#### Abstract

: Two new xanthone derivatives, 12-dimethoxypinselin (1) and 12-O-acetyl-AGI-B4 (2), as well as two new phenolic bisabolane-type sesquiterpenes, 11,12dihydroxysydonic acid (15) and 1-hydroxyboivinianic acid (16), together with one new alkaloid, scopulamide (21) and one new $\alpha$-pyrone derivative, scopupyrone (26), in addition to twenty-three known compounds (3-14, 17-20, 22-25, 27-29) were isolated from solid rice cultures of the marine-derived fungus Scopulariopsis sp. obtained from the Red Sea hard coral Stylophora sp. All compounds were unambiguously identified through extensive NMR spectroscopic analyses, and by comparison with the literature. Marfey's reaction was performed to determine the absolute configuration of scopulamide (21) and TDDFT-ECD calculations were used to assign the configuration of AGI-B4 (3) and scopupyrone (26). All isolated compounds were evaluated for their cytotoxicity against L5178Y mouse lymphoma cells and the structure-activity relationships were discussed.

Keywords: Scopulariopsis sp.; Xanthone; Sesquiterpene; Structural elucidation; Cytotoxicity

## 1. Introduction

Marine microorganisms have been recognized as an important source of bioactive secondary metabolites. ${ }^{1}$ For example, phomactins, ${ }^{2}$ a class of fungal diterpenoids, which were initially found in the fungus Phoma sp. obtained from the shell of the crab Chionoecetesopilio, attracted attention due to their pronounced platelet activating factor antagonizing activity. Moreover, peribysins ${ }^{3}$ isolated from the sea hare-derived fungus Periconia byssoides are well-known as cell-adhesion inhibitors, and tryptostatins, ${ }^{4}$ structurally unique indole alkaloids, which were firstly isolated from Aspergillus fumigatus, a fungus obtained from a sea sediment sample, exhibit mammalian cell cycle inhibition activity. In addition, some of these metabolites have advanced to clinical trials and may potentially be launched as pharmaceutical drugs in the future. One of the most prominent examples of fungal derived bioactive compounds is plinabulin (NPI-2358), a synthetic analogue of the diketopiperazine alkaloid halimide which is produced by Aspergillus sp. CNC-139 isolated from the alga Halimeda lacrimosa. Plinabulin acts as a vascular disrupting agent (VDA) and inhibits tubulin polymerization, resulting in selective collapse of tumor endothelial vasculature. It is currently undergoing phase II clinical trials for patients with advanced non-small-cell lung cancer. ${ }^{5}$

In continuation of our ongoing efforts to identify new fungal products from rare and unusual econiches, ${ }^{6-11}$ we investigated the marine-derived fungus Scopulariopsis sp., which was isolated from the inner tissues of the Red Sea hard coral Stylophora sp. collected in Egypt. The ethyl acetate extract of this fungus when grown on solid rice medium was found to exhibit cytotoxicity against the mouse lymphoma cell line L5178Y in a preliminary bioassay. Moreover, a literature survey revealed that chemical studies on fungi of this genus have rarely been conducted. So far two

## ACCEPTED MANUSCRIPT

cytotoxic cyclodepsipeptides, ${ }^{12}$ two naphthalene derivatives, ${ }^{13}$ and one alkaloid named fumiquinazoline $L^{14}$ had been reported. In the present study, 29 compounds including 11 xanthones (1-11), 5 sesquiterpene derivatives (12-16), 4 phenyl ethers (17-20), 5 alkaloids (21-25), and 4 miscellaneous compounds (26-29) were isolated from solid rice cultures of Scopulariopsis sp.. Among them, 12-dimethoxypinselin (1), 12-O-acetyl-AGI-B4 (2), 11,12-dihydroxysydonic acid (15), 1hydroxyboivinianic acid (16), scopulamide (21) and scopupyrone (26) are new natural products. Besides, sydowinin B (6) and 11-hydroxysydonic acid (14) were also isolated from the host coral Stylophora sp. in this study. Herein, we describe the isolation, structural elucidation and cytotoxic activity of the compounds obtained.

## 2. Results and discussion

Scopulariopsis sp. was grown on solid rice medium and subsequently extracted with EtOAc, followed by partitioning of the dried extract between $n$-hexane and $90 \%$ aqueous MeOH . The resulting aqueous MeOH phase was fractionated by repeated column chromatography over silica gel, Sephadex LH-20, followed by semipreparative HPLC to afford compounds 1-29.

Compound 1 was isolated as a pale yellow solid. The molecular formula was determined as $\mathrm{C}_{18} \mathrm{H}_{16} \mathrm{O}_{8}$, based on the pseudomolecular ion peak of $[\mathrm{M}+\mathrm{H}]^{+}$at $\mathrm{m} / \mathrm{z}$ 361.0915, indicating 11 degrees of unsaturation. Its UV spectrum, which displayed absorption bands at $\lambda_{\max } 203,237,265$ and 380 nm , was similar to that of pinselin (5), ${ }^{15}$ suggesting that both compounds share the same core structure. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1}$ (Table 1) exhibited four aromatic protons at $\delta_{\mathrm{H}} 7.51(1 \mathrm{H}, \mathrm{d}, J=9.1 \mathrm{~Hz})$, $7.36(1 \mathrm{H}, \mathrm{d}, J=9.1 \mathrm{~Hz}), 7.06(1 \mathrm{H}, \mathrm{br}$ s $)$, and $6.81(1 \mathrm{H}, \mathrm{br} \mathrm{s})$, three methoxy groups at $\delta_{\mathrm{H}} 3.97(3 \mathrm{H}, \mathrm{s})$ and $3.36(6 \mathrm{H}, \mathrm{s})$, and an oxygenated methine at $\delta_{\mathrm{H}} 5.42(1 \mathrm{H}, \mathrm{s})$. Meanwhile, ${ }^{13}$ C NMR data (Table 1) along with HSQC and HMBC spectral analysis revealed the presence of 18 carbons, including one chelated carbonyl group ( $\delta_{\mathrm{C}} 181.2$ ), one carboxyl group ( $\delta_{\mathrm{C}} 170.2$ ), eight quaternary carbons ( $\delta_{\mathrm{C}} 162.3,157.1,154.3$, $150.1,136.7,118.8,118.4$, and 109.4), five tertiary carbons ( $\delta_{\mathrm{C}} 127.1,120.8,108.9$, 106.1, and 103.1), and three methoxy groups ( $\delta_{\mathrm{C}} 53.1,53.1$, and 52.9). These NMR data were comparable to those of pinselin (5) ${ }^{15}$ except for the replacement of the aromatic methyl substituent by an additional oxygenated methine ( $\delta_{\mathrm{C}} 103.1, \delta_{\mathrm{H}} 5.42$ ) and the appearance of two additional methoxy groups ( $\delta_{\mathrm{C}} 53.1, \delta_{\mathrm{H}} 3.36$ ). In the HMBC spectrum of $\mathbf{1}, \mathrm{H}-5\left(\delta_{\mathrm{H}} 7.06\right)$ and $\mathrm{H}-7\left(\delta_{\mathrm{H}} 6.81\right)$ exhibited correlations to the carbon of the additional oxygenated methine ( $\mathrm{C}-12$ ), while the latter proton displayed correlations to $\mathrm{C}-5\left(\delta_{\mathrm{C}} 106.1\right)$ and $\mathrm{C}-7$ ( $\delta_{\mathrm{C}} 108.9$ ) respectively, supporting the
assignment of the oxygenated methine at $\mathrm{C}-12$. Besides, the HMBC correlations from the protons of the two additional methoxy groups to C -12 indicated their linkage at C 12. The gross structure of $\mathbf{1}$ was further confirmed by detailed examination of COSY and HMBC spectra (Figure 1). Hence, compound 1 was elucidated as 12dimethoxypinselin.

