Ligand exchange reactions have been used for the synthesis of metallacyclic complexes of Ni and Pd of the type [ $\mathrm{M} \Gamma\left(\mathrm{CH}_{2} \mathrm{CMe}_{2}-\mathrm{O}-\mathrm{C}_{6} \mathrm{H}_{4}\right)(\mathrm{P}-\mathrm{N})$ ], where $\mathrm{P}-\mathrm{N}$ is the phosphinito-imine ligand $\mathrm{P}(\mathrm{iPr}) 2 \mathrm{OC}(\mathrm{Me}) \mathrm{N}(2,6-\mathrm{C} 6 \mathrm{H} 3(\mathrm{iPr}) 2$. The protic acid [H(OEt2)(BAr'4)] (Ar' = 3,5-C6H3(CF3)2) selectively cleaves one of the two $\sigma$ metal-carbon bonds, affording cationic monoalkyl complexes. Nickel monoalkyls stabilized with Et2O or MeCN ligands are thermally unstable and spontaneously undergo a decomposition process that ultimately leads to the breakdown of the phosphinito-imine ligand. In contrast, cationic alkylpalladium derivatives are thermally very stable, allowing the isolation of a formally unsaturated monoalkyl complex stabilized by an intramolecular $\pi$-arene interaction. Although monoalkynickel and -palladium phosphinitoimine derivatives are inactive as ethylene polymerization or copolymerization catalysts, they readily experience migratory insertion reactions. A palladium chelate arising from the successive insertion of CO and ethylene has been isolated and characterized.

## Introduction

The last two decades have witnessed a sustained interest in late transition metal catalysts for olefin oligomerization, polymerization and copolymerization.1-8 In the quest for finding successful ligand/metal combinations, a large number of chelating ligands containing sets of different donor atoms have been investigated.6,9-13 Some of these hybrid ligands have found important industrial applications, for instance the phosphinoenolates ([P,O] donors) used in the SHOP process.14-16 Combining two different donor atoms in a single ligand greatly expands the variety of catalyst structures available at a low synthetic cost and, at the same time, it offers the possibility of bringing together desirable features found in different types of catalysts. For example, Brookhart's nickel ethylene polymerization catalysts containing $\alpha$ diimine nitrogen ligands7 are very active but have low thermal stability and are quite sensitive to impurities, while nickel phosphinoenolates are exceptionally robust oligomerization
catalysts. A ligand design combining key features of phosphinoenolates and $\alpha$-diimines should produce a very active and stable polymerization catalyst. This seemingly ingenuous reasoning proves true in some cases; shortly after the discovery of $\alpha$-diimine catalysts, Grubbs reported that nickel salicylaldiminate-based complexes containing imine and anionic phenolate fragments are very active olefin polymerization catalysts that tolerate polar impurities and can incorporate some types of functional monomers.17-19 These catalysts can perform ethylene polymerization even in aqueous emulsion, which undoubtedly constitutes an impressive achievement for a Ziegler-Natta related catalyst. 20 Following the same line of thought, a large number of $[P, N]$ ligands have been screened, with the aim of combining the exceptional properties of imine-based polymerization catalysts with the well-known stability of late transition metal phosphine complexes. Thus, nickel complexes with [P,N] ligands bearing bulky N -arylimino groups (phosphine-imine ligands) are very stable catalysts, which perform steadily at temperatures above $60^{\circ} \mathrm{C}$ producing polyethylenes or heavy oligomer mixtures. $21-23$ Other nickel complexes with different $[P, N]$ ligand designs containing nitrogen heterocycles as donor fragments, are very active ethylene oligomerization catalysts which produce mainly butenes and hexenes.24-33

Nickel catalysts with $[\mathrm{P}, \mathrm{N}]$ ligands are usually generated from simple halide complexes by activation with organoaluminium derivatives. The choice of the co-catalyst (e.g., AIEtCl2, AlEt2Cl or alumoxane derivatives), 23,27 and the catalyst/cocatalyst ratio are critical parameters which determine their activity and selectivity. In contrast, activation of the corresponding palladium complexes using aluminium cocatalysts appears to be inefficient, therefore they have seldom been reported.22,34 Very likely, one of the main causes for the dramatic influence of organoaluminium cocatalysts in these systems is their ability to attack sensitive organic functionalities present in the ligands. 27 For example, they can remove acidic H atoms23 from enolizable $[\mathrm{P}, \mathrm{N}]$ ligands, 22,31 which leads to the formation of electrically neutral species. This is supported by the independent synthesis and isolation of complexes of anionic $[P, N]$ enolates.35-37 Consequently, it has been shown that the activity and selectivity of the catalysts based on $[P, N]$ ligands improves when these are non-enolizable. 23 Another strategy to overcome problems associated to co-catalysts is to replace halide catalyst/aluminium cocatalyst systems by well-defined $\sigma$-alkyl complexes that do not require activation by organoaluminium compounds.38,39 A number of palladium methyl derivatives of the type $\left[\mathrm{Pd}(\mathrm{Me})\left(\mathrm{L}^{\prime}\right)(\mathrm{P}-\mathrm{N})\right]+$ have been reported (where $\mathrm{L}^{\prime}$ is a weakly coordinating ligand, usually MeCN ) which oligomerize ethylene21,23,25,32,33,40-42 or copolymerize olefins and CO without cocatalysts.42-45 Although these systems are only moderately active, they provide a wealth of information on the mechanism of polymerization and copolymerization reactions, because they enabled the isolation of stable products arising from the migratory insertion of olefins and/or CO into the $\mathrm{Pd}-\mathrm{CH} 3$ bond.23,41-48 These compounds can undergo unusual but potentially very interesting processes, such as the insertion of polar monomers. $43,46,47$ Therefore, it is rather surprising that analogous $\sigma$-alkyl or aryl complexes of nickel stabilized with $[P, N]$ ligands have received very little attention as single-component catalysts. A few neutral $\sigma$-organonickel derivatives with anionic $[P, N]$ ligands have been tested for this purpose, but in general they showed low catalytic activity.35,49-53

We recently described a series of Ni and Pd complexes bearing phosphinito-imines, a new type of non-enolizable [P,N] ligand that can be readily obtained from amides RCONHAr and chlorophosphines CIPR2.54 Similarly to related phosphine-imine complexes, Ni phosphinitoimine derivatives have become very active catalysts in the presence of organoaluminium cocatalysts (MMAO, ClAIEt2), while the corresponding Pd derivatives are inactive. Nickel catalysts produce mainly butenes with minor amounts of hexenes and octenes, which is surprising considering that these compounds are structurally analogous to phosphine-imine complexes that are ethylene polymerization catalysts. These results encouraged us to continue our work, synthesizing $\sigma$-alkyl complexes of Ni and Pd with phosphinito-imine ligands, which could undergo migratory insertion reactions into the metal-carbon bond, and possibly catalyze ethylene polymerization and/or copolymerization with carbon monoxide. For this purpose we resorted to facile ligand displacement reactions from the metallacycle complexes [ M $\left.\left(\mathrm{CH}_{2} \mathrm{CMe}_{2}-\mathrm{o}-\mathrm{C}_{6} 7 \mathrm{H}_{4}\right)\left(\mathrm{L}_{2}\right)\right](\mathrm{M}=\mathrm{Ni}, \mathrm{L}=$ pyridine (Py), 1a;55 M = Pd, L2 = 2,6-cyclooctadiene (cod), 1b56). These are very convenient precursors, significantly more stable than analogous openchain dialkyl derivatives and readily prepared from simple starting materials.

