#### Abstract

We present the results from a search for the light neutral scalar Higgs boson $h^{0}$ and the pseudoscalar Higgs boson $A^{0}$ of the minimal super-symmetric standard model. The analysis is based on a data sample corresponding to 71000 hadronic $Z^{0}$ decays recorded with the L3 detector at LEP. No evidence for the existence of the neutral Higgs bosons $h^{0}$ and $A^{0}$ has been found. The region of $\mathrm{h}^{0}$ and $\mathrm{A}^{0}$ masses up to 41.5 GeV is excluded at $95 \%$ confidence level.

## 1. Introduction

Although the standard model [1] provides a precise description of existing data on electroweak interactions, the Higgs boson, an essential ingredient of the model, has remained undetected. The Higgs sector [2] is crucial to ensure the renormalizability of the theory and to give masses to the gauge bosons ( $\mathrm{Z}^{0}$, $\mathrm{W}^{ \pm}$). In the standard model one doublet of a complex Higgs field gives rise to a single physical Higgs boson, $\mathrm{H}_{\mathrm{SM}}^{0}$.

The standard model has several theoretical difficulties. For example, scalar particles receive divergent corrections to their masses (hierarchy problem). The minimal supersymmetric standard model [3] (MSSM) addresses this and other theoretical

1 Supported by the German Bundesministerium für Forschung und Technologie.
problems in a consistent manner [4]. While the standard model Higgs boson may have a mass as high as one TeV , the lightest MSSM Higgs boson $\mathrm{h}^{0}$ is confined to have a mass lower than the mass of the gauge boson $Z^{0}$ [5].
In this paper, we present a search for the light neutral Higgs bosons of the MSSM. Previous results on this subject can be found in ref. [6].

## 2. The Higgs bosons $\mathbf{h}^{0}, \mathrm{~A}^{0}$

In the MSSM two doublets of complex Higgs fields lead to five physical Higgs bosons [4]: two neutral scalars $\mathrm{h}^{0}, \mathrm{H}^{0}$ ( $C P$ even), one neutral pseudoscalar $\mathrm{A}^{0}$ ( $C P$ odd), and two charged scalars $\mathrm{H}^{+}, \mathrm{H}^{-}$. At current LEP energies only the search for $h^{0}$ and $A^{0}$ is possible due to the following theoretical constraints [5]:
$m_{\mathrm{h}^{0}}<m_{\mathrm{Z}^{0}}, \quad m_{\mathrm{h}^{0}}<m_{\mathrm{A}^{0}}$,
$m_{\mathrm{H}^{0}}>m_{\mathrm{Z}^{0}}, \quad m_{\mathrm{H}^{ \pm}}>m_{\mathrm{W} \pm}$.
The masses and couplings of the Higgs bosons in this model are highly constrained and can be expressed in terms of two free parameters such as ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ) or ( $m_{\mathrm{h}^{0}}, \tan \beta$ ), where $\tan \beta=v_{2} / v_{1}$ is the ratio of the vacuum expectation values of the two Higgs doublets. Therefore, for a given $m_{\mathrm{h}} 0, \tan \beta$ is directly related to $m_{\mathrm{A}^{0}}$. If the vacuum expectation $v_{2}$ becomes much larger than $\nu_{1}$ (i.e. $\tan \beta \gg 1$ ) then $m_{A^{0}}$ decreases to be close to $m_{h^{0}}$. On the other hand, when the vacuum expectation values are nearly equal (i.e. $\tan \beta \rightarrow 1$ ) then $m_{A 0}$ becomes large and the $h^{0}$ becomes essentially the Higgs boson from the standard model $\mathrm{H}_{\mathrm{SM}}^{0}$. In this analysis we restrict ourselves to the theoretically favoured case [7] $\tan \beta>1$, where the constraint comes from recent limits on the mass of the top quark $[8,9]$.

