In the racemic title molecular salt, $\mathrm{C}_{17} \mathrm{H}_{17} \mathrm{~F}_{6} \mathrm{~N}_{2} \mathrm{O}^{+} \cdot \mathrm{C}_{2} \mathrm{ClF}_{2} \mathrm{O}_{3}{ }^{-}$(systematic name: 2-\{[2,8-bis(trifluoromethyl)quinolin-4-yl](hydroxy)methyl\}piperidin-1-ium chlorodifluoroacetate), the cation, which is protonated at the piperidine N atom, has the shape of the letter, $L$, with the piperidin-1-ium group being approximately orthogonal to the quinolinyl residue [the $\mathrm{C}_{\mathrm{q}}-\mathrm{C}_{\mathrm{m}}-\mathrm{C}_{\mathrm{m}}-\mathrm{N}_{\mathrm{a}}(\mathrm{q}=$ quinolinyl; $\mathrm{m}=$ methine; $\mathrm{a}=$ ammonium) torsion angle is $\left.177.79(18)^{\circ}\right]$. An intramolecular, charge-assisted ammonium- $N-H \cdots O$ (hydroxyl) hydrogen bond ensures the hydroxy-O and ammonium- N atoms lie to the same side of the molecule $\left[\mathrm{O}_{\mathrm{h}}-\mathrm{C}_{\mathrm{m}}-\mathrm{C}_{\mathrm{m}}-\mathrm{N}_{\mathrm{a}}(\mathrm{h}=\right.$ hydroxyl $\left.)=-59.7(2)^{\circ}\right]$. In the crystal, charge-assisted hydroxyl- $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}^{-}$(carboxylate) and ammonium- $\mathrm{N}^{+}-$ $\mathrm{H} \cdots \mathrm{O}^{-}$(carboxylate) hydrogen bonds generate a supramolecular chain along [010]; the chain is consolidated by $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions. Links between chains to form supramolecular layers are of the type $\mathrm{C}-\mathrm{Cl} \cdots \pi\left(\right.$ quinolinyl- $\mathrm{C}_{6}$ ) and the layers thus formed stack along the $a$-axis direction without directional interactions between them. The analysis of the calculated Hirshfeld surface points to the dominance of $\mathrm{F} \cdots \mathrm{H}$ contacts to the surface ( $40.8 \%$ ) with significant contributions from $\mathrm{F} \cdots \mathrm{F}(10.5 \%)$ and $\mathrm{C} \cdots \mathrm{F}(7.0 \%)$ contacts.

## 1. Chemical context

Practical interest in compounds related to the title salt relates to the biological activity of Mefloquine ([2,8-bis(trifluoro-methyl)quinolin-4-yl]-piperidin-2-ylmethanol). This arises when the racemic compound is reacted with HCl : the resulting salt, $\quad\left[\left(R^{*}, S^{*}\right)-(2-\{[2,8\right.$-bis(trifluoromethyl)quinolin-4-yl](hy-droxymethyl)piperidin-1-ium chloride is an anti-malarial drug, being effective against the causative agent, Plasmodium falciparum (Maguire et al., 2006). Subsequently, diverse pharmaceutical potential has been disclosed, namely, as antibacterial (Mao et al., 2007), anti-mycobacterial (Gonçalves et al., 2012) and as anti-cancer agents (Rodrigues et al., 2014). With the preceding facts in mind, it is not surprising that crystallography has played a key role in establishing the molecular structures of this class of compound. Of particular crystallographic interest has been the characterization of a pair of kryptoracemates of mefloquinium salts in recent years (Jotani et al., 2016; Wardell, Wardell et al., 2016). The phenomenon of kryptoracemic behaviour has been reviewed in the last decade for both organic and coordination compounds (Fábián \& Brock, 2010; Bernal \& Watkins, 2015).

