascularization. Over the past few years, we have

used a number of strategies to manipulate resident and recruited macrophages in an effort to understand their seemingly paradoxical functions, specifically in the context of rodent models of traumatic spinal cord injury (SCI). Data will be presented showing that SCLelicits CNS macrophages with a distinct molecular phenotype, one that simultaneously favors cell killing and axon growth/regeneration. Newer data also will be presented to show that it is possible to manipulate the lesion microenvironment and/or the CNS macrophages such that the natural course of inflammation progresses to favor tissue repair without concomitant cell killing. In this context, preliminary applications of therapeutic gene transfer and bioengineering will be discussed. Supported by NIH-NINDS and The Craig H. Neilsen Foundation.

### **W 837 Advances in Carcinogenic Risk Assessment of Low-Level Genotoxic Impurities in Pharmaceuticals.**

W. W. Ku<sup>1</sup> and D. Jacobson Kram<sup>2</sup>. <sup>1</sup>*Nonclinical Drug Safety US, Boehringer Ingelheim Inc., Ridgefield, CT*; <sup>2</sup>*Center for Drug Evaluation and Research, US FDA, Silver Spring, MD.*

Pharmaceutical syntheses involve the use of reactive starting materials, intermediates, and reagents, some of which are known or potential genotoxicants and carcinogens. Therefore, genotoxic and potentially carcinogenic impurities may appear in the final drug product. Risk assessment approaches have focused on defining impurity limits which pose acceptable risk over a patient's duration of drug treatment. Over the past decade, regulatory guidances (EMA, US FDA draft) have been introduced. Drug-associated genotoxic impurities became an ICH guideline topic (M7) in 2009, and an Expert Working Group is currently developing a harmonized guideline. The ICH M7 effort presents an opportunity to review existing guidelines, evaluate new information and experiences since their introduction, and improve the integration of safety and quality aspects for detection, risk management and control. This workshop will provide a historical overview and introduce newer concepts to SOT members for discussion on several approaches being considered in M7. The workshop will cover the following topics along with case studies: (1) a brief overview of regulatory risk assessment approaches developed over the past decade and introduce current M7 concepts being considered; (2) review current *in silico* Q(SAR) and genotoxicity testing approaches to predict or identify hazards and qualify impurity risk; (3) introduce advances in the framework and rationale for applying less-than-lifetime acceptable risk limits during clinical development and marketing; (4) highlight differences in chemical space between pharmaceutical synthetic intermediates or impurities and that used to derive the original lifetime threshold of toxicological concern (TTC) limit, and its potential implications for risk characterization; and (5) review approaches for addressing risk of multiple genotoxic impurities in a drug product.

### **W 838 Genotoxic Impurities—Regulatory Advances in Risk Assessment Approaches.**

P. Kasper. *Federal Institute for Drugs and Medical Devices, Bonn, Germany.* Sponsor: W. Ku.

The control of impurities in drug substances/products is regulated by internationally harmonized guidelines (ICH Q3A/B). However, these documents lack any specific instructions on how to treat impurities with a genotoxic potential. This has led to considerable differences between regulatory authorities on what levels of daily intake of genotoxic impurities are acceptable and prompted the European Medicines Agency (EMA) to release a "Guideline on the Limits of Genotoxic Impurities" in 2007 followed by publication of a draft guidance by CDER/FDA in 2009. Several basic principles are common to both documents and are currently under discussion for further development in the ICH process.

Genotoxic impurities are defined as compounds that are DNA-reactive and have the potential to directly cause DNA damage when present at low levels leading to mutations and therefore, potentially causing cancer. Consequently, *in silico* prediction of DNA reactivity/mutagenicity and Ames mutagenicity testing are basically the recommended approaches for hazard identification. Since risk assessment based on such limited set of data is not feasible a generic "Threshold of Toxicological Concern" (TTC)-value of 1.5 µg/day corresponding to a 10<sup>-5</sup> lifetime risk of cancer is used as a pragmatic approach for control of impurities that are Ames-positive. Derived from linear extrapolation of rodent potency data from over 700 carcinogens and based on an accumulation of worst-case assumptions the TTC value is a very conservative and therefore sufficiently safe limit. Possible deviations from the default TTC approach are currently under discussion and include cases when more extensive and appropriate data for a proper assessment of potential risks are available, e.g., data from carcinogenicity studies with the impurity or mechanistic data providing evidence for a threshold. Also specific clinical aspects may justify an adjustment of accepted daily intake levels of mutagenic impurities, such as for instance treatment of life-threatening condition, short life expectancy of patients, or indications with less-than-lifetime exposure.

### **W 839 Advances in Mutagenic Impurity Hazard Assessment: Best Practices and Current Developments.**

K. Dobo. *Drug Safety Research and Development, Pfizer Global Research and Development, Groton, CT.* Sponsor: W. Ku.

For many years, pharmaceutical companies have been using *in silico* methods as a primary tool for the identification of mutagenic impurities or degradants in drug substances or products as recommended in the European Medicines Agency (EMA) guidance, as well as the CDER/FDA draft guidance. Although neither guideline provides specific recommendations on the conduct of *in silico* assessments, a recently published survey of industry practice showed that the *in silico* methods employed by 8 companies are highly similar. More importantly, the survey showed that *in silico* analysis alone or in conjunction with an expert evaluation provides a high degree of confidence that an impurity that is predicted non-mutagenic will produce a negative result in the Ames assay. Despite the encouraging survey results, there remain many specific points of concern which are currently being addressed by a European pharmaceutical industry (EFPIA) working group in collaboration with regulators. The working group intends to provide recommendations on the conduct of (Q)SAR assessments, which, if followed, would be considered sufficiently rigorous methodology. Although many pharmaceutical impurities can be confidently categorized as mutagenic or non-mutagenic based on *in silico* methodology alone, there are instances in which biological testing is necessary. The Ames assay is considered to be the most practical and appropriate test for the identification of directly DNA reactive substances that warrant TTC control. In most cases the outcome of this assay is sufficient to define and implement appropriate impurity control measures. However, on occasion (e.g. Ames positive degradant that can't be controlled to TTC limits) additional testing is necessary to further address the biological relevance and risk of Ames positive results. Case studies will be used to illustrate potential scenarios warranting additional testing and factors to take into consideration when deciding what studies to conduct.

### **W 840 Less Than Lifetime (LTL) Carcinogenic Risk Limits for Mutagenic Impurities during Clinical Development and in Marketed Products.**

L. Mueller. *Non-Clinical Drug Safety, F. Hoffmann-La Roche Ltd., Basel, Switzerland.*

Mueller et al have provided in 2006 a framework for the application of the threshold of toxicological concern concept to pharmaceuticals with introduction of a "staged TTC". In this staged approach, acceptable daily intake levels were defined for the clinical development phase of pharmaceuticals, i.e. for up to 1 year intake. In the meantime, this "staged concept" was also introduced into regulatory framework in the existing EU regulatory process on genotoxic impurities. In the ICH M7 group, the principle has been expanded based on the application of Haber's Rule relating concentration (or dose) and duration of exposure. According to a recent review by Felter et al. (2011), the majority of carcinogens are more potent in rodents if the same cumulative dose is given over a shorter period (e.g. three months) than a longer one (e.g. two years). Although the number of compounds tested in such scenarios is low and it is unclear if these data can be extrapolated to very low exposure scenarios, it was proposed to adjust the acceptable daily exposure to mutagenic carcinogens for shorter durations with an extra uncertainty factor in comparison to longer durations of intake. On the other hand, it was recognized that medication treatment durations are often less than lifetime and depend on many factors (indication, nature of disease being treated and late onset of disease in life). Hence, it appeared unreasonable to propose the lifetime TTC or 1.5 µg/day for mutagenic carcinogens in most marketed pharmaceuticals. In adopting this consideration, it is currently proposed to place clinical trials of longer duration (>1 year) and medical intervention schemes of shorter than 10 years into one category of "up to 10 years" with the assignment of an adjusted TTC of 10 µg/day. The presentation will include examples for such clinical trials and pharmaceuticals in use.

### **W 841 Many Potential Mutagens Used in Pharmaceutical Syntheses Are in Less Potent Classes Than the Carcinogens Used to Derive the TTC, Justifying Higher Levels without Increasing Risk.**

S. Galloway. *Merck Research Laboratories, West Point, PA.* Sponsor: W. Ku.

The TTC for mutagenic impurities was derived using several worst-case assumptions, and was based on the more potent carcinogens in the public databases. The TTC is needed only when insufficient information exists to estimate safe levels of a mutagen. Most reactive chemicals used in pharmaceutical syntheses are not in the categories of potent carcinogens on which the TTC was based (Delaney, Reg.Tox.

Pharm 49, 107-24, 2007), confirmed here by data from 12 companies and 602 "alerting" structures. Thus, for many synthetic intermediates with structural alerts for mutagenicity, higher daily intakes are appropriate without increased risk. Especially in early stages of pharmaceutical development the risks from exposure to potentially mutagenic impurities are negligible without imposing the default TTC for each. The most common classes are alkylating agents and aromatic amines. For alkyl halides, the relation between the complexity of the structure and carcinogenic potency is well established, (Brigo and Muller, in Teasdale, "Genotoxic Impurities", Wiley 2010) and justifies an acceptable daily intake for mono-functional alkyl halides 10 times the default TTC. Aromatic amines have a wide range of carcinogenic potencies, and we lack sufficient knowledge to define the likely potency of each new one. However the structural characteristics of the most potent carcinogens are well defined, so one can rule out that a new aromatic amine is a highly potent one. The "cohort of concern" (COC) was highlighted as so potent that even the default TTC did not provide sufficient control of exposure. The COC comprises aflatoxins and N-nitroso compounds, not usually relevant to pharmaceuticals, but also azoxy structures. The known alkyl azoxy compounds are thought to be mutagenic by forming carbocations and alkylating DNA. In pharmaceutical syntheses, aromatic azoxy groups are used, which cannot form the alkyl carbocation, so are not in the highly potent class and need not be excluded from the TTC/ADI approach.

#### **W 842 Addressing Risks of the Potential Presence of Multiple Genotoxic/Carcinogenic Impurities in Pharmaceuticals.**

J. Bercu. *Amgen Inc., Thousand Oaks, CA.*

There has been an evolution of risk assessment and regulatory guidance for multiple genotoxic/carcinogenic impurities in pharmaceuticals. While experiences from other relevant industries have been adapted to pharmaceutical impurities (e.g. food, environmental), there are also unique aspects applied to pharmaceutical process development. Scientific discussions have included application of a probabilistic risk assessment to low level genotoxic substances, impacts of structurally/mechanistic similar impurities versus non-similar impurities, and the risk of synergism/potentiation. The science has shaped regulatory guidance to ensure product quality and patient safety throughout development and in registered use. The European Medicines Agency (EMA) and US Food and Drug Administration (FDA) have developed guidances (USFDA is in draft) which include control of multiple genotoxic/carcinogenic impurities. The International Conference on Harmonization (ICH) is developing guidance (i.e., ICH M7) on DNA reactive (mutagenic) impurities. According to the ICH M7 concept paper, one of the issues to resolve is multiple impurities. Industry is developing strategies to implement these regulatory guidances. In conclusion, there are many challenges and issues to resolve, but the advancement of risk assessment for multiple genotoxic/carcinogenic impurities will best occur through science and regulatory guidance.

#### **W 843 Health Risks of Sodium (Salt) Intake: Too Much or Too Little?**

M. G. Soni<sup>1</sup> and P. M. Bolger<sup>2</sup>. <sup>1</sup>Soni & Associates Inc, Vero Beach, FL; <sup>2</sup>Charles Street, Annapolis, MD.

Public health advocates have been concerned for decades that Americans consume unhealthy amounts of dietary sodium. Recently, the Institute of Medicine (IOM) recommended a Tolerable Upper Intake Level of 2,300 mg sodium/day and an Adequate Intake of just 1,500 mg/day, based on risks of adverse health effects, particularly hypertension. However, the average sodium intake is estimated to be 3,500 mg/day. The risk for morbidity and mortality due to excessive or insufficient salt intake varies because of biochemical individuality. The available evidence from a wide variety of clinical trials shows a direct relation between salt intake and blood pressure. A recent meta-analysis suggests that salt reduction tended to increase levels of hormones (renin, aldosterone), cholesterol, and triglycerides, which are all thought to be risk factors for heart disease. It has been asserted that while the risks of consuming too much salt are real, the risks have been exaggerated for the general population, or that the studies done on the consumption of salt can be interpreted in many different ways. There have also been recent scientific debates upon whether "excess" sodium in our diet has any adverse effect at all on healthy individuals and whether the last 50 years of scientific research that strongly correlates salt intake and hypertension might just be a well intentioned misinterpretation of the scientific data. In an effort to broaden the understanding of the aforementioned issues pertaining to salt intake and risk, the following key aspects will be addressed in this session: (1) Health risks associated with sodium intake; (2) Should salts' GRAS status be modified? (3) Any unintended consequences of salt reduction. (4) Is there a sufficient evidence for salt reduction?

#### **W 844 Sodium Homeostasis and Cardiovascular Health.**

P. M. Bolger. *Charles Street, Annapolis, MD.*

Under normal circumstances the mammalian physiological system is a highly complex and exceedingly efficient homeostatic system for monitoring and regulating electrolyte levels throughout the human body. These essential mechanisms include neurological (e.g., pituitary function) and endocrinological (e.g., adrenal) components as well as various organs (e.g., kidneys) and are vital in maintaining a healthy cardiovascular system. In this regard, it is important to understand various homeostatic control systems for key electrolytes, with particular attention to the critical role of sodium in the maintenance of cellular function and cardiovascular health. The key sodium dependent mechanisms with particular emphasis on those that involve renal function also need attention. An integrative approach will be needed to demonstrate the multi-factorial and organ system functions that are involved in the overall systemic homeostatic system to regulate sodium status.

#### **W 845 Strategies to Reduce Sodium Intake in the United States.**

J. Henney. *College of Medicine, University of Cincinnati, Cincinnati, OH.* Sponsor: M. Soni.

Reducing sodium intake is a critical public health need for all Americans. In spite of nearly 40 years of voluntary effort to reduce sodium intake, Americans average daily intake of more than 3,400 mg. of sodium (approx. 1.5 teaspoons) exceeds the existing maximum intake level 2,300 mg/d (1 teaspoon of salt) established by the 2005 Dietary Guidelines for Americans. High sodium intake puts the population-young and old, male and female, and all ethnic groups at risk for hypertension, and subsequent cardiovascular and/or renal events. The study committee convened by the Institute of Medicine consulted many sources and was provided additional information and insight at its public meeting and through the committee's website. The committees recommendations were in three categories: Primary; Supporting and Interim. Primary Recommended Strategy: A coordinated approach to set mandatory standards for safe levels of sodium in food using existing FDA authorities to modify the Generally Recognized as Safe (GRAS) status of salt and other sodium containing compounds. Supporting strategies: A nationally organized campaign to educate the public about risks, healthy food choices and support for government, industry and consumer effort; Update nutrition labeling; Training for restaurant /food service operations; Purchasing specifications by large food purchasers; Enhanced monitoring; Research. Interim strategies: Food manufacturers and restaurant/food service operations voluntarily accelerate and broaden efforts; The food industry, government, professional and public health partners should work together to promote voluntary collaborations to reduce sodium in foods. The specific recommendations and rationale for each strategy will be discussed along with the actions taken since the release of the report.

#### **W 846 The Effects of Sodium Reduction on Blood Pressure, Hormones, Lipids, and Mortality.**

N. Graudal. *Department of Internal Medicine/Infectious Medicine/Rheumatology, Copenhagen University Hospital, Copenhagen, Denmark.* Sponsor: M. Soni.

The average normal salt (NaCl) intake in the world is about 9 g per day. The result of a meta-analysis of 167 intervention studies randomly allocating participants to a low salt diet or a normal salt diet indicates that the effect of a reduced salt intake of about 6 g on blood pressure is less than 1 mmHg in people with normal blood pressure and about 3 mmHg in people with hypertension. These effects were contrasted by significant increases in variables associated with a poor survival prognosis, such as renin, aldosterone, cholesterol and triglyceride. It is therefore not obvious that sodium reduction leads to health benefits. In agreement with this, population studies generally cannot confirm that people on low sodium diets have less morbidity or mortality than people on normal sodium diets, on the contrary these studies show a trend towards increased all cause mortality among individuals on low sodium diet.

#### **W 847 Unintended Consequences of Salt Reduction.**

M. Satin. *Science and Research, Salt Institute, Alexandria, VA.* Sponsor: M. Soni.

While there is considerable clinical evidence to indicate that substantial reductions in dietary sodium intake may result in single digit reductions in systolic blood pressure for salt-sensitive individuals, further evidence reveals that these same reductions may cause a significant increase in morbidity and mortality across a broad

range of the population. It is generally agreed that most of these negative health outcomes are a consequence of the increase in renin-angiotensin-aldosterone system activity that accompanies reductions in salt consumption. Other negative health outcomes may result from the changes in nutrient consumption patterns that accompany recommended salt reductions. The ideal level of sodium consumption for individuals will result from a rational balance of positive and negative health outcomes. As new research findings continue to emerge and concern over potential unintended consequences of restricting sodium intake grows, it is imperative to ensure that nutrition policies reflect the most current, robust and scientifically sound research.

