# ON ROOTED DIRECTED PATH GRAPHS

### MARISA GUTIERREZ<sup>1,2</sup> AND SILVIA B TONDATO<sup>1</sup>

ABSTRACT. An asteroidal triple is a stable set of three vertices such that each pair is connected by a path avoiding the neighborhood of the third vertex. Asteroidal triples play a central role in a classical characterization of interval graphs, which are the intersection graphs of a family of intervals on the real line, by Lekkerkerker and Boland and in a characterization of directed path graphs, which are the intersection graphs of directed paths in a directed tree, by Cameron, Hoáng and Lévêque. For this characterization, they introduce the notion of a special connection. Two non-adjacent vertices are linked by a special connection if either they have a common neighbor or they are the endpoints of two vertex-disjoint chordless paths satisfying certain technical conditions. They proved that if a pair of non adjacent vertices are linked by a special connection then in any directed path model T, the subpaths of T corresponding to the vertices forming the special connection have to overlap and they force T to be completely directed in one direction between these vertices.

On the other hand, special connections along with the concept of asteroidal quadruple play an important role to study rooted directed path graphs.

An asteroidal quadruple is a stable set of four vertices such that any three of them is an asteroidal triple.

A rooted directed path graph is the intersection graphs of directed paths in a rooted directed tree. It is easy to see that a rooted directed path graph contains no asteroidal quadruples linked by special connections [1].

A strong asteroidal is a stable set of n vertices  $\{a_1, ..., a_n\}$   $(n \ge 2)$  of G, such that  $G \setminus N[a_i]$  is a connected graph for i = 1, ..., n. Minimal forbidden induced subgraphs for interval graphs, for directed path graphs and for path graphs(that are the intersection graphs of subpaths in a tree) have a strong asteroidal.

In this work, we define other special connections, these special connections along with the defined by Cameron, Hoáng and Lévêque are nine in total, and we prove that every one force T to be completely directed in one direction between these vertices. Therefore, if  $a_1, a_2, a_3$  is a strong asteroidal and there is a special connection between  $a_1$  and  $a_2$  then none directed path model can be rooted on a maximal clique that contains  $a_3$ . Moreover, we prove that the converse is true in case of leafage three, i.e the model can not be rooted on a maximal clique that contains  $a_3$  then one of the nine special connection is linked  $a_1$  and  $a_2$ . As byproduct of our result, we build new forbidden induced subgraphs for rooted directed path graphs.

### 1. INTRODUCTION

A graph is *chordal* if it contains no cycle of length at least four as an induced subgraph. A classical result [4] states that a graph is chordal if and only if it is the (vertex) intersection graph of a family of subtrees of a tree.

Natural subclass of chordal graphs are path graphs, directed path graphs, rooted directed path graphs and interval graphs. A graph is a *path graph* if it is the intersection graph of a family of subpaths of a tree. A graph is a *directed path* 

graph if it is the intersection graph of a family of directed subpaths of a directed tree. A graph is a rooted path graph if it is the intersection graph of a family of directed subpaths of a rooted tree. A graph is an *interval graph* if it is the intersection graph of a family of subpaths of a path.

By definition we have the following inclusions between the different considered classes (and these inclusions are strict): interval  $\subset$  rooted directed path  $\subset$  directed path  $\subset$  path  $\subset$  chordal.

Lekkerkerler and Boland [5] proved that a chordal graph is an interval graph if and only if it contains no asteroidal triple. As byproduct, they found a characterization of interval graphs by forbidden induced subgraphs.

Panda [8] found a characterization of directed path graph by forbidden induced subgraphs, and then Cameron, Hoáng and Lévêque [2] gave a characterization of directed path graph in terms of forbidden asteroids. For this purpose, they introduce the concept of a special connection. Two non adjacent vertices are linked by a special connection if they have a common neighbor or they are the endpoints of two vertex-disjoint paths of length three satisfying certain technical conditions. Special connections are interesting when considering directed path graphs because if a and b, two non adjacent vertices of a directed path graph, are linked by a special connection, then in every directed path model, the subpaths of T corresponding to the vertices forming the special connection have to overlap and they force T to be completely directed in one direction between a and b.

Clearly, rooted directed path graphs contain no asteroidal quadruples linked by special connections. The converse was conjectured by Cameron, Hoáng and Lévêque but in this original form, the conjecture is incomplete since they could not describe all the connections between two non adjacent vertices that force to any tree to be completely directed in one direction between these vertices.

In this article, we define some special connections, which along with the defines in [1] are nine in total, and we prove that every one force T to be completely directed in one direction between these vertices. Therefore, if  $a_1, a_2, a_3$  is a strong asteroidal and there is a special connection between  $a_1$  and  $a_2$  then none directed path model can be rooted on a maximal clique that contains  $a_3$ . Furthermore, we prove that the converse is true in case of leafage three, i.e the model can not be rooted on a maximal clique that contains  $a_3$  then one of the nine special connection is linked  $a_1$  and  $a_2$ . As byproduct of our result, we build new forbidden induced subgraphs for rooted directed path graphs.

The paper is organized as follows: in Section 2, we give some definitions and background. In Section 3, we define special connections and prove that if a pair of non adjacent vertices are linked by a special connection then in any directed path model T, the subpaths of T corresponding to the vertices forming the special connection have to overlap and they force T to be completely directed in one direction between these vertices. In section 4, we give some properties about model that can not be rooted on bold maximal clique. Finally, in Section 5, we proved that G is a directed path graph with leafage three, and it has a strong asteroidal triple  $a_1, a_2, a_3$  such that there is a special connection between  $a_1$  and  $a_2$  if and only if none directed path model can be rooted on the maximal clique that contains  $a_3$ .

#### 2. Definitions and background

If G is a graph and  $V' \subseteq V(G)$ , then  $G \setminus V'$  denotes the subgraph of G induced by  $V(G) \setminus V'$ . If  $E' \subseteq E(G)$ , then G - E' denotes the subgraph of G induced by  $E(G) \setminus E'$ . If G, G' are two graphs, then G + G' denotes the graph whose vertices are  $V(G) \cup V(G')$  and edges are  $E(G) \cup E(G')$ . Note that if T, T' are two trees such that  $|V(T) \cap V(T')| = 0$ , then T + T' is a forest.

A clique in a graph G is a set of pairwise adjacent vertices. Let C(G) be the set of all maximal cliques of G.

The neighborhood of a vertex x is the set N(x) of vertices adjacent to x and the closed neighborhood of x is the set  $N[x] = \{x\} \cup N(x)$ . A vertex is simplicial if its closed neighborhood is a maximal clique. Two adjacent vertices x and y are twins if N[x] = N[y].

A strong asteroidal of a graph G is a stable set  $\{a_1, ..., a_n\}$   $(n \ge 2)$  of vertices of G such that  $G \setminus N[a_i]$  is a connected graph for i = 1, ..., n.

A clique tree T of a graph G is a tree whose vertices are the elements of C(G)and such that for each vertex x of G, those elements of C(G) that contain x induce a subtree of T, which we will denote by  $T_x$ . Note that G is the intersection graph of the subtrees  $(T_x)_{x \in V(G)}$ . In this paper, whenever we talk about the intersection of subgraphs of a graph we mean that the vertex sets of the subgraphs intersect.

Given two non adjacent vertices a, b of G, and a clique tree T of G, it is defined T(a, b) to be the subtree of T of minimum size that contains at least a vertex of  $T_a$  and  $T_b$ .

Gavril [4] proved that a graph is chordal if and only if it has a clique tree. Clique trees are called *models* of the graph.

Observe that if G has a strong asteroidal  $a_1, ..., a_n$  then every clique tree has  $N[a_i]$  as a leaf for i = 1, ..., n. So  $a_i$  is a simplicial vertex of G for i = 1, ..., n.

In [7], Monma and Wei introduced the notation UV, DV and RDV to refer to the classes of path graphs, directed path graphs and rooted directed path graphs respectively. They also proved the following clique tree characterizations for these classes. A graph is a *path graph* or a UV graph if it admits a UV-model, i.e. a clique tree T such that  $T_x$  is a subpath of T for every  $x \in V(G)$ . A graph is a directed path graph or a DV graph if it admits a DV-model, i.e. a clique tree T whose edges can be directed such that  $T_x$  is a directed subpath of T for every  $x \in V(G)$ . A graph is a rooted path graph or an RDV graph, if it admits an RDV-model, i.e. a clique tree T that can be rooted and whose edges are directed from the root toward the leaves such that  $T_x$  is a directed subpath of T for every  $x \in V(G)$ .

It has been proved in [3] that if G is a DV-graph, then any UV-model of G can be directed to obtain a DV-model of G. We say that a DV-model T of a DV graph G can be *rooted* if T can be rooted on a vertex such that it becomes an RDV-model of G.

Let T be a clique tree. We often use capital letters to denotes the vertices of a clique tree as this vertices correspond to maximal cliques of G. In order to simplify the notation, we often write  $X \in T$  instead of  $X \in V(T)$ , and  $e \in T$  instead of  $e \in E(T)$ . If T' is a subtree of T, then  $G_{T'}$  denotes the subgraph of G that is induced by the vertices of  $\bigcup_{X \in V(T')} X$ .

Let T be a tree. For  $V' \subseteq V(T)$ , let T[V'] be the minimal subtree of T containing V'. Then for  $X, Y \in V(T)$ , T[X, Y] is the subpath of T between X and Y. Let  $T[X, Y] = T[X, Y] \setminus Y$ ,  $T(X, Y] = T[X, Y] \setminus X$  and  $T(X, Y) = T[X, Y] \setminus \{X, Y\}$ .

Note that some of these paths may be empty or reduced to a single vertex when X and Y are equal or adjacent. If  $X \in V(T)$  and  $e \in E(T)$  with e = AB and  $A \in T[X, B]$ , then let T[X, e] = T[X, B], T[X, e] = T[X, A], T(X, e] = T(X, B] and T(X, e) = T(X, A]. Given a vertex  $X \in V(T(Y, Z))$ , we say that there is a vertex crossing X in T[Y, Z] if  $X' \cap X'' \neq \emptyset$  where X' and X'' are the two neighbors of X in T[Y, Z].

Let T be a tree, we denote by ln(T) the number of leaves of T. The *leafage* of a chordal graph G is a minimum integer  $\ell$  such that G admits a model T with  $ln(T) = \ell$ . Note that if G has a strong asteroidal  $a_1, ..., a_n$  then  $l(G) \ge n$ .

In a clique tree T, the *label* of an edge AB of T is defined as  $lab(AB) = A \cap B$ . We will say that e, e' in the same clique tree T are *twin edges* if lab(e) = lab(e')

Let T be a DV-model of G, let Q be a vertex of T, and let e be an edge of T. Let  $T_1$  and  $T_2$  be the two connected components of T - e where Q is in  $T_1$ . We say that vertices in lab(e) have the same end with respect to Q if there exists a vertex Q' in  $T_1$ , possibly Q' = Q, such that for each  $x \in lab(e)$ , one endpoint of  $T_x$  is Q'

We say that  $X \in V(T)$  dominates  $e \in E(T)$  if  $lab(e) \subseteq X$ . On the other hand, an edge e satisfying a given property P is maximally farthest from a vertex C if there is no edge e', different from e, satisfying this property and such that e is between C and e'.

#### 3. Special connections

Let a and b be two non adjacent vertices of a graph G. We will define nine type of connection between these vertices. Observe that Type 1, 2 and 3 were already defined in [2]

- Type 1: there exists a path P = a, x, b in G.
- Type 2: there exist two paths  $P = a, y_1, y_2, b$  and  $Q = a, x_1, x_2, b$  in G such that  $\{x_1, y_1, y_2\}$  and  $\{x_1, x_2, y_2\}$  are cliques of G.
- **Type 3:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and two vertices  $s_1, s_2$  in G such that  $\{x_1, x_2, y_1, y_2\}$   $\{x_1, y_1, y_2, s_1\}$  and  $\{x_1, x_2, y_2, s_2\}$  are cliques of G. In this case it is said that  $\{x_1, x_2, y_1, y_2, s_1, s_2\}$  induces an antenna.

In the follows we define new special connections.

- **Type 4:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $t, u, z_i$  for  $i \in \{1, ..., o\}$  such that  $\{x_1, x_2, y_1, y_2, z_o\}$ ,  $\{x_1, y_1, z_i, z_{i+1}\}_{i=1,...,o-1}$ ,  $\{y_1, z_1, u\}$  and  $\{x_1, x_2, y_1, t\}$  are cliques of G. Figure 1.
- **Type 5:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $s_1, s, t, t_i$  for  $i \in \{1, ..., p\}$ ,  $u, z_i$  for  $i \in \{1, ..., o\}$  such that  $\{x_1, x_2, y_1, y_2, z_o, s_1\}$ ,  $\{x_1, x_2, y_1, y_2, z_o, t_p\}$ ,  $\{x_1, x_2, y_1, z_o, t_p, s\}$ ,  $\{x_1, y_1, z_i, z_{i+1}\}_{i=1,..., p-1}$ ,  $\{y_1, z_1, u\}$ ,  $\{x_1, y_1, z_o, t_i, t_{i+1}\}_{i=1,..., p-1}$  and  $\{x_1, y_1, t_1, t\}$  are cliques of G. Figure 2.
- **Type 6:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $t, t_i$  for  $i \in \{1, ..., p\}, u, z_i$  for  $i \in \{1, ..., o\}$  such that  $\{x_1, x_2, y_1, y_2, z_o\}, \{x_1, x_2, y_1, z_o, t_p\}, \{x_1, y_1, z_i, z_{i+1}\}_{i=1,...,o-1}, \{x_1, y_1, z_o, t_i, t_{i+1}\}_{i=1,...,p-1}, \{y_1, z_1, u\}$  and  $\{x_1, y_1, t_1, t\}$  are cliques of G. Figure 3.
- **Type 7:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $s, t, t_i$  for  $i \in \{1, ..., p\}$ ,  $u, u', z_i$  for  $i \in \{1, ..., o\}$ ,  $z'_i$  for  $i \in \{1, ..., o\}$ , such that  $\{x_1, x_2, y_1, y_2, z_o, t_p, z'_q\}$ ,  $\{x_1, x_2, y_1, z_o, t_p, s\}$ ,  $\{y_1, z_1, u\}$ ,

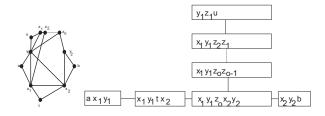

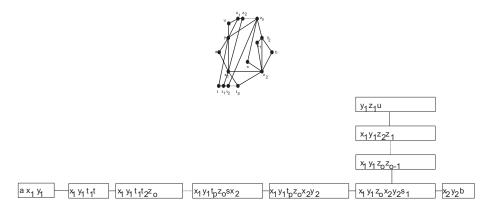

FIGURE 1. Type 4 and an RDV-model. In the graph, we leave out edges of cliques of size greater or equal than four.

