#### Abstract

The first example of an intramolecular ester enolate-imine cyclisation reaction for the asymmetric synthesis of polycyclic $\beta$-lactams and cyclic $\beta$-amino acid derivatives has been developed. 

In Chapter 1, the synthesis of monocyclic $\beta$-lactams using intermolecular ester enolateimine cyclisation reactions is reviewed. The use of chiral auxiliaries contained within the ester or imino functionality to control the diastereoselectivity of the reaction is discussed, as well as enantioselective approaches. The utilization of this methodology for the synthesis of natural products such as Taxol is described, as well as the use of polymer support protocols to improve the efficiency of this reaction.

In Chapter 2, the synthesis of an appropriate cyclisation substrate containing an ester and imino functionality with a chiral auxiliary fragment is reported. Appropriate conditions were established that enabled an intramolecular enolate-imine cyclisation reaction to be used for the synthesis of the tricyclic $\beta$-lactam benzocispentacin in good yield and excellent de. The formation of $\beta$-amino ester side products was investigated and an explanation for the production of $\beta$-lactams as major products over their corresponding $\beta$-amino esters is proposed. This protocol was then applied to the asymmetric synthesis of six benzocispentacin derivatives all with good yields and excellent de, with the configuration of one of these derivatives being confirmed by X-ray crystallography. A deprotection methodology was then established to afford their corresponding tricyclic NH- $\beta$-lactams and cis and trans bicyclic $\beta$-amino esters.

In Chapter 3, the newly devised methodology was also applied to acyclic substrates for the synthesis of the antifungal cispentacin. The ability to access both cis- and transpentacin in both high yields and excellent de as monomers for foldamer synthesis is reported. A small series of bicyclic $\beta$-lactam analogues was prepared in a short and efficient methodology, with the intramolecular enolate-imine cyclisation reaction being the key step to all these syntheses.

## Acknowledgements

Firstly, I would like to thank Dr Steven Bull for offering me the chance to do a PhD and for being both a supportive and encouraging supervisor. I would like to thank him for guiding me during my time at Bath and for an unforgettable experience. In addition, I am extremely appreciative to Steve, Jennifer Peed, Dr James Taylor and Dr Tracy Nixon for all of their support helping to proof read this thesis.

Thanks must also go to Dr James Muir at AstraZeneca who provided me with lots of support and chemicals throughout and also all the staff at Macclesfield who made my CASE placement a thoroughly enjoyable experience. I would like to thank Dr Andrew Leach for generously spending time to provide me with the computational modelling. In particular, I would also like to thank Dr Steve Coombes and Dr Tony Bristow who helped solve the structure of the particularly tricky cispentacin impurity, and also Dr Peter Moore who not only gave me lots of direction but was a good friend during my time at AZ.

During my time at Bath I have had the pleasure to work with many great people who have helped improve me as a chemist and made my PhD an experience I will never forget. During my first few years Dr Tracy Nixon, Dr Iwan Davies, Paul Fordred and Dr Hannah Maytum provided invaluable advice and support that helped me through my biggest educational learning curve. Thanks goes to all past and present members of the Bull group who have helped make my time so enjoyable and for putting up with me, in particular Robert Archer, Lucy Peacock, Richard Blackburn and Ruth Lawrence, all of whom have provided constant support and many entertaining moment. I would like to give special thanks to Jennifer Peed and Dr James Taylor for being really great friends when I needed them the most.

Finally, I would like to thank the people who have been there behind the scenes, who have constantly encouraged me and provided me with a sympathetic ear. Thanks to Dave Tickell and Denitza Williams who have always understood my PhD dilemmas and always given me great advice. I would like to thank my brother and sister, Samantha and Alex Evans, for always taking a keen interest in how it was all going. Most importantly I would like to thank my Mum and Dad who gave me the determination and ambition which enabled me to achieve this PhD.

## 1 The Ester Enolate-Imine Condensation Reaction for the Synthesis of $\beta$-lactams

### 1.1 Introduction

In the past century, the design and development of $\beta$-lactam antibiotics has been highly influential within drug discovery, due to their biological and pharmacological activity. The biological effects of the $\beta$-lactam ring system were first identified due to the discovery of penicillin in 1928, this led to the discovery of the most widely used of all the antimicrobial agents. ${ }^{1} \beta$-lactam antibiotics are highly successful therapeutic agents which can inhibit both penicillin binding proteins and serine proteases, ${ }^{2}$ this is in addition to their bactericidal action on enzymes that cross-link the peptidoglycan of the bacterial cell wall. A variety of subgroups of $\beta$-lactam antibiotics have been developed and some of the most commonly synthesised targets include penicillins $\mathbf{1}$, cephalosporins 2, carbapenems 3 and the monocyclic norcardicins 4 (Figure 1). These antibiotics successfully interfere with the peptidoglycan cell wall synthesis, due to their ability to inhibit bacterial enzymes, transpeptidases and carboxypeptidases. ${ }^{3}$

Figure 1- Examples of $\boldsymbol{\beta}$-lactam antibiotic subgroups

In addition, $\beta$-lactam scaffolds have also been widely used as building blocks for synthesis of peptides, peptidomimetics, natural products and alkaloids, that have been subject to a series of detailed reviews. ${ }^{4-5}$

There are several main methods for the synthesis of $\beta$-lactams which include the Staudinger reaction, the Gilman-Speeter reaction and the Kinugasa reaction. In order to prepare $\beta$-lactams in their enantiopure form using these methodologies then either a chiral catalyst, chiral auxiliary or chiral starting materials need to be employed for stereocontrol.

The Staudinger [2+2] cycloaddition was first reported in 1907, which involved the cycloaddition of stable ketenes such as diphenylketene 5 with an imine 6 to furnish the first example of the strained four membered lactam ring 7. ${ }^{6}$ The nucleophilic addition of the nitrogen lone pair of the imine onto the carbon of the ketene results in the formation of a zwitterion which subsequently undergoes a cycloaddition forming a $\beta$-lactam (Scheme 1).

Scheme 1- Staudinger reaction producing first $\beta$-lactam ${ }^{6}$

The Staudinger reaction is the most common methodology for the synthesis of $\beta$-lactams with much recent research aimed at developing an enantioselective reaction using chiral catalysts (Scheme 2). ${ }^{7-8}$

Reagents \& Conditions: (i) Catalyst 11 (10 mol\%), $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ (10 mol\%), THF, rt
Scheme 2- Chiral $N$-heterocyclic carbene catalysed Staudinger reaction ${ }^{7}$

In 1972, the synthesis of $\beta$-lactams was shown to be possible by reacting copper(I) phenylacetylide 12 with nitrones in anhydrous pyridine (Scheme 3). The reaction times were typically short, with readily available starting materials forming exclusively cis- $\beta$ lactams in good yield. ${ }^{9}$

Reagents \& Conditions: (i) Pyridine, rt, 1 hr
Scheme 3- First reported Kinugasa reaction ${ }^{9}$

Since its initial discovery, the scope and limitations of the Kinugasa reaction has been explored, with more recent examples obtaining $\beta$-lactams enantioselectively as well as the development of an intramolecular version of the reaction (Scheme 4). ${ }^{10}$

Reagents \& Conditions: (i) CuBr (5 \%), ligand 17 (5 \%), CyNMe $2, \mathrm{MeCN}, 0^{\circ} \mathrm{C}$
Scheme 4- Catalytic enantioselective intramolecular Kinugasa reaction ${ }^{11}$

Finally, the enolate-imine cyclisation reaction (Gilman-Speeter) is another highly utilized methodology employed for the synthesis of $\beta$-lactams. This methodology forms the basis of the research programme described in this thesis, and as a consequence the highlights of this important reaction will now be reviewed in detail.