[^0]Figure 1. Key COSY (bold lines) and HMBC (arrows) correlations of compounds $\mathbf{1}$ and $\mathbf{2}$.

Compound 2 was obtained as a yellow solid and its UV spectrum was almost identical to that of AGI-B4 (3) ${ }^{16}$. The molecular formula of 2 was determined as $\mathrm{C}_{18} \mathrm{H}_{16} \mathrm{O}_{8}$ by HRESIMS, indicating 42 additional amu compared to 3 . Comparison of the NMR data (Table 1) with those of $\mathbf{3}$ revealed that the two compounds were structurally similar, except for the presence of an additional acetyl group in $\mathbf{2}$ as evident from the signals at $\delta_{\mathrm{C}} 170.6(\mathrm{qC})$ and $20.3\left(\mathrm{CH}_{3}\right)$ in the ${ }^{13} \mathrm{C}$ NMR and the corresponding signal at $\delta_{\mathrm{H}} 2.13(3 \mathrm{H}, \mathrm{s})$ in the ${ }^{1} \mathrm{H}$ NMR spectrum. The location of this acetyl group at $\mathrm{C}-12$ was confirmed by the HMBC correlation from $\mathrm{H}-12\left(\delta_{\mathrm{H}} 5.18, \mathrm{~s}\right)$ to the acetyl carbonyl carbon. The relative configuration of $\mathbf{2}$ was deduced from the coupling constant $\left({ }^{3} J_{1,2}=3.2 \mathrm{~Hz}\right)$, which is similar to that of $\mathbf{3}\left({ }^{3} J_{1,2}=3.7 \mathrm{~Hz}\right)$. Thus compound 2 was identified as the $12-O$-acetyl-AGI-B4. The ECD spectrum of 2 showed a baseline curve, which considering the chiral dihydroxanthone chromophore, suggested that $\mathbf{2}$ was either a racemate or it had a low enantiomeric excess. This was confirmed by chiral HPLC analysis using Chiralpack IA column, which showed 17\% enantiomeric excess of $\mathbf{2}$. In contrast, the related derivative $\mathbf{3}$ gave a distinct ECD spectrum and its specific rotation, $[\alpha]_{\mathrm{D}}^{20}-28.0(c 0.40, \mathrm{MeOH})$ was found much larger than the reported value $[\alpha]_{D}^{20}-1.6(c 0.4, \mathrm{MeOH}) .{ }^{16}$ According to these results, it is probable that the reported sample with -1.6 specific rotation was a racemic mixture or it had very low enantiomeric excess. Meanwhile, chiral HPLC analysis for compound 3 showed that it had 70\% enantiomeric excess.

Although the relative configuration of $\mathbf{3}$ was determined by X-ray analysis, ${ }^{16}$ its absolute configuration has not been reported yet. The solution TDDFT-ECD calculation protocol was applied to determine the absolute configuration of 3. ECD calculations were performed on the arbitrarily chosen $(1 R, 2 R)$-enantiomer of $\mathbf{3}$. The initial MMFF conformational search yielded 24 conformers in a $21 \mathrm{~kJ} / \mathrm{mol}$ energy
window, the B3LYP/6-31G(d) in vacuo reoptimization of which resulted in 10 lowenergy ( $\geq 2 \%$ ) conformers (Figure 2). In all the ten low-energy conformers, the C-1 methoxycarbonyl and 2-hydroxyl groups adopted axial orientation, which was in agreement with the measured small value of the ${ }^{3} J_{1,2}$ coupling constant. The $\omega_{\mathrm{C}-3, \mathrm{C}-4, \mathrm{C}-}$ 4a,C-9a torsional angle had a negative value for all the conformers with values between $-9^{\circ}$ and $-11^{\circ}$. The structures of conformers differed in the orientation of the methoxycarbonyl group and the proton of the 2-and 12-hydroxyl groups. Boltzmannaveraged ECD spectra calculated for the above conformers at various levels (B3LYP/TZVP, BH\&HLYP/TZVP and PBE0/TZVP) reproduced well the experimental spectrum with BH\&HLYP/TZVP giving the best agreement (Figure 3). Since all the applied theoretical levels and all the low-energy conformers gave similar and consistent results, the absolute configuration of $\mathbf{3}$ could be unambiguously determined as $1 R, 2 R$.

Compound 15 was obtained as a white amorphous powder, with $[\alpha]_{D}^{20}$ of $+4.3(c$ $0.23, \mathrm{MeOH})$. The UV spectrum showed absorption maxima at 220,246 and 302 nm , and resembles that of sydonic acid (13) ${ }^{17}$ and 11-hydroxysydonic acid (14) ${ }^{18}$. Its molecular formula was determined as $\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{O}_{6}$ by HRESIMS, containing one additional oxygen atom compared to 14 . The NMR data (Table 2) of $\mathbf{1 5}$ were comparable to those of $\mathbf{1 4}$, except for the appearance of the signals of a hydroxymethyl substituent ( $\delta_{\mathrm{C}} 69.8, \delta_{\mathrm{H}} 3.28$ ) in $\mathbf{1 5}$, instead of the signals for a methyl group ( $\delta_{\mathrm{C}} 29.6, \delta_{\mathrm{H}} 1.10$ ) in 14 . The HMBC correlations from the protons of this hydroxymethyl group to $\mathrm{C}-10\left(\delta_{\mathrm{C}} 39.3\right)$, $\mathrm{C}-11\left(\delta_{\mathrm{C}} 72.1\right)$ and $\mathrm{C}-13\left(\delta_{\mathrm{C}} 23.8\right)$ indicated the hydroxymethyl substituent of $\mathbf{1 5}$ to be present at C-12. Analysis of the COSY and HMBC spectra (Figure 4) confirmed the planar structure of 15. The absolute configuration at C-7 in $\mathbf{1 5}$ was determined as $S$, due to the similarity of the ECD spectrum compared with $(S)$-sydonol. ${ }^{17}$ Attempts to determine the absolute
configuration at C-11 using the modified Mosher's method were unsuccessful due to the limited amount of the sample.