 $\begin{array}{l} \{x_1, y_1, z_o, z_i', z_{i+1}', t_p\}_{i=1, \dots, q-1}, \ \{x_1, y_1, z_o, z_1', u'\}, \ \{x_1, y_1, z_i, z_{i+1}\}_{i=1, \dots, o-1}, \\ \{x_1, y_1, t_1, t\} \ \text{and} \ \{x_1, y_1, z_o, t_i, t_{i+1}\}_{i=1, \dots, p-1} \ \text{are cliques of} \ G. \ \text{Figure 4}. \end{array}$ 

- **Type 8:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $t, t', t_i$  for  $i \in \{1, ..., p\}, t'_i$  for  $i \in \{1, ..., r\}, u, u', z_i$  for  $i \in \{1, ..., o\}, z'_i$ for  $i \in \{1, ..., q\}$  such that  $\{x_1, x_2, y_1, y_2, z_o, t_p, z'_q\}, \{x_1, x_2, y_1, z_o, z'_q, t_p, t'_r\}, \{x_1, y_1, z_o, t_p, t'_1, t'\}, \{x_1, y_1, z_o, t_i, t_{i+1}\}_{i=1,...,p-1}, \{y_1, z_1, u\}, \{x_1, y_1, z_o, z'_q, t_p, t'_i, t'_i\}_{i=1,...,r-1}, \{x_1, y_1, z_o, z'_1, u'\}, \{x_1, y_1, z_i, z_{i+1}\}_{i=1,...,r-1}, \{x_1, y_1, z_o, t'_1, u'\}, \{x_1, y_1, z_i, z_{i+1}\}_{i=1,...,r-1}, \{x_1, y_1, t_1, t\}, and \{x_1, y_1, z_o, t_p, z'_i, z'_{i+1}\}_{i=1,...,q-1}$  are cliques of G. Figure 5. • **Type 9:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and
- **Type 9:** there exist two paths  $P = a, y_1, y_2, b, Q = a, x_1, x_2, b$ , and vertices in G:  $s, s_1, t, t', t_i$  for  $i \in \{1, ..., p\}, t'_i$  for  $i \in \{1, ..., r\}, u, u', z_i$  for  $i \in \{1, ..., o\}, z'_i$  for  $i \in \{1, ..., q\}$  such that  $\{x_1, x_2, y_1, y_2, z_o, t_p, z'_q, t'_r, s_1\}, \{x_1, x_2, y_1, z_o, z'_q, t_p, t'_r, s\}, \{x_1, y_1, z_o, t_p, t'_1, t'\}, \{x_1, y_1, z_o, t_i, t_{i+1}\}_{i=1,...,p-1}, \{x_1, y_1, z_o, z'_q, t_p, t'_i, t'_{i+1}\}_{i=1,...,r-1}, \{x_1, y_1, t_1, t\}, \{x_1, y_1, z_i, t'_{i+1}\}_{i=1,...,q-1}$  are cliques of G. Figure 6.

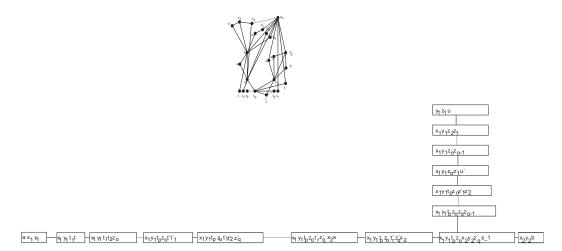

FIGURE 6. Type 9 and an RDV-model. In the graph, we leave out edges of cliques of size greater or equal than four.

**Theorem 1.** Let G be a DV graph, and let a, b be two non adjacent vertices of G that are linked by Type i with  $1 \le i \le 9$ . Then, for every T, DV-model of G, the subpath T(a, b) is a directed path.

*Proof.* Let  $Q_a$  be a maximal clique that contains a, and  $Q_b$  be a maximal clique that contains b.

- (1) Types 1, 2, 3. In [2] was proved that if a and b are linked by Type i with  $i \in \{1, 2, 3\}$  then  $T[Q_a, Q_b]$  is a directed path of T.
- (2) We can assume that there is a special connection of Type 4, 5, 6, 7, 8 or 9. The edge of T[Q<sub>a</sub>, Q<sub>b</sub>] incidents to Q<sub>a</sub> must have in its label S at least one vertex of {x<sub>1</sub>, x<sub>2</sub>} ({y<sub>1</sub>, y<sub>2</sub>}), otherwise a and b are in two different components of G \ S contradicting that a, x<sub>1</sub>, x<sub>2</sub>, b (a, y<sub>1</sub>, y<sub>2</sub>, b) is a path. Analogously, the edge incidents to Q<sub>b</sub> must have in its label at least one vertex of {y<sub>1</sub>, y<sub>2</sub>} ({x<sub>1</sub>, x<sub>2</sub>}). Vertex a is not adjacent to x<sub>2</sub>, and b is not adjacent to y<sub>1</sub> then Q<sub>a</sub> ∩ {x<sub>1</sub>, x<sub>2</sub>, y<sub>1</sub>, y<sub>2</sub>} = {x<sub>1</sub>, y<sub>1</sub>} and Q<sub>b</sub> ∩ {x<sub>1</sub>, x<sub>2</sub>, y<sub>1</sub>, y<sub>2</sub>} = {x<sub>2</sub>, y<sub>2</sub>}.
  - (a) Suppose that the connections is of Type 4.

Let  $Q', Q_o, Q$  and  $Q_i$  be maximal cliques of G such that  $Q' \supset \{x_1, x_2, y_1, t\}, Q_o \supset \{x_1, x_2, y_1, y_2, z_o\}, Q \supset \{y_1, z_1, u\}, and <math>Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for i = 1, ..., o - 1.

We will prove that  $Q_a, Q', Q_o, Q_b$  appear in this order in T.

As a is not adjacent to  $x_2$ , b is not adjacent to  $x_1$  and  $x_1, x_2$  are vertices in  $Q_o \cap Q'$ , then we have  $Q_a \notin T[Q_o, Q']$  and  $Q_b \notin T[Q_o, Q']$ . Observe that  $x_1$  and  $y_1$  are vertices in  $(Q' \cap Q_a) - (Q_o \cap Q_b)$ ,  $x_2$  and  $y_2$  are in  $(Q_o \cap Q_b) - (Q' \cap Q_a)$ ,  $x_2 \in Q' \cap Q_b$  but neither  $x_1$  or  $y_1$  or  $y_2$ are in  $Q' \cap Q_b$ . Thus  $Q_a, Q', Q_o, Q_b$  appear in this order in T. Since  $x_1 \in Q_a \cap Q_o$  and  $x_2 \in Q' \cap Q_b$  it is follows that  $T[Q_a, Q_b]$  is a directed path of T.

On the other hand  $Q_i \notin T[Q', Q_o]$  for  $i \neq o$  since  $x_2$  is not adjacent to  $z_i$  for  $i \neq o$ . As  $x_1, y_1$  and  $z_i$  are vertices in  $Q_i \cap Q_{i+1}$  for i = 1, ..., o-1,

 $x_1$  and  $y_1$  are in  $Q_i \cap Q_a$ , and  $z_1, y_1$  are vertices in  $Q_1 \cap Q$ , then  $Q_a, Q', Q_o, Q_{o-1}, ..., Q_1, Q$  appear in this order in T. Vertex b is not adjacent to  $y_1$ , so  $Q_b \notin T[Q_a, Q]$ .

(b) Suppose that the connection is of Type 5.

Let  $Q_o, Q'_o, Q'_p, Q_i, Q, Q'_i$  and Q' be maximal cliques of G such that  $Q_o \supset \{x_1, x_2, y_1, y_2, z_o, s_1\}, Q'_o \supset \{x_1, x_2, y_1, y_2, z_o, t_p\}, Q'_p \supset \{x_1, x_2, y_1, z_o, t_p, s\}, Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for  $i = 1, ..., o - 1, Q \supset \{y_1, z_1, u\}, Q'_i \supset \{x_1, y_1, z_o, t_i, t_{i+1}\}$  for i = 1, ..., p - 1, and  $Q' \supset \{x_1, y_1, t_1, t\}$ . We will prove that  $Q_a, Q', Q'_1, ..., Q'_p, Q'_o, Q_o, Q_b$  appear in this order in T.

Vertex  $s_1$  is not adjacent to  $t_p$ , and s is not adjacent to  $y_2$  then  $Q_o \notin$  $T[Q'_o, Q'_p]$  and  $Q'_p \notin T[Q'_o, Q_o]$  respectively. Observe that  $x_1, x_2, y_1,$  $z_o$  and  $t_p$  are vertices in  $Q'_o \cap Q'_p$  but  $y_2 \notin Q'_o \cap Q'_p$ . Also  $x_1, x_2,$  $y_1, y_2$  and  $z_o$  are in  $Q'_o \cap Q_o$  but  $t_p \notin Q'_o \cap Q_o$ . Thus  $Q'_p, Q'_o, Q_o$ appear in this order in T. On the other hand,  $Q'_i \notin T[Q'_v, Q_o]$  for  $i \neq p$  since  $t_i$  is not adjacent to  $x_2$ . As  $\{x_1, y_1, z_o, t_i\} \subset Q'_i \cap Q'_{i+1}$ and  $\{x_1, y_1, z_o\} \subset Q'_i \cap Q_o$ , but  $t_i \notin Q_o$  for  $i \neq p$  it is follows that  $Q'_1, ..., Q'_p, Q'_o, Q_o$  appear in this order in T. Note that  $Q' \notin T[Q'_1, Q_o]$ since  $z_o$  is not adjacent to t;  $\{x_1, y_1, t_1\} \subset Q' \cap Q'_1$ ,  $x_1$  and  $y_1$  are in  $Q' \cap Q_o$  but  $t_1 \notin Q_o$ , so  $Q', Q'_1, ..., Q'_p, Q'_o, Q_o$  appear in this order in T. Since a is not adjacent to  $t_i$  for i = 1, ..., p, and is also not adjacent to  $x_2$  then  $Q_a \notin T[Q', Q_o]$ . Vertex b is not adjacent to  $t_i$ for i = 1, ..., p and is also not adjacent to  $y_1$ , so  $Q_b \notin T[Q', Q_o]$ . As  $x_1, y_1 \in (Q_a \cap Q') - (Q_o \cap Q_b) \text{ and } x_2, y_2 \in (Q_o \cap Q_b) - (Q_a \cap Q'),$ it is follows that  $Q_a, Q', Q'_1, ..., Q'_p, Q'_o, Q_o, Q_b$  appear in this order in T. Since  $x_1 \in Q_a \cap Q_o$  and  $x_2 \in Q' \cap Q_b$  then  $T[Q_a, Q_b]$  is a directed path of T.

Using the same argument of Case 2a,  $Q_a, Q', Q'_1, ..., Q'_o, Q_o, Q_{o-1}, ..., Q_1, Q$  appear in this order in T and also  $Q_b \notin T[Q_a, Q]$ .

(c) Suppose that the connection is of Types 6 or 7.

In case that the connection is of Type 6, let  $Q_o, Q'_p, Q_i, Q, Q'_i$  and Q' be maximal cliques of G such that:  $Q_o \supset \{x_1, x_2, y_1, y_2, z_o\}, Q'_p \supset \{x_1, x_2, y_1, z_o, t_p\}, Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for  $i = 1, ..., o - 1, Q \supset \{y_1, z_1, u\}, Q'_i \supset \{x_1, y_1, z_o, t_i, t_{i+1}\}$  for i = 1, ..., p - 1, and  $Q' \supset \{x_1, y_1, t_1, t\}$ .

In case that the connection is of Type 7, let  $Q_o, Q'_p, Q''_i, Q'', Q_i, Q_i'$  and Q' be maximal cliques of G such that:  $Q_o \supset \{x_1, x_2, y_1, y_2, z_o, t_p, z'_q\}$ ,  $Q'_p \supset \{x_1, x_2, y_1, z_o, t_p, s\}, Q''_i \supset \{x_1, y_1, z_o, z'_i, z'_{i+1}, t_p\}$  for i = 1, ..., q - 1,  $Q'' \supset \{x_1, y_1, z_o, z'_1, u'\}, Q' \supset \{x_1, y_1, t_1, t\}, Q \supset \{y_1, z_1, u\}, Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for i = 1, ..., o - 1, and  $Q'_i \supset \{x_1, y_1, z_o, t_i, t_{i+1}\}$  for i = 1, ..., p - 1.

In both cases, we will prove that  $Q_a, Q', Q'_1, ..., Q'_p, Q_o, Q_b$  appear in this order in T.

We know that  $\{x_1, x_2, y_1, z_o, t_p\} \subset Q_o \cap Q'_p$  if the connection is of Type 7, and  $\{x_1, x_2, y_1, z_o\} \subset Q_o \cap Q'_p$  if the connection is of Type 6. But in both cases we have  $y_2 \notin Q_o \cap Q'_p$ . Vertex  $t_i$  is not adjacent to  $x_2$  for  $i \neq p$  then  $Q'_i \notin T[Q_o, Q'_p]$ . Observe that  $\{x_1, y_1, z_o, t_i\} \subset Q'_i \cap Q'_{i+1}, \{x_1, y_1, z_o\} \subset Q'_i \cap Q_o$  but  $t_i \notin Q_o$  for  $i \neq p$ . Thus  $Q'_1, \dots, Q'_p, Q_o$  appear

in this order in T. Note that  $Q' \notin T[Q'_1, Q_o]$  since  $z_o$  is not adjacent to t. Vertices  $x_1, y_1$  and  $t_1$  are in  $Q' \cap Q'_1, x_1$  and  $y_1$  are  $Q' \cap Q_o$  but  $t_1 \notin Q_o$ , so  $Q', Q'_1, ..., Q'_p, Q_o$  appear in this order in T. Vertex a is not adjacent to  $t_i$  for i = 1, ..., p, and is also not adjacent to  $x_2$  then  $Q_a \notin T[Q', Q_o]$ . Since b is not adjacent to  $t_i$  for i = 1, ..., p and b is not adjacent to  $y_1$  so  $Q_b \notin T[Q', Q_o]$ . As  $x_1, y_1 \in (Q_a \cap Q') - (Q_o \cap Q_b)$  and  $x_2, y_2 \in (Q_o \cap Q_b) - (Q_a \cap Q')$ , then  $Q_a, Q', Q'_1, ..., Q'_p, Q_o, Q_b$  appear in this order in T. Since  $x_1 \in Q_a \cap Q_o$  and  $x_2 \in Q' \cap Q_b$  it follows that  $T[Q_a, Q_b]$  is a directed path of T.

On the other hand, in case that the connection is of Type 6, using the same argument of Case 2a, we have  $Q_a, Q', Q'_1, ..., Q_o, Q_{o-1}, ..., Q_1, Q$  appear in this order in T. And as b is not adjacent to  $y_1$  then  $Q_b \notin T[Q_a, Q]$ .