### 1.2 Enolate-Imine Condensation Reactions - Introduction

The first enolate-imine condensation reaction was originally reported by Gilman and Speeter in 1943 who employed a Reformatsky type reaction of the zinc enolate of $\alpha$ -bromo-ester 18 with an imine for the production of an $N$-aryl- $\beta$-lactam such as 19 (Scheme 5). ${ }^{12}$

Reagents \& Conditions: (i) Zn, toluene
Scheme 5- First reported example of the Gilman-Speeter reaction for the synthesis of a $\beta$-lactam ${ }^{12}$

The ester enolate-imine condensation reaction can be considered analogous to the aldol condensation, whereby a metal enolate is generated that then effects nucleophilic attack at an imine to afford an intermediate $\beta$-amino ester, which subsequently undergoes a ring closure reaction to form a $\beta$-lactam structure (Scheme 6). This type of enolate-imine condensation reaction has attracted a large amount of interest, with much research concentrating on selectively accessing either cis- or trans- $\beta$-lactams. In this respect it represents an alternative to the established Staudinger methodology that involves [2+2] cycloaddition of a ketene and an imine. ${ }^{6}$

Scheme 6- Basic mechanism of the ester enolate-imine condensation reaction

Theoretical calculations support the proposed stepwise mechanism of the enolateimine condensation reaction which were carried out to include the electrostatic effects of the solvent. ${ }^{13}$ The reaction commences with C-C bond formation between the enolate and the imine which was calculated to be both irreversible and the rate determining step, ${ }^{13}$ this is then followed by a rapid ring closure reaction that results in elimination of methoxide to afford the $\beta$-lactam ring. ${ }^{13}$ The cis/trans stereochemistry of
the resulting $\beta$-lactam is dependent on the type of transition state formed in the initial nucleophilic addition step, which can proceed either via a chair or boat conformation depending on the conditions and type of metal counterion used for enolate formation (Figure 2). ${ }^{14-16}$

Figure 2- Effect of metal counterion on $\boldsymbol{\beta}$-lactam formation

In 1989, the then emerging area of using enolate-imine cyclisation reactions for the synthesis of $\beta$-lactams was comprehensively reviewed, with a particular focus on the scope and limitation of different metal enolates on the yield and stereoselectivity of this reaction. ${ }^{17}$ This review will now describe on progress in this area for the asymmetric synthesis of $\beta$-lactams, and demonstrate how this efficient methodology has been used for the synthesis of a number of medicinally useful $\beta$-lactam targets. For consistency and clarity, the review will follow the format originally used by Hart in 1989, first describing progress in generating and using different types of enolate species, followed by asymmetric development and natural product syntheses. ${ }^{17}$ In this respect, it will briefly highlight the important factors known prior to 1989, and report important new developments that have contributed to this methodology now being widely used for the stereoselective synthesis of $\beta$-lactams.

### 1.3 Selected Metal Enolates

The greatest area of progress in demonstrating the potential of using enolate-imine cyclisation reactions for $\beta$-lactam formation has been in the use of lithium and/or zinc enolates, whilst protocols employing titanium, aluminium and boron enolates have all been used to selectively generate $\beta$-lactams with good levels of stereocontrol.

### 1.3.1 Zinc Enolates

The initial Reformatsky reaction carried out by Gilman et al. (Scheme 5) was further investigated, with a series of studies reporting that the reaction of zinc enolates of ethyl $\alpha$-bromoacetate 20 with numerous $N$-aryl aldimines gave good yields of $N$-aryl- $\beta$ lactams (Scheme 7), ${ }^{18}$ in particular the yields of 3 -unsubstituted $\beta$-lactams were shown to be improved in the presence of ultrasound. ${ }^{19}$ Investigations into the stereoselectivity of $\beta$-lactam formation revealed that the cis- $\beta$-lactam was normally formed as the major product when the $\alpha$-substituent of the ester enolate was an alkyl group, or THF was used as solvent for the reaction. ${ }^{20-21}$ Theoretical calculations revealed that reaction of the zinc enolate and imine occur via a twisted boat transition state in the case of tri- and tetra-coordinated zinc atoms in order to minimise steric interactions and electronic repulsion of electronegative atoms in the transition state. ${ }^{22}$

Reagents \& Conditions: (i) Zn, THF, reflux
Scheme 7-Reaction of the zinc enolate of $\alpha$-bromo-ester 20 with an aldimine for cis- $\beta$-lactam 22 synthesis ${ }^{20}$

It was also shown that varying the temperature of the reaction enabled either $\beta$-lactam 24, or $\beta$-amino ester 25 to be accessed from these types of reactions (Scheme 8). It was proven that isomerization was taking place as only the erythro-isomer of the $\beta$ amino ester 25 was observed at lower temperature, whereas when the reaction was warmed to $42^{\circ} \mathrm{C}$ the cis- $\beta$-lactam 24 was isolated in $80 \%$ de, which suggests that the
first step of the enolate-imine reaction might be a reversible reaction under these conditions. ${ }^{23,24}$

Reagents \& Conditions: (i) Methylal, $42^{\circ} \mathrm{C}$; (ii) Methylal, $-10^{\circ} \mathrm{C}$
Scheme 8- Effects of reaction conditions on Reformatsky enolate-imine cyclisation products

Any suggestion that these cyclisation reactions were occurring via a ketene Staudingertype mechanism were quickly ruled out, when it was shown that reaction of imine $\mathbf{6}$ with isopropyl-ketene 27 gave exclusively the corresponding trans- $\beta$-lactam 28 (Scheme 9). ${ }^{25}$

Scheme 9- Staudinger reaction resulting in synthesis of trans- $\beta$-lactam $\mathbf{2 8} \mathbf{2 5}^{\mathbf{2 5}}$

In 1991, the zinc enolate of $N, N$-disubstituted glycine ester 29 was generated via transmetallation of the lithium enolate, for the one-pot synthesis of trans-3-amino-2azetidinones 31 in high yields and de (Scheme 10). ${ }^{26}$ After an extensive study into the effects of the metal cation, solvent and substituents on the $\alpha$-amino zinc ester enolates, it was found that the best trans- selectivity was obtained using apolar solvents and a bulky/electron withdrawing protecting group on the $\alpha$-amino nitrogen of the enolate fragment. ${ }^{26}$

Reagents \& Conditions: (i) a) LDA, $\mathrm{Et}_{2} \mathrm{O},-78^{\circ} \mathrm{C}$ b) $\mathrm{ZnCl}_{2}$; (ii) $-78^{\circ} \mathrm{C}$ to rt, $\mathrm{H}_{2} \mathrm{O}$; (iii) $\mathrm{H}^{+} / \mathrm{H}_{2} \mathrm{O}$
Scheme 10- Synthesis of trans-2 azetinones using $N$, $N$-disubstituted glycine esters ${ }^{26}$

In addition, zinc enolates have previously been shown to interact with both activated ( $N$-substituted with an electron withdrawing group) and unactivated imines ( $N$ substituted with an electron donating group), which is advantageous when compared to lithium enolates which generally only react with activated imines. The catalytic use of $\mathrm{ZnCl}_{2}$ was shown to marginally increase the cis:trans diastereoselectivity from 58:42 to 73:27 for $\beta$-lactam 35 (Scheme 11). ${ }^{26}$

Reagents \& Conditions: (i) a) LDA b) 0.25 equiv. $\mathrm{ZnCl}_{2}$; (ii) THF, reflux, 1 hr
Scheme 11- Reformatsky reaction using $N$-alkyl-imines ${ }^{26}$

Functionalisation of C 4 on the 3 -amino-2-azetidinone has further effects on the cis:trans selectivity of the cyclisation reaction used for its formation. The bis-imine 36 had a much higher selectivity for the trans $\beta$-lactam compared to oxygen or sulfur analogues as it is proposed that these types of imines cyclise via a more restricted transition state (Scheme 12). ${ }^{27}$

Reagents \& Conditions: (i) a) LDA, $\mathrm{Et}_{2} \mathrm{O}-78^{\circ} \mathrm{C}$; b) $\mathrm{ZnCl}_{2}$; (ii) $-78^{\circ} \mathrm{C}$ to rt, $\mathrm{H}_{2} \mathrm{O}$
Scheme 12-C4 substituted trans- $\beta$-lactams ${ }^{27}$

More recently in 2003, it was found that treatment of 4-bromo-crotonate with a mixture of $\mathrm{Zn} / \mathrm{Cp}_{2} \mathrm{TiCl}_{2}$ afforded a zinc enolate that reacted with imine 38 to exclusively afford a trans- $\beta$-lactam 40 in 81\% yield (Scheme 13). ${ }^{28}$

Reagents \& Conditions: (i) $\mathrm{Zn} / \mathrm{Cp}_{2} \mathrm{TiCl}_{2}, \mathrm{THF}$, rt
Scheme 13- $\mathbf{Z n} / \mathrm{Cp}_{2} \mathbf{T i C l}_{2}$ catalysed Reformatsky reaction ${ }^{28}$

### 1.3.2 Lithium Enolates

The first report of using lithium enolates for the enolate-imine condensation reaction was described in 1980, with lithium enolates of $\alpha, \alpha$-disubstituted acetates reacting with $N$-arylaldimines to furnish either cis- or trans- $\beta$-lactams in good yields and excellent de. ${ }^{29}$ The conditions of the reaction, in particular the solvent, were shown to have a significant impact on the stereoselectivity of these reactions (Scheme 14). When THF was chosen as solvent then reaction of an $(E)$-enolate with an $N$-aryl-imine 38 resulted in formation of cis- $\beta$-lactam 42 as the major isomer in $83 \%$ yield, similar to the results observed using zinc enolates (Scheme 8). Conversely, when HMPA was added to the reaction, it resulted in a ( $Z$ )-enolate that selectively afforded a trans- $\beta$-lactam 43 in $80 \%$ yield as the major isomer. ${ }^{29,30}$

