*to coastal and ocean management. It is well-established that management of the coasts and oceans is transitioning to integrate ecosystem concepts and considerations into management decisions. To implement such a transition, baseline knowledge of ecological systems and management systems is needed. Much work has focused on the compiling and synthesizing of ecosystem understanding, but relatively little effort has provided comparable information about management from a comprehensive perspective. In this paper, we describe our exploration and development of an accurate metric to gauge government agency involvement, which represents an important aspect of management. The results of three text analysis-based metrics (frequencies of statutes and regulations, legal sections, and terms) are tested against survey results completed by domain experts. Results showed that the frequency of sections and terms were similarly accurate when compared to survey results. Further, we report an open source tool we have developed that allows users to perform the agency involvement analysis. A variety of applications and potential uses are described. This article highlights an avenue for digital government approaches to progress natural resource management in dealing with emerging problems of today and of the future.*

## I. INTRODUCTION

Scientific studies of fishery collapses, harmful algal blooms, hypoxic zones, invasive species, and other threats indicate that ocean health is in decline.<sup>1</sup> Emerging threats of climate change, ocean acidification, sea level rise, continued coastal development, and others plague the projected future of marine ecosystems.<sup>2</sup> The impacts of these threats are often as consequences of the culmination of multiple

source activities.<sup>3</sup> One key to restoring, mitigating, and preventing further destruction is in strategically altering management institutions that guide the current practices so that decisions are made accounting for the multitude of environmental impacts.<sup>4</sup> Government agencies, non-governmental organizations, policy makers, and other ocean policy constituents now seek to alter management so that it is guided by ecosystem principles and considerations.<sup>5</sup>

Historically, the oceans have been managed within isolated sectors of state and federal government. Currently, there is a growing momentum to transition out of the sector-based approach into an ecosystem-based management (“EBM”) system.<sup>6</sup> A major roadblock to implementation of EBM is that it requires coordination and communication among sectors within and between levels of government.<sup>7</sup>

Fundamentally, coordination in any domain of management requires knowledge of baseline information about what agencies need to collaborate and in what capacity; such foundational information is

not always easily accessible, depending on the complexity of the issue. For instance, when Hurricane Katrina hit New Orleans, the appropriate government agencies did not respond rapidly. The delay in response was largely due to the lack of knowledge for what agencies were responsible, who needed to coordinate with whom, and how the chain of authority was supposed to respond.<sup>8</sup>

Given the sector-based nature of ocean and coastal management, compounded with the overlapping nature of the activities and natural resources,<sup>9</sup> there is a strong need for digital government tools to systematically generate and access baseline data about government agency involvement. Arming government agencies with tools to retrieve basic information about which agencies should be involved in an issue at hand without weeks or months of analysis could facilitate inter- and intra-agency coordination as well as strategic policy-making.<sup>10</sup> This type of information retrieval tool could also be useful as a starting point to direct longer and more in-depth analyses. Such further analyses would include those currently conducted for policy and legal analysis, which would include court cases and other non-statutory materials (including legislative histories), international treaties, business decisions by the government, budget and implementation information, and other pertinent information.

Traditionally, retrieving information about what agencies should coordinate for a given issue and in what capacity is performed by certain personnel coupled with legal analysis. Such a process can be lengthy, but often situations require a rapid response, as evidenced by Hurricane Katrina. Ekstrom and Lau (2008) presented a preliminary algorithm that maps out what agencies are involved in a variety of topics by virtue of laws and regulations using relative term frequencies.<sup>11</sup> Such an approach allows a user to identify objectively

what agencies are involved in the management of a topic across sectors and levels of government. While this *involvement* measure does not necessarily translate directly into management action, it does provide an objective and quantitative measure of *assumed* involvement that can be harnessed from the laws and regulations (and eventually other types of management-relevant documents). Knowing relative agency involvement does not indicate whether necessary coordination is occurring, but rather provides a first step for users needing baseline management information to identify emerging issues (e.g. tidal energy, offshore aquaculture, wind farm development, etc.). The next steps forward in developing a retrieval system to make baseline management data easily accessible is to develop and explore parameters that quantitatively reveal relative degrees of agency involvement in any user-defined topic.

### A. INVASIVE SPECIES BACKGROUND

Invasive species management challenges provide an example of overlapping jurisdictions and the need for coordination in coastal and ocean management.<sup>12</sup> Aquatic invasive species management in the United States costs an estimated \$9 billion every year.<sup>13</sup> One species alone, the zebra mussel, cost the nation over \$5 billion for the damaged water intake pipes in the Great Lakes region.<sup>14</sup> The State of California has identified 607 aquatic invasive species in the State's estuarine waters. There are over twenty pathways (commonly referred to as "vectors") through which non-native aquatic species are

introduced into the state waters. These include (but are not limited to) ballast water exchange, commercial fishing gear, recreational boating, aquarium trade, live bait and live seafood imports, and aquaculture of non-native species.<sup>15</sup>

One of the main goals set by the California Aquatic Invasive Species Management Plan was for the State to conduct an analysis of existing management, identifying what laws and regulations the State already has that pertain to each specific pathway and invasive species. Additionally, one of the plan's primary tasks is to identify which agencies are and should be involved in management of invasive species. Given the complexity and long list of pathways through which non-native species are introduced into the state waters, this can be a time consuming project. We used this existing management challenge in California as a scenario to explore the utility of the agency involvement metric.