## Results and discussion

## Synthesis of metallacyclic complexes

Phosphinito-imine ligands can be readily generated in situ as described previously. 54 As shown in Scheme 1, ligand 2 is obtained by deprotonating N -(2,6-diisopropylphenyl)acetamide with n BuLi, followed by treatment with chlorodiisopropylphosphine at $-78{ }^{\circ} \mathrm{C}$. The latter reaction produces 2 along with its phosphinoamide tautomer, $2^{\prime}$. Since the metallacycle fragment contained in the precursors 1 is not symmetric, it was foreseen that their reaction with the 2 , $2^{\prime}$ mixture could produce up to four isomeric products. However treatment of the precursor nickel complex 1a with $2 / 2^{\prime}$ cleanly affords only two products, 3 a and $3 a^{\prime}$, characterized by sharp 31P signals at $\delta 188.2$ and 185.9 ppm . The positions of these signals are not far from that of the complex [ $\mathrm{NiBr} 2(2)]$ ( 178.0 ppm ), indicating that both 3 a and $3 \mathrm{a}^{\prime}$ incorporate the ligand as the phosphinito-imine tautomer. 54 Hence, the phosphinoamide tautomer 2' rearranges upon coordination to the Ni center, as observed previously in the synthesis of [ $\mathrm{NiBr} 2(2)]$. Their 1 H and 13C NMR spectra show that 3 a and $3 \mathrm{a}^{\prime}$ are cis/trans isomers

Monitoring the ligand exchange reaction by 31P NMR shows that the initial $3 a / 3 a^{\prime}$ ratio is somewhat variable, ranging from ca. 1:1 to almost $3: 1$, depending on the experiment. Pure samples of the major isomer, 3a, can be isolated by careful recrystallization of the reaction mixture. Isomer 3a does not convert into $3 a^{\prime}$ in solution at room temperature, therefore any conformational exchange is necessarily slow. In the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum of 3 a the characteristic signal of the metallacyclic CH 2 at $\delta 57.5 \mathrm{ppm}$ is split into a doublet with $2 \mathrm{JCP}=72 \mathrm{~Hz}$, while the coupling of the nickel-bound aromatic carbon ( 171.9 ppm ) is only 8 Hz . This is a clear indication that the CH 2 group is trans to the phosphorus atom. The second isomer, $3 \mathrm{a}^{\prime}$, was characterized as a mixture with 3a. As expected, the 13C resonances for the metal-bound carbons display the opposite carbon-phosphorus coupling pattern, with the larger coupling constant ( 98 Hz ) corresponding to the quaternary aryl atom. In contrast with the conformational stability of 3a and $3 a^{\prime}$, it was shown that the dihalide complex [ $\left.\mathrm{NiBr} 2(2)\right]$ undergoes a fluxional process involving a tetrahedral, high-spin intermediate with a barrier of only 12.1 kcal mol -1.54 For 3a
and $3 a^{\prime}$, conformational inversion through a tetrahedral isomer is much more difficult because such intermediate is destabilized by the strongly $\sigma$-bound carbon ligand.

The reaction of the palladium metallacycle 1 b with $2 / 2^{\prime}$ produces a mixture of three products, originating resonances at $\delta 180.6,175.6$ and 110.8 ppm in the $31 \mathrm{P}\{1 \mathrm{H}\}$ NMR spectrum. The first two signals are in the same region as those of the phosphinito-imine complexes $3 \mathrm{a} / 3 \mathrm{a}^{\prime}$, therefore they can be assigned to the corresponding cis/trans pair of palladium metallacycles $3 b / 3 b^{\prime}$. In most experiments, these are formed in an approximately constant 1.8:1 ratio. The amount of the third component, 4 , varies widely from one experiment to another. Careful recrystallization of the mixture from hexane at $-30^{\circ} \mathrm{C}$ produced fractions of yellow and colorless crystals. The former contain isomers $3 \mathrm{~b} / 3 \mathrm{~b}^{\prime}$, and the latter correspond to pure compound 4. As expected, the NMR spectra of $3 b / 3 b^{\prime}$ closely resemble those of $3 a / 3 a^{\prime}$. Similarly to their nickel analogues, the isomer with the higher field 31P resonance, 3b, corresponds to the isomer in which the CH 2 group is placed in trans to P , as deduced from the 2 JCP coupling constants measured in the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum. Although 3 b and $3 \mathrm{~b}^{\prime}$ could not be fully separated by fractional crystallization, samples with different isomer ratios were obtained that are stable in solution at room temperature. Thus, cis/trans exchange of the palladium phosphinito-imine metallacycles is also very slow or does not take place at room temperature.

The shielding of the 31P signal of 4 relative to those of $3 \mathrm{~b} / 3 \mathrm{~b}^{\prime}$ parallels the relationship between the chemical shifts of the free compound $2^{\prime}(90 \mathrm{ppm})$ with regard to $2(139 \mathrm{ppm})$. This strongly suggests that compound 4 contains phosphinoamide ligand instead of phosphinito-imine. In addition, the resonance due to the quaternary carbon atom of the 2,6diisopropylphenyl in the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum of 4 shows a carbon-phosphorus coupling of 6 Hz that is not observed in the spectra of phosphinito-imine complexes. This coupling, also observed in related complexes, 57 points out the proximity of the nitrogen-bound carbon and the 31P nuclei and therefore can be regarded as a fingerprint for the phosphinoamide structure.

The 1 H and $13 \mathrm{C}\{1 \mathrm{H}\}$ spectra of 4 show the characteristic signals of the metallacyclic fragment. The carbon resonances for the Pd-bound CH 2 and quaternary aromatic carbon appear as doublets with respectively small $(4 \mathrm{~Hz})$ and large ( 123 Hz ) 2 JCP coupling constants, consistent with the CH 2 and PR2 occupying mutually cis positions. This arrangement reflects the thermodynamic preference to place the weak $\sigma$-donor carbonyl group in trans to the CH 2 , which has a significantly stronger trans influence than the aryl group (antisymbiotic effect).58,59

The reaction of 1 b with $2 / 2^{\prime}$ is so far the only case in which we observed the coordination of phosphinito-imine and phosphinoamide tautomers. In this system, the phosphinito-imine is thermodynamically favored over the phosphinoamide, and therefore it is not surprising that the phosphinoamide ligand of 4 rearranges readily to phosphinito-imine. Such conversion is driven to completion when 4 is heated in THF solution at $60^{\circ} \mathrm{C}$ for 5 h . Thus, the synthesis of the phosphinito-imine complexes $3 \mathrm{~b} / 3 \mathrm{~b}^{\prime}$ is best accomplished by heating the reaction mixture obtained from 1 b and 2 once the ligand exchange has taken place, as described in the Experimental section. Interestingly, the $3 \mathrm{~b} / 3 \mathrm{~b}^{\prime}$ ratio obtained is always close to $1.8: 1$, which suggests that 3 b is slightly thermodynamically favored over $3 \mathrm{~b}^{\prime}$.

The identities of the Pd complexes $3 \mathrm{~b}, 3 \mathrm{~b}^{\prime}$ and 4 were confirmed on the basis of X-ray diffraction studies (Fig. 1-3). The structures of the phosphinito-imine complexes were determined from a single crystal containing $3 b / 3 b^{\prime}$ isomers in 1:1 ratio. The three complexes exhibit slightly distorted square-planar structures. The metallacyclic fragment exhibits an "open envelope" folded conformation, also observed in related Pd cyclometallated neophyl derivatives. 56 It is interesting to compare the lengths of the Pd-C bonds in the three complexes, since they reflect the different trans influence of the $\mathrm{P}, \mathrm{N}$ and O donor atoms. Thus, on going from $3 b$ to $3 b^{\prime}$ the $\mathrm{Pd}-\mathrm{CH} 2$ bond contracts from 2.081(3) Å to 2.049(3) $\AA$, whilst the $\mathrm{Pd}-\mathrm{C}($ aryl) elongates from $2.008(3)$ to $2.076(3) \AA$, due to the stronger $\sigma$-donor capacity of $P$ compared to N. However, this trend cannot be directly translated to the structure of 4 . In this compound the $\mathrm{Pd}-\mathrm{C}\left(\right.$ aryl) bond is 2.0241 (13) $\AA$, significantly shorter than in $3 \mathrm{~b}^{\prime}$, where the aryl group is also trans to the $P$ donor. On the other hand, the $\mathrm{Pd}-\mathrm{CH} 2$ bond length is nearly the same in both compounds, even though the imine group sitting in the trans position in $3 b^{\prime}$ is a better $\sigma$-donor than the carbonyl of 4 . This is probably due to the existence of significant steric repulsions between the close-by aryl fragments in $3 b^{\prime}$, which are absent from 4 or 3 b . In $3 \mathrm{~b}^{\prime}$ these repulsions weaken the $\mathrm{Pd}-\mathrm{C}($ aryl) bond, but reinforce the other $\mathrm{Pd}-\mathrm{C}$ interaction by a compensating effect. In line with this argument, the average of both Pd-C bonds decreases in the order $3 b(2.061 A \circ)>3 b^{\prime}(2.046 \AA)>4(2.033 \AA)$, which suggests that the phosphinito-imine binds somewhat more strongly in $3 b$ than in $3 b^{\prime}$, while the phosphinoamide is a weaker ligand than phosphinito-imine, in spite of the steric effects. The almost strict planarity of the $[P, N]$ chelate in $3 b$ and $3 b^{\prime}$ also suggests higher overall stability than the cycle formed by the $[P, O]$ ligand in 4 , which is puckered with a $\mathrm{Pd}-\mathrm{P}-\mathrm{N}-\mathrm{C} 12$ torsion angle of $10.1^{\circ}$.

