#### Abstract

The aim of this study was to determine associations and the values of power analysis as their reliability degrees between Year or Cultivars and traits such as fruit weight (FW), total acid (TA) and, the soluble substance that can be dissolved in water (SSDW) from various ten raspberry cultivars in an adaptation study regarding horticulture field by using Chi-Square and Likelihood Ratio Chi-Square statistics after FW, TA and SSDW were categorized as binary (low and high). Association between FW and CULTIVAR, association between SSDW and YEAR, association between SSDW and CULTIVAR, association between TA and CULTIVAR were much more significant $(\mathrm{P}<0.001)$. Besides, corresponding power values for Chi-Square and Likelihood Ratio Chi-Square statistics were very close on each other and had a reliability of approximately $100 \%$ and enough sample size. Contrary to these four contingency tables, associations between both FW-YEAR and TA-YEAR were non-significant and non-reliable because corresponding power values for Chi-Square and Likelihood Ratio Chi-Square statistic were 50-51\% (a power of moderate-level) and 22-23\% (power of low level), respectively and sufficient sample sizes for both FW-YEAR and TA-YEAR should be 240 and 560, respectively in order to provide a power of $80 \%$. As a result, in order to be obtained reliable results and determined enough sample size in Chi-Square and Likelihood Ratio Chi-Square Statistics, power analysis should be performed.

Key words: Chi-Square, Likelihood Ratio Chi-Square Statistics, Power Analysis, Raspberry, Horticulture, Fruit weight, Total acid, SSDW.

## INTRODUCTION

Chi-Square and Likelihood Ratio Chi-Square statistics have been commonly used as criteria of independence and goodness of fit in contingency table ${ }^{[4,9,3,5]}$. However, it is well-known that Likelihood Ratio Chi-Square statistics were generally preferred to other when observed frequencies of the cells of a contingency table were less than five and sample sizes were very small ${ }^{[1,5]}$. Besides, in the event that total sample size was enough, both statistics might give similar results ${ }^{[1,5]}$. To select the better of these two statistics, researchers should perform power analysis as regards them, which give an idea to one about whether sample sizes will be enough. The most important question for a researcher is "How many observations should we survey to ensure statistics having a power of $\% 80-90$ "? Moreover, it should be forgotten that non-significant results for both statistics does not guarantee independence. On the other hands, if power values for both are too-low (for example, a power of $\% 20-40$ ), the experiment that one carried out is not sensitive enough to determine dependent.

As a result, one of important things for a researcher is to get a reliable result as statistical analysis. For this reason, ones might utilize of Power Analysis for every trial regarding all scientific areas. After traits such as fruit weight (FW), total acid (TA) and, the soluble substance that can be dissolved in water (SSDW) from various ten raspberry cultivars in an adaptation study (regarding horticulture field which was carried out by Atila et al. ${ }^{[2]}$ ) were categorized as binary (low and high), categorized traits with both year and cultivars were one by one formed contingency tables. Hereafter, by using special SAS macro regarding Chi-Square and Likelihood Ratio Chi-Square statistics ${ }^{[8]}$, the present paper aimed:

First, what was examined was an association between any trait and year or cultivars? Second, power analysis of statistics such as Chi-Square and Likelihood ratio Chi-square (which is called as G test) on all contingency tables were performed using a Special SAS macro (http://ftp.sas.com/techsup/download/stat/powerrxc.html).

Third, in point of determination of power values and ideal sample size, this paper gave to place to whether the values of power analysis in contingency table as regards samples from various ten raspberry cultivars in horticulture area were suitable and reliable.

[^0]
## MATERIALS AND METHODS

Materials: The materials that were used for this research were Rubin, Summit, Holland Short, Heritage I, Heritage II, Tulameen, Aksu Red, Nuburg, Canby and Willamette. The pomological characteristics (Fruit weight, Total acid and SSDW) of raspberry species were investigated and compared with each other. What's more, it was searched whether the single or double product of Heritage is more economical. This research was conducted between the years of 2002 and $2005^{[2]}$.

Rubin: A variety which is thorny and has pink flowers.
Summit: A variety which has bigger thorns than Rubin and has white flowers. It is fruitful in both spring and autumn.

Holland Short: A variety which has thorny and has pinkwhite flowers. It is fruitful in both spring and autumn.

Heritage: A variety which has thorny and has pink-white flowers. It is divided into two varieties Heritage I and Heritage II. While Heritage I is fruitful in spring, Heritage II is in both spring and autumn.

Tulameen: A variety which has thorny and has white flowers.

Aksu Red: A variety has got big fruit and has small thorny.