## B. OBJECTIVE

We began this project seeking to determine the most accurate parameter for gauging agency involvement. This investigation continues the work from Ekstrom and Lau (2008) which presents a preliminary technique that displays term frequencies in laws organized visually around their relevant agencies (Figure 1).<sup>16</sup> Lines are drawn from each law and regulation to the authoritative government agency (represented by an acronym). Each document is represented by a node (gray = regulation, black = statute) that is sized by the value of term frequency for the term queried. Thus, in Figure 1 the nodes have been eliminated with only a line remaining for those laws and regulations in which the term "fishing" does not occur. To progress this technique a step further, we sought to quantify agency involvement again using the laws and regulations, with the help of a domain-specific taxonomy. In this work, we incorporated domain expert survey responses in order to verify the accuracy of various parameters used in the analysis. We also used the survey data to determine if one parameter was more accurate than another, and to determine whether and how using lower level taxonomic terms would increase the accuracy of the metric.

---

<sup>15</sup> California Department of Fish and Game, "Management Plan," 63 (see n. 13).

<sup>16</sup> Ekstrom, "Exploratory Text Mining," 534 (see n. 11).

After conducting a domain expert survey and running the analyses, we found our six measures yielded similar results, all of which were quite accurate in identifying the most involved agencies. As such, using the most accurate set of parameters, we developed an application that provides this agency involvement metric for public use.

This paper is divided into two parts. First, we present the techniques of the analysis and accuracy tests, including a description of the data and survey implemented. Second, we present the prototype application that provides users with access to the agency involvement data.

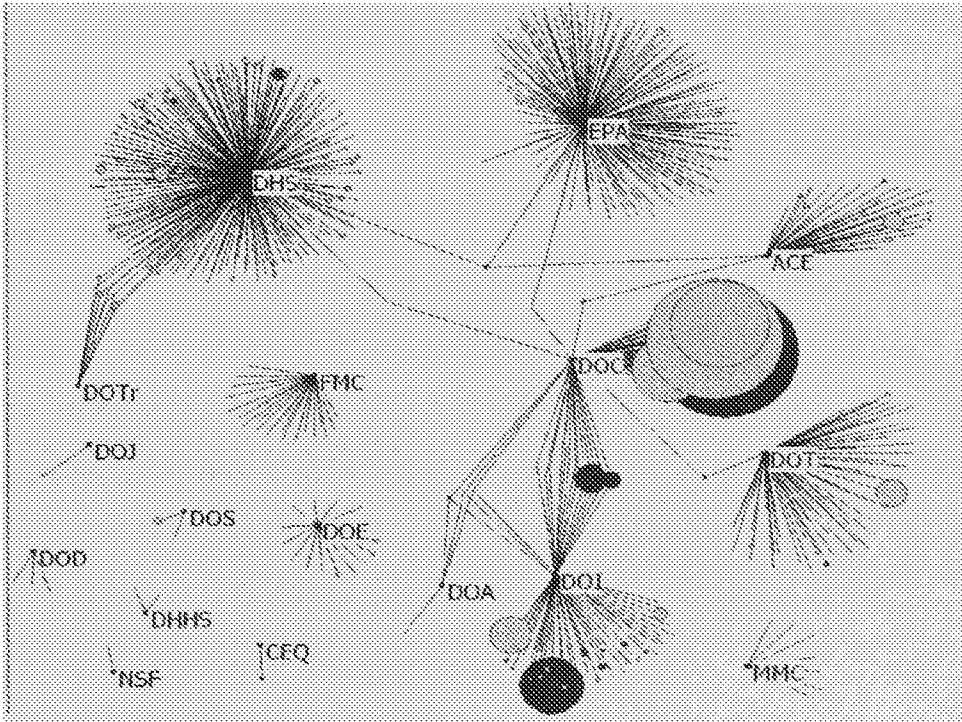

Figure 1: Network diagram depicting relative federal agency involvement in the topic of fishing, by virtue of the term frequency in the laws and regulations.<sup>17</sup> Lines are drawn from laws (black nodes) and regulations (gray nodes) to authoritative agencies, and node size varies with topic frequency.

## II. DATASET

### A. DOCUMENT COLLECTION

To develop and test the six measures of the agency involvement metric, two types of data were used for this exploratory analysis: (a) document collection of marine and coastal laws and regulations, and (b) a record of agency responsibility for each document. For the latter dataset, each regulation was tagged for which agency wrote it and each statute was tagged for which agency or agencies Congress granted authority to implement it.

#### 1. SCOPE OF DOCUMENT COLLECTION

The document collection used is composed of a comprehensive set of statutes and regulations related to the marine and coastal region of the California coast of the United States. The documents are codified as federal United States and the California laws and regulations from the year 2006.<sup>18</sup>

#### 2. RECORD OF AGENCIES TO DOCUMENTS

Important metadata for the law collection is the agency authority for each document. In the form of an agency-by-document table (Table 1), the agency or agencies with responsibility to implement each statute or regulation was recorded.<sup>19</sup>

Fishery Conservation and Management Act	0	0	1	0	0
Deepwater Port Act	0	0	1	0	1

## B. TERMINOLOGICAL TAXONOMIES

Using a single word and phrase in a query to represent a concept often is not sufficient in information retrieval systems.<sup>20</sup> Several approaches for querying document collections are typically used to assist in information retrieval, including structure-based queries, Boolean searches, context queries, and natural language queries.<sup>21</sup> Terminological taxonomies, a more advanced approach to query-building, are a hierarchical organization of terms and phrases to define a single topic or concept. This approach has shown to increase the accuracy of information retrieval when they are created for domain specific inquiries and constructed using domain specific vocabularies.<sup>22</sup>