## Protonation of metallacyclic complexes

Previous studies showed that protic acids selectively cleave the metal-aryl bond of nickel and palladium complexes containing the metallacyclic fragment $M \Gamma\left(\mathrm{CH}_{2} \mathrm{CMe}_{2}-\mathrm{O}-\mathrm{C}_{6} \mathrm{H}_{4}\right)$, such as 3a or 3b, to afford the corresponding neophyl complexes.56,60 Reactive species with an open coordination site can be generated by using acids containing low coordination-capability anions, such as the tetraarylborate [H(OEt)2]+[BAr'4]- ( $\left.\mathrm{Ar}^{\prime}=3,5-\mathrm{C} 6 \mathrm{H} 3(\mathrm{CF} 3) 2\right) .61,62$ As shown in Scheme 2, protonation of isomeric mixtures of phosphinito-imine complexes with [ $\mathrm{H}(\mathrm{OEt}) 2]+[\mathrm{BAr}$ '4]- proceeds cleanly under various conditions, affording cationic products that invariably exist as single isomers. This indicates that, in contrast with the parent metallacycles, these cationic monoalkyls isomerize readily to the thermodynamically favored isomer.

Treatment of the nickel metallacycles 3a/3a' with [H(OEt)2]+[BAr'4]- produces a thermally unstable complex, 5 , which can be isolated as a yellow precipitate when the reaction is carried out in hexane at $-78{ }^{\circ} \mathrm{C}$. Its $31 \mathrm{P}\{1 \mathrm{H}\}$ spectrum, recorded in CD 2 Cl 2 at $-40^{\circ} \mathrm{C}$, shows a single resonance at $\delta 193.4 \mathrm{ppm}$ consistent with the presence of the phosphinito-imine ligand. The 1 H and $13 \mathrm{C}\{1 \mathrm{H}\}$ spectra show signals corresponding to a coordinated molecule of diethyl ether, probably occupying the position trans to the phosphinito group. These signals are broad even at $-80^{\circ} \mathrm{C}$, suggesting that the ether ligand is extremely labile, and experiences rapid intermolecular exchange. The fluxional process is responsible for the broadening of other signals in the spectrum, which prevents the unambiguous identification of the resonances
corresponding to the nickel-bound CH 2 group. At $0^{\circ} \mathrm{C}$, the NMR spectra undergo irreversible changes due to the decomposition of the complex. In the $31 \mathrm{P}\{1 \mathrm{H}\}$ spectrum, the characteristic signal of 5 is cleanly replaced by a sharp resonance at $\delta 24 \mathrm{ppm}$. This splits into a doublet with a large coupling constant of 451 Hz when proton decoupling is turned off, denoting the presence of a hydrogen atom directly bound to P . The corresponding proton resonance is observed in the 1 H spectrum as a wide doublet signal at $\delta 5.07 \mathrm{ppm}$, which is in good agreement with data reported for tertiary phosphonium salts. 63 On the basis of its 1 H and $13 \mathrm{C}\{1 \mathrm{H}\}$ spectra, this decomposition product was identified as the cation [HP(CH2CMe2Ph)(iPr2)]+. The assignment was confirmed by comparison of its NMR data (31P, 1 H and 13 C ) with those of an authentic sample of the corresponding phosphonium tetrafluoroborate salt prepared by an independent method (see Experimental). Since no other decomposition products were detected,64 it is difficult to propose a mechanism for the breakdown process. However, very likely it involves the reductive C-P coupling of the phosphinite group and the alkyl chain as the initial stage.

Protonation of the palladium metallacycles $3 \mathrm{~b} / 3 \mathrm{~b}^{\prime}$ with $[\mathrm{H}(\mathrm{OEt}) 2]+\left[\mathrm{BAr} \mathrm{r}^{\prime} 4\right]$ - leads to compound 6 , which, in contrast with 5 , is thermally stable in solution and resists exposure to air in the solid state for prolonged periods of time. The $31 \mathrm{P}\{1 \mathrm{H}\}, 1 \mathrm{H}$ and $13 \mathrm{C}\{1 \mathrm{H}\}$ NMR spectra of 6 clearly indicate the presence of the phosphinito-imine ligand and the palladium-bound alkyl fragment, but not diethyl ether nor any other auxiliary ligand. The CH2 group bound to Pd gives rise to a doublet at $\delta 16.6 \mathrm{ppm}$ in the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum with $2 \mathrm{JPC}=7 \mathrm{~Hz}$. The small value of the coupling constant denotes the cis arrangement of the strongly $\sigma$-donor phosphinito and alkyl ligands, as demanded by the antisymbiotic effect.61,62 Since the existence of a coordinative unsaturation of the Pd center would not be consistent with the robustness of the complex, it can be concluded that the metal center is stabilized by an intramolecular metalarene $\pi$ interaction. Such interaction is not rare for $\mathrm{Pd}(I I)$ complexes.65-69 We reported before several examples of apparently unsaturated neophylpalladium complexes which exhibit intramolecular $\pi, \eta 1$ or $\pi, \eta 2$ coordination of the phenyl group. 61,62 Arene $\pi$-coordination is bespoken by the upfield shift of the 13C resonances of the aromatic carbon atoms involved in the interaction. Although the resonance corresponding to the ipso carbon of the phenyl group is obscured by other signals in the densely populated aromatic region of the 13C spectrum, a signal at $\delta 119.4 \mathrm{ppm}$ was unambiguously assigned to the ortho CH groups on the basis of the 1 H and the $1 \mathrm{H}-13 \mathrm{C}$ HSQC heterocorrelation spectra. This signal is shifted by ca. 12 ppm to higher field from its normal position in neophyl derivatives. The chemical equivalence of the ortho and ortho' carbon atoms is maintained down to $-75^{\circ} \mathrm{C}$, indicating that this $\pi$ interaction is either symmetrical or that the Pd atom undergoes shifts between both ortho positions with a very low energy barrier.

The electrospray ionization (ESI) mass spectrum of 6 recorded from a diethylether solution is dominated by an intense signal for the cation molecular ion ( $\mathrm{m} / \mathrm{z}=574$ ) with the correct isotope pattern (Fig. 4). When this ion is isolated in the ion-trap analyzer and subsequently subjected to chemically induced fragmentation (CID), new peaks are observed with $\mathrm{m} / \mathrm{z}=518$ and 440 . These can be attributed to the successive neutral losses of isobutene ( $\mathrm{m}=44$ ) and benzene ( $m=78$ ). Although 6 is indefinitely stable in condensed phase, the fragmentation pattern is strongly reminiscent of the spontaneous decomposition that the related neophyl derivative $[\mathrm{Pd}(\sigma: \pi-\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(\mathrm{dmpe})]+$ undergoes in solution. This process involves the
formation of anstable phenylpalladium species via $\beta$-phenyl elimination, the inverse of migratory insertion.

In agreement with the solution NMR data, the crystal structure of compound 6 (Fig. 5) shows that the neophyl group acts as a bidentate ligand, with the $\sigma \mathrm{Pd}-\mathrm{CH} 2$ bond and the $\pi$-bound phenyl groups occupying the cis and trans positions with regard to the $P$ atom, respectively. Due to the low electron donor capacity of the arene, the trans Pd-P bond is unusually short, $2.1712(13) \AA$, nearly the same length as the $\mathrm{Pd}-\mathrm{N}$ bond, $1.172(4) \AA$. The Pd -arene $\pi$ interaction is characterized by very similar Pd-C3 (ipso) and Pd-C4 (ortho) distances, 2.491(5) and $2.463(5)$ Å respectively. The nearly symmetrical $\eta 2$ coordination mode of the aromatic ring contrasts with the bonding in related Pd complexes containing intramolecular $\pi$-arene interactions, where the Pd-C (ipso) is always significantly shorter than the shortest of the two Pd-C (ortho) distances. A theoretical analysis concluded that these are best considered as $\eta 1$ arene complexes, and that the interaction of the metal center with the ortho carbons has little relevance from the bonding point of view. 66 The preference of 6 for $\eta 2$ bonding is probably a consequence of the proximity of the $N$-aryl substituent of the imine functionality. As can be seen in the X-ray structure, the phenyl and 2,6-diisopropylphenyl aromatic rings arrange in almost parallel alignment suggesting the existence of attractive $\pi$-stacking forces between them. These forces could be responsible for a shift of the phenyl ring, bringing the metal center closer to the ortho carbon atom C4. In spite of being coordinated to the Pd atom, the $C(3)-C(4)$ bond length is essentially unaltered and identical to that of the "free" $C(3)-C(8)$ bond. This is consistent with the $\pi$-bond description as a ligand to metal electron donation, with little or no backdonation from the metal to the arene ring.