Figure 4. Key COSY (bold lines) and HMBC (arrows) correlations of compounds 15 and $\mathbf{1 6 .}$
The molecular formula of compound $\mathbf{1 6}$ was established as $\mathrm{C}_{12} \mathrm{H}_{12} \mathrm{O}_{5}$, implying seven degrees of unsaturation. The 1D and 2D NMR data indicated the gross structure of $\mathbf{1 6}$ to be similar to that of 1-hydroxyboivinianin $\mathrm{A},{ }^{19}$ except for the replacement of an aromatic methyl substituent by a carboxyl substituent. This was evident from the $\mathrm{C}-12$ resonance ( $\delta_{\mathrm{C}} 170.3$ ) and the HMBC correlations from $\mathrm{H}-4$ ( $\delta_{\mathrm{H}} 7.48$ ) and $\mathrm{H}-6$
$\left(\delta_{\mathrm{H}} 7.47\right)$ to it. Therefore, $\mathbf{1 6}$ was identified as 1-hydroxyboivinianic acid. The ECD spectrum of $\mathbf{1 6}$ was a baseline curve, which proved that it was a racemic mixture.

Scopulamide (21) was recovered as a yellow amorphous powder, and its molecular formula was determined as $\mathrm{C}_{16} \mathrm{H}_{21} \mathrm{NO}_{6}$ based on HRESIMS data $\left([\mathrm{M}+\mathrm{H}]^{+}\right.$ at $m / z$ 324.1438, calcd. 324.1447), indicating seven degrees of unsaturation. The UV spectrum exhibited absorption maxima at 205, 251 and 299 nm , which is similar to that of pyrenochaetic acid derivatives. ${ }^{20}$ The ${ }^{1} \mathrm{H}$ NMR spectrum (Table 3) of 21 revealed the presence of three methyl groups, including an aliphatic methyl signal at $\delta_{\mathrm{H}} 0.96\left(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}, \mathrm{H}_{3}-10\right)$, an aromatic methyl signal at $\delta_{\mathrm{H}} 2.21\left(3 \mathrm{H}, \mathrm{s}, \mathrm{H}_{3}-12\right)$, and a methoxy signal at $\delta_{\mathrm{H}} 3.89\left(3 \mathrm{H}, \mathrm{s}, \mathrm{H}_{3}-11\right)$. Besides, two methylene signals at $\delta_{\mathrm{H}}$ $2.74\left(2 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}, \mathrm{H}_{2}-8\right)$ and $\delta_{\mathrm{H}} 1.66\left(2 \mathrm{H}\right.$, sext, $\left.J=7.3 \mathrm{~Hz}, \mathrm{H}_{2}-9\right)$, as well as two aromatic protons located at $\delta_{\mathrm{H}} 7.44(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{H}-2)$ and $7.42(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{H}-6)$ were found. Upon comparing these data with the literature, it was clear that a partial structure of 21 is in accordance with that of pyrenochaetic acid C, ${ }^{20}$ which was confirmed by analysis of 2D NMR spectra (Figure 5). In the HMBC spectrum of 21, $\mathrm{H}-2$ showed a correlation to $\mathrm{C}-6\left(\delta_{\mathrm{C}} 122.2\right)$, $\mathrm{H}-6$ showed a correlation to $\mathrm{C}-2\left(\delta_{\mathrm{C}}\right.$ 108.5 ), and both $\mathrm{H}-2$ and $\mathrm{H}-6$ exhibited correlations to $\mathrm{C}-4\left(\delta_{\mathrm{C}} 135.0\right)$ and $\mathrm{C}-13\left(\delta_{\mathrm{C}}\right.$ 166.7), while $\mathrm{H}_{3}-12$ displayed correlations to $\mathrm{C}-4, \mathrm{C}-5\left(\delta_{\mathrm{C}} 135.8\right)$ and $\mathrm{C}-6$, and $\mathrm{H}_{3}-11$ exhibited correlations to C-3 ( $\delta_{\mathrm{C}} 157.2$ ). In addition, the COSY correlations between $\mathrm{H}_{2}-8$ and $\mathrm{H}_{2}-9$ and in turn between $\mathrm{H}_{2}-9$ and $\mathrm{H}_{3}-10$, as well as the HMBC correlations from $\mathrm{H}_{2}-8$ and $\mathrm{H}_{2}-9$ to $\mathrm{C}-7$ ( $\delta_{\mathrm{C}}$ 206.7) were observed. These findings supported a 1,3,4,5-tetrasubstituted benzene ring with a carboxyl group at C-1, a methoxy group at C-3, a propyl side chain moiety at C-4, and a methyl group at C-5. Apart from these signals, a hydroxymethylene group ( $\delta_{\mathrm{C}} 62.5, \delta_{\mathrm{H}} 4.03$ and $3.96, \mathrm{CH}_{2}-16$ ), a methine ( $\delta_{\mathrm{C}}$ $\left.56.1, \delta_{\mathrm{H}} 4.73, \mathrm{CH}-14\right)$, and an amide proton $\left(\delta_{\mathrm{H}} 7.86, \mathrm{NH}\right)$ were observed. The COSY
correlations between $\mathrm{H}_{2}-16 / \mathrm{H}-14$ and $\mathrm{H}-14 / \mathrm{NH}$, as well as the weak NOE correlations from NH to $\mathrm{H}-2$ and H-6, combined with its molecular formula, indicated the presence of a serine moiety linked to the carboxyl group via an amide bond. In order to determine the absolute configuration of 21, acid hydrolysis followed by subsequent derivatization of the liberated serine moiety using Marfey's method ${ }^{21}$ were conducted. Comparison of the retention time (using LCMS) of the resulting product with those of L- and D-serine that were available as authentic standards and that were subjected to the same treatment as $\mathbf{2 1}$, revealed the presence of L-serine in $\mathbf{2 1}$. Consequently, scopulamide (21) was determined as pyrenochaetic acid C connected to an L-serine amino acid moiety through an amide linkage. This is the first report of an N containing pyrenochaetic acid derivative.