## 1. CONSTRUCTING TERMINOLOGICAL TAXONOMY

We sought to determine the benefit, if any, of considering a lower (more detailed) taxonomic level to retrieve agency involvement information from natural resource management law and regulation. It is important for system users to understand the benefits and limitations of using only general terms, as opposed to also incorporating specific terms, to define their topic. To explore such benefits and limitations, Ekstrom, in consultation with domain experts, constructed a domain specific terminological taxonomy using the California Aquatic Invasive Species Management Plan.<sup>23</sup> This document contains an extensive description of the individual pathways of aquatic invasive species in California and a full species list (with vernacular and scientific names). Given that pre-defined terminological taxonomies do not necessarily exist for every domain, a user could use such a management plan document to construct topic queries from either the general-only or general and specific levels of terms. The taxonomy was created using:

- pathway industries (human activities or industries through which invasive species enter California);
- categories of invasive species.

The pathway industries and categories of species were composed of a general level (L1, Table 2) and a more detailed level of terms (L2, Table 2). We divided the Management Plan's aquatic invasive species into four general categories: fish, plant, invertebrate, and amphibian. For the higher level of taxonomy, we investigated eleven pathway industries: commercial fishing, recreational boating, recreational equipment, aquarium and aquascaping trade, live bait, live seafood import, aquaculture, shipping and navigation, and drilling platforms, and amphibious and sea planes. Each of these industries is defined by the State of California to facilitate the entrance of non-native aquatic species into the state waters.<sup>24</sup> Each general category contained a variety of more specific terms to define each concept.

---

<sup>23</sup> California Department of Fish and Game, "Management Plan," 19 (see n. 13).

<sup>24</sup> *Ibid.*

Table 2. Sample of terminological taxonomy applied.

<b>Concept</b>	<b>Taxonomic Level</b>	<b>Term(s)</b>
Commercial fishing	L1	Commercial fishing, commercial fisheries, commercial fishery
	L2	Gear
	L2	Fishing net
	L2	Fishing line
	L2	Trawl
	L2	Trap
Aquaculture	L1	Aquaculture, mariculture, fish farming, tuna pen, sea ranching
	L2	Trade species
	L2	Hitchhiker species
	L2	Parasite
	L2	Stock enhancement
Invasive invertebrate	L1	+(invasive exotic introduced nonindigenous imported nonnative "non-native" "biological pollutant" alien cryptogenic established) +("invertebrate" "invertebrates")
	L2	Asian overbite clam, <i>Corbula amurensis</i>
	L2	Channeled apple snail, <i>Pomacea canaliculata</i>
	L2	Chinese mitten crab, <i>Eriocheir sinensis</i>
	L2	European green crab, <i>Carcinus maenas</i>
	L2	Golden mussel, <i>Limnoperna fortunei</i>
	L2	New Zealand mudsnail, <i>Potamopyrgus antipodarum</i>
	L2	Northern Pacific seastar, <i>Asterias amurensis</i>
	L2	Quagga mussel, <i>Dreissena bugensis</i>
	L2	Sabellid polychaete, <i>Terebrasabella heterouncinata</i>
	L2	Shipworm, <i>Teredo navalis</i>
	L2	Zebra mussel, <i>Dreissena polymorpha</i>

A use case of our system is given here. A user interested in the topic commercial fishing can query our system using the phrase commercial fishing to gather relevant laws. Perusing the management plan, the user might want to expand into lower level taxonomy terms to define what constitutes the topic commercial fishing, such as gear, and specific gears including traps, fishing line, fishing nets, and trawl which are the specific avenues through which invasive species enter California waters through the commercial fishing industry (Table 2). However, the value of defining topics by using the lower level (L2) list of terms and phrases from the taxonomy is unknown to the user. As such, we sought to test whether it is necessary to include the more detailed terms, lower in the terminological taxonomy, in a search query to accurately retrieve all the relevant agencies involved in management of the topic.

### C. EXPLORING PARAMETERS

In order to gauge agency involvement using our collection of laws and regulations, we compute the occurrence *frequency* of the *topic* in our collection, where each document is tagged with its enforcing agency. As this is a pilot study, it has never been established what *frequency* we should be recording, and thus we will be testing three frequency parameters here:

- Parent document (codified chapter or division) count per topic;
- Legal section count per topic;
- Term frequency per topic per agency.

Apart from the frequency parameter, we also need to establish the definition of a *topic*. Here, we will investigate the value of lower level taxonomy terms. Two techniques were applied to define the topic parameter to test the added benefit of terminological taxonomies:

- Without taxonomy (single concept defined by general level, L1);
- With taxonomy (single concept defined by combined general and specific levels, L1 and L2).

The three frequency parameters and two topic parameters combine to six measures of interest. Using these six measures to devise the agency involvement algorithm, we aimed to identify whether any measure generates the full array of agencies involved in a topic. In addition, we sought to determine whether any (or all of) the measures accurately reveals the top most involved agencies.

### 1. FREQUENCY OF DOCUMENT UNIT

The first parameter used to measure agency involvement was the frequency of documents containing the topic query under the responsibility of each agency (Table 3).

Table 3. Sample of recorded document frequency by agencies for one concept without (L1) and with (L1, L2) inclusion of the terminological taxonomy.