Due to the thermal instability of complex 5, we decided to prepare a more stable cationic nickel complex by replacing the diethyl ether molecule by a better donor acetonitrile ligand. Thus, complex 7a was prepared reacting 5 with an excess of acetonitrile. 7a is stable in solution at room temperature but it readily decomposes when warmed to $40^{\circ} \mathrm{C}$ and similarly to 5 , produces the phosphonium ion [ $\mathrm{HP}(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(\mathrm{iPr}) 2]+$. The palladium analogue, 7 b , is also obtained when complex 6 is treated with acetonitrile.
The reactions described above enabled a qualitative assessment of the stability of $\pi$-arene interactions in Ni and Pd complexes. Since 6 is stable in diethyl ether solution but reacts with acetonitrile, it can be concluded that the internal $\pi$-arene linkage is weaker than a MeCN ligand, but it is stronger than Et2O. Although the nickel analogue of 6 , the cation $[\mathrm{Ni}(\sigma: \pi-$ $\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(2)]+$, could also exist (the related compound [ $\mathrm{Ni}(\sigma: \pi-\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(\mathrm{dtbpe})]+$ was prepared and structurally characterized by Hillhouse and co-workers70), formation of the diethylether complex 5 is more favorable when the nickel metallacycles 3a/a' react with the acid [ $\mathrm{H}(\mathrm{OEt2}) 2]\left[\mathrm{BAr} \mathrm{r}^{\prime} 4\right.$, implying that the arene moiety binds more weakly to the Ni center than Et2O. Interestingly, both ions [ $\mathrm{M}(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(2)]+(\mathrm{M}=\mathrm{Ni}$ or Pd$)$ are readily generated in the gas phase and observed in the ESI mass spectra of $7 a$ and $7 b$. These spectra show no peaks for the corresponding molecular ions, but only for the ions resulting from acetonitrile loss. The ions observed in the spectra of 7 b and 6 undergo identical sequences of neutral losses when subjected to CID fragmentation. The corresponding ion for 7a ([M]+ - CH3CN, m/z $=526)$ also exhibits the same fragmentation pattern, giving rise to the peaks resulting from successive isobutene and benzene losses ( $\mathrm{m} / \mathrm{z}=470$ and 393 ). This indicates that the structure of this nickel ion $[\mathrm{Ni}(\mathrm{CH} 2 \mathrm{Me} 2 \mathrm{Ph})(2)]+$ is probably analogous to that of 6 .

Compounds 7a and 7b are more readily prepared by reacting the metallacycles $3 \mathrm{a} / \mathrm{a}^{\prime}$ or $3 \mathrm{~b} / \mathrm{b}^{\prime}$ with $[\mathrm{H}(\mathrm{OEt}) 2]+\left[\mathrm{BAr}^{\prime} 4\right]-$ in acetonitrile. These compounds are characterized by single 31P resonances at 188.7 and 190.2 ppm , within the region of phosphinito-imine complexes. The presence of the acetonitrile ligand is substantiated by the observation of weak absorption bands at $2322 \mathrm{~cm}-1$ in the IR spectra of both compounds. 71 Their NMR spectra appear well resolved at room temperature, but some signals exhibit significant broadening which evidence that these compounds undergo fluxional processes that are different for each of them. Thus, broadening of the 1 H and 13 C resonances of the acetonitrile signals in the spectra of 7 a point to intermolecular exchange of this ligand, as observed with diethylether for 5 , while these signals appear sharp and well defined for 7b. On the other hand, the signal of ipso phenyl carbon of 7 b is missing from its 13 C spectrum, while the signal of the ortho shows an appreciable line broadening. Although this might be indicative of a reversible interaction of the phenyl with the Pd center, it is surprising that such process does not have a similar effect on the signals of acetonitrile, which would be competing for the same coordination position.

The crystal structures of the acetonitrile complexes 7a and 7b are shown in Fig. 6 and 7. These molecules display slightly distorted square-planar configurations with the stronger $\sigma$-donor PR2 and alkyl fragments sitting in mutually cis positions. In both molecules the phenyl ring is far removed from the metal center and therefore no $\pi$-interactions are present. Apart from the bond length differences due to the covalent radii of Ni and Pd , the only evident distinction between the two structures is the conformation adopted by the neophyl group. In the palladium complex, the CMe2Ph fragment is projected perpendicularly from the coordination plane, while in the Ni derivative, the $\mathrm{Ni}-\mathrm{C} 21$ and $\mathrm{C} 21-\mathrm{C} 22$ bonds rotate to bring the phenyl group to a position roughly parallel to the vector defined by the acetonitrile ligand. This difference is probably caused by steric repulsions between the bulky CMe 2 Ph and $\mathrm{P}(\mathrm{iPr}) 2$ fragments in the more congested environment of the nickel complex. It is worth noting that the Pd-P distance in 7 b is ca. $0.02 \AA$ longer than in 6 , reflecting the stronger $\sigma$ donor ability of MeCN compared to the arene.

## Reactions of the cationic alkyl complexes with ethylene and CO

The cationic complexes $5,6,7$ a or 7 b were unsuccessful as single-component catalysts for ethylene oligomerization/polymerization or the copolymerization of ethylene and CO. The lack of activity of the nickel derivatives could be explained on the basis of their thermal instability, as even the stabilized acetonitrile adduct decomposes under mild conditions. The fact that decomposition of the nickel cationic alkyls involves the cleavage of the phosphinito-imine ligand and the formation of tertiary phosphonium salts suggests that the previously reported catalysts for ethylene oligomerization catalysts generated from nickel phosphinito-imine dihalide complexes and organoaluminum co-catalysts could actually involve a simple nickel containing a tertiary phosphane ligand. 54

Introducing a large excess of ethylene to a CD 2 Cl 2 solution of 6 at room temperature and atmospheric pressure does not alter significantly its NMR spectra, indicating that ethylene does not displace readily the intramolecular Pd-arene interaction. Although our data does not rule out the possibility that a small amount of the alkyl-ethylene complex is formed under
these conditions, the subsequent migratory insertion step is probably unfavorable. Brookhart has shown that the energy barrier for ethylene insertion into a $\mathrm{Pd}-\mathrm{C}$ bond is considerably higher for complexes containing hybrid $P, N$ ligands (ca. 19-25 kcal mol-1) than for related complexes containing symmetrical diphosphine or diimine ligands (ca. 17 kcal mol-1).23,31 The failure of palladium phosphinito-imine complexes to catalyze CO/ethylene copolymerization is more surprising, since several Pd complexes containing closely related phosphine-imine ligands are able to catalyze this reaction.42-48 Therefore, we decided to investigate the reactions of complexes $6,7 a$ and $7 b$ with carbon monoxide.