#### **W 848 The Importance of Population-Wide Sodium Reduction As a Means to Prevent Cardiovascular Disease and Stroke.**

D. Arnett. *Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL.* Sponsor: M. Soni.

High blood pressure is one of the leading causes of preventable mortality and morbidity, worldwide. National health agencies and professional societies around the world recommend reduction in dietary sodium as a means to lower blood pressure and preventing CVD. The American Heart Association (AHA) recommends limiting daily sodium intake to less than 1,500 mg/d for all Americans. For the estimated one in three who will develop high blood pressure in their lifetime, a high-sodium diet may be to blame. Many consumers do not realize that sodium is ubiquitous in the environment and found in many unsuspecting foods at levels that are often unnecessary. Consequently, consumers continue to purchase foods that are relatively high in sodium and increase their risk of hypertension and related health risks. There is overwhelming scientific evidence that lowering sodium intake improves cardiovascular outcomes. Even a modest reduction in sodium intake is likely to result in substantial health benefits, especially when it is achieved in the general population. The AHA has undertaken an organizational approach to sodium reduction in the United States. The health risks associated with consuming too much sodium in the diet are clear and cannot be ignored.

#### **W 849 Unique Challenges in Biologic Drug Development: Separating Mechanism of Action from Mechanism of Toxicity.**

L. Andrews<sup>1</sup> and M. Todd<sup>2</sup>. <sup>1</sup>Genzyme, Framingham, MA; <sup>2</sup>Pfizer, La Jolla, CA.

A common safety concern of biotherapeutic agents is toxicity associated with mechanism of action (MoA). The term MoA refers to the specific biochemical interaction through which a drug substance produces its pharmacological effect. This workshop will address areas of significant impact to biotherapeutic drug development where there is a known disassociation of MoA and MoT in toxicity studies and/or in translation to the clinic. Most nonclinical toxicity studies are conducted in healthy animals which may not predict the effects of a biotherapeutic when used in the patients with specific diseases. The latest paradigms for using animal disease models, including study conduct and interpretation, will be explored. For many years, the likelihood of off-target toxicity was considered to be very low for most biotherapeutics. Data will be presented highlighting that off-target toxicity, particularly hematotoxicity, can occur and may be more prevalent than previously thought. Effort has also been put into better understanding the development and impact of antidrug antibodies (ADA) in nonclinical toxicity studies and their relevance to clinical ADA. In addition to impacting biotherapeutic drug exposure, ADA may also cause a variety of non-MoA associated toxicities including acute hypersensitivity, immune complex disease, and neutralization of the endogenous target. The incidence of ADA-associated toxicities has been increasing and the current understanding of these toxicities and their clinical relevance will be discussed.

#### **W 850 Introduction to the Mechanism of Action/Mechanism of Toxicity Challenges of Biotherapeutics.**

C. Grimaldi. *Boehringer Ingelheim, Ridgefield, CT.* Sponsor: L. Andrews.

Toxicities associated with biologics are often attributed to the mode of action (MoA). Mechanisms of toxicity (MoT) can be caused by "exaggerated pharmacology" which can occur as a direct effect of the biotherapeutic on the intended cell type or biochemical pathway, or as an indirect effect on unintended cell types or pathways. The extent of the pharmacologic response can be influenced by numerous factors including, but not limited to, biophysical properties of the biotherapeutic agent such as binding potency, effector function and immune stimulatory properties, drug dose and/or duration, tissue distribution of the target, perturbation of

signaling networks and disease state. Since the expected pharmacologic mode of action of biotherapeutics is usually understood, the mechanisms of toxicities may be predicted using relevant test systems. To this end, specialized pharmacologic endpoints are needed in addition to the conventional nonclinical safety assays for toxicity testing in animals. Important considerations to evaluate MoA/MoT include the use of alternative animal models, safety biomarkers, drug exposure and immunogenicity, impact of drug delivery routes and modalities, novel drug formats and the impact of process changes and engineering on drug safety. Challenges for nonclinical toxicity testing of biotherapeutics include how and when to incorporate "fit-for-purpose" investigational approaches, and importantly how to extrapolate in vitro and in vivo data to the clinical setting.

#### **W 851 Use of Animal Models of Disease in Safety Assessments of Biotherapeutics—Is This the Future?**

J. Cavanaugh. *Access Bio, Boyce, VA.*

A guiding principle in the design of preclinical safety studies is to parallel as closely as possible the clinical conditions of use and exposure. In accordance with this principle, much attention is paid to the dosing regimen with respect to route of administration, duration of treatment and dosing interval. With respect to mirroring the characteristics of the patient population to be exposed normal animals appropriately parallel the typical Phase I population in normal subjects (healthy volunteers). Where toxicologists deviate from the principle of correlation of clinical conditions of exposure is in the evaluation of potential toxicity in patients in the later safety and activity/efficacy clinical trials. The deviation from this principle relates primarily to the physiological state of the clinical populations involved as they are no longer healthy volunteers but rather individuals who either have a specific disease and/or are very ill. Therefore a relevant question for the toxicologist to ask is whether toxicology studies in "normal animals" adequately assess the risks in "sick people". The answer to this question has even greater significance for biopharmaceuticals when first in human (FIH) Phase I trials are conducted in subjects with disease for ethical and practical reasons. Thus animal models of disease are being used not only to establish preclinical POC but also to assess exaggerated pharmacology and toxicity in an attempt to improve relevance and extrapolation of results to the intended disease population.

#### **W 852 Antidrug Antibodies: Interpreting Toxicology Studies and Translating Nonclinical Findings to the Clinic.**

C. Horvath. *Genzyme, Framingham, MA.*

Animals frequently mount an anti-drug antibody (ADA) response to biological drugs during toxicology studies. In some cases ADAs have no effect on the product's behavior; while in others they may produce a variety of undesirable effects. ADAs may affect the pharmacodynamics, pharmacokinetic, bioavailability and efficacy of a test article. For example, enhanced clearance of a test article from the circulation by ADAs will affect exposure in a toxicology study. The production of ADAs can also result in potentially life-threatening adverse effects. A histamine mediated Type I hypersensitivity response can be experienced when dosing large foreign proteins into rodents. This response can often be mitigated by co-medicating with antihistamines, such as diphenhydramine, but can significantly affect the ability to conduct repeat dosing in rodent models. A Type III hypersensitivity reaction can lead to tissue injury, such as vasculitis, as a result of the formation of immune complexes. Additionally, the neutralization of an endogenous protein may occur when the ADA directed against the drug cross-reacts with an endogenous protein. The level and resulting toxic effects of an ADA response to a particular product can be different in various animal species and are not predictive from one species to another. In general, immunogenicity in animals does not predict immunogenicity in humans, however, caution must be taken when translating the relevancy of any ADA-mediated toxicity observed in an animal to human safety. It is important to consider the implications of ADAs when interpreting the results of a toxicity study and include a comprehensive investigation of potential ADA-mediated lesions to determine if they are solely related to the presence of ADAs or to the pharmacology of the target. The ramifications of nonclinical ADA-mediated toxicity on the clinic can range from additional clinical monitoring to product development termination.

#### **W 853 Unexpected Toxicities of Biotherapeutics on Peripheral Blood Cells.**

N. Evers. *Amgen, Seattle, WA.* Sponsor: L. Andrews.

Monoclonal antibodies and other biotherapeutics are an increasing proportion of drugs being developed by pharmaceutical companies. Unintended effects of biotherapeutics on peripheral blood cells may occur in nonclinical testing or only after

clinical trials or product launch. Nonclinical studies generally predict clinical hematotoxicity for recombinant cytokines and growth factors, but have not been predictive for the majority of biotherapeutics with clinical hematologic liabilities, especially those that are immune mediated and/or of low incidence. Hematotoxicities may be species-specific and affect one or multiple blood cell lineages. Mechanistically, hematotoxicity caused by monoclonal antibodies or other biotherapeutics can be directly related to the activity of the test article, or can be indirect generally due to immune-related events. Direct effects can be due to binding to the intended target or to an off-target molecule. Recently, several publications have demonstrated species-specific hematotoxicity due to off-target binding; these effects have been observed in both rats and NHPs. Indirect hematotoxicity is often due to autoimmunity, biological cascades, antidrug antibodies, or other immune system responses. Hematotoxicities due to biological cascades generally involve mediators of systemic inflammation, such as cytokines, complement, and immune complexes, and often are observed as acute post-dosing events. Platelets are particularly susceptible to effects of biotherapeutics, perhaps due to the high expression of activating FcRs. In vitro assays can be utilized to further investigate and understand the pathogenesis of unexpected effects of large molecules on blood cells. Characterizing the hematotoxicity (e.g. primary or secondary, relevance to humans, underlying mechanism, monitorability, etc) is important for risk assessment. Despite the potential for unexpected hematologic toxicity, the risk-benefit profile of most biotherapeutics is favorable; hematologic effects are readily monitorable and managed by dose modification, drug withdrawal and/or therapeutic intervention.

**PS 854 Effectopedia: The Online Encyclopedia and Graphical Editor for AOPs.**

A. Clippinger<sup>1</sup>, H. Aladjov<sup>2</sup> and G. Veith<sup>3</sup>. <sup>1</sup>*People for the Ethical Treatment of Animals, Norfolk, VA*; <sup>2</sup>*Institute of Biophysics and Biomedical Engineering, Bulgarian Academy of Sciences, Sofia, Bulgaria*; <sup>3</sup>*International QSAR Foundation, Two Harbors, MN*. Sponsor: K. Sullivan.

The 21st-Century shift to more prospective hazard identification and hypothesis generation requires greater strategic application of systems biology, QSAR and archived toxicological data in the form of adverse outcome pathways (AOPs). AOPs describe the causal linkages among biological responses to chemicals over time. The complexity of integrating science can be a barrier to progress in terms of the toxicity pathways and networks involved as well as the need to organize knowledge from many disciplines.

Effectopedia is an open-knowledge aggregation and collaboration tool for delineating AOPs in an encyclopedic and predictive manner. It includes discrete cause-effect studies and critical reviews that are relevant to toxicology. To achieve human and machine interpretability, Effectopedia uses an ontology-enhanced, natural language interface that offers clarifying questions and special tags to define the semantic knowledge while preserving the natural language description of the AOP's elements. The use of ontologies also allows Effectopedia contributors to publish their contributions as nanopublications.

Effectopedia serves as a graphical editor to delineate causal linkages at any level of biological organization and test species. It creates a common organizational space that (1) helps experts identify gaps in knowledge of causal linkages of biological responses and (2) acts as a web-based conference room for dialogue and synthesis by experts with interest in specific AOPs. Effectopedia's live documents are instantly open for focused discussions and feedback, whilst giving credit to original authors and reviewers. New contributions are immediately distributed to interested parties, keeping all information current and documented. Uncoupling the contribution and review processes also permits organizations to define their own seals of approval and associate them with special interest pathways without slowing down the Wiki-inspired stream of contributions.

**PS 855 Exposure Data Curation for Integration into the Comparative Toxicogenomics Database (CTD).**

C. G. Murphy, C. Mattingly and A. P. Davis. *Biology, North Carolina State University, Raleigh, NC.*

Toxicology research is rapidly transitioning from the observational study of adverse effects of chemical exposures on living organisms to a predictive science based on mechanistic understanding of chemical actions. Integration of exposure information into the network of interactions among chemicals, genes, diseases, and molecular pathways is essential to this transition. Therefore, we initiated a project to curate exposure data for inclusion into the publicly available Comparative Toxicogenomics Database (CTD; <http://ctdbase.org>). CTD is a manually curated database containing over 16 million toxicogenomic relationships of chemical-gene-disease interactions and Gene Ontology and pathway annotations that are integrated with analysis tools to promote understanding of the molecular mechanisms

underlying environmental diseases. Building on the community-based development of the ExO exposure ontology, (<http://ctdbase.org/downloads/#exposures>), biocurators manually curate four types of inter-related exposure data from the scientific literature: Exposure Stressor, Exposure Receptor, Exposure Event, and Exposure Outcome. Both controlled vocabulary and free text data fields are used to allow searches among variables, while retaining details specific to the exposure study. Inclusion of exposure information into CTD will create a centralized exposure data resource that will facilitate the identification of connections between real-world exposures, chemicals, genes, proteins, diseases, and molecular pathways. Here we describe our exposure curation paradigm, initial content, and vision for integration into CTD.

**PS 856 Expansion of Toxicity Reference Database (ToxRefDB) Study Data for In Vivo Phenotypic Modeling.**

K. W. McLaurin, S. Sneed, I. Thillainadarajah and M. T. Martin. *NCCT/ORD, US EPA, Durham, NC.*

The US EPA's Toxicity Reference Database (ToxRefDB) was originally populated with pesticide registration toxicity. ToxRefDB now incorporates guideline-like studies from the pharmaceutical industry, National Toxicology Program (NTP), and publicly available research literature. ToxRefDB now captures 5000 animal studies on 1000 chemicals and study data was captured using a standardized, multilayered effect vocabulary across varied study types and species. Seven predominant, data rich study type and species combinations were examined in this analysis: subchronic rat (590), chronic rat (590), chronic mouse (518), chronic dog (325), developmental rat (663), developmental rabbit (512), and multigenerational reproduction rat studies (504). While the majority of chemicals did not have complete toxicity study coverage, there was substantial overlap with study type and species combinations. Of 590 chemicals tested in chronic rat studies: 488 have been tested in chronic mouse studies, 416 in subchronic rat studies, 415 in developmental rat studies, 372 in developmental rabbit studies, and 373 multigenerational rat studies. Differences in key study parameters such as dosing duration, species, strain, and life-stage provided a heterogeneous view of chemical toxicity profiles while helping to gain evidence as common phenotypic outcomes arise. Across 382 chemicals with a subchronic and chronic rat study, 42% observed liver pathology in both (correlation = 0.486). The hierarchical effect vocabulary was mapped from study type and species combination to endpoint supercategory, category, subcategory, class, and subclass, down to effect type, target and description covering over 27000 effect possibilities. This multilayered vocabulary allows for comparison of effects occurring within a biological continuum creating a more effective comparison of hundreds of chemicals now captured by ToxRefDB.

This abstract does not necessarily reflect US EPA policy.

**PS 857 Application of US FDA, Center for Food Safety and Applied Nutrition's Knowledge-Base to Two Use Cases for Food Contact Substances: FCS Inventory Assessment by Read-Across and Prediction Models.**

K. Arvidson<sup>1</sup>, J. Aungst<sup>1</sup>, S. Boyer<sup>2</sup>, C. Hasselgren<sup>2</sup>, E. Matthews<sup>1</sup>, K. Muldoon-Jacobs<sup>1</sup>, A. McCarthy<sup>1</sup>, J. Rathman<sup>3</sup> and C. Yang<sup>3</sup>. <sup>1</sup>*US FDA, College Park, MD*; <sup>2</sup>*AstraZeneca R&D, Mölndal, Sweden*; <sup>3</sup>*Altamira LLC, Columbus, OH.*

The Chemical Evaluation and Risk Estimation System (CERES) project at FDA Center for Food Safety and Applied Nutrition delivers a foundation providing workflows for decision support activities for both pre-market and post-market safety assessments of food additives, food contact substances, and potential contaminants. CERES v1.0 is a data repository and platform for database searching and computational tools. The content includes chemical structures and properties, regulatory records, toxicity studies, and other biological screening assays. CERES is also an institutional knowledgebase where historical regulatory decisions on a given substance are found. The system also assists new decision-making processes in a systematic and consistent manner. In cases where no information is available for a particular substance, CERES provides tools to estimate the toxicity and to assist with other aspects of safety assessment. Two use cases of the CERES system are described in this presentation. One is the read-across process within the CERES system to estimate a carcinogenicity potential of a compound. The analog searching capability along with the supporting experimental data as well as genetic toxicity and carcinogenicity models based on mode-of-actions are employed. Various information types are combined using a weight-of-evidence (WOE) decision theory method. The second use case is a post-market analysis of all historical food-contact substances in the database of the Office of Food Additives Safety using the MOA (mode-of-action) QSAR models within CERES, e.g., genetic toxicity endpoints, carcinogenicity, and reproductive-developmental endpoints. In addition, a plan to connect CERES to other predictive methods to enhance the system will be discussed.

**PS 858 Flexible and Transparent Computational Workflows for the Prediction of Target Organ Toxicity.**

A. N. Richarz<sup>1</sup>, S. J. Enoch<sup>1</sup>, M. Hewitt<sup>1</sup>, J. C. Madden<sup>1</sup>, K. Przybylak<sup>1</sup>, C. Yang<sup>2</sup>, M. R. Berthold<sup>3</sup>, T. Meinl<sup>3</sup>, P. Ohl<sup>3</sup> and M. T. Cronin<sup>1</sup>. <sup>1</sup>*School of Pharmacy and Chemistry, Liverpool John Moores University, Liverpool, United Kingdom*; <sup>2</sup>*Altamira LLC, Columbus, OH*; <sup>3</sup>*KNIME.com AG, Zurich, Switzerland*.