Topic	Level	Agency			
		ACE	EPA	DOC	DHS
Commercial fishing	L1	3	3	22	20
	L1, L2	3	18	27	32

### 2. FREQUENCY OF LEGAL SECTION

As the second parameter to measure agency involvement, we calculated the number of legal sections containing the topic query under the assumed responsibility of each agency (Table 4). Text analysis is often performed on elements derived from larger documents. Increasing the granularity of a set of documents enables a higher resolution of analysis. Documents are typically divided based on structure or size in more digestible elements. For example, a corpus of text from a book may be divided into chapters, paragraphs, or sentences for more detailed analysis.<sup>25</sup> Similarly, laws and regulations are organized in sections, which is the smallest consistent composition in which these documents are structured. As such, we use the frequency of individual sections as one of the exploratory parameters for agency involvement.

---

<sup>25</sup> See Klaus Krippendorff, *Content Analysis*, (Thousand Oaks: Sage Publications, 2004).

Table 4. Sample of section frequency by agencies for one concept without (L1) and with (L1, L2) inclusion of the terminological taxonomy.

Topic	Level	Agency			
		ACE	EPA	DOC	DHS
Commercial fishing	L1	7	4	115	60
	L1, L2	25	33	212	110

### 3. FREQUENCY OF CONCEPT TERM

The third parameter was the number of occurrences of the topic query in the entire document corpus (Table 5). Regular expression is leveraged for pattern matching and computing the occurrence frequency of concept terms.

Table 5. Sample of term frequency by agencies for one concept without (L1) and with (L1, L2) inclusion of the terminological taxonomy.

Topic	Level	Agency			
		ACE	EPA	DOC	DHS
Commercial fishing	L1	8	4	343	84
	L1, L2	19	257	1362	125

### D. SURVEY

The survey was designed to gather agency involvement information from domain experts from whom we could verify the accuracy of the parameters. We targeted individuals with experience in the management of pathways related to aquatic invasive species in California. The survey was performed by asking the six experts to rank the top agency or agencies, up to five, that they know are responsible for the management of a given topic. A list of the fifteen topics was included in the survey (eleven of which were pathways and four of which were species groupings). Respondents were asked to only fill in information for those in which they were confident.

Each of the three frequency parameters was run for the fifteen topics in our taxonomy at the broad level (L1) and at the more detailed level (L2). Thus, for each topic there were six measures of results for comparison. The parameter results were compared against survey

data filled out by six agency domain experts in ocean and coastal management to evaluate the accuracy of the parameters.

### III. EVALUATION AND ASSESSMENT

#### A. RESULTS

Preliminary results showed that the term frequency parameter (Table 5) and the section frequency parameter (Table 4) generate accurate results of agency involvement, based on the top-ranked agencies involved, more often than the document frequency parameter. Error tests (Root Mean Square Error) based on top four ranked agencies showed no notable difference in error among the three parameters, nor between the application of the parameters with and without the taxonomy.

In evaluating the accuracy of the parameters, we found that for some topics all of the parameters were accurate. For analysis of federal laws and agencies, all three frequency parameters performed on two of the ten topics (*recreational boating* and *aquaculture*), with and without the taxonomy, accurately revealed the highest ranked agency. For analysis on the State laws and agencies, all three frequency parameters performed on eight of the twelve topics, with and without the taxonomy, accurately revealed the highest ranked agency.

Of the three frequency parameters, document frequency is shown to be the least accurate measure of agency involvement. In several cases, the document frequency parameter generated results inconsistent with the survey. For example, for the topic of *commercial fishing* in federal law (Figure 2), two notable inconsistencies between use of the taxonomy and without the taxonomy are in the document frequency count for the Environmental Protection Agency ("EPA") and the Department of Homeland Security ("DHS"). Both inaccuracies are generated using the document frequency parameter (Parameter A, Figure 2) while the other two parameters yielded results consistent with the surveys (Parameters B and C, Figure 2). Without the lower level taxonomy terms, the EPA shows minimal involvement, whereas incorporation of the taxonomy shows the EPA is highly involved, surpassing the rank of the third and fourth agencies (Parameter A, Figure 2). The dramatic increase is primarily due to the inclusion of the term *trap*. The laws and regulations under the EPA containing this term relate to waste control standards and monitoring procedures, which is a different context than the one intended for fishing traps. For example, one section of

the EPA’s regulations of Emission Standards refers to *trap* in the following manner (emphasis added): “Particulate *trap* means a filtering device that is designed to physically *trap* all particulate matter above a certain size.”<sup>26</sup> Therefore, this Level 2 term creates misleading results. Another error generated by the document frequency parameter is that when the taxonomy is applied, the DHS ranks as the top most involved agency, above the Department of Commerce (“DOC”), generating result inconsistent with the survey responses. The inconsistency is likely because the DHS documents in which the topic *commercial fishing* occurs tend to contain one or few references to the topic. In addition, the documents under DOC in which the topic *commercial fishing* occurs tend to contain many references to the topic.

Parameter A. Concept’s Document Frequency per Agency

<sup>26</sup> 40 C.F.R. § 1039.801 (2006). [emphasis added]

Parameter B. Concept's Section Frequency per Agency

Parameter C. Concept's Term Frequency per Agency.

Figure 2. Bar charts of exploratory agency involvement metrics for the topic of commercial fishing. Parameters run without terminological taxonomy in dark gray and those run with taxonomy in light gray. Primary and secondary agencies according to surveys are indicated with a star (☆) or triangle (▲) next to the agency acronym.