The carbonylation reactions of complexes 7 a and 7 b proceed in a straightforward manner affording the corresponding acyl complexes, which were isolated in good yield (Scheme 3). The nickel derivative 7 a reacts rapidly at room temperature with 1 atm. of CO yielding the acyl complex 8 a , characterized by a 31 P resonance at $\delta 181.4 \mathrm{ppm}$. The IR spectrum of this compound has three absorption bands at 1625, 1709 and $2321 \mathrm{~cm}-1$, assigned to the $\mathrm{C}=\mathrm{N}$ (imine), $\mathrm{C}=\mathrm{O}$ (acyl), and $\mathrm{C} \equiv \mathrm{N}$ (nitrile) stretch vibrations. The presence of the acyl fragment is also supported by the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum, which shows the carbonyl resonance at $\delta 241.5 \mathrm{ppm}$ as a doublet due to the coupling to phosphorus. The $2 J C P$ coupling constant, 20 Hz , is consistent with the cis arrangement of the acyl relative to the phosphinite group, as shown in Scheme 3. The ESI spectrum of 8a does not show the expected ion peak at $\mathrm{m} / \mathrm{z} 595 \mathrm{amu}$, but, two ion clusters with peaks at 554 and 526 amu resulting from the loss of acetonitrile and acetonitrile and CO, respectively. This is not surprising considering that CO insertion is generally reversible. The tendency of 8 a to decarbonylate was confirmed when a dichloromethane solution of this compound in a septum-capped NMR tube was heated at 40 ${ }^{\circ} \mathrm{C}$ and monitored by 31P NMR. After 3 days, the resonance of 8 a fully disappears and was replaced by two new peaks at $\delta 188$ and 24 ppm, corresponding to 7 a and to the phosphonium product arising from its decomposition.

The palladium alkyl complex 7b also reacts with CO, but with considerably more difficulty than its nickel counterpart. The reaction does not take place in dichloromethane solution under the ambient conditions. Full conversion to the acyl complex 8 b could be achieved after stirring under 4 bar of CO for 1 h . The spectroscopic features of this acyl derivative are similar to those of 8a. Thus, the IR absorptions for the $\mathrm{C}=\mathrm{N}, \mathrm{C}=\mathrm{O}$ and $\mathrm{C}=\mathrm{N}$ stretches appear at 1638, 1728 and $2320 \mathrm{~cm}-1$, respectively, and the acyl carbon gives rise to a doublet at $\delta 219.9 \mathrm{ppm}$ in the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum with $2 \mathrm{JCP}=20 \mathrm{~Hz} .8$ also decarbonylates in the gas phase, but its ESI spectrum only shows a single ion with $\mathrm{m} / \mathrm{z}=574 \mathrm{amu}$, corresponding to the loss of acetonitrile and CO. Nevertheless, 8 b is very stable in solution up to $60^{\circ} \mathrm{C}$, which is in contrast with the low stability of many cationic palladium acyl complexes either in solution or in the solid state.7276 Fig. 8 shows the crystal structure of compound 8 b . As can be seen, the acyl functionality is oriented almost perpendicularly to the mean coordination plane, forming an angle of $114.3^{\circ}$, while the neophyl fragment adopts approximately the same configuration as in the precursor complex 7b.

In contrast to the nitrile complexes 8 , the $\pi$-arene derivative 6 was recovered unaltered after treatment with CO. As already mentioned, this compound does not catalyze ethylene/CO copolymerization either. However, when exposed to 6 bar of a 1:1 CO/ethylene mixture at 60 ${ }^{\circ} \mathrm{C}$, it cleanly reacts giving rise to a new product, 9 , isolated as a colorless crystalline solid in
$>60 \%$ yield after recrystallization. The crystal structure of this compound (Fig. 9) displays a fivemembered metallacycle arising from the consecutive insertions of CO and ethylene into the $\mathrm{Pd}-\mathrm{CH} 2$ bond. Its spectroscopic features are in good agreement with the solid-state structure. For example, the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum shows a singlet at $\delta 253.6 \mathrm{ppm}$ attributed to the carbonyl carbon, while the ethylene fragment gives rise to two triplets at $\delta 1.56$ and 2.67 ppm in the 1 H spectrum. The ESI spectrum shows a peak cluster at $\mathrm{m} / \mathrm{z}=630$ corresponding to the molecular ion. CID fragmentation of this ion causes the simultaneous loss of ethylene and CO, affording the $[\mathrm{Pd}(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(2)]+$ ion $(\mathrm{m} / \mathrm{z}=533)$, which subsequently eliminates isobutene $(\mathrm{m} / \mathrm{z}=$ 517 ) and benzene ( $\mathrm{m} / \mathrm{z}=440$ ), as previously observed in the spectra of 6 and 7 b .

The formation of complex 9 demonstrates that the lack of reactivity of 6 towards CO is only apparent, since the formation of an acyl species must precede the ethylene insertion. In order to detect such species, the reactivity of 6 towards CO was investigated in situ with variable temperature NMR. Using a thick-walled NMR tube, the 31P, 1H and 13C NMR spectra of 6 were recorded under a pressure of 4 bar of CO . At $-20^{\circ} \mathrm{C}$, the $31 \mathrm{P}\{1 \mathrm{H}\}$ spectrum shows a main signal at 170.0 ppm and a minor peak at 185.6 ppm in ca. $7: 1$ ratio. The $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum of the main species displays a resonance at 215.6 ppm that is consistent with the presence of an acyl ligand, and is similar to the corresponding signal of the acetonitrile acyl complex 8b (219.9 ppm ). The deshielding of the signal for the neophyl CH 2 group, at 73.2 ppm , further supports CO insertion. All signals in the phenyl region are in their normal positions, indicating that the $\pi$ arene interaction is displaced, probably by a CO ligand. Evidence for the presence of a carbonyl ligand was obtained by treating 6 with 13CO. Due to the limited availability of this reagent, 13 CO was bubbled at normal pressure through a CD 2 Cl 2 solution of 6 at $-60{ }^{\circ} \mathrm{C}$ and NMR spectra were recorded at this temperature. Under these conditions, three signals in 2:1:7 ratio were observed in the $31 \mathrm{P}\{1 \mathrm{H}\}$ spectrum at $186.6,185.2$ and 169.8 ppm , the latter corresponding to the major species detected in the former experiment. The signals at 169.8 and 186.2 ppm are split in doublets with 2 JCP coupling constants of 114 and 80 Hz , respectively, both of them consistent with a trans coordination of carbonyl to the P atom. The singlet at 185.2 ppm corresponds to a small amount of unreacted 6. According to these data, the major species is the acyl-carbonyl complex $[\mathrm{Pd}(\mathrm{COCH} 2 \mathrm{CMe} 2 \mathrm{Ph})(\mathrm{CO})(\mathrm{P}-\mathrm{N})]+, 11$, and the peak for the minor species at 186.6 ppm corresponds to the carbonyl derivative $[\mathrm{Pd}(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})(\mathrm{CO})(\mathrm{P}-\mathrm{N})]+, 10$. The carbonyl resonances for these compounds are observed in the $13 \mathrm{C}\{1 \mathrm{H}\}$ spectrum as doublets at $\delta 175.6$ and 172.6 ppm , respectively.

Complexes 10 and 11 are formed in chemical equilibrium. As expected, the acyl species is favored at low temperature. Under a CO pressure of 4 bar the intensity ratio of the 31P resonances of 11 and 10 gradually decreases from $7: 1$ at $-20^{\circ} \mathrm{C}$ to ca. $1: 1$ at $30^{\circ} \mathrm{C}$. At $-20^{\circ} \mathrm{C}$, the 1 H spectrum of alkyl 10 is appreciably broadened, suggesting that rapid dissociative exchange of CO might be taking place, with the formation of small amounts of 6 . Under these conditions, the signals of 11 appear sharp and well resolved, because CO de-insertion is a much slower process. These observations enable us to draw the mechanistic picture for the formation of complex 9 from 6 illustrated in Scheme 4. Noteworthy, although the CO ligand of 11 is less labile than in 10, only the former is reactive enough to undergo ethylene insertion.

Chelate species similar to 9 are important intermediates in the palladium-catalyzed alternating copolymerization of ethylene and $\mathrm{CO} \cdot 6,8,77,78$ In general, these complexes are unstable, although a number of them have been isolated and characterized.42,77-82 Hybrid P,N43-48 or P,083 ligands increase the stability of these compounds, but also decrease their reactivity, preventing the progress of the copolymerization reaction.

## Conclusions

A series of $\sigma$-organonickel and -palladium complexes stabilized by phosphinito-imine ligands have been synthesized and fully characterized. Metallacyclic complexes 3 are readily available through ligand exchange from the suitable precursors directly using in situ generated mixtures of phosphinito-imine ligand and its amidophosphine tautomer. The coordinated amidophosphine tautomer rearranges to the phosphinito-imine form. This rearrangement is very fast for nickel complexes, but the palladium amidophosphine complex, 4, is stable enough to be isolated and characterized. Metallacycles $3 \mathrm{a} / \mathrm{b}$ react with complete regioselectivity with protic acids, which made the synthesis of several cationic alkyl derivatives possible. These cationic alkyls are obtained exclusively as the thermodynamically more favorable isomer, in which the strongly $\sigma$-donor $P$ and $C$ ligands avoid occupying mutually trans positions. This implies that cis/trans isomerization of the less stable isomer is not only feasible but a facile process.

