Grateful acknowledgment is made to the NC-7 Vegetable Crops Subcommittee for their help and encouragement.

**ON THE COVER:** Left, PI 79532, Missouri accession 160, *Lycopersicon pimpinellifolium*; right, commercial variety containing germplasm for Fusarium wilt resistance derived from *L. pimpinellifolium*. The wild species, *L. pimpinellifolium*, frequently referred to as the currant tomato, has contributed genes for resistance to more diseases than any other tomato species. It is estimated conservatively that more than 30 commercial varieties have this species in their parentage and it is likely that there are many more.

# Horticultural Characters and Reaction to Two Diseases of the World Collection of the Genus *Lycopersicon*<sup>1</sup>

and ALBERT F. DODGE<sup>2</sup>

## INTRODUCTION

During the past 30 years, between two and three thousand accessions including representatives of the known species of the genus *Lycopersicon* have been introduced into the United States by the U. S. Department of Agriculture, by research workers in public and private agencies, and by private individuals, either through correspondence or trips abroad. Even though the tomato is considered to be indigenous to South America and possibly Central America, many collections came from other areas of the world. However, the wild species were collected largely in their natural habitat.

The North Central Regional Plant Introduction Station, in cooperation with the Ohio Agricultural Research and Development Center and the Crops Research Division, Agricultural Research Service, U.S.D.A., has assembled 2658 of these tomato introductions under the New Crops Project NC-7. The accessions have been classified for species and reaction to two diseases, described for certain horticultural characters, and are being maintained by storage of viable seed, except in a few cases where it is necessary to maintain the stocks as clones. This collection includes 138 genetic stocks as well as tetraploids, diploids resulting from doubling the chromosome number in haploids, and male steriles.

Classification, description, and disease studies have been conducted at the Ohio Agricultural Research and Development Center. Seed multiplication, storage, and distribution are handled at the Regional Plant Introduction Station, Ames, Iowa. Each year following completion of the evaluation of accessions worked with that year, a cumulative seed list is published and seed is made available for immediate distribution. Seed requests from foreign investigators should be directed to the New Crops Research Branch, Crops Research Division, Agricultural

Research Service, U. S. Department of Agriculture, Beltsville, Maryland.

Alexander, Lincoln, and Wright (5) screened a part of this collection for diseases which occur in Ohio and Indiana. Disease resistance in 144 accessions of the wild species was described by Alexander and Hoover (3, 4). Hoover, Alexander, Paddock, Crum, and Dodge (14) reported on 1253 accessions which were classified for species, resistance to two diseases, and certain horticultural characters. To make this new bulletin complete, accessions described in Regional Bulletin 65 are included with the 1405 accessions which have been accumulated and classified during the intervening 12-year period. Additional data on the disease resistance of many accessions have been accumulated by other research workers. It is hoped that these data may be assembled and published.

The data secured for every accession are published in detail because it has been found that, even though many accessions are indistinguishable phenotypically, they frequently are genotypically distinct. This has been especially demonstrated for disease resistance by Alexander and Hoover (4).

A start on a detailed gene analysis of the genus *Lycopersicon* has been made by Barton *et al* (6), Clayberg *et al* (11), Butler (8), and Clayberg (10). The quicker a gene analysis can be completed, the more rapidly the plant breeder can progress. However, it is not within the scope of this project to conduct detailed studies for plant characteristics. It is intended that the accessions be maintained and classified to serve as a germplasm bank for horticulturists, plant pathologists, geneticists, and all other workers interested in research on tomato.

This paper describes a world collection of tomato stocks now held and distributed by the North Central Regional Plant Introduction Station, Ames, Iowa. For the past several years, several thousand seed samples have been distributed annually. Thus, this inventory is published to provide descriptive information on available tomato introductions to workers interested in tomato improvement research.

<sup>1</sup>This work was supported in part by Regional Research Funds of the U. S. Department of Agriculture under the North Central Regional Plant Introduction State-Federal Cooperative Project NC-7.