Reagents \& Conditions: (i) a) LDA, THF; b) N-benzylidene-4-methoxyaniline 38, $25^{\circ} \mathrm{C}$; (ii) a) LDA, THF;
b) THF-HMPA, N-benzylidene-4-methoxyaniline $38,25^{\circ} \mathrm{C}$

Scheme 14- Effect of solvent on the $\boldsymbol{\beta}$-lactam using lithium enolates ${ }^{29}$

In 1985, Overman et al. demonstrated that $N$-substituted- $\alpha$-amino nitriles 44 could be used as precursors to generate $N$-substituted formaldimines in situ, which then reacted with lithium enolates of $N$-protected glycine ester derivative 29 to afford the $\mathrm{C}_{4}$ unsubstituted $\beta$-lactam 45 in high yield (Scheme 15). ${ }^{31}$

44

Reagents \& Conditions: (i) LDA (2.0 equiv.), THF (ii) Amine 44; (iii) $\mathrm{H}_{2} \mathrm{O}$
Scheme 15- Reaction of a lithium enolate to afford a 3-amino- $\beta$-lactam ${ }^{31}$

The development of a new methodology to generate $N$-(TIPS)- and $N$-(TBDMS)-imines enabled their effect on the selectivity of enolate-imine cyclisation reactions to be determined. The reaction of the lithium enolate of STABASE 29 and the N (TBDMS)imine 46 was shown to exclusively afford the trans- $\beta$-lactam 47 in $70 \%$ yield (Scheme 16). ${ }^{32}$ In comparison, $N$-(TMS)-imines are reported to selectively produce cis-$\beta$-lactams when used under the same conditions.

Reagents \& Conditions: (i) THF, $-78^{\circ} \mathrm{C}$; (ii) $\mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{CbzCl}$, acetone
Scheme 16- Use of $\boldsymbol{N}$-(TBDMS)imines for $\boldsymbol{\beta}$-lactam synthesis ${ }^{32}$

In addition, it has been demonstrated that the methodology for the synthesis of enolates can have significant implications on the stereochemistry of the resulting $\beta$ lactam 50. For example, the enolate could be formed by either the conjugate addition of LDA to methyl crotonate 48 (method $\mathbf{A}$ ), or via treatment of the corresponding $\beta$-amino ester 49 with LDA (method B). As such, the enolate was reacted with imine 52 to afford trans- $\beta$-lactam 50, that was subsequently de-aminated to afford $\alpha$-alkylidene- $\beta$ lactam 51 as a mixture of $E / Z$ isomers, that were then screened as potential $\beta$ lactamase inhibitors (Scheme 17). ${ }^{33}$

Reagents \& Conditions: (i) LDA, $-78^{\circ} \mathrm{C}$, (ii) (ethane-1,2-diylidene)bis(4-methoxyaniline) 52
Scheme 17- Synthesis of $\alpha$-alkylidene- $\beta$-lactams ${ }^{33}$

Further work suggested that the stereoselectivity of the reaction is affected by the methodology used to generate the enolate for $\beta$-lactam synthesis. Method A produced $\beta$-lactam 50a as the major diastereomer, whereas method $\mathbf{B}$ produced $\beta$-lactam 50b as the major diastereomer. ${ }^{34}$

50a
Method A

Figure 3- Major enantiomers formed during synthesis of $\boldsymbol{\beta}$-lactam $\mathbf{5 0}^{\mathbf{3 4}}$

This methodology was then applied for the synthesis of $\alpha$-ethylidene $\beta$-lactams using the enolate-imine reaction to allow access to polyoximic acids, these were subsequently used for the formation of a range of polyoxins. ${ }^{34}$

The result of $\alpha$-hetero ester enolates with $N$-aryl imines has been well documented with the majority of substituents forming the trans- $\beta$-lactam. ${ }^{14}$ An investigation into the stereoselective synthesis of 3-fluoro-azetidinones revealed that the use of the keteneimine methodology to generate $\alpha$-fluoro- $\beta$-lactams was much more selective than the corresponding ester enolate-imine condensation reaction. A series of experimental conditions were investigated which revealed that the best conditions for the reaction of lithium fluoro-enolate 54 with N -aryl-imine 38 resulted in the predominant formation of the trans- $\beta$-lactam 55 in $56 \%$ de and $68 \%$ yield (Scheme 18). ${ }^{35}$

Reagents \& Conditions: (i) LDA, $-78^{\circ} \mathrm{C}, \mathrm{THF}$
Scheme 18- Synthesis of 3-fluoro-azetidinones ${ }^{35}$

More recently, alternative conditions for the synthesis of these types of 3-fluoro azetindinones have been devised using the ( $Z$ )-enolate of thioester 56 which afforded the cis- $\beta$-lactam 57 in $73 \%$ yield and $94 \%$ de (Scheme 19). ${ }^{36}$

Reagents \& Conditions: (i) LDA, $-78^{\circ} \mathrm{C}$, THF; (ii) rt, 4hrs
Scheme 19- Synthesis of 3-fluoro azetidinones using thioesters ${ }^{37}$

Previously, the highly selective synthesis of cis- $\beta$-amino acyl iron complexes has been reported using lithium enolates of chiral racemic iron acyl complexes and N -aryl imines. ${ }^{38}$ In 2001, the preparation of $\beta$-lactams containing ferrocene units at the 3 position via reaction of the lithium enolate of ethyl 3-ferrocenylpropanoate with imine 38 was reported. This ester enolate-imine condensation produced $\beta$-lactam 59 as the major product and the hydroxy- $\beta$-lactam 60 as a minor side product (Scheme 20). ${ }^{39}$

Reagents \& Conditions: (i) LDA, $-78^{\circ} \mathrm{C}, \mathrm{THF}$
Scheme 20-Synthesis of C3-ferrocene substituted $\boldsymbol{\beta}$-lactams ${ }^{39}$

### 1.3.3 Titanium Enolates

Cinquini et al. originally reported on the synthesis of $\beta$-lactams via the reaction of titanium enolates of 2-pyridylthioesters with imines, ${ }^{40}$ which revealed that an increase in
steric bulk on the $\alpha$-substituent resulted in an increase in trans selectivity. For example, it was shown that reaction of the lithium enolate of thioester 61 containing an $\alpha$ isopropyl group with $N$-benzyl-imine 62 gave trans- $\beta$-lactam 63 in an $83 \%$ yield (Scheme 21).

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, E t_{3} \mathrm{~N},-78^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$, 6 hrs
Scheme 21-Reaction of the enolate of thioester 61 with imine 62 affords trans- $\beta$-lactam 63 with good levels of stereocontrol ${ }^{40}$

It was proposed that this trans- $\beta$-lactam 63 was formed via a transition state that involved an intramolecular chelate between the pyridine nitrogen atom and the titanium counterion of the enolate (Figure 4). ${ }^{40}$

Figure 4- Transition state of titanium enolate of 2-pyridylthioester that affords $\boldsymbol{\beta}$-lactam 63 with good levels of (trans) $\boldsymbol{\beta}$-lactam selectivity ${ }^{40}$

The reactivity of titanium (IV) and tin (IV) enolates of the thiopyridyl ester 64 with imines was investigated in order to determinine whether improved trans:cis ratios could be obtained. ${ }^{41}$ Tin enolates were found to afford better levels of stereocontrol with the use of $\mathrm{SnCl}_{4}$ affording the corresponding cis- $\beta$-lactam 66 in $80 \%$ de, whilst $\mathrm{SnBr}_{4}$ gave trans- $\beta$-lactam 65 in 74\% de (Table 1). ${ }^{41}$

Table 1- Comparison of the reactivity of $\operatorname{tin}(I V)$ and titanium (IV) enolates with $N$-aryl-imines ${ }^{41}$

The influence of the imine structure on the trans/cis ratio of these cyclisation reactions was further investigated by analysing the diastereoselectivity for reactions of enolates of achiral thioesters with achiral imines containing different substituents. It was found that trans- $\beta$-lactams were formed as a result of reaction of imines with bulky and nonchelating heteroatoms, whereas cis- $\beta$-lactams were formed as major products from imines that contained small or chelating groups. ${ }^{42}$

Table 2- Effect of imine substituent on trans/cis ratio ${ }^{42}$

| Entry | $\mathbf{R}$ | Yield (\%) | trans:cis ratio |
| :---: | :---: | :---: | :---: |
| 1 | Ph | 99 | $70: 30$ |
| 2 | $\mathrm{HC}=\mathrm{CHPh}$ | 99 | $60: 40$ |
| 3 | $n$-Pr | 48 | $37: 63$ |
| 4 | $\mathrm{CH}_{2} \mathrm{OTBDPS}$ | 40 | $46: 54$ |
| 5 | $\mathrm{CH}_{2} \mathrm{OBn}$ | 40 | $23: 77$ |