Briefly, for a material to be classified as kryptoracemic, it must satisfy the following crystallographic criteria: the space group must be one of the 65 Sohncke space groups, i.e. lacking an inversion centre, rotatory inversion axis, glide plane or a mirror plane, and $Z^{\prime}$ would usually be greater than 1 (unless the molecule lies on a rotation axis). In a continuation of structural studies of Mefloquine derivatives (Wardell et al., 2011; Wardell, Jotani et al., 2016), herein the crystal and molecular structures of the title salt, (I), isolated from the 1:1 crystallization of racemic Mefloquine and chlorodifluoroacetic acid are described along with an analysis of its calculated Hirshfeld surface.

## 2. Structural commentary

The ions comprising the asymmetric unit of (I) are shown in Fig. 1. The illustrated cation has two chiral centres, namely $R$ at C 12 and $S$ at C13, i.e. it is the [(+)-erythro-mefloquinium] isomer. However, it should be noted that the centrosymmetric unit cell has equal numbers of the other $S$-, $R$ - enantiomer, indicating that no resolution occurred during the crystallization experiment as has been observed in some of the earlier studies (see Chemical context). The pattern of hydrogen-bonding interactions involving the ammonium- $\mathrm{N}-$ H H atoms (see Supramolecular features) provides confirmation of protonation at the N 2 atom during crystallization and, therefore, the formation of a piperidin-1-ium cation. At the same time, delocalization of the $\pi$-electron density over the carboxylate residue is confirmed by the equivalence of the $\mathrm{C} 18-\mathrm{O} 2$, O 3 bond lengths, i.e. $2 \times 1.238$ (3) $\AA$.

The quinolinyl residue is not strictly planar with the r.m.s. deviation for the ten fitted non-H atoms being $0.0399 \AA$. This is also reflected in the dihedral angle formed between the (N1,C1-C4,C9) and (C4-C9) rings of 3.95 (15) A. This aspect of the structure notwithstanding, the hydroxyl-O and ammo-nium- N atoms lie to opposite sides of the plane through the quinolinyl residue. This is seen in the value of the $\mathrm{C} 2-\mathrm{C} 3-$ C12-O1 torsion angle of $-20.3(3)^{\circ} c f$. with that of $177.79(18)^{\circ}$ for $\mathrm{C} 3-\mathrm{C} 12-\mathrm{C} 13-\mathrm{N} 2$. The latter angle indicates the piperidin-1-ium residue is almost perpendicular to the quinolinyl residue with the methylene-C17 group orientated towards the fused-ring system as seen in the gauche C3$\mathrm{C} 12-\mathrm{C} 13-\mathrm{C} 17$ torsion angle of $-60.7(3)^{\circ}$. The observed

Symmetry codes: (i) $x, y-1, z$; (ii) $-x+1,-y+1,-z+1$; (iii) $x, y+1, z$; (iv) $-x+1, y+\frac{1}{2},-z+\frac{1}{2}$.
conformation, whereby the hydroxy-O and ammonium-N atoms lie to the same side of the molecule [the $\mathrm{O} 1-\mathrm{C} 12-$ $\mathrm{C} 13-\mathrm{N} 2$ torsion angle is $-59.7(2)^{\circ}$ ], is stabilized by an intramolecular, charge-assisted ammonium- $\mathrm{N}^{+}$H...O1(hydroxyl) hydrogen bond, Table 1. In general terms, the shape of the cation is based on the letter, $L$.

The anion in (I) adopts a conformation where the Cl 1 atom lies to one side of the $\mathrm{O}_{2} \mathrm{C}_{2}$ plane [r.m.s. deviation $=0.0089 \AA$ ], with the $\mathrm{O} 2-\mathrm{C} 18-\mathrm{C} 19-\mathrm{Cl} 1$ torsion angle being $-93.3(2)^{\circ}$, and the F7 and F8 atoms lying to the other side, the O2$\mathrm{C} 18-\mathrm{C} 19-\mathrm{F} 7, \mathrm{~F} 8$ torsion angles $=28.8$ (3) and $146.3(2)^{\circ}$, respectively. The conformation of the $\mathrm{CClF}_{2}$ residue in (I) has been observed in the structure of the acid (Schilling \& Mootz, 1995), the acid monohydrate and tetrahydrate (Dahlems et al., 1996) and in salts, e.g. with mono-protonated 1,4-diazabicyclo[2.2.2]octane (dabco), i.e. 4-aza-1-azoniabicyclo[2.2.2]octane, for which three independent ion pairs comprise the asymmetric unit (Shi et al., 2013).