26

Figure 5. Key COSY (bold lines) and HMBC (arrows) correlations of compounds 21 and 26.
Compound 26 exhibited absorption maxima at 205 and 300 nm in the UV spectrum, suggesting the presence of an $\alpha$-pyrone moiety. ${ }^{22}$ The HRESIMS data supported the molecular formula $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{4}$, indicating four degrees of unsaturation. Analysis of the ${ }^{1} \mathrm{H}$ NMR data (Table 3), showed the presence of one methoxy group at $\delta_{\mathrm{H}} 3.95\left(3 \mathrm{H}, \mathrm{s}, \mathrm{H}_{3}-12\right)$, three methyl groups at $\delta_{\mathrm{H}} 1.15\left(3 \mathrm{H}, \mathrm{d}, J=6.2 \mathrm{~Hz}, \mathrm{H}_{3}-10\right), 1.26$ $\left(3 \mathrm{H}, \mathrm{d}, J=7.0 \mathrm{~Hz}, \mathrm{H}_{3}-13\right)$ and $1.86\left(3 \mathrm{H}, \mathrm{s}, \mathrm{H}_{3}-11\right)$, one methylene group at $\delta_{\mathrm{H}} 1.57$ and $1.81\left(1 \mathrm{H}, \mathrm{m}\right.$, each, $\left.\mathrm{H}_{2}-8\right)$, and three methine protons at $\delta_{\mathrm{H}} 6.45(1 \mathrm{H}, \mathrm{s}, \mathrm{H}-5$, aromatic), $3.57(1 \mathrm{H}, \mathrm{m}, \mathrm{H}-9$, oxygenated), and $2.93(1 \mathrm{H}, \mathrm{m}, \mathrm{H}-7)$. The COSY correlations between $\mathrm{H}_{3}-13 / \mathrm{H}-7, \mathrm{H}-7 / \mathrm{H}_{2}-8, \mathrm{H}_{2}-8 / \mathrm{H}-9$, and $\mathrm{H}-9 / \mathrm{H}_{3}-10$, as well as the HMBC correlations from $\mathrm{H}_{3}-10$ to $\mathrm{C}-8\left(\delta_{\mathrm{C}} 44.5\right)$ and C-9 ( $\delta_{\mathrm{C}} 65.8$ ), and from $\mathrm{H}_{3}-13$ to $\mathrm{C}-7$ ( $\delta_{\mathrm{C}} 36.7$ ) and C-8 indicated that a 1-methyl-3-hydroxybut-1-yl group was present in 26. Furthermore, key HMBC correlations from $\mathrm{H}_{3}-11$ to $\mathrm{C}-2\left(\delta_{\mathrm{C}} 167.8\right), \mathrm{C}-3\left(\delta_{\mathrm{C}}\right.$ 100.9), and C-4 ( $\delta_{\mathrm{C}} 168.8$ ), from $\mathrm{H}_{3}-12$ to $\mathrm{C}-4$, from $\mathrm{H}-5$ to $\mathrm{C}-3$ and $\mathrm{C}-7$, and from $\mathrm{H}_{3}-13$ to C-6 ( $\delta_{\mathrm{C}} 168.6$ ) confirmed the presence of $\alpha$-pyrone nucleus and the attachment of methyl, methoxy and 1-methyl-3-hydroxybutyl groups at C-3, 4, and 6 positions, respectively. Thus, the structure of $\mathbf{2 6}$ was confirmed as a new natural product for which the name scopupyrone is proposed. Due to the conformational flexibility of the side-chain, the relative configuration of the two stereogenic centers could not be determined by NMR. The ECD features are governed primarily by the C-

7 stereogenic center attached directly to the $2 H$-pyran-2-one chromophore, while the C-9 stereogenic center is expected to have only negligible contribution.

For the configurational assignment of C-7 in 26, the TDDFT-ECD spectrum was calculated for the solution conformers of the arbitrarily chosen $(7 S, 9 R)$-26. The B3LYP/6-31G(d) in vacuo reoptimization of the 123 MMFF conformers of (7S,9R)26 resulted in 8 low-energy conformers above $2 \%$ (Figure 6).

Figure 6. Structures and populations of the low-energy in vacuo B3LYP/6-31G(d) conformers $(\geq 2 \%)$ of $(7 S, 9 R)-\mathbf{2 6}$.

The computed conformers differed in the conformation of the 1-methyl-3-hydroxybut-1-yl side-chain. Since the C-7 stereogenic center of $\mathbf{2 6}$ is contiguous to the achiral $2 H$-pyran-2-one chromophore, the conformation of the side-chain and especially the $\omega_{\mathrm{H}-7, \mathrm{C}-7, \mathrm{C}-6, \mathrm{C}-5}$ torsional angle is decisive for the ECD spectrum. In the lowest-energy conformer (conf A, 33.9\%), the C-7-H-7 bond was nearly cis-coplanar with the $\mathrm{C}-5-\mathrm{H}-5$ bond with $-16.4^{\circ}$ for the $\omega_{\mathrm{H}-7, \mathrm{C}-7, \mathrm{C}-6, \mathrm{C}-5}$ torsional angle. Similar cis-co-planar conformation is represented by conformers B, C, E, G and H with $+0.8^{\circ},-1.5^{\circ},+7.9^{\circ},+1.0^{\circ}$ and $-5.6^{\circ} \omega_{\mathrm{H}-7, \mathrm{C}-7, \mathrm{C}-6, \mathrm{C}-5}$ torsional angles totalling
$37.4 \%$ population, respectively. In conformers D and $\mathrm{F}, \mathrm{C}-13$ was nearly syn-coplanar with $\mathrm{H}-5$ resulting in $-129.8^{\circ}$ and $-142.0^{\circ} \omega_{\mathrm{H}-7, \mathrm{C}-7, \mathrm{C}-6, \mathrm{C}-5}$ torsional angles with a total population of $11.9 \%$. The ECD spectra computed for the different conformers reflected well the differences of the $\omega_{\mathrm{H}-7, \mathrm{C}-7, \mathrm{C}-6, \mathrm{C}-5}$ torsional angles; the $\mathrm{C}-7-\mathrm{H}-7$ syn-co-planar conformers (conf A, B, C, E, G and H) had mirror image ECD curves of the experimental spectrum, while two major ECD transitions inverted signs in the computed ECD of conformers D and F and hence they were quite similar to the experimental ones (Figure 7).