Furthermore, in an attempt to determine how the enolate geometry of an achiral thioester affects the trans/cis ratio during $\beta$-lactam formation, enolate 68 was trapped as a silylketene acetal. The trapped ( $E$-enolate (geometry determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy) was subsequently reacted with achiral imine 38 and a Lewis acid, titanium(IV)chloride, to afford the trans- $\beta$-lactam 69 in high de. ${ }^{43}$ In general, when the titanium ( $\Xi$ )-enolate of the silyl ketene thioacetal was formed, the trans $\beta$-lactam was observed in the corresponding $(E) /(Z)$ ratio. ${ }^{43}$

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, \mathrm{DCM}, 0^{\circ} \mathrm{C}$ to rt, 12 hrs
Scheme 22- Ketene-silyl acetals as nucleophiles for $\beta$-lactam synthesis ${ }^{43}$

### 1.3.4 Other Conditions

The reaction of aluminium enolates of thioesters 71 with N -alkylimines 72 for the synthesis of a range of analogues of trans- $\beta$-lactams 73 in high yield and good de was first reported in 1987 (Scheme 23). ${ }^{44,45}$ Alternatively, if a more sterically demanding ester substituent is used, such as an isopropyl group, then the cis- $\beta$-lactam predominates.

Reagents \& Conditions: (i) a) LDA, THF; b) Et $t_{2} A l C l$; c) Imine 72
Scheme 23- Aluminium enolate and enolisable $N$-alkylimines for $\beta$-lactam formation ${ }^{45}$
This use of aluminum enolates was further exploited via a transmetallation of the lithium enolate of $\mathrm{N}, \mathrm{N}$-disubsituted glycine thioester 29 with an excess of $\mathrm{Me}_{2} \mathrm{AICl}$ which gave
a dialkylaluminium ( $Z$ )-enolate that reacts with $N$-methyl-imine 35 to furnish trans- $\beta$ lactam 74 in $92 \%$ de and $87 \%$ yield (Scheme 24). ${ }^{46}$

Reagents \& Conditions: (i) LDA, Me $\operatorname{AlCl}$ (1.2 equiv.), benzene, $0^{\circ} \mathrm{C}$ to rt, 0.5 hrs ; (ii) reflux
Scheme 24- Synthesis of aluminium enolates and effect on stereoselectivity of $\boldsymbol{\beta}$-lactam ${ }^{46}$

The ability to isolate a single diastereomer of a $\beta$-lactam in good yield using an organocopper ester enolate-imine condensation reaction was first reported during the synthesis of the antibiotic thienamycin. ${ }^{47}$ Conjugate addition of a silyl anion generates an enolate from ester 75 that then reacts with imine $\mathbf{7 6}$ to afford trans- $\beta$-lactam 77 with good levels of stereocontrol.

Reagents \& Conditions: (i) $\left(\mathrm{PhMe}_{2} \mathrm{Si}_{2}{ }_{2} \mathrm{CuCNLi} 2_{2}, \mathrm{THF}, 0{ }^{\circ} \mathrm{C}, 20\right.$ mins; (ii) Imine 76, THF, $0{ }^{\circ} \mathrm{C}$ to rt, 3 hrs
Scheme 25- Organocopper ester enolate-imine condensation reaction ${ }^{47}$

More recently, a novel strategy for the generation of iridium enolates was developed involving an in situ reduction of an $\alpha, \beta$-unsaturated ester 78 with a iridium hydride species, that generates an iridium enolate in situ which reacts with $N$-aryl-imine 6, to afford the trans- $\beta$-lactam 79 in $68 \%$ yield and $90 \%$ de (Scheme 26 ). ${ }^{48}$

Reagents \& Conditions: (i) $2.5 \mathrm{~mol} \%[(\mathrm{cod}) \mathrm{IrCl}]_{2}, 10 \mathrm{~mol} \% \mathrm{P}(\mathrm{OPh})_{3}, \mathrm{Et}_{2} \mathrm{MeSiH}, 60^{\circ} \mathrm{C}$, 6 hrs
Scheme 26- Iridium catalysed reductive coupling of imines and acrylates ${ }^{48}$

### 1.4 Chiral Esters

The ability to prepare enantiopure $\beta$-lactams is of great importance as they can be used as both versatile chiral building blocks for synthesis or as important biologically active agents. The first significant report of carrying out ester enolate-imine cyclisation reactions using a chiral ester fragment was reported in 1980, where it was demonstrated that reaction of the lithium enolate of menthyl ester $\mathbf{8 0}$ with imine $\mathbf{6}$ gave $\beta$-lactam 81 in $60 \%$ ee (Scheme 27). ${ }^{29}$ The use of a chiral ester fragment to direct stereocontrol in this manner has the advantage that the final $\beta$-lactam cyclisation step results in cleavage of the chiral alcohol fragment, and as such does not require an additional deprotection step.

Reagents \& Conditions: (i) LDA, THF
Scheme 27- Asymmetric synthesis of $\beta$-lactam synthesis using a menthyl ester for diastereocontrol ${ }^{29}$

Furthermore, several alternative chiral auxiliaries were trialed, with the most successful the $(E)$-lithium enolate of $\alpha$-monosubstituted chiral ester 82 , which was reacted with
cinnamaldimine 83 to produce the major $\beta$-lactam 84 in $74 \%$ yield and an excellent $91 \%$ ee. ${ }^{49}$

Scheme 28- Synthesis of $\boldsymbol{\beta}$-lactams using camphor derived esters ${ }^{49}$

Since these initial reports there have been several major developments in this area, with chiral esters being successfully employed for the synthesis of highly functionalized $\beta$-lactams with high levels of stereocontrol.

In 1990, Ojima et al. described the reaction of $N, N$-bis(silyl)glycinate chiral esters $\mathbf{8 5}$, that contain a (-)-menthyl ester group, with $N$-aryl-imine 38 to afford trans- $\beta$-lactams with good levels of stereocontrol. ${ }^{50}$ The stereochemistry of the initial cyclisation reaction was explained using a transition state, involving attack of a chiral ( $Z$ )-enolate at the Reface of the imine, to afford after subsequent cyclisation the trans-( $3 R, 4 R$ )- $\beta$-lactam 86 in $>99 \%$ ee (Scheme 29). ${ }^{50}$ In addition, lithium enolates of chiral esters containing both (+)- and (-)-trans-2-phenyl-1-cyclohexyl fragments were also shown to be successful in affording $\beta$-lactam 86 in $58 \%$ yield and in $>99 \%$ ee.

Reagents \& Conditions: (i) LDA, THF, $-78^{\circ} \mathrm{C}, 4 \mathrm{hrs}$
Scheme 29- Chiral enolate ester-imine condensation using a (-)-menthyl derived chiral auxiliary ${ }^{50}$

When the cis-exo isomer of (+)-camphor was used as the chiral auxiliary, then the lithium enolate of ester 87 gave the substituted ( $S$ )- $\beta$-lactam $\mathbf{8 8 a}$ in $91 \%$ yield and very high ee (Scheme 30). ${ }^{51}$

Reagents \& Conditions: (i) LDA, $E t_{2} \mathrm{O},-78^{\circ} \mathrm{C}$ to $-40^{\circ} \mathrm{C}$
Scheme 30- Ester enolate-imine condensation reaction controlled by a (+)-camphor auxiliary ${ }^{51}$

Alternatively, when the cis-endo isomer of (+)-camphor was used as the chiral auxiliary, then the opposite configuration was observed yielding an $(R)-\beta$-lactam 88 b in $92 \% e e$,
with the addition of stoichiometric amounts of additives such as triethylborane or tetrabutyltin being shown to further improve selectivity levels. ${ }^{51}$

Reagents \& Conditions: (i) $L D A, E t_{2} O,-78^{\circ} \mathrm{C}$ to $-40^{\circ} \mathrm{C}$
Scheme 31- Ester enolate-imine condensation reaction controlled by a (+)-camphor auxiliary ${ }^{51}$

In 1995, it was reported that it was possible to exclusively access either cis- or trans- $\beta$ lactams in high ee using different triphenylglycol derived esters as the nucleophilic component. The ( $R$ )-ester 90 was doubly deprotonated to afford a chiral propionate enolate, that was reacted with imine 91 to afford the trans- $\beta$-lactam 92 in $>97 \%$ ee (Scheme 32). ${ }^{52}$

Reagents \& Conditions: (i) LDA (2.0equiv.), THF, $-50^{\circ} \mathrm{C}$ to $-35^{\circ} \mathrm{C}$
Scheme 32- Double lithiated chiral propionate for trans $\beta$-lactam synthesis ${ }^{52}$

