Abstract

We report here the cloning and the characterization of the *Tetrahymena pyriformis* chaperonin-containing-TCP1 theta gene (TpCCT θ), an orthologue of the mouse chaperonin gene CCT θ . TpCCT θ gene is interrupted by eight introns, ranging in size between 91 and 419 nucleotides, and encodes a protein consisting of 540 amino acid residues (59.1 kDa), with a putative pI of 5.73. The amino acid sequence of TpCCT θ reveals 39.4–46.0% identity with the sequences of *Candida albicans* and mouse CCT θ subunits and 28.0–32.6% identity with the other TpCCT subunits known so far. We have studied the expression of this gene in exponentially growing *Tetrahymena* cells and in cells treated with colchicine for different times. The steady-state levels of CCT θ mRNA rapidly decrease in the first 30 min of colchicine treatment. Interestingly, treatment for subsequent 60 min gives expression levels higher than those found in exponentially growing cells. © 1999 Elsevier Science B.V. All rights reserved.

Keywords: CCT0-chaperonin gene; Ciliated protozoan; Gene expression; Colchicine

Inside cells the majority of newly synthesized proteins require a class of proteins, generally designated as molecular chaperones, to achieve their correct three-dimensional structure [1]. One of the most studied classes of the molecular chaperones is the chaperonins, which recognize and bind unfolded polypeptides to prevent premature folding and aggregation [2]. Based on sequence homology chaperonins can be grouped in two subfamilies. The first, Hsp60 family, is represented by GroEL in the eubacterial cytoplasm, Rubisco binding protein in chloroplast and its mitochondrial homologue Hsp60 [3]. The second family is represented by TF55, thermosome and the CCT complex, being found in archaebacteria and eukaryotic cytoplasm, respectively [4-6]. The eukaryotic cytosolic chaperonin, named CCT (Chaperonin Containing TCP-1 (t-complex polypeptide 1)) is a large hetero-oligomeric complex of about 900 kDa, composed of eight different but related polypeptides, namely CCT α , CCT β ...CCT ξ , of apparent molecular mass ranging from 52 to 65 kDa, arranged in two stacked rings. In mouse and yeast the genes encoding the eight CCT-subunit polypeptides have been isolated, whereas several CCT-subunit orthologues were already identified in a variety of organisms ranging from ciliates to human cells [7–9]. Together with co-factors and possibly other components still

remaining to be described, CCT mediates the folding or refolding of tubulins [10,11] and actins [12], and perhaps other unknown proteins. Studies of expression of some of the CCT-subunit genes show that the CCT α is highly expressed in testis [13], embryos of early stages and rapidly growing cells in tissue culture [9,14], suggesting that CCT is involved in cellcycle regulated events. Several studies indicate a relationship between the chaperonin and the cytoskeleton. Analysis of temperature-sensitive mutants of yeast CCT subunits shows abnormal microtubular structures [15] and disruption of actin microfilaments [16]. In yeast, all the CCT-subunit genes are essential and none of them when overexpressed rescues the mutation in any of the other, suggesting that each of the CCT subunits has distinct function. The assumption that tubulin is one of the major substrates of CCT raises the hypothesis that this chaperonin could be a new factor involved in generating MT function diversity. Indeed, microtubules are dynamic polymers that participate in a wide variety of cellular functions, such as cytoskeleton organization, intracellular transport and cell division, as well as flagellar and ciliary movement [17]. MTs are composed of α and β -tubulin heterodimers that constitute their basic structural unit. Tubulins have binding sites for a variety of antimitotic agents as, e.g., colchicine. This agent is known to affect the dynamics of microtubule polymerization both in vitro and in vivo [18,19]. It has been described that colchicine binds to the tubulin heterodimer changing its conformation and in consequence reduces the ability of the tubulin to dissociate from the microtubule end, hence impairing the capacity of the microtubule end to accept additional tubulin heterodimers [18].

In the ciliate *Tetrahymena* three members of the CCT-subunit gene family, namely TpCCT α [20], TpCCT γ [8] and TpCCT η [21], have already been cloned and characterized. These genes exhibit a co-

ordinate response and are up-regulated with the tubulin genes during cilia regeneration and during active cell division, indicating a possible role of these subunits in these processes.

In the present work another member of the *Tetra-hymena* CCT gene family, TpCCT θ , was characterized, and its expression was studied in reciliating cells and cells treated with colchicine at different times.