Parameter A. Concept's Document Frequency per Agency

Parameter B. Concept's Section Frequency per Agency

Parameter C. Concept's Term Frequency per Agency.

Figure 3. Bar charts of exploratory agency involvement metrics for the topic of recreational boating. Parameters run without terminological taxonomy in dark gray and those run with taxonomy in light gray. Primary and secondary agencies according to surveys are indicated with a star (★) next to the agency acronym.

Contrary to the topic of commercial fishing, some cases demonstrated an added benefit of applying the taxonomy. For example, recreational equipment without the use of the terminological taxonomy did not occur in any federal law or regulation. However, the use of the lower level terms did reveal agencies involved. In other situations, as with recreational boating, the rank of agency involvement remained consistent with and without the taxonomy (Figure 3). However, results for the two topic parameters, namely with and without the consideration of the taxonomy, were identical for the top two agencies and generated very similar overall results.

## B. INTERPRETATION OF PRELIMINARY RESULTS

### 1. COMPARING PARAMETERS

The most notable finding from our preliminary investigation of developing an agency involvement metric is that the parameters of the term frequency and section frequency were more consistently accurate

than the document frequency. In examining the highest ranked agency involved, we found the taxonomy did not increase the accuracy of the parameters, and in the case of *commercial fishing*, decreased the accuracy of the parameters.

Those topics with inconsistent parameter results (federal *shipping*; State of California: *recreational boating* and *shipping and navigation*) tended also to have inconsistent survey results. Thus, the variability in the survey data may indicate that no clear lead agency exists for managing these issues. Instead, these issues may be managed by a handful of agencies and survey respondents could be familiar with different aspects of the management.

## 2. UTILITY OF INCORPORATING TAXONOMY

Overall, there was very little notable added benefit of including terms from the lower level of the taxonomy, with two exceptions. One topic, *recreational equipment*, at the higher-level terminology did not occur in the federal portion of the document collection (*recreational equipment*). Incorporation of the detailed terms showed that federal agencies were in fact involved in the management of the issue. Thus, the use of lower level terms is suggested for cases where the higher-level terms do not appear. The second added benefit of the taxonomy was that in most cases it appeared to create a bigger margin of difference between the agencies involved, thus resulting in an agency involvement chart with observable differences among agencies.

In analysis of highest ranked agency in the federal level, inclusion of the more detailed lower level terms increased the accuracy of the results in only two topics, *recreational boating* and *shipping and navigation*. In analysis of the highest ranked agency for the state level, inclusion of the more detailed terms did not increase the accuracy of the parameters for any topic. Inclusion of the lower level terms decreased the accuracy of the document frequency parameter for two topics (*invasive plants* and *recreational boating*).

Given that in some cases the inclusion of the taxonomy caused a decrease in accuracy, this serves as a warning for users implementing lower level terms. It is important that such terms are selected and implemented with caution because it can generate erroneous results, especially if used with the document frequency parameter.

## IV. AGENCY INVOLVEMENT TOOL

As we have determined in the previous section that the term frequency parameter and the section frequency parameter provided

similarly accurate results, we can now implement a publicly accessible tool to generate the basic agency involvement metric using either frequency parameter. We chose to use the section frequency count. The topic parameter will be defined by the user. The functionality of gauging agency involvement is part of a larger application (“MINOE”) geared to assist those interested in ecosystem-based management to navigate through the morass of law and regulation related to any topic.<sup>27</sup>

### A. FEATURES AND FUNCTIONALITY

Foremost, the application gives easy access to determining what agencies have laws and regulations that discuss a user-defined topic. This information can be generated for single and multiple geopolitical jurisdictions, such as across federal and state, or state to state. A user therefore can identify what agencies at the federal and state levels relate to the management of a topic. Take, for example, the case in which state agency personnel are involved in designing a new plan of management for aquatic invasive species. They may need to identify the following:

- The other California state agencies, if any, involved in the topic so that resources can be shared and relevant plans can be coordinated, or gaps in management can be identified and filled strategically;
- The federal level agencies involved, if any, and through what laws and regulations.

To begin, the user defines the concept of interest using terms and phrases. A user also may create more advanced definitions of the concept with Boolean search capabilities to capture synonyms, as shown below:

*"live bait" (+import +live) "fishing bait" "live freshwater bait"*

The user may enter multiple or single topics of interest in the user interface, as illustrated in Figure 4.

<sup>27</sup> Version 1.0 of *MINOE: Management Identification for the Needs of Ocean Ecosystems* is available for download at <http://minoe.stanford.edu> (accessed April 17, 2010).

Figure 4. Form for user to input terms, phrases or Boolean search to define each concept of inquiry

Then a window opens to allow the user to select the search criteria (Figure 5). These include the geopolitical jurisdiction and the document scope. Currently the application contains four geopolitical jurisdiction options: three states (Washington, Oregon, and California) and the federal United States. The document scope currently includes codified statutes and regulations.<sup>28</sup> The user also may select a specific document or group of documents to include in the analysis, as a filtering option.

<sup>28</sup> Ekstrom, "California Current Large Marine Ecosystem," 529 (see n. 18); Ekstrom, "Exploratory Text Mining," 55 (see n. 11).