Conversely, when the O-methyl derivative of a $(R)$-triphenylglycol ester 93 was monodeprotonated to afford enolate then reaction with imine 91 gave the alternative cis- $\beta$-lactam 94 in $>97 \%$ ee (Scheme 33). ${ }^{52}$

Reagents \& Conditions: (i) LDA (1.0equiv.), THF, $-50^{\circ} \mathrm{C}$ to $-35^{\circ} \mathrm{C}$
Scheme 33- Mono-lithiated chiral propionate for cis $\beta$-lactam synthesis ${ }^{52}$

This methodology was subsequently applied to the asymmetric synthesis of the cholesterol absorption inhibitor (-)-SCH 48461 96, which was successfully produced in $>98 \%$ ee (Scheme 34). ${ }^{53}$

Reagents \& Conditions: (i) LiN(i-Pr) $)_{2}$ (2.0equiv.), THF, $-78^{\circ} \mathrm{C}$ to $-65^{\circ} \mathrm{C}$, 1 hr ; (ii) Imine 52, THF, $-78{ }^{\circ} \mathrm{C}$ to $r t$

Scheme 34- Synthesis of (-)-SCH 48461 using triphenylglycol ester $95{ }^{53}$

The highly enantioselective construction of chiral (3R)-3-alkyl-3-hydroxy- $\beta$-lactams was made possible by generating an ( $E$ )-enolate from Seebach's auxiliary 97, which reacts with the imine 98 from its Re face- trans to the bulky tbutyl group chiral auxiliary fragment. The resultant intermediate then cyclises onto its carbonyl group, with elimination of the chiral auxiliary fragment affording $\beta$-lactam 99 in $94 \%$ yield after recrystallisation (Scheme 35). ${ }^{54}$

Reagents \& Conditions: (i) LHMDS, $-78^{\circ} \mathrm{C}$, THF/HMPA
Scheme 35- Enantioselective synthesis of $\boldsymbol{\beta}$-lactams using 1,3-dioxolan-4-ones ${ }^{54}$

Several years after the use of an organocopper ester enolate-imine condensation reaction using an achiral imine and an achiral ester (Scheme 25), the full potential of organocuprate catalysed conjugate addition reactions was established for the asymmetric conjugate addition of carbon nucleophiles to chiral $\alpha, \beta$-unsaturated esters 100. The resultant enolate intermediate was reacted with a glyoxylate imine 76 to afford $\beta$-lactam 101 in good de and ee (Scheme 36). ${ }^{55}$ This multi-component strategy was subsequently employed for the asymmetric synthesis of the antibiotic family Nikkomycins. ${ }^{56}$

Reagents \& Conditions: (i) $\mathrm{Me}_{2} \mathrm{CuLi}, 0^{\circ} \mathrm{C}, \mathrm{THF}, 3 \mathrm{hrs}$
Scheme 36- Use of lithium dialkylcuprates for the asymmetric synthesis of $\beta$-lactams ${ }^{55}$

More recently in 2004, an efficient and diastereoselective synthesis of trans- $\beta$-lactams was reported using enolates derived from a carboximide auxiliary prepared from salicylamide. ${ }^{57}$ This classic Reformatsky reaction occured via generation of a zinc (Z)enolate that was shown to afford either trans- $\beta$-lactam 103, or $\beta$-amino amide derivatives, depending on the nature of the substrate substituents (Scheme 37). ${ }^{57}$

Reagents \& Conditions: (i) Zn, THF, reflux, 2hrs
Scheme 37- Enantioselective Reformatsky reaction using a chiral auxiliary ${ }^{58}$

It was possible to rationalize the stereochemistry of the reaction by reasoning that the ( $Z$ )-enolate formed attacks on the Re-face due to steric hindrance from the isopropyl group blocking the Si-face. This results in the formation of the $(3 R, 4 S) \beta$-lactam as the major isomer which was isolated in an $85 \%$ ee, whilst the chiral auxiliary could be recycled as required.

### 1.5 Chiral Imines

The first reported attempt at utilizing chiral imine components in ester-enolate imine cyclisation reactions were described using zinc enolates as nucleophiles which resulted in relatively poor diastereoselectivity. ${ }^{59}$ However, this methodology was more successfully utilized for the synthesis of monosubstituted $\beta$-lactam 106 which was prepared with good stereocontrol due to formation of a chelated transition state between the $(E)$-enolate of 29 and $\alpha$-cyano amine $105 .{ }^{31}$

Scheme 38- $\beta$-lactam synthesis using chiral $\alpha$-cyano amines ${ }^{31}$

Early results also showed that $\beta$-lactams could be formed in good ee using either tin ${ }^{60}$ or boron ${ }^{61}$ enolates, however these reactions resulted in the formation of $\beta$-amino ester products that required subsequent cyclisation to afford the desired $\beta$-lactam.

In 1992, a bulky chiral imine containing an acetonide functionality was employed for the asymmetric synthesis of mono-substituted $\beta$-lactams. Lithium enolate 107 was added to the chiral imine acetal 108 to give trans- $\beta$-lactam 109 in $66 \%$ yield with high diastereoselectivity. ${ }^{62}$ The absolute configuration was determined by subsequently converting 109 into the trans- $\beta$-lactam 110, that had been used previously as an intermediate for the synthesis of the antibiotic (+)-PS-5. ${ }^{62}$

Reagents \& Conditions: (i) THF, $-70^{\circ} \mathrm{C}$
Scheme 39- Synthesis of (+)-PS-5 intermediate using chiral imines ${ }^{62}$

Further to this study, the ability to selectively access either enantiomer of a monosubstituted $\beta$-lactam 113 has been reported. In this study, the generation of lithium or zinc enolates with the $(S, S)$-tartrate derived imine 112 affords ( $4 S$ )- $\beta$-lactam 113a, whilst a titanium enolate resulted in the (4R)- $\beta$-lactam 113b being observed. ${ }^{63}$

Scheme 40- Effect of metal enolates on stereochemistry of $\boldsymbol{\beta}$-lactam formation ${ }^{63}$

This method was further extended to the synthesis of $\beta$-lactams containing two contiguous stereocentres that incorporate a C3 amino substituent. The zinc enolate of $N$-protected tert-butyl glycinate 114 was reacted with chiral imine 112 affording $(3 R, 4 S)-\beta$-lactam 115a, whilst its corresponding titanium enolate afforded $(3 S, 4 R)-\beta$ lactam 115b. ${ }^{64}$

Reagents \& Conditions: (i) $\mathrm{Ti}\left(\mathrm{O}^{i} \mathrm{Pr}\right)_{3} \mathrm{Cl}, \mathrm{THF}$, chiral imine 112, $-78^{\circ} \mathrm{C}$ to $-40^{\circ} \mathrm{C}$, 12 hrs ; (ii) $\mathrm{ZnCl}, \mathrm{THF}$, chiral imine $112,-78^{\circ} \mathrm{C}$ to $-40^{\circ} \mathrm{C}$, 12 hrs

Scheme 41- Control of stereochemistry for C3-amino $\beta$-lactams using different metal enolates ${ }^{64}$

The effect of different metal enolates on the outcome of the stereochemistry of $\beta$ lactams when using a chiral imine was subsequently employed to synthesise all four diastereomers of 3,4-dialkyl-substituted $\beta$-lactams in good yield and high de. ${ }^{65}$ The $(3 S, 4 R)-\beta$-lactam 116b was obtained by epimerization of the corresponding $(3 S, 4 R)-\beta$ lactam 116a.

Reagents \& Conditions: a) \& b) (i) HMPA (12 equiv.), $-78{ }^{\circ} \mathrm{C}$ to $-60{ }^{\circ} \mathrm{C}$; c) i$)-78{ }^{\circ} \mathrm{C}$ to rt
Scheme 42- Effect of different metals on the stereochemical outcome of $\boldsymbol{\beta}$-lactam synthesis

In contrast, the products formed from reaction of ester enolates of $\alpha$-chloroacetates with chiral imines are dependent on the nature of the enolate counterion, with a titanium enolate affording ( $3 R, 4 R$ )-3-chloroazetidine-2-one 118, whereas lithium or zinc enolates afford the alternative $(2 R, 3 S)$ - or $(2 S, 3 R)$-aziridines 119 respectively. ${ }^{66}$

118

119a

119b

Figure 5- Products of reaction of metal enolates of $\alpha$-haloacetates with a chiral imine ${ }^{66}$

The synthesis of enantiopure 3 -amino-4-(1'-O-silyl)-substituted monocyclic $\beta$-lactams was first reported via reaction of achiral ester enolate 29 with a chiral silylimine 120. ${ }^{67}$ The trans-selectivity observed in Scheme 43 has been rationalized by recent studies,
which suggests the trans-configuration is observed when the $\alpha$-imine substituent is bulky. ${ }^{67}$