Figure 7. Experimental ECD spectrum of 26 in MeCN compared with the computed BH\&HLYP/TZVP ECD spectra of the in vacuo B3LYP/6-31G(d) conformers A (blue) and D (red) of (7S,9R)-26.

The Boltzmann-weighted computed ECD spectra of ( $7 S, 9 R$ )-26 gave mirror image curves of the experimental spectrum with all the three methods tested (Figure 8), which clearly suggested $7 R$ absolute configuration for $\mathbf{2 6}$. The absolute configuration of the C-9 stereogenic center cannot be determined by ECD calculations.

Figure 8. Experimental ECD spectrum of $\mathbf{2 6}$ in MeCN compared with the Boltzmann-weighted BH\&HLYP/TZVP ECD spectrum of (7S,9R)-26 computed for the B3LYP/6-31G(d) in vacuo conformers. Bars represent the rotational strength of the lowest-energy conformer.

Due to the presence of the low-energy conformer D and F having opposite ECD curves, the reliability of our ECD calculation greatly depends on the proper estimation of population for the two types of conformation. Thus we thought it was necessary to confirm the above results by applying a newer functional, larger basis set and PCM solvent model. ${ }^{23,24}$

Reoptimization of the MMFF conformers was repeated at B97D/TZVP PCM/MeCN level ${ }^{23,25}$ affording 14 conformers above $2 \%$ population (Figure S37). Similarly to the previous in vacuo calculation, the C-7-H-7 syn-co-planar conformers were found the major ones represented by 9 conformers with a total population of $59.0 \%$, while the C-13-H-5 syn-co-planar conformers had $15.1 \%$ total population from 5 minor conformers. Thus the Boltzmann-averaged calculated ECD spectra were in line with the B3LYP in vacuo results (Figure S38) verifying the absolute configuration of (-)-26 as $7 R$.

In addition to the new natural products discussed above, 23 known compounds were also isolated. By comparison of their NMR and mass data with the literature,
they were identified as AGI-B4 (3), ${ }^{16}$ huperxanthone $\mathrm{C}(\mathbf{4}),{ }^{26}$ pinselin (5), ${ }^{15}$ sydowinin B (6), ${ }^{27} \quad$ 13-O-acetylsydowinin $\quad \mathrm{B}(7),{ }^{28} \quad$ 2,11-dihydroxy-1-methoxycarbonyl-9carboxylxanthone(8), ${ }^{29}$ sydowinin A (9), ${ }^{26,30}$ 8-(methoxycarbonyl)-1-hydroxy-9-oxo$9 H$-xanthene-3-carboxylic acid (10), ${ }^{31}$ methyl-3,8-dihydroxy-6-methyl-9-oxo-9H-xanthene-1-carboxylate $(\mathbf{1 1}),{ }^{32}$ sydowic acid (12), ${ }^{33}$ sydonic acid (13) ${ }^{17}$, 11hydroxysydonic acid (14) ${ }^{18}$, violaceol I (17), ${ }^{34}$ violaceol II (18), ${ }^{34}$ diorcinol (19), ${ }^{34}$ rikuzenol (20) ${ }^{35}$, lumichrome (22), ${ }^{36}$ WIN 64821 (23), ${ }^{37}$ scopularide A (24), ${ }^{12}$ and scopularide $\mathrm{B}(\mathbf{2 5}),{ }^{12}$ pyrenochaetic acid $\mathrm{A}(\mathbf{2 7}),{ }^{20} 7$-hydroxy-2,5-dimethylchromone $(\mathbf{2 8})^{38}$ and ergosterol (29). ${ }^{39}$ It is worth to note that with the exception of the cyclodepsipeptides that had previously been reported from the genus Scopulariopsis, the remaining compounds which were identified in this study are reported here for the first time for this genus. Interestingly, we also isolated sydowinin B (6) and 11hydroxysydonic acid (14) from the extract of host coral Stylophora sp., suggesting that production of structurally similar compounds by Scopulariopsis sp. as found in this study may also take place when the fungus is confined within its host.

All compounds (1-29) were tested for their cytotoxicity, by examining their effects on the growth of the murine lymphoma cell line (L5178Y) using the MTT method. The xanthone derivative AGI-B4 (3), the cyclic depsipeptide scopularide A (24), and the phenyl ethers violaceols I and II (17 and 18) displayed significant cytotoxicity with $\mathrm{IC}_{50}$ values of $1.5,1.2,9.5$ and $9.2 \mu \mathrm{M}$, respectively, similar to that of the positive control kahalalide $\mathrm{F}\left(\mathrm{IC}_{50} 4.3 \mu \mathrm{M}\right)$, while the remaining compounds exhibited no activity $\left(\mathrm{IC}_{50}>15 \mu \mathrm{M}\right)$. The cytotoxicity of AGI-B4 (3) and the lack of activity observed for the remaining xanthone derivatives (1-2, 4-11), indicated that both the dihydroxanthenone nucleus and a free hydroxyl group at C-12 are structural features that are important for the cytotoxic activity of the analyzed xanthones.

Comparison of the cytotoxicity between scopularide A (24) and B (25) suggested that the length of the aliphatic side chain and hence probably the lipophilicity are also important for the cytotoxicity. Moreover, regarding the isolated biphenyl ether derivatives, the cytotoxicity of violaceols I and II (17 and 18) and no detectable activity for $\mathbf{1 9}$, led to the assumption that increasing the number of hydroxy groups in these molecules enhanced the cytotoxic activity.

