# Program Verification in the presence of complex numbers, functions with branch cuts etc. 

J.H. Davenport - J.H.Davenport@bath.ac.uk

September 24, 2012

#### Abstract

In considering the reliability of numerical programs, it is normal to "limit our study to the semantics dealing with numerical precision" (Martel, 2005) Mar05. On the other hand, there is a great deal of work on the reliability of programs that essentially ignores the numerics. The thesis of this paper is that there is a class of problems that fall between these two, which could be described as "does the low-level arithmetic implement the high-level mathematics". Many of these problems arise because mathematics, particularly the mathematics of the complex numbers, is more difficult than expected: for example the complex function $\log$ is not continuous, writing down a program to compute an inverse function is more complicated than just solving an equation, and many algebraic simplification rules are not universally valid.

The good news is that these problems are theoretically capable of being solved, and are practically close to being solved, but not yet solved, in several real-world examples. However, there is still a long way to go before implementations match the theoretical possibilities.

## 1 Introduction

It is customary, even though not often explicitly stated, to think that programming errors in numerical programs come in three distinct flavours, which we can categorise as follows.
blunder (of the coding variety) This is the sort of error traditionally addressed in "program verification": are all array elements properly initialised before use, "fence post" errors ${ }^{1}$ are array bounds always respected etc.? These problems are essentially independent of the numerics of the problem, and indeed are normally taught/described in integer contexts.

[^0]parallelism Issues of deadlocks or races occurring due to the parallelism of an otherwise correct sequential program. Again, these problems are essentially independent of the numerics of the problem.
numerical Do truncation and round-off errors, individually or combined, mean that the program computes approximations to the "true" answers which are out of tolerance. This is the area traditionally addressed in Numerical Analysis. There are really two subquestions here: the rounding question, i.e. does $\mathbf{R}_{\text {IEEE }}$ (or whatever other arithmetic we are using) approximate $\mathbf{R}$ sufficiently well, and the truncation error question, e.g. is the discretisation $h$ small enough that it is the mathematical $\epsilon$ or is $\sum_{1}^{N}$ equivalent to $\sum_{1}^{\infty}$. Unfortunately the two interact; for example reducing $h$ in $f^{\prime}(x) \approx \frac{f(x+h)-f(x)}{h}$ to reduce the truncation error increases the rounding problems.

We note that CE05, taken as a specimen of the verification literature, contains 30 papers, of which only Mar05] deals with strictly numerical issues, four with parallelism issues, and the rest ( $83 \%$ ) with the first kind.

It is the thesis of this paper that there is a fourth kind of error, which we can describe as follows
manipulation A piece of algebra, which is "obviously correct", turns out not to be correct when interpreted, not as abstract algebra, but as the manipulation of functions $\mathbf{R} \rightarrow \mathbf{R}$ or $\mathbf{C} \rightarrow \mathbf{C}$.

Note: throughout this paper we take the standard definitions of the branch cuts of the elementary functions from [AS64, Nat10, as tightened in CDJW00]. Other definitions would have different, but not fewer, problems. We also use the Anglo-Saxon convention that log etc. (and $\sqrt{ }$ ) denote single-valued functions $(\log 1=0, \sqrt{4}=2)$, whereas Log etc. denote multi-valued functions $(\log (1)=$ $\{2 k \pi i: k \in \mathbf{Z}\}$, $\operatorname{Sqrt}(4)=\{2,-2\})$.

The author would like to thank Russell Bradford, Acyr Locatelli, Gregory Sankaran and David Wilson of the Bath Triangular Sets seminar for their input, and the referees for their comments, but the errors and omissions are all his.

## 2 Examples

The problems we are going to describe arise largely (though not entirely ${ }^{2}$ from complex numbers, and it is sometimes said "real programs don't use complex numbers", despite the fact that the introduction of COMPLEX into Fortran II was probably the first instance of a language data type that did not correspond to a machine data type. The author knows of several major uses of complex numbers and complex analysis, in particular many problems which arise in fluid dynamics, where two-dimensional real space $\mathbf{R}^{2}=\{(x, y)\}$ is viewed as the complex plane $\mathbf{C}=\{z=x+i y\}$. It is then normal to map this copy of $\mathbf{C}$

[^1]to another (in which the variable is traditionally denoted $w$ or $\zeta$ ) where the problem is easier to solve. Such an analytic map $z \mapsto w$ is termed a conformal map.