Reagents \& Conditions: (i) LDA, $-78^{\circ} \mathrm{C}, \mathrm{THF}$
Scheme 43- Synthesis of 3-amino-4-(1'-hydroxy)-substituted $\boldsymbol{\beta}$-lactams ${ }^{67}$

The ability to employ chiral substituents on the nitrogen atom was explored by incorporating chiral $\alpha$-amino acids into the imine starting material. It was reported that the double activation of both enolate of ester 29 and imine 122 was necessary for the zinc enolate to cyclise, which furnished the (3S,4S)- $\beta$-lactam 123 in good yield and high $e e .{ }^{68-69}$

Reagents \& Conditions: (i) $\mathrm{LDA}, \mathrm{ZnCl}_{2}$
Scheme $44 \boldsymbol{\beta}$-lactam formation from double zinc activation of enolate and imine components ${ }^{68}$

It has been established that the use of zinc enolates for the ester enolate-imine cyclisation reaction normally favours the formation of trans- $\beta$-lactams. Consequently, an investigation was undertaken to examine the variables that could potentially encourage formation of the corresponding cis- $\beta$-lactam from reaction of enolates of ethyl 2,2,5,5-tetramethyl-1-aza-2,5-disilacyclopentane-1-acetate with $N$-alkyl imines. The factor that showed the most significant effect on changing the cis-transdiasteromeric ratio was the addition of a highly polar cosolvent, with TMU, DMPU and HMPA markedly increasing the amount of cis- $\beta$-lactam 126 formed. For example, reaction of the zinc enolate of 29 with a chiral imine 124 derived from $\alpha$ methylbenzylamine gave trans-(3S,4S)- $\beta$-lactam 125 in $95 \%$ de with a $92 \%$ yield (Scheme 45), ${ }^{70}$ whilst addition of HMPA resulted in formation of the corresponding cisisomer 126 as the major product. ${ }^{15,70}$

Reagents \& Conditions: (i) a) LDA, $\mathrm{Et}_{2} \mathrm{O}$; b) $\mathrm{ZnCl}_{2}$; (ii) $-78^{\circ} \mathrm{C}$ to $\mathrm{rt}, \mathrm{H}_{2} \mathrm{O}$; (iii) $\mathrm{HMPA}, \mathrm{THF},-78^{\circ} \mathrm{C}$
Scheme 45- Effect of cosolvent HMPA on cis:trans selectivity ${ }^{70,15}$

The ability to prepare $\beta$-lactams containing two new contiguous stereocentres via enolate-imine condensation reactions has been widely investigated by Cainelli et al. ${ }^{16}$ It was demonstrated that changing the nature of the enolate counterion and the nature of
the O-protecting group on the imine affected the stereochemical outcome of the reaction. The presence of a bulky $O$-silyl substituent within the imine results in formation of the trans $\beta$-lactam in high ee. As seen in Scheme 46, altering the imine substituent from a methyl 128 to a phenyl 129 fragment resulted in an increase in the ee of $\beta$-lactam from $92 \%$ (130) to $>98 \%$ (131).

Scheme 46- Effect of imine substituents on stereoselectivity of $\beta$-lactam formation ${ }^{16}$

An investigation into the effects of reacting enolates of 2-pyridyl thioesters with different chiral imines has been undertaken by Annunziata et al. who demonstrated that the titanium enolate of thioester 64 reacted with imine 132 to afford the cis- $\beta$-lactam 133 in $>98 \%$ de (Scheme 47). ${ }^{71}$ In light of this accomplishment, $\beta$-lactam 133 was further developed as a potential precursor for the synthesis of a biologically active renin inhibitor. ${ }^{72}$

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DCM},-78^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$, 3 hrs

## Scheme 47- Stereoselective synthesis of cis- $\beta$-lactams using a chiral imine ${ }^{71}$

Imines derived from $\alpha$-substituted benzylamines react with titanium enolates of 2pyridyl thioesters to give trans $\beta$-lactams in good yield and high selectivity as shown in Scheme $48 .{ }^{73}$ The selectivity of these reactions was rationalized using a transition state
involving coordination of titanium to both the enolate and the 2-pyridyl group, ${ }^{74}$ with improved stereocontrol occurring as the steric demand of either the imine or thioester substituent increases. ${ }^{73}$

$134135 \mathrm{R}=\mathrm{Et}$ ( $79 \%$ yield, $86 \%$ de, $60 \%$ ee)
$136 \mathrm{R}=\mathrm{i} \operatorname{Pr}(62 \%$ yield, $86 \% \mathrm{de}, 82 \%$ ee)

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, E t_{3} \mathrm{~N}, \mathrm{DCM},-78^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$, 5 hrs
Scheme 48- Use of $\alpha$-methylbenzylamine as a chiral auxiliary for imine formation

In contrast, when the matched enolate-imine condensation reaction between the titanium enolate of chiral thioester 137 and chiral imine 138 was carried out, then a highly stereoselective reaction was observed, yielding the trans (3S,4S)- $\beta$-lactam 139 in high de. ${ }^{75}$

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, E t_{3} \mathrm{~N}, \mathrm{DCM},-78^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$, 5 hrs
Scheme 49- Matched stereocontrol using a titanium enolate of chiral thioester and a chiral imine ${ }^{75}$

This excellent level of stereocontrol enabled a variety of different functional groups to be introduced, furnishing substrates that could be employed for the synthesis of carbapenem antibiotics, including thienamycin substrate derivatives. ${ }^{75}$

140

141

Figure 6- Structures of Thienamycin 140 and Meropenem 141

More recently in 2007, Boyer et al ${ }^{76}$ demonstrated that zinc enolates could be used to prepare (rac)-gem-difluorinated $\beta$-lactams 144 under standard Refomatsky conditions as potential metallocarboxy-peptidase inhibitors. ${ }^{77}$ The stereochemical outcome of this reaction could be controlled using ( $R$ )-phenylglycinol 142 as a chiral auxiliary, this enables chelation between the nitrogen and the zinc alkoxide to afford a five membered transition state, resulting in excellent diastereoselectivity. ${ }^{76}$

Scheme 50- Synthesis of gem-difluoro- $\beta$-lactams via a Reformatsky reaction ${ }^{76}$

### 1.6 Enantioselective Synthesis - External Ligands

A number of protocols have been developed that enable stoichiometric amounts of external chiral ligands to be used as promoters to carry out the asymmetric synthesis of $\beta$-lactams from achiral ester/imine starting materials. Boron enolates have been shown to afford cis- $\beta$-lactams with good levels of stereocontrol, ${ }^{78}$ which enabled an enantioselective ester enolate-imine cyclisation reaction to be developed using a stoichiometric amount of the chiral additive ( $1 R, 2 S$ )-2-(dimethylamino)-1-phenylpropan-1-ol. ${ }^{79}$ The chiral amino alcohol additive 146 acts both as a base to generate a boron enolate, as well as acting as a chiral ligand to coordinate to $\mathrm{BCl}_{3}$ to generate a chiral Lewis acid species that facilitated the enantioselective synthesis of trans- $\beta$-lactam 145 in 74\% ee (Scheme 51). ${ }^{79}$

Reagents \& Conditions: (i) [ $\mathrm{BCl}_{3} \cdot \mathrm{Me} e_{2} S+$ chiral amino alcohol 146], $D C M,-78^{\circ} \mathrm{C}$ to rt
Scheme 51- Effect of boron halide adduct as Lewis acids on absolute stereochemistry ${ }^{79}$

In addition, (1R,2R)-1,2-dimethoxy-1,2-diphenylethane 149 has been used as a chiral ligand to coordinate the lithium counterion of ester enolate $146,{ }^{80}$ to afford $\beta$-lactam 148 in $85 \%$ yield and $90 \%$ ee (Scheme 52).