Department of Agriculture and Iowa State University cooperating, Ames, Iowa; Leonard J. Alexander and Gene Oakes, Ohio Agricultural Research and Development Center, Wooster, Ohio

## NORTH CENTRAL REGIONAL NEW CROPS PROJECT NC-7

The North Central Regional New Crops Project NC-7 is entitled, "The Introduction, Multiplication, Preservation, and Evaluation of New Plants for Industrial and Agricultural Utilization." This is a cooperative program of the 13 State Agricultural Experiment Stations of the North Central Region, which includes Alaska, and the Crops Research Division, ARS, USDA. Other USDA agencies cooperating in this program are the Soil Conservation Service, Forest Service, and the Northern Utilization Research and Development Division, Agricultural Research Service.

The New Crops Research Branch, Crops Research Division, assumes leadership in conducting foreign and domestic plant explorations, identifying and classifying the plant materials collected, clearing the plant materials through proper inspection and quarantine procedure, and placing the stocks with the four Regional Plant Introduction Stations, research agencies, or individual crops research specialists. The New Crops Research Branch also provides technical assistance and gives administrative guidance and coordination to the work of the four regional new crops projects.

Regional Plant Introduction Stations have been established in each of the four Experiment Station Regions of the United States. The North Central Plant Introduction Station is located at Iowa State University, Ames. This Regional Station is provided with a technical staff for growing and making preliminary evaluation of new introductions and for processing and storage of seed under controlled temperature and humidity. The maintenance and distribution of seed stocks is a very important phase of the work. Any research worker may request seed from the germplasm storage. In return, he is requested to submit a report on the performance of the

germplasm, including any new or valuable traits observed. The Regional Station maintains performance records of the evaluations.

Seed of about 11,800 accessions of some 75 genera has been successfully increased and described and is available for distribution from the North Central Regional Station. Another 1600 introductions are active but have not increased sufficiently. In addition, many fruit collections and collections of native plants are maintained in cooperation with state experiment stations.

The Regional Station is performing its major function of germplasm storage for the North Central Region. A Regional Station may also have responsibility for primary maintenance of collections of certain crop introductions for all regions. For example, the North Central Regional Station has the primary responsibility for the preliminary evaluation, seed increase, storage, and distribution of the world collection of tomato introductions.

The Regional Station also cooperates with the National Seed Storage Laboratory, Fort Collins, Colorado, by sending seed of individual introductions which have proven value or by sending entire crop collections which have been described and evaluated. Only reserve supplies of seed are sent so as not to interfere with the anticipated requirements for distribution by the Regional Station. The National Laboratory is a long-term seed storage facility and ordinarily does not receive seed requests unless the seed is not available elsewhere. The placement of seed at this laboratory provides a safeguard against possible loss of valuable introductions. To date, seed of about 2,000 tomato introductions listed in this bulletin has been sent to the National Laboratory. Additional accessions will be sent as they become available.

### MATERIALS AND METHODS

The tomato accessions in this collection, comprising both wild and domestic species, were introduced from many parts of the world through exploration, exchange, gift, or purchase. Many wild and domestic tomato accessions were obtained by Blood and Tremelling in 1937 throughout South America. More recently specialists including Morrison, Schreiber, Norvell, Rick, Correll, and Smith have collected in these areas. Correll, Larson, Alvarez, and Schwanitz obtained additional material in Mexico and Central America. Many introductions of the domestic species were collected in Asia, Asia Minor, and Africa by Koelz, Harland, and Archer, respectively.

Domestic species were obtained from many European sources as well as from other areas of the world not mentioned above. Other accessions were developed by research workers as desirable plant breeding material, gene markers, tetraploids, or male sterile lines. Valuable germplasm in the form of old standard varieties has been included in the seed collection. It has also been deemed advisable to include new varieties as they are released.

These accessions were grown during the 17-year period 1949-1965. As soon as an accession was increased enough for distribution, the seed was placed in storage in the Regional Plant Introduction Station

TABLE 1.—Characters Used to Classify and Describe the Accessions of Common Tomato

and entered in the regional seed list. Unfruitful tomato accessions have been maintained vegetatively and distributed as cuttings.

Seed of certain accessions may occasionally be in short supply because of low inventory, poor viability, or both. In such cases, there may be a delay in supplying seed. A few accessions may not be available as seed for immediate distribution because they are difficult to increase. These are designated by an asterisk following the PI number. If the requested accessions cannot be provided, the Regional Station will try to make appropriate substitution and advise the cooperator.

For all except the genetic stocks, the soil used was a well-drained Wooster silt loam in good physical condition but extremely low in fertility. This type of soil was selected because it was observed that the green-fruited species fruited better under conditions of low fertility.