In silico modeling of target organ toxicity has been held back in part by an inability to capture all relevant information into a meaningful reductionist approach. It has also been considered at times too simplistic, using data of often variable quality and seldom allowing the user to assess the relevance to the intended use. The purpose of this study was to develop a novel computational toxicology workflow system, to allow the users greater control and understanding of the target organ toxicity prediction. The workflows were built on the KNIME open-access platform which allows pipelining via a graphical user interface. Various building blocks, known as nodes, were incorporated, to access chemical inventories and/or databases, to profile structures and calculate properties and to report prediction results. The “basic” user sees a web-interface, whilst a “trained” user can go behind this to interrogate the nodes and, if required, link to additional data sources or investigate and update the models. The workflow was developed to address in particular the prediction of target organ toxicity of cosmetic ingredients. It comprises an inventory of over 4,400 unique chemical structures (cosmetic ingredients and related substances). The database contains repeat dose toxicity data for over 1,100 compounds including NOEL values. Thus, a user is able to search for similar compounds in the inventory file or database. The compound is then profiled using relevant structural alerts and chemotypes, currently comprising 108 alerts for protein reactivity, 85 for DNA binding, 32 for phospholipidosis and 16 for other liver toxicity endpoints. The workflows are flexible and transparent, they are successful in guiding a user through the process of making a prediction of target organ toxicity. Supported by the EU FP7 COSMOS Project.

**PS 859 Chemotypes: A New Structure Representation Standard for Incorporating Atom/Bond Properties into Structural Alerts for Toxicity Effects and Mechanisms.**

C. Yang<sup>1</sup>, K. Arvidson<sup>2</sup>, A. Detroyer<sup>3</sup>, J. Gasteiger<sup>4</sup>, J. Maruszczyk<sup>4</sup>, J. Rathman<sup>1</sup>, A. M. Richard<sup>5</sup>, S. Ringeissen<sup>3</sup>, C. Schwab<sup>4</sup>, A. Tarkhov<sup>4</sup> and A. Worth<sup>6</sup>. <sup>1</sup>*Altamira, LLC, Columbus, OH*; <sup>2</sup>*US FDA, College Park, MD*; <sup>3</sup>*L'Oréal, Aulnay S/S, France*; <sup>4</sup>*Molecular Networks, Erlangen, Germany*; <sup>5</sup>*US EPA, RPT, NC*; <sup>6</sup>*JRC, Ispra, Italy*.

The representation of structural moieties that carry biological activity information, historically referred to as structural alerts, has a long association with Structure Activity Relationships (SAR). Typically, structural knowledge development is performed only by experts and implemented using SMARTS or proprietary formats. With few exceptions, scientists have generally not been able to query structures with customized substructure rules. Furthermore, there are needs for standardized representations and the ability to encode attributes such as atomic and/or bond properties within structural constructs. Recent efforts to apply cheminformatics to systems-biology have called for innovation in this SAR area by integrating properties with structure connectivity. To this end, an XML-based representation of chemotypes has been developed to define substructures in which each atom and bond can be annotated with atomic, bond, and/or electronic properties, adhering to a controlled vocabulary, that go beyond the confines of conventional structural classes. These chemotypes have been implemented in a publicly free software application to enable search and data filtering. This chemotyper has been developed as part of a project from FDA's Center for Food Safety and Applied Nutrition to aid in updating FDA structure categories used by toxicology reviewers and to support the mode-of-action modeling (MOA) approach adopted in the Chemical Evaluation and Risk Estimation System. A series of chemotypes have been developed to incorporate SAR-informed annotations associated with phenotypic effects in hepatotoxicity and developmental morphology, as well as skin irritation and sensitization. These chemotypes enhanced accuracy of categorizations and MOA model predictions. This abstract does not necessarily reflect EPA policies.

**PS 860 In Silico Models of Sequence-Specific Mutagenicity: Exploring Chemical-Mutation Site Associations.**

A. Sedykh<sup>1</sup>, Y. Low<sup>1</sup>, S. Chakravarti<sup>2</sup>, R. Saiakhov<sup>2</sup> and A. Tropsha<sup>1</sup>. <sup>1</sup>*Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC*; <sup>2</sup>*MultiCASE, Beachwood, OH*.

The Ames Salmonella test for genotoxicity has undergone several transformations since its introduction in 1971. The initial strains, histidine-deficient mutants involving different mutation-prone DNA sequences, were designed to detect specific

frameshifts and base substitutions. Later, many strains with the same target sequence but improved antibiotic resistance, cellular permeability or impaired repair mechanisms were introduced as more sensitive alternatives. However, most existing Quantitative Structure-Activity Relationship (QSAR) models predict either mutagenicities in major strains or overall mutagenicity. We hypothesized that using additional sensitive strains can provide more refined models predicting sequence-specific mutations. Hence, we curated the Chemical Carcinogenesis Research Information System (CCRIS) database (n=6,545) and the CASE Ultra data set (n=5,438) to create a larger database of 6,967 molecules with fewer missing entries (42% vs 33-39% in original sources). Using mutagenicities reported either in the presence or absence of metabolizing enzymes, we built QSAR models for five sequence-specific mutation sites (hisD3052, hisD3018, hisD6610-hisO1242, hisG46 and hisC3076). These 10 models were compared with the previous strain-specific models in CASE Ultra. Sequence-specific models generally exhibited greater sensitivity (68-88%) and dataset coverage (88-98%) but lower specificity (51-72%). Conversely, previous strain-specific models, built on unbalanced data sets, exhibited high specificity (82-99%) but low sensitivity (17-82%). We have further analyzed the models in terms of statistically significant chemical fragments that were interpreted as structural alerts, highlighting the susceptibility of targeted DNA sequences to certain chemical features. For example, fluorenes, due to their planar structures, are good intercalators often associated with frameshifts in hisD3052. The curated data, models, and new structural alerts will be included in future releases of CASE Ultra.

**PS 861 ToxML: A Structured and Serialisable Exchange Standard for Toxicology.**

M. A. Ali<sup>1</sup>, M. L. Patel<sup>1</sup>, P. N. Judson<sup>2</sup> and D. R. Benz<sup>3</sup>. <sup>1</sup>*Lhasa Limited, Leeds, United Kingdom*; <sup>2</sup>*Judson Consulting Service, Harrogate, United Kingdom*; <sup>3</sup>*US FDA Center for Drug Evaluation and Research, Silver Spring, MD*.

The amount of toxicity data available for those wishing to share and communicate knowledge, or to use for data mining and modelling, is continually growing within the biomedical disciplines. The challenge with this expanding amount of data is that it exists in a multitude of different formats. ToxML is an open standard based on Extensible Markup Language (XML) that consists of an XML Schema (XSD) defining the toxicology schema and lists of controlled vocabulary that ensure consistency of usage. The use of XML means that the data can be created, stored and transported in a structured format that is not bound to a specific software application or programming language. The data file model resulting from this approach is very versatile and allows for the aggregation of experimental data up to the compound level in the detail needed to support areas such as quantitative structure-activity relationship (QSAR) development. ToxML formats have been developed, so far, for 27 toxicity study types. These cover both in vivo and in vitro, and currently include the following super toxicity endpoints: genetic toxicity, carcinogenicity, skin sensitisation, skin penetration, in vivo repeat dose toxicity, in vivo single dose toxicity and ecotoxicity.

Informatics groups at the FDA CDER-CFSAN use ToxML to populate repositories with the results of FDA toxicological and clinical data harvesting efforts, and employ the resulting information to model QSARs. We describe an example of how ToxML could be used as a practical data exchange standard for genetic toxicology information. The standard is maintained by a curation team overseen by the ToxML organisation. The standard is published on a web site ([www.toxml.org](http://www.toxml.org)) together with tools to view, edit and download it. Contributions from the user community to the ongoing evolution of the standard are facilitated in an open forum via a wiki on the web site.

**PS 862 ToxCast™ Workflow: High-Throughput Screening Assay Data Processing, Analysis and Management.**

P. G. Kothiyal<sup>1,2</sup>, M. T. Martin<sup>1</sup>, A. M. Frame<sup>1</sup>, A. M. Richard<sup>1</sup>, R. Judson<sup>1</sup> and D. Reif<sup>1</sup>. <sup>1</sup>*National Center for Computational Toxicology, Office of Research and Development, US EPA, Research Triangle Park, NC*; <sup>2</sup>*Bioinformatics Program, North Carolina State University, Raleigh, NC*.

USEPA's National Center for Computational Toxicology (NCCT) is developing the ToxCast program with the aim of providing high-quality screening data on thousands of chemicals. The huge library of compounds and wide diversity of high-throughput assays in ToxCast present daunting practical challenges with respect to data processing, analysis, and management with the goal of providing transparent and sustainable data outputs across these massive data sets. To successfully address these goals, the data analysis workflow was designed with 8 levels of processing from raw data to finalized hit calls and is distributed within two major portions of the workflow: “Pipeline” (levels 1-4) and “Curve fit” (levels 5-8). The pipeline portion takes incoming raw data files, performs automated chemical and assay mapping, provides plate/batch effect correction, and assay specific data normalization to supply highly consistent data formats for the curve fitting process. The curve-fitting

and hit-calling process consists of cytotoxicity-point and outlier detection/masking, concentration activity estimates using dose response modeling, systematic data confounder detection (e.g., fluorescence or non-specific activity). The finalized results are subsequently uploaded into ToxCastDB for data integration and analysis as well as to serve as the primary portal for publication and data release. In addition, the ToxCast workflow has data quality and error identification features quantifying assay performance and quality. The ToxCast data workflow has been systematically developed to efficiently address data management challenges, increase curve-fitting and hit-calling accuracy, and to allow for technology specific customization resulting in repeatable and transparent analyses. This work does not necessarily reflect Agency policy.

**PS 863 High-Throughput Electronic Literature Libraries (E-Libraries) to Support Development of Toxicity Prediction Models and Adverse Outcome Pathways (AOPs).**

N. C. Baker<sup>1</sup>, T. B. Knudsen<sup>2</sup> and K. M. Crofton<sup>2</sup>. <sup>1</sup>Lockheed Martin/US EPA, Research Triangle Park, NC; <sup>2</sup>NCCT, US EPA, Research Triangle Park, NC.

The elucidation of adverse outcome pathways (AOPs) and mechanistic models of toxicity depends on a thorough understanding of the relationships among protein targets, molecular pathways, cellular processes, adverse outcomes, and exogenous chemicals in a given biological system. Scientists rely on the biomedical literature for a significant portion of this information; however, common tools and resources such as PubMed are designed primarily for article retrieval and may fall short in synthesis of important relationships from the large amounts of available literature. We developed a series of electronic libraries (e-libraries) to provide investigators a way to streamline information retrieval from the biomedical literature and focus the retrieval on key relationships. The foundation for the e-libraries is a broad literature database in the form of a compilation of the MeSH annotations extracted from each MEDLINE record. These annotations are processed and organized so that the relationships among target proteins, biological effects, and chemicals are more easily extracted. For a particular area of interest (e.g., cleft palate, limb development, endocrine disruption) or for a particular set of chemicals (e.g., ToxCast) the literature database is batch-searched for articles containing the corresponding MeSH terms and the co-annotated terms. To produce the e-library, the terms are organized and written to Excel spreadsheets. Finding relevant articles is facilitated by allowing users to use built-in filtering capabilities. A filtering flag for species for instance, will allow the user to see only the rows about a desired species. The e-libraries have been constructed around subject areas as diverse as cleft palate, zebrafish, retinal development, flame retardants, and endocrine disruption. Access to e-libraries has been used to assist all kinds of research from basic exploratory research to development of AOPs and computer simulations. [This abstract does not necessarily reflect EPA policy.]

**PS 864 Interactive Web Application (Dashboards) to Integrate Data on Chemical Hazard and Exposure.**

S. Watford, M. Martin, A. M. Frame, R. Judson, N. C. Baker, I. Shah, J. F. Wambaugh and D. Reif. National Center for Computational Toxicology, Office of Research and Development, US EPA, Research Triangle Park, NC.

The USEPA has developed web-based interfaces (Dashboards) to synthesize multiple sources of data from Aggregated Computational Toxicology Resource (ACToR) into customized information displays. Users may select subsets of chemicals and data types to focus on for the assessment process. The data are organized into custom classes to present all relevant information for a given task. While not all chemicals will have complete information across all classes, each class reports available data including relevant high-throughput assay results, regulatory information, relevant articles from the biomedical literature, exposure data, and in vivo toxicity data. Custom widgets display each type of data according to its nature (e.g. dose-response plots or tables for assay data and summary tables for exposure data). Chemical-specific summary scores that consider all information in each class are presented in a dynamic summary table that highlights areas deserving additional attention. Transparency in decision-making is preserved since Dashboards record and save all user selections and decisions. Expert judgment can be used to override score criteria if necessary, again with such events recorded for transparency purposes. The scores are carried over into a prioritization process where the chemicals are ranked in a weight-of-evidence scheme to identify candidates for focused assessment. For example, the Dashboard created to support analysis of potential endocrine disruptors contains over 8000 chemicals with the classes Estrogen, Androgen, Thyroid, Steroidogenesis, Exposure, Occurrence, and Health Effects. The aggregation of relevant data and use of Dashboards to generate custom displays streamlines the toxicity assessment process and allows users to zoom from larger chemical subsets down to very focused chemical-wise views. While the initial Dashboards have been created to support EPA programmatic needs, future versions will include a public-facing web interface. This abstract does not necessarily reflect US EPA policy.

**PS 865 Literature Visualization and Navigation to Facilitate Development and Application of Computational Biological Models.**

N. Pena, S. R. Crowell, S. Dowson, D. McQuerry and J. G. Teeguarden. Systems Toxicology, Pacific Northwest National Laboratory, Richland, WA.

Physiologically based pharmacokinetic (PBPK) and quantitative structure activity relationship (QSAR) modeling rely heavily on mining of published literature for model development and parameterization, a time and resource intensive process. Because PBPK and QSAR modeling are relatively new disciplines, there is a need for readily accessible and high quality resources to support the increasing model use. Resource needs are broad, ranging from parameter values to model archives and publication archives. A common thread is the need to organize the available model related literature in a fashion that supports rapid access and organization according to data needs and more detailed analysis. We have developed a tree map application, a powerful, visually intuitive literature navigation interface, which exploits the naturally hierarchical nature of information used in biological modeling. Tree maps organize data thematically, and can be navigated by the user choosing a theme of interest, and then drilling down through sub-themes to the level of individual documents (existing models or relevant publications). Subject matter experts developed a taxonomy of themes in biological modeling, and relevant documents were identified in the literature by means of specific search strings. IN-SPIRE Visual Document Analysis was used to identify linguistically significant themes within the data, and to develop and test search strings used by the tree map to identify relevant documents from within the database of biological modeling publications. Documents were then labeled with their relationships within the class structure, loaded into a database, and a tree map user interface generated. With continuing refinement of search strings and development of the tree map application, this work has the potential to yield a powerful, evergreen (automatically updating) search tool specifically designed to aid in biological model development and utilization. An external demo of the tree map can be found at <https://nvacdemo.pnl.gov/srs/dashboard/epa/>

**PS 866 Database of Chemicals Assayed for Estrogenic Activity in the US FDA's Endocrine Disrupting Knowledge Base (EDKB).**

J. Shen, L. Xu, W. Tong and H. Hong. <sup>1</sup>University of Georgia, Athens, GA; <sup>2</sup>Jiangnan University, Wuxi, China.

Endocrine disruptors (EDs) are chemicals with ability to disrupt endocrine system. EDs have sparked intense international scientific discussion and debate and provoked regulatory action. The FDA's National Center for Toxicological Research (NCTR) developed a publicly available Endocrine Disrupting Knowledge Base (EDKB) (<http://goo.gl/Qn0nv>) 13 years ago. It has been a widely used resource in the scientific community. Currently, we are expanding the data collection in the EDKB by including the most up-to-date literatures. Since many EDs display estrogenic activities and affect the normal estrogen signaling pathway, we first updated the estrogenic data and developed a database of chemicals assayed for estrogenic activity as a component in EDKB. The database contains over 16,500 activity data of about 7,000 compounds from many public resources. The activity data are categorized based on assay types into binding assay, reporter gene assay and cell proliferation assay. The database also contains protein subtypes and domains used in the assays. Original data were converted into the same units such as logRBA for binding data (RBA=Relative Binding Affinity). Quality control was performed to ensure the data quality. The database was implemented using Instant JChem. A user-friendly interface was designed and developed for rapid navigating and searching the database. Searching multiple fields such as chemical structure, substructure, chemical name, CAS, assay type, assay species, activity range, and references can be conducted using logical operations. To the best of our knowledge, this database is the most comprehensive collection of chemicals assayed for estrogenic activity. It provides the scientific and regulatory communities a free source to search estrogenic activity data for chemicals of interest and to develop predictive models for predicting chemicals for which no assay data are available.

**PS 867 The Comparative Toxicogenomics Database.**

C. Mattingly<sup>1</sup>, C. G. Murphy<sup>1</sup>, R. Johnson<sup>2</sup>, J. M. Lay<sup>2</sup>, K. Lennon-Hopkins<sup>2</sup>, C. Saraceni-Richards<sup>1</sup>, D. Sciaky<sup>2</sup>, B. L. King<sup>2</sup>, M. C. Rosenstein<sup>2</sup>, T. C. Wieggers<sup>1</sup> and A. P. Davis<sup>1</sup>. <sup>1</sup>North Carolina State University, Raleigh, NC; <sup>2</sup>MDIBL, Salisbury Cove, ME.