Reagents \& Conditions: (i) LICA, ligand 149, toluene, $-50^{\circ} \mathrm{C}$
Scheme 52- The effect of an external chiral ligand on $\beta$-lactam synthesis ${ }^{80}$

These reaction conditions were further optimised using (1R,2R)-2-(2-methoxyethoxy)$N, N$-dimethyl-1,2-diphenylethanamine 150 as a ligand, in addition to altering the different aromatic substituents on the imine substrate, which enabled a range of chiral $\beta$-lactams to be prepared in high yields and high enantioselectivites. ${ }^{81}$

Table 3- "Matched" condensation of enolate 146 with imines catalysed by (1R,2R)-2-(2-methoxyethoxy)- $N, N$-dimethyl-1,2-diphenylethanamine 150 forming $\beta$-lactams

The stereoselective synthesis of $\beta$-lactam 152 was enhanced by addition of the chiral ether ligand 150 to the lithium enolate of menthyl isobutyrate. A catalytic amount of the chiral tridentate ligand significantly increased the enantiomeric excess from $50 \%$ to $94 \% e e .^{82}$ Furthermore, changes made to the structure of the chiral ligand, or the chiral lithium enolate, enabled either $\beta$-amino ester or $\beta$-lactam products to be obtained. ${ }^{82}$

Scheme 53- Matched effect of chiral lithium enolates $\&$ chiral external ligands ${ }^{82}$

In light of this success, investigations employing chiral bisoxazoline (BOX) ligands for use with achiral lithium ester enolates were reported, ${ }^{83}$ with the best conditions being obtained when $20 \mathrm{~mol} \%$ of the BOX ligand containing an isopropyl substituent 154, was employed, giving $\beta$-lactam 153 in $96 \%$ yield and $70 \%$ ee (Scheme 54). ${ }^{83}$

Reagents \& Conditions: (i) Ligand 154 (0.2 equiv.), toluene, $-20^{\circ} \mathrm{C}$, 4 hrs

### 1.7 Polymer Supported $\beta$-Lactam Synthesis

A number of approaches have been developed that enable the ester enolate-imine cyclisation reaction to be transferred to polymer support potentially allowing for the high-throughput synthesis of libraries of $\beta$-lactams. ${ }^{84}$ The first polymer-supported synthesis of a $\beta$-lactam was reported in 1998, whereby an imine 155 was immobilized via a soluble MeOPEG (poly(ethylene glycol)) bound linker which was reacted with a titanium enolate to afford the $\beta$-lactam 157. ${ }^{85}$ The linker was removed by acid catalysed methanolysis of the polymer bound $\beta$-lactam 158 to give the free $\beta$-lactam in $54 \%$ yield. ${ }^{85}$

Reagents \& Conditions: (i) $\mathrm{TiCl}_{4}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DCM}, 23^{\circ} \mathrm{C}, 15 \mathrm{hrs}$
Scheme 55- Synthesis of $\boldsymbol{\beta}$-lactams on polymer supported imines ${ }^{85}$

A modified PEG support was subsequently employed to prepare an immobilized chiral imine 160 that was reacted with the titanium enolate of a chiral thioester 159 to generate the trans- $\beta$-lactam 161 in good ee. ${ }^{86}$

Scheme 56- Enantiomerically pure immobilized imine and enolate in $\boldsymbol{\beta}$-lactam formation ${ }^{86}$

An alternative strategy has been devised by Schunk et al. involving immobilisation of the ester functionality to polymer support using a T1-triazine linker that is stable under basic conditions. ${ }^{87}$ Subsequent generation of the lithium enolate of the polymersupported ester 163, followed by reaction with a range of imines and cleavage from polymer support gave a series of eight cis- $\beta$-lactams in excellent de and good yields. ${ }^{87}$ The full potential of this immobilized ester enolate methodology was subsequently demonstrated for the synthesis of a variety of libraries of $\beta$-lactams. ${ }^{88}$

Reagents \& Conditions: (i) LiHMDS, THF, $-78^{\circ} \mathrm{C}$, 20 mins; (ii) $-78^{\circ} \mathrm{C}$ to rt, 23 hrs ; (iii) a) $5 \% \mathrm{TFA}, \mathrm{DCM}$; b) THF/DMF, $60{ }^{\circ} \mathrm{C}, 15 \mathrm{~min}$

Scheme 57- Synthesis of $\boldsymbol{\beta}$-lactams using an immobilised titanium ester enolate ${ }^{87}$

However, the incorporation of a chiral auxiliary onto the polymer supported ester in order to control the enantioselectivity of the $\beta$-lactam has yet to be reported.

### 1.8 Natural Product \& Antibiotic Synthesis

The ability of the enolate-imine condensation reaction to produce $\beta$-lactams in both high $d e$ and ee for a variety of highly substituted analogues has led to its use for the synthesis of a wide range of complex natural products. Many antibiotics contain the $\beta$ lactam moiety as their key feature and as such this methodology can be utilized to provide access to many of the biologically important targets. Initially, there was a large focus on employing $\beta$-hydroxybutyrates as the chiral ester component within the enolate-imine condensation reaction, as these types of substrates could potentially provide an enantioselective route to carbapenem antibiotics, such as thienamycin $140 .{ }^{14}$

140

165

Figure 7- Structure of Thienamycin $140{ }^{89}$ and antibiotic PS-5 165

One of the most significant developments involved reaction of the zinc enolate of $\beta$ hydroxybutyrate 166 with imine 167 which generated $\beta$-lactam 168 in $78 \%$ yield as the only stereoisomer, this was proposed to proceed via a chelated transition state involving an ( $E$ )-enolate and the imine (Scheme 58). ${ }^{90}$

Reagents \& Conditions: (i) Et 2 Zn; (ii) LiHMDS, THF
Scheme 58- Synthesis of $\beta$-lactams using chiral $\beta$-hydroxybutyrate $\mathbf{1 6 6}{ }^{\mathbf{9 0}}$

The condensation of $\beta$-hydroxybutyrate enolates with $N$-aryl imines and $N$-trimethylsilyl imines is well documented, reporting good yields with the stereoselectivity highly dependent on the chosen reaction conditions. ${ }^{14}$

In addition, early work was also directed towards the synthesis of $\beta$-lactam 171 as an intermediate for the synthesis of the structurally related antibiotic PS-5 165. The aim was to synthesise 4 -acetoxy $\beta$-lactams via an enantioselective enolate-imine condensation reaction ${ }^{91-92}$ involving the addition of lithium ester enolate 169 to a chiral imine 120 to give the trans- $\beta$-lactam 170 in good de, which was subsequently converted into the 4 -acetoxy $\beta$-lactam 171 in $61 \%$ yield. ${ }^{67}$ A synthesis employing 4acetoxy $\beta$-lactam 171 had previously been reported and therefore enables a formal synthesis of (+)-P5-5 165 (Scheme 59). ${ }^{93}$

Reagents \& Conditions: (i) LDA, THF; (ii) a) TBAF, MeCN; (b) Pb(OAc) ${ }_{4}$, benzene, reflux; (iii) 1,2-DCE, $R h_{2}(\mathrm{OAc})_{4} ; ~(i v)\left(\mathrm{ClP}(\mathrm{O})\left(\mathrm{OC}_{6} \mathrm{H}_{5}\right)_{2}, i \mathrm{iPr}_{2} \mathrm{NEt}, \mathrm{MeCN}\right.$, $N$-acetylcysteamine; (v) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}$, THF

## Scheme 59- Synthesis of 4-acetoxy $\boldsymbol{\beta}$-lactams for PS-5 synthesis ${ }^{92-93}$

In 1991, the asymmetric synthesis of chiral $\beta$-lactam building blocks that could be incorporated into the construction of the side chain of the anti-cancer agent taxol was successfully developed. Both high yield and high ee were obtained for formation of cis-
$\beta$-lactam 178 using a lithium chiral ester-enolate condensation reaction with $N$-TMSimine 177, that employed a (-)-trans-2-phenyl-1-cyclohexyl chiral ester fragment for diastereocontrol. ${ }^{94}$ This methodology was also employed for the generation of a series of taxol analogues with modified $\mathrm{C}-13$ side chains. ${ }^{95}$

## Reagents \& Conditions: (i) LDA, THF, $-78^{\circ} \mathrm{C}$

Scheme 60-Asymmetric synthesis of $\boldsymbol{\beta}$-lactam 178 for use as taxol C-13 side chain ${ }^{94}$

The use of this type of ester enolate-imine condensation reaction to incorporate heteroatom substituents into the parent $\beta$-lactam enabled the synthesis and biological evaluation of a range of heteroaromatic taxanes, some of which were shown to be more cytotoxic against B16 melanoma cells than paclitaxel 179.