In case that the connection is of Type 7, as  $z'_i$  is not adjacent to  $z_j$  for  $j \in \{1, ..., o-1\}$  and  $i \in \{1, ..., q\}$  it follows that  $Q''_1, Q''_i \notin T[Q_j, Q_{j+1}]$ . Also  $Q''_i \notin T[Q'_1, Q_o]$  since  $z'_i$  is not adjacent to  $t_j$  for  $i \in \{1, ..., q-1\}$  and  $j \in \{1, ..., p-1\}$ . Observe that  $\{x_1, y_1, z_o, t_p, z'_i\} \subset Q''_i \cap Q''_{i+1}$  for  $i \neq q, \{x_1, y_1, z_o, t_p\} \subset Q''_i \cap Q_o, \{x_1, y_1\} \subset Q_a \cap Q''_i$ , and  $\{x_1, y_1, z_o\} \subset Q''_i \cap Q_{o-1}$  then  $Q_a, Q'_1, ..., Q_o, Q''_q, ..., Q''_1, Q_{o-1}, ..., Q$  appear in this order in T, and also  $Q_b \notin T[Q_a, Q]$ .

(d) Suppose that the connection is of Type 8 or 9.

In case that the connection is of Type 8, let  $Q_o, Q'_p, Q^{iv}, Q'_i, Q''_i'', Q', Q'', Q'', Q, Q_i \text{ and } Q''_i$  be maximal cliques of G such that  $Q_o \supset \{x_1, x_2, y_1, y_2, z_o, t_p, z'_q\}$ ,  $Q'_p \supset \{x_1, x_2, y_1, z_o, z'_q, t_p, t'_r\}$ ,  $Q^{iv}\{x_1, y_1, z_o, t_p, t'_1, t'\}$ ,  $Q'_i \supset \{x_1, y_1, z_o, t_i, t_{i+1}\}$  for  $i = 1, ..., p - 1, Q'''_i \supset \{x_1, y_1, z_o, z'_q, t_p, t'_i, t'_{i+1}\}$  for  $i = 1, ..., r - 1, Q' \supset \{x_1, y_1, t_1, t\}$ ,  $Q'' \supset \{x_1, y_1, z_o, z'_1, u'\}$ ,  $Q \supset \{y_1, z_1, u\}$ ,  $Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for i = 1, ..., o - 1, and  $Q''_i \supset \{x_1, y_1, z_o, t_p, z'_i, z'_{i+1}\}$  for i = 1, ..., q - 1.

In case that the connection is of Type 9, let  $Q_o, Q'_p, Q^{iv}, Q'_i, Q'', Q''', Q''_i, Q''_i, Q''_i, Q_i, Q_i and Q_i''$  be maximal cliques of G such that  $Q_o \supset \{x_1, x_2, y_1, y_2, z_o, t_p, t'_q, t'_r, s_1\}$ ,  $Q'_p \supset \{x_1, x_2, y_1, z_o, z'_q, t_p, t'_r, s\}$ ,  $Q^{iv} \supset \{x_1, y_1, z_o, t_p, t'_1, t'\}$ ,  $Q'_i \supset \{x_1, y_1, z_o, t_i, t_{i+1}\}$  for i = 1, ..., p - 1,  $Q'' \supset \{x_1, y_1, z_o, z'_1, u'\}$ ,  $Q''_i \supset \{x_1, y_1, z_o, z'_q, t_p, t'_i, t'_{i+1}\}$  for i = 1, ..., r - 1,  $Q' \supset \{x_1, y_1, t_1, t\}$ ,  $Q_i \supset \{x_1, y_1, z_i, z_{i+1}\}$  for i = 1, ..., o - 1,  $Q \supset \{y_1, z_1, u\}$ , and  $Q''_i \supset \{x_1, y_1, z_o, t_p, z'_i, z'_{i+1}\}$  for i = 1, ..., q - 1.

In both cases, we will prove that  $Q_a, Q', Q'_1, ..., Q'_{p-1}, Q^{iv}, Q''_1, ..., Q''_{r-1}, Q'_p, Q_o, Q_b$  appear in this order in T.

We know that  $\{x_1, x_2, y_1, z_o, t_p, z'_q\} \subset Q_o \cap Q'_p$  but  $y_2 \notin Q_o \cap Q'_p$ . As  $t'_i$  is not adjacent to  $x_2$  for  $i \neq r$ , so  $Q''_i \notin T[Q_o, Q'_p]$ .

Observe that  $\{x_1, y_1, z_o, z'_q, t'_i\} \subset Q'''_i \cap Q'''_{i+1}, \{x_1, y_1, z_o, z'_q, t_p, t'_r\} \subset Q''_{r-1} \cap Q'_p$  but  $t'_r \notin Q_o, \{x_1, y_1, z_o, z'_q, t_p\} \subset Q''_i \cap Q'_p$  but  $t'_i \notin Q'_p$  for  $i \neq r$ . Then  $Q''_1, ..., Q''_{r-1}, Q'_p, Q_o$  appear in this order in T.

On the other hand,  $Q^{iv} \notin T[Q'_1, Q_o]$  since  $z'_q$  is not adjacent to t'. Vertices  $x_1, y_1, z_o, t_p$  and  $t'_1$  are in  $Q^{iv} \cap Q''_1, x_1, y_1, z_o$  and  $t_p$  are in  $Q^{iv} \cap Q_o$  but  $t'_1 \notin Q_o$  it is follows that  $Q^{iv}, Q''_1, ..., Q''_{r-1}, Q'_p, Q_o$  appear in this order in T.

As  $t_i$  is not adjacent to  $t_p$  for  $i \neq p-1$  then  $Q'_i \notin T[Q^{iv}, Q_o]$ . Observe that  $\{x_1, y_1, z_o, t_i\} \subset Q'_i \cap Q'_{i+1}, \{x_1, y_1, z_o\} \subset Q'_i \cap Q_o$  but  $t_i \notin Q_o$  for

 $i \neq p$  and  $\{x_1, y_1, z_o, t_p, t'_1\} \subset Q'_{p-1} \cap Q^{iv}, \{x_1, y_1, z_o, t_p\} \subset Q'_{p-1} \cap Q_o$ and  $t_1 \notin Q_o$ . Thus  $Q'_1, ..., Q'_{p-1}Q^{iv}, Q''_1, ...Q''_{r-1}, Q'_p, Q_o$  appear in this order in T.

On the other hand,  $Q' \notin T[Q'_1, Q_o]$  since  $z_o$  is not adjacent to t;  $\{x_1, y_1, t_1\} \subset Q' \cap Q'_1, \{x_1, y_1\} \subset Q' \cap Q_o$  but  $t_1 \notin Q_o$ , so  $Q', Q'_1, ..., Q'_{p-1}, Q^{iv}, Q'''_1, ..., Q''_{r-1}, Q'_p, Q_o$  appear in this order in T. Since a is not adjacent to  $t_i$  for i = 1, ..., p and a is not adjacent to  $x_2$ , then  $Q_a \notin T[Q', Q_o]$ . Vertex b is not adjacent to  $t_i$  for i = 1, ..., p and a is not adjacent to  $x_2$ , then  $Q_a \notin T[Q', Q_o]$ . Vertex b is not adjacent to  $t_i$  for i = 1, ..., p and is also not adjacent to  $y_1$ , so  $Q_b \notin T[Q', Q_o]$ . As  $x_1, y_1 \in (Q_a \cap Q') - (Q_o \cap Q_b)$  and  $x_2, y_2 \in (Q_o \cap Q_b) - (Q_a \cap Q')$ , then  $Q_a, Q', Q'_1, ..., Q'_{p-1}, Q^{iv}, Q'''_1, ..., Q''_{r-1}, Q'_p, Q_o, Q_b$  appear in this order in T. Since  $x_1 \in Q_a \cap Q_o$  and  $x_2 \in Q' \cap Q_b$  it is follows that  $T[Q_a, Q_b]$  is a directed path of T.

Using the same argument of Case 2c for Type 7, we have  $Q_a, Q', ..., Q_o, Q''_q, ..., Q''_1, Q'', Q_{o-1}, ..., Q$  appear in this order in T, and also  $Q_b \notin T[Q_a, Q]$ .

We will say that there is a *special connection* between two non adjacent vertices a and b if

- (1) there exists a connection of Type 1 between a and b; or
- (2) there exist two induced paths in  $G, P = a, y_1, ..., y_n, b$  and  $Q = a, x_1, ..., x_m, b$ , such that
  - (a)  $P \cap Q = \{a, b\}$
  - (b) if  $\{x_i, x_{i+1}, y_j, y_{j+1}\}$  is a clique for  $i \in \{1, ..., m-1\}$  and  $j \in \{1, ..., n-1\}$ then there is a connection of Type  $k \in \{3, 4, 5, 6, 7, 8, 9\}$  between  $x_{i-1}$ and  $y_{j+2}$  for  $i \neq 1, j \neq n-1$ , or between a and  $y_{j+2}$  for  $j \neq n-1$ , or between  $x_{i-1}$  and b for  $i \neq 1$ , or between a and b, or between  $y_{j-1}$ and  $x_{i+2}$  for  $j \neq 1, i \neq m-1$ , or between a and  $x_{i+2}$  for  $i \neq m-1$  or between  $y_{j-1}$  and b for  $j \neq 1$ .
  - (c) if  $\{x_i, x_{i+1}, y_j, y_{j+1}\}$  is not a clique then there is a special connection of Type 2 between  $x_{i-1}$  and  $y_{j+2}$  for  $i \neq 1, j \neq n-1$ , or between aand  $y_{j+2}$  for  $j \neq n-1$ , or between  $x_{i-1}$  and b for  $i \neq 1$ , or between a and b, or between  $y_{j-1}$  and  $x_{i+2}$  for  $j \neq 1, i \neq m-1$ , or between aand  $x_{i+2}$  for  $i \neq m-1$ , or between  $y_{j-1}$  and b for  $j \neq 1$ .

## 4. Properties

If G is a DV graph that has a strong asteroidal triple  $a_1, a_2, a_3$ , then  $G \setminus N[a_i]$  is a connected graph for i = 1, 2, 3. Hence for every T, a DV-model of G,  $N[a_i]$  for i = 1, 2, 3 must be a leaf of T. Let  $C_i$  be the closest vertex to  $N[a_i]$  such that it has degree at least three, for i = 1, 2, 3. If  $|V(T[N[a_i], C_i])| > 2$ , we will denote by  $e_i = A_i B_i$ , the edge in  $T[N[a_i], C_i]$ , with  $A_i$  the neighbor of  $N[a_i]$  and  $B_i \neq N[a_i]$ . If there exists an edge dominated by  $e_i$  then we choose  $e'_i$  to maximally farthest from  $e_i$ . We denote this edge by  $e'_i = A'_i B'_i$  with  $B'_i \in T[A'_i, C_i]$ .

We will say that a DV graph G is minimally non rooted on a maximal clique H if none DV-model T of G can be rooted on H but for every  $x \in V(G) \setminus H$ ,  $G \setminus x$  has a DV-model that can be rooted on H.

In the follows, if T has three leaves we will denote by C the vertex of degree exactly three in T.

**Lemma 1.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$ , and it is minimal non rooted on  $N[a_3]$ .

- (1) Let T be a DV-model of G.
  - (a) Then for all e edge in  $T[N[a_i], C_i]$  for i = 1, 2, there are at least two vertices  $x, y \in lab(e)$  such that  $T_x$  and  $T_y$  have different end towards  $C_i$ .
  - (b) There are not twin edges in  $T[N[a_i], C_i]$  for i = 1, 2, 3.
  - (c) If  $|V(T[N[a_i], C_i])| > 2$  for i = 1, 2 then there is a dominated edge by  $e_i$  that is not in  $T[N[a_i], C_i]$ .
- (2) If T is a DV-model of G that has three leaves, then T does not have twin edges one in  $T[N[a_i], C]$  for i = 1, 2, and the other in  $T[N[a_3], C]$ .
- Proof. (1) (a) Suppose by contradicting that every vertex x in lab(e) has the same end to  $C_i$ . Let  $e = AB \in T[N[a_i], C_i]$  for i = 1, 2 with  $B \in T[A, C_i]$  and  $T' = T E(T[N[a_i], B])$ . All vertices of lab(e) are twins in  $G_{T'}$ . Let T'' be a DV-model of  $G_{T'}$ . Since  $a_1, a_2, a_3$  is a strong asteroidal triple  $N[a_3]$  and  $N[a_j]$  for  $j \neq i, 3$  are leaves of T'', and by minimality we have T'' can be rooted on  $N[a_3]$ . For  $x \in lab(e)$ ,  $T''_x = T''[Z, W]$  and  $W \in T''[Z, N[a_3]]$ . Let  $\overline{T} = T'' + ZA + T[A, N[a_i]]$ . It is easy to check that  $\overline{T}$  is a DV-model of G that can be rooted on  $N[a_3]$ , a contradiction.
  - (b) Suppose by contradicting that there are two twin edges in T[N[a<sub>i</sub>], C<sub>i</sub>] for i ∈ {1,2,3}. Let e = AB and e' = A'B' be twin edges with A, B, A', B' appearing in this order in T[N[a<sub>i</sub>], C<sub>i</sub>], and T' = T − E(T[A, B']) + AB'. By minimality, there is T'' a DV-model of G<sub>T'</sub> that can be rooted on N[a<sub>3</sub>]. Let ẽ = Ã B' be an equivalent edge of AB' in T''. Thus, it is possible to build a DV-model of G from T'' by adding T(A, B') as follows: T'' − ÃB' + ÃT(A', B)B'. Clearly, this DV-model can be rooted on N[a<sub>3</sub>], a contradiction.
  - (c) Suppose by contradiction that  $e_i$  can not dominate an edge outside of  $T[N[a_i], C_i]$ ; i.e  $e'_i \in T[N[a_i], C_i]$ . Let  $T' = T - T[N[a_i], A'_i)$ . By the choice of  $e'_i$ , it is clear that  $A'_i$  is always a leaf in every DV-model of  $G_{T'}$ . By minimality, there is T'' a DV-model of  $G_{T'}$  that can be rooted on  $N[a_3]$ . It is easy to see that  $T'' + T[A'_i, N[a_i]]$  is a DV-model of G that can be rooted on  $N[a_3]$ , a contradiction.
  - (2) Suppose by contradiction that e and e' are twin edges, one in  $T[N[a_i], C]$ and the other in  $T[C, N[a_3]]$  for i = 1, 2. Let  $e = AB \in T[N[a_i], C]$ and  $e' = A'B' \in T[C, N[a_3]]$  with  $B \in T[A, C]$  and  $B' \in T[C, A']$ . Let  $T' = T - \{e, e'\} + AB' + BA'$ . It is a *DV*-model of *G*. Since *T* can not be rooted on  $N[a_3]$  so there is a vertex crossing by *C* in  $T[N[a_1], N[a_2]]$ , and then  $B \neq C$ . As there is a vertex crossing by *C* in  $T[N[a_i], N[a_3]]$  then there is no vertex crossing by *C* in  $T[N[a_i], N[a_3]]$  then there is no vertex crossing by *C* in  $T[N[a_i], N[a_3]]$  then there is no vertex crossing by *C* in  $T[N[a_i], A[a_3]]$  a contradiction.