The goal of the Comparative Toxicogenomics Database (CTD; <http://ctdbase.org>) initiative is to inform hypothesis development about mechanisms of chemical actions and the impact of environmental exposures on human health. CTD is a freely

available tool that provides a foundation of manually curated data describing chemical-gene interactions and chemical-disease and gene-disease relationships. Curated data are integrated with external data sets (e.g., Gene Ontology and pathway data) and tools that allow users to navigate and analyze over 16 million biological relationships relevant to environmental health sciences (EHS). Here we describe CTD functionality and highlight several new analysis and data visualization features, including: a Gene Set Enricher tool that provides deeper insight into the functional themes and pathways associated with user-defined genes or genes forming the basis of inferred chemical-disease relationships; filtering options that allow users to better customize queries and analyses; and a 'slim' list for our disease vocabulary that was implemented with graphical views to provide visual summaries of disease categories associated with chemicals in CTD. We also present information about emerging projects, including the use of curated data for developing chemotypes (a chemical substructure that carries information about biological activity), text-mining workflows for identifying chemical-gene-disease data, novel pathway development tools, and exposure data curation. We continue to expand the depth and functionality of CTD to meet the evolving needs of the EHS research community.

## PS 868 Mode-of-Action Ontology: An Application Ontology for Risk Assessment Data Mining.

K. L. Painter<sup>1</sup> and L. D. Burgoon<sup>2</sup>. <sup>1</sup>Oak Ridge Institute for Science and Education, Research Triangle Park, NC; <sup>2</sup>National Center for Environmental Assessment, US EPA, Research Triangle Park, NC.

Automated natural language processing (NLP) will make the practice of risk assessment more efficient. In the future, computer algorithms will use NLP to screen the literature for appropriate studies, identify relevant data, and help synthesize mode of action (MOA) evidence across several studies. However, before we can utilize the data from NLP searches, ontologies must be built to facilitate efficient data storage and sharing using existing standards. We developed the Mode of Action Ontology (MOAO) to support automated NLP discovery, integration, and management of mode of action knowledge. MOAO is a semantic model that 1) describes MOA knowledge, 2) easily combines data from multiple sources, 3) makes MOA knowledge more transparent and easily available to the public via semantic web interfaces, and 4) will allow computers to discover latent information and relationships via logical inference. MOAO is the first ontology we are aware of that describes mode of action information for toxicological purposes. MOAO was conceptualized as an application ontology, borrowing terms from existing high-quality ontologies produced for various biological sub-specialties. This allows us to maximize integration with outside data sources. In this way, MOAO can be a model for how other sub-domains in toxicology can reap the benefits of ontologies without the overhead of constructing one completely from scratch. We leverage the work by the Open Biological and Biomedical Ontologies (OBO) Foundry and the Basic Formal Ontology (BFO) to facilitate the integration of our ontology with others. The reference ontologies which MOAO uses include the Gene Ontology (GO), ChEBI (Chemical Entities of Biological Interest), the Uber Anatomy Ontology (UBERON), the NCBI Taxonomy, and the NCI Thesaurus. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

## PS 869 Development of a COSMOS Database to Support *In Silico* Modelling for Cosmetics Ingredients and Related Chemicals.

J. Rathman<sup>1,2</sup>, C. Yang<sup>1</sup>, K. Arvidson<sup>3</sup>, M. T. Cronin<sup>5</sup>, S. Enoch<sup>5</sup>, D. Hristozov<sup>3</sup>, Y. Lan<sup>6</sup>, J. C. Madden<sup>5</sup>, D. Neagu<sup>6</sup>, A. N. Richarz<sup>5</sup>, M. Ridley<sup>6</sup>, O. Sacher<sup>4</sup>, C. Schwab<sup>4</sup> and L. Yang<sup>6</sup>. <sup>1</sup>Altamira, LLC, Columbus, OH; <sup>2</sup>The Ohio State University, Columbus, OH; <sup>3</sup>Office of Food Additive Safety, CFSAN US FDA, College Park, MD; <sup>4</sup>Molecular Networks, Erlangen, Germany; <sup>5</sup>Liverpool John Moores University, Liverpool, United Kingdom; <sup>6</sup>University of Bradford, Bradford, United Kingdom.

The Seventh Amendment of the EC's Cosmetics Directive foresees a deadline in 2013 for the replacement of animal testing of cosmetic products for repeated dose/reproductive toxicity and toxicokinetics. To this end, the COSMOS project has been initiated to fill the gap in knowledge and technology via *in silico* toxicology. The management and sharing of chemical, biological and toxicity data play a central role. The COSMOS database activities cover three main directions: an overview of toxicity data sources and studies; the design of the data model and the data entry tool for the database; and the definition of a data curation strategy. The new COSMOSDB provides a publicly available web-based searching/retrieval system and also serves for sharing resources, models and supporting workflow developments. The database is "compound-centred" and represents both EU COSING and US PCPC inventories for cosmetics ingredients. For biological data, the database supports repeated dose toxicity, metabolism information and dermal absorption data. The data have been collected, curated, quality-controlled, stored and

managed in a flexible and sustainable manner to support predictive modelling tasks. An effective curation strategy for toxicity data has also been reflected in building the data entry system. Based on the review of existing approaches on good practice to assess quality entries, the reliability of the toxicity data is supported by all available data from multiple sources. Additional functionalities for data aggregation within a data governance framework are described. The COSMOS project is funded by European Community's 7th Framework Program (FP7/2007-2013) and by Cosmetics Europe.

## PS 870 The Toxbank Infrastructure Project to Support the Replacement for Repeated Dose Toxicity.

G. J. Myatt<sup>1</sup>, E. Benfenati<sup>3</sup>, D. Bower<sup>1</sup>, R. Ceder<sup>2</sup>, K. P. Cross<sup>1</sup>, R. C. Grafström<sup>2</sup>, L. Healey<sup>4</sup>, C. Helma<sup>5</sup>, N. Jeliakova<sup>6</sup>, V. Jeliakova<sup>6</sup>, L. Kidane<sup>4</sup>, P. Kohonen<sup>2</sup>, S. Maggioni<sup>3</sup>, S. Miller<sup>1</sup>, M. Rautenberg<sup>6</sup>, G. Stacey<sup>4</sup>, J. Wiseman<sup>8</sup> and B. Hardy<sup>7</sup>. <sup>1</sup>ReD, Leadscope, Columbus, OH; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy; <sup>4</sup>National Institute for Biological Standards and Control, Potters Bar, United Kingdom; <sup>5</sup>In silico toxicology, Basel, Switzerland; <sup>6</sup>Ideaconsult, Sofia, Bulgaria; <sup>7</sup>Douglas Connect, Zeiningen, Switzerland; <sup>8</sup>Pharmatope, Wayne, PA. Sponsor: R. Benz.

The aim of the €50 million SEURAT-1 (Safety Evaluation Ultimately Replacing Animal Testing-1) research cluster, sponsored by the European Union and Cosmetics Europe, is to generate a proof-of-concept replacement for repeated dose systemic toxicity testing on animals. The SEURAT-1 strategy is to adopt a mode-of-action framework to describe repeated dose toxicity, combining *in vitro* and *in silico* methods in an intelligent manner to derive predictions of *in vivo* toxicity responses. ToxBank is the cross-cluster infrastructure project whose activities include the development of a data warehouse, the selection of reference compounds for use across the cluster to support the mode-of-action framework, a physical compounds repository, and a reference resource for biomaterials. The ToxBank data warehouse provides a web-accessible shared repository for protocols and experimental results supporting SEURAT-1 research objectives such as toxicity pathway elucidation and biomarker discovery. Information in ToxBank is uploaded from the research activities of the cluster partners and relevant information on the reference compounds from public databases. In this poster we describe the data warehouse and implementation based on open standards, the selection of reference compounds, and an analysis linking the reference compounds to public omics data.

## PS 871 Software for Integration of Experimental, Chemical, and Environmental Data.

E. Peterson<sup>1</sup>, K. Hobbie<sup>2</sup>, S. C. Tilton<sup>1</sup>, R. L. Tanguay<sup>2</sup>, K. Anderson<sup>2</sup> and K. M. Waters<sup>1</sup>. <sup>1</sup>PNNL, Richland, WA; <sup>2</sup>OSU, Corvallis, OR.

The Oregon State University Superfund Research Program evaluates the potential health effects of polycyclic aromatic hydrocarbons (PAHs). More than 100 parent PAH compounds, and an unknown number of PAH derivatives and metabolites have been identified. PAHs raise concern at over 800 Superfund Sites and serve as the risk driver for remediation at 20% of all Superfund sediment sites. Assessing the health effects of PAHs is a major challenge because environmental exposures to these chemicals are from complex mixtures of PAHs and other toxicants. Integration of exposure data with biological activity and pharmacokinetics is essential to evaluate the effects presented by these mixtures on human health. Increasingly researchers are generating data streams of high content data from analytical, high-throughput, and 'omic' studies, which make direct applications from these technologies out of reach for clinicians and regulators. However, more accurate and precise thresholds for risk assessments and prediction will ultimately arise from leveraging the integration of data from across disciplines. Therefore, the principle challenge for mixture assessments, epitomized by PAHs, is the efficient integration of large and diverse data sets. To this end we've extended PNNL's Experimental Data Management System (EDMS) to create a seamless data workflow among researchers and analysts. EDMS has been extended to track and manage relationships among any and all data points across a project. This allows us to integrate chemical and biological data for environmental extracts (LIMS and EDMS) with analogous data on pure chemical compounds. EDMS provides a query mechanism that will reach through all the relationships of data from chemical compounds to the analytics and statistics run on the experimental data. Query results, visualizations, and data processing results are all also stored together with and related to the experimental information. This reduces data replication and supports a streamlining of analysis, collaboration and experimental design allowing researchers to take advantage of all the data generated.

**PS 872 Computational Methods to Reveal Cross-Species, Dose-Response Patterns in Nonclinical Studies.**

S. Nath, J. Kimball, S. Madhavan, V. Krishnan and L. Prabhakar. *PointCross Life Sciences, Foster City, CA*. Sponsor: *R. Guy*.

Drug development scientists and regulatory reviewers alike have a need to understand toxicity patterns of a drug candidate across animal species prior to human trials. Effective exploitation of collected study data has previously been impeded by differences in mnemonics, terminologies and units across sponsor and CRO data. Moreover, computational techniques to analyze large volumes of disparate quantitative and qualitative study data, and their respective endpoints, have not been routinely available for use by practicing toxicologists and reviewers.

To address these common challenges for the FDA and the Industry, we have developed new repository techniques to prepare and hold in vivo harmonized datasets (including standardized formats like SEND, the Standard for Exchange of Nonclinical Data), and extracted metadata, as a first step towards advanced analytics and study reviews. Predictive, comparative and cluster analysis techniques have been performed on large study repository datasets to reveal similarities and differences in dose-response patterns across species in terms of their magnitude, shape and trends. Finally, signal processing techniques such as Z-transform box plots have been adapted to present trends in ways that scientists and regulatory reviewers can easily use to interpret potential toxicity patterns and their inter-relationships. Collectively, new computational tools are available to better exploit legacy and ongoing data that are already being collected, provide better decision support for species selection and protocol design, and advance our understanding of how dose-response patterns translate across species for the same compound and to detect other compounds that share similar responses. Implications of applying such computational methods to improve safety prediction across species, and eventually into humans, will be discussed particularly in light of the FDA's mandate to require standardized e-Data submissions, including SEND datasets, as a way to further regulatory science.

**PS 873 ToxCast High-Throughput Screening Assay Annotation Using Bioassay Ontology and Expanded Assay Target Information.**

J. Phuong<sup>1,2</sup>, K. Houck<sup>1</sup> and M. T. Martin<sup>1</sup>. <sup>1</sup>NCCT, US EPA, Research Triangle Park, NC; <sup>2</sup>Environmental Science & Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

The ToxCast assay library includes 427 high- to Low-throughput screening assays with a total of 700 assay components. Assessing a battery of cellular, pathway, protein and gene perturbations, the total number of assay endpoints (assay\_component\_endpoints) generated is 1106. Selecting the appropriate data sets to use for modeling purposes encounters questions such as suitable cell type, assay design specifics, protein form, measured target and detection method. To simplify these concepts, the BioAssay Ontology was applied to annotate 36 descriptors for assay design and target information and to create a scheme for identifying assay\_component\_endpoints. Assay design information is distinguished by assay design types (n=23), detection technology types (n=11), and cell types (n=36), which consists of 14 species and 18 tissues. Assay target information is separated by technological target mapped to gene(s) (n=381), technological target types (n=15), intended target genes (n=362), intended target families (n=145), intended target types (n=14), and biological process targets (n=11). An example of applying the assay target information to identify all applicable assay\_component\_endpoints is given for the Aryl Hydrocarbon Receptor (AhR). AhR is assessed by four assay\_components (ATG\_AhR\_CIS, Tox21\_AhR\_BLA\_Agonist, CLZD\_CYP1A1, and CLZD\_CYP1A2) in eight assay\_component\_endpoints. The ATG\_AhR\_CIS assay uses an mRNA induction design to target transcription factor activity. The Tox21\_AhR\_BLA\_Agonist assay uses a beta lactamase reporter gene induction design to measure receptor activity. Lastly, the CLZD assays measure the mRNA induction of two AhR target genes, CYP1A1 and CYP1A2, at multiple time-points to measure AhR receptor gene regulation activity. With this approach, the intended assay targets and the means used to measure their activities can be clearly communicated in explicit ways to allow for integration into larger systems-models. This abstract does not necessarily reflect U.S. EPA policy.

**PS 874 A Novel Hybrid Approach in Combining a QSAR-Based Expert System and a Quantitative Read Across Methodology to Achieve Better In Silico Genotoxicity Assessment of Drugs, Impurities and Metabolites.**

S. Chakravarti<sup>1</sup>, R. Saiakhov<sup>1</sup> and G. Klopman<sup>1,2</sup>. <sup>1</sup>Multicase Inc., Beachwood, OH; <sup>2</sup>Chemistry, Case Western Reserve University, Cleveland, OH.

**Purpose:** Purpose of this study is to develop and apply a novel technique of combining the predictions of the CASE Ultra expert system models and a new quantitative read across modeling methodology to obtain better genotoxicity predictions as opposed to using just one technique. The hybrid methodology successfully provides the interpretability of toxicity alerts and reduces false positives, false negatives while increasing the test coverage. This in silico tool can be successfully used for assessment of potential toxicity or beneficial therapeutic effects of new drug candidates, impurities and metabolites.

**Method and Data:** CASE Ultra is a computer program that automatically extracts structure-activity knowledge from chemical databases and applies the knowledge for predicting activity in test chemicals. It also gives a very clear explanation of its predictions so that they are easily interpretable by chemists and toxicologists. Recently we have developed a novel read across modeling technique for quantitative prediction of toxicity that uses the full neighborhood profiles of chemicals. In case of Salmonella mutagenicity predictions, the read across prediction was applied in a systematic way on top of the predictions from the CASE Ultra mutagenicity models, and significant improvements in the sensitivity, specificity and coverage were achieved. The details of the methodology and results of prediction for a large external test set are presented.

**Results of the Study:** The improvements in the predictive performance as a result of the hybrid technique is demonstrated for Salmonella mutagenicity prediction in an external test set. Improvements in the prediction sensitivity, specificity and coverage were in the order of 3-5%, 2-5% and 5% respectively.

**PS 875 Systematic 'Omics Analysis Review Tool to Support Risk Assessment.**

E. McConnell<sup>1</sup>, S. Bell<sup>1</sup>, I. Cote<sup>2</sup>, R. Wang<sup>3</sup>, E. J. Perkins<sup>4</sup>, N. Garcia-Reyero<sup>5</sup>, P. Gong<sup>4</sup> and L. D. Burgoon<sup>6</sup>. <sup>1</sup>Oak Ridge Institute for Science and Education, Research Triangle Park, NC; <sup>2</sup>NCEA, US EPA, Washington DC; <sup>3</sup>NERL, US EPA, Cincinnati, OH; <sup>4</sup>USACE, Vicksburg, MS; <sup>5</sup>Mississippi State University, Starkville, MS; <sup>6</sup>NCEA, US EPA, Research Triangle Park, NC.

Incorporating data from molecular and systems biology studies, especially omics data, presents a major challenge for risk assessors. Omics studies of varying quality and relevance are currently reported in the literature. Risk assessors need a standardized, transparent way of screening literature based on study quality prior to performing in-depth analyses of the data and including the results in human health risk assessments (HHRA). The Systematic Omics Analysis Review (SOAR) tool is a spreadsheet of 35 objective questions, currently focused on transcriptomic microarray studies, developed by domain experts. The tool will identify if a study meets basic published quality criteria, such as those defined by the Minimum Information About a Microarray Experiment (MIAME) guideline and the Toxicological data Reliability assessment (ToxR) Tool. Although the tool is currently constructed for human use in reviewing microarray literature, future work will automate the literature screening process using natural language processing as a first pass filter, with fewer subjective questions left for human determination afterward. The questions cover four sections (Test System, Test Substance, Experimental Design, and Microarray Data). Seven scientists were recruited to validate the tool by using it to rate 16 published manuscripts that study chemical exposure with microarrays. Using their feedback, questions were weighted based on importance of the information and a suitability cutoff was set for each of the four question sections. The SOAR tool was found to be simple, systematic way of performing a first-pass screening of microarray literature, which will introduce modern research methodologies into traditional HHRA procedures.