For the purpose of evaluation and classification, 10 to 20 plants were grown in single plots. However, fewer plants were secured in working with old seed in some instances. In a few instances no plants were secured and thus the accession was lost. In most cases where only one or at most a very few plants were secured, plants of the accession were grown and evaluated another year. Where accessions were evaluated for 2 or more years, it was observed that the evaluations were in a high degree of agreement.

Earliness of maturity was judged largely by the performance of the varieties Stokesdale and Rutgers. Under Ohio conditions these varieties are early-medium and medium-late, respectively.

In the previous regional tomato bulletin published in 1955, gene symbols for describing the accessions

were used as listed by Young and MacArthur (26) and by Barton *et al* (6). In this publication, the gene symbols used are those listed by Barton *et al* (6), Clayberg (10), and Clayberg *et al* (11).

The accessions were classified in the field for their reaction to the leaf blight phase of early blight, incited by *Alternaria solani* (Ell. & Mart.) Jones and Grout, and for their reaction to the tobacco mosaic virus (13). Inoculations with tobacco mosaic virus were made in the field. Two methods of inoculation for TMV were used without noticeable differences in results. In the years 1949, 1950, and from 1957 on, the plants were inoculated by rubbing a minimum of three leaflets with Carborundum and plant juice which had been extracted from plants infected with a green strain of the virus. In the years 1951 to 1956, inoculations were made by blowing the inoculum into a minimum of three leaflets, using the method described by Richards and Munger (18). Both compressed air and compressed nitrogen gas were used with this method of inoculation. Prior to inoculation, the infective juice was diluted with an equal volume of water and Carborundum was added. Inoculations with *A. solani* were made by dusting the plants during a wet period with pulverized infected tomato leaves. The inoculum was prepared by grinding tomato leaves which had been killed by *A. solani*. These leaves were collected from the Marietta Vegetable Crops Branch, Ohio Agricultural Research and Development Center. The ground leaves were diluted with an equal volume of inert material.

The accessions were evaluated for vine and fruit characters based upon estimates, not upon definite measurements. Fruit size was estimated to the nearest  $\frac{1}{8}$  inch by observation. In many instances where there was a slight variation within an accession, the

estimate for a specific character was an average of all plants. In cases of wider variation, the estimate for a character was best denoted by describing the different types. However, where individual plants of an accession were constant for characters except for one plant, the variation exhibited by it was disregarded.

Five classes were used to describe each character whenever possible. However, this was not possible in all cases. The characters for which the accessions of the common tomato were evaluated and the classes used to describe them are shown in Table 1. In the case of the small, hairy-fruited wild species, data on skin cracking, number of locules, and fasciation of fruits were omitted from the description. These characters as well as that of fruit shape were also omitted from the record of the *Lycopersicon pimpinellifolium* accessions.

Special explanation is necessary for the gene symbols found under the heading "Genotype" in Tables 5, 6, 7, and 8. Most accessions appeared to be fairly constant for certain characters and, to reduce the number of columns in the tables, accessions were described with respect to the nine characters shown in Table 2.

The accessions were not uniform when received in many instances. Some appeared to be segregating for some characters, whereas other accessions appear-

ed to consist of mixtures of seed. For the latter, usually there appeared to be only one or at the most a few off-type plants. In this case, seed was not saved from these plants. However, where accessions were not uniform and appeared to be segregating, seed was saved from all plants. Thus, no attempt was made to secure pure lines of the accessions but rather a definite attempt was made to maintain the germplasm possessed by the accessions when introduced into this country. When a desirable gene or genes are discovered by individual workers, the new material can be inbred for homozygosity.

Genetic stocks have known genes and stocks must be listed with their gene symbols to be of most value. The complete list of gene symbols used, the linkage group to which each belongs when known, and a description of the character which each gene induces are shown in Table 3.

When increasing seed of genetic stocks, care was used to save seed only from typical plants. Since it was not physically possible to hand self such a large number of genetic stocks, investigators may find an occasional off-type plant. However, such plants can readily be recognized and discarded. In other genetic stocks, certain characters, if homozygous, are lethal or render the plant sterile. Hence in these cases stocks are distributed which segregate for the character.