**Theorem 2.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$ , and it is minimal non rooted on  $N[a_3]$ . If T is a DV-model of G that has three leaves, two twin edges one in  $T[N[a_1], C]$  and the other in  $T[N[a_2], C]$ , then there is a special connection of Type 1 or Type 2 between  $a_1$  and  $a_2$ .

*Proof.* Since T has twin edges it follows that  $|V(T[N[a_i], C])| \geq 3$  for some  $i \in \{1, 2\}$ . If there exists a vertex  $x \in N[a_1] \cap N[a_2]$  then there is a special connection of Type 1 between  $a_1$  and  $a_2$ .

Suppose that there is not a vertex in this condition. By Lemma 1a, and by the position of twin edges in T it follows that  $N[a_1]A_1$  can not be a dominated edge of  $e_2$  if it exists, and  $N[a_2]A_2$  can not be a dominated edge of  $e_1$  if it exists.

Let  $e \in T[N[a_1], C]$  and  $e' \in T[C, N[a_2]]$  be twin edges such that its distance is maximum in T. As  $N[a_i]A_i$  is not dominated by  $e_j$  with  $\{i, j\} = \{1, 2\}$ , and by the choice of  $e'_i$ , it is clear that  $e'_1 \in T[e', A_2]$  and  $e'_2 \in T[e, A_1]$ . But by the election of e and e' to maximum distance in T,  $e'_1$  must be e' and  $e'_2$  must be e. Then  $lab(e) = lab(e') \subset A_1 \cap A_2$ .

On the other hand, by Lemma 1a there are two vertices  $x, y \in lab(e)$  such that  $T_x = T[Ix, Dx], T_y = T[Iy, Dy], Ix \neq Iy, Dx \neq Dy$  with  $Dx = N[a_2]$  and  $Iy = N[a_1]$ . By the before exposed,  $x \notin N[a_1]$  and  $y \notin N[a_2]$ . Also by Lemma 1a, there are vertices  $y_1 \in lab(N[a_1]A_1)$  and  $x_1 \in lab(N[a_2]A_2)$  such that  $Dy_1 \neq Dy = A_2$  and  $Ix_1 \neq Ix = A_1$ . Clearly,  $x_1 \notin N[a_1]$  and  $y_1 \notin N[a_2]$ . Observe that  $y_1 \notin lab(e'_2)$  and  $x_1 \notin lab(e'_1)$ . Hence, there is a special connection of Type 2 between  $a_1$  and  $a_2$ . More clearly,  $P = a_1, y, x_1, a_2$  and  $Q = a_1, y_1, x, a_2$  are paths in G, and  $\{x, y, y_1\}, \{y, x, x_1\}$  are cliques of G.

**Corollary 1.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$ , and it is minimal non rooted on  $N[a_3]$ . If there exists T a DV-model of G with three leaves such that  $e'_i$  is in  $T[N[a_j], C]$   $\{i, j\} = \{1, 2\}$  then there is a special connection of Type 1 or Type 2 between  $a_1$  and  $a_2$ .

*Proof.* If  $e'_1 = N[a_2]A_2$  or  $e'_2 = N[a_1]A_1$ , by Lemma 1a there is  $x \in N[a_1] \cap N[a_2]$ . Hence, there is a special connection of Type 1 between  $a_1$  and  $a_2$ . Otherwise, as  $e'_1 \in T[A_2, C]$  and  $e'_2 \in T[A_1, C]$  then  $lab(e'_1) = lab(e'_2)$ . So by Theorem 2, there is a special connection of Type 1 or Type 2 between  $a_1$  and  $a_2$ .

**Claim 1.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$ , and none DV-model of G can be rooted on  $N[a_3]$ . If there exists T a DV-model of G with three leaves, and  $e = AB \in T[N[a_3], C]$  is dominated by  $e' \in T(N[a_1], C]$ with  $B \in T[C, A]$  then none edge of T(e', C] can have in its label vertices with the same end towards  $N[a_1]$ .

By way of contradiction, suppose that there is  $e'' \in T(e', C]$  such that all vertices in lab(e'') have the same end towards  $N[a_1]$ . Let  $A_1$  be the end of these vertices. Let e'' = A''B'' with  $B'' \in T[A'', C]$ . As  $lab(e) \subset lab(e')$  and  $e'' \in T(e', C]$ then  $lab(e) \subset lab(e'') \subset A_1$ . Also, the vertices in lab(e'') have  $A_1$  as a leaf. Let  $T' = T - \{e'', e\} + B''A_1 + AA''$ . It is clear that T' is a DV-model of G. Observe that there is no vertex crossing by  $A_1$  in  $T'[N[a_1], C]$  because of  $A_1$  is a leaf of each vertex in lab(e''). Also, there is no vertex crossing by C in  $T'[N[a_2], B]$  since there is no vertex crossing by C in  $T[N[a_2], N[a_3]]$ . Clearly, T' is a DV-model of G that can be rooted on  $N[a_3]$ , a contradiction. This proves claim (1).

**Claim 2.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$ , and none DV-model of G can be rooted on  $N[a_3]$ . Let T be a DV-model of G with three leaves,  $X, Y \in V(T)$  be such that one and only one of them is in  $T[N[a_i], C]$ for i = 1, 2 and the other is in  $T[N[a_3], C]$ . If e = AB be an edge in T[X, C] with  $B \in T[A, C]$ , which is dominated by  $D \in T[Y, C]$ , then  $\forall e' \in T[C, D']$  lab $(e') \notin B$ whenever  $DD' \in E(T[Y, C])$ .

By way of contradiction, suppose that there is  $e' \in T[C, D']$  such that  $lab(e') \subset B$ . Let e' = A''B'' be such that  $B'' \in T[C, A'']$ . Clearly  $T' = T - \{e, e'\} + A''B + AB''$  is a model of G.

Suppose that X is in  $T[N[a_1], C]$ . Observe that  $e' \in T[C, D']$ , and A" may be D'. Since e is dominated by D then  $lab(e) \subset B''$ . Thus T' is a DV-model of G. Clearly, T' does not have a vertex crossing by C in  $T'[N[a_1], N[a_2]]$  since there is no vertex crossing by C in  $T[N[a_3], N[a_2]]$ . Hence, T' can be rooted on  $N[a_3]$ , a contradiction.

The proof is the same if Y is in  $T[N[a_1], C]$ . This proves claim (2).

### Election 1 of vertices in label of edges:

Let T be a DV-model of G and A, B be vertices that appear in this order in T. Let e(1) be the edge in T[A, B] incidents to A.

- Take a vertex  $w_1 \in lab(e(1))$  such that  $T_{w_1}$  is the shortest towards B. Let  $T_{w_1} = T[Iw_1, Dw_1]$  with  $A \in T[Iw_1, Dw_1]$ . If  $B \notin T[A, Dw_1]$  then we repeat the following process, i > 0:
- Let e(i+1) be the edge in  $T[Dw_i, B]$  incidents to  $Dw_i$  and  $w_{i+1} \in lab(e(i+1))$  such that  $T_{w_{i+1}}$  is the shortest towards B, if  $w_{i+1} \in Iw_i$  (for i = 1, take A instead of  $Iw_i$ ) then  $w_i = w_{i+1}$ , we continue until cover all T[A, B].

Observe that  $T_{w_i} \not\subseteq T_{w_{i+1}}$ .

The preceding election of vertices, is a technical tool in order to define special connection of Type 4,5,.., or 9.

#### 5. Proof of the main Theorem

Finally, in this section we give the result that is the goal of this article, a characterization of rooted directed path graphs whose rooted models can not be rooted on a bold maximal clique.

**Theorem 3.** Let G be a DV graph such that it has a strong asteroidal triple  $a_1, a_2, a_3$  and leafage three. There is a special connection between  $a_1$  and  $a_2$  if and only if none DV-model of G can be rooted on  $N[a_3]$ .

## *Proof.* $\Rightarrow$ By Theorem 1.

 $\Leftarrow$  Suppose that G is the smallest graphs such that none DV-model of G can be rooted on  $N[a_3]$ . Since l(G) = 3 and  $G \setminus N[a_i]$  is a connected graph for i = 1, 2, 3then  $N[a_i]$  is a leaf in every model of G. Let T be a DV-model of G that reaches the leafage, and C be the vertex of degree three in T. Since T can not be rooted on  $N[a_3]$  then there is a vertex crossing by C in  $T[N[a_1], N[a_2]]$ . By Lemma 1b, we can assume that there are not two edges with the same label in  $T[N[a_i], C]$  for all  $i \in \{1, 2, 3\}$ . Clearly if  $T[N[a_i], C]$  has exactly two vertices for i = 1, 2 then there exists a vertex  $x \in N[a_1] \cap N[a_2]$ , so there is a special connection of Type 1 between  $a_1$  and  $a_2$ .

Now, we can assume that  $T[N[a_i], C]$ , for some  $i \in \{1, 2\}$ , has at least three vertices.

Suppose that  $T[N[a_1], C]$  has at least three vertices. Thus there exists  $e_1 \in T[N[a_1], C]$ , and by Lemma 1c there exists  $e'_1 \notin T[N[a_1], C]$ . If  $e'_1$  is in  $T[N[a_2], C]$  then by Corollary 1 there is a special connection of Type 1 or 2 between  $a_1$  and  $a_2$ .

Suppose that it is in  $T[N[a_3], C]$ . As T is a DV-model of G, and there is a vertex crossing by C in  $T[N[a_1], N[a_2]]$  if  $CN[a_2] \notin E(T)$  then  $e'_2 = N[a_1]A_1$ . Therefore, by Corollary 1, there is a special connection of Type 1 or Type 2 between  $a_1$  and  $a_2$ .

Consider  $CN[a_2] \in E(T)$ .

By Lemma 1a,  $|lab(N[a_1]A_1)|$  and  $|lab(N[a_2]C)|$  is greater than one. Let  $x_1, y_1 \in lab(N[a_1]A_1)$  and  $x_2, y_2 \in lab(N[a_2]C)$  be such that  $|\{Q \in C(G) | x_i \in Q\}| > |\{Q \in C(G) | y_i \in Q\}| > 1$ ,  $|\{Q \in C(G) | x_i \in Q\}|$  is maximum, and  $|\{Q \in C(G) | y_i \in Q\}|$  is minimum for i = 1, 2. Observe that if  $x_1 \in N[a_2]$  or  $x_2 \in N[a_1]$  then there is a special connection of Type 1 between  $a_1$  and  $a_2$ .

In the follows, we suppose that  $x_1 \notin N[a_2]$  and  $x_2 \notin N[a_1]$ . Let  $X_i$  be the leaf of  $T_{x_i}$  and  $Y_i$  be the leaf of  $T_{y_i}$  different from  $N[a_i]$  for i = 1, 2 respectively. Observe that  $X_2, Y_2 \in T[N[a_1], N[a_2]]$  but  $X_1, Y_1$  may be in  $T[C, N[a_3]]$ .

First of all, we know that  $lab(e'_1) \subset A_1$ . As  $lab(e'_1) \nsubseteq N[a_1]$ , since  $G \setminus N[a_1]$  is a connected graph, there is a vertex  $v \in lab(e'_1) \cap A_1 - N[a_1]$ .

In the follows, we will analyze several cases taking into account if  $\{x_1, x_2, y_1, y_2\}$  is or not a clique of G. We will study two situations depending on if there is or not an edge  $e \in T[N[a_1], X_2]$  such that  $lab(e) \subset C$ .

**Case 0:**  $T_{x_1} \cap T_{x_2} \neq \emptyset$  but  $T_{y_2} \cap T_{x_1} = \emptyset$  and  $T_{y_1} \cap T_{x_2} = \emptyset$ . Clearly  $x_1 \notin C$ . Let  $P = a_1, y_1, v, y_2, a_2$  and  $Q = a_1, x_1, x_2, a_2$  be paths in G. Then there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{y_1, v, x_1\}$ ,  $\{v, x_1, x_2\}$ ,  $\{v, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1, y_2$ , and between  $y_1, a_2$ ; see Figure 7.

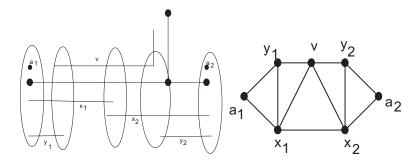

FIGURE 7. Case 0: Type 2 between  $a_1$ ,  $y_2$  and  $y_1$ ,  $a_2$ .

• There is not an edge  $e \in T[N[a_1], X_2]$  such that  $lab(e) \subseteq C$ .

**Case 1:**  $T_{x_1} \cap T_{x_2} = \emptyset$ . By the choice of  $x_1$ , each vertex in  $lab(e'_1)$  must have  $A_1$  as a leaf. Clearly, there is a path  $P = a_1, y_1, v, y_2, a_2$  in G between  $a_1$  and  $a_2$ . We will need other path Q in G between  $a_1$  and  $a_2$ . Observe that: a) by the election of  $x_1$ , for all  $\overline{e} \in T[X_1, X_2] \ lab(\overline{e}) \cap N[a_1] = \emptyset$ ; b) by Claim 1, as  $e'_1 \in T[C, N[a_3]]$  is a dominated edge by  $e_1 \in T(N[a_1], C]$ ,  $\forall \overline{e} \in T[X_1, X_2]$ , the vertices in its label can not have the same end to  $N[a_1]$ . Since  $v \in lab(\overline{e})$ , and its end is  $A_1$  it follows that there is  $w \in lab(\overline{e}) - A_1$ .

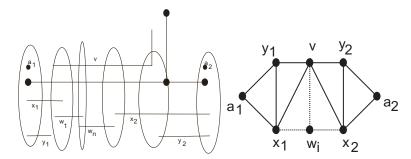

FIGURE 8. Case 1.1: Type 2 between  $a_1$ ,  $w_2$ ;  $w_{n-1}$ ,  $a_2$  and Type 1 between  $w_i$ ,  $w_{i+2}$ .

As was mentioned above, we need to search other path and Claim 1 will provide the vertices of this. We choose vertices through Election 1, we take  $A = X_1, B = X_2$  and  $w_i \notin A_1$  for i = 1, ..., n. Clearly,  $Q = a_1, x_1, w_1, ..., w_n$ ,  $x_2, a_2$  is a path in G different from P between  $a_1$  and  $a_2$ . Observe that  $w_n$ may be in C. In this last case, as  $lab(e) \nsubseteq C$  for all  $e \in T[C_{a_1}, X_2]$  it follows that there exists a vertex  $w' \in lab(e(n)) - C$  that has  $A_1$  as one of its leaves. Recall that  $w_n$  was chosen in the label of e(n).

Next, we will study if there is or not a clique in G of size four with two vertices of P and two vertices of Q.

