ABSTRACT

We provide a comprehensive diffusion MRI dataset acquired with a novel biomimetic phantom mimicking human white matter. The fiber substrates in the diffusion phantom were constructed from hollow textile axons (“taxons”) with an inner diameter of $11.8 \pm 1.2 \mu\text{m}$ and outer diameter of $33.5 \pm 2.3 \mu\text{m}$. Data were acquired on the 3 T CONNECTOM MRI scanner with multiple diffusion times and multiple q-values per diffusion time, which is a dedicated acquisition for validation of microstructural imaging methods, such as compartment size and volume fraction mapping. Minimal preprocessing was performed to correct for susceptibility and eddy current distortions. Data were deposited in the XNAT Central database (project ID: dMRI_Phant_MGH).

Specifications Table

Subject area	Neuroimaging
More specific subject area	Diffusion MRI
Type of data	MRI data
How data was acquired	3 T MRI, Siemens CONNECTOM
Data format	NIfTI
Experimental factors	No special treatment was performed before the experiment.
Experimental features	Data were minimally preprocessed to correct for susceptibility and eddy current distortions.
Data source location	Boston, Massachusetts, USA
Data accessibility	Data is deposited in the XNAT Central database (https://central.xnat.org), Project ID: dMRI_Phant_MGH
Related research article	Fan, Q., Nummenmaa, A., Wichtmann, B., Witzel, T., Mekkaoui, C., Schneider, W., Wald, L.L., Huang, S.Y., Validation of diffusion MRI estimates of compartment size and volume fraction in a biomimetic brain phantom using a human MRI scanner with 300mT/m maximum gradient strength. <i>Neuroimage</i> . (2018). doi:10.1016/j.neuroimage.2018.01.004

Value of the data

- The Connectome scanner at the MGH Martinos Imaging Center is equipped with up to 300 mT/m gradient strength for *in vivo* human imaging, which is the first of the three installed so far worldwide, and thus access to the system is extremely limited.
- The Connectome system provides seven-fold higher gradient strength for diffusion encoding than state-of-art clinical scanners, which pushes upon the limits of diffusion resolution and provides unprecedented opportunity for microstructural imaging using diffusion MRI.
- A biomimetic phantom mimicking human white matter was used to acquire the data, which to our best knowledge is the only existing prototype that is constructed with both intra- and extra-cellular compartments with known inner diameter, to provide a more realistic standard for diffusion MRI measurements of axon diameter and related microstructural metrics.
- Our data was acquired with a comprehensive imaging protocol of about 40 hours of scanning time, which can be analyzed in multiple ways and allows great flexibility for other researchers to test their own algorithms.
- Two datasets were provided, corresponding to Connectome and Prisma capabilities respectively, which can provide insight into the impact of gradient strength on the performance of diffusion MRI methods to be tested by other researchers.

1. Data

The motivation of this dataset was to validate estimates of compartment size and volume fraction using a biomimetic brain phantom constructed from hollow polypropylene yarns with known diameter. We acquired a comprehensive set of diffusion MRI measurements in the phantom using multiple gradient directions, diffusion times and gradient strengths on a human MRI scanner equipped with gradient strengths up to 300 mT/m.

2. Experimental design, materials, and methods

2.1. Phantom composition

The fiber substrates in the diffusion phantom were constructed from hollow multifilament polypropylene yarns to generate textile axons (“taxons”) with an inner diameter of $11.8 \pm 1.2 \mu\text{m}$ and outer diameter of $33.5 \pm 2.3 \mu\text{m}$ [1] (Psychology Software Tools, Inc., Sharpsburg, Pennsylvania). The taxons were arranged in parallel within a 3D-printed taxon holder with rectangular chambers. Each of the chambers was built with fixed width and varying depths (i.e., 10 to 25 mm in Fig. 1) to achieve different fiber packing densities along the length of the fiber bundle. Fiber crossings of 90° , 45° and 30° were also created by interleaving the polypropylene filaments in separate 3D printed placeholders. See [2] for further information on phantom composition.

2.2. MRI experiments

All scans were performed on the Siemens 3 T CONNECTOM MRI system with maximum gradient strength of 300 mT/m using a Siemens product 20-channel head-neck coil. A series of 2-mm isotropic resolution axial diffusion-weighted spin echo echo planar images (EPI) were acquired in the phantom using the following parameters: TR/TE = 4100/110 ms, gradient strength $G_{\text{max}} = 300 \text{ mT/m}$ and 80 mT/m respectively for the $G_{\text{max}} = 300 \text{ mT/m}$ dataset and the $G_{\text{max}} = 80 \text{ mT/m}$ dataset, with a fixed diffusion gradient pulse duration $\delta = 8 \text{ ms}$. Diffusion times of $\Delta = 20, 30, 40, \text{ and } 50 \text{ ms}$ were sampled, which correspond to mean diffusion displacements of 9–15 μm , respectively, assuming an intrinsic diffusivity of $2.2 \times 10^{-9} \text{ m}^2/\text{s}$. Data were collected with 256 non-collinear diffusion-encoding gradient directions, which were evenly distributed on a sphere, with 20 interspersed $b = 0$ images. For each diffusion time in the $G_{\text{max}} = 300 \text{ mT/m}$ dataset, the gradient strength linearly varied from 24 to 300 mT/m to produce b -values ranging between 50 to 18,250 s/mm^2 , and for the $G_{\text{max}} = 80 \text{ mT/m}$ dataset, the gradient strength ranges from 17 to 80 mT/m with a range of b -value of 50 to 1400 s/mm^2 (Fig. 2, Table 1). Data were acquired in both anterior to posterior and posterior to anterior phase encoding directions to correct for image distortions due to susceptibility artifact. The total acquisition time was 38 h. Other imaging parameters included a field-of-view of $256 \times 256 \text{ mm}$, partial Fourier of 6/8, and receive bandwidth of 1148 Hz/pixel. A regular non-accelerated EPI sequence was used to minimize parallel imaging artifact.

Fig. 1. Illustration of the design of a representative taxon holder. The rectangular chamber has a fixed width but varying depth along the length of the chamber, such that the packing density decreases as the depth of the chamber increases.

Fig. 2. Exemplary diffusion weighted MR images. A representative axial slice through the center of the diffusion module of the phantom is shown. Diffusion-sensitizing gradients were applied perpendicular to the plane shown. The $G_{\max}=300$ mT/m dataset is shown in the upper panel and the $G_{\max}=80$ mT/m dataset in the lower panel.

The shared data has been minimally preprocessed to correct for distortions due to gradient nonlinearity, susceptibility effects, B_0 drift, and eddy currents [3–5]. Due to the length of the phantom scan (about a day), the static magnetic field (B_0) drifts due to hardware heating during the scan resulted in small image displacements along the phase encoding direction, which mimicked head motion [6]. To address this issue, the first $b=0$ image of all individual shells (i.e., for each q -value) were concatenated and used for a joint field map estimate using TOPUP [7,8], where image displacements due to B_0 drift were modeled in the same way as head motion. Eddy current correction was performed using the EDDY [3] tool in FSL.