## SPECIES CLASSIFICATION

The accessions, with certain exceptions, were classified by species, sub-species, and varieties according to Muller (16). Subsequent to Muller's monograph on the genus *Lycopersicon*, Luckwill (15) prepared a monograph on the same genus which contributes additional information. However, the monograph by Muller appeared to be more pertinent to the material studied in this work and therefore his classification was followed.

### Classification of the Red-Fruited Species

In the species *Lycopersicon esculentum* Mill., no attempt was made to distinguish between the species and the form *pyriforme* (Dun.) C. H. Mull. and variety *cerasiforme* (Dun.) A. Gray. In fact, it was found that an almost continuous series exists between *L. pimpinellifolium* (Jusl.) Mill. and *L. esculentum*. Such a series includes all accessions which normally should be classified as variety *cerasiforme*. Likewise,

TABLE 2.—Characters and Their Gene Symbols Used in Tables 5 through 8.

Character	Dominant Factor	Gene Symbol	Recessive Factor	Gene Symbol
Character			Character	
Normal leaflet		C	Potato leaflet	c
Smooth stem		H	Hairy stem	h
Smooth fruit		P	Pubescent fruit	p
Non-green flesh		Gf	Green flesh	gf
Red flesh color		R	Yellow flesh color	r
Red flesh color		T	Tangerine flesh color	t
Green shoulder		U	Uniform unripe fruit color	u
Non-wilty leaflet		Wt	Wilting leaflet	wt
Yellow fruit skin		Y	Colorless fruit skin	y

the fruit types of many accessions varied from a slight suggestion of *pyriforme* type to a pear shape. Therefore, instead of attempting to make a discontinuous series, the accessions of this species are all listed together with the exception that named varieties and large-fruited accessions which appear to be varieties are listed separately.

Four hundred forty-one accessions of the species *Lycopersicon esculentum* are named commercial varieties. One hundred seventeen others are believed to

be commercial varieties but the names were not obtained by collectors. All of these accessions are included under a subheading in the species *L. esculentum*.

The genetic stocks have been largely derived from the species *Lycopersicon esculentum*, although a few have been derived from the species *L. pimpinellifolium*. A few also have resulted from species crosses. These are listed together under a separate heading, Genetic Stocks.

\*Genes located by two point or trisomic test only.

\*\*Gene symbols not yet assigned.

A large number of accessions (143) possessed many of the characteristics of the two species *Lycopersicon pimpinellifolium* and *L. esculentum*. These accessions are classed separately under the headings, Known or Suspected Crosses. Since the two species *L. pimpinellifolium* and *L. esculentum* readily hybridize, most of the suspected crosses presumably resulted from chance outcrosses in nature. However, the occurrence of three known crosses is indicated. Seven other known hybrids of the domestic tomato with three green-fruited species are described.

*Lycopersicon cheesmanii* f. *minor* (Hook) C. H. Mull., although now considered an orange-fruited species, is referred to under the heading, Green-Fruited Species.

#### Classification of the Green-Fruited Species

Only eight accessions of *Lycopersicon glandulosum* Mull. have been received. The type species of *L. hirsutum* Humb. and Bonpl. and the f. *glabratum* Mull. are distinctive and are classified according to Muller. The type species *L. peruvianum* (L.) Mill. and the variety *dentatum* Dun of it are so nearly alike that no attempt was made to distinguish between them. Therefore, they are listed together. The variety *humifusum* Mull. is easily distinguished from the type species and is listed separately.

Rick (23) has presented evidence to show that the indigenous Galapagos Island tomato is not green-fruited but that this little known plant is orange fruited and rather closely related to *L. pimpinellifolium* and *L. esculentum*. However, since it has always

been classified as a green-fruited species and since the fruit has rarely been observed, in this study it is still listed as *L. cheesmanii* f. *minor* (Hook F.) Mull. (*L. esculentum* var. *minor* Hook F.).

The classification of the species and the tables in which they are placed are as follows:

## RESULTS

The classification of the 2658 accessions for species, vine and fruit characters, genetic characteristics, resistance to the leaf blight phase of early blight, *Alternaria solani*, and resistance to tobacco mosaic virus is shown in Tables 5 through 8. Genetic stocks are listed in Table 4. However, for convenience in

finding specific accessions, all are listed in numerical order by PI number in Table 9, showing collector or donor notes and table assignments. The collectors' notes were summarized from various official sources, including the USDA Plant Inventories (1927-1964). Thus Table 9 serves as a guide to contents of Tables 4 through 8.