### 2.1 Kahan's example

This example comes from Kah87, pp. 187-189], and the ultimate motivation is fluid flow in a slotted strip ( $z$ space), which we wish to transform to a more convenient shape ( $w$ space).

With the usual definitions, the necessary conformal map

$$
\begin{equation*}
w=g(z):=2 \operatorname{arccosh}\left(1+\frac{2 z}{3}\right)-\operatorname{arccosh}\left(\frac{5 z+12}{3(z+4)}\right) \tag{1}
\end{equation*}
$$

is only the same as the ostensibly more efficient

$$
\begin{equation*}
w \stackrel{?}{=} q(z):=2 \operatorname{arccosh}\left(2(z+3) \sqrt{\frac{z+3}{27(z+4)}}\right) \tag{2}
\end{equation*}
$$

if we avoid the negative real axis and the area

$$
\begin{equation*}
\left\{z=x+i y:|y| \leq \sqrt{\frac{(x+3)^{2}(-2 x-9)}{2 x+5}} \wedge-9 / 2 \leq x \leq-3\right\} \tag{3}
\end{equation*}
$$

In fact, most computer algebra systems will refuse, these days, to convert one into the other, but this does not constitute a proof of difference.

Challenge 1 Demonstrate automatically that $g$ and $q$ are not equal, by producing a $z$ at which they give different results.
The technology described in [BBDP07] will isolate the curve $y= \pm \sqrt{\frac{(x+3)^{2}(-2 x-9)}{2 x+5}}$ as a potential obstacle (it is the branch cut of $q$ ), but the geometry questions are too hard for a fully-automated solution at the moment.

However, simplification is possible: $g$ can legitimately be rewritten to

$$
\begin{equation*}
w=h(z):=2 \ln \left(\frac{1}{3} \frac{\sqrt{3 z+12}(\sqrt{z+3}+\sqrt{z})^{2}}{2 \sqrt{z+3}+\sqrt{z}}\right) \tag{4}
\end{equation*}
$$

The technology in BBDP07] can show this, i.e. $\forall z \in \mathbf{C} g(z)=h(z)$, but again the geometry questions are too hard for a fully-automated solution at the moment. Indeed Maple 16 currently gets this wrong: coulditbe (g<>h) ; returns true, which ought to indicate that there is a counter-example.

Challenge 2 Demonstrate automatically that $g$ and $h$ are equal.
The technology in [BBDP07, implemented in a mixture of Maple and QEPCAD, could in principle do this, but the geometry questions are too hard for a fullyautomated solution at the moment. In addition, we would be left with the problem of trusting the underlying demonstration code, so there is the additional problem of translating this methodology into a tool such as MetiTarski Pau12.

### 2.2 Joukowski (a)

Consider the Joukowski map [Hen74, pp. 294-298]:

$$
\begin{equation*}
f: z \mapsto \frac{1}{2}\left(z+\frac{1}{z}\right) \tag{5}
\end{equation*}
$$

Lemma $1 f$ is injective as a function from $D:=\{z:|z|>1\}$.
If $z \mapsto \zeta$ then $1 / z \mapsto \zeta$, and there are no other pre-images of $\zeta$ (since the algebraic inverse of (5) is the solution of a quadratic). If $|z|>1$, then $|1 / z|<1$, so $z$ is unique in $D$.