Figure 1
The molecular structures of the ions comprising the asymmetric unit of (I) showing the atom-labelling scheme and displacement ellipsoids at the $70 \%$ probability level. The dashed line signifies the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond.

## 3. Supramolecular features

The presence of charge-assisted hydroxyl-O $-\mathrm{H} \cdots \mathrm{O}^{-}$(carb(carboxylate) and ammonium $-\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}^{-}$(carboxylate) hydrogen bonding features prominently in the molecular packing of (I) and leads to a supramolecular chain propagating along the $b$-axis direction, Fig. $1 a$ and Table 1. The ammonium $-\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}^{-}$(carboxylate) hydrogen bonds link two cations and two anions about a centre of inversion to form eight-membered $\{\cdots \mathrm{HNH} \cdots \mathrm{O}\}_{2}$ synthons, Fig. $2 b$. These are

(b)

Figure 2
Molecular packing in (I): (a) The supramolecular chain along the $b$-axis direction, being sustained by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding with non-participating H atoms omitted, (b) a simplified view of the chain highlighting the formation of the eight- and 18 -membered supramolecular synthons and (c) a view of the unit-cell contents shown in projection down the $b$-axis direction. The $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}, \mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{Cl} \cdots \pi$ interactions are shown as orange, blue and purple dashed lines, respectively.

Table 2
Summary of short interatomic contacts ( A ) in (I).

| Contact | Distance | Symmetry operation |
| :--- | :--- | :--- |
| H7 $\cdots \mathrm{H} 15 B$ | 2.08 | $x, \frac{3}{2}-y,-\frac{1}{2}+z$ |
| F1 $16 B$ | 2.56 | $2-x, 1-y, 1-z$ |
| F6 $\cdots$ H15B | 2.58 | $x, \frac{3}{2}-y,-\frac{1}{2}+z$ |
| F4 $\quad$ F5 | $2.903(2)$ | $2-x, \frac{1}{2}+y, 1-z$ |

linked into a supramolecular chain via hydroxyl-O$\mathrm{H} \cdots \mathrm{O}^{-}$(carboxylate) hydrogen bonding, which leads to 18 membered $\left\{\cdots \mathrm{OCO} \cdots \mathrm{HNC}_{2} \mathrm{OH}\right\}_{2}$ synthons, Fig. $2 b$. In this scheme, the carboxylate-O2 atom forms two hydrogen bonds. Additional stability to the supramolecular chain is afforded by quinolinyl- $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ (carboxylate) and methylene-C$\mathrm{H} \cdots \mathrm{O}$ (hydroxyl) interactions, Table 1. The chains are connected into layers via $\mathrm{C}-\mathrm{Cl} \cdots \pi(\mathrm{C} 4-\mathrm{C} 9)$ interactions, Table 1. The layers stack along the $a$-axis direction without directional interactions between them, Fig. $2 c$.

## 4. Hirshfeld surface analysis

The Hirshfeld surface calculations for the title salt (I) were performed in accord with an earlier publication on a related salt (Jotani et al., 2016) and satisfactorily describe the additional influence of interatomic halogen-halogen, halogenhydrogen and halogen $\cdots \pi$ contacts upon the packing. In addition to bright-red spots on the Hirshfeld surfaces mapped over $d_{\text {norm }}$ in Fig. $3 a$ and $b$ (labelled 1-3), corresponding to intermolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}, \mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions, Table 1, the presence of tiny faint-red spots, having labels $\mathrm{S} 1-\mathrm{S} 4$ in Fig. $3 c$ and $d$, indicate the influence of short

Figure 3
Views of the Hirshfeld surface of (I) mapped over $d_{\text {norm }}$ in the range -0.077 to +1.575 au , highlighting: (a) and (b) intermolecular hydrogen bonds (with labels $1-3$ ) by black-dashed lines, and (c) and (d) short interatomic $\mathrm{H} \cdots \mathrm{H}, \mathrm{F} \cdots \mathrm{H}$ and $\mathrm{F} \cdots \mathrm{F}$ contacts (with labels S1-S4) by skyblue, red and black dashed lines, respectively.