Cationic alkylnickel phosphinito-imine complexes are thermally sensitive, spontaneously undergoing a decomposition process involving the breakdown of the phosphinito-imine ligand and formation of the phosphonium ion [ $\mathrm{HP}(\mathrm{iPr}) 2(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})]+$. However, the analogous Pd complexes are much more stable. Compound 6, a base-free complex stabilized by an intramolecular $\pi$-arene interaction is surprisingly robust. ESI mass spectra of the cationic nickel complexes showed that the analogous base-free nickel species can also be generated in the gas phase.

Disappointingly, cationic alkyl phosphinito-imine complexes are not active as singlecomponent catalysts for olefin polymerization or copolymerization reactions. However, these compounds readily undergo migratory insertion of CO to give the corresponding acyls, and complex 6 reacts consecutively with CO and ethylene, quantitatively affording a very stable chelate derivative, 9. Lack of catalytic activity could be ascribed to thermal instability in the case of the nickel complexes, but not so for the much more stable palladium derivatives. For the latter, the lack of reactivity towards ethylene, and the high stability of 9 are the reasons. As pointed out by Brookhart, 21,39 the strongly disparate donor capabilities of the PR2 and imine groups of the PN ligand stabilize these compounds, hence increasing the energy barrier for migratory insertion. Nevertheless, the ability of both nickel and palladium alkyls to undergo the cis/trans isomerization suggests that more reactive species should be accessible during hypothetical olefin polymerization or copolymerization process. Thus, similar cationic $\sigma$-alkyl complexes of nickel and palladium stabilized by other [P,N] ligands could prove catalytically active complexes. We are currently exploring various alternatives along this line of research.

## Experimental section

## General considerations

All experiments were carried out under dry nitrogen using standard Schlenk techniques. Solvents were rigorously dried and degassed before use. Microanalyses were performed by the Analytical Service of the Instituto de Investigaciones Químicas (Sevilla, Spain). Infrared spectra were recorded on a Bruker Vector 22 spectrometer, and NMR spectra on Bruker DRX 400 and 500 MHz and Bruker DPX 300 MHz spectrometers. The 1 H and $13 \mathrm{C}\{1 \mathrm{H}\}$ NMR resonances of the solvent were used as the internal standard, but the chemical shifts are reported with respect to TMS. Assignation of the resonances was routinely aided by using gated 13C, 2D homonuclear H-H COSY and phase-sensitive NOESY spectra, and binuclear 13C-1H HSQC heterocorrelations. 31P NMR resonances are referenced to external 85\% H3PO4. Compounds $\mathrm{H}(\mathrm{OEt} 2) 2 \mathrm{BAr} \mathrm{r}^{\prime}, 84 \mathrm{~N}(2,6-\mathrm{Pr} 2 \mathrm{C} 6 \mathrm{H} 3) \mathrm{C}(\mathrm{O}) \mathrm{Me}, 85 \quad\left[\mathrm{Ni}\left[\left(\mathrm{CH}_{2} \mathrm{CMe}_{2}-\mathrm{O}-\mathrm{C}_{6} 7 \mathrm{H}_{4}\right)\left(\mathrm{Py}_{2}\right)\right] \text { (1a) }\right)^{55}$ and $[\mathrm{Pd} \square$ $\left(\mathrm{CH}_{2} \mathrm{CMe}_{2}-\mathrm{O}-\mathrm{C}_{6} 7 \mathrm{H}_{4}\right)$ (cod)] (1b) 56 were prepared as reported previously. Ligand 2 was generated in solution and used in situ as described before. 54

Synthesis of $3 \mathrm{a} / \mathbf{3 a}^{\prime}$. A THF solution of ligand $2 / 2^{\prime}(1.2 \mathrm{mmol})$ prepared in situ as described above was added to a solution of 1a ( $420 \mathrm{mg}, 1.2 \mathrm{mmol}$ ) in 10 mL of THF at $-78{ }^{\circ} \mathrm{C}$. The reaction mixture was allowed to warm to room temperature while stirred. After 30 min , the solvent was evaporated under vacuum, and the orange residue was extracted with 40 mL of hexane and filtered through Celite. The extract contains a mixture of isomers 3 a and $3 a^{\prime}$. The solution was concentrated and cooled to $-10^{\circ} \mathrm{C}$ to afford compound 3 a as an orange solid. Synthesis of compound 5. 20 mL of a hexane solution of compounds $3 \mathrm{a} / 3 \mathrm{a}^{\prime}$ ( $274 \mathrm{mg}, 0.52$ mmol) cooled at $-78{ }^{\circ} \mathrm{C}$ were added to a stirred suspension of $524 \mathrm{mg}(0.52 \mathrm{mmol})$ of $\mathrm{H}(\mathrm{Et} 2 \mathrm{O}) 2 \mathrm{BAr} \mathrm{r}^{\prime}$ in 10 mL of hexane at $-78^{\circ} \mathrm{C}$, causing immediate precipitation of a yellow solid. After 30 min of stirring at this temperature, the solution was filtered and the solid was rinsed with hexane $(3 \times 10 \mathrm{~mL})$ at $-50{ }^{\circ} \mathrm{C}$. The product was dried under vacuum, keeping the temperature below $-40{ }^{\circ} \mathrm{C}$. Yield: $84 \%(0.64 \mathrm{~g})$. The thermal instability of compound 5 prevented a satisfactory elemental analysis. 1 H NMR ( $-40^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2,300 \mathrm{MHz}$ ): $\delta 0.82(\mathrm{~d}, 6 \mathrm{H}$, $3 \mathrm{JHH}=7 \mathrm{~Hz}, \mathrm{~N}\{(\mathrm{CHMe} 2) 2 \mathrm{C} 6 \mathrm{H} 3\}), 1.04(\mathrm{~d}, 6 \mathrm{H}, 3 \mathrm{JHH}=7 \mathrm{~Hz}, \mathrm{~N}\{(\mathrm{CHMe} 2) 2 \mathrm{C} 6 \mathrm{H} 3\}), 1.10(\mathrm{~m}, 6 \mathrm{H}$, PCHMe2), 1.10 (bs, 6H, (CH3CH2)2O), 1.41 ( $\mathrm{s}, 6 \mathrm{H}, \mathrm{CMe} 2$ ), 1.47 (bm, 6H, PCHMe2), 1.78 ( $\mathrm{s}, 3 \mathrm{H}$, $\mathrm{MeC}(\mathrm{O}) \mathrm{N}), 2.37$ (bm, 2H, PCHMe2), 2.88 (bm, 2H, N\{(CHMe2)2C6H3\}), 3.43 (bs, 4H, (CH3CH2)2O), 7.13 (d, $2 \mathrm{H}, 3 \mathrm{JHH}=7 \mathrm{~Hz}, \mathrm{o}-\mathrm{CHar}, \mathrm{N}-\mathrm{Ar}), 7.18-7.38(\mathrm{~m}, 5 \mathrm{H}, \mathrm{o}-\mathrm{C} 6 \mathrm{H} 4$ and $\mathrm{N}-\mathrm{Ar})$, $7.40(\mathrm{~d}, 1 \mathrm{H}, 3 \mathrm{JHH}=7 \mathrm{~Hz}, \mathrm{o}-\mathrm{CHar}, \mathrm{o}-\mathrm{C} 6 \mathrm{H} 4), 7.48$ ( $\mathrm{s}, 4 \mathrm{H}, \mathrm{BAr} \mathrm{r}^{\prime} 4$ ), 7.64 ( $\mathrm{s}, 8 \mathrm{H}, \mathrm{BAr}^{\prime} 4$ ). 13C\{1H\} NMR $\left(-40^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2,75 \mathrm{MHz}\right): \delta 15.5$ ( $\left.\mathrm{s},(\mathrm{CH} 3 \mathrm{CH} 2) 2 \mathrm{O}\right), 16.5$ ( $\left.\mathrm{s}, \mathrm{PCHMe} 2\right), 17.0(\mathrm{~s}, \mathrm{MeC}(\mathrm{O}) \mathrm{N}), 17.5$ ( $\mathrm{s}, \mathrm{PCHMe2)}$, 17.5 ( $\mathrm{s}, \mathrm{N}\{(\mathrm{CHMe2)2C6H3} \mathrm{\})}$,28.0 ( $\mathrm{d}, 1 \mathrm{JCP}=25 \mathrm{~Hz}, \mathrm{PCHMe2)}, 29.1$ ( s , $\mathrm{N}\{(\mathrm{CHMe} 2) 2 \mathrm{C} 6 \mathrm{H} 3\}), 34.0$ ( $\mathrm{s}, \mathrm{CMe} 2$ ), 39.9 ( $\mathrm{s}, \mathrm{CMe} 2$ ), 66.4 ( $\mathrm{s},(\mathrm{CH} 3 \mathrm{CH} 2) 2 \mathrm{O}), 117.4$ ( $\mathrm{s}, \mathrm{p}-\mathrm{CHar}$, BAr'4), 125.0 ( $q, 1$ JCF = 272 Hz, CF3 BAr'4), 125.2 ( $s, m-C H a r, ~ N-A r$ ), 126.0 ( $s, o-C H a r, ~ o-C 6 H 4$ ), 127.7 ( $\mathrm{s}, \mathrm{p}-\mathrm{CHar}, \mathrm{N}-\mathrm{Ar}$ ), 127.8 ( $\mathrm{s}, \mathrm{p}-\mathrm{CHar}, \mathrm{o}-\mathrm{C} 6 \mathrm{H} 4$ ), 128.9 ( $\mathrm{s}, \mathrm{m}-\mathrm{CHar}, \mathrm{o}-\mathrm{C} 6 \mathrm{H} 4$ ), 129.3 ( $\mathrm{q}, 2 \mathrm{JCF}=$ 31 Hz, CF3-Car, BAr'4), 133.2 (s, ipso-Car, N-Ar), 135.2 (s, o-CHar, BAr'4), 141.1 (s, o-Car, N-Ar), 150.5 (bs, Ni-Car), 166.2 (q, 1JCB = $50 \mathrm{~Hz}, \mathrm{~B}-\mathrm{Car}$ ), 171.2 (s, MeC(O)N). $31 \mathrm{P}\{1 \mathrm{H}\} \mathrm{NMR}\left(-40^{\circ} \mathrm{C}\right.$, CD2Cl2, 121 MHz ): $\delta 193.4$ (bs).