Nuburg: A variety has got big fruit and has small-yellow thorny.

Canby: A variety which has thorny and strong of winter.
Willamette: A variety has got big fruit and small thorny. It is strong of winter and fruitful.
A total of 120 sample sizes were used for each trait.
Methods: Traits such as fruit weight (FW), total acid (TA) and, the soluble substance that can be dissolved in water (SSDW) obtained from various ten raspberry

| Table 1: The cut-off values for each trait |  |  |
| :--- | :---: | :---: |
|  | Low amount (1) <br> (equal and less than) | High amount (2) <br> (equal and more than) |
| Trait | 19.17 | 19.18 |
| FW | 20.31 | 20.32 |
| TA | 27.71 | 27.72 |
| SSDW |  |  |

FW: Fruit weight; TA: Total acid; SSDW: the soluble substance that can be dissolved in water

|  | Researcher's Decision |  |
| :---: | :---: | :---: |
| Case | Reject $\mathrm{H}_{0}$ | Do not Reject $\mathrm{H}_{0}$ |
| $\mathrm{H}_{0}$ true | Type I error probability ( $\alpha$ ) (Significance level) | Correct decision probability (1- $\propto$ ) (Confidence level) |
| $\mathrm{H}_{0}$ false | Correct decision probability (1- $\beta$ ) (POWER) | Type I error probability ( $\beta$ ) |

cultivars divided into two categorizes, namely, low (1) and high (2) weight as binary. Mean of each trait was calculated then each value was assigned as 1 (low) when values were less than mean value; otherwise as 2 (high). The cut-off values of assigned values for each trait are presented in Table 1. For example: if one value for FW in data set is 20.88, new value for it can be assigned as 2 .

The notation of Chi-Square (1) and Likelihood Ratio Chi-Square statistics (2) are given below ${ }^{[3,1,6]}$ :

$$
\begin{align*}
& \mathrm{x}^{2}=\sum \frac{\left(\mathrm{f}-\mathrm{f}_{\mathrm{i}}\right)^{2}}{\mathrm{f}_{\mathrm{i}}}  \tag{1}\\
& \mathrm{G}=2 \sum \mathrm{f} \cdot \ln \left(\frac{\mathrm{f}}{\mathrm{f}_{\mathrm{i}}}\right) \tag{2}
\end{align*}
$$

Where, $f$, observed frequency and $f_{i}$, expected frequency.
According to Table 2, the statistical significance of a test is the probability that the null hypothesis $\left(\mathrm{H}_{0}\right)$ will be rejected when it is true. Besides, Power of a test is the probability (1-f) that researchers will reject it when null hypothesis $\left(\mathrm{H}_{0}\right)$ in reality is false. Power value desired should be at least $80 \%$ as to statistics criteria ${ }^{[1]}$.

Power Theory for Chi-Square and G Statistics: Assume that $\mathrm{H}_{0}$ is the same to model M for a contingency table. Let $\pi_{\mathrm{i}}$ indicate the true probability in $\mathrm{i}^{\text {th }}$ cell and Let $\pi_{\mathrm{i}}(\mathrm{M})$ represent the value to which the Maximum likelihood (ML) estimate $\pi_{\mathrm{i}}$ for model M converges, where $\Sigma \pi_{\mathrm{i}}=\Sigma \pi_{\mathrm{i}}(\mathrm{M})$. For multinomial sample of size n , the non-centrality parameter for Chi-Square (3) can be expressed as follows:

$$
\begin{equation*}
\lambda=\mathrm{n} \sum_{\mathrm{i}} \frac{\left[\pi_{\mathrm{i}}-\pi_{\mathrm{i}}(\mathrm{M})\right]^{2}}{\pi_{\mathrm{i}}(\mathrm{M})} \tag{3}
\end{equation*}
$$

Expression 3 is the similar form as Chi-Square statistics, with for the sample proportion $p_{i}$ and $\pi_{\mathrm{i}}$ in place of $\pi_{\mathrm{i}}$. The non-centrality parameter for Likelihood Ratio Chi-Square Statistics (4) can be written in this manner:

$$
\begin{equation*}
\lambda=2 \mathrm{n} \sum_{\mathrm{i}} \pi_{\mathrm{i}} \log \frac{\pi_{\mathrm{i}}}{\pi_{\mathrm{i}}(\mathrm{M})} \tag{4}
\end{equation*}
$$

## RESULTS AND DISCUSSIONS

The values, probability and power values of Likelihood Ratio Chi-Square and Chi-Square Statistics in all contingency tables which were calculated for alpha $=0.05$. Examining Table 3, the values, probability and power values of Likelihood Ratio Chi-Square and Chi-Square Statistics regarding other contingency tables except for contingency tables of FW-YEAR and TA-YEAR were much more significant $(\mathrm{P}<0.001)$.