Figure 4
Two views of the Hirshfeld surface of (I) mapped over the electrostatic potential in the range -0.133 to +0.219 au . The red and blue regions represent negative and positive electrostatic potentials, respectively.

Figure 5
Two views of Hirshfeld surface of (I) mapped over the shape-index property highlighting ( $a$ ) $\mathrm{C}-\mathrm{Cl} \cdots \pi$ and (b) $\mathrm{C}-\mathrm{F} \cdots \pi$ contacts by yellow and black dotted lines, respectively
interatomic $\mathrm{H} \cdots \mathrm{H}, \mathrm{F} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{F}$ and $\mathrm{F} \cdots \mathrm{F}$ contacts [Table 2; calculated in CrystalExplorer3.1 (Wolff et al., 2012)]. On the Hirshfeld surfaces mapped over electrostatic potential in Fig. 4, the donors and acceptors of intermolecular hydrogen bonds are illustrated through the appearance of blue and red regions corresponding to positive and negative electrostatic potential, respectively. The presence of intermolecular side-on

Table 3
Percentage contributions of interatomic contacts to the Hirshfeld surface for (I).

|  | Percentage contribution |
| :--- | :--- |
| Contact | (I) |
| $\mathrm{H} \cdots \mathrm{H}$ | 11.9 |
| $\mathrm{~F} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{F}$ | 40.8 |
| $\mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}$ | 11.2 |
| $\mathrm{~F} \cdots \mathrm{~F}$ | 10.5 |
| $\mathrm{C} \cdots \mathrm{F} / \mathrm{F} \cdots \mathrm{C}$ | 7.0 |
| $\mathrm{Cl} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cl}$ | 4.6 |
| $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ | 3.5 |
| $\mathrm{~F} \cdots \mathrm{Cl} / \mathrm{Cl} \cdots \mathrm{F}$ | 3.1 |
| $\mathrm{C} \cdots \mathrm{Cl} / \mathrm{Cl} \cdots \mathrm{C}$ | 2.6 |
| $\mathrm{~N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}$ | 2.2 |
| $\mathrm{C} \cdots \mathrm{C}$ | 0.6 |
| $\mathrm{O} \cdots \mathrm{O}$ | 0.3 |
| $\mathrm{~N} \cdots \mathrm{~F} / \mathrm{F} \cdots \mathrm{N}$ | 0.3 |
| $\mathrm{C} \cdots \mathrm{N} / \mathrm{N} \cdots \mathrm{C}$ | 0.2 |
| $\mathrm{C} \cdots \mathrm{O} / \mathrm{O} \cdots \mathrm{C}$ | 0.1 |
| $\mathrm{O} \cdots \mathrm{Cl} / \mathrm{Cl} \cdots \mathrm{O}$ | 0.1 |

C-halogen $\cdots \pi$ interactions namely $\mathrm{C} 19-\mathrm{Cl} 1 \cdots \pi(\mathrm{C} 4-\mathrm{C} 9)$ and $\mathrm{C} 10-\mathrm{F} 3 \cdots \pi(\mathrm{C} 4-\mathrm{C} 9)$, Table 1, are evident from the Hirshfeld surfaces mapped with shape-index property illustrated in Fig. 5.

The overall two-dimensional fingerprint plot and those delineated (McKinnon et al., 2007) into $\mathrm{H} \cdots \mathrm{H}, \mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}$, $\mathrm{F} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{F}, \mathrm{F} \cdots \mathrm{F}, \mathrm{C} \cdots \mathrm{F} / \mathrm{F} \cdots \mathrm{C}, \mathrm{Cl} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{C} \cdots \mathrm{Cl} /$ $\mathrm{Cl} \cdots \mathrm{C}$ contacts are illustrated in Fig. 6; the percentage contributions from the different interatomic contacts to the Hirshfeld surface are summarized in Table 3. The formation of a salt between the piperidinium cation and carboxylate anion through the charge-assisted hydrogen bonds and the presence of a number of $\mathrm{H} \cdots \mathrm{Cl}, \mathrm{F}$ and O contacts result in the relatively small, i.e. $11.9 \%$, contribution from $\mathrm{H} \cdots \mathrm{H}$ contacts to the Hirshfeld surface. Conversely, the relative high number of