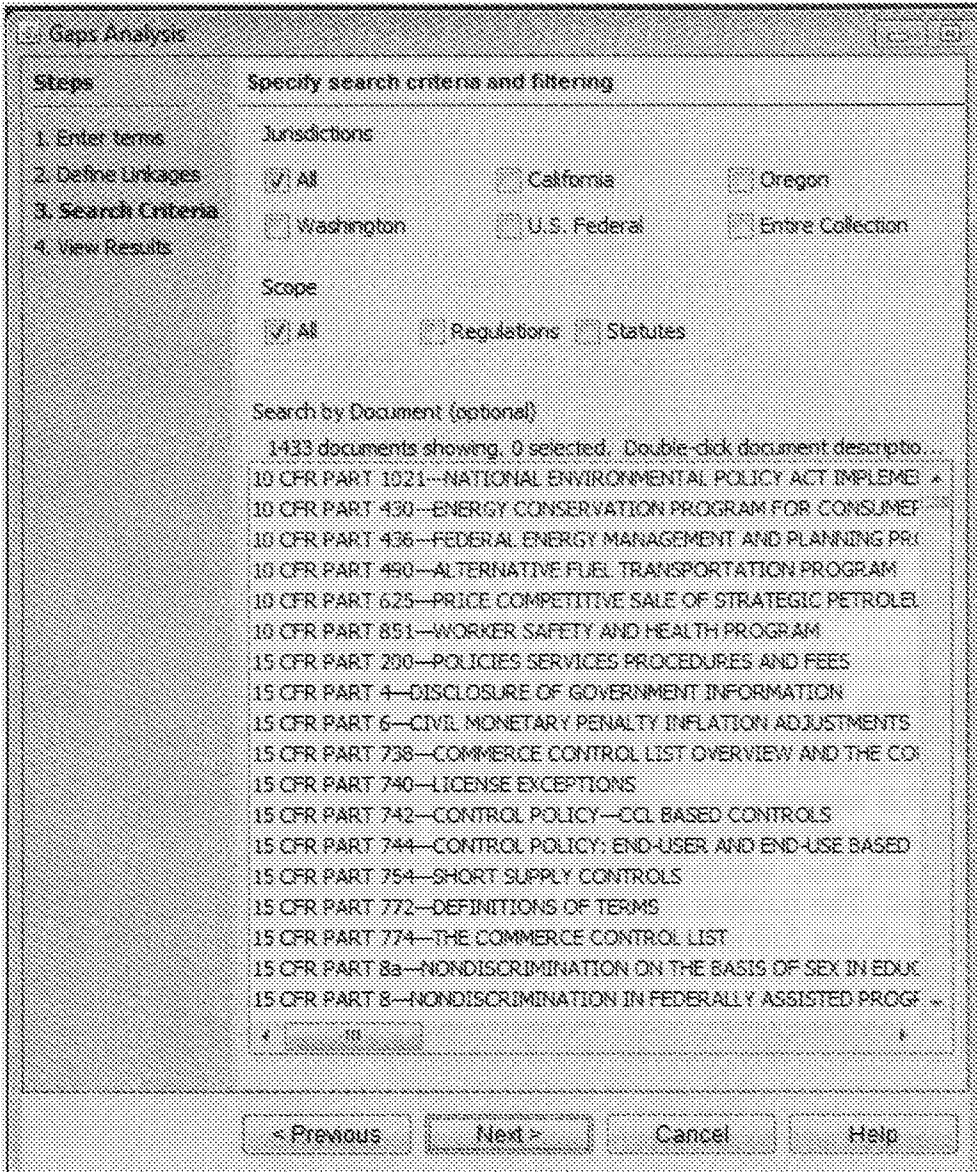

Figure 5. MINOE's filtering options

Once filtering criteria are selected, the next interactive window provides a portal to the agency involvement metric and the text of the corresponding laws.

The first screen, as shown in Figure 6, contains the total number of sections in which each concept occurs. A user may view each by clicking the labeled tab, providing a user-friendly way to compare between jurisdictions.

