18

19 **3. Summary**

20 Recent works on animal personalities have demonstrated that individuals may
21 show consistent behaviour across situations and contexts. These studies were often
22 carried out in one location and/or during short time intervals. Many animals, however,
23 migrate and spend their life in several geographically distinct locations, and they may
24 either adopt specific behaviours to the local environment or keep consistent
25 behaviours over ecologically distinct locations. Long-distance migratory species offer
26 excellent opportunities to test whether the animals maintain their personalities over
27 large geographic scale, although the practical difficulties associated with these studies
28 have hampered such tests. Here we demonstrate for the first time consistency in
29 disturbance-tolerance behaviour in a long-distance migratory bird, using the common
30 crane *Grus grus* as an ecological model species. Cranes that hatched in undisturbed
31 habitats in Finland choose undisturbed migratory stop-over sites in Hungary, 1300 -
32 2000 km away from their breeding ground. This is remarkable, because these sites are
33 not only separated by large distances, they also differ ecologically: the breeding sites
34 are wooded bogs and sub-Arctic tundra, whereas the migratory stop-over sites are
35 temperate zone alkaline grasslands. The significance of our study goes beyond
36 evolutionary biology and behavioural ecology: local effects on behaviour may carry
37 over large distances, and this hitherto hidden implication of habitat selection needs to
38 be incorporated into conservation planning.

41 conservation

42

43 **5. Introduction**

44 Animals in the same population usually differ in their behaviour and
45 underlying physiology [1-2]. Moreover, the same set of animals may show the same
46 kind of differences in different situations (e.g. in level of predator avoidance at
47 different foraging sites) and contexts (e.g. boldness in foraging and social
48 interactions). For instance, great tits *Parus major* show consistent individual
49 differences in exploring open field areas [3], and in mosquito fish *Gambusia affinis*
50 asocial individuals show greater dispersal tendency [4]. Although individuals may
51 adjust their behaviour depending on situations, nevertheless consistent differences
52 between individuals usually remain. These are frequently characterized as animal
53 personalities [5], temperament [6], behavioural syndromes or coping styles [7].

54 Many animals spend their life in several geographically distinct locations, and
55 previous studies that investigate personality traits in a given location over short
56 periods of time may not be able to estimate the importance of behavioural
57 consistencies across contrasted ecological settings. Migratory insects, fishes, birds and
58 mammals encounter wide range of habitats during their annual movements [8-9]; for
59 instance Arctic terns *Sterna paradisea* fly over 70,000 km each year and cover vast
60 range of habitats between their Arctic breeding ground and their wintering sites near
61 Antarctica [10].

62 Animals may adopt two behavioural strategies when they encounter different
63 ecological settings. On the one hand, they may exhibit different types of behaviour
64 depending on local conditions during migration. On the other hand, they may show
65 consistent behaviour even across highly contrasted environments [11].

66 Migratory species provide excellent opportunities to test these possibilities. Although
67 the ability of migratory animals to exhibit consistent behavioural responses over large
68 geographical areas has been suspected [12-13], no study has yet demonstrated such
69 behaviour due to the challenges of tracking animal behaviour over large geographic
70 distances.

71 Here we investigate the behavioural consistency in a long-distance migratory
72 bird, the common crane using disturbance-tolerance behaviour. Human disturbance
73 has large effect on the distribution, ecology and behaviour of animals [14-15], for
74 instance, the spatial distribution of human settlements and density of roads influence
75 avian habitat selection [16-17]. We hypothesised that the cranes' behavioural
76 responses to human disturbance are consistent between their natal site and their
77 migratory stop-over site that are separated by over 1000 km.

78

79 **6. Material and Methods**

80 We collected data between 1995-2007 in Hortobágy National Park in Hungary
81 (N 47°30' E 21°0', Hortobágy henceforth) that is the largest alkaline steppe in Europe
82 (80,200 ha), an UNESCO World Heritage Site and protected by Ramsar Convention.
83 Hortobágy is surrounded by 18 settlements (min - max no. of inhabitants: 1950 -
84 50,000).