Figure 6
The full two-dimensional fingerprint plot for (I) and those delineated into $\mathrm{H} \cdots \mathrm{H}, \mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}, \mathrm{F} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{F}, \mathrm{F} \cdots \mathrm{F}, \mathrm{C} \cdots \mathrm{F} / \mathrm{F} \cdots \mathrm{C}, \mathrm{Cl} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{C} \cdots \mathrm{Cl} / \mathrm{Cl} \cdots \mathrm{C}$ contacts.
fluorine atoms lying on the surfaces of both the cation and anion, largely participating in F...H contacts, gives rise to their providing the greatest contribution, i.e. $40.8 \%$, to the surface.

In the fingerprint plot delineated into $\mathrm{H} \cdots \mathrm{H}$ contacts in Fig. 6, the short interatomic $\mathrm{H} \cdots \mathrm{H}$ contact involving quino-line-H7 and methylene- $\mathrm{H} 15 B$, both derived from the cation, Table 2, is viewed as pencil-like tip at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 2.0 \AA$. In the fingerprint plot delineated into $\mathrm{O} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{O}$ contacts, the spikes associated with the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds and $\mathrm{C}-$ $\mathrm{H} \cdots \mathrm{O}$ interactions are merged within the plot. The obvious feature in the plot is a pair of spikes with tips at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 1.8 \AA$, which correspond to the most dominant $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond; this is also responsible for most of the points concentrated in the narrower region of spikes. The influence of short interatomic halogen-hydrogen and halogen-halogen contacts in the crystal, Table 2, is observed as a pair of forceps-like tips at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 2.5 \AA(\mathrm{~F} \cdots \mathrm{H})$ and $3.0 \AA(\mathrm{Cl} \cdots \mathrm{H})$, and an arrowshaped tip at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 2.8 \AA$ in the fingerprint plots delineated into $\mathrm{F} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{F}, \mathrm{Cl} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{F} \cdots \mathrm{F}$ contacts, respectively. The involvement of chloride and fluoride atoms in Chalogen $\cdots \pi$ contacts, Table 1, results in the small but significant percentage contribution from $\mathrm{C} \cdots \mathrm{F} / \mathrm{F} \cdots \mathrm{C}$ and $\mathrm{C} \cdots \mathrm{Cl} /$ Cl...C contacts to the Hirshfeld surface, Table 3. These intermolecular contacts are also characterized as forceps-like and anchor-shaped distributions of points in the fingerprint plots delineated into the respective contacts, Fig. 6. The small percentage contribution from other remaining interatomic contacts summarized in Table 3 have negligible effect on the packing in the crystal.

## 5. Database survey

Kryptoracemic behaviour is rare and is found in only $0.1 \%$ of all organic structures (Fábián \& Brock, 2010). This observation clearly implies that $99.9 \%$ of racemic compounds, molecules with meso symmetry and achiral molecules will crystallize about a centre of inversion. Given there are fewer than 30 structures containing Mefloquine/derivatives of Mefloquine included in the Cambridge Structural Database (Groom et al., 2016), the reporting of two kryptoracemates of mefloquinium cations in recent times (Jotani et al., 2016; Wardell, Wardell et al., 2016) suggests a higher than anticipated propensity for this phenomenon. The two examples were isolated from attempts at chiral resolution of Mefloquine with carboxylic acids. In the first of the two reported structures, the asymmetric unit comprised a pair of pseudoenantiomeric mefloquinium cations with the charge-balance provided by chloride and 4 -fluorobenzenesulfonate anions (Jotani et al., 2016). In the second example, again two mefloquinium cations are pseudo-racemic, with the charge-balance provided by two independent 3,3,3-trifluoro-2-methoxy-2phenylpropanoate anions, i.e. $(+)-\mathrm{PhC}\left(\mathrm{CF}_{3}\right)(\mathrm{OMe}) \mathrm{CO}_{2}{ }^{-}$ (Wardell, Wardell et al., 2016). The appearance of kryptoracemic salts of mefloquinium with non-chiral and chiral counter-ions warrants further investigation into this

comparatively rare behaviour in order to reveal the reasons for such crystallization outcomes.