Decomposition of compound 5 and synthesis of [HP(iPr2)2(CH2CMe2Ph)][BF4]. A solution of complex 5 in CD 2 Cl 2 was allowed to warm from $-40^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$ in the NMR probe, and NMR spectra were recorded. The signals of 5 disappear and are replaced by those for the phosphonium cation $[\mathrm{HP}(\mathrm{iPr} 2) 2(\mathrm{CH} 2 \mathrm{CMe} 2 \mathrm{Ph})]+$. The assignation was confirmed by comparison with an authentic sample of the cation as the BF4- salt, which was prepared as follows: 1 mL ( 6.2 mmol ) of PiPr 2 Cl was added to a stirred solution of neophylmagnesium chloride ( 7.8 mmol ) in 60 mL of diethyl ether at $-40^{\circ} \mathrm{C}$. The stirring was continued at room temperature for 24 h . After this time, the mixture was quenched with 50 mL of a saturated aqueous solution of NH 4 Cl . The organic layer was separated, dried over Na2SO4 and filtered. An ethereal solution of HBF4 was added at room temperature, and the product precipitated as a white solid. The mixture was allowed to stand for 12 h , the solid was collected by filtration and dried under vacuum. Anal. Calcd for C16H28BF4P: C, 56.38; H, 8.35. Synthesis of complex 7a. Method A: $261 \mathrm{mg}(0.5 \mathrm{mmol})$ of compound 5 was dissolved in 20 mL of acetonitrile at $-40^{\circ} \mathrm{C}$. The mixture was allowed to reach room temperature over 30 min . Solvent was then evaporated under vacuum, and the orange residue was rinsed with 20 mL of hexane and recrystallized from Et2O:hexane (2:1) at $-10^{\circ} \mathrm{C}$. Yield: $63 \%(0.45 \mathrm{~g}$ ). Method B: A solution of $1.08 \mathrm{~g}(1.07 \mathrm{mmol})$ of $\mathrm{H}(\mathrm{Et} 2 \mathrm{O}) 2 \mathrm{BAr}^{\prime} 4 \mathrm{in} 30 \mathrm{~mL}$ of acetonitrile was added dropwise to a solution containing 564 mg ( 1.07 mmol ) of compound $3 \mathrm{a} / \mathrm{a}^{\prime}$ in 30 mL of acetonitrile at -60 ${ }^{\circ} \mathrm{C}$. The cooling bath was removed and the reaction mixture was stirred for 30 min . Removal of the solvent under vacuum afforded an orange solid that was rinsed with $2 \times 30 \mathrm{~mL}$ of hexane and recrystallized from a mixture Et2O:hexane (2:1) at $-10{ }^{\circ} \mathrm{C}$ to give 7 a as an orange crystalline solid. Yield: 69\% (1.06 g). Anal. Calcd for C64H62BF24N2NiOP: C, 53.69; H, 4.37; N, 1.96. Found: C, 53.58; H, 4.16; N, 1.88. Synthesis of compound 9. A Fischer Porter reactor was flushed with nitrogen and charged with 20 mL of toluene and a mixture of ethylene:CO 1:1 at 6 bar. After stabilizing the temperature at $60{ }^{\circ} \mathrm{C}$, a solution of $200 \mathrm{mg}(0.14 \mathrm{mmol})$ of compound 6 in 2 mL of dichloromethane was transferred with a syringe counter pressure through a septum-capped port. The reaction mixture was stirred for 1 h . The solution was then filtered to remove $\operatorname{Pd}(0)$ traces, and the solvent was removed under vacuum. The resulting solid was rinsed with 5 mL of hexane and recrystallized from a mixture Et2O:hexane (2:1) at $-10^{\circ} \mathrm{C}$. Compound 9 was obtained as a colorless crystalline solid in $62 \%$ yield ( 277 mg ). IR (Nujol mull): v( $\mathrm{C}=\mathrm{N}$ ) $1609 \mathrm{~cm}-1, \mathrm{v}(\mathrm{C}=\mathrm{O}$ ) $1734 \mathrm{~cm}-1$. Anal. Calcd for C65H63BF24N2O2PPd: C, 52.24; H, 4.25; N, 0.94. Reaction of complex 6 with CO. Observation of compounds 10 and 11. A thick-walled NMR tube fitted with a Young PTFE valve was charged with a CD 2 Cl 2 solution of compound 6 and CO at 4 bar. $31 \mathrm{P}\{1 \mathrm{H}\}$ spectra were recorded at different temperatures between $30^{\circ} \mathrm{C}$ and $-20^{\circ} \mathrm{C}$. Two signals were observed, corresponding to compounds 10 and 11. The position of the signals varied only slightly with the temperature but their intensity ratio changed significantly: $1: 1$ at $30^{\circ} \mathrm{C}$; $1: 3$ at $25^{\circ} \mathrm{C}$, and $1: 6$ at $-20^{\circ} \mathrm{C}$. Resonances of the minor product 10 were partially obscured by those of 11 . Compound 10: 1H NMR ( $-20^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2,500 \mathrm{MHz}$ ): $\delta 1.02(\mathrm{bd}, 6 \mathrm{H}$, $\mathrm{N}\{(\mathrm{CHMe} 2) 2 \mathrm{C} 6 \mathrm{H} 3\}), 1.94$ (bs, 3H, MeC(O)N), 2.58 (bm, 2H, N\{(CHMe2)2C6H3\}), 7.39 (bd, 1H, oCHar, Ph). 13C\{1H\} NMR ( $-20^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2,125 \mathrm{MHz}$ ): 16.3 (s, PCHMe2), 16.8 (d, $2 \mathrm{JCP}=4.5 \mathrm{~Hz}$, PCHMe2) 23.4 ( $s, N\{(C H M e 2) 2 C 6 H 3\}), 23.5$ ( $s, N\{(C H M e 2) 2 C 6 H 3\}), 28.9$ (d, 1JCP $=31 \mathrm{~Hz}$, PCHMe2), 32.8 (bs, CMe2), 36.3 (bs, CMe2), 140.2 (s, o-Car, N-Ar). 31P\{1H\} ( $-20^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2$, 202 MHz ): $\delta 186.3$ (bs). Solution IR ( $\mathrm{CH} 2 \mathrm{Cl} 2, \mathrm{CO}, 4 \mathrm{bar}, 293 \mathrm{~K}$ ): $1712 \mathrm{~cm}-1$ ( $\mathrm{v}(\mathrm{C}=\mathrm{O}$ ) acyl; coordinate CO bands were not observed, due to overlapping with the free $C=0$ absorption).