## CLASSIFICATION AND EVALUATION OF THE GENETIC STOCKS

The genetic stocks maintained at the Regional Station represent only a portion of the total genetic stocks available. Genes not held at the Regional Station are maintained by others (10).

Information concerning the genetic stocks is presented in Table 4. It is subdivided under four headings: (a) verified gene stocks, (b) tetraploids, (c) auto-diploids, (d) male steriles and other unfruitfuls.

The origin of the genetic stocks with accession numbers is listed in the column headed source. Certain accessions carry only the originator's name. Other items carry the scientist's name as well as an accession number used at his laboratory. In addition, certain accession numbers may include reference to the number of times it was grown prior to its transfer to the regional collection. Reference to the individual plant number from which seed was first taken also may be included. An M means that seed was massed from several plants. An Fs means that the harvested seed resulted from field selfing (natural pollination).

In the genotype column, gene symbols are used in accordance with Barton *et al* (6), Clayberg *et al* (11), and Clayberg (10). The symbols

are arranged from left to right according to linkage group and Butler's maps (7, 8). Each linkage group is enclosed with parentheses. Genes with unknown linkage relationships are listed alphabetically at the right of a colon after the last linkage group. Characteristics not yet assigned a gene symbol are listed last on the right. Characteristics and genes are listed only where the accession is different from Marglobe. This is in accordance with Barton *et al* (6).

In Table 4, section d, an evaluation of vine, foliage, and fruit characters was not recorded because the male steriles were observed as segregates in progenies from backcrossing within the variety where the male sterile originated. All male steriles and unfruitful plants had vines which grew more profusely than the fruitful plants in the variety of origin and had few, if any, fruits. Most such fruits were parthenocarpic but some had a few seeds. Seed was harvested from all normal segregates. Detailed descriptions of these male steriles have been published by Butler and Rick (9) and Rick (19, 20, 21, and 22).

\*\* - Seed to be distributed is from normal heterozygotes.

+ - Segregating.

## CLASSIFICATION AND EVALUATION OF THE GREEN-FRUITED SPECIES

The fruits of the three species in Table 5 are mostly greenish or white and are globose. Generally the fruits of *Lycopersicon peruvianum* become lavender or purple striped as they approach maturity. Since the fruit color and fruit shape of these species are constant, records were not made for these characters. In some instances, it was not possible to classify accessions of these species for mosaic resistance and susceptibility. Such cases are indicated in Table 5 by dashes. In certain accessions, so few fruit, if any, ripened that it was impossible to classify them for intensity of flesh color. These cases are also indicated by dashes in Table 5. The locule number of the fruits of all wild species is 2. Therefore, no records concerning this character are given in Tables 5 and 6.

The green-fruited species can be hybridized with the domestic species only with the greatest of difficulty. The most successful methods of obtaining hybrids were described by Smith (24) and by Alexander (1). These methods employ embryo culture but, even so, an exceedingly small percentage of seedlings is obtained. To make full use of the potentially valuable germplasm of these species, an easier method of hybridization is needed. It is possible to obtain enough seed from  $F_1$  plants to produce  $F_2$  progenies. In a back-cross program, Alexander found that embryo culture was needed for the second back-cross but from there on most plants were fertile (2).

TABLE 5.—Horticultural Characters and Disease Reaction of the Green-fruited Species, *Lycopersicon glandulosum* Mull., *L. hirsutum* Humb. and Bonpl., and *L. peruvianum* (L.) Mill.; and One Orange-fruited Species, *Lycopersicon cheesmanii* f. minor (Hook F.) Mull.

## CLASSIFICATION AND EVALUATION OF *Lycopersicon pimpinellifolium*

The currant tomato, *Lycopersicon pimpinellifolium*, has been used as the source of genes for resistance to several diseases and for this reason is a highly valuable tomato. The degree of cross fertility between this species and the domestic species, *L. esculentum*, is high. Thus any de-

sirable character or characters which this species possesses are readily available to plant breeders. The fruits of accessions of the species, *L. pimpinellifolium*, are remarkably free of cracks. The classification of the species is shown in Table 6.