## 3. Experimental section

### 3.1. General experimental procedures

Optical rotations were measured on a Perkin-Elmer-241 MC polarimeter. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and 2D NMR spectral data were recorded in deuterated solvents on Bruker ARX 300 or Avance DMX 600 NMR spectrometers. Mass spectra were obtained on a LC-MS HP1100 Agilent Finnigan LCQ Deca XP Thermoquest and high-resolution mass (HRESIMS) spectra were measured on a FTHRMS-Orbitrap (Thermo Finnigan) mass spectrometer. HPLC analysis was performed with a Dionex Ultimate 3000 LC system coupled with a photodiode array detector (UVD340S), with detection wavelengths of 235, 254, 280 and 340 nm . The separation column ( $125 \mathrm{x} 4 \mathrm{~mm}, \mathrm{~L} x \mathrm{ID}$ ) was prefilled with Eurospher-10 $\mathrm{C}_{18}$ (Knauer, Germany), whereas the following gradient was used ( $\mathrm{MeOH}, 0.01 \% \mathrm{HCOOH}$ in $\mathrm{H}_{2} \mathrm{O}$ ): $0 \mathrm{~min}, 10 \% \mathrm{MeOH} ; 5 \mathrm{~min}, 10 \% \mathrm{MeOH} ; 35 \mathrm{~min}$, $100 \% \mathrm{MeOH} ; 45 \mathrm{~min}, 100 \% \mathrm{MeOH}$, with a flow rate of $1 \mathrm{~mL} / \mathrm{min}$. Semi-preparative HPLC separation was performed on a semi-preparative RP-HPLC system of LaChrom-Merck Hitachi (pump: L7100 and UV detector L7400; column: Eurospher $100 \mathrm{C}_{18}, 300 \times 8 \mathrm{~mm}$, Knauer, Germany) with a flow rate of $5.0 \mathrm{~mL} / \mathrm{min}$. Routine normal phase column chromatography was performed using Merck MN Silica gel 60 M (0.04-0.063 mm) or Sephadex LH-20 as stationary phases. TLC analyses and preparative TLC were performed on precoated Silica Gel 60 F254 plates (Merck,

Darmstadt, Germany) followed by detection under UV at 254 and 365 nm or after spraying with anisaldehyde reagent or methanol-sulphuric acid (95:5), respectively. Solvents were distilled before use and spectroscopic grade solvents were used for spectroscopic measurements.

### 3.2. Fungal material

The fungal strain Scopulariopsis sp. was isolated from the fresh crushed inner tissues of the Red Sea hard coral Stylophora sp. as described previously. ${ }^{40}$ The coral was collected in November 2012 near the coastline of Ain El-Sokhna area, Red Sea, Egypt, and identified as Stylophora sp.. A voucher specimen (code ST-1112) was deposited at the Department of Pharmacognosy, Faculty of Pharmacy, Ain-Shams University, Cairo, Egypt. For isolation of fungi the coral sample was thoroughly cleaned with distilled water, then surface sterilization was done with $70 \%$ ethanol for 2 min , followed by rinsing with sterile water. To exclude the presence of surfaceadhered fungi, an imprint of the coral surface on biomalt agar was performed. The coral pieces were then aseptically crushed and homogenized. Small tissue samples from the inside of the coral were cut aseptically using a sterile blade and pressed onto malt agar plates containing the antibiotic chloramphenicol to suppress bacterial growth (composition of isolation medium: $15 \mathrm{~g} / \mathrm{L}$ malt extract, $15 \mathrm{~g} / \mathrm{L}$ agar, and 0.2 $\mathrm{g} / \mathrm{L}$ chloramphenicol in distilled water, $\mathrm{pH} 7.4-7.8$, adjusted with $10 \% \mathrm{NaOH}$ or $36.5 \% \mathrm{HCl})$. After incubation at room temperature $\left(25^{\circ} \mathrm{C}\right)$, the fungal strain under investigation was found to grow exclusively out of the coral tissue, but not on control plates (imprints from the coral surface). From growing cultures, a pure fungal strain (ST-F1) was isolated by repeated reinoculation on fresh malt agar plates.

### 3.3. Identification of the fungal strain

The fungus was identified using a molecular biological protocol by DNA amplification and sequencing of the ITS region (GenBank accession no: KP027401) as described previously. ${ }^{40}$ This fungal strain was identified as Scopulariopsis sp.. A voucher strain is kept in the Institute of Pharmaceutical Biology and Biotechnology, Heinrich-Heine University, Düsseldorf, Gemrany, with the ID code (ST-F1).

### 3.4. Cultivation, extraction and isolation

Mass growth of the fungus for the isolation and identification of secondary metabolites was performed in Erlenmeyer flasks (1L each). The fungus was cultivated on solid rice medium ( 100 g rice and 110 mL water, which was kept overnight before being autoclaved for 20 min at a temperature of $121^{\circ} \mathrm{C}$ ) in 10 Erlenmeyer flasks ( 1 L each) for four weeks under static conditions at $25^{\circ} \mathrm{C}$.

Each flask of the fungal culture on solid rice medium was extracted three times with 600 mL EtOAc. After combining the extracts and evaporation of EtOAc, partitioning was done for the residue ( 15 g ) between $n$-hexane and $90 \%$ aqueous methanol. Evaporation of the $90 \%$ methanol fraction gave 10 g , which was fractionated by vacuum liquid chromatography (VLC) on silica gel using a gradient elution of $n$-hexane/EtOAc (100:0 to $0: 100$ ) and $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}$ (100:0 to $0: 100$ ), where an eluting volume of 500 mL was used for each step. Elution started with $n$ hexane/ethyl acetate gradient in $20 \%$ steps, and when $60 \% n$-hexane was reached, $10 \%$ steps were employed till $100 \% \mathrm{EtOAc}$, then $\mathrm{DCM} / \mathrm{MeOH}$ gradient was applied in $20 \%$ steps till $100 \% \mathrm{MeOH}$, yielding fourteen fractions (STFV1-V14).