The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.

**PS 876 Web-Based Benchmark Dose Modeling Module As a Prototype Component of an Informatics-Based System for Human Health Assessments of Chemicals.**

A. J. Shapiro<sup>1,4</sup>, N. Cook<sup>1</sup>, P. Ross<sup>4</sup>, J. Fox<sup>2</sup>, V. Coglianò<sup>2</sup>, W. A. Chiu<sup>2</sup>, N. Wang<sup>2</sup>, L. Zeise<sup>3</sup>, K. Guyton<sup>2</sup> and L. Rusyn<sup>1</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC; <sup>2</sup>NCEA, US EPA, Washington DC; <sup>3</sup>Scientific Affairs Division, Cal/EPA, San Francisco, CA; <sup>4</sup>ICF International, Fairfax, VA.

We propose developing a modular, cloud-ready, informatics-based system to synthesize multiple data sources into overall human health assessments of chemicals. This system would seamlessly integrate and document the overall workflow from literature search and review, data extraction, and evidence synthesis, to dose-response analysis and uncertainty characterization. Crucial benefits of such a system include improved data integrity, greater transparency, standardization of data presentation, and increased consistency. By including both a web-based workspace for assessment teams, and complementary web-based portal for reviewers and stakeholders, all interested parties would have dynamic access to completed and ongoing assessments. The modular approach will also facilitate rapid prototyping, testing, review, and incorporation of methodological improvements. Here we present a prototype module for benchmark dose (BMD) modeling used to develop points-of-departure, from which toxicity values are derived. Previously-developed BMDS Wizard and DRAGON Excel-based programs were used to develop a web-based tool where assessment teams can view/upload/enter dose-response data sets into the module, perform BMD modeling, and export results. Example summary views and plots are available online, or can be converted to report format. In addition, multiple nested views of the data and analyses enable interested users to rapidly "dive into the details." We conclude that given new data streams, diverse user needs, and multiple stakeholder interests, assuring the utility, integrity, and objectivity of human health assessments will be greatly facilitated by a modular, upgradeable, informatics-based system for their development, review, and dissemination. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the US or California EPA.

**PS 877 An Optimized Cheminformatics Method for Determining Hazard Communication Information for Research Samples.**

N. M. Berdasco, D. M. Wilson, P. S. Price, J. A. Hammond and C. M. Thornton. *TERC, The Dow Chemical Company, Midland, MI.*

A Research Sample Safety Data Sheet (RSSDS) is a hazard communication document, which describes health and safety properties and characteristics of a chemical substance, typically for one-time-use only. This document enables research samples to be safely packaged and shipped worldwide using commercial carriers in compliance with all regulatory requirements. It is the critical vehicle for communicating relevant toxicity information to workers, shippers and first responders in case of unplanned release. It can be a time critical service where the client expectation is that cycle time (CT) will be short, typically 24-48 hrs. Implementation of the Global Harmonized System (GHS) around the world necessitates the inclusion of GHS classifications for substances and mixtures. This requirement has greatly increased the complexity of RSSDS hazard assessment, especially in situations where hazard profiles must be estimated for novel chemicals where only the structure is known. This poster describes an optimized method for the delivery of hazard information as developed by The Dow Chemical Company. The method utilizes cheminformatics tools such as QSAR modeling, read-across and identification of analogs to enhance the ability to predict hazards for novel chemicals, enabling clients to comply with complex international regulations and product stewardship while still meeting competitive timelines for product development and sampling.

**PS 878 California Communities Environmental Health Screening Tool (CalEnviroScreen).**

G. V. Alexeeff<sup>1</sup>, J. Faust<sup>1</sup>, L. August<sup>1</sup>, R. Cendak<sup>1</sup>, W. Wieland<sup>1</sup>, T. Kadir<sup>1</sup>, L. Cushing<sup>2</sup>, K. Randles<sup>1</sup>, C. Milanese<sup>1</sup> and L. Zeise<sup>1</sup>. <sup>1</sup>OEHH, Cal/EPA, Oakland and Sacramento, CA; <sup>2</sup>Energy and Resources Group, University of California Berkeley, Berkeley, CA.

Many Californians are burdened by multiple sources of pollution and some people are more vulnerable to the exposures. We developed a method, called CalEnviroScreen, which uses existing environmental, health and socioeconomic data to create a cumulative impacts score for different geographic area across California. We conducted a preliminary statewide screen at the ZIP code level to identify communities most burdened by multiple sources of pollution with populations that may be especially vulnerable to its effects. The method uses a concept of

total pollution burden based on measures of exposure, public health effects and environmental effects. This is modified by measures of sensitive populations and relevant socio-economic factors. The screen considered data for ambient ozone and PM<sub>2.5</sub> concentrations, traffic density, toxic releases from facilities, pesticide use, cleanup sites, impaired water bodies, leaking underground storage tanks, solid and hazardous waste facilities, low birth weight infants, asthma, prevalence of children and elderly, educational attainment, income, poverty and race/ethnicity. The analysis consisted of a relative comparison of approximately 1800 ZIP codes in California using a relative risk model structure. The comparisons can be viewed by individual indicators, measures of burden or measures of vulnerability. The results are presented graphically using Geographic Information System tools for each indicator and are summarized by categories of exposures, environmental effects, public health effects, sensitive individuals and socioeconomic factors. Sensitivity analyses are used to test the model structure and the usefulness of each indicator selected.

**PS 879 Cellesis: A Novel System Biology Toxicology Tool.**

C. F. Biscarrat, P. Picamal and N. A. Compagnone. *Department of Toxicology, ICDD, Meyreuil, France.* Sponsor: Y. Will.

Understanding and predicting adverse drug reactions (ADRs) are crucial goals in toxicology, since unrecognized toxicity is the most frequent reason for drug withdrawal. We have developed a novel technology based on dynamical image analysis of intracellular organelles in live cells. Mitostream®, the dynamic measure of the mitochondrial behavior, is a system biology experimental technology predictive of the severity and incidence of ADRs. It is a powerful HCA to help identify drug-induced toxicity, differentiate risk between compounds and evaluate the potential for rare but severe adverse events. Mitostream® decodes the mitochondrial behavior, quantifying motility, morphology, permeability and network organization with multiple endpoints associated to qualitative descriptors to model their interrelationship. We developed the Cellesis algorithm to identify classifiers and predictors able to fuse the matrix of recorded multi-modal markers into a unique statistical toxicity index.

An original set of 27 molecules was studied to classify drugs on a toxicity scale. The algorithm classified properly 83% of the drugs with 94% specificity and 75% sensitivity. We extended the set to include more non-toxic compounds and compounds with rare but severe toxicity as well as compounds that did not target the mitochondria. The second training set included 47 compounds and yielded 85% proper classification, a specificity of 91% and a sensitivity of 92%. Independent industrial validation was performed through the Consortium for Technology Evaluation at the DSEC, testing 10 new compounds. Chosen by our industrial partners these compounds classified properly with similar performances, showing a good association between Cellesis-predicted ADRs and the lowest tolerable dose seen in the clinic. A set of NSAID was further studied. Results showed 86 % proper classification through Cellesis-predicted ADRs. Specificity was 92%, sensitivity was reduced to 85%, some apparent false positive had a below threshold reported clinical ADRs despite having been withdrawn post-marketing due to idiosyncratic hepatotoxicity.

**PS 880 Development of a Systems Computational Model to Investigate Early Biological Events in Hepatic Activation of Constitutive Androstane Receptor (CAR) by Phenobarbital.**

H. A. El-Masri<sup>1</sup>, S. Hester<sup>1</sup>, C. E. Wood<sup>1</sup>, I. Shah<sup>2</sup>, D. C. Wolf<sup>1</sup> and C. Corton<sup>1</sup>. <sup>1</sup>NHEERL, US EPA, Research Triangle Park, NC; <sup>2</sup>NCCT, US EPA, Research Triangle Park, NC.

Activation of the nuclear receptor CAR (constitutive active/androstane receptor) is implicated in the control several key biological events such as metabolic pathways. Here, we combined data from literature with information obtained from *in vitro* assays in the US EPA ToxCast database, and *in vivo* outcomes in the US EPA ToxRef database to link CAR activation to a proposed adverse outcome pathway (AOP) of hepatic tumors. Key *in vivo* pathological events for this proposed hepatic tumor AOP are similar to those of other non-genotoxic receptor-mediated chemicals (i.e., hypertrophy, cellular proliferation, preneoplastic foci, and neoplasia), highlighting the importance of upstream biological mechanisms mediating the early proliferative signals of CAR activation. Using phenobarbital (PB), a known rodent tumor promoter and CAR activator, we developed a computational model for the early initiating events of CAR activation leading to its nuclear translocation. Based on literature evidence, the computational model describes the cascade of biological events leading to CAR nuclear translocation. These events are initiated by PB activation of Adenylyl Cyclase (AC) leading to an increase in the rate of ATP transformation to cyclic AMP. In turn, cyclic AMP increases intercellular calcium levels which inhibit the activity of AC via a negative feedback loop mechanism. However, the resulting transient increase in cyclic AMP levels activates protein

phosphatase 2A (PP2A) which inhibits ERK. This inhibition is required for the nuclear translocation of CAR and the subsequent binding to a PB-enhancer module (PBREM) indicated by CYP2B6 gene induction. Future work will bridge these events with key targets mediating proliferative responses in the proposed AOP for hepatic nuclear receptor mediated carcinogenesis. Our computational systems model illustrates the impact of early events for dose-response modeling of receptor-mediated AOPs. This abstract does not reflect EPA policy.

## PS 881 Mechanistic Modeling Illuminates the Most Important Unknowns in Bile Acid Mediated DILI.

J. L. Woodhead<sup>1</sup>, K. Yang<sup>2</sup>, K. L. Brouwer<sup>2</sup>, P. B. Watkins<sup>1</sup>, S. Q. Siler<sup>1</sup> and B. A. Howell<sup>1</sup>. <sup>1</sup>The Hamner-UNC Institute for Drug Safety Sciences, Research Triangle Park, NC; <sup>2</sup>UNC-Eshelman School of Pharmacy, Chapel Hill, NC.

BSEP inhibition and consequent bile acid (BA) buildup has been proposed to be an important mechanism in drug-induced liver injury (DILI). There are many gaps in the knowledge of BA homeostasis and its disruption by transporter inhibitors. Modeling can help us understand which of these knowledge gaps should be filled first in order to provide maximum understanding. We have constructed a model of BA homeostasis and toxicity within DILIsym<sup>TM</sup>, a mechanistic model of DILI that includes bile acid flux into and out of hepatocytes, the role of the farnesoid X receptor (FXR) in the regulation of BA transport and synthesis, and gallbladder BA release and recirculation. We first analyzed our system's behavior in the presence of a simulated BSEP inhibitor similar to glibenclamide. We predict a 41% increase in total hepatocyte content of amide conjugated chenodeoxycholic acid (CDCA). However, the simulated BSEP inhibition resulted in no change in either unconjugated CDCA or the amide-conjugated lithocholic acid (LCA), and the hepatocyte content of unconjugated LCA decreased by 15%. We next performed a sensitivity analysis on our system's response to BSEP inhibition in order to determine which parameter has the greatest effect on hepatocyte content of BAs and hence BSEP inhibitor-induced hepatotoxicity. We found that the most important unknown in the system is the intrahepatic BA concentration that triggers FXR-mediated regulation of BA transporters, while other parameters such as the affinity constants for transport of CDCA and LCA and ileal LCA transport efficiency were less important. We conclude that the highest priorities for wet lab research to inform our model and enhance our understanding of BSEP inhibitor mediated DILI are: 1) quantifying the relationship between intrahepatic concentrations of individual bile acids and FXR activation, and 2) quantifying the link between intracellular CDCA amide conjugates and toxicity.

## PS 882 Quantitative Dose-Response in a Virtual Hepatic Lobule.

J. F. Wambaugh<sup>1</sup>, J. Jack<sup>1</sup>, J. Liu<sup>1</sup>, H. A. El-Masri<sup>2</sup>, J. Davis<sup>1</sup>, W. Setzer<sup>1</sup> and I. Shah<sup>1</sup>. <sup>1</sup>National Center for Computational Toxicology, US EPA, Research Triangle Park, NC; <sup>2</sup>National Health and Environmental Effects Research Laboratory, US EPA, Research Triangle Park, NC.

The U.S. EPA Virtual Liver (vLiver) is a cellular systems model of hepatic tissue that provides simulated *in vivo* context for liver-relevant ToxCast and other *in vitro* data. To protect public health it is necessary to quantitatively estimate the risk of long-term low dose exposure to environmental pollutants. The vLiver model currently allows testing of early key events in adverse outcome pathways (AOP) by integrating multiple types of *in vitro* data in order to predict *in vivo* (animal) data. The model was used to simulate hepatocyte proliferation in 28 day repeat dose studies as an early event in non-genotoxic liver cancer AOPs. *In vitro* hepatocyte assays are often limited in assessing proliferation, in part due to the cells being removed from a tissue context – this context is created via simulation. A hepatic lobule microdosimetry model, developed in conjunction with a high throughput physiologically-based pharmacokinetic model, links whole-body exposure to cell-scale concentrations. For seven chemicals (fenarimol, imazalil, azoxystrobin, bifenazate, fenamidone, fluoxastrobin, and paclobutrazol) free chemical concentrations in the liver were predicted as a function of dose and time. A ToxCast assay for up-regulation of activator protein 1 (AP-1) in HepG2 cells – a transcription factor for cell-cycle initiation and progression – was used as a surrogate for hepatocyte proliferation. Model simulations predicted the administered dose (mg/kg/day) needed for excess proliferation *in vivo*. Five of the seven chemicals displayed non-proliferative liver lesions in rats (ToxRefDB) at similar doses, while the two without lesions were among the three chemicals predicted to require the highest dose. This demonstrates the potential for *in silico* models to predict the *in vivo* administered doses that, based on *in vitro* data, may lead to *in vivo* adverse effects. This abstract does not necessarily reflect EPA policy.

## PS 883 Quantitative Extrapolation of *In Vitro* Data to Risk Management Decisions: Using Hepatic Ah Receptor and Its Agonists As an Example.

X. Chang<sup>1</sup>, M. DeVito<sup>1</sup> and M. Easterling<sup>2</sup>. <sup>1</sup>DNTP, NIEHS, Research Triangle Park, NC; <sup>2</sup>SRA International, Research Triangle Park, NC.

A critical question in human risk assessment is how best to incorporate *in vitro* data. In a quantitative *in vitro* to *in vivo* extrapolation, one assumption is that media concentration equals blood concentration. Here, we evaluate this assumption by applying physiologically based pharmacokinetic (PBPK) models to predict cellular responses in primary rat hepatocytes exposed to an aryl hydrocarbon receptor (AhR) agonist. PBPK models for AhR agonists (e.g., TCDD, PeCDF, PCB126) were developed based on NTP two-year rat carcinogenicity bioassay data. The model predicts tissue concentrations and CYP1A1 induction well and demonstrates that ligand binding affinity is an important parameter for AhR-mediated enzyme induction and distribution of these chemicals. Using this model, we predicted the dose response for Cyp1a1 induction in whole rat liver at 48 h after an oral dose of TCDD. The predicted results were compared to literature data on rat primary hepatocyte treated with TCDD for 48 hours. The EC50 obtained for Cyp1a1 induction *in vitro* is about 100 fold less than that predicted *in vivo* (i.e., the primary cell culture system is about 100 times more sensitive). To identify which factors might contribute to this difference, we built a primary hepatocyte culture model, based on rat primary hepatocyte data from the literature and incorporated the same parameters used in the *in vivo* PBPK model of AhR agonists. Based on differences in parameter values between the two models, we identified critical factors determining the difference in sensitivity between *in vivo* and *in vitro* (e.g., TCDD availability). The hepatocyte culture model built for TCDD can predict the toxicities or downstream events for other AhR agonist by changing the parameter associated to AhR binding affinity only. This evaluation provides a model example of a quantitative *in vitro* to *in vivo* extrapolation for nuclear receptors and informs on how to better use *in vitro* data for risk assessment. This abstract does not necessarily reflect the policies or views of NIH.

## PS 884 Predicting Plasma Profiles following Oral Dosing for Drug Liver Transporter Substrates Using Physiologically-Based Pharmacokinetic Modeling.

H. A. Barton<sup>1</sup>, Y. Lai<sup>1</sup>, J. R. Gosset<sup>2</sup> and H. M. Jones<sup>2</sup>. <sup>1</sup>Pharmacokinetics, Pharmacodynamics, and Metabolism, Pfizer, Inc., Groton, CT; <sup>2</sup>PDM, Pfizer, Inc., Cambridge, MA.