**Case 1.1:** There is not a clique in G of size four with two vertices of P and two vertices of Q. Then  $y_1$  and  $w_1$  are not adjacent vertices; also  $y_2$  and  $w_n$  are not adjacent vertices. Therefore, there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{y_1, v, x_1\}$ ,  $\{x_1, v, w_1\}$ ,  $\{w_i, v, w_{i+1}\}_{i=1,..,n-1}$ ,  $\{w_n, v, x_2\}$ ,  $\{v, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$  and  $w_{n-1}$ ,  $a_2$ ; and of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; see Figure 8.

**Case 1.2:** There is only one clique in G of size four with two vertices of P and two vertices of Q. First, suppose that  $\{x_1, y_1, w_1, v\}$  is the clique. Since there is one and only one clique of size four,  $y_2$  and  $w_n$  are not adjacent vertices. On the other hand,  $y_1$  and  $w_1$  are adjacent vertices and  $w_1 \notin A_1$  then  $A_1$  must be separated by a vertex  $s_1$  in direction to  $N[a_1]$ . By the choice of  $y_1, s_1 \notin N[a_1]$  so it is a simplicial vertex of G. Let  $s_2$  be a separator vertex of  $X_1$  to C such that  $|\{Q \in C(G)| s_2 \in Q\}|$  is minimum. By the election of  $w_1$ , it is clear that  $s_2 \notin Dw_1$  then it is not adjacent vertex to  $w_2$ . Therefore there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{w_i, v, w_{i+1}\}_{i=1,..,n-1}$ ,  $\{w_n, v, x_2\}$ ,  $\{v, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G, and  $\{x_1, y_1, w_1, v, s_1, s_2\}$  induces an antenna.

Observe that there is a special connection: of Type 3 between  $a_1$  and  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and of Type 2 between  $w_{n-1}$ ,  $a_2$ ; see Figure 9.

**Case 1.3:** There is one only one clique in G of size four with two vertices of P and two vertices of Q. Now, suppose that  $\{x_2, y_2, w_n, v\}$  is the clique.

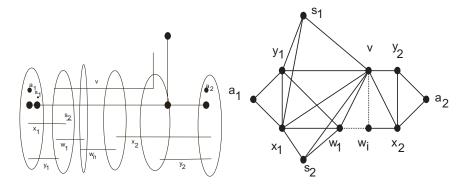

FIGURE 9. Case 1.2: Type 3 between  $a_1, w_2$ ; Type 1 between  $w_i, w_{i+2}$ ; Type 2 between  $w_{n-1}, a_2$ 

As there is only one clique of size four,  $y_1$  and  $w_1$  are not adjacent vertices. We will analyze two situations depending on whether  $w_n$  is or not in C.

(1)  $w_n \notin C$ . Let  $s_3$  be separator vertex of C to  $N[a_3]$ . Clearly  $s_3$  is not adjacent to  $w_n$ . Let  $s_4$  be a separator vertex of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G) | s_4 \in Q\}|$  is minimum. By the election of  $w_n, s_4$  is not adjacent vertex to  $w_{n-1}$ . Then there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}, \{y_1, v, x_1\}, \{w_i, v, w_{i+1}\}_{i=1,..,n-1}$  and  $\{x_2, y_2, a_2\}$  are cliques of G, and  $\{x_2, y_2, w_n, v, s_3, s_4\}$  induces an antenna.

Observe that there is a special connection: of Type 2 between  $a_1, w_2$ ; of Type 1 between  $w_i, w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and Type 3 between  $w_{n-1}, a_2$ ; see Figure 10.

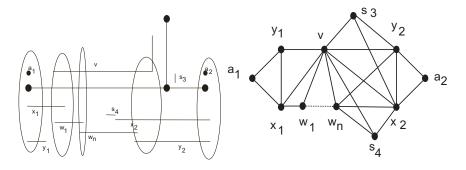

FIGURE 10. Case 1.3.1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i, w_{i+2}$ ; Type 3 between  $w_{n-1}, a_2$ 

(2)  $w_n \in C$ . Hence there is a vertex in lab(e(n)) - C that has  $A_1$  as one of its leaves. Let w' be the vertex such that  $|\{Q \in C(G) | w' \in Q\}|$  is maximum. Let W' be the other leaf of w'. If  $w' \in X_2$  then we take  $P = a_1, y_1, w', x_2, a_2$  and  $Q = a_1, x_1, w_1, ..., w_n, y_2, a_2$  paths in G. In case that  $y_2 \notin W'$  then there is a special connection: of Type 2 between  $a_1, w_2$ ; of Type 1 between  $w_i, w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and of Type 2 between  $w_{n-1}, a_2$ ; see Figure 11.

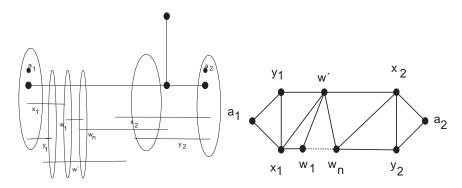

FIGURE 11. Case 1.3.2: Type 2 between  $a_1$ ,  $w_2$  and  $w_{n-1}$ ,  $a_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$ 

In case that  $y_2 \in W'$ , by the same argument used in 1 taken  $w_n, w'$  instead of  $w_n, v$ , there is a special connection of Type 3 between  $w_{n-1}$ ,  $a_2$ ; see Figure 12.

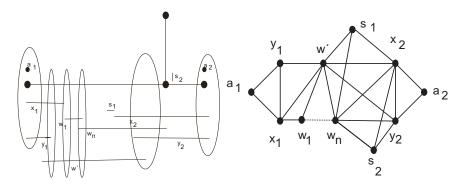

FIGURE 12. Case 1.3.2: Type 2 between  $a_1$ ,  $w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$  and Type 3 between  $w_{n-1}$ ,  $a_2$ 

Now, suppose that  $w' \notin X_2$ . Then we choose vertices in label of edges of  $T[W', X_2]$  that are not in C through Election 1 with A = W' and  $B = X_2$ . Let  $t_i$  be these vertices for i = 1, ..., m such that  $t_1$  is the first vertex chosen. Observe that by the choice of  $w', t_1 \notin A_1$  and by the election of  $w_n, t_1 \notin lab(e(n))$  then  $t_1$  is not adjacent to  $w_{n-1}$ . Let  $P = a_1, y_1, w', t_1, ..., t_m, x_2, a_2$  and  $Q = a_1, x_1, w_1, ..., w_n, y_2, a_2$  be paths in G. Note that  $\{w_n, t_m, y_2, x_2\}$  and  $\{y_1, x_1, w', w_1\}$  may be cliques. Clearly,  $\{y_1, x_1, w', w_1\}$  is not a clique because of  $\{y_1, x_1, v, w_1\}$  is not a clique. In case that  $\{w_n, t_m, x_2, y_2\}$  is not a clique then there is a special connection between  $a_1$  and  $a_2$ . More clearly  $\{a_1, y_1, x_1\}$ ,  $\{w', x_1, w_1\}, \{w', w_i, w_{i+1}\}_{i=1,..,n-1}, \{w', t_1, w_n\}, \{t_i, t_{i+1}, w_n\}_{i=1,..,m}, \{t_m, x_2, w_n\}, \{x_2, w_n, y_2\}, \{x_2, y_2, a_2\}$  are cliques of G. Observe that there is a special connection of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between w',  $t_2$ ; between  $t_i$ ,  $t_{i+2}$  with  $i \in \{1, ..., m-2\}$ , and of Type 2 between  $t_{m-1}$ ,  $a_2$ ; see Figure 13.

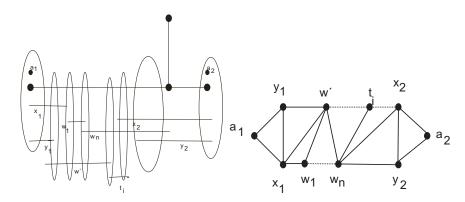

FIGURE 13. Case 1.3.2: Type 2 between  $a_1$ ,  $w_2$  and  $t_{m-1}$ ,  $a_2$ ; Type 1 between w',  $t_2$  and  $t_i$ ,  $t_{i+2}$ 

In case that  $\{w_n, t_m, y_2, x_2\}$  is a clique, let  $s_3$  be separator vertex of C to  $N[a_3]$ . Clearly,  $s_3$  is not adjacent to  $t_m$  since  $t_m \notin C$ . Let  $s_4$  be a separator vertex of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G) | s_4 \in Q\}|$  is minimum. By the election of  $t_m$ ,  $s_4$  is not adjacent vertex to  $t_{m-1}$ . Hence, there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, y_1, x_1\}, \{w', x_1, w_1\}, \{w', w_i, w_{i+1}\}_{i=1,.,n-1}, \{w', t_1, w_n\}, \{t_i, t_{i+1}, w_n\}_{i=1,..,m}, \{x_2, y_2, a_2\}$  are cliques of G, and  $\{t_m, x_2, y_2, w_n, s_3, s_4\}$  induces an antenna.

Observe that there is a special connection of Type 3 between  $t_{m-1}$  and  $a_2$ ; see Figure 14.

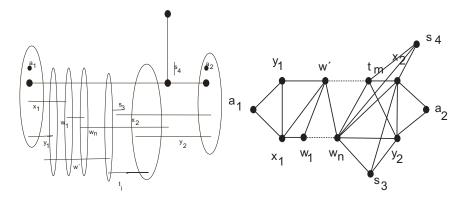

FIGURE 14. Case 1.3.2: Type 2 between  $a_1$ ,  $w_2$ ; Type 1 between w',  $t_2$  and  $t_i$ ,  $t_{i+2}$ ; Type 3 between  $t_{m-1}$ ,  $a_2$ 

**Case 1.4:** There are two cliques in G of size four with two vertices of P and two vertices of Q, and they are  $\{x_1, y_1, w_1, v\}$  and  $\{x_2, y_2, w_n, v\}$ . In this situation, we obtain a combination of the previous cases.

**Case 2:**  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \neq \emptyset$  but  $T_{y_2} \cap T_{x_1} = \emptyset$ , or  $T_{x_1} \cap T_{x_2} \cap T_{y_2} \neq \emptyset$ but  $T_{y_1} \cap T_{x_2} = \emptyset$ . In both situations is clear that there are two paths  $P = a_1, y_1, v, y_2, a_2$  and  $Q = a_1, x_1, x_2, a_2$  in G between  $a_1$  and  $a_2$ . Next, we will study if there is or not a clique in G of size four with two vertices of P and two vertices of Q.

**Case 2.1:**  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \neq \emptyset$  but  $T_{y_2} \cap T_{x_1} = \emptyset$ . Clearly  $\{x_1, y_1, v, x_2\}$  is a clique of G. By the election of  $x_1$ , every vertex of  $lab(e'_1)$  has  $A_1$  as a leaf. It is necessary to study two situations depending on  $T_{x_2}$  and  $T_v$  have or not the same end to  $N[a_1]$ . More clearly, if  $A_1$  is or not a leaf of both of them.

First, we suppose that  $T_{x_2}$  and  $T_v$  have the same leaf in direction to  $N[a_1]$ , i.e both of them have  $A_1$  as a leaf. By Claim 1, for each  $\overline{e} \in T[X_1, Y_2]$  the vertices in its label can not the same end to  $N[a_1]$ . As  $T_v$  and  $T_{x_2}$  have the same leaf  $A_1$  to  $N[a_1]$  then we choose vertices  $w_i \in lab(\overline{e}) - A_1$  through Election 1 with i = 1, ..., n. Let  $P' = a_1, y_1, x_2, a_2$  and  $Q' = a_1, x_1, w_1, ..., w_n, y_2, a_2$  be paths in G between  $a_1$  and  $a_2$ . Observe that  $\{x_1, x_2, y_1, w_1\}$  may be a clique. In case that  $w_1 \notin Y_1$  then there is not a clique of size four with two vertices of each path. Hence, there is a special connection between  $a_1, a_2$ . More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{x_1, x_2, y_1\}$ ,  $\{x_1, x_2, w_1\}$ ,  $\{w_i, w_{i+1}, x_2\}_{i=1,...,n-1}$ ,  $\{w_n, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G.

Note that there is a special connection: of Type 2 between  $a_1, w_2$ ; of Type 1 between  $w_i, w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and between  $w_n, a_2$ , see Figure 15.

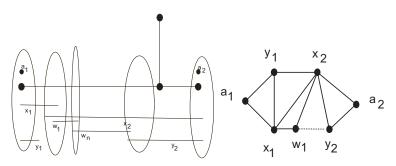

FIGURE 15. Case 2.1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$  and  $w_n, a_2$ 

In case that  $w_1 \in Y_1$ , as  $w_1 \notin A_1$  then  $Y_1 \neq A_1$ . Let  $s_1$  be a separator vertex of  $X_2 = A_1$  to  $N[a_1]$  such that  $|\{Q \in C(G) | s_1 \in Q\}|$  is minimum. By the choice of  $y_1$ ,  $s_1$  is a simplicial vertex of G. As  $w_1 \in Y_1$  then  $X_1 \neq Dw_1$ . Let  $s_2$  be a separator vertex of  $X_1$  to  $C_2$  such that  $|\{Q \in C(G) | s_2 \in Q\}|$  is minimum. By the election of  $w_1$ ,  $s_2$  is not adjacent to  $w_2$ . Hence there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}, \{w_i, w_{i+1}, x_2\}_{i=1,...,n}, \{w_n, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G, and  $\{x_1, y_1, w_1, x_2, s_1, s_2\}$  induces an antenna.

Note that there is a special connection: of Type 3 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and between  $w_n$ ,  $a_2$ ; see Figure 16.

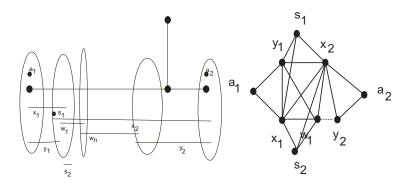

FIGURE 16. Case 2.1: Type 3 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$  and  $w_n, a_2$ 

Finally, we can assume that  $T_{x_2}$  and  $T_v$  do not have the same leaf in direction to  $N[a_1]$ . By the election of  $x_1$ , it is clear that  $v \notin N[a_1]$ . As  $x_2 \notin N[a_1]$  and  $X_2 \neq A_1$  then  $x_2 \notin A_1$ . Observe that  $Y_1 \neq A_1$  since  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \neq \emptyset$ . Let  $s_1$  and  $s_2$  be vertices such that  $s_1$  is a separator vertex of  $A_1$  to  $N[a_1]$ ,  $s_2$  is a separator vertex of  $X_1$  to C and  $|\{Q \in C(G)| \ s_2 \in Q\}|$ is minimum. By the choice of  $y_1, s_1 \notin N[a_1]$  so it is a simplicial vertex of G. If  $s_2$  is adjacent to  $y_2$ , let  $P' = a_1, y_1, x_2, a_2$  and  $Q' = a_1, x_1, s_2, y_2, a_2$ be paths in G between  $a_1$  and  $a_2$ . Clearly, there is not a clique of size four with two vertices of each path. Then there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}, \{x_1, x_2, s_2\}, \{x_1, x_2, y_1\}, \{s_2, x_2, y_2\}$ and  $\{x_2, y_2, a_2\}$  are cliques of G.