Crystallization of the $40 \%$ EtOAc VLC fraction STFV3 ( 800 mg ) afforded white crystals of 29 ( 28 mg ). The remaining supernatant STFV3F ( 740 mg ) was chromatographed on a Sephadex LH-20 column ( $100 \times 5 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as eluting solvent and similar fractions were combined using TLC analysis to afford $\mathbf{1 9}$
(3 mg). Fraction STFV4 which was eluted from the VLC with 60\% EtOAc ( 235 mg ), was further purified using a Sephadex LH-20 column ( $80 \times 4 \mathrm{~cm}$ ) with $100 \% \mathrm{MeOH}$ to give $11(2.5 \mathrm{mg})$. Fraction STFV5 ( 545 mg ) which was eluted with $80 \% \mathrm{EtOAc}$, was chromatographed over a Sephadex LH-20 column (100 x 5 cm ) using 100\% MeOH as eluent to give 10 subfractions coded STFV5S1 to S10. STFV5S4 (18 mg) was further purified using semi-preparative RP-HPLC with $58 \% \mathrm{MeOH}$ as eluting system to afford $28(1.3 \mathrm{mg})$ and $\mathbf{1 3}(1 \mathrm{mg})$. Meanwhile, STFV5S5 ( 125 mg ) was subjected to a Sephadex LH-20 column (70 x 4 cm ), using DCM-MeOH (1:1) as mobile phase to yield $\mathbf{1 7}(6.5 \mathrm{mg}), \mathbf{1 8}(6 \mathrm{mg}), \mathbf{1}(1.2 \mathrm{mg}), 7(8.2 \mathrm{mg})$ and $\mathbf{5}(1.8 \mathrm{mg})$. STFV5S8 (16 mg) was subjected to purification by semi-preparative RP-HPLC using $52 \%$ aqueous MeOH to recover $20(1.8 \mathrm{mg})$. Fraction STFV6 ( 365 mg ) that was eluted with $100 \%$ DCM, was subjected to a Sephadex LH-20 column ( $100 \times 5 \mathrm{~cm}$ ) eluting with $\mathrm{DCM}-\mathrm{MeOH}$ (1:1). Fractions were combined according to their TLC profiles into 8 subfractions (STFV6S1 to S8). Subfraction STFV6S5 (18.5 mg) was further purified by semi-preparative HPLC with a gradient of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ to yield $\mathbf{1 6}$ $(0.9 \mathrm{mg})$ and $2(1.0 \mathrm{mg})$ at $46 \%$ and $61 \% \mathrm{MeOH}$, respectively. Similarly, the VLC fraction STFV7 ( $25 \% \mathrm{MeOH}, 1.82 \mathrm{~g}$ ) was re-fractionated over a VLC column as previously described, yielding 14 different subfractions (STFV7V1 to V14). The subfraction STFV7V3 ( 380 mg ) was chromatographed over a Sephadex LH-20 column (100 x 5 cm ) with $100 \% \mathrm{MeOH}$ to obtain five pure compounds $\mathbf{1 4}(14 \mathrm{mg}), \mathbf{3}$ $(8 \mathrm{mg}), \mathbf{2 2}(0.9 \mathrm{mg}), \mathbf{9}(1.3 \mathrm{mg})$ and $\mathbf{6}(12 \mathrm{mg})$. Subfraction STFV7V4 $(180 \mathrm{mg})$ was subjected to a Sephadex LH-20 column ( $70 \times 4 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as eluent to afford $26(0.5 \mathrm{mg})$ and $\mathbf{1 2}(8 \mathrm{mg})$. STFV7V6 ( 1.3 g ) was subjected to an additional VLC column as described before, giving 12 subfractions (STFV7V6V1 to V12), where subfraction STFV7V6V5 ( 380 mg ) was chromatographed over a Sephadex LH-

20 column ( $100 \times 5 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as elution to give 8 subfractions (STFV7V6V5S1 to S8). Purification of the resulting subfraction STFV7V6V5S2 (60 mg ) using semi-preparative HPLC with $85 \% \mathrm{MeOH}$ afforded $25(8.2 \mathrm{mg})$ and 24 ( 40.5 mg ) and purification of subfraction STFV7V6V5S6 (18 mg) using semipreparative HPLC with $69 \% \mathrm{MeOH}$ yielded 23 ( 1.4 mg ). Meanwhile, subfraction STFV7V6V5S7 (32 mg) was subjected to Sephadex LH-20 column chromatography eluting with $100 \% \mathrm{MeOH}$ to afford $4(3.5 \mathrm{mg})$. The combined subfractions (STFV7V6V5S8 to S11, 42.5 mg ), were further purified by a Sephadex LH-20 column ( $50 \times 3 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as eluent to afford $\mathbf{1 0}(1.2 \mathrm{mg})$. Combination of subfractions STFV7V7 and STFV7V8 (138 mg), followed by chromatography on a Sephadex LH-20 column ( 70 x 4 cm ) using $100 \% \mathrm{MeOH}$, gave 8 ( 8.8 mg ). The VLC fraction STFV8 ( 98 mg ) which was eluted with $40 \% \mathrm{MeOH}$, was fractionated over a Sephadex LH-20 column ( $70 \times 4 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as eluting solvent, leading to 6 subfractions (STFV8S1 to S6). Further purification of the subfraction STFV8S4 using semi-preparative HPLC using 42\% MeOH afforded 15 ( 1.8 mg ). VLC fraction STFV9 (23 mg), which was eluted with $60 \% \mathrm{MeOH}$, was directly subjected to semipreparative HPLC with $53 \% \mathrm{MeOH}$ as eluting solvent to afford 21 ( 1.8 mg ). Finally, fraction STFV10 (128 mg) eluted with $80 \% \mathrm{MeOH}$, was fractionated over a Sephadex LH-20 column ( $70 \times 4 \mathrm{~cm}$ ) using $100 \% \mathrm{MeOH}$ as an eluent, resulting in 6 subfractions (STFV10S1 to S6), where the third subfraction STFV10S3 was further purified by semi-preparative HPLC with $55 \% \mathrm{MeOH}$ to yield 27 ( 1.1 mg ).
3.4.1. 12-Dimethoxypinselin (1). Yellow solid; UV (MeOH) $\lambda_{\max }$ : 203, 237, 265 and $380 \mathrm{~nm} ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 1; HRESIMS $[\mathrm{M}+\mathrm{H}]{ }^{+} \mathrm{m} / \mathrm{z} 361.0915$ (calcd. for $\mathrm{C}_{18} \mathrm{H}_{17} \mathrm{O}_{8}, 361.0923$ ).
3.4.2. 12-O-Acetyl-AGI-B4 (2). Yellow amorphous solid; $[\alpha]_{\mathrm{D}}^{20} 0$ (c 0.16, MeOH); UV $(\mathrm{MeOH}) \lambda_{\text {max }}: 213,269$ and $343 \mathrm{~nm} ; 17 \%$ ee according to chiral HPLC analysis with Chiralpack IA $(4.6 \times 150 \mathrm{~mm}, 5 \mu \mathrm{~m}, 1.0 \mathrm{ml} / \mathrm{min}), 2.97 \mathrm{~min}$ retention time $\left(\mathrm{t}_{\mathrm{R}}\right)$ for the first eluting enantiomer and 4.04 min for the second-eluting one; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 1; HRESIMS $[\mathrm{M}+\mathrm{H}]^{+} m / z 361.0913$ (calcd. for $\mathrm{C}_{18} \mathrm{H}_{17} \mathrm{O}_{8}, 361.0923$ ). 3.4.3. (1R,2R)-AGI-B4 (3). Yellow amorphous solid; $[\alpha]_{\mathrm{D}}^{20}-28.0$ (c 0.40, MeOH); UV $(\mathrm{MeOH}) \lambda_{\text {max }}: 213,272$ and 345 nm ; ECD $\left(\mathrm{MeCN}, \lambda[\mathrm{nm}](\Delta \varepsilon), c=4.91 \times 10^{-5} \mathrm{M}\right)$ : 348 (-2.1), 302 (4.4), 293sh (3.3), 263 (4.6), 237sh (-9.4), 218sh (-11.5), 208sh (-13.9), 202 (-15.5); ESIMS $[\mathrm{M}+\mathrm{H}]^{+} m / z 319$.
3.4.4. 11,12-Dihydroxysydonic acid (15). White amorphous solid; $[\alpha]_{D}^{20}+4.3$ (c 0.23 , $\mathrm{MeOH}) ; \mathrm{UV}(\mathrm{MeOH}) \lambda_{\text {max }}: 220,246$ and $302 \mathrm{~nm} ; \mathrm{ECD}(\mathrm{MeCN}, \lambda[\mathrm{nm}](\Delta \varepsilon), c=$ $\left.5.59 \times 10^{-4} \mathrm{M}\right): 298(0.1), 210(-0.3) ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 2; HRESIMS $[\mathrm{M}+\mathrm{Na}]^{+} \mathrm{m} / \mathrm{z} 321.1307$ (calcd. for $\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{NaO}_{6}, 321.1314$ ).
3.4.5. 1-Hydroxyboivinianic acid (16). White amorphous solid; $[\alpha]_{\mathrm{D}}^{20} 0$ (c 0.07, $\mathrm{MeOH}) ; \mathrm{UV}(\mathrm{MeOH}) \lambda_{\max }: 211,242$ and $299 \mathrm{~nm} ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 2; HRESIMS $[\mathrm{M}+\mathrm{H}]^{+} \mathrm{m} / \mathrm{z} 237.0759$ (calcd for $\mathrm{C}_{12} \mathrm{H}_{13} \mathrm{O}_{5}, 237.0763$ ).
3.4.6. Scopulamide (21). Yellow amorphous solid; $[\alpha]_{\mathrm{D}}^{20}+21.2$ (c $\left.0.25, \mathrm{MeOH}\right)$; UV (MeOH) $\lambda_{\text {max }}: 205,251$ and $299 \mathrm{~nm} ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 3; HRESIMS $[\mathrm{M}+\mathrm{H}]^{+} \mathrm{m} / \mathrm{z} 324.1438$ (calcd. for $\mathrm{C}_{16} \mathrm{H}_{22} \mathrm{NO}_{6}, 324.1447$ ).
3.4.7. Scopupyrone (26). White amorphous powder; $[\alpha]_{D}^{20}-18.5$ (c 0.16, MeOH); UV $(\mathrm{MeOH}) \lambda_{\text {max }}: 205$ and 300 nm ; ECD (MeCN, $\left.\lambda[\mathrm{nm}](\Delta \varepsilon), c=7.37 \times 10^{-4} \mathrm{M}\right): 299$ (-0.3), $233(-0.1), 207(0.2) ;{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR data see Table 3; HRESIMS $[\mathrm{M}+\mathrm{H}]^{+}$ $m / z 227.1277$ (calcd for $\mathrm{C}_{12} \mathrm{H}_{19} \mathrm{O}_{4}, 227.1283$ ).