A novel prediction approach for OATP substrates was developed using *in vitro* sandwich cultured hepatocyte (SCHH) data as input into a physiologically based pharmacokinetic (PBPK) model and was validated for intravenous (iv) dosing (Jones et al., 2012). The aim of our work was to extend this to the prediction of oral profiles. Data for plasma concentrations following oral doses were obtained from literature. Simple descriptors of oral absorption (fa, ka) were predicted using a physiologically based gastrointestinal (GI) tract model, which were then used in the published transporter PBPK model with a single compartment for oral absorption. The seven literature compounds were bosentan, cerivastatin, fluvastatin, pravastatin, repaglinide, rosuvastatin, and valsartan. *In vitro* passive permeability and solubility under fed and fasted conditions were measured as inputs to the GI model. We tested whether the oral absorption parameters were reasonable by combining them with the transporter parameters obtained from fitting the iv plasma data. Characterizing plasma pharmacokinetics using area under the curve to infinity (AUC(0-inf)), maximum concentrations (Cmax), and time to maximum concentration (Tmax), the fold error for the seven compounds was 1.6, 2.3, and 1.9 respectively, indicating the oral absorption parameters were reasonable. Forward predictions for the seven compounds based on SCHH data and the oral absorption parameters provided a test of both aspects of predicting oral plasma time course. The average fold errors for the seven compounds increased somewhat to 2.5, 3.3, and 2.4, respectively. This method was then applied to oral plasma data for four in-house compounds resulting in reasonable predictions for three of the four. An initial prediction method has been developed using *in vitro* and *in silico* inputs to estimate plasma profiles and pharmacokinetic parameters for iv and oral dosing of anionic drugs that are substrates for liver transporters.

**PS 885 A Mechanistic Approach to Understand Idiosyncratic Toxicity of Perhexiline and Sulindac.**

S. Das, R. Kumar, N. Rajeswara, S. Raghavan, Y. Chandrasekaran, N. Mandyam, S. Louha, A. Khanna, D. Srivastava, K. Ra and K. Subramanian. *Strand Life Sciences, Bangalore, India.*

Idiosyncratic DILI is one of the most common causes of safety-related post-marketing drug withdrawals. We have developed a dynamic systems based integrative approach that aids in its understanding by combining a mathematical model along with a panel of in vitro enzyme and transporter assays.

We tested perhexiline and sulindac in this assay system and fed the assay results into a mathematical model of liver biology. Our simulations identified the key mechanism behind the steatohepatitis caused by perhexiline. They predict perhexiline induced alterations in mitochondrial function, i.e. inhibition of oxidative phosphorylation, generation of oxidative stress along with inhibition of mitochondrial beta-oxidation leads to steatosis. An interesting insight gained in this process was the fact that whole cell measurements such as ATP or GSH alone can provide an erroneous understanding of the impact of a compound in vivo. On the other hand measuring various enzymatic functions enabled us to quantify the impact of ROS in vivo.

In the case of Sulindac, intracellular accumulation of GSH in HepG2 cell line indicated impairment of transport system. Applying this impairment in the model, our simulations predict bile and bilirubin accumulation indicating the potential for idiosyncratic cholestasis.

Thus our system enables us to understand mechanistic insights into the effect of leads and make predictions on their effects in vivo without necessitating the use of whole animal studies.

**PS 886 An Integrated Structure-Based Systems Approach to Predict Hepatotoxicity.**

A. Das, N. Mandyam, N. Tiwari and K. Subramanian. *Strand Life Sciences, Bangalore, India.*

We have developed a systems biology model for hepatotoxicity prediction. The input for the model is a set of in vitro assays that capture the effects of a chemical compound on selected proteins. The model takes these assay results as input, simulates their likely effects on selected pathways in a liver cell and outputs the toxicity effects in vivo. Though this approach has good predictive value and provides mechanistic insights into the toxicity response, the time consuming and expensive assays are a bottleneck for using the model in a high-throughput manner.

Using structure based approaches, we have virtualised the assays to use this model to rapidly evaluate hepatotoxicity of molecules. The binding affinity of a molecule to each of the proteins is estimated using structure prediction, flexible and induced docking and pharmacophore approaches and classified as low, intermediate or high. This forms the input to the systems model which then estimates the integrated impact of these perturbations on various pathways in the liver. We expected that the model output, though not as precise as with in vitro inputs, can flag likely hepatotoxicity of a molecule.

As an initial proof of concept, we tested this approach in a set of molecules, pioglitazone, tolcapone, rofecoxib, quiniacrine, propantheline bromide, benoxinate, bumetanide, AZ177 and acetaminophen. We found that this method is able to flag the key toxic mechanisms of each of these molecules and is able to predict synergistic toxic effects. We believe that this approach can be used as screening tool to rapidly and accurately assess mechanistic toxic effects and has utility during lead discovery and optimization.

**PS 887 Application of an In Silico Approach to Predict Intrinsic In Vitro Cytotoxicity for Compounds in Primary Human Hepatocytes during Preclinical Development.**

R. Pai, B. Wei, P. Chang, J. Crawford, W. Young, D. Ortwine, D. Misner and D. Dambach. *Genentech Inc., S. San Francisco, CA.*

Drug-induced liver injury is a major cause of compound attrition in preclinical and clinical development and, often, intrinsic hepatotoxicity can be related to chemical structure. Screening in primary human hepatocytes has been routinely used to assess toxicity in the preclinical setting to allow for assessment of metabolic contribution. However, the knowledge gained from this screening has not been fully utilized to drive medicinal chemistry design before compound synthesis. Herein, we present work in progress in the development of a computational model that is used to predict the outcome of hepatocyte screening for a set of preclinical compounds with significant accuracy. Cytotoxicity was determined by treating cryoplateable human hepatocytes with individual compounds and evaluating cellular ATP levels. In vitro

cytotoxicity was classified based on IC50 values into three buckets: high (<50  $\mu$ M), medium (50-100  $\mu$ M) and low toxicity (>100  $\mu$ M) groups. Using a machine learning approach, a large set of structural and non-structural descriptors were evaluated for their usefulness to classify cytotoxicity on a training set of 72 compounds. Three calculated physicochemical properties emerged as the most predictive descriptors (most-basic-pKa, plasma protein binding % and logP), and were used to construct a decision tree model. Subsequently, predictions were made for 102 compounds prospectively. The positive predictive values were 77% & 65%, and negative predictive values were 72% & 85% for high (H) and low (L) toxicity groups, respectively. Interestingly, addition of structural descriptors did not improve the accuracy of prediction, suggesting that the intrinsic toxicity of those compounds were not specific to their structures. We show that this model proved useful in reducing compound attrition for an ongoing project. Furthermore, the physicochemical property space that this work has implicated as being associated with toxicity may also provide clues toward understanding the underlying mechanism(s).

**PS 888 In Vitro In Vivo Correlation: Apparent or Ambiguous? Analysis of Pfizer Compounds in US EPA's ToxCast Chemicals-Assay Space.**

F. Shah and N. Greene. *Compound Safety Prediction, Worldwide Medicinal Chemistry, Pfizer Worldwide Research and Development, Groton, CT.*

In 2009, Pfizer collaborated with EPA in their ToxCast initiative to identify predictive bioactivity signatures for toxic compounds using 'dead' pharmaceuticals. A total of 52 Pfizer compounds with preclinical data were profiled in multiple assay platforms measuring bioactivity against diverse assay end-points. The first part of this work was focused on the analysis of Pfizer compounds in ToxCast chemicals and pharmacological space. These include a) comparison of bioactivity profile of Pfizer compounds with other pharma and EPA compounds; b) analysis of compounds sharing similar chemical and pharmacological space as of Pfizer compounds; and c) ability of assay platforms to reproduce the primary mode of action of Pfizer compounds. Analysis revealed that compound from EPA set seemed to have different pharmacological and chemistry space than pharma compounds. It also highlighted assay platforms and sensitive endpoints that are more relevant to understand the off-target activities of compounds. The second part involves correlation of in vitro ToxCast assay signals with in vivo findings related to liver injury, observed either in preclinical or clinical studies. The analysis pinpointed diverse cytotoxicity endpoints within ToxCast as markers of compound potential to cause preclinical or clinical liver injury.

**PS 889 Improved In Silico Methods to Group Liver Toxicants Related to Adverse Outcome Pathways.**

M. T. Cronin, S. J. Enoch, M. Hewitt, J. C. Madden, M. Nelms, K. Przybylak and A. N. Richarz. *School of Pharmacy and Chemistry, Liverpool John Moores University, Liverpool, United Kingdom. Sponsor: C. Yang.*

Prediction of repeat dose toxicity by in silico methods remains an elusive goal. Current quantitative structure-activity relationship (QSAR) approaches have acknowledged limitations. A more pragmatic approach is to identify relevant molecular initiating events associated with an adverse effect – integrated into the Adverse Outcome Pathway (AOP) concept – and attempt to group chemicals accordingly. Such an approach will have a greater probability of success if targeted at organ level toxicity. The purpose of this study was to develop novel structural alerts to enable to the grouping of potential liver toxicants. Specifically, the utility of current approaches for grouping according to protein reactivity (relating to reactive hepatotoxicity) was investigated along with novel methods to group chemicals and extract usable information from the grouping, placing in the context of relevant AOPs. The objective, therefore, was not to necessarily provide a better predictive model for liver toxicity, but to improve structural alerts to group compounds to perform read-across for liver toxicity. Data for over 900 compounds classified as either being toxic or non-toxic to the liver were assessed in this study. Attempts to group compounds on the basis of protein reactivity (the OECD Profiler in the OECD QSAR Toolbox) had poor predictivity, only identifying approximately 34% of liver toxicants, whilst nearly 25% of non-toxicants were found to contain a reactive structural alert. Therefore, the liver toxicants were grouped according to structural similarity using the ToxMatch software. Over 80 categories were found by this automated method from which 16 robust categories were manually curated, many of which were associated to mitochondrial toxicity AOPs. The suite of reactive and non-reactive MIEs, defined by structural alerts and chemotypes, provides a basis for grouping potential liver toxicants. Supported by the EU FP7 COSMOS and eTox Projects.

**PS 890 Construction of a Human Hepatotoxicity Database for QSAR Modeling.**

N. L. Kruhlak and X. Zhu. *CDER/OPS/OTR/DDSR, US FDA, Silver Spring, MD.*  
Sponsor: R. Benz.

Drug-induced liver injury (DILI) represents the second most common reason for pre-market attrition of drug candidates and post-market withdrawal of approved products, prompting the need for better tools to predict these serious effects. Quantitative structure-activity relationship (QSAR) modeling uses computational algorithms in conjunction with large chemical data sets to identify correlations between molecular structural features and biological activity, and lends itself well to the task of improving the prediction of drug safety by exploiting FDA's vast institutional knowledge of DILI and other adverse event (AE) data. This report describes the development of a new method for creating a DILI QSAR training set based on FDA's Adverse Event Reporting System data. The method utilizes the Multi-item Gamma Poisson Shrinker (MGPS) algorithm, the gold standard used by FDA CDER's Office of Surveillance and Epidemiology for AE signal identification, to generate Empirical Bayesian Geometric Mean (EGBM) scores for all drugs in the database binned by MedDRA preferred term. A set of 38 preferred terms (PTs) describing serious hepatic events, such as hepatic failure, hepatocellular injury, and hepatic cirrhosis, was selected based on related physiology and their adverse event counts were pooled to provide a more robust dataset for scoring purposes. An independently obtained verification set of 107 known hepatotoxins with evidence ranging from clinical manifestations (n=93) to market withdrawals (n=14), was used as a calibration set to determine whether the standard EGBM cutoff of 2.0 was appropriate for partitioning the training set. While 92% of the withdrawn drugs were correctly classified, only 50% of the positives with clinical manifestations were correctly classified, emphasizing the need for additional parameters and/or PTs to supplement the AE data used in the training set. This method created a set of over 2000 unique molecular entities that were structurally suitable for QSAR modeling.

**PS 891 Virtual Liver: Mapping Pathways to Liver Injury by Linking In Vitro Assays to In Vivo Outcomes.**

I. Shah<sup>1</sup>, J. Liu<sup>1</sup>, C. Corton<sup>2</sup>, S. Hester<sup>2</sup>, K. Houck<sup>1</sup>, T. B. Knudsen<sup>1</sup>, H. A. El-Masri<sup>2</sup>, J. Simmons<sup>2</sup>, J. F. Wambaugh<sup>1</sup> and C. Wood<sup>2</sup>. <sup>1</sup>NCCT, US EPA, Durham, NC; <sup>2</sup>NHEERL, US EPA, Durham, NC.

The EPA ToxCast project uses high-throughput screening (HTS) to evaluate in vitro bioactivity of chemicals. Here we are attempting to bridge HTS data with histopathological effects in ToxRefDB using a data-driven computational approach. Starting with 2,200 guideline studies for 763 chemicals stored in ToxRefDB, we defined 8 broad categories of hepatic histological effects consisting of hypertrophy, cytotoxicity, inflammation, regeneration, steatosis, fibrosis, preneoplasia, and neoplasia. A subset of 560/763 chemicals were screened in 500 ToxCast assays. Univariate statistical analysis found 91 assays in which chemicals had a significantly ( $p < 0.05$ ) greater potency for hepatic effects. We identify mechanistic relationships between the molecular and cellular targets of these assays from literature and use an information-theoretic criterion to calculate the most plausible sequence of key events for each outcome. The results are summarized as a dependency network including molecular initiating events (e.g. AhR, PXR, and PPAR), signal transduction (PI3K/AKT, p53, NFkB, JNK), cellular alterations (oxidative stress, mitochondrial dysfunction, cytoskeletal changes, cell cycle arrest and apoptosis), and histological effects. The analysis also suggests markers of hepatic lesion severity: chemicals that cause hypertrophy without injury have a 3-fold potency ( $p < 0.05$ ) for stress kinase activation; for hypertrophy and injury a 2-fold greater potency for G2/M arrest and p53 activation; and for steatosis a 2-fold greater potency for mitochondrial dysfunction. This work should inform current efforts to translate HTS data from a molecular scale to clinically-relevant health effects.

This work was reviewed by EPA and approved for publication but does not necessarily reflect official agency policy.

**PS 892 A Multiscale Dose-Response Model of AhR Toxicity Pathway Activation in the Human Liver.**

S. Bhattacharya, P. D. McMullen and M. E. Andersen. *Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.*

We have developed a spatial, multicellular agent-based computational model of the human liver lobule to study the contribution to hepatotoxic injury from multiple levels of biological organization. This multi-scale "virtual tissue" model combines

molecular circuits in individual hepatocytes with cell-cell interactions and blood-mediated transport of toxicants through hepatic sinusoids, and dosimetry estimated by whole-body PBPK models, to enable quantitative, mechanistic prediction of dose-response. We use the activation of the aryl hydrocarbon receptor (AhR) toxicity pathway in hepatocytes exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and other dioxin-like compounds (DLCs) as a case study for data integration and multi-scale model development for mechanistic dose-response prediction. By explicitly accounting for basal gradients in AhR expression across the lobule and stochastic uptake of TCDD molecules by individual hepatocytes, we were able to reproduce experimentally observed zonal heterogeneity in TCDD accumulation and cytochrome P450 1A1 expression. A detailed implementation of the AhR signaling and transcriptional cascade in each hepatocyte in this multicellular model enabled us to characterize differential dose response for various AhR-mediated endpoints at the tissue level, including cytotoxicity and cell proliferation.

**PS 893 Evaluation of Perchlorate Intake on Maternal and Fetal Serum T4 Levels Using a BBDR Model.**

A. Lumen<sup>1,3</sup>, D. R. Mattie<sup>2</sup> and J. W. Fisher<sup>3</sup>. <sup>1</sup>HJF, Rockville, MD; <sup>2</sup>711 HPW/RHDJ, Wright-Patterson AFB, OH; <sup>3</sup>US FDA/NCTR, Jefferson, AR.

Perchlorate (ClO<sub>4</sub><sup>-</sup>) is both a naturally occurring and man-made chemical widely distributed in the environment with low levels detected in food and drinking water. Disturbances in the maternal hypothalamic-pituitary-thyroid (HPT) axis leading to hypothyroxinemia and hypothyroidism have been shown to cause negative effects on the neurodevelopment of the fetus. Downstream perturbations of maternal and fetal HPT axes following ClO<sub>4</sub><sup>-</sup> competitive inhibition of sodium iodide symporter-mediated thyroidal iodide (I<sup>-</sup>) uptake have not been evaluated quantitatively. In order to quantitate effects of dietary I<sup>-</sup> intake, ClO<sub>4</sub><sup>-</sup> exposure and their interactions on maternal and fetal HPT axis, a biologically based dose response (BBDR) model for HPT axes in the pregnant woman and fetus was developed. The BBDR model includes sub-models for I<sup>-</sup>, ClO<sub>4</sub><sup>-</sup>, thyroxine (T<sub>4</sub>) and triiodothyronine (T<sub>3</sub>). The model was successfully calibrated for euthyroid, marginal iodide deficiency and ClO<sub>4</sub><sup>-</sup> exposure. Serum thyroid hormone changes were predicted for dietary I<sup>-</sup> intake ranging from 75 to 250 µg/day and for ClO<sub>4</sub><sup>-</sup> exposures of 0.01 to 1000 µg/kg/day. Model simulations suggest that ClO<sub>4</sub><sup>-</sup> at environmentally relevant ranges of exposure (~0.1 µg/kg/day) does not result in significant decreases in maternal and fetal free serum T<sub>4</sub> concentrations for maternal I<sup>-</sup> intake of 75 to 250 µg/day. For a daily I<sup>-</sup> intake of 200 µg/day, the daily dose of ClO<sub>4</sub><sup>-</sup> required to reduce serum free T<sub>4</sub> (fT<sub>4</sub>) levels from representative euthyroid region to a hypothyroxinemic state was estimated to be about 50-fold greater (32 µg/kg/day) than the current reference dose (RfD, 0.7 µg/kg/day). As I<sup>-</sup> intakes were lowered (150, 100 and 75 µg/day), ClO<sub>4</sub><sup>-</sup> doses required for similar reductions in fT<sub>4</sub> levels were reduced to 28, 16, and 4 µg/kg/day, respectively. This BBDR-HPT axis model for pregnancy provides a novel tool for public health assessments for endocrine active chemicals found in food and the environment. Funded by the Air Force Center for Engineering & the Environment through 711 HPW/RHDJ, WPAFB, OH.