The lightest Higgs boson $h^{0}$ can be produced either through the Bjorken process [10]:
$\mathrm{Z}^{0} \rightarrow \mathrm{~h}^{0} \mathrm{Z}^{0 \star}$,
or in association with $\mathrm{A}^{0}$ :
$\mathrm{Z}^{0} \rightarrow \mathrm{~h}^{0} \mathrm{~A}^{0}$.
The $\mathrm{h}^{0} \mathrm{ZZ}$ coupling is proportional to $\sin (\alpha-\beta)$, where $\alpha$ is the mixing angle between the two neutral scalars, so that the partial width for process (1) becomes large as the production rate of process (2) decreases with decreasing $\cos ^{2}(\alpha-\beta)$,
$\sin ^{2}(\alpha-\beta)=\frac{\Gamma\left(\mathrm{Z}^{0} \rightarrow \mathrm{~h}^{0} \mathrm{Z}^{0 \star}\right)}{\gamma\left(\mathrm{Z}^{0} \rightarrow \mathrm{H}_{\mathrm{SM}}^{0} \mathrm{Z}^{0 \star}\right)}$,
and thus limits on the mass of the standard model Higgs can be translated into restrictions on the masses of $\mathrm{h}^{0}$ and $\mathrm{A}^{0}$. Since there is no $\mathrm{A}^{0} \mathrm{ZZ}$ coupling ( $\mathrm{A}^{0} C P$ odd), at the tree level the $A^{0}$ can only be produced in association with $h^{0}$. The partial width for process (2) is proportional [11] to $\cos ^{2}(\alpha-\beta)$ where
$\cos ^{2}(\alpha-\beta)=\frac{m_{\mathrm{h}^{0}}^{2}\left(m_{\mathrm{Z}^{0}}^{2}-m_{\mathrm{h}^{0}}^{2}\right)}{m_{\mathrm{A}^{0}}^{2}\left(m_{\mathrm{Z}^{0}}^{2}+m_{\mathrm{A}^{0}}^{2}-2 m_{\mathrm{h}^{0}}^{2}\right)}$.
The production rate becomes maximal when $m_{A^{0}} \approx$ $m_{\mathrm{h} 0}(\tan \beta$ large $)$.

The Higgs boson decays predominantly into the most massive kinematically accessible particle pair.

In the MSSM one Higgs doublet couples to the uptype fermions only while the other couples to downtype fermions. In the case where $\tan \beta>1$ the decay to up-type fermions is suppressed [11]. The branching ratios within the MSSM $[12,13]$ are used for calculating the branching ratios of the Higgs bosons $h^{0}$ and $A^{0}$. In this paper we present the search for reaction (2) by considering the 3 dominant decay channels from the pair production of the Higgs bosons $h^{0}$ and $\mathrm{A}^{0}$ :
$\mathrm{h}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}}, \quad \mathrm{~A}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}}$,
$\mathrm{h}^{0} \rightarrow \tau \bar{\tau}, \quad \mathrm{~A}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}}$,
$\mathrm{h}^{0} \rightarrow \tau \bar{\tau}, \quad \mathrm{~A}^{0} \rightarrow \tau \bar{\tau}$.
The signatures and the search strategies for these three processes are quite different from each other and are described in the subsequent sections. We also give a limit on the process (1) by translating our standard model Higgs limits [ 14,15 ] to the MSSM.

## 3. The L3 detector

The L 3 detector covers $99 \%$ of $4 \pi$ [16]. The detector includes a central vertex chamber, a precise electromagnetic calorimeter composed of bismuth germanium oxide crystals, a uranium and brass hadron calorimeter with proportional wire chamber readout, a high accuracy muon chamber system, and a ring of scintillation trigger counters. These detectors are installed in a magnet with an inner diameter of 12 m . The magnet provides a uniform field of 0.5 T along the beam direction. The luminosity is measured with two small angle electromagnetic calorimeters.

The fine segmentation of the electromagnetic detector and the hadron calorimeter allows us to measure the axis of jets with an angular resolution of $2.5^{\circ}$, and to measure the total energy of hadronic events from $Z^{0}$ decay with a resolution of $10 \%$ [17].

Events are collected at center of mass energies $\sqrt{s}=88.2-94.2 \mathrm{GeV}$ from the 1990 LEP running period. For the search in the dimuon data sample, we use the data from March to August corresponding to 71000 hadronic events, which leads to the upper mass limit. The other analysis results are based on data collected from March to July, which corresponds to 55000 hadronic events. The simulated distributions
in the cut quantities and in event shape variables agree very closely with the corresponding measured distributions [18].