Degenerate primers were designed taking into account the sequence corresponding to the amino acid sequence conserved among all CCT subunits NGATI (CCTnd) and the specific sequence DDIERAV/IV (CCT8c) present in all CCT0 subunits so far known (CCTnd: 5'-GCCTCTAGAAAYGAYGGTGCYA-CYATY-3' and CCT8c: 5'-CRAYRGCTCTTTC-RATRTCRTC-3'). These primers were used to amplify Tetrahymena pyriformis genomic DNA usingpolymerase chain reaction (PCR) cycling described previously [21]. The PCR products with 0.75 and 1.5 kb were cloned into pUC19 and sequenced. Given that the 1.5 kb product encodes the predicted amino acid sequence sharing a significant similarity with its mouse counterpart [22], the recombinant plasmid was named pCCT05. The fragment cloned in pCCT05 was labelled using the Megaprimer DNA labelling system and [α-³²P]dATP (3000 Ci/mmol) (Amersham) following the manufacturer's instructions, and then used to screen a T. pyriformis Sau 3AI genomic library and followed as essentially described in [8]. The DNA of one of the positive phage, named Tp λ 6CCT θ , was analysed by restriction mapping following by subcloning the restriction fragments into pUC19. In order to sequence these fragments, sequential deletions were generated using a double-stranded Nested Detection kit (Pharmacia). Sequencing was performed on denatured plasmid DNA using a T7 sequencing kit (Pharmacia) according to the supplier's instructions. Sequence analysis was carried out using the GCG package

(1991) (Genetics Computer Group) and the program DNASIS 5.0 (Hitachi-LKB).

Sequence analysis of the TpCCT θ subunit gene has shown that the coding region of this gene is interrupted by eight introns, as shown in Fig. 1. The introns are always flanked by the invariant dinucleotides GT and AG. TpCCT0 introns range in size between 91 and 419 nucleotides, which is similar to that found for the other TpCCT genes so far characterized. However, this gene contains one or two additional introns when compared to those of TpCCT η , TpCCT α and TpCCT γ genes, respectively [20]. The TpCCT θ gene encodes a protein consisting of 540 amino acid residues, with a predicted molecular mass of about 59.1 kDa and a putative pI of 5.73. The predicted TpCCT θ polypeptide has an identical size to CCT0 subunits from distinct organisms so far studied (Tp 540, Sc 568, Sp 546, Ca 546, Mm 548 and Hh 548) with the exception for Saccharomyces cerevisiae CCT0 subunit, which has 28 extra amino acid residues. The amino acid sequence comparison among CCT θ subunits from different species reveals a high degree of sequence similarity: 68.7% with S. cerevisiae (P47079), 68.8% with Schizosaccharomyces pombe (P78921), 63.8% with Candida albicans (P47828) and 69.9% with mouse and humans [22]; and a lower degree of sequence identity, with 41.9%, 42.3%, 39.4% and 46.0%, respectively. When this type of analysis is limited to Tetrahymena CCT subunits the degree of sequence identity and similarity decreases. Indeed a similarity of 56.9%, 55.3% and 53.2% was obtained when compared with the CCT α , CCT γ and CCT η subunits, whereas the identity values were 32.6%, 28.0% and 29.1%, respectively. These results support the idea that although the different CCT subunits are structurally related, they are more conserved interspecies than between intraspecies. Fig. 2 shows the alignment of the predicted amino acid sequence of *Tetrahymena* TpCCT θ and those of known CCT0 subunits from other organisms. This alignment reveals three conserved regions between all CCT subunits, as well as with other members of the chaperonin family [14]: the motifs TNDGATIL (TSDAATIM) (positions 64–71), GDGTTSV (GDATNLV) (positions 95-102) and V(P/A)GGG (AAGAG) (positions 408-412). Interestingly, a highly conserved region DDIER-AIDDGVN (positions 385–396) that is not shared

by the other CCT subunits and seems to be exclusively present in CCT θ subunits. It is possible that this sequence may be associated to a specific function of the CCT θ subunits inside the hetero-oligomeric complex of the chaperonins.

Previously we were able to show that T. pyriformis contains the hetero-oligomeric complex CCT and to assign in the two-dimensional (2-D) gel, using a set of polyclonal antibodies, the protein spots to the CCT α , CCT β , CCT γ and CCT η [20]. In order to identify the CCT θ subunit in the 2-D gel, we have compared the putative pI values of the distinct TpCCT subunits so far known (see Table 1). Taking into account these results it is plausible to propose that spot P6 in the 2-D gel of *Tetrahymena* CCT (see Fig. 3) corresponds to TpCCT θ and CCT ε is P5 as it has the most acidic pI. Moreover, Soares et al. [24] have observed that UM-1 antibody strongly recognize Hsp60, TpCCTβ, TpCCTγ, TpCCTη and P5, whereas TpCCTa, P6 and P7 spots were weakly recognized. In fact, UM-1 antibody was prepared against the chaperonin consensus motif which is highly conserved between all chaperonin sequences, that seems to be involved in ATP binding and hydrolysis [23]. When a comparison between the amino acid sequence used to produce the UM-1 antibody (QDDEVGDGTTSVV) and the corresponding sequence in TpCCT0 (QENECGDATNLVI) was done, we observe that these sequences only share six identical amino acids residues out of 13. This poor similarity can explain the weak signal for spot P6 (only visible after longer exposures) obtained when UM-1 antibody is used. It is worthwhile noting that CCT θ from mouse testis is also weakly recognized by UM-1 antibody [23], a fact that reinforces the idea that the UM1 antibody has different affinities for the distinct CCT subunits.