**PS 894 Cross-Species and Life Stage PBPK Modeling of Dibenzo[def,p]chrysene.**

S. R. Crowell<sup>1</sup>, S. Hanson-Drury<sup>1</sup>, J. Soelberg<sup>1</sup>, N. Sadler<sup>1</sup>, A. Wright<sup>1</sup>, A. Sharma<sup>2</sup>, E. P. Madsen<sup>3</sup>, D. E. Williams<sup>3</sup> and R. A. Corley<sup>1</sup>. <sup>1</sup>Pacific Northwest National Laboratory, Richland, WA; <sup>2</sup>Penn State University, Hershey, PA; <sup>3</sup>Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous, often carcinogenic environmental contaminants generated as by-products of combustion processes. PAHs are found at almost half of Superfund sites, and are drivers for remediation in a significant percentage of those sites. Dibenzo[def,p]chrysene (DBC) is a high molecular weight and highly potent transplacental carcinogenic PAH. We developed the first species- and life stage-specific physiologically based pharmacokinetic (PBPK) models for high molecular weight PAHs that can be used to predict target tissue doses of PAH metabolites important to their carcinogenic mode of action. In rodents, we measured metabolic enzyme activity, rates of metabolism, and pharmacokinetics during vulnerable life stages such as pregnancy and fetal development. Pregnant animals had elevated tissue concentrations of DBC and its metabolites (2 – 4 fold increase in C<sub>MAX</sub>), and suppressed rates of clearance compared to naïve mice. Using activity-based protein profiling (ABPP), a unique proteomic approach for characterizing functional proteins in complex biological systems, to measure and compare enzyme activity, we found that multiple enzymes important for PAH metabolism have significantly altered activity during pregnancy and development in rodents and humans. Incorporating changes in anatomy and physiology during pregnancy as well as measured reductions in P450 enzyme activity accounted for

observed pharmacokinetic differences in mice. We have extrapolated our PBPK models to describe human dosimetry on the basis of human anatomy and physiology, and chemical specific human *in vitro* metabolic rates. In order to evaluate the extrapolated human model, a controlled human pharmacokinetic study of DBC at environmentally relevant exposure levels (30 ng bolus exposure) has been performed by our collaborators. Initial simulations of DBC concentrations in blood are remarkably similar to those observed in preliminary data from human volunteers.

**PS 895 Evaluating Early-Life Sensitivity to Pyrethroids by Physiologically-Based Pharmacokinetic (PBPK) Modeling Using *In Vitro* to *In Vivo* Extrapolation.**

H. Wu<sup>1</sup>, M. Yoon<sup>1</sup>, S. Anand<sup>2</sup>, B. G. Lake<sup>3</sup>, T. Osimitz<sup>4</sup>, N. Assaf<sup>5</sup>, A. Efremenko<sup>1</sup> and H. J. Clewell<sup>1</sup>. <sup>1</sup>The Hammer Institute for Health Sciences, Research Triangle Park, NC; <sup>2</sup>DuPont Haskell, Newark, DE; <sup>3</sup>LFR Molecular Sciences, Leatherhead, United Kingdom; <sup>4</sup>Science Strategies, LLC, Charlottesville, VA; <sup>5</sup>Valent BioSciences, Libertyville, IL.

The increased sensitivity of post-natal day (PND) 21 (weanling) rats to acute high-dose neurotoxicity of deltamethrin (DLM) poses the question of whether children will be more sensitive than adults both of whom are exposed to a much lower dose than rats. Age-related pharmacokinetic (PK) differences are hypothesized to be responsible for the observed differences in rats. We developed a PBPK model for human children based on rat PK and rat and human *in vitro* data. Our model incorporated species and age-dependent differences in metabolism of DLM as well as physiological changes during growth. The predicted age-dependent changes in brain C<sub>max</sub> correlated well with the maturation of metabolic capacity suggesting the lower metabolic clearance as a mechanism for the increased sensitivity in neonatal rats. The predicted C<sub>max</sub> in brain of PND 21 pups after a single oral dose of 4 mg/kg was 50% higher compared to PND 70 rats. The human model was developed similarly by incorporating maturation physiology and developmental changes in DLM metabolizing enzymes. Unlike the rat, the predicted brain C<sub>max</sub> of DLM was comparable between children and adults. After a single oral dose of DLM (0.1 mg/kg), the predicted C<sub>max</sub> was 1.4, 1.7, 2.4, and 2.0 pg/g, respectively, for children ages 1, 5, and 10 years old, and adults. The observed species differences in age-dependent PK seems to be largely attributable to the species differences in enzyme ontogeny and resulting metabolic clearance rates for DLM as well as differences in doses. In conjunction with age-specific exposure data, the current model will enable us to evaluate early life sensitivity in humans under environmentally relevant exposure conditions for this chemical and can be readily applicable to other pyrethroids with proper parameterization (supported by CAPHRA).

**PS 896 Evaluating Age-Related Sensitivity to Carbaryl-Induced Behavioral Changes by PBPK/PD Modeling.**

D. Billings<sup>1</sup>, M. Yoon<sup>1</sup>, V. C. Moser<sup>2</sup>, R. C. MacPhail<sup>2</sup> and H. J. Clewell<sup>1</sup>. <sup>1</sup>The Hammer Institutes for Health Sciences, Research Triangle Park, NC; <sup>2</sup>TAD/NHEERL/ORD, US EPA, Research Triangle Park, NC.

Due to its reversible inhibition of cholinesterases (ChEs), acute neurotoxicity is the primary effect of concern for carbaryl. Sensitivity to acute behavioral neurotoxicity of carbaryl was observed to be greater in aged rats, which was not fully attributable to differences in ChE inhibition. We used a PBPK/PD model to evaluate appropriate dose metrics to describe the observed age-related sensitivity to carbaryl in Brown Norway rats, using the change in horizontal motor activity as a marker of biological effect. The current model extends our previous PBPK/PD model in adult Sprague-Dawley rats that describes carbaryl disposition and inhibition of ChE in brain and blood. Age-appropriate physiological parameters were incorporated in the model in conjunction with age-specific metabolism parameters determined in primary hepatocytes isolated from young adult and aged rats (4, 12 and 24 month old). The model-simulated values compared well with the data both for peak and time-dependent changes in carbaryl concentration in the brain, liver and plasma as well as inhibition of ChE in brain and erythrocytes after a single oral exposure of carbaryl (3, 7.5, 15, or 22.5 mg/kg). While changes in motor activity were correlated with the degree of ChE inhibition at the time of peak effect (40 min), the model did not reproduce the recovery of activity in the older rats up to 240 min. The age-related difference was not explained by kinetics of reaction with ChE by carbaryl, but suggested differences in recovery dynamics in aged rats. The current study demonstrated the use of a PBPK/PD model to describe age-dependent acute effects and recovery from carbaryl, and provided a novel explanation for prolonged recovery in old animals. This is an abstract of a proposed presentation and does not reflect EPA policy (supported by EPA STAR grant R833452 and ACC-LRI).

**PS 897 Interpreting Biomonitoring Data for Di-n-Butyl and Di-(2-Ethylhexyl) Phthalate Metabolites in Urine Using a Physiologically-Based Pharmacokinetic Model and Reverse Dosimetry: Estimation of Cumulative *In Utero* Exposure.**

J. Campbell, R. A. Clewell, M. E. Andersen and H. J. Clewell. The Hammer Institutes for Health Sciences, Research Triangle Park, NC.

At high doses, several phthalate esters, including d-n-butyl and di-2-ethylhexyl phthalate (DBP and DEHP respectively), disrupt normal male reproductive development in rats. Human biomonitoring data have demonstrated phthalate exposure in humans of all ages based on serum, urine, cord blood and breast milk measurements. We used PBPK modeling and reverse dosimetry to infer likely environmental exposures from human biomonitoring data on phthalates in urine. Human PBPK models for DBP and DEHP and their primary metabolites – mono-n-butyl and mono-2-ethylhexyl phthalate (MBP and MEHP) – during pregnancy were developed from published rodent PBPK models and human data. To estimate daily intake of DBP and DEHP consistent with population measures of urinary metabolite levels, Monte Carlo analyses were performed to generate an inverted distribution between urine concentration and steady state exposure. Based on the NHANES III biomonitoring data, the predicted distribution of daily intake for DBP in the U.S. had a median of 0.65 µg/kg/day with a 95th percentile of 5.0 µg/kg/day. For DEHP the estimated daily intakes were higher, with a median of 1.86 µg/kg/day and a 95th percentile of 20.4 µg/kg/day. Applying forward dosimetry with the pregnancy PBPK model, the 95th percentile exposure concentration resulted in an average fetal plasma concentration of 6.77 µg/L for MBP and 1.4 µg/L for MEHP. These values can be compared to an average concentration of 1680 µg/L for MBP and 71.2 µg/L for MEHP in rat fetal plasma, simulated with the rat PBPK models at the NOAELs of 30 and 5 mg/kg, respectively, for developmental effects.

**PS 898 Species Extrapolation of Life-Stage PBPK Models to Investigate Ethanol Developmental Toxicity Using *In Vitro* to *In Vivo* Methods.**

E. D. McLanahan<sup>1</sup>, S. A. Martin<sup>2</sup>, S. Hunter<sup>2</sup> and H. A. El-Masri<sup>2</sup>. <sup>1</sup>ORD/NCEA, US EPA, Research Triangle Park, NC; <sup>2</sup>ORD/NHEERL, US EPA, Research Triangle Park, NC.

Ethanol (EtOH), which induces fetal alcohol spectrum disorder-related effects, was selected to investigate the use of PBPK models in a quantitative *in vitro* to *in vivo* extrapolation (IVIVE) paradigm. Mouse whole embryo culture data on EtOH time-concentration dependent induction of neural tube defects (NTDs) was used to assess embryotoxicity. Initially, published rat life-stage PBPK models were extrapolated to adult non-pregnant and pregnant mice and humans using species specific (SS) growth equations and parameters. Each model was able to predict blood EtOH concentrations (BEC) following multiple routes of exposure. Once calibrated with published data, the mouse and human models produced adequate simulations (within factor of 2) of time-course BEC data. An IVIVE was performed by estimating SS BECs in rat and mouse dams using *in silico* simulations for induction of NTDs *in vitro*. Then, a human model IVIVE was performed using rodent *in vitro* and pregnant human toxicity and epidemiological reports of EtOH exposure during windows of gestational susceptibility. As reported in the human literature, 150 mg/dl BEC is associated with developmental neurotoxicity. In human embryonic stem cells (hESCs), 145 mg/dl EtOH is associated with apoptosis and altered neuroprogenitor differentiation and proliferation. The similarity in effective concentration illustrates the utility of using BEC in pregnant women as a predictor of adverse developmental effects. However, since hESCs are more sensitive to EtOH-induced effects than mouse conceptuses *in vitro*, a human IVIVE based on mouse *in vitro* data exceeds the reported 150 mg/dl BEC. The human model predicted exposure scenarios within a factor of 2 of the observed toxic BECs. This research demonstrates both the capability of models to extrapolate between *in vitro* animal and *in vivo* human studies and the first pregnancy models for EtOH in mice and humans. The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. EPA.

**PS 899 A Simple *In Vitro* Approach for the Rapid Detection of Neurotoxicity.**

Q. Gu, S. Lantz, M. G. Paule and L. Schmued. Division of Neurotoxicology, US FDA National Center for Toxicological Research, Jefferson, AR.

Neurodegeneration is the underlying cause of a vast majority of neurological disorders and often a result of brain trauma, stroke, or neurotoxic insult. A widely used and reliable method for labeling degenerative neurons in *ex vivo* brain tissue involves the use of the Fluoro-Jade stains. Recently we described a novel method for

the labeling of degenerating neurons in unfixed brain tissue samples using Fluoro-Jade-C (FJC) (Gu et al. *Journal of Neuroscience Methods* 2012, 28:40-43). This method is simple, fast, and applicable to unfixed brain tissue sections and works at neutral pH. Based on these features, we extended our experimentation by examining the utility of FJC in vitro using cell cultures. Using neural stem cells, for example, we report here specific FJC labeling following treatment with neurotoxicants such as cadmium. The FJC labeling appears to be specific to neural cells, since other cell types such as cultured kidney epithelial cells did not show similar labeling even when cells were dying or dead. Further characterization and validation of this in vitro approach is underway. By employing FJC labeling in multi-well culture plates and using high-content time-lapsed recordings and additional techniques, a primary goal will be to achieve high-throughput monitoring and analysis of morphological, biochemical and molecular changes associated with the entire neurodegenerative process in cell culture models after neurotoxicant exposures. This in vitro approach has the potential to not only reduce animal use and suffering in toxicity tests but also to facilitate high-throughput screens for potentially neurotoxic compounds.

Supported by NCTR Protocols E07460 and E07477.

## PS 900 Evaluation of the Neuroactivity of ToxCast Compounds Using Multiwell Microelectrode Array Recordings of Primary Cortical Neurons.

P. Valdivia<sup>1,2</sup>, M. Martin<sup>3</sup>, W. LaFew<sup>4</sup>, J. Ross<sup>2</sup>, K. Houck<sup>3</sup> and T. J. Shafer<sup>4</sup>.

<sup>1</sup>Duke University, Durham, NC; <sup>2</sup>Axion Biosystems, Atlanta, GA; <sup>3</sup>NCCT, ORD, US EPA, Research Triangle Park, NC; <sup>4</sup>ISTD, ORD, US EPA, Research Triangle Park, NC.

Assessment of spontaneous activity in neuronal cultures on microelectrode arrays (MEA) is a sensitive method to detect responses to drugs, chemicals, and particles. While single-well MEA systems lack the efficiency to screen large numbers of compounds, recently developed multi-well MEA systems have increased throughput of MEAs. The present experiments examined the ability of a subset of EPA's ToxCast library of compounds to alter neuronal activity using 48 well MEA plates. Sixty-eight compounds were selected from the ToxCast Phase I and II chemical libraries based on known neuroactivity or data from 14 ToxCast in vitro assays indicating that they interacted with ion channels. Two compounds expected not to alter neuronal function, acetaminophen and saccharin, were included as negative controls. One hr of baseline activity was recorded prior to exposing the cortical networks to 40  $\mu$ M of each compound for 1 hr and the weighted mean firing rate (wMFR) was determined in the absence and presence of each chemical. All experiments were conducted on day in vitro 14 or 15. Based on DMSO-treated wells, chemicals that increased or decreased activity by  $>23.6\%$  were considered hits. Of the 68 compounds, 47 altered wMFR by more than the threshold. Saccharin and acetaminophen did not change wMFR beyond the threshold. Four of six pyrethroids, and 3/3 conazoles were detected as hits. Interestingly only 1/7 nicotinic agonists (nicotine&neonicotinoids) were hits, but were close to the threshold. These data demonstrate that multiwell MEAs can be used efficiently to screen chemicals for potential neurotoxicity and that the results are concordant with predictions from 14 ToxCast ion channel assays. Further, changes in wMFR may not be a sensitive measure to detect nicotinic effects in this culture model (This abstract was supported by CRADA #644-11 with Axion Biosystems. This abstract does not reflect Agency Policy).

## PS 901 Development of an In Vitro Multiwell Microelectrode Array (MEA) Neurotoxicity Assay with Human IPS-Derived Neurons.

Seizurogenic neurotoxicity produces significant drug attrition during drug discovery. Current available in vitro assays fail to predict this toxicity due to the failure of general cytotoxicity assays to predict sublethal target specific electrophysiological liabilities. Ion channel and receptor activity assays can be used to predict some seizure potential, but this only focuses on specifically measured targets for prediction and may miss a response which relies on a combination of endpoints. Most evaluation of seizure inducing compounds occurs later in preclinical development in in vivo studies which have higher costs and could result in species specific results. Therefore, the development of an in vitro assay to screen compounds for seizurogenic potential in a human neural model would give the potential to screen compounds earlier at lower cost and greater reliability. Here we demonstrate the use of

multiwell MEAs to screen for seizurogenic compounds in human IPS derived neurons (hsN). HsNs were seeded in 48 well MEAs and spontaneous activity began at 3 days post plating with greater activity at 7 days when the assay is performed. Neural action potentials were detected and the results were reported as mean firing rate (MFR). The seizurogenic compounds tested show dose dependent increase in MFR with changes in spike train organization, while all of the negative controls were unaffected. The seizurogenic compounds tested were Picrotoxin, Gabazine, L-Glutamate, and pentylenetetrazole (PTZ). Negative compounds tested were acetaminophen, naproxen, and DMSO. To further demonstrate the responsiveness of the cells in the assay, we tested Domoic Acid, a neurotoxin known to cause amnesia, and found that it completely blocked network activity while not causing cell death. These results illustrate the power of the human Neural MEA assay for predicting compound induced neural toxicity, especially the seizurogenic response.