In fact $f$ is a bijection from $D$ to $\mathbf{C}^{\ddagger}:=\mathbf{C} \backslash[-1,1]$, and hence has an inverse.
Of course, (5) is the conformal map $\mathbf{C} \rightarrow \mathbf{C}$ that equates to the map

$$
\begin{equation*}
f_{R}:(x, y) \mapsto\left(\frac{1}{2} x+\frac{1}{2} \frac{x}{x^{2}+y^{2}}, \frac{1}{2} y-\frac{1}{2} \frac{y}{x^{2}+y^{2}}\right) \tag{6}
\end{equation*}
$$

$\mathbf{R}^{2} \rightarrow \mathbf{R}^{2}$. However, it is not obvious from (6) alone that $f_{R}$ is a bijection $D \rightarrow \mathbf{C}^{\ddagger}$, i.e. that

$$
\begin{gather*}
\forall x_{1} \forall x_{2} \forall y_{1} \forall y_{2} \quad\left(x_{1}^{2}+y_{1}^{2}>1 \wedge x_{2}^{2}+y_{2}^{2}>1 \wedge x_{1}+\frac{x_{1}}{x_{1}^{2}+y_{1}^{2}}=x_{2}+\frac{x_{2}}{x_{2}^{2}+y_{2}^{2}} \wedge\right. \\
\left.y_{1}-\frac{y_{1}}{x_{1}^{2}+y_{1}^{2}}=y_{2}-\frac{y_{2}}{x_{2}^{2}+y_{2}^{2}}\right) \Rightarrow\left(x_{1}=x_{2} \wedge y_{1}=y_{2}\right) \tag{7}
\end{gather*}
$$

Challenge 3 Demonstrate automatically the truth of (7).
We have been unable to do this with either the QEPCAD Bro03] implementation of Partial Cylindrical Algebraic Decomposition CH91] or the Maple implementation of Cylindrical Algebraic Decomposition via triangular decomposition CMMXY09.

However, Brown [Bro12] has been able to reformulate the problem (manually) to make it amenable to QEPCAD, and indeed solved it in under 12 seconds.

Challenge 4 Automate these techniques and transforms.
Having established (or not) that $f$ is a bijection $D \rightarrow \mathbf{C}^{\ddagger}$, we want its inverse. Formally, this is trivial, as one referee said

The inverse of Joukowski is the solution of a quadratic with the usual sign ambiguity:
if $\zeta=\frac{1}{2}\left(z+\frac{1}{z}\right)$, then $2 z \zeta=z^{2}+1$ and $z=\zeta \pm \sqrt{\zeta^{2}-1}$. This is easily within the grasp of computer algebra, as seen in Figure 1. The only challenge might be the choice implicit in the $\pm$ symbol: which do we choose?

Figure 1: Maple's solve on inverting Joukowski
> [solve(zeta $=1 / 2 *(z+1 / z), z)] ;$

$$
\left[\zeta+\sqrt{\zeta^{2}-1}, \zeta-\sqrt{\zeta^{2}-1}\right]
$$

Figure 2: Maple's actual solve on inverting injective Joukowski
$>$ [solve(zeta $=1 / 2 *(z+1 / z), z)]$ assuming $\operatorname{abs}(z)>1$

$$
\left[\zeta+\sqrt{\zeta^{2}-1}, \zeta-\sqrt{\zeta^{2}-1}\right]
$$

Unfortunately, the answer is "neither", or at least "neither, uniformly". The true answer is that, for $f$ a bijection from $\{z:|z|>1\}$ to $\mathbf{C} \backslash[-1,1]$, its inverse is

$$
f_{1}(\zeta)=\zeta \begin{cases}+\sqrt{\zeta^{2}-1} & \Im(\zeta)>0  \tag{8}\\ -\sqrt{\zeta^{2}-1} & \Im \zeta)<0 \\ +\sqrt{\zeta^{2}-1} & \Im(\zeta)=0 \wedge \Re(\zeta)>1 \\ -\sqrt{\zeta^{2}-1} & \Im(\zeta)=0 \wedge \Re(\zeta)<-1\end{cases}
$$

In fact, a better (at least, free of case distinctions) definition is

$$
\begin{equation*}
f_{2}(\zeta)=\zeta+\sqrt{\zeta-1} \sqrt{\zeta+1} \tag{9}
\end{equation*}
$$

The techniques of BBDP07] are able to verify (9), in the sense of showing that $f_{2}(f(z))-z$ is the zero function on $\{z:|z|>1\}$.
Challenge 5 Derive automatically, and demonstrate the validity of, either (8) or (9). In terms of Maple, we would want to see Figure 3, rather than the actual Figure 2.

In terms of derivation, the techniques of CJ96 seem worthy of investigation, but the author has been unable to do this derivation satisfactorily by this route.