## 4. Search for $\mathbf{h}^{\mathbf{0}} \mathbf{A}^{\mathbf{0}} \rightarrow \mathbf{b} \mathbf{b} \mathbf{b} \overline{\mathbf{b}}$

The signature of the decay channel where both Higgs bosons decay to $b \bar{b}$ quarks is a hadronic 4 -jet event.

The primary trigger for hadronic events requires a total energy of 15 GeV in the central region of the calorimeters (polar angle region $|\cos \theta|<0.74$ ), or 20 GeV in the entire detector. This trigger is in a logical OR with a trigger using the barrel scintillation counters and with a charged track trigger. The total trigger efficiency for accepted events of types $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{q} \overline{\mathrm{q}}$ and $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{h}^{0} \mathrm{~A}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}} \mathrm{~b} \overline{\mathrm{~b}}$ exceeds $99 \%$.

Hadronic events were generated by the parton shower program JETSET 7.2 [19] with $\Lambda_{\mathrm{LL}}=290$ MeV and with string fragmentation. To simulate the gluon radiation and fragmentation of the $b$ quarks from the Higgs decays, the same program has been used. The generated events were passed through the L3 detector simulation [20] which includes the effects of energy loss, multiple scattering, interactions and decays in the detector materials and beam pipe.

The event selection is based on the energy measured in the electromagnetic and hadron calorimeters:
(1) $0.6<\frac{E_{\mathrm{vis}}}{\sqrt{s}}<1.4$,
(2) $\frac{\left|E_{\|}\right|}{E_{\text {vis }}}<0.40, \frac{E_{\perp}}{E_{\text {vis }}}<0.40$
(3) $N_{\text {cluster }} \geqslant 12$,
where $E_{\text {vis }}$ is the total energy observed in the detector, $E_{\|}$is the energy imbalance along the beam direction, and $E_{\perp}$ is the transverse energy imbalance. Neighbouring calorimetric hits which are most likely to be produced by the same particle are grouped into clusters. Thus the cut on the number of clusters rejects low multiplicity events $\left(\mathrm{Z}^{0} \rightarrow \mathrm{e}^{+} \mathrm{e}^{-}, \mu^{+} \mu^{-}\right.$, $\tau^{+} \tau^{-}$). Cuts (1)-(3) select $99 \%$ of $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow \mathrm{h}^{0} \mathrm{~A}^{0} \rightarrow$ $\mathrm{b} \overline{\mathrm{b}} \mathrm{b} \overline{\mathrm{b}}$ events.

Jets are reconstructed out of clusters in the calorimeters by using an invariant mass jet algorithm
[21]. First the energy of each cluster is scaled by $\sqrt{s} / E_{\text {vis }}$. For each pair of clusters $i$ and $j$ the scaled invariant mass squared
$y_{i j}=2 E_{i} E_{j} / s \cdot\left(1-\cos \theta_{i j}\right)$
is then evaluated. $E_{i}$ and $E_{j}$ are the cluster energies and $\theta_{i j}$ is the angle between clusters $i$ and $j$. The cluster pair for which $y_{i j}$ is smallest is replaced by a pseudocluster $k$. This procedure is repeated until all scaled invariant masses squared, $y_{i j}$, exceeds the jet resolution parameter $y_{\mathrm{cu}}$. The remaining pseudoclusters are called jets. Using this recombination scheme there is close agreement between jet rates at the parton level, the rates after hadronization, and the rates after reconstruction in the L3 detector [ 9,22 ]. We require that exactly four jets remain after this procedure for a jet resolution parameter $y_{\text {cut }}=0.06$. We find a 4 -jet rate of $0.57 \%$ in the data and a 4 -jet rate of $0.42 \%$ in the simulation of $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow$ hadrons, where the difference reflects the limited precision of the parton shower Monte Carlo and the uncertainty in the fragmentation.

