**Abstract** Experimentally determined ultrasonic velocity, density and viscosity have been used to compute various acoustical parameters such as adiabatic compressibility, free length, free volume, internal pressure, etc. These parameters provide valuable information about the various properties of liquids and liquid mixtures. This note presents a compact C-program to compute all the important acoustical parameters of pure liquids.

**Keywords** Acoustical parameters, pure liquids, C-program

**PACS No.** 43.35.Bf, 07.05.kf

Ultrasonic studies seem to be a complementary technique to spectroscopic [1, 2] and dielectric [3, 4] methods. The derived acoustical parameters from the experimentally measured values of ultrasonic velocity, density and viscosity provide a tool for understanding the molecular behaviour of liquid mixtures. The excess values of these parameters and their nonlinear variations observed in liquid mixtures reveal the nature of molecular interactions. To facilitate the computation of various acoustical parameters a compact C-program is developed and presented.

The definitions and formula of the most commonly used acoustical parameters of pure liquids are briefly presented as follows:

**Adiabatic compressibility :**

$\beta$  (pascal<sup>-1</sup>) is the fractional decrease of volume per unit increase of pressure, when no heat flows in or out [5] and is given by,

$$\beta = \frac{1}{\rho U^2} \quad (1)$$

\* Corresponding Author

<sup>1</sup> Physics Wing, Directorate of Distant Education, Annamalai University, Annamalainagar-608 002, Tamil Nadu, India

where,  $\rho$  is density in kg m<sup>-3</sup> and  $U$  is ultrasonic velocity in

**Free length :**

$L_j$  (meters) is the distance between the surface of the neighbouring molecules [6] and is given by

$$L_j = K_T \beta^{1/2}, \quad (2)$$

where  $K_T$  is temperature-dependent constant (for example, it has a value of  $199.53 \times 10^{-8}$  at 303 K).

**Free Volume :**

This is the free space between the molecules for movement, denoted as  $V_f$  (m<sup>3</sup> mol<sup>-1</sup>) and is given by [7]

$$V_f = \left| \frac{M_{eff} U}{\eta K} \right|^{1/2} \quad (3)$$

where  $M_{eff}$  is Molecular effective weight,  $\eta$  is viscosity in NS m<sup>-2</sup> and  $K$  is temperature independent constant (it has a value of  $4.28 \times 10^9$  for all liquids).

**Internal Pressure :**

$\pi_i$  (poise) is the cohesive force, which is a resultant of force of attraction and force of repulsion between the molecules [8]. It can be conveniently expressed as

$$\pi_i = bRT \left[ \frac{K\eta}{U} \right]^{1/2} \left[ \frac{\rho^{3/4}}{M^{1/2}} \right] \quad (4)$$

where  $b$  is cubic packing,  $R$  is universal gas constant and  $T$  is absolute temperature ( $b$  has a constant value of 2 for all liquids).

**Molar available volume :**

$V_u$  ( $\text{m}^3 \text{mol}^{-1}$ ) is difference between the molar volume at  $T$  ( $K$ ) and at 0 ( $K$ ). It is the direct measure of the compactness and strength of bonding between the molecules of the liquid. The available volume of liquid can be calculated from combined Jacobson and Schaaff's equation [9, 10].

$$V_u = V_T \left[ 1 - \frac{U}{U_\alpha} \right] \quad (5)$$

where  $V_T$  is molar volume at  $T^\circ\text{K}$  and  $U_\alpha$  is 1600 m/sec.

**Specific acoustic impedance :**

This is denoted by  $Z$  ( $\text{kg m}^{-2} \text{s}^{-1}$ ) and for a liquid, is related to the ultrasonic velocity as given below [11]

$$Z = \rho U \quad (6)$$

**Relaxation time :**

This ( $\tau$  sec) describes the rate at which molecules return to their original positions after being displaced by force. The relaxation time is estimated from the following relation [12]

$$\tau = \frac{4}{3} \eta \beta \quad (7)$$

**Gibb's free energy :**

This ( $\Delta G$  in  $\text{kJ mol}^{-1}$ ) can be estimated from the following relation [13]:

$$\Delta G = -2.303 kT \log k T \tau \quad (8)$$

where  $k$  is Boltzmann constant,  $T$  is temperature in Kelvin and  $h$  is Plank's constant.

Attenuation of ultrasonic waves is a characteristic of the material and it is represented by the *absorption coefficient*,  $\alpha$  ( $\text{s}^{-2} \text{m}^{-1}$ ). The attenuation constant  $\alpha$  is given by

$$\alpha = \frac{2\omega^2 \eta}{3\rho U^3} \quad (9)$$

where,  $\omega$  is  $2\pi f$ ,  $f$  is frequency

These acoustical parameters can be very easily computed using the developed simple C-program given in the Appendix. The variable names representing the acoustical parameters

**Table 1.** Values of density ( $\rho$ ), viscosity ( $\eta$ ), ultrasonic velocity ( $U$ ) and acoustical parameters of pure liquids  
 $T = 303 \text{ K}$ ,  $f = 3 \text{ MHz}$

\*Ref [14], \*Ref [15], \*Ref [16], The remaining Ref [13]

and the other variable names used in the program are given below:

abs	:	Absorption coefficient,
ac	:	Adiabatic compressibility,
ai	:	Acoustic impedance,
av	:	Available volume,
fl	:	Free length,
fv	:	Free volume,
ip	:	Internal pressure,
n	:	Relaxation time,
m	:	Molecular weight,
d	:	Density,
e1	:	Viscosity,
u	:	Velocity,
w	:	Angular frequency,
f	:	Frequency,
t	:	Temperature (K),
ua = u <sub>ra</sub>	:	1600 m/sec, and
r	:	Universal gas constant.

Using the compact, simple, and easily readable C-program, the acoustical parameters of pure liquids are readily computed without any ambiguity. The program has been executed and the values of the various acoustical parameters obtained for some (eleven) pure liquids, are compared with the previously available literature values (Table 1).