### 3.5. Computational methods

Mixed torsional/low-mode conformational searches were carried out by means of the Macromodel 9.9.223 software ${ }^{41}$ using the Merck Molecular Force Field (MMFF) with an implicit solvent model for $\mathrm{CHCl}_{3}$ applying a $21 \mathrm{~kJ} / \mathrm{mol}$ energy window. Geometry reoptimizations of the resultant conformers [B3LYP/6-31G(d) level in vacuo and B97D/TZVP ${ }^{23,25}$ with PCM solvent model for MeCN ] and TDDFT calculations were performed with Gaussian $09^{42}$ using various functionals (B3LYP, BH\&HLYP, PBE0) and the TZVP basis set. ECD spectra were generated as the sum of Gaussians ${ }^{43}$ with 2400 and $3000 \mathrm{~cm}^{-1}$ half-height width (corresponding to ca. 16 and 20 nm at 260 nm , respectively), using dipole-velocity-computed rotational strengths. Boltzmann distributions were estimated from the ZPVE-corrected B3LYP/6-31G(d) energies in the gas-phase calculations and from the B97D/TZVP energies in the PCM model ones. The MOLEKEL software ${ }^{44}$ package was used for visualization of the results.

### 3.6. Marfey's reaction

Marfey's reaction was performed to determine the absolute configuration of serine that was present as a substituent in the new compound $\mathbf{2 1}$. To carry out the hydrolysis step, 0.5 mg of 21 was completely dried and dissolved in 1 mL of 6 N HCl , then left in the oven for 24 hours at $110{ }^{\circ} \mathrm{C}$. After cooling and removal of the remaining solvent in the vacuum, $100 \mu \mathrm{~L}$ of Marfey's reagent ( N - $\alpha$-(2,4-dinitro-5-fluorophenyl)-L-alanine amide) ( 0.1 mg in $100 \mu \mathrm{~L}$ acetone) and $20 \mu \mathrm{~L}$ of 1 M $\mathrm{NaHCO}_{3}$ were added to the residue and then incubated for 1 h at $40^{\circ} \mathrm{C}$. After cooling, $10 \mu \mathrm{~L}$ of 2 M HCl was added and mixed to stop the reaction. After freeze-drying overnight, the dried residue was dissolved in 1 mL methanol and then HPLC-MS measurement was conducted along with authentic L- and D-serine (ICN Biomedicals

Inc.) at a concentration of 50 mM each that had been treated in the same way as described above.

### 3.7. Cytotoxicity assay

Cytotoxicity was tested against the L5178Y mouse lymphoma cell line, using a microplate 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay as described previously. ${ }^{45}$ All experiments were carried out in triplicate and repeated thrice. The cytotoxic depsipeptide kahalalide F with $\mathrm{IC}_{50}$ of $4.3 \mu \mathrm{M}$ was used as positive control and medium containing $0.1 \%$ EGMME-DMSO was employed as negative control.

## Acknowledgements

A scholarship granted and financed by the Egyptian government (Ministry of High Education) to M.S.E. is gratefully acknowledged. T.K. and A.M. thank the Hungarian National Research Foundation (OTKA K105871) for financial support and the National Information Infrastructure Development Institute (NIIFI 10038) for CPU time. P.P wishes to thank the Manchot Foundation for support.

## Supplementary data

UV, HRESIMS, 1D and 2D NMR data for the new compounds (1, 2, 15, 16, 21, and 26); ECD calculation for compound 26.