Table 3: The values, probability and power values of Likelihood Ratio Chi-Square and Chi-Square Statistics in each contingency tables for

| Pairs of traits | L.R.Chi Square Statistic Value | L.R.Chi Statistic Probability | Chi-Square Statistic Value | Chi-Square <br> Statistic Probability | Power of L.R.Chi Statistic | Power of Chi-Square |

| 120 | 0.50537 | 0.50688 | 380 | 0.96347 | 0.96404 |
| 140 | 0.57604 | 0.57766 | 400 | 0.97129 | 0.97176 |
| 160 | 0.64023 | 0.64189 | 460 | 0.97752 | 0.97792 |
| 180 | 0.69749 | 0.69914 | 480 | 0.98248 | 0.98280 |
| 200 | 0.74778 | 0.74938 | 500 | 0.98639 | 0.98666 |
| 220 | 0.79135 | 0.79286 | 520 | 0.98947 | 0.98969 |
| 240 | 0.82864 | 0.83005 | 540 | 0.99187 | 0.99205 |
| 260 | 0.86022 | 0.86150 | 560 | 0.99375 | 0.99390 |
| 280 | 0.88670 | 0.88785 | 580 | 0.99521 | 0.99533 |

It could be concluded that

- There was close association or dependent between FW and CULTIVAR ( $\mathrm{P}<0.001$ ).
- There was close association or dependent between SSDW and YEAR ( $\mathrm{P}<0.001$ ).
- There was close association or dependent between SSDW and CULTIVAR ( $\mathrm{P}<0.001$ ).
- There was close association or dependent between TA and CULTIVAR $(\mathrm{P}<0.001)$.

According to results of four contingency mentioned above, power values of Likelihood Ratio Chi-Square and Chi-Square Statistics calculated for these four contingency tables were much higher and desired (almost $100 \%$ ). In other words, both statistics for them had a reliability of more than $99 \%$ and total sample sizes were quite sufficient (120).

However, the values, probability and power values calculated for contingency tables on FW-YEAR and

TA-YEAR were non-significant. It should be forgotten that non-significant results for both statistics does not guarantee independence. Consequently, examining in Table 3, the experiments (contingency tables on FW-YEAR and TA-YEAR) that one carried out is not sensitive enough to determine dependent. Because power values calculated for contingency tables on FW-YEAR and TA-YEAR were $50.537 \%$ for Chi-Square and $50.688 \%$ for other, as well as 22.476 for Chi-Square and 22.610 \% for other, respectively. This case means non-reliable.

When we artificially and arbitrary increased 40 to 580 by 20 by using special SAS macro mentioned above in order to estimate sufficient sample size or to obtain at least a power of $80 \%$ for contingency table of FW-YEAR, sufficient sample size for the contingency table should be 240 (Table 4).

However, if sample size were 580, the power values of Chi-square and G statistics would be achieved to nearly $100 \%$ for both statistics.
J. Appl. Sci. Res., 2(11): 931-935, 2006

| 400 | 0.65411 | 0.65740 | 880 | 0.95491 | 0.95619 |
| 420 | 0.67786 | 0.68114 | 900 | 0.95907 | 0.96027 |
| 440 | 0.70042 | 0.70368 | 920 | 0.96288 | 0.96400 |
| 460 | 0.72179 | 0.72502 | 940 | 0.96636 | 0.96740 |
| 480 | 0.74200 | 0.74518 | 960 | 0.96954 | 0.97051 |
| 500 | 0.76106 | 0.76418 | 980 | 0.97243 | 0.97334 |

When we artificially and arbitrary increased 40 to 980 by 20 by means of special SAS macro mentioned above in order to obtain at least a power of $80 \%$ for contingency table of TA-YEAR, sufficient sample size for the contingency table should be 560 .

However, if sample size were 980, the power values of Chi-square and G statistics would be achieved to approximately $98 \%$ for both statistics.

## CONCLUSION

In order to be obtained reliable results and determined enough sample size in Chi-Square
and Likelihood Ratio Chi-Square Statistics, power analysis should be performed. It could be concluded that:

- Performances of power analysis for both statistics were close on each other in all contingency tables
- Except contingency tables regarding FW-YEAR and TA-YEAR, both power values and total sample size of others were much more reliable.

Researchers should not forget that power analysis in Chi-Square and Litelihood ratio Chi-Square statistics technique means reliability.