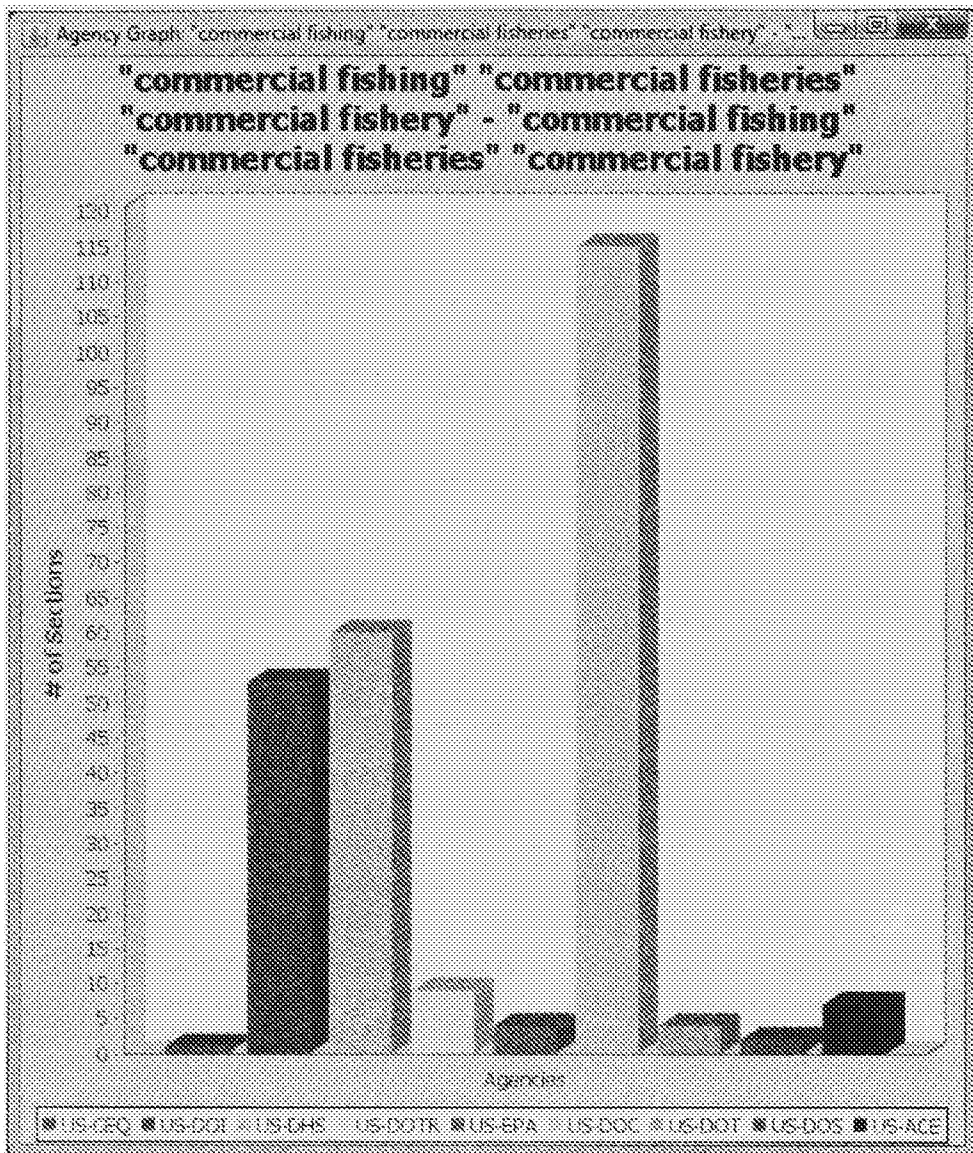

Figure 7. Bar graph gauging agency involvement (based on number of sections containing topic) for the topic of commercial fishing without use of taxonomy

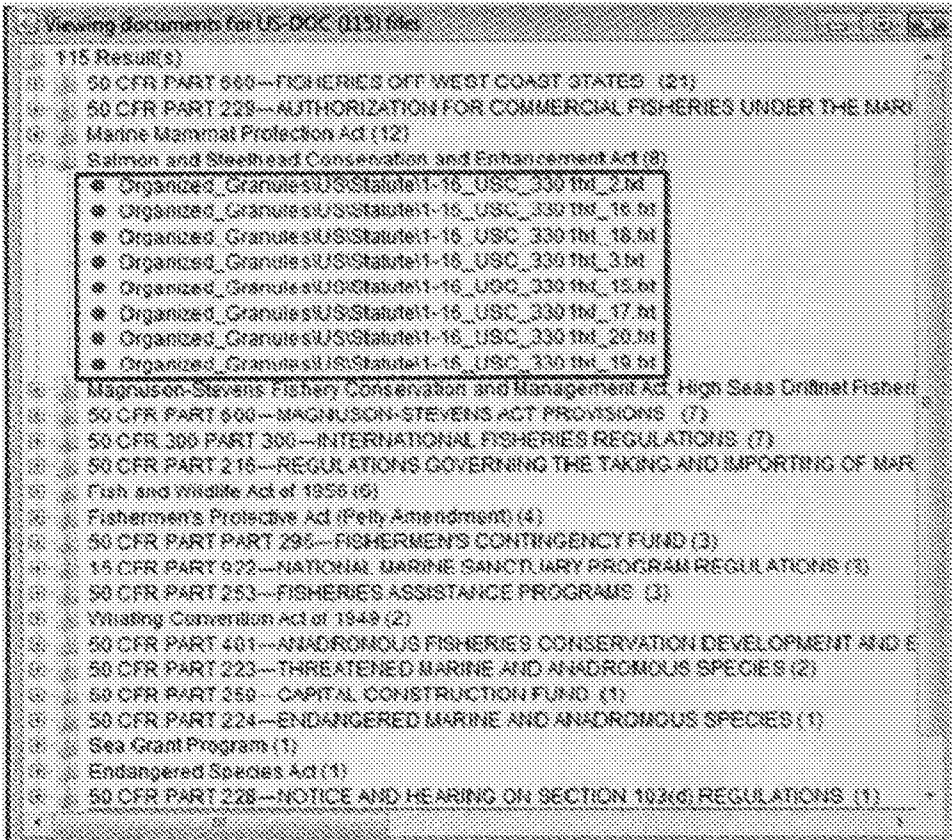

Figure 8. Screenshot of MINOE's law and regulation text viewing and searching feature.

The list of displayed laws may be opened to view the list of individual sections, which may then be selected to view the text. Once the text of the regulation is open, there is a toolbar in the upper left corner that allows the user to search any keyword or phrase (Figure 9). Every occurrence of the search keyword or phrase is highlighted.

## B. APPLICATION AND UTILITY

We recognize no application will replace the domain expertise of an experienced practitioner for understanding how an activity is managed. However, given that the application produced highly accurate results of the most involved agencies for state and federal levels of management, our tool does provide a myriad of benefits even in its basic form. Such benefits may assist domain experts as well as non-experts as a first step to further investigation:

- Provides objective estimation of agency involvement using a suite of laws and

regulations from comprehensive suite of sectors;

- Facilitates inclusion of terminological taxonomies through Boolean search capabilities;
- Provides information in a transparent manner, allowing easy access to the source text for determining context.