## PS 902 In Vitro Neurotoxicity of Tetrabromobisphenol-A (TBBPA).

R. H. Westerink, R. G. van Kleef, M. van den Berg and H. S. Hendriks. *Neurotoxicology Research Group, Institute for Risk Assessment Sciences (IRAS) - Utrecht University, Utrecht, Netherlands.*

Tetrabromobisphenol-A (TBBPA) is a widely used brominated flame retardant. Studies on the in vitro neurotoxic potential of TBBPA focused on cytotoxicity and presynaptic effects of neurotransmission, while recent studies indicate that persistent organic pollutants can also affect postsynaptic inhibitory human GABAA and excitatory  $\alpha 4\beta 2$  nicotinic acetylcholine (nACh) receptors. Possible effects of TBBPA on these neurotransmitter receptors are of considerable interest as these receptors are critically involved in neurotransmission, synaptic plasticity and brain development. We therefore investigated the effects of TBBPA on these receptors, expressed in *Xenopus* oocytes, using the two-electrode voltage-clamp technique. Our results demonstrate that TBBPA acts as full ( $\geq 10 \mu$ M) and partial ( $\geq 0.1 \mu$ M) agonist on human GABAA receptors, while it acts as antagonist ( $\geq 10 \mu$ M) on human  $\alpha 4\beta 2$  nACh receptors. To further study the effects of TBBPA on calcium-permeable nACh receptors, effects in B35 cell were examined using single cell fluorescent calcium imaging. TBBPA ( $\geq 1 \mu$ M) inhibits ACh receptors in B35 cells as evidenced by a reduction in the ACh-evoked increases in the intracellular calcium concentration ( $[Ca^{2+}]_i$ ). Additionally, TBBPA ( $>1 \mu$ M) induces a strong and concentration-dependent increase in basal  $[Ca^{2+}]_i$  in B35 cells. In dopaminergic PC12 cells, TBBPA ( $>1 \mu$ M) also increases basal  $[Ca^{2+}]_i$ . The increase in basal  $[Ca^{2+}]_i$  is also evident under calcium-free conditions, indicating it originates from intracellular calcium stores. Moreover, depolarization-evoked increases in  $[Ca^{2+}]_i$  are strongly reduced by TBBPA ( $\geq 1 \mu$ M), indicating TBBPA-induced inhibition of voltage-gated calcium channels. Our in vitro studies thus demonstrate that TBBPA exerts multiple adverse effects on functional endpoints for neurotransmission, justifying the quest for flame retardants with reduced neurotoxic potential. Funding: EU-FP7 (ENFIRO; grant agreement FP7-ENV-2008-1-226563).

## PS 903 Modulation of Nicotinic Acetylcholine Receptor by Brominated and Alternative Halogen-Free Flame Retardants.

H. S. Hendriks, R. G. van Kleef and R. H. Westerink. *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands.*

The large scale use of brominated flame retardants (BFRs) is associated with ecological and toxicological concerns. Previous *in vitro* research demonstrated that nicotinic acetylcholine (nACh) receptors are a direct target for e.g., PBDEs and TBBPA. These (neuro)toxic effects of BFRs argue for replacement by safe(r) and less persistent alternatives. Since it is essential to assess the (neuro)toxic potential of proposed halogen-free flame retardants (HFFRs) before they are used on large scale and in high volume, we measured the effects of three frequently used BFRs and 13 possible halogen-free substitutes on the function of human  $\alpha 4\beta 2$  nACh receptors, expressed in *Xenopus* oocytes, using the two-electrode voltage-clamp technique. Our initial rank-order potency based on the *in vitro* inhibition of nACh receptors indicates the neurotoxic potential of the HFFR triphenylphosphate (TPP), aluminium diethylphosphinate (Alpi), ammonium polyphosphate (APP), and the nanoclay cloisite 30B (MMT). However, additional studies focusing on expected concentrations in humans and the environment are required before these compounds can be excluded as viable alternatives. Importantly, five out of the sixteen tested compounds (brominated polystyrene (BPS), bisphenol-A bis(diphenylphosphate) (BDP), resorcinol bis(diphenylphosphate) (RDP), 9,10-dihydro-9-oxa-10-phosphaphenanthrene-10-oxide (DOPO), and zinc stannate (ZS)) are classified as not potent. Based on this specific neurotoxic endpoint, these five compounds could therefore be selected for additional testing to further assess the viability of these HFFRs as alternatives to replace current BFRs.

**PS 904 Neurotoxic Effects of Bisphenol AF by the Calcium-Induced ROS and MAPKs.**

S. Kim and S. Lee. *Pharmacology, Kyungpook National University Medical School, Daegu, Republic of Korea.*

Bisphenol AF (BPAF), a newly introduced chemical structurally related to bisphenol A (BPA), is used extensively in fluoroelastomers and polyesters, and has been known to induce estrogen-dependent responses. However, the toxicity of BPAF is largely unknown except for its endocrine-related effects. In this study, we investigated the neurotoxicity of BPAF and underlying mechanisms of action using hippocampal cell line (HT-22) and mouse primary neuronal cells. We found that BPAF induced apoptosis in both HT-22 and primary neuronal cells. To clarify the underlying mechanisms of BPAF-induced apoptosis, various signaling molecules were evaluated. BPAF increased the level of intracellular calcium, followed by the generation of reactive oxygen species (ROS). BPAF upregulated the phosphorylation of mitogen-activated protein kinase (MAPK): extracellular signal-regulated kinase (ERK), p38 and c-Jun N-terminal kinase (JNK), and nuclear translocation of nuclear factor (NF)- $\kappa$ B. Using specific inhibitors, we confirmed that calcium, ROS, p38, and JNK mediated the BPAF-induced apoptosis. In addition, BPAF inhibited microglial activation in a microglia/neuroblastoma coculture model by the reduction of nitric oxide production. We found that BPAF interrupted the normal physiological functions of microglia at non-toxic levels. Taken together, our results suggest that BPAF, the substitute of BPA, also have neurotoxic properties.

**PS 905 Potent Induction of a Series of Endogenous Antioxidative Enzymes by Triterpenoid CDDO-IM Leads to Neuprotection Against Oxidative and Electrophilic Injury.**

A. Speen, C. Jones, R. Patel and Z. Jia. *Department of Biology, University of North Carolina Greensboro, Greensboro, NC.*

Evidence suggests oxidative and electrophilic stress as a major factor contributing to the neuronal cell death in neurodegenerative disorders, especially Parkinson's disease (PD). Early depletion in the levels of thiol antioxidant glutathione (GSH), which may lead to generation of reactive oxygen species, is an important biochemical feature of PD. However, whether induction of endogenous antioxidative enzymes by a novel triterpenoid CDDO-IM (2-cyano-3,12 dioxoooleana-1,9 dien-28-oyl imidazoline) affords protection against oxidative and electrophilic neurocytotoxicity has not been carefully investigated. Retinoic acid-induced differentiation of human neuroblastoma SH-SY5Y cells are known to possess properties of mature neurons and thus have been widely used in vitro model for the study of neurotoxicity and neuprotection. In this study, we showed that incubation of retinoic acid-induced differentiation of human neuroblastoma SH-SY5Y cells with nanomolar concentrations of CDDO-IM (1-400 nM) for 24 h resulted in significant increase in the levels of reduced glutathione (GSH) and NAD(P)H:quinone oxidoreductase 1 (NQO1), two critical cellular defenses in detoxification of reactive oxygen species and electrophilic quinone molecules. Pretreatment of the cells with CDDO-IM was found to afford remarkable protection against the neurocytotoxicity elicited by acrolein, 4-hydroxynonenal, 3-morpholininosynonimine hydrochloride, xanthine oxidase/xanthine, and hydrogen peroxide. Taken together, this study demonstrates for the first time that CDDO-IM potentially induces the cellular GSH system and NQO1 in retinoic acid-induced differentiation of human neuroblastoma SH-SY5Y cells, which is accompanied by dramatically increased resistance of these cells to the damage induced by various neurotoxicants. The results of this study may have important implications for the development of novel neuroprotective strategies.

**PS 906 1, 3-Dinitrobenzene Induces Age-Specific Responses in Primary Neurons.**

L. Maurer<sup>1</sup>, N. D. Hein<sup>2</sup>, J. D. Latham<sup>1</sup>, R. Landis<sup>3</sup>, I. Speirs<sup>1</sup> and M. A. Philbert<sup>1</sup>. <sup>1</sup>Toxicology Program, University of Michigan, Ann Arbor, MI; <sup>2</sup>Neurology, University of Michigan, Ann Arbor, MI; <sup>3</sup>Kalamazoo College, Kalamazoo, MI.

During the normal aging process, the brain successively loses the ability to cope with pathophysiological stressors. The accumulation of iron in the aging brain potentially contributes to this by increasing redox activity. Astrocytes participate in the preservation of neurons during chemically induced stress by releasing adenosine, thereby silencing the electrical (hence energetic and metabolic) requirements

of neurons. 1,3-dinitrobenzene (DNB) stimulates adenosine release from astrocytes, and is used as a neural stressor probe in this study. Primary neurons and astrocytes were exposed to DNB (0, 100nM, or 100  $\mu$ M) and 10  $\mu$ M adenosine with 100nM or 100 $\mu$ M DNB. Neurons were isolated from male F344 rats (1 mo, 3 mo, & 18 mo), maintained for two weeks and exposed to DNB. Astrocytes were isolated and maintained for five weeks and cocultured with neurons. Adenosine triphosphate (ATP) was measured in both cell types. Neurons from 3 mo brains exhibited higher ATP than neurons from other age groups. Cocultured astrocytes had higher ATP levels than neurons at all age groups. Neurons were assayed at a later timepoint for lactate dehydrogenase (LDH). Neurons from brains of 1 mo and 18 mo rats, but not 3 mo rats, exposed to DNB exhibit statistically significantly higher LDH than neurons treated with both DNB and adenosine. Immunocytochemistry for the presence of transferrin (Tf) and mitochondrial frataxin (mtFr) was performed on neurons. Increases in Tf were observed in older neurons. Colocalization of Tf and mtFr was observed in the oldest age group. These results suggest that neurons from older animals sequester more mitochondrial iron than younger cohorts, increasing potential for higher redox activity, rendering them more vulnerable to chemical insults such as DNB. Future work will elucidate the significance of mitochondrial iron in the aging process.

**PS 907 Magnetic Resonance Imaging and Spectroscopic Markers of Kainic Acid-Induced Excitotoxicity in the Rat Brain.**

S. Liachenko<sup>1</sup>, J. Ramu<sup>1</sup>, M. G. Paule<sup>1</sup>, L. Schmued<sup>1</sup> and J. P. Hanig<sup>2</sup>. <sup>1</sup>Neurotoxicology, NCTR/US FDA, Jefferson, AR; <sup>2</sup>Office of Testing & Research, CDER/US FDA, White Oak, DC.

Neurotoxicity assessment in drug development is typically accomplished using microscopic analysis, which may be time consuming and not always comprehensive. In this study we describe changes in brain after acute administration of kainic acid (KA) using non-invasive magnetic resonance imaging (MRI) and spectroscopy (MRS) in comparison to histopathology. Adult male Sprague-Dawley rats (N = 24, 361  $\pm$  36 g) were anesthetized with isoflurane and positioned inside a 7 tesla MRI scanner. T2 relaxation mapping of the whole brain and proton MRS in the left hippocampus were performed. KA (10 mg/kg, ip) was then administered to all animals after baseline scans and imaging was continued for another 2 hours. One group of animals (N = 6) was euthanized at this time. The MRI procedure was repeated one day (N = 6) and 2 days later (N = 12) and these animals were then euthanized. All rats were perfusion-fixed and their brains underwent histopathological assessment. KA led to an increase in T2 in the hippocampus as early as 1 hour after administration. These changes were more pronounced at 2 hours and drastically so at 1 and 2 days after the treatment at which point the findings spread to wider areas of the brain, including the amygdala, thalamus, and cortex. MRS revealed immediate increases in glutamate and glutamine concentrations right after KA administration followed by decreases at 1 and 2 days, at which point N-acetyl-aspartate signal was also decreased. Lactate was not detectable in the normal brain but appeared at 15 min and increased to a maximum at 2 hours after treatment. At 1 and 2 days lactate was still detectable. The T2 water relaxation correlated with histopathological changes in the brain at all time points. These data provide the basis for the development of imaging biomarkers for the early detection of neurotoxicity, which would benefit public health by increasing the number of tools available for safety evaluation of new drugs. (Supported by NCTR and CDER, FDA, #E0741801).

**PS 908 Effect of Acute Administration of Beta-N-Methylaminoalanine (L-BMAA) on Rat Hippocampus Neurochemical Profile Determined with 1H Magnetic Resonance Spectroscopy (MRS).**

J. Ramu<sup>1</sup>, J. P. Hanig<sup>2</sup>, E. C. Garner<sup>3</sup>, M. G. Paule<sup>1</sup> and S. Liachenko<sup>1</sup>. <sup>1</sup>Neurotoxicology, NCTR/US FDA, Jefferson, AR; <sup>2</sup>Office of Testing & Research, CDER/US FDA, White Oak, MD; <sup>3</sup>Lovelace Respiratory Research Institute, Albuquerque, NM.

L-BMAA is a non-proteogenic amino acid present in cyanobacteria and in cycad seed, exposure to which is implicated in western Pacific amyotrophic lateral sclerosis and parkinsonism-dementia complex (ALS-PDC). After absorption, L-BMAA is transported into the brain, metabolized, and L-BMAA and/or its metabolites may accumulate in brain protein. This bound form may serve as a sink from which L-BMAA or its metabolites are released, contributing to its neurotoxic effect. L-BMAA has been shown to be excitotoxic, acting as a glutamate receptor agonist. In

this study we used non-invasive <sup>1</sup>H-MRS to investigate the changes in the hippocampal neurometabolic profile after single dose of L-BMAA. Nine adult male Sprague-Dawley rats (390 ± 8 g) were anesthetized with isoflurane and positioned in 7 tesla MRI scanner. MRS in the left hippocampus (voxel size 4 x 4 x 2 mm) was performed before and for 1.5 hrs after BMAA administration (100 mg/kg, ip). Signal intensity of N-acetyl-aspartate, gamma-aminobutyric acid (GABA), creatine, choline, glutamate, glutamine, myo-inositol, and taurine were measured relative to water peak in water-unsuppressed reference spectrum. At the end of observation period the GABA signal was elevated relative to the baseline (+23%, P = 0.051) and taurine was decreased (-10%, P = 0.014). Signal intensity of other neurotransmitters did not change. These data may be consistent with L-BMAA mediated glutamate agonist activity. Both GABA and taurine are released into extracellular space after stimulation of NMDA receptors. Increase in GABA may be due to a combination of uptake and increased synthesis. The lowering of hippocampal taurine may reflect a reduction in re-uptake after release. These data suggest that L-BMAA has measurable effect on glutaminergic pathways in undisturbed, intact tissues in rats.

## PS 909 Pattern of Pathologic Changes Observed in the CNS of Chronic Toluene Abusers.

D. Pyatt<sup>1,2</sup> and P. Kerzic<sup>3</sup>. <sup>1</sup>Summit Toxicology, Superior, CO; <sup>2</sup>Schools of Pharmacy and Public Health, University of Colorado, Denver, CO; <sup>3</sup>Cinpathogen, Los Angeles, CA.

Toluene is a common volatile organic chemical (VOC) found in petroleum-based products and has wide-spread industrial use as a solvent in paints, lacquers, inks, adhesives and cleaning agents (degreasing). The toxicity of toluene has been well described in experimental animals, occupationally exposed humans and healthy volunteers. Considerable toxicological data has also been obtained from individuals who purposely expose themselves to high levels of toluene and/or toluene containing solvents to achieve the narcotic effect common to most organic solvents. Collectively, this data has demonstrated that high-dose prolonged exposure to toluene can cause neurological toxicity, ranging from non-specific, reversible symptoms to permanent pathological changes in the 'white matter' of the brain. Evaluation of chronic toluene abusers by magnetic resonance imaging (MRI) have revealed a series of pathologic alterations that appear to be common to most, if not all, toluene abusers that suffer from permanent neurological alterations. These individuals almost always provide evidence of direct toxic insult, including diffuse atrophy in the brain and/or areas of de-myelination and axonal dying. Other frequently reported pathological changes include hypo-intensity of the thalamus region and basal ganglia, high T2 signal intensity in the periventricular white matter and a loss of grey-white demarcation or differentiation. Most authors report a clear dose-response relationship, describing exposures (durations as well as intensities) necessary to cause these lesions observed in the white matter. While none of the reported alterations are dispositive of toluene exposure, the consistent pathological pattern observed in the MRIs of chronic toluene abusers (or those with severe occupational exposures) has not been previously appreciated or reported. The existing scientific evidence relevant to this issue, including exposure-response data (where available), has been comprehensively evaluated and is presented herein.

## PS 910 Effects of Short- and Long-Term Exposure to 1-Bromopropane on Neurogenesis in Adult Rats.