Total cytoplasmic RNAs from exponentially growing cells, cells recovering their cilia and cells treated with colchicine (4 mg/ml) at different times were ex-

Fig. 2. Alignment and comparison of *Tetrahymena* TpCCT θ deduced amino acid sequence with CCT θ from other species. The deduced amino acid sequence of the *T. pyriformis* CCT θ polypeptide was aligned and compared with those of CCT θ from other organisms (accession numbers in the EMBL database are indicated): *Saccharomyces cerevisiae* (ScCCT θ – P47079), *Schizosaccharomyces pombe* (SpCCT θ – P78921), *Candida albicans* (CaCCT θ – P47828), *Mus musculus* (MmCCC θ – P42932) and *Homo sapiens* (HsCCT θ – P50990). Gaps have been inserted when required to maximize the alignment and are represented by dots. Sequences conserved between almost all chaperonins, including the traditional chaperonins, are underlined. Sequence exclusively conserved between CCT θ subunit is double-underlined.

tracted from *T. pyriformis* cells as reported by Soares et al. [24]. RNAs were subjected to Northern blot analysis as described by Sambrook et al. [25] and the membranes were incubated with pCCT θ 5 1.5 kb fragment as probe in RNA hybridization buffer at 35°C [21]. The results show that TpCCT θ is expressed coordinately with the other TpCCT subunit genes (TpCCT α , TpCCT γ and TpCCT η) as well as

Fig. 3. Two-dimensional isoelectric focusing (IEF) and SDS– PAGE analysis of *Tetrahymena* CCT from exponentially growing cells. Protein extracts containing CCT particles isolated from exponentially growing *Tetrahymena* cells by sucrose-gradient fractionation followed by ATP-affinity column chromatography were resolved by two-dimensional electrophoresis and detected by silver staining. The subunits TpCCT α , TpCCT η , TpCCT γ and TpCCT β where identified as described in [20].

with tubulin genes during cilia regeneration (results not shown) [8,20,21]. These results indicate that at least these four subunits are required for the function of the chaperonin during the biogenesis of the new cilia. We have also studied the expression of TpCCT θ in cells treated with a microtubule depolymerizing agent, colchicine (4 mg/ml). Results in Fig. 4a illustrate the hybridization pattern of the mRNA levels from exponentially growing cells and cells treated for different times with colchicine. As one can observe, TpCCT θ produces a unique transcript with about 2.1 kb during the whole period of colchi-

Fig. 4. TpCCT θ mRNA levels in *Tetrahymena* cells treated with colchicine. Total cytoplasmic RNA (30 µg) from exponentially growing cells (lane 1) and from cells treated with colchicine (final concentration 4 mg/ml) after 15 min (lane 2), 30 min (lane 3), 60 min (lane 4) and 90 min (lane 5), was analysed in 1.5% agarose formaldehyde gels, transferred onto nitrocellulose filters and hybridized (a) with pCCT θ 5 1.5 kb fragment as probe and (b) with the 239 bp *PstI–SphI* DNA fragment from pTU11 [26].

cine treatment, as well as in control cells. The amount of the steady-state population of the CCT θ mRNA decreases rapidly until 30 min of colchicine treatment as compared to control cells. However, the amount of the steady-state population of this transcript significantly increases after 60 min, reaching levels higher than those found in exponentially growing cells for up to 90 min of drug treatment. Densitometric quantification of the relevant bands indicates a 1.3- and 3.5-fold increase of the levels at 60 and 90 min of treated cells, respectively, compared to exponentially growing cells. As a loading and hybridization control we used the 239 bp PstI-SphI DNA fragment isolated from the ubiquitin fusion gene as probe in the same RNA blot [26]. The results obtained (Fig. 4b) show that the respective mRNA levels do not change during colchicine treatment.

The fact that colchicine binds specifically to the tubulin heterodimer, modifying the exchange rate of tubulin at microtubule ends, suggests that the TpCCT θ gene is able to change its pattern of expression in response to an alteration of microtubule polymerization. Experiments are in progress with the aim of elucidating the potential meaning of the colchicine effect.