The Monte Carlo simulations have been performed at $21 \mathrm{~h}^{0}, \mathrm{~A}^{0}$ mass combinations within the range of $22 \mathrm{GeV} \leqslant m_{\mathrm{h}^{0}} \leqslant m_{\mathrm{A}^{0}} \leqslant 42 \mathrm{GeV}$. We choose the jet-jet combination with the minimal $\Delta m^{2}=\left(m_{1}-m_{\mathrm{h}^{0}}\right)^{2}+\left(m_{2}-m_{\mathrm{A}^{0}}\right)^{2}$, where $m_{1}$ and $m_{2}$ ( $m_{1}<m_{2}$ ) are the reconstructed invariant masses, out of the three possible combinations. We then reconstruct the kinematics of the Higgs bosons candidates. The remainder of the cuts are
(4) $N_{\mathrm{jet}}=4$ for jet resolution parameter $y_{\mathrm{cut}}=0.06$,
(5) $\cos \Theta_{\text {production }}<0.4$,
(6) $\Delta m^{2}<22 \mathrm{GeV}^{2}$,
(7) $\left|\Theta_{\text {meas.opening }}-\Theta_{\text {exp.opening }}\left(m_{\mathbf{h}^{0}}, m_{\mathrm{A}^{0}}\right)\right| \leqslant 20^{\circ}$,
(8) $\cos \Theta_{\text {decay }}<0.6$,
where $\Theta_{\text {production }}$ is the production angle, $\Theta_{\text {opening }}$ is the opening angle between jets belonging to the two Higgs candidates, and $\Theta_{\text {decay }}$ is the angle between the reconstructed Higgs direction and the jet directions in the restframe of the Higgs. The cut imposed on the production angles $\Theta_{\text {production }}$ of both Higgs bosons is
shown in fig. 1. Since the event kinematics depend on the mass pair ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ), the cut on the opening angles must also depend on ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ). The acceptance for cuts (4)-(8) as a function of $m_{h^{0}}$ and $m_{\mathrm{A}^{0}}$ is estimated by performing Monte Carlo simulations.
Fig. 2 shows the invariant mass distributions in the ( $m_{1}, m_{2}$ ) plane for (a) data, and for (b) simulated $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow$ hadrons along with the Higgs signal for $m_{\mathrm{h}^{0}}=m_{\mathrm{A}^{0}}=32 \mathrm{GeV}$ after cuts (1)-(5). We see the dominance of the simulated Higgs signal in the plot of the three possible jet-jet combinations.

The expected signal and the data are compared in the matrix of points in the ( $m_{1}, m_{2}$ ) plane. To set a conservative limit we have reduced the number of expected events by $11 \%$ which accounts for system-

Fig. 1. Cosines of the reconstructed production angles of both Higgs candidates in the $h^{0} A^{0} \rightarrow b \overline{b b}$ search. The jet-jet combination with smallest $\Delta m$ is chosen. The simulated mass pair is $m_{\mathrm{h}^{0}}=m_{\mathrm{A}^{0}}=32 \mathrm{GeV}$. Cuts (1)-(4) are applied. The $\mathrm{q} \bar{q}$ simulation is normalized to the number of data entries, whereas the signal simulation is normalized with respect to the expected cross section and branching ratio. Each event contributes twice.
atic errors from the uncertainty in Monte Carlo statistics, event selection and production cross section. The ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ) region A excluded at $\geqslant 95 \%$ confidence level is shown in fig. 3.
An independent search in the $\mathrm{b} \overline{\mathrm{b}} \mathrm{b} \overline{\mathrm{b}}$ channel has been performed using hadron events with two muons. Triggers for inclusive dimuon events are described elsewhere [23]. They have a combined efficiency of greater than $99 \%$. To search for $h^{0} A^{0} \rightarrow b \bar{b} b \bar{b}$ decays in the inclusive dimuon data sample we employ the following selection criteria:
(1) The event is required to have two muon candidates, each of which must satisfy:
(a) $d_{\perp}<3 \sigma_{d_{\perp}}$ and $d_{\|}<4 \sigma_{d_{1}}$,
(b) $E_{\mu}>4 \mathrm{GeV}$,
(2) $N_{\text {clusters }}>50$,
(3) $\cos \Theta_{\text {thrust }}<0.65$,
(4) $E_{\mathrm{jet} 1}<35 \mathrm{GeV}$ and $E_{\mathrm{jet} 2}<26 \mathrm{GeV}$,
where $d_{\perp}\left(d_{\|}\right)$is the distance of closest approach to the vertex in the transverse (longitudinal) plane, $\sigma_{d_{\perp}}\left(\sigma_{d_{1}}\right)$ is the respective measurement error and $E_{\mu}$ is the measured energy of the muon. $E_{\mathrm{jet} 1}$ and $E_{\mathrm{jet} 2}$ are the energies of the two most energetic jets.

