The genus *Theileria* comprises apicomplexan parasites that are tick-transmitted and infect ruminants with important trade and industry impact in endemic countries (1). Infectious agents build up elaborate machinery to work together by means of host cell pathways and takeover their genetic and epigenetic mechanisms to modify phenotypic status of host cells. Among the Apicomplexa phylum encompassing obligate intracellular parasites, the only genus that introduces its DNA into mammalian host cells is *Theileria*, which is known to cause veterinary and human diseases (2). Various species, including *Theileria parva* and *Theileria annulata*, infect leukocytes causing alterations in their phenotypes that are common with several cancers, remarkably immortalization, hyperproliferation, and spreading (1).

Pin1 is a distinctive peptidyl prolyl isomerase (PPIase) that catalyzes the cis/trans isomerization of peptidyl–prolyl peptide bonds of its substrate proteins by binding to their specific phosphorylated Ser/Thr-Pro (pSer/Thr-Pro) motifs. This modifies the conformation of target proteins and, therefore, has an effect on their stability, intracellular localization, and/or biological roles. The atypical overexpression of Pin1 is observed in a number of malignancies, which is linked with tumor cell proliferation, migration, and invasion (3). PIN1 is an enzyme with peptidyl-prolyl isomerase activity that catalyzes the cis/trans isomerization of peptide bonds flanked by proline and phosphorylated serine/threonine residues. By shifting the conformation of its protein substrates, PIN1 amplifies the behavior of vital proteins that support cell cycle progression and oncogenesis (4).

Marsolier et al. (2) became aware of *Theileria* Pin1 transcripts in B cells infected with *T. annulata* or *T. parva*. Confocal microscopy and immunoblot analysis placed the parasite Pin1 protein together in the host cell cytoplasm and nucleus (2). These authors affirm that the pooled results illustrate that *Theileria* produces a “bona fide” phosphorylation-dependent PPIase, which may well add to host cell transformation (2).

In the report of Marsolier et al. (2), the authors also studied c-Jun pathway. These authors showed that c-Jun is vital for *Theileria* transformation and host cell proliferation. In B lymphocytes infected in culture with *T. annulata* (TBL3 cells), c-Jun appears to be triggered by

reduced ubiquitin ligase bovine protein FBW7 degradation more willingly than phosphorylation by JNK signaling. Later, establishment of a feedback loop, relating to c-Jun control of the miR-155 oncomiR, might generate an epigenetic exchange to sustain transformation and proliferation (2). This miR-155 may have biomarker value and can be easily detected by biosensors that our group already developed and detect its variation at attomolar levels (5).

In fact, host cell proliferation is an important hallmark of cancer (6). Our group has previously shown that cells treated with *Schistosoma haematobium* extracts increase proliferation (7).

It has also been demonstrated that schistosomes possess a PPLase activity (8). This protein might explain the increased proliferation observed in the cells treated with Schistosomes extracts (7). It will be as well appealing in the future to verify whether PIN1 from schistosomes also show evidence of a similar stimulating consequence of cell proliferation.

The other well-known cancer inducing parasite *Opisthorchis* and *Clonorchis* have also been shown to exhibit PPLase activity. *Clonorchis sinensis* adult in biliary ducts has been shown to release *C. sinensis* cyclophilin A, a protein with PPLase activity, into the liver and play a role in inflammation and biliary epithelium proliferation and adenomatoid hyperplasia (9).

Hutadilok et al. (10) have shown that a prolyl hydroxylase activity was observed in hamsters infected with the human liver fluke *Opisthorchis viverrini*. This activity accompanied an increase in liver collagen that is associated with an increase in the proliferation of fibroblasts (10).

In conclusion, infection with the eukaryotic protozoan *Theileria* parasite causes diseases of medical or economic importance like tropical theileriosis and East Coast Fever. This apicomplexan is an obligate intracellular parasite of host lymphocytes. Amidst this group of parasites, *Theileria* is the only genus known to transform their host cell. This parasite secretes a prolyl isomerase that promotes transformation of host cells through inhibiting c-JUN pathway. Given the striking similarities of how *Theileria* induces transformation of their host lymphocytes and tumorigenesis, these findings might have major implications for infection-induced cancer and the mechanisms that underlie this causality that might be common with other cancer-inducing parasites.