Note that there is a special connection: of Type 2 between  $a_1$ ,  $y_2$ , and of Type 1 between  $s_2$ ,  $a_2$ ; see Figure 17.

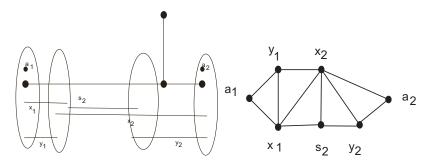

FIGURE 17. Case 2.1: Type 3 between  $a_1, y_2$ ; Type 1 between  $v, a_2$ 

If  $s_2$  is not adjacent to  $y_2$ , let  $P = a_1, y_1, v, y_2, a_2$  and  $Q = a_1, x_1, x_2, a_2$ be paths in G between  $a_1$  and  $a_2$ . Clearly there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{y_1, x_1, v, x_2, s_1, s_2\}$  induces an antenna and  $\{a_1, x_1, y_1\}$ ,  $\{v, x_2, y_2\}$ ,  $\{x_2, y_2, a_2\}$  are cliques of G.

Note that there is a special connection: of Type 3 between  $a_1$ ,  $y_2$ , and of Type 1 between v,  $a_2$ ; see Figure 18.

**Case 2.2:**  $T_{x_1} \cap T_{x_2} \cap T_{y_2} \neq \emptyset$  but  $T_{y_1} \cap T_{x_2} = \emptyset$ . Clearly, there are two paths in G between  $a_1$  and  $a_2$ ;  $P = a_1, x_1, x_2, a_2$  and  $Q = a_1, y_1, v, y_2, a_2$ .

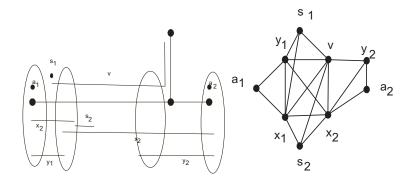

FIGURE 18. Case 2.1: Type 2 between  $a_1, y_2$ ; Type 1 between  $s_2, a_2$ 

On the other hand,  $\{x_1, x_2, y_2, v\}$  is a clique of G. We will analyze if  $x_1$  is or not in C.

First,  $x_1 \notin C$ . Clearly  $Y_2 \neq C$ . By the election of  $x_1$ , every vertex in  $lab(e'_1)$  has  $A_1$  as a leaf. Let  $s_2$  be a separator vertex of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G) | s_2 \in Q\}|$  is minimum.

If  $s_2 \in Y_1$  then we can change the paths in order to Type 2 appears. Let  $P' = a_1, y_1, s_2, x_2, a_2$  and  $Q' = a_1, x_1, y_2, a_2$  be paths in G. More clearly,  $\{a_1, x_1, y_1\}, \{s_2, x_1, y_1\}, \{s_2, x_1, x_2\}, \{x_1, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G.

Note that there is a special connection of Type 1 between  $a_1$ ,  $s_2$ ; and of Type 2 between  $y_1$ ,  $a_2$ ; see Figure 19.

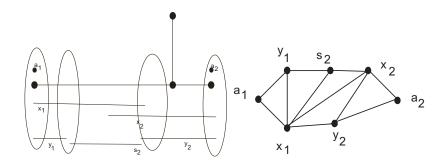

FIGURE 19. Case 2.2: Type 1 between  $a_1, s_2$ ; Type 2 between  $y_1, a_2$ 

If  $s_2 \notin Y_1$ , let  $s_1$  be a separator vertex of C to  $N[a_3]$ , then there is a special connection between  $a_1, a_2$ . More clearly,  $\{y_2, x_2, v, x_1, s_1, s_2\}$  induces an antenna and  $\{a_1, x_1, y_1\}$ ,  $\{v, x_1, y_1\}$ ,  $\{x_2, y_2, a_2\}$  are cliques of G.

Observe that there is a special connection: of Type 1 between  $a_1$ , v, and of Type 3 between  $y_1$ ,  $a_2$ ; see Figure 20.

Finally,  $x_1 \in C$ . We know that  $\forall e \in T[Y_1, X_2]$ ,  $lab(e) \notin C$ . We choose  $w_i \in lab(e) - C$  through Election 1 with  $A = Y_1$  and  $B = X_2$ . Let  $P' = a_1, x_1, y_2, a_2$  and  $Q' = y_1, w_1, ..., w_n, x_2, a_2$  be paths in G between  $a_1$  and  $a_2$ .

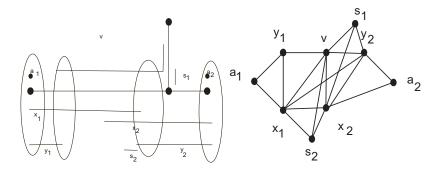

FIGURE 20. Case 2.2: Type 1 between  $a_1$ , v; Type 3 between  $y_1$ ,  $a_2$ 

If  $w_n$  is not adjacent to  $y_2$  then there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}, \{x_1, y_1, w_1\}, \{w_i, w_{i+1}, x_1\}_{i=1,..,n-1}, \{w_n, x_1, x_2\}, \{x_1, x_2, y_2\}$  and  $\{x_2, y_2, a_2\}$  are cliques of G.

Observe that there is a special connection: of Type 1 between  $a_1$ ,  $w_1$ ; between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and of Type 2 between  $w_{n-1}$ ,  $a_2$ ; see Figure 21.

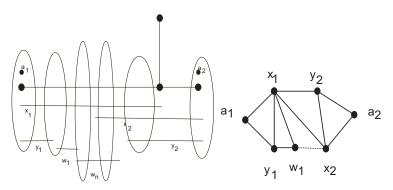

FIGURE 21. Case 2.2: Type 1 between  $a_1$ ,  $w_1$ ; between  $w_i$ ,  $w_{i+2}$ ; Type 2 between  $w_{n-1}$ ,  $a_2$ 

If  $w_n$  is adjacent to  $y_2$  then  $Y_2 \neq C$  by the election of  $w_n \notin C$ . Clearly, there is a clique of size four with two of each path, it is  $\{x_1, x_2, y_2, w_n\}$ . Let  $s_1$  and  $s_2$  be vertices such that  $s_1$  is a separator of C to  $N[a_3]$ ,  $s_2$  is a separator of  $X_2$  to  $N[a_1]$  and  $|\{Q \in C(G) | s_i \in Q\}|$  is minimum for i = 1, 2. By the election of  $w_i$ ,  $s_2$  is not adjacent to  $w_{n-1}$ . Hence there is a special connection between  $a_1$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}, \{x_1, y_1, w_1\}, \{w_i, w_{i+1}, x_1\}_{i=1,..,n-1}, \{x_2, y_2, a_2\}$  are cliques of G, and  $\{w_n, x_1, x_2, y_2, s_1, s_2\}$  induces an antenna.

Observe that there is a special connection: of Type 1 between  $a_1$ ,  $w_1$ ; between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ , and of Type 3 between  $w_{n-1}$ ,  $a_2$ ; see Figure 22.

**Case 3:**  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \cap T_{y_2} \neq \emptyset$ . Clearly, there are two paths in G between  $a_1$  and  $a_2$ . Let  $P = a_1, y_1, y_2, a_2$  and  $Q = a_1, x_1, x_2, a_2$  be these paths. Also  $\{x_1, y_1, x_2, y_2\}$  is a clique of G which has two vertices of P and

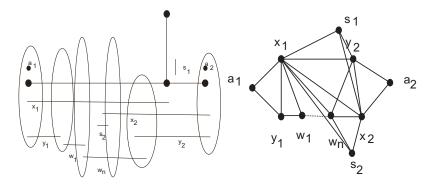

FIGURE 22. Case 2.2: Type 1 between  $a_1$ ,  $w_1$  and  $w_i$ ,  $w_{i+2}$ ; Type 3 between  $w_{n-1}$ ,  $a_2$ 

two vertices of Q. We will study two situations depending on  $x_1$  is or not in C.

First,  $x_1 \notin C$ . Since  $X_2 \neq N[a_1]$  then  $Y_1 \neq A_1$ . Let  $s_1$  be a separator vertex of  $X_2$  to  $N[a_1]$ ,  $s_2$  be a separator vertex of  $X_1$  to  $N[a_2]$  such that  $|\{Q \in C(G) | s_i \in Q\}|$  is minimum for i = 1, 2. By the election of  $y_i$  for  $i = 1, 2, s_2 \notin N[a_2]$  and  $s_1 \notin N[a_1]$ . Hence there is a special connection of Type 3 between  $a_1$  and  $a_2$ ; see Figure 23.

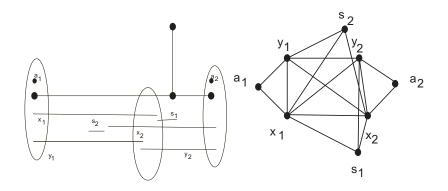

FIGURE 23. Case 3: Type 3 between  $a_1, a_2$ 

We now suppose that  $x_1 \in C$ . Since there is not an edge whose label is contained in C, then  $y_1 \notin C$ . Hence  $Y_2 \neq C$ . Observe that  $X_2 \neq Y_1$ but  $Y_1$  may be  $Y_2$ . Let  $s_2$  be a separator vertex of  $X_2$  to  $N[a_1]$ ,  $s_1$  be a separator vertex of C to  $N[a_2]$  such that  $|\{Q \in C(G) | s_i \in Q\}|$  is minimum for i = 1, 2. By the before exposed,  $s_2 \notin N[a_1]$  and  $s_1 \notin N[a_2]$ . Hence there is a special connection of Type 3 between  $a_1$  and  $a_2$ ; see Figure 24.

In both cases,  $\{a_1, x_1, y_1\}$ ,  $\{a_2, x_2, y_2\}$  are cliques of G, and  $\{s_1, s_2, x_1, x_2, y_1, y_2\}$  induces an antenna.

• There is an edge  $e \in T[N[a_1], X_2]$  such that  $lab(e) \subseteq C$ .

**Case 1:**  $T_{x_1} \cap T_{x_2} = \emptyset$ . By the election of  $x_1$ , each vertex in  $lab(e'_1)$  must have  $A_1$  as a leaf. Clearly, there is a path  $P = a_1, y_1, v, y_2, a_2$  in G between  $a_1$  and  $a_2$ . We will need other path Q in G between  $a_1$  and  $a_2$ . Observe

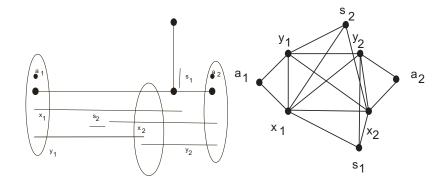

FIGURE 24. Case 3: Type 3 between  $a_1, a_2$ 

that: a) by the election of  $x_1$ , for all  $\overline{e} \in T[X_1, X_2]$ ,  $lab(\overline{e}) \cap N[a_1] = \emptyset$ ; b) by Claim 1 as  $e'_1 \in T[C, N[a_3]]$  is a dominated edge by  $e_1 \in T(N[a_1], C]$ ,  $\forall \overline{e} \in T[X_1, X_2]$ , the vertices in its label can not have the same ends to  $N[a_1]$ . Hence as  $v \in lab(\overline{e})$  for all  $\overline{e} \in T[X_1, X_2]$ , there is  $w \in lab(\overline{e}) - A_1$ . As was mentioned above, we need to search vertices for other path. We choose vertices through Election 1 taken  $A = X_1$ ,  $B = X_2$  and  $w_i \notin A_1$ for i = 1, ..., n. Clearly,  $Q = a_1, x_1, w_1, ..., w_n, x_2, a_2$  is a path in G different from P between  $a_1$  and  $a_2$ . As there is an edge in  $T[X_1, X_2]$  whose label is contained in C then  $w_n$  is in C. Clearly  $\{x_2, y_2, w_n, v\}$  is a clique of G, and  $\{x_1, y_1, v, w_1\}$  may be a clique. Let  $W'Dw_n \in E(T)$  be such that  $Dw_n \in$ T[C, W']. Let u be a separator vertex of W' to  $N[a_3]$ , i.e  $u \in W' - Dw_n$ . Let e(n) = XY be the edge which was chosen  $w_n$  with  $Y \in T[X, C]$ . Observe that Y may be  $X_2$ . On the other hand, e(n) is dominated by  $Dw_n$  because of the choice of  $w_n$ , which is the shortest vertex to C, and  $lab(e(n)) \subset C$ . We will analyze if there is or not another edge  $\tilde{e} \in T[Y, X_2]$  such that  $lab(\tilde{e}) \subset C.$ 

□ Suppose that other edge does not exist. By Claim 2, as e(n) is an edge dominated by  $Dw_n \in T[C, N[a_3]]$  then for every edge in T[W', C] its label is not contained in Y. Hence we choose vertices in label of edges  $\overline{e} \in T[W', C]$  that are not in Y, through Election 1 taken A = W' and B = C. Let  $z_i \notin Y$  be such that  $T_{z_i} = T[Iz_i, Dz_i]$  with  $Iz_i \in T(Y, Dz_i]$  for i = 1, ..., o, and  $z_o$  is the last vertex chosen. By the choice of  $z_i \notin Y$  for i = 1, ..., o, it follows that  $e'_1 \notin T[W', C]$ .

Now, we will analyze two situations depending on the position of  $Iz_o$  in T(Y, C]:

First, we consider  $Iz_o \in T(X_2, C]$ . Let t be a separator vertex of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G) | t \in Q\}|$  is minimum. Observe that  $t \notin X$ . Also t is not adjacent to  $y_2$  or  $z_o$ . Then, there is a special connection between  $a_1$  and  $a_2$ . More clearly, in case that  $\{x_1, y_1, v, w_1\}$  is not a clique it follows that  $\{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{w_i, v, w_{i+1}\}_{i=1,..,n-1}, \{x_2, y_2, a_2\}, \{v, w_n, x_2, y_2, z_o\}, \{z_i, z_{i+1}, v, w_n\}_{i=1..,o-1}, \{u, v, z_1\}$  and  $\{v, w_n, x_2, t\}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 4 between  $w_{n-1}$  and  $a_2$ ; see Figure 25.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the same argument used in Case 1.2, there are two vertices  $s_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s_1, s_2\}$ induces an antenna.

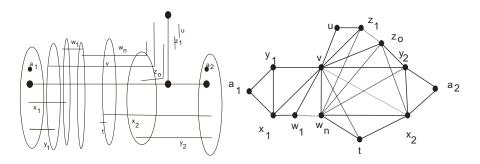

FIGURE 25. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$ ; Type 4 between  $w_{n-1}$  and  $a_2$ 

Finally, we consider  $Iz_o \in T(Y, X_2]$ . Let  $e(o) = A_o B_o$  be the edge which  $z_o$  was chosen, with  $B_o \in T[C, A_o]$ . Let Z' be the vertex of T such that  $Iz_oZ' \in E(T)$  and  $Iz_o \in T[Z', X_2]$ . Observe that  $Z' \neq X$  since  $Iz_o \neq Y$ . Also, by the election of  $z_o$ , e(o) is a dominated edge by  $I_{z_o}$  then by Claim 2 for every e' edge in  $T[Z', X_2]$  its label is not contained in  $B_o$ . Hence we choose vertices through Election 1 in label of edges of  $T[Z', X_2]$  such that they are not in  $B_o$ . Let  $t_i \notin B_o$  be the vertices chosen with  $i \in \{1, ..., p\}$ , and  $t_p$  be the last vertex chosen. It is clear that  $t_p$  may be in C. But there is not an edge different from e(n) such that it is contained in C then  $t_p \notin C$ . Clearly,  $t_p$  may be adjacent or not to  $y_2$ .