There are several potential users for a system that automatically retrieves agency involvement information, including the government, non-governmental organizations, policy advocates, resource users, concerned citizens, and policy course instructors and students. As a tool for agencies, it could be used to assist in improving collaboration, enhancing strategic resource sharing, and increasing strategic policymaking. Such a metric could assist lawmakers in determining what agencies should be involved in a proposed law or policy based on an emerging issue such as ocean acidification or climate change adaptation. The technique could also be useful for individual agencies at a survey level in writing new regulations to determine whether there are resource-sharing opportunities with other agencies in order to fulfill mandates.

In terms of invasive species management, the preliminary technique with further development and verification could be used to help identify what agencies play a role in the regulation of entrance pathway-related activities. Beyond government uses, non-governmental organizations and other issue-focused advocacy groups could use such a tool to identify agencies and applicable law to target for lobbying in order to fulfill the groups' goals. Other types of stakeholders, including resource users or community members may find such a tool useful in that it could promote accessibility to how various issues are managed, and thus help provide pathways for promoting increased public participation in decision-making.

## 1. TOOL FOR BUILDING MANAGEMENT SCENARIOS

The increasing interest and need for applying the ecosystem concept in management and decision-making have generated a growing number of scenario-building tools and research programs

focused on valuing ecosystem services.<sup>29</sup> These tools thus far focus on the natural science of ecosystems and are beginning to integrate these data with economic information. However, until now, no information retrieval policy or regulation tools have been developed that have the capacity to integrate and interoperate with these ecological and economic EBM tools.

Ecopath with Ecosim (“EwE”), originally developed by Jeffrey Polovina and colleagues at the National Marine Fisheries Service,<sup>30</sup> has been built, and is continually being developed by a team of scientists and software engineers at the University of British Columbia to assist in identifying optimal management strategies for fisheries management.<sup>31</sup> EwE creates quantitative ecosystem models of direct and indirect linkages between species, habitats, and other ecosystem elements. Using a suite of management scenarios, the EwE can help scientists and managers identify what aspects of the economic supply chain will be affected by various ecosystem changes.<sup>32</sup> Our application presented in this paper could be added to provide users with useful information about the existing legal framework in which ecosystem elements are being regulated, whether the ecosystem linkages are accounted for in any regulations, and what agency or suite of agencies should be involved in the implementing the scenario.

The Natural Capital Project (“NatCap”), based out of Stanford University in collaboration with The Nature Conservancy and the World Wildlife Fund, has developed a software tool that calculates an economic cost benefit analysis of management decision scenarios

based on valuation of ecosystem services.<sup>33</sup> Using the optimal scenarios generated by the NatCap software, MINOE could assist users to retrieve baseline information about what agencies (and through what laws) are involved in a variety of ecosystem elements that pertain to the scenario. This could help users identify most feasible scenarios to follow and, combined with further research, could assist in the development of policy recommendations to implement the scenario.

## 2. TOOL FOR POLICY MAKERS

The presented tool can also be used for research to identify discrepancies between law and policy. For example, federal environmental regulation may lag behind state environmental policy where states are more environmentally progressive than federal laws. With the new administration, digital government tools, such as MINOE presented in this paper, could be useful to help systematically identify such mismatches. Although further in-depth evaluation would be necessary for policy development, it could assist in the first level of analysis for the federal government to progress its environmental policy.

## C. FUTURE WORK

There are several prospects for applying the tool presented in this paper in identifying agency involvement. However, the tool is only in its beta version and requires further exploration and expansion of features. In the future, we plan to:

- Explore other parameters that represent management besides law and regulation: *E.g.* Align with economic data to determine the feasibility of tracking implementation through budget allocations;
- Apply technique to management plans;
- Apply techniques to the geospatial boundary data of legal jurisdictions. In some cases, a law

pertains to a specific region or habitat, such as freshwater and not marine. Therefore, incorporating the spatial or other type of zonal tagging would assist in improving the accuracy of the agency involvement metric in development;

- Include taxonomy with the weighting of terms in lower levels based on each term's relatedness to defining the concept;
- Elaborate the capacity of user queries with Natural Language Processing algorithms, including investigating meanings implied by the language used in the documents.

Through analysis of preliminary surveys and text analysis, we found that of the three frequency parameters used to measure agency involvement (document frequency, section frequency, and term frequency), document frequency was the least accurate metric. In addition, use of lower-level terms from our taxonomy was shown useful for some topics and misleading for others. Therefore, we developed a tool that allows a user to input single or multiple levels of terminological taxonomies to retrieve information for a single topic. In addition, we developed the system using the section frequency as the metric to identify agency involvement. Upon further development, there are several opportunities to apply this open source tool, highlighting the need for digital government research to develop tools that can assist improvement of natural resource management.

## V. ACKNOWLEDGEMENTS

Our thanks to the David and Lucile Packard Foundation (Ecosystem-Based Management Tools Initiative Fund) for supporting this research. The authors would also like to acknowledge partial support by the National Science Foundation grant IIS-0811460. We appreciate Jonathon Gurish of the California Coastal Conservancy and others who reviewed earlier drafts of this article and thank those ocean and coastal governance experts who took the time to fill out our surveys. Any opinion expressed in this paper are those of the authors and do not necessarily reflect the opinions of the David and Lucile Packard Foundation or the National Science Foundation.