\*The shape of *L. pimpinellifolium* was found to be globose in all cases.

## **CLASSIFICATION AND EVALUATION OF KNOWN INTERSPECIFIC CROSSES AND OF SUSPECTED CROSSES BETWEEN *Lycopersicon esculentum* and *L. pimpinellifolium***

Progenies of certain known crosses are listed in Table 7. These include *Lycopersicon esculentum* x *L. hirsutum*, *L. esculentum* x *L. peruvianum*, and *L. esculentum* x *L. pimpinellifolium*. The cross *L. esculentum* x *L. hirsutum* was made by Bruinsma Seed Company of Naaldwijk, Holland. Four selections are used as rootstalks for grafts to produce resistance to corky root, verticillium and fusarium wilts, and nematodes. The lines are heterozygous for these characters. Three crosses between *L. esculentum* x *L. peruvianum* were made by Alexander in Ohio to introduce mosaic resistance into commercial tomato varieties. Crosses including *L. pimpinellifolium* as one parent were made at three locations. The Ohio cross (PI 224589) was made by Paddock and Alexander (17) to study the inheritance of the genetic character cana or cauliflower. The second set of crosses was made by a German breeder but the reason for the crosses is unknown. In West Virginia, Gallegly and Marvel (12)

worked with resistance to late blight, *Phytophthora infestans* (Mont.) D. By. They used three sources of resistance. Two of the sources were PI 204980 and PI 204976. These are suspected crosses between *L. esculentum* and *L. pimpinellifolium*. The third source of resistance was *L. esculentum*, PI 204972.

Many accessions possessing characters which resemble *Lycopersicon esculentum* and at the same time possessing characters which resemble *L. pimpinellifolium* are grouped under the heading, Suspected Crosses. Progenies in the  $F_1$ ,  $F_2$ ,  $F_3$ , and succeeding generations from known crosses between the two species have yielded plants which closely resemble plants of the accessions in this group. This is the reason the accessions are thus separated. This group includes some accessions which normally would be classified as *L. esculentum* var. *cerasiforme*. The classification of this group is shown in Table 7.

TABLE 7.—Horticultural Characters and Disease Reaction of Some Known Interspecific Crosses and Suspected Crosses between *Lycopersicon esculentum* x *L. pimpinellifolium* (Jusl.) Mill.

## CLASSIFICATION AND EVALUATION OF THE DOMESTIC SPECIES, *Lycopersicon esculentum*

The classification of the species, *Lycopersicon esculentum*, is shown in Table 8. Approximately 83 percent of all accessions assembled were of this species. The fruit size ranged from very small to very large. Table 8 is divided into two sections: 8a, named and presumed varieties; and 8b, type species, including *F. pyriforme* and var. *cerasiforme*. In Table 8a, there are 441 named varieties which have been preserved for one or more reasons and 117 other accessions which were collected and are presumed to be named varieties.

It is difficult to describe the type species of *Lycopersicon esculentum* because of the wide divergence of characters in the species. The fruit size varies from less than 1 inch to more than 3 inches. The shape varies from globose to pear shape to San Marzano. The flesh color may be white, red, yellow, green, or tangerine. The skin is either colorless or yellow and the number of locules is extremely variable. Likewise, there are many variations in plant types. Perhaps these great variations result in part from mutations.

**TABLE 8.—Horticultural Characters and Disease Reaction of the Domestic Tomato, *Lycopersicon esculentum* Mill., Including Form *pyriforme* (Dun.) C. H. Mull., and Variety *cerasiforme* (Dun.) A. Gray.**

## DISCUSSION

In this general survey, it is difficult to find many accessions which possess specific characters with which a plant breeder may work exclusively. Rather, it is only possible to point out that certain accessions probably possess the character which may be needed. It is then incumbent upon the worker to determine by experimental trial the specific accession which possesses the desired character. Since many of the accessions were not homozygous when received for classification and evaluation and no attempt has been made to select for homozygosity, the research worker must isolate the desired character or characters in a homozygous condition. An exception to the above condition exists in the genetic stocks. With these stocks, efforts were made to keep them in the homozygous condition in which they were received. However, because of the large number of stocks handled it was not possible to hand self them. Thus an occasional off-type plant may be observed in these inbred recessive gene stocks. The male sterile and some unfruitful stocks must be maintained in a heterozygous condition and therefore segregate for the recessive male sterile character.