From Monte Carlo studies, we find that the acceptance of the $\mathrm{h}^{0} \mathrm{~A}^{0}$ production after these cuts is $1.25 \%$ at $m_{\mathrm{h}^{0}}=m_{\mathrm{A}^{0}}=40 \mathrm{GeV}$ and it slowly decreases as one moves away from this point in the ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ) mass plane. We expect 4.7 events from the signal and 1.4 events from $\mathrm{e}^{+} \mathrm{e}^{-} \rightarrow$ hadrons. No events survive the cuts in the entire mass region. The dominant error is due to Monte Carlo statistics. The total error in the region of high masses is estimated to be $19 \%$. In fig. 3 the mass region B in the ( $m_{\mathrm{h} 0}, m_{\mathrm{A}^{0}}$ ) plane is excluded by this part of the analysis at the $95 \%$ confidence level.

## 5. Search for $\mathbf{h}^{0} \mathbf{A}^{0} \rightarrow \tau \bar{\tau} \mathrm{~b} \overline{\mathrm{~b}}$

The decay channel of $h^{0} \rightarrow \tau \bar{\tau}$ and $\mathrm{A}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}}$ gives two taus in association with shower activities in the electromagnetic and hadron calorimeters. The search region for this process is

$$
4 \mathrm{GeV}<m_{\mathrm{h}^{0}}<30 \mathrm{GeV}, \quad m_{\mathrm{A}^{0}}>10 \mathrm{GeV}
$$

Fig. 2. $m_{1}$ (lower invariant mass) versus $m_{2}$ (higher invariant mass) for all three invariant mass combinations in the $h^{0} \mathrm{~A}^{0} \rightarrow b \bar{b} b \overline{\mathrm{~b}}$ search. The plots (normalized as in fig. 1) show (a) data and (b) simulated signal ( $m_{\mathrm{h}^{0}}=m_{\mathrm{A}^{0}}=32 \mathrm{GeV}$ ) plus background. Cuts (1)-(5) are applied.

The lower limits are due to the decay thresholds of $h^{0}, A^{0}$ to $\tau \bar{\tau}$ and $b \bar{b}$, respectively. The trigger efficiency for accepted events of this type exceeds $99 \%$. We apply the following cuts:
(1) $40 \mathrm{GeV}<E_{\text {vis }}<80 \mathrm{GeV}$,
(2) $\frac{\left|E_{\|}\right|}{E_{\text {vis }}}<0.50, \frac{E_{\perp}}{E_{\text {vis }}}<0.50$,
(3) $N_{\text {cluster }} \geqslant 12$.