 $\begin{array}{l} \Diamond t_p \text{ is adjacent to } y_2. \text{ As } t_p \notin C \text{ there is a separator vertex of } C \text{ to } N[a_3]. \\ \text{Let } s_1 \text{ be the separator of } C \text{ to } N[a_3] \text{ minimizing } |\{Q \in C(G)| \ s_1 \in Q\}|. \\ \text{As } z_o \text{ was chosen instead of } s_1 \text{ then } z_{o-1} \text{ is not adjacent to } s_1. \text{ Let } s \\ \text{be a separator of } X_2 \text{ to } N[a_1] \text{ such that } |\{Q \in C(G)| \ s \in Q\}| \text{ is minimum. By the election of } t_p, \text{ it is clear that } s \text{ is not adjacent to } t_{p-1}. \\ \text{Let } t \text{ be a separator of } It_1 \text{ to } N[a_1] \text{ such that } |\{Q \in C(G)| \ s \in Q\}| \text{ is minimum. Observe that } t \notin X. \\ \text{There is a special connection between } a_1 \text{ and } a_2. \\ \text{More clearly, in case that } \{x_1, y_1, w_1, v\} \text{ is not a clique then } \{a_1, x_1, y_1\}, \ \{x_1, v, y_1\}, \ \{x_1, v, w_1\}, \ \{w_i, v, w_{i+1}\}_{i=1,\dots,n-1}, \ \{z_i, z_{i+1}, v, w_n\}_{i=1,\dots,o-1}, \ \{x_2, y_2, a_2\}, \ \{u, v, z_1\}, \ \{v, w_n, z_o, x_2, t_p, s\}, \ \{t_p, x_2, y_2, z_o, w_n, v\}, \ \{t, w_n, v, t_1\}, \ \{t_i, t_{i+1}, v, w_n, z_o\}_{i=1,\dots,p-1} \text{ and } \ \{v, w_n, x_2, y_2, z_o, s_1\} \text{ are cliques of } G. \end{array} \right$ 

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 5 between  $w_{n-1}$  and  $a_2$ ; see Figure 26.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the before exposed, there are two vertices  $s'_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s'_1, s_2\}$  induces an antenna.

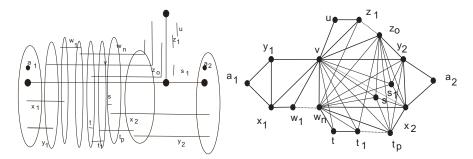

FIGURE 26. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i, w_{i+2}$ ; of Type 5 between  $w_{n-1}, a_2$ 

 $\Diamond \ t_p$  is not adjacent to  $y_2$ . As before, considering only the separator of  $It_1$  to  $N[a_1]$ . Then there is a special connection between  $a_1$  and  $a_2$ . More clearly, in case that  $\{x_1,y_1,w_1,v\}$  is not a clique then  $\{a_1,x_1,y_1\}$ ,  $\{x_1,v,y_1\}, \{x_1,v,w_1\}, \{w_i,v,w_{i+1}\}_{i=1,\dots,n}, \{z_i,z_{i+1},v,w_n\}_{i=1,\dots,o-1}, \{x_2,y_2,a_2\}, \{u,v,z_1\}, \{t,v,w_n,t_1\}, \{t_i,t_{i+1},v,w_n,z_o\}_{i=1,\dots,p-1}, \{t_p,x_2,v,w_n,z_o\}$  and  $\{v,w_n,x_2,y_2,z_o\}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1, w_2$ ; of Type 1 between  $w_i, w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 6 between  $w_{n-1}$  and  $a_2$ ; see Figure 27.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the before exposed, there are two vertices  $s_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s_1, s_2\}$  induces an antenna.

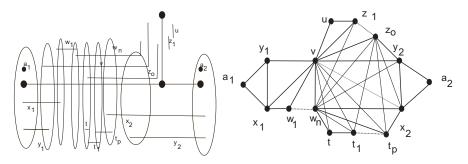

FIGURE 27. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$ ; Type 6 between  $w_{n-1}, a_2$ 

 $\Box$  Suppose that there is an edge in  $T[B, X_2]$  which is contained in C. Let  $\tilde{e}$  be the nearest C. Observe that  $lab(e(n)) \subset lab(\tilde{e})$ , but by our assumption  $lab(\tilde{e}) \not\subseteq lab(e(n))$ , let  $m \in lab(\tilde{e}) - lab(e(n))$  such that  $T_m$  is the shortest to  $N[a_3]$  with Dm its leaf in  $T[C, N[a_3]]$ . Clearly,  $m \neq w_n, v$ . Observe that for all edge  $\tilde{\tilde{e}}$  in  $T(\tilde{e}, X_2]$ ,  $lab(\tilde{e}) \not\subseteq C$ . Therefore there are vertices in the label of edges of  $T(\tilde{e}, X_2]$  that are not in C.

In case that  $Dm \in T[Dw_n, N[a_3]]$ ,  $\tilde{e}$  is dominated by  $Dw_n$  then by Claim 2 there are vertices in the label of edges of T[W', C] that are not in  $\tilde{B}$  with  $\tilde{e} = \tilde{A}\tilde{B}$  and  $\tilde{B} \in T[\tilde{A}, C]$ . Let  $z_i$  be these vertices for i = 1, ..., o chosen through Election 1. Therefore  $I_{z_o} \notin \widetilde{B}$ . Also, by the election of  $\tilde{e}$ , the vertices  $t_i$  chosen as before are not in C, in particular the vertex  $t_p \notin C$ . Hence we get situations described previously, i.e Type 4 or Type 5 or Type 6. More clearly, in case that  $\{x_1, y_1, w_1, v\}$  is not a clique then if  $Iz_o \in T(X_2, C], \{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{w_i, v, w_{i+1}\}_{i=1,\dots,n-1},$  $\{x_2, y_2, a_2\}, \{v, w_n, x_2, y_2, z_o\}, \{z_i, z_{i+1}, v, w_n\}_{i=1..,o-1}, \{u, v, z_1\}, \text{ and }$  $\{v, w_n, x_2, t\}$  are cliques of G. If  $Iz_o \in T(\widetilde{B}, X_2]$  then in case that  $t_p$ is adjacent to  $y_2$ ,  $\{a_1, x_1, y_1\}$ ,  $\{x_1, v, y_1\}$ ,  $\{x_1, v, w_1\}$ ,  $\{x_2, y_2, a_2\}$ ,  $\{w_i, v, v_1\}$ ,  $\{x_2, y_2, a_2\}$ ,  $\{w_i, v_i, v_i\}$  $x_2, y_2, z_o, w_n, v$ ,  $\{t, w_n, v, t_1\}$ ,  $\{t_i, t_{i+1}, v, w_n, z_o\}_{i=1,\dots,p-1}$  and  $\{v, w_n, x_2, v_n, v_n\}$  $y_2, z_o, s_1$  are cliques of G. In case that  $t_p$  is not adjacent to  $y_2$  then  $\{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{x_2, y_2, a_2\}, \{w_i, v, w_{i+1}\}_{i=1, \dots, n}, \{z_i, z_{i+1}, y_{i+1}\}, \{z_i, z_i, y_{i+1}\}, \{z_i, z_i, y_{i+1}\}, \{z_i, z_i, y_i\}, \{z_i, z_i, y_{i+1}\}, \{z_i, z_i, y_i\}, \{z_i, y_i\}, \{z_i,$  $v, w_n\}_{i=1,..,o-1}, \{u, v, z_1\}, \{t, v, w_n, t_1\}, \{t_i, t_{i+1}, v, w_n, z_o\}_{i=1,..,p-1}, \{t_p, x_2, t_{i+1}, v, t_{i+1$  $v, w_n, z_o$  and  $\{v, w_n, x_2, y_2, z_o\}$  are cliques of G. In case that  $\{x_1, y_1, v, v_n\}$  $w_1$  is a clique of G, by the before exposed, there are two vertices  $s'_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s'_1, s_2\}$  induces an antenna.

In case that  $Dm \in T[C, Dw_n)$ , e(n) is dominated by  $Dw_n$  then by Claim 2 there are vertices chosen through Election 1 that are not in Y. As before, let  $z_i$  be these vertices for i = 1, .., o. If  $z_o \notin \widetilde{B}$  then we get situations described previously. If  $z_o \in \widetilde{B}$ , as Dm dominates  $\widetilde{e}$ , none edge of T[M', C]  $(DmM' \in E(T)$  with  $M' \in T[M, Dw_n])$  is dominated by B, then  $e(o) \notin T[C, M']$ . It is clear that  $Iz_o \notin T[X_2, C]$ . Also  $t_p = m$ . In this case  $t_p \in C$ . By Claim 2 as  $\tilde{e}$  is a dominated edge by  $Dt_p = Dm$ , in the label of edges of T[C, M'] there are vertices that are not in B. Let  $z'_i$  be vertices chosen in the label of edges in T[C, M'] that are not in B through Election 1 taken A = M', B = C for i = 1, ..., q, and with  $z'_q$  the last vertex chosen. Let u' be adjacent to  $z'_1$  but not adjacent to  $z'_2$ . If  $z'_q \in T(X_2, C]$  then let s be a separator of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G) | s \in Q\}|$  is minimum. We obtain a special connection between  $a_1$  and  $a_2$ . More clearly, in case that  $\{x_1, y_1, v, w_1\}$  is not a clique then  $\{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{w_i, v, w_{i+1}\}_{i=1,\dots,n-1},$  $\{x_2, y_2, a_2\}, \{z_i, z_{i+1}, v, w_n\}_{i=1...,o-1}, \{u, v, z_1\}, \{t_i, t_{i+1}, v, w_n, z_o\}_{i=1,...,p-1},$  $\{t, v, w_n, t_1\}, \{u', z'_1, z_o, w_n, v\}, \{s, t_p, w_n, v, z_o, x_2\}, \{z'_q, x_2, y_2, v, w_n, t_p, z_o\}$ and  $\{z'_{i}, z'_{i+1}, v, w_n, t_p, z_o\}_{i=1,.,q-1}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 7 between  $w_{n-1}$  and  $a_2$ ; see Figure 28.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the before exposed, there are two vertices  $s'_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s'_1, s_2\}$  induces an antenna.

If  $z'_q \in T(B, X_2]$ , as the edge e(q) where  $z'_q$  was chosen is dominated by  $Iz'_q$ , it follows by Claim 2 that there are vertices  $t'_i$  that are not in  $B_q$ , with  $e(q) = A_q B_q$  and  $B_q \in T[C, A_q]$ , for i = 1, ..., r. Also by the election of  $\tilde{e}$ , they are not in C. Let  $t'_r$  be the last vertex chosen. Observe that  $t'_r$  may be adjacent to  $y_2$ .

If  $t'_r$  is not adjacent to  $y_2$  then there is a special connection between  $a_1$  and  $a_2$ . More clearly, in case that  $\{x_1, y_1, w_1, v\}$  is not a clique then  $\{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{w_i, v, w_{i+1}\}_{i=1,..,n-1}, \{x_2, y_2, a_2\}, \{z_i, w_i\}$ 

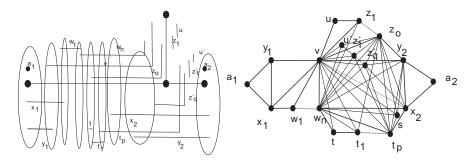

FIGURE 28. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i, w_{i+2}$ ; Type 7 between  $w_{n-1}, a_2$ 

 $\begin{array}{l} z_{i+1}, \ v, w_n \}_{i=1 \dots o - 1}, \ \{u, v, z_1\}, \ \{t_i, \ t_{i+1}, v, w_n, z_o \}_{i=1, \dots, p - 1}, \ \{t, v, w_n, t_1\}, \\ \{t', t_1', \ t_p, v, w_n, z_o \}, \ \{t_i', t_{i+1}', \ z_o, z_q', \ t_p, v, w_n \}_{i=1, \dots, r - 1}, \ \{t'_r, t_p, \ v, w_n, z_o, z_q', \ x_2\}, \ \{t_p, v, \ w_n, z_o, \ z_i', z_{i+1}' \}_{i=1, \dots, q - 1} \ \text{and} \ \{u', z_1', \ z_o, w_n, v\} \ \text{are cliques of} \ G. \end{array}$ 

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 8 between  $w_{n-1}$  and  $a_2$ ; see Figure 29.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the before exposed, there are two vertices  $s_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s_1, s_2\}$  induces an antenna.

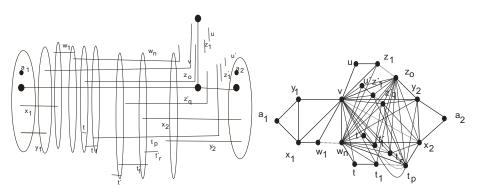

FIGURE 29. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$ ; Type 8 between  $w_{n-1}, a_2$ 

If  $t'_r$  is adjacent to  $y_2$ , let s be a separator of  $X_2$  to  $N[a_1]$  such that  $|\{Q \in C(G)| \ s \in Q\}|$  is minimum. By the election of  $t'_r$ , it is clear that s is not adjacent to  $t'_{r-1}$ , recall  $t'_r \notin C$ . Then, let  $s_1$  be a separator vertex of C to  $N[a_3]$  such that  $|\{Q \in C(G)| \ s_1 \in Q\}|$  is minimum. Observe that  $s_1 \neq z'_q$  since  $z'_q \in T(\tilde{B}, X_2]$ . Hence there is a special connection between  $a_1$  and  $a_2$ . More clearly, in case that  $\{x_1, y_1, w_1, v\}$  is not a clique then  $\{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_1, v, w_1\}, \{w_i, v, w_{i+1}\}_{i=1,..,n-1}, \{x_2, y_2, a_2\}, \{z_i, z_{i+1}, v, w_n\}_{i=1,..,o-1}, \{u, v, z_1\}, \{t_i, t_{i+1}, v, w_n, z_o\}_{i=1,..,p-1}, \{t, v, w_n, t_1\}, \{t', t'_1, t_p, v, w_n, z_o\}, \{t'_i, t'_{i+1}, z_o, z'_q, t_p, v, w_n\}_{i=1,..,r-1}, \{t'_r, t_p, v, w_n, z_o\}$ 

 $z'_q, x_2, y_2, s_1$ ,  $\{t_p, v, w_n, z_o, z'_i, z'_{i+1}\}_{i=1,\dots,q-1}$ ,  $\{t_p, v, w_n, z_o, z'_1, u'\}$  and  $\{s, t'_r, z'_q, t_p, z_o, v, w_n, x_2\}$  are cliques of G.