### 2.3 Joukowski (b)

Here the function is again given by (5).

Figure 3: Ideal Maple solve on inverting injective Joukowski

$$
\begin{gathered}
>\text { solve(zeta }=1 / 2 *(z+1 / z), z) \text { assuming } \operatorname{abs}(z)>1 \\
\zeta+\sqrt{\zeta-1} \sqrt{\zeta+1}
\end{gathered}
$$

Lemma $2 f$ is injective as a function from $H:=\{z: \Im z>0\}$.
As in Lemma 1, if $z \mapsto \zeta$ then $1 / z \mapsto \zeta$, and there are no other pre-images of $\zeta$. If $\Im(z)>0, \Im(1 / z)<0$, and $f$ in therefore injective from $H$.

In fact, $f$ is a bijection from $H$ to $\mathbf{C} \backslash((-\infty,-1] \cup[1, \infty))$, and hence has an inverse.

Again, it is not obvious from (6) alone that $f_{R}$ is a bijection, now from $\{(x, y) \mid y>0\}$, i.e. that

$$
\begin{align*}
& \forall x_{1} \forall x_{2} \forall y_{1} \forall y_{2} \quad\left(y_{1}>0 \wedge y_{2}>0 \wedge x_{1}+\frac{x_{1}}{x_{1}^{2}+y_{1}^{2}}=x_{2}+\frac{x_{2}}{x_{2}^{2}+y_{2}^{2}} \wedge\right.  \tag{10}\\
&\left.y_{1}-\frac{y_{1}}{x_{1}^{2}+y_{1}^{2}}=y_{2}-\frac{y_{2}}{x_{2}^{2}+y_{2}^{2}}\right) \Rightarrow\left(x_{1}=x_{2} \wedge y_{1}=y_{2}\right)
\end{align*}
$$

Challenge 6 Demonstrate automatically the truth of (10).
It is likely that the ideas of Bro12 can do this, but again these need automation.
We have the same challenge over the inverse of $f$ : again formally it is $f^{-1} \stackrel{?}{=} \zeta \pm \sqrt{\zeta^{2}-1}$, and the only challenge is the $\pm$ symbol: which do we choose? Here [Hen74, (5.1-13), p. 298] argues for

$$
\begin{equation*}
f_{3}(\zeta)=\zeta+\underbrace{\sqrt{\zeta-1}}_{\arg \in(-\pi / 2, \pi / 2]} \underbrace{\sqrt{\zeta+1}}_{\arg \in(0, \pi]} . \tag{11}
\end{equation*}
$$

Challenge 7 Find a way to represent functions such as $\underbrace{\sqrt{\zeta+1}}_{\arg \in(0, \pi]}$
Fortunately this one is soluble in this case ${ }^{3}$, we can write $\underbrace{\sqrt{\zeta+1}}_{\arg \in(0, \pi]}=i \underbrace{\sqrt{-\zeta-1}}_{\arg \in(-\pi / 2, \pi / 2]}$, and the latter is the normal sqrt function of AS64. Hence we have an inverse function

$$
\begin{equation*}
f_{4}(\zeta)=\zeta+\sqrt{\zeta-1} i \sqrt{-\zeta-1} \tag{12}
\end{equation*}
$$

Challenge 8 Demonstrate automatically that this is an inverse to $f$ on $\{z$ : $\Im z>0\}$.

### 2.4 A Real Example

Just in case the reader thinks that the real numbers are immune from these problems, consider the addition rule for the inverse tangent, quoted as

$$
\operatorname{Arctan}(x) \pm \operatorname{Arctan}(y)=\operatorname{Arctan}\left(\frac{x \pm y}{1 \mp x y}\right) \cdot[\operatorname{AS64},(4.4 .34)][\text { Nat10, },(4.24 .15)]
$$

[^2]Despite the caveat in Nat10 that "The above equations are interpreted in the sense that every value of the left-hand side is a value of the right-hand side and vice versa", it is in fact the case that the 'obvious' two equations are true separately, viz.

$$
\begin{align*}
& \operatorname{Arctan}(x)+\operatorname{Arctan}(y)=\operatorname{Arctan}\left(\frac{x+y}{1-x y}\right)  \tag{13}\\
& \operatorname{Arctan}(x)-\operatorname{Arctan}(y)=\operatorname{Arctan}\left(\frac{x-y}{1+x y}\right) \tag{14}
\end{align*}
$$

Consider (13): This is valid for the multi-valued Arctan, but for the singlevalued arctan only when $|1-x y|<1$, due to a "branch cut at infinity" of arctan. Nevertheless, the single-valued version of 13 is often cited as true: see for example Ter12, (5.2.5)].