85 We use data on 273 cranes that were marked as chicks in Finland between
86 1985 and 2007 by individual combinations of colour rings, and resighted in
87 Hortobágy between 1995 and 2007 (Fig 1a). Locations of nest sites were collected by
88 PM, and resighting data were acquired from the Hungarian Bird Ringing Centre
89 (Budapest). Five proxy variables of human disturbance were estimated from 1:16,000

90 maps of the National Land Survey of Finland
91 (<http://kansalaisen.karttapaikka.fi/kartanhaku/osoitehaku.html>), and the Hortobágy
92 National Park's GIS map (unpublished), respectively: proximity (km^{-1}) to the nearest
93 (1) tarmac road and (2) human settlement, and perturbation i.e. density (ha^{-1}) of (3)
94 tarmac roads, (4) human settlements and (5) human population. Since common crane
95 territories are approximately 3-4 hectares [10], we estimated these variables within a 1
96 km radius around nests. On migration, the cranes move between roost sites and
97 feeding sites, and since these are within 10 km, we estimated all five variables in a 10
98 km radius around roost sites [18].

99 Out of 273 cranes, 138 were observed at least twice (up to 10 times) in
100 Hortobágy. For individuals observed several times in a year, we calculated the
101 within-year repeatability of the disturbance variables. For those cranes which have
102 been recorded repeatedly in different years we calculated between-year repeatability
103 of the disturbance variables [19]. To investigate the consistency in behaviour between
104 natal sites in Finland and migratory sites in Hortobágy, we fitted Linear Mixed Effects
105 Models (LMMs) using disturbance-variables on the migratory site as response
106 variables, and disturbance variables on the natal sites as fixed effects for all possible
107 pairwise combinations (25 models in total, [20]). A positive t value, a proxy of effect
108 size, indicates consistent result with the working hypothesis. Regions within Finland
109 (as a control for spatial autocorrelation), and Bird ID were included in LMMs as
110 nested random factors. We performed all statistical analyses in R [21].

111

112 **7. Results**

113 Cranes used 10.24 ± 1.03 [mean \pm SE] different roost sites in Hortobágy each year,
114 and those cranes that were observed several times within a year used 3 (2-4.75) sites
115 per year. Four of the five disturbance-tolerance variables were significantly repeatable
116 both within and between years for individual cranes (Table 1). This indicates a high
117 level of behavioural consistency both within a particular year, and over the study
118 period for a given individual.

119 Out of 25 pairwise models, 24 showed positive relationships between
120 disturbance tolerance in the natal and migratory sites (binomial test using 0.5
121 expectation, $p < 10^{-5}$, Table 2). Support for the research hypothesis was also indicated
122 by the positive average *t*-values, and that their 95% confidence intervals did not
123 include zero (Fig 1b).

124

125 **8. Discussion**

126 Common cranes show consistent disturbance-tolerance behaviour between
127 years, and between natal and migratory sites separated by over 1000 km. As far as we
128 are aware, our study is the only that demonstrates long-lasting individual differences
129 in response to human disturbance using individually marked birds. Consistent
130 disturbance-tolerance behaviour may emerge in three mutually non-exclusive ways.
131 First, young cranes may be imprinted to certain levels of human disturbance by the
132 location of their nest, and they seek out these features during migration. Second,
133 common cranes have extensive parental care that last up to 10 months after hatching
134 [10]. Therefore, the young crane's migratory behaviour may be influenced by their
135 parents' behaviour [22]. This carry-over of information may lead to cultural
136 transmission of habitat preference in regards to disturbance [23]. Third, habitat

137 preference may have a genetic component so that certain genotypes tolerate more
138 disturbance than others.

139 Previous studies demonstrated consistent behaviour in various context
140 including exploration, aggression, anti-predator behaviour, parental provisioning and
141 cooperation [24-26]. Our work adds to these by showing personality-related traits in
142 disturbance-tolerance behaviour. Also, we expand the scope of personality by
143 showing that cranes behave consistently over a long time period and between habitats
144 with very different ecological conditions, such as northern wooded bogs, subarctic
145 tundra and temperate zone alkaline grassland.

146 It would be interesting to investigate whether habitat preference correlates
147 with other personality traits e.g. flushing distance, exploration behaviour, or
148 physiological reactions to handling. Unfortunately, we are unable to address this
149 proposition here because of the lack of appropriate data from individually marked
150 cranes.

151 The process we demonstrate here is similar to the ecological carry-over,
152 whereby events during one period of the annual cycle in migratory animals influence
153 reproductive success in a subsequent season [13, 27-28]. We propose that both the
154 carry-over from one season to another, and the consistent behavioural responses to
155 disturbance we demonstrate here, imply that conservation-decisions for migratory
156 species should be made at a larger geographic scale than is currently the case.

157 To conclude, disturbance sensitivity, a consistent personality trait is retained in
158 migratory species over large temporal and spatial scales as well as habitat types, and
159 thus affecting habitat choice. These effects should be incorporated into conservation
160 planning and policies.
