# Correction: Improved Methodical Approach for Quantitative BRET Analysis of G Protein Coupled Receptor Dimerization

Bence Szalai, Péter Hoffmann, Susanne Prokop, László Erdélyi, Péter Várnai, László Hunyady

Some technical errors occurred during preparation of the plots for [S2 Fig](#). The plots for the main figures of the paper were prepared using a value of 1.2 a.u. as the threshold to separate the high (blue) and low (red) luminescence points. Due to an error, most of the plots in [S2 Fig](#) were created using an incorrect value of 1.25 a.u. as the high/low threshold. The Fluorescence/BRET ratio plot of the  $V_2R$ -RLuc +  $\beta_2$ AdR-Venus plot in [S2 Fig](#) was created using an incorrect value of 1.0 a.u. as the high/low threshold.

Additionally, the underlying raw data set deposited to GitHub had a cut off of 2.0 a.u., which is a limited set of data for the  $V_2R$ -RLuc/ $V_2R$ -Venus and  $V_2R$ -RLuc/ $\beta_2$ AdR-Venus interactions. The original plots were generated with a maximum Fluorescence axis cut off of 2.1 a.u., which is also a limited set of data for the  $V_2R$ -RLuc/ $V_2R$ -Venus and  $V_2R$ -RLuc/ $\beta_2$ AdR-Venus interactions. The authors confirm that when the full set of data is used, changes in the luminescence threshold do not affect the conclusion that the interactions between the  $V_2R$ -RLuc and  $\beta_2$ AdR-Venus are not significant, while the evidence indicates homodimerization of  $V_2$  receptors.

The authors apologise for the errors, and here we provide a revised [Fig 4](#) created using the full data set, with a Fluorescence axis of 0–3.0 a.u.. We also provide a revised [S2 Fig](#) in which plots were created using the full data set, with Fluorescence axes extended to 3.0 a.u. where necessary and using a high/low luminescence threshold of 1.2 a.u.. In all revised plots, the regression line is forced through the origin.

**Fig 4. Dimerization of  $V_2$  vasopressin receptor and CaSR calcium sensing receptor with various other GPCRs.** HEK293 cells were transiently transfected with increasing amounts of  $V_2$ R-RLuc (A and B) or CaSR-RLuc (C) and with increasing amounts of either  $AT_1$ R-Venus,  $AT_2$ R-Venus,  $\beta_2$ AdR-Venus, CaSR-Venus,  $CB_1$ R-Venus or  $V_2$ R-Venus. Various amounts of empty pcDNA3.1 plasmid was added to maintain constant total transfected plasmid amount. Total luminescence and Venus fluorescence were measured at the beginning of each experiment. BRET ratio was calculated as  $Emission_{530}/Emission_{485}$ , and was plotted as a function of measured fluorescence. (A) Representative Type I plots for  $V_2$ R- $\beta_2$ AdR interaction (left plot) and  $V_2$ R- $V_2$ R interaction (right plot). Measured points were sorted into low/high luminescence groups based on the total measured luminescence (S2 Fig). (B and C) The slope of linear regression was calculated for the low and high luminescence groups of different GPCR pairs, and was plotted as a column diagram. Difference between the slopes of linear regression was determined by ANCOVA.  $n = 3-8$ .

doi:10.1371/journal.pone.0156824.g001

Performing the statistical analysis by forcing the regression line through the origin resulted in the p values shown in S1 Table.

New ANOVA analyses were also performed. The “slope” for each data point was obtained by calculating BRET ratio / Fluorescence. The average slope for high and low luminescence groups was calculated, and a two-way ANOVA was performed using these data. Our results are shown in S3 Fig. This alternative analysis also confirmed our previous results (homodimerization of  $V_2$ R and CaSR, and absence of dimerization between the investigated heterodimers).

The full data set and the R script for statistical analysis have been deposited to GitHub as file GPCR2.dat and statistics.R (<https://github.com/bence-szalai/Improved-methodical-approach-for-quantitative-BRET-analysis-of-G-protein-coupled-receptor-dimerizati>).

## Supporting Information

**S1 Table. Calculated p values for the difference between the slopes for high/low luminescence points.**

(DOCX)

**S2 Fig. Fluorescence-Luminescence, Type I and Type II plots of GPCR dimerization experiments: HEK293 cells were transfected with various amounts of different donor and acceptor coding plasmids.** Measured points were sorted into low/high luminescence groups based on the total measured luminescence (red: low luminescence, blue: high luminescence). Fluorescence-Luminescence (left), Fluorescence-BRET ratio (middle) and Intensity ratio-BRET ratio (right) plots were created for different donor-acceptor pairs. Summary of this plot can be found in [Fig 4B and 4C](#).

(PDF)

**S3 Fig. Analysis of the dimerization of V<sub>2</sub> vasopressin and CaSR calcium sensing receptor with various other GPCRs using ANOVA.** For each data point BRET ratio / Fluorescence ratio was calculated. Two-way ANOVA was performed (acceptor receptor and high/low luminescence as the two factors) with Bonferroni post hoc test on these data to evaluate the effect of high/low luminescence of BRET ratio / Fluorescence. Data are plotted as mean +/- S.E.M. \*\*\*: p<0.001