Reaction of compound 6 with 13CO. 13CO was bubbled through a CD2CI2 solution of 6, cooled to $-60^{\circ} \mathrm{C} .13 \mathrm{C}\{1 \mathrm{H}\} \mathrm{NMR}\left(-60^{\circ} \mathrm{C}, \mathrm{CD} 2 \mathrm{Cl} 2,100 \mathrm{MHz}\right)$, selected data: $\delta 172.6(\mathrm{~d}, 2 \mathrm{JCP}=79.4 \mathrm{~Hz}$,

Pd-CO, 10); 175.6 (d, 2JCP = $117 \mathrm{~Hz}, \mathrm{Pd}-\mathrm{CO}, 11$ ); 216.4 (s, Pd-C(O)-R, 11). 31P\{1H\} NMR ( $-60^{\circ} \mathrm{C}$, CD2Cl2, 161 MHz ): $\delta 169.9$ (d, 2JPC = $79.4 \mathrm{~Hz}, 11$ ); 185.7 (s, 6); 186.6 (d, $2 \mathrm{JPC}=115 \mathrm{~Hz}, 10$ ).

X-ray structure analysis for $\mathbf{3 b}, \mathbf{3} \mathbf{b}^{\mathbf{\prime}}, \mathbf{4}, \mathbf{6}, \mathbf{7 a}, \mathbf{7 b}, \mathbf{8 b}$ and 9 . A summary of crystallographic data and structure refinement results for these new crystalline compounds is given in Table 1. Crystals coated with dry perfluoropolyether were mounted on glass fibers and fixed in a cold nitrogen stream. Intensity data were collected on a Bruker-Nonius X8Kappa Apex II CCD diffractometer (3b/3b', 4, 7a, 7b, 8b and 9) equipped with a graphite monochromator to obtain $\lambda(\mathrm{Mo} \mathrm{K} \alpha)=0.71073 \AA$ radiation, or on a Bruker SMART 6000 CCD area-detector diffractometer (6) equipped with a laboratory rotating anode source, coupled to Göbel mirror optics to obtain a monochromated $\mathrm{Cu}-\mathrm{K} \alpha(\lambda=1.54184 \AA$ ) radiation. The data were reduced by SAINT86 and corrected for absorption effects by the multi-scan method (SADBAS). 87 The structures were solved by direct methods (SIR-2002)88 and refined against all F2 data by fullmatrix least squares techniques (SHELXTL-6.12) 89 minimizing w[Fo2-Fc2]2. All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were included in calculated positions and refined allowing to ride on their respective attached carbon atoms with the isotropic temperature factors (Uiso values) fixed at 1.2 times ( 1.5 times for the methyl group) the Ueq values of the corresponding carbon atoms.

64.The spectra of the phosphonium salt look unexpectedly clear because the signals for the 2,6-diisopropylphenyl fragment disappear from the spectrum once decomposition of 5 has
taken place. We have no indications of what could be the final fate of the imine fragment, but it is possible that these could be forming part of a paramagnetic species.

Footnotes
† Dedicated to Prof. David J. Cole-Hamilton on the occasion of his retirement and for his outstanding contribution to transition metal catalysis. An outstanding scientist, an excellent supervisor, and a wonderful friend.
$\ddagger$ CCDC reference numbers $876279-876285$ for $3 b, 3 b^{\prime}, 4,6,7 a, 7 b, 8 b$ and 9 . For crystallographic data in CIF or other electronic format see DOI: 10.1039/c2dt31334k

## Figure captions

Figure 1. Crystal structure of 3b. Selected bond distances (Å) and angles ( ${ }^{\circ}$ ): Pd2-P2, 2.2867(9); Pd2-N2 2.173(2); Pd2-C51, 2.081(3); Pd2-C56, 2.008(3); P2-O2, 1.700(2); C43-O2, 1.358(4); C43-N2, 1.280(4); P2-Pd2-N2, 79.42(7); C51-Pd2-C56, 79.62(14); C51-C52-C55-C(56), 24.0(4); N2-Pd2-P2-O2, 5.91(9).

Figure 2. Crystal structure of $3 b^{\prime}$. Selected bond distances ( $A$ ) and angles ( ${ }^{\circ}$ ): Pd1-P1, 2.2453(8); Pd1-N1 2.215(3); Pd1-C21, 2.049(3); Pd1-C26, 2.076(3); P1-O1, 1.693(2); C13-O1, 1.359(4); C13-N1, 1.283(4); P1-Pd1-N1, 78.95(7); C21-Pd1-C26, 79.59(13); C21-C22-C25C26, 27.3(4); N1-Pd1-P1-O1, 3.73(11).

Figure 3. Crystal structure of 4. Selected bond distances ( $\AA$ ) and angles $\left({ }^{\circ}\right)$ : Pd1-P1, 2.2939(3); Pd1-O1 2.1854(9); Pd1-C8, 2.0431(12); Pd1-C1, 2.0241(13); P1-N1, 1.7765(11); C12-N1, 1.3777(17); C12-O1, 1.2366(16); P1-Pd1-O1, 79.27(3); C8-Pd1-C1, 79.00(5); C8-C7-C6-C1, 26.10(14); O1-Pd1-P1-N1, 10.14(5).

Figure 4. ESI-MS spectrum of compound 6. Upper part: full spectrum. The inset shows an expansion of $\mathrm{M}+$, and calculated isotope pattern. Lower part, CID fragmentation of $\mathrm{M}+$.

Figure 5. Crystal structure of 6. Selected bond distances (Å) and angles ( ${ }^{\circ}$ ): Pd1-C1, 2.074(4); Pd1—P1, 2.1712(13); Pd1-N1, 2.172(4); Pd1-C(3), 2.491(5); Pd-C(4) 2.463(5); C3-C4, 1.403(7); C3-C8, 1.404(7); C23-N1, 1.280(6); C23-O1, 1.344(6); P1-Pd1-N1, 81.55(11); N1-Pd1-C1, 171.87(15); P1-Pd1-C1, 92.75(14); C1-C2-C3-C4, 46.2(5).

Figure 6. Crystal structure of 7a. Selected bond distances ( $\AA$ ) and angles ( ${ }^{\circ}$ ): Ni1-C21, 1.971(3); Ni1-N2, 1.893(3); Ni1-N1, 1.984(2); Ni1-P1, 2.0880(8); C13-N1, 1.282(4); C13-O1, 1.356(4); P1-O1, 1.683(2); C21-Ni1-N2, 95.51(6); P1-Ni1-N1, 83.78(7).

Figure 7. Crystal structure of 7b. Selected bond distances ( A ) and angles ( ${ }^{\circ}$ ): Pd1-C21, 2.0657(14); Pd1-N2, 2.0881(13); Pd1-N1, 2.1572(12); Pd1-P1, 2.1893(4); C13-N1, 1.2796(19); C13-O1, 1.3510(18); P1-O1, 1.6820(11); C21-Pd1-N2, 88.73(25); P1-Pd1-N1, 81.68.

Figure 8. Crystal structure of 8b. Selected bond distances (Å) and angles: Pd1-C21, 2.006(5); Pd1-N2, 2.089(4); Pd1-N1, 2.167(4); Pd-P1, 2.2097(12); C21-O2, 1.107(7); C13-N1, 1.283(6); C13-O1, 1.360(6); C21-Pd1-N2, 88.21(19); P1-Pd1-N1, 81.38(11); Pd1-C21-O2, 121.2(5); C22-C21-Pd1, 109.8(4).

Figure 9. Crystal structure of 9. Selected bond distances (Å) and angles: Pd1-C21, 2.039(6); Pd1-N1, 2.124(5); Pd-P1, 2.1682(16); Pd1-O2, 2.133(4) C23-O2, 1.237(2); C13-N1, 1.287(8); C13-O1, 1.352(7); C21-Pd1-O2, 81.9(2); P1-Pd1-N1, 81.84(14); C21-C22-C23-O2, 22.8(8).