Cut (1) takes into account the fact that in tau decays more energy escapes undetected compared to hadronic events. The acceptance for the generated $\tau \bar{\tau} \mathrm{b} \overline{\mathrm{b}}$ events after these cuts is about $85 \%$.
Candidate $\tau \bar{\tau} \mathrm{b} \overline{\mathrm{b}}$ events are identified by dividing events into two hemispheres using the thrust axis as a normal vector and counting the number of clusters in each hemisphere. The hemisphere with the lower number of clusters should contain the $\tau \bar{\tau}$ candidates and is required to have less than eight clusters. The clusters are combined into jets using the algorithm already described but with a $y_{\text {cut }}$ value of 0.001 which allows separation of tau pairs down to a mass of 2.9 GeV . We select events in the central region to enhance the signal which has a $\sin ^{2} \Theta$ distribution (fig.
4). the summary of the remaining cuts is:
(4) $N_{\text {cluster }}<8$ in the tau hemisphere ,
(5) exactly two jets with $y_{\mathrm{cut}}=0.001$
in the tau hemisphere ,
(6) $\cos \Theta_{\text {thrust }}<0.7$,
(7) $0.64<\cos \Theta_{\tau \tau}<0.98$ for $4<m_{\mathrm{h} 0}<12 \mathrm{GeV}$,
$0.4<\cos \Theta_{\tau \tau}<0.88$ for $12<m_{\mathrm{h} 0}<22 \mathrm{GeV}$,
$0.1<\cos \Theta_{\tau \tau}<0.6$ for $22<m_{\mathrm{h}^{0}}<30 \mathrm{GeV}$,
(8) $0.95<$ Thrust $<0.99$ for $4<m_{h^{0}}<12 \mathrm{GeV}$,
$0.91<$ Thrust $<0.96$ for $12<m_{h^{0}}<22 \mathrm{GeV}$,
$0.84<$ Thrust $<0.92$ for $22<m_{\mathrm{h} 0}<30 \mathrm{GeV}$,
(9) exactly one charged track reconstructed in the central vertex chamber in the direction of each reconstructed tau,
where $\Theta_{\tau \tau}$ is the angle between the reconstructed taus. The overall acceptance for cuts 1 to 9 varies in the range of $6 \%$ to $11 \%$ depending on the Higgs masses. Background contributions are estimated by

Fig. 3. Exclusion plot for the Higgs masses in the MSSM searches in the mass parameter space ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ) at $95 \% \mathrm{CL}$. The MSSM constrains the search area to $m_{A^{0}}>m_{h^{0}}$. Region A is the excluded area from the $h^{0} \mathrm{~A}^{0} \rightarrow \mathrm{~b} \overline{\mathrm{~b}} \mathrm{~b} \overline{\mathrm{~b}}$ search in the hadronic data sample. Region $B$ is excluded from the $h^{0} A^{0} \rightarrow b \bar{b} b \bar{b}$ search in the dimuon data. Region $C$ is excluded from the $h^{0} \mathrm{~A}^{0} \rightarrow \tau \bar{\tau} \mathrm{~b} \overline{\mathrm{~b}}$ search. Region $D$ is the excluded area from the $\mathrm{h}^{0} \mathrm{~A}^{0} \rightarrow \tau \bar{\tau} \tau \bar{\tau}$ search. Region $E$ is excluded from the inferred limit from the standard model Higgs search. For all decay channels, we assume $\tan \beta>1$.
simulating $68 \mathrm{~K} \mathrm{e}^{+} \mathrm{e}^{-} \rightarrow$ hadrons events, and by using the KORALZ generator [24] for simulating $5 \mathrm{~K} \tau \bar{\tau}$ events. None of these MC events and none of the data events pass all cuts. A combined statistical and systematic error of $14 \%$ has been calculated. The corresponding excluded mass region is shown as area C in fig. 3.

## 6. Search for $\mathbf{h}^{\mathbf{0}} \mathbf{A}^{\mathbf{0}} \rightarrow \tau \bar{\tau} \tau \bar{\tau}$

The signatures of four taus are low visible energy, a 4-jet topology with low cluster multiplicity, and events preferentially perpendicular to the beam axis due to the $\sin ^{2} \Theta$ distribution of the production angle. For this analysis we restrict the ( $m_{\mathrm{h}^{0}}, m_{\mathrm{A}^{0}}$ ) parameter space to the area of a large branching ratio for the production of four taus in the final state. The $m_{\mathrm{h} 0}$ range begins at the $\tau \bar{\tau}$ threshold at about 4 GeV and ends at about 11 GeV where the $\mathrm{b} \overline{\mathrm{b}}$ decays channel