Since certain accessions appeared to be indistinguishable from one another, it was believed at first that many should be discarded. However, it was observed subsequently that even though certain accessions appear phenotypically alike, some possessed resistance to certain diseases when inoculated with disease-producing organisms and others did not (4). This has proven to be true with almost all groups of the genus *Lycopersicon*. Since one accession of the same species may be valuable for one character and another valuable for another character, all accessions have been maintained and their descriptions published without attempting to emphasize the value of any. The isolation of valuable accessions for horticultural characters can only be done by detailed studies for certain specific characters as is being done for disease resistance. Furthermore, gene requirements change because needs for new types of disease resistance continually arise. Thus, many of the accessions have been rescreened for new characters since the initiation of this project. It is reasonable to expect that this rescreening process will be carried on in the future.

Some workers have made notable advances in securing higher types of disease resistance by plant selection within segregating accessions. Notable suc-

cess, in this respect, was obtained by Gallegly and Marvel (12) for resistance to tomato late blight. Other instances of disease-resistant tomato segregates have been noted by Alexander and Hoover (4) and by Alexander (2). This success should stimulate other workers to try plant selection within accessions. However, plant selection should not be limited to disease resistance as it would appear just as likely that superior horticultural characters could be isolated.

The long-range objective of the intensive screening project for disease resistance is to eventually screen all accessions included in this publication as well as those subsequently collected. Many of the accessions included in Tables 5, 6, and 7 have been screened for resistance to 16 pathogenic diseases and 2 physiological diseases which seriously affect tomato production in North America (3). However, it seemed important to publish the results secured from the screening of wild species and certain small-fruited *Lycopersicon esculentum* types because resistance to several diseases was discovered. This was done (4). Several workers have since screened many accessions for new genes for disease resistance but these data have not been assembled. However, it is hoped that they will be assembled and the results published in the future.

The problem of collecting and evaluating tomato accessions will continue, even though the number of new accessions introduced each year is not great. It is expected that new interspecific hybrids will be added to the collection as they are made. This will be a valuable addition because one worker may make the cross for one purpose and another worker may find valuable genes in the same cross for his project.

To preserve the valuable germplasm of the old tested and tried varieties, they have been included in this study. It also has been deemed advisable to collect new varieties as they are released. The reason for including the latter, even though they may not survive the test of time, is that they probably contain certain valuable characters or they would not have been introduced as varieties.

The objective of this project is to bring together at one location as many tomato accessions as possible and to screen them in a preliminary manner. Thus duplication of work by many research workers is avoided. From the accessions described here, they can select those which appear most likely to serve their purposes.

## SUMMARY

Twenty-six hundred and fifty-eight accessions of the genus *Lycopersicon* have been assembled. Parental breeding material and genetic stocks were included. There are 8 accessions of *Lycopersicon glandulosum*; 14 accessions of *L. hirsutum* including f. *glabratum*; 57 accessions of *L. peruvianum* including the variety *dentatum* and var. *humifusum* and 1 introduction of the orange-fruited *L. cheesmanii* f. *minor* from the Galapagos Islands; 71 accessions of the species *L. pimpinellifolium*; 150 accessions classified as either suspected or known crosses; 2242 accessions of the domestic species, *L. esculentum*, of which 441 are named varieties, 117 presumed commercial varieties, and 1684 ordinary types; and 138 genetic stocks, mostly of the species *L. esculentum* but a few of *L. pimpinellifolium*. This collection has been classified by species

reaction to two diseases and certain horticultural characters. Resistance to two diseases, tobacco mosaic virus and the leaf blight phase of early blight incited by *Alternaria solani*, was determined by artificial infection. The accessions were evaluated for the horticultural characters: leaf type and size, hairy stem, pubescent fruit, flesh color, uniform unripe fruit color, wilty leaflet, fruit skin color, type and amount of cracking, fruit size and shape, intensity of flesh color, fasciation, number of locules, fruiting ability, maturity, and vine characteristics, including size, growth, and habit.

Genetic stocks were multiplied. These stocks include gene marker lines, autodiploids, tetraploids, and male steriles.

Seed of these accessions has been multiplied and placed in storage at the North Central Regional Plant Introduction Station at Ames, Iowa.