Over the reals, this is a non-challenge, the techniques of BBDP07] do solve it easily, and produce a counterexample.

## 3 So why are these challenges?

### 3.1 Complex functions and branch cuts

These are difficult subjects, which have tended to be brushed under the carpet. The first truly algorithmic approach is ten years old ( $\widehat{\mathrm{BCD}^{+} 02}$, refined in [BBDP07]), and has various difficulties.

1. At its core is the use of Cylindrical Algebraic Decomposition of $\mathbf{R}^{N}$ to find the connected components of $\mathbf{C}^{N / 2} \backslash\{$ branch cuts $\}$. The complexity of this is doubly exponential in $N$ : upper bound of $d^{O\left(2^{N}\right)}$ Hon91 and lower bounds of $2^{2^{(N-1) / 3}}$ BD07, DH88. While better algorithms are in principle known (BRSEDS12 is $d^{O(N \sqrt{N})}$ ), we do not know of any accessible implementations.
Furthermore, we are clearly limited to small values of $N$, at which point looking at $O(\ldots)$ complexity is of limited use. We note that the crossover point between $2^{(N-1) / 3}$ and $N \sqrt{N}$ is at $N=21$. A more detailed comparison is given in Hon91. Hence there is a need for practical research on low- $N$ Cylindrical Algebraic Decomposition.
2. While the fundamental branch cut of $\log$ is simple enough, being $\{z=$ $x+i y \mid y=0 \wedge x<0\}$, actual branch cuts are messier. Part of the branch cut of (2) is

$$
\begin{equation*}
2 x^{3}+21 x^{2}+72 x+2 x y^{2}+5 y^{2}+81=0 \wedge \text { other conditions, } \tag{15}
\end{equation*}
$$

whose solution accounts for the curious expression in (3). While there has been some progress in manipulating such images of half-lines (described in PBD10, Phi11]), there is almost certainly more to be done.

### 3.2 Injectivity

Lemmas 1 and 2 might seem to be statements about complex functions of one variable, so why do we need to handle (or fail to handle) statements about four real variables to prove them? There are three, rather distinct, reasons for this.

1. The statements require the $|\cdot|$ function (Lemma 1) or the $\Im$ function (Lemma 2), neither of which are complex analytic functions. Hence some recourse to real analysis (and therefore twice as many variables) seems inevitable, though it would be nice to have a more formal statement and proof of this.
2. Equations (7) and (10) are the direct translations of the basic definition of injectivity. In practice, certainly if we were looking at functions $\mathbf{R} \rightarrow \mathbf{R}$, we would want to use the fact that the function concerned was continuous.

Challenge 9 Find a better formulation of injectivity questions $\mathbf{R}^{N} \rightarrow$ $\mathbf{R}^{N}$, making use of the properties of the functions concerned (certainly continuity, possibly rationality).
3. While equations (7) and 10 are statements from the existential theory of the reals, and so the theoretically more efficient algorithms quoted in Hon91 are in principle applicable, the more modern developments described in PJ09 do not seem to be directly applicable. However, we can transform then into a disjunction of statements to each of which the Weak Positivstellensatz PJ09, Theorem 1] is applicable.

Challenge 10 Solve these problems using the techniques of [PJ09],

## 4 Conclusions

The aim of this paper has been to demonstrate that translating mathematical problems into programs may require some algebraic manipulations whose accuracy is not as obvious as one might think, and whose verification is currently not as straightforward as we would like, despite the fact that their correctness is, in principle, decidable. A summary is given in Table 1.
These are, largely, concrete challenges that, we hope, will spur practical advances in this domain.