Fig. 4. $\cos \Theta_{\text {thrust }}$ for data, $q \bar{q}$ simulation and signal simulation in the $\mathrm{h}^{0} \mathrm{~A}^{0} \rightarrow \tau \overline{\mathrm{\tau}} \mathrm{~b} \overline{\mathrm{~b}}$ search. The peak in the data and in the $\mathrm{q} \overline{\mathrm{q}}$ simulation is due to the $E_{\text {vis }}<80 \mathrm{GeV}$ cut, which enhances the rate of events losing energy along the beam direction. Less than eight clusters in the tau hemisphere leading to exactly two jets is required.
starts to dominate. The trigger efficiency for accepted events of this type exceeds $99 \%$. The following cuts are applied:
(1) $40 \mathrm{GeV}<E_{\text {vis }}<60 \mathrm{GeV}$,
(2) $\frac{\left|E_{\|}\right|}{E_{\text {vis }}}<0.50, \frac{E_{\perp}}{E_{\text {vis }}}<0.50$,
(3) $12 \leqslant N_{\text {clusters }} \leqslant 22$,
(4) $N_{\mathrm{jel}}=4$ for jet resolution parameter
$\mathrm{y}_{\mathrm{cut}}=0.001$,
(5) $E_{\mathrm{jet}}>2 \mathrm{GeV}$,
(6) $\cos \Theta_{\text {thrust }}<0.3$,

In the region $4 \mathrm{GeV} \leqslant m_{\mathrm{h}^{0}} \leqslant m_{\mathrm{A}^{0}} \leqslant 11 \mathrm{GeV}$ the ex-
pected signal after all cuts is typically more than twelve events. One data event survives the cuts. This is in agreement with the expected number of background events from $Z^{0} \rightarrow$ hadrons and $Z^{0} \rightarrow \tau \bar{\tau}$ leading to the exclusion contour $D$ as shown in fig. 3, after taking into account statistical and systematic errors of $12 \%$.

## 7. Limits from the standard model Higgs search

The expected numbers of standard model Higgs events which would have been detected by L3 has been reported elsewhere [14,15]. Setting $m_{h^{0}}=$ $m_{\mathrm{H}_{\mathrm{SM}}^{0}}$ in eqs. (3) and (4), we can calculate a corresponding lower limit on $m_{A^{0}}$ at the $95 \%$ confidence level, if corrections for the somewhat different MSSM Higgs decay branching ratios are made. For Higgs masses larger than 11 GeV the $b \overline{\mathrm{~b}}$ decay channel dominates which results in the same detection efficiency for the standard model Higgs search [14] and the MSSM Higgs search.

Below 11 GeV the $\tau \bar{\tau}$ decay channel starts to dominate. In our standard model Higgs search, the acceptance is $5 \%$ for $h^{0} \rightarrow \tau \bar{\tau}$ and $36 \%$ for $h^{0} \rightarrow$ hadrons in the channel $\mathrm{Z}^{0} \rightarrow \mathrm{H}_{\mathrm{SM}}^{0} \nu \bar{v}$, which leads to a lower detection efficiency for the MSSM compared to the standard model. We use the different acceptances of the modified branching ratios of $\mathrm{h}^{0}$ to calculate the number of expected events in the MSSM. The corresponding limit on $m_{A^{\circ}}$ has been calculated by taking the one Higgs candidate [14] from the standard model search into account.

For Higgs masses in the range $2 m_{\mu}<m_{\mathrm{h} 0}<2 \mathrm{GeV}$ we can directly translate the number of expected events from the standard model search into a lower limit on $m_{\mathrm{A}^{0}}$. For masses below $2 m_{\mu}$ the limit on $m_{\mathrm{A}^{0}}$ is computed taking into account the variation of the partial width of the $h^{0}$ into electrons and photons. Fig. 3 shows the corresponding excluded area E.

## 8. Conclusions

We have searched for the pair production of the scalar Higgs boson $h^{0}$ and the pseudoscalar Higgs boson $A^{0}$. Three decay channels of the $h^{0} \mathrm{~A}^{0}$ bosons have been studied. The limit inferred from the standard
model Higgs search has been combined with the limit from the direct search for the pair produced Higgs bosons. No evidence for the existence of the MSSM Higgs has been found. Nearly the entire mass region up to 41.5 GeV is excluded.

## Acknowledgement

We wish to thank CERN for its hospitality and help. We want particularly to express our gratitude to the LEP division: it is their excellent achievements which made this experiment possible. We acknowledge the effort of all engineers and technicians who have participated in the construction and maintenance of this experiment. We acknowledge the support of all the funding agencies which contributed to this experiment.