Observe that there is a special connection: of Type 2 between  $a_1$ ,  $w_2$ ; of Type 1 between  $w_i$ ,  $w_{i+2}$  with  $i \in \{1, ..., n-2\}$ ; and of Type 9 between  $w_{n-1}$  and  $a_2$ ; see Figure 30.

In case that  $\{x_1, y_1, v, w_1\}$  is a clique of G, by the before exposed, there are two vertices  $s'_1, s_2$  in G such that  $\{x_1, y_1, v, w_1, s'_1, s_2\}$  induces an antenna.

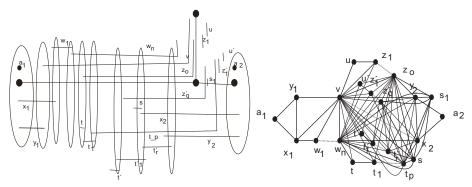

FIGURE 30. Case 1: Type 2 between  $a_1, w_2$ ; Type 1 between  $w_i$ ,  $w_{i+2}$ ; Type 9 between  $w_{n-1}, a_2$ 

**Case 2:**  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \neq \emptyset$  but  $T_{y_2} \cap T_{x_1} = \emptyset$ , or  $T_{x_1} \cap T_{x_2} \cap T_{y_2} \neq \emptyset$  but  $T_{y_1} \cap T_{x_2} = \emptyset$ . By our assumption, there is an edge in  $T[N[a_1], X_2]$  whose label is contained in C. Hence  $T_{x_1} \cap T_{x_2} \cap T_{y_1} = \emptyset$ .

Clearly, there are two paths in G between  $a_1$  and  $a_2$ ;  $P = a_1, x_1, x_2, a_2$ and  $Q = a_1, y_1, v, y_2, a_2$ . On the other hand,  $\{x_1, x_2, y_2, v\}$  is a clique of G. In this situations,  $x_1$  may be in  $lab(e'_1)$ . We know that there is an edge in  $T[Y_1, X_2]$  whose label is contained in C. Let  $\tilde{e} = \tilde{A}\tilde{B}$  be the nearest C with  $\tilde{B} \in T[\tilde{A}, C]$ , and  $m \in lab(\tilde{e})$  such that  $T_m$  is the shortest to  $N[a_3]$  and Dm its leaf in  $T[C, N[a_3]]$ . Observe that m is not v. Moreover  $Dm \neq B'_1$ otherwise  $T' = T - \{e'_1, \tilde{e}\} + \tilde{A}B'_1 + A'_1\tilde{B}$  is a DV-model that can be rooted on  $N[a_3]$ , a contradiction.

On the other hand, we choose  $w_i$  in label of edges in  $T[Y_1, X_2]$  with the Election 1 taken  $A = Y_1$  and  $B = X_2$ . Let  $w_n$  be the last vertex chosen, and  $Dw_n$  be the leaf of  $w_n$  to  $N[a_3]$ . Observe that  $w_n$  may be  $x_1$  or m.

If  $m = x_1$ , let  $X'_1X_1$  be the edge of T with  $X'_1 \in T[X_1, N[a_3]]$ . As  $X_1$  dominates  $\tilde{e}$  it follows by Claim 2 that for all edge  $\bar{e} \in T[C, X'_1] \ lab(\bar{e}) \notin \tilde{B}$ . Then we choose vertices in the label of edges in T[C, X'] through Election 1 with  $A = X'_1$  and B = C such that are not in  $\tilde{B}$ . Let  $z_i$  be these vertices chosen for i = 1, ..., o, and  $z_o$  be the lasted vertex chosen. As in the Case 1, we will analyze if  $Iz_o$  is or not in  $T(\tilde{B}, X_2]$ , and we obtain special connection of Type 4, 5 or 6, taken  $x_1$  instead of  $w_i$  in Case 1. More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{x_1, v, y_1\}$ ,  $\{x_2, y_2, a_2\}$ ,  $\{v, x_1, x_2, y_2, z_o\}$ ,  $\{z_i, z_{i+1}, v, x_1\}_{i=1..., o-1}$ ,  $\{u, v, z_1\}$  and  $\{v, x_1, x_2, t\}$  are cliques of G; so there is a special connection of Type 4 between  $y_1$ ,  $a_2$ , and of Type 1 between  $a_1$ , v; see Figure 31. Or  $\{a_1, x_1, y_1\}$ ,  $\{x_1, v, y_1\}$ ,  $\{x_2, y_2, a_2\}$ ,

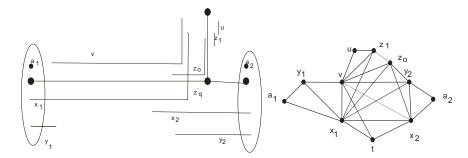

FIGURE 31. Case 2: Type 4 between  $y_1$ ,  $a_2$  and Type 1 between  $a_1$ , v

 $\begin{aligned} &\{z_i, z_{i+1}, v, x_1\}_{i=1,.,o-1}, \{u, v, z_1\}, \{v, x_1, z_o, x_2, t_p, s\}, \{t_p, x_2, y_2, z_o, x_1, v\}, \\ &\{t, x_1, v, t_1\}, \{t_i, t_{i+1}, v, x_1, z_o\}_{i=1,..,p-1} \text{ and } \{v, x_1, x_2, y_2, z_o, s_1\} \text{ are cliques} \\ &\text{of } G; \text{ so there is a special connection of Type 5 between } y_1, a_2 \text{ and of} \\ &\text{Type 1 between } a_1, v. \text{ Or } \{a_1, x_1, y_1\}, \{x_1, v, y_1\}, \{x_2, y_2, a_2\}, \{z_i, z_{i+1}, v, x_1\}_{i=1,..,o-1}, \{u, v, z_1\}, \{t, v, x_1, t_1\}, \{t_i, t_{i+1}, v, x_1, z_o\}_{i=1,..,p-1}, \{t_p, x_2, v, x_1, z_o\} \text{ and } \{v, x_1, x_2, y_2, z_o\} \text{ are cliques of } G; \text{ so there is a special connection of Type 1 between } a_1, v; \text{ see Figure } 32. \end{aligned}$ 

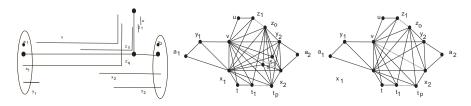

FIGURE 32. Case 2: Type 5 between  $y_1$ ,  $a_2$  and Type 1 between  $a_1$ , v or Type 6 between  $y_1$ ,  $a_2$  and Type 1 between  $a_1$ , v

If  $m = w_n$ , let  $P' = a_1, y_1, w_1, ..., w_n, x_2, a_2$  and  $Q' = a_1, x_1, y_2, a_2$  be paths in G between  $a_1$  and  $a_2$ . Hence there is a special connection of Type 4 or Type 5 or Type 6 between  $w_{n-1}$  and  $a_2$ . More clearly,  $\{a_1, x_1, y_1\}$ ,  $\{w_1, x_1, y_1\}$ ,  $\{w_i, w_{i+1}, x_1\}_{i=1,...,n-1}$ ,  $\{x_2, y_2, a_2\}$ ,  $\{t, x_2, w_n, x_1\}$ ,  $\{z_o, x_1, w_n, x_2, y_2\}$ ,  $\{z_i, z_{i+1}, w_n, x_1\}_{i=1,...,n-1}$  and  $\{z_1, x_1, u\}$  are cliques of G. Or  $\{a_1, x_1, y_1\}$ ,  $\{w_1, x_1, y_1\}$ ,  $\{w_i, w_{i+1}, x_1\}_{i=1,...,n-1}$ ,  $\{x_2, y_2, a_2\}$ ,  $\{t_p, y_2, x_2, z_o, w_n, x_1\}$ ,  $\{x_2, t_p, z_o, s, w_n, x_1\}$ ,  $\{z_o, t_i, t_{i+1}, x_1, w_n\}_{i=1,...,p-1}$ ,  $\{t, w_n, x_1, t_1\}$ ,  $\{z_o, x_1, w_n, x_2, y_2\}$ ,  $\{z_i, z_{i+1}, w_n, x_1\}_{i=1,...,n-1}$  and  $\{z_1, x_1, u\}$  are cliques of G. Or  $\{a_1, x_1, y_1\}$ ,  $\{w_1, x_1, y_1\}$ ,  $\{w_i, w_{i+1}, x_1\}_{i=1,...,n-1}$ ,  $\{x_2, y_2, a_2, \}$ ,  $\{y_2, x_2, z_o, w_n, x_1\}$ ,  $\{x_2, t_p, z_o, w_n, x_1\}$ ,  $\{z_o, t_i, t_{i+1}, x_1, w_n\}_{i=1,...,p-1}$ ,  $\{t, w_n, x_1, t_1\}$ ,  $\{z_i, z_{i+1}, w_n, x_1\}_{i=1,...,n-1}$  and  $\{z_1, x_1, u\}$  are cliques of G; see Figure 33.

If  $m \neq x_1, w_n$ , let  $P' = a_1, y_1, w_1, ..., w_n, x_2, a_2$  and  $Q' = a_1, x_1, y_2, a_2$  be paths in G between  $a_1$  and  $a_2$ . Hence there is a special connection of Type 4 or Type 5 or Type 6 or Type 7 or Type 8 or Type 9 between  $w_{n-1}$  and  $a_2$ considering the analysis of Case 1 when there are another edge contained in C.

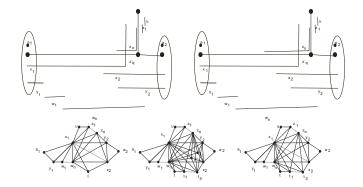

FIGURE 33. Case 2: Type 4 or Type 5 or Type 6 between  $w_{n-1}$ ,  $a_2$  and Type 1 between  $a_1$ ,  $w_1$ 

**Case 3:**  $T_{x_1} \cap T_{x_2} \cap T_{y_1} \cap T_{y_2} \neq \emptyset$ . Clearly, there are two paths in G between  $a_1$  and  $a_2$ . Let  $P = a_1, y_1, y_2, a_2$  and  $Q = a_1, x_1, x_2, a_2$  be paths in G. Also  $\{x_1, y_1, x_2, y_2\}$  is a clique of G. By the existence of an edge  $e \in T[N[a_1], X_2]$  such that  $lab(e) \subset C$ , we have  $x_1 \in C$  and  $y_1 \in C$ . Observe that  $N[a_1]A_1$  has label contained in C, and may have other edge. On the other hand,  $x_1$  and  $y_1$  can not be both vertices of  $lab(e'_1)$  otherwise T' = $T - \{N[a_1]A_1, e'_1\} + N[a_1]B'_1 + A'_1A_1$  is a DV-model of G rooted on  $N[a_3]$ , a contradiction. Hence  $y_1 \notin lab(e'_1)$ , moreover  $y_1 \notin B'_1$ . Let  $Y'_1Y_1 \in E(T)$ be such that  $Y'_1 \in T[Y_1, N[a_3]]$ , and let  $\tilde{e} = AB$  be the closest edge to C dominated by  $Y_1$ . Clearly  $lab(\tilde{e}) \subset C$ . By Claim 2, for all  $e' \in T[C, Y'_1]$ , we have  $lab(e') \not\subseteq B$ . By the before exposed, there are vertices  $z_i \in lab(e') - B$ which were chosen through Election 1, and if  $z_o$  is the last vertex chosen then analyzing where is  $Iz_o$ , we obtain the situations describe in Case 1, i.e there is a special connection of Type 4 or Type 5 or Type 6 taken  $w_n = y_1$  and  $v = x_1$ . More clearly,  $\{a_1, x_1, y_1\}, \{x_2, y_2, a_2, \}, \{t, x_2, y_1, x_1\}, \{t, x_2, y_1, x_2, y_1, x_1\}, \{t, x_2, y_1, x_1$  $\{z_o, x_1, y_1, x_2, y_2\}, \{z_i, z_{i+1}, y_1, x_1\}_{i=1,..,o-1}$  and  $\{z_1, x_1, u\}$  are cliques of  $\begin{array}{l} G. \text{ Or } \{a_1, x_1, y_1\}, \{x_2, y_2, a_2, \}, \{t_p, y_2, x_2, z_o, y_1, x_1\}, \{x_2, t_p, z_o, s, y_1, x_1\}, \\ \end{array}$  $\{z_o, t_i, t_{i+1}, x_1, y_1\}_{i=1,\dots,p-1}, \{t, y_1, x_1, t_1\}, \{z_o, x_1, y_1, x_2, y_2\}, \{z_i, z_{i+1}, y_1, y_1, y_2, y_2\}, \{z_i, z_{i+1}, y_1, y_1, y_2, y_2\}, \{z_i, z_i, y_1, y_2, y_2\}, \{z_i, y_1, y_2, y_2\}, \{z_i, z_i, y_1, y_2, y_2\}, \{z_i, y_2, y_2\}, \{z$  $\{y_2, x_2, z_o, y_1, x_1\}, \{x_2, t_p, z_o, y_1, x_1\}, \{z_o, t_i, t_{i+1}, x_1, y_1\}_{i=1,\dots,p-1}, \{t, y_1, x_1, y_1\}_{i=1,\dots,p-1}, \{t, y_1, x_1, y_1\}_{i=1,\dots,p-1}, \{t, y_1, y_2\}_{i=1,\dots,p-1}, \{t, y_2, y_2\}_{i=1,\dots,p-1}, \{t, y_2, y_2\}_{i=1,\dots,p-1}, \{t, y_2, y_2\}_{i=1,\dots$  $t_1$ ,  $\{z_i, z_{i+1}, y_1, x_1\}_{i=1,\dots,o-1}$  and  $\{z_1, x_1, u\}$  are cliques of G; see Figure 34.

The following Corollary allows us to construct different forbidden induced subgraphs for rooted directed path graphs to those described in [1].

**Corollary 2.** Let G be a DV graph with an asteroidal quadruple  $\{a_1, a_2, a_3, a_4\}$ . If  $a_1, a_2$  and  $a_3, a_4$  are linked by a special connection then G is not an RDV graph.

*Proof.* Let  $Q_{a_i}$  be a clique that contains  $a_i$  for i = 1, 2, 3, 4 and T be a DV-model of G. As  $a_1, a_2, a_3, a_4$  is an asteroidal quadruple then  $T[Q_{a_1}, Q_{a_2}, Q_{a_3}, Q_{a_4}]$  has four leaves. By Theorem 1,  $T(a_1, a_2)$  and  $T(a_3, a_4)$  are directed path then T can not be rooted. Therefore G is not an RDV graph.

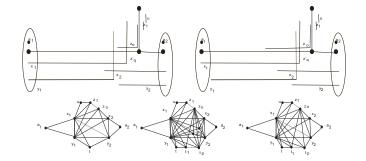

FIGURE 34. Case 3: Type 4 or Type 5 or Type 6 between  $a_1$ ,  $a_2$