## 6. Synthesis and crystallization

A solution of mefloquinium chloride ( 1 mmol ) and sodium difluorochoroacetate ( 1 mmol ) in $\mathrm{EtOH}(10 \mathrm{ml})$ was refluxed for 20 mins . The reaction mixture was left at room temperature and after two days, colourless crystals of the title salt, (I), were collected; M.p. $473-475 \mathrm{~K} .{ }^{1} \mathrm{H}$ NMR (DMSO- $d_{6}$ ) $\delta: 1.20-$ $1.35(2 \mathrm{H}, m), 1.55-1.75(4 \mathrm{H}, m), 3.04(1 \mathrm{H}, b r t), 3.53(1 \mathrm{H}, b r d)$, $5.90(1 \mathrm{H}, s), 6.94(1 \mathrm{H}, b r d), 8.01(1 \mathrm{H}, t, J=8.0 \mathrm{~Hz}), 8.13(1 \mathrm{H}$, $s), 8.42(1 \mathrm{H}, d, J=8.02 \mathrm{~Hz}), 8.72(1 H, d, J=8.0 \mathrm{~Hz}), 9.48(1 \mathrm{H}$, $b r s) ; \mathrm{N}-\mathrm{H}$ H not observed. ${ }^{13} \mathrm{C}$ NMR (DMSO- $d_{6}$ ) $\delta: 21.43$ $(2 \times), 21.59,44.51,58.90,67.85,1135.50 .121 .17\left(J_{\mathrm{C}, \mathrm{F}}=\right.$ $273.8 \mathrm{~Hz})$, $121.21\left(J_{\mathrm{C}, \mathrm{F}}=311.0 \mathrm{~Hz}\right)$, $123.64\left(J_{\mathrm{C}, \mathrm{F}}=271.7 .8 \mathrm{~Hz}\right)$, 126.37, $127.93\left(J_{\mathrm{C}, \mathrm{F}}=29.2 \mathrm{~Hz}\right), 128.32$, 128.68. $129.9\left(J_{\mathrm{C}, \mathrm{F}}=\right.$ $5.2 \mathrm{~Hz}), 142.78,146.73\left(J_{\mathrm{C}, \mathrm{F}}=34.5 \mathrm{~Hz}\right), 150.97,159.82\left(J_{\mathrm{C}, \mathrm{F}}=\right.$ 25.2 Hz). ${ }^{19}$ F NMR (DMSO- $d_{6}$ ) $\delta:-58.65,-58.84,-66.68$. IR $\left(\mathrm{cm}^{-1}\right) 3300-2400(s, v \mathrm{br}), 1662(\mathrm{~s})$.

## 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. The carbon-bound H atoms were
placed in calculated positions $(\mathrm{C}-\mathrm{H}=0.95-1.00 \AA$ ) and were included in the refinement in the riding-model approximation, with $U_{\text {iso }}(\mathrm{H})$ set to $1.2 U_{\text {eq }}(\mathrm{C})$. The O - and N -bound H atoms were refined with the distance restraints $\mathrm{O}-\mathrm{H}=0.84 \pm 0.01$ and $0.88 \pm 0.01 \AA$, respectively, and with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$ and $1.2 U_{\text {eq }}(\mathrm{N})$, respectively.

## Acknowledgements

The use of the EPSRC X-ray crystallographic service at the University of Southampton, England, and the valuable assistance of the staff there is gratefully acknowledged.

## Funding information

JLW acknowledges support from CNPq (Brazil).

\end{aligned}
$$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Hydrogen-bond geometry ( $A,{ }^{\circ}$ )
Cg 1 is the centroid of the (C4-C9) ring.