Figure 8- Structure of Paclitaxel 179

For example, the reaction of a chiral lithium enolate 180 with $N$-TMS-imine 181 gave the cis-2-furyl substituted $\beta$-lactam 182 in high ee. ${ }^{96}$

Scheme 61- Synthesis of 2-furyl substituted $\beta$-lactams for incorporation into heteroaromatic taxanes ${ }^{96}$

In 1993, Bandini et al. demonstrated that it was possible to synthesise the $\beta$-lactam antibiotic (+)-1 $\beta$-methyl PS-5 186, by employing the ester enolate-imine condensation reaction as the pivotal $\beta$-lactam ring-forming step. ${ }^{97}$ The use of chiral imine 120 enabled the synthesis of an enantiomerically pure 3,4-disubstituted trans- $\beta$-lactam 185 that was subsequently converted into the carbapenem antibiotic (+)-1 $\beta$-methyl PS-5 186. ${ }^{97}$

186

Scheme 62-Synthesis of (+)-1 $\beta$-methyl PS- 5 via an ester enolate-imine condensation recation ${ }^{97}$

The first asymmetric synthesis of SCH 48461 96, a proven cholesterol absorption inhibitor, could also be carried out using an ester-imine condensation that employed a
chiral ester fragment to introduce stereocontrol. ${ }^{98}$ Four different chiral auxiliaries were investigated including $D / L-m e n t h o l ~ a n d ~(+) /(-)$ Oppolzer's chiral auxiliary with ee's of up to $93 \%$ being obtained. ${ }^{98}$ This cis- $\beta$-lactam 188 was then epimerized under basic conditions to give the corresponding trans-( $3 S, 4 S$ )- $\beta$-lactam 96 in quantitative yield. HMPA was employed as an additive during the enolate-imine condensation reaction in an attempt to directly afford the trans- $\beta$-lactam, however these conditions led to a complete loss of stereocontrol. ${ }^{98}$ Furthermore, this methodology could be used to prepare a series of analogues of SCH 4846196 in order to determine the structureactivity relationships of the azetidinone fragment. ${ }^{99}$

96

Reagents \& Conditions: (i) LDA, THF, $-78^{\circ} \mathrm{C}$, (ii) $K O^{t} \mathrm{Bu}, \mathrm{THF}$
Scheme 63- Asymmetric synthesis of cholesterol absorption inhibitor SCH $48461{ }^{98}$

This ester-imine condensation methodology allowed access to a series of N -alkyl and $N$-acyl-2- $\beta$-lactams, which led to the conclusion that the alkoxy group on the N substitued aromatic ring was not required for its pharmacological effect. ${ }^{99}$

### 1.9 Conclusion

The ester enolate-imine condensation reaction has long been considered one of the main methods for the synthesis of $\beta$-lactams. Control of the reaction conditions and appropriate selection of the metal enolate can be used to selectively alter the trans:cis ratio of the resultant $\beta$-lactam. In addition, the introduction of a chiral auxiliary into either the ester or imine functionality has the potential to afford asymmetric syntheses of a diverse range of substituted $\beta$-lactams. The use of this methodology for the asymmetric synthesis of antibiotics and biologically active substrates has been demonstrated highlighting the potential of this reaction for total synthesis.

## 2 Results \& Discussion - Development of an Intramolecular Enolate-Imine Cyclisation Reaction for the Synthesis of Benzocispentacin

### 2.1 Introduction

The ability to synthesise a range of enantiomerically pure $\beta$-amino acids is essential to allow access to a variety of $\beta$-peptide foldamer motifs. ${ }^{100}$ Recent developments in the field of foldamer synthesis have led to a renewed interest in diversifying the number of $\beta$-amino acids available as building blocks for such scaffolds. ${ }^{101}$ There are a range of existing methodologies for the asymmetric synthesis of simple cyclic $\beta$-amino acids containing a single stereocentre, ${ }^{102-103}$ but methodologies for constructing cyclic $\beta$ amino acids that contain more than one stereocentre are much less advanced. An attractive approach is to generate $\beta$-amino acids that contain multiple stereocentres, in particular $\beta$-amino acid scaffolds containing aromatic substituents. They have the potential to encourage folding in oligoamides using secondary $\pi-\pi$ stacking interactions ${ }^{104}$ to afford foldamers that have a wide range of potential applications.

The original aim of the research project was to carry out a series of intramolecular enolate-imine cyclisation reactions, screening different chiral auxiliaries ( R or $\mathrm{R}_{1}$ ) to afford enantiopure cyclic $\beta$-amino acids such as cis-189 or trans-190 (Scheme 64). At the outset this involved the screening of a series of 5 -exo-trig cyclisation reactions involving intramolecular nucleophilic attack of various enolates onto an imine with the stereochemistry controlled by an appropriate chiral auxiliary.

Scheme 64- Development of $\boldsymbol{\beta}$-amino acid monomers for foldamer synthesis

### 2.2 Background - Foldamer Synthesis

In the past decade, a vast array of research has been carried out into the synthesis of foldamers with significant contributions from the groups of Gellman ${ }^{105-106}$ and Seebach. ${ }^{107-109}$ The detailed discussion of this area is beyond the remit of this chapter, but an understanding of the fundamental properties of this research area are key to understanding why cyclic $\beta$-amino acids are such desirable targets.

Generally, a foldamer is considered to be an artificially adopted structure that assumes specific conformations that replicate biological macromolecules. In their original report, Gellman et al. investigated backbones that favour helical secondary structures and defined foldamers as 'synthetic oligomers with unnatural backbones'(Figure 9). ${ }^{110}$

Figure 9- Examples of helix bundle quaternary structures ${ }^{111}$

Oligomers incorporating $\beta$-amino acids producing foldamers continue to be widely investigated, ${ }^{112}$ due to the potential of $\beta$-peptides to modify biological activities. ${ }^{113-114}$ The additional methylene unit allows extra conformational space that confers excellent folding properties within the $\beta$-peptide, ${ }^{115}$ whilst they are also stable to proteolytic degradation. ${ }^{116}$ The use of $\beta$-amino acids containing aromatic substituents can drive folding through $\pi-\pi$ stacking interactions and favourable side chain-solvent contact in secondary and tertiary stuctures. ${ }^{104,117}$ This enables reduction of destabilising backbone-solvent interactions while allowing relatively rigid conformations. ${ }^{117}$ Such repeating units are not found in natural biomolecules as short range interactions in $\alpha$ peptides are mainly observed through hydrogen bonding. More recently work has begun into designing heterogeneous backbone foldamers, consisting of both $\alpha$ and $\beta$ amino acid moieties which can afford additional different spatial orientations. ${ }^{111,118}$

In particular, Gellman et al. ${ }^{119}$ have highlighted the use of trans $\beta$-amino acids such as trans-2-aminocyclohexanecarboxylic acid (ACHC) within $\beta$-peptides to generate 14helical conformations. The helical numbering system is based upon the number of atoms in the hydrogen bonded rings, with different configurations resulting in a left or right handed helix. NMR techniques and crystallographic structures have been used to confirm the successful folding properties of conformationally restricted ACHC within a $\beta$-peptide 14 helix (Figure 10). ${ }^{119}$

| $\alpha$-Peptide |  | $\beta$-Peptides |
| :---: | :---: | :---: | :---: |
| poly-Ala |  |  |
| poly- $\beta^{3}$-hAla |  |  |

Figure 10- Structure of $\alpha$ and $\boldsymbol{\beta}$ helices with carbon atoms in green, nitrogen atoms in blue and oxygen atoms in red, with hydrogens omitted for clarity ${ }^{119}$

Such $\beta$-peptides are being developed as foldamers with biomedical applications such as antimicrobial activity or protein surface mimicry, after having initially demonstrated promising biological activity. ${ }^{111}$ This has significant implications in the drug discovery process as these foldamers could have great potential as drugs that inhibit proteinprotein interactions (PPl's) that are related to disease. For example, one recent success involves the synthesis of $\alpha / \beta$-oligomers which can mimic both the structure and function of an $\alpha$-helical segment of the HIV membrane protein gp41, and as a result
these foldamers have been shown to exhibit potent antiviral activity in HIV antiinfectivity assays. ${ }^{120}$

The success of foldamer research relies on the wide availability of chiral monomers for the generation of specific conformations. As such, the development of methodology for the efficient asymmetric synthesis of cyclic $\beta$-amino acid monomers is essential to allow further exploration of secondary and tertiary structures.

### 2.3 Background - Previous Benzocispentacin Syntheses

There are several reports of different synthetic methods for the asymmetric synthesis of the cyclic $\beta$-amino acids shown in Scheme 64. These 1-aminoindane-2-carboxylic acid derived $\beta$-amino acids are more commonly referred to as benzocispentacin, which have not only been used for the synthesis of receptor agonists ${ }^{121}$ but have also been used for $\beta$-peptide synthesis. ${ }^{122}$

Over a decade ago, the asymmetric synthesis of methyl ( $1 S, 2 R$ )-1-amino-2,3-dihydro$1 H$-indene-2-carboxylate 193 was achieved by the tandem conjugate addition of a chiral lithium amide 192 equivalent to $\alpha, \beta$-unsaturated ester 191, followed by a subsequent intramolecular electrophilic trap of the intermediate ester enolate. ${ }^{123}$ The protected trans $\beta$-amino ester 193 was obtained in $80 \%$ yield and $87 \%$ de and was successfully deprotected to afford the parent $\beta$-amino ester 194 (Scheme 65). ${ }^{123}$

Reagents \& Conditions: (i) THF, $-78^{\circ} \mathrm{C}$; (ii) a) $\mathrm{MeOH}, \mathrm{HCl}$; b) $\mathrm{Pd}(\mathrm{OH})_{2}, \mathrm{NH}_{4} \mathrm{HCO}_{2}, \mathrm{MeOH}, \mathrm{HCl}$
Scheme 65- Synthesis of bicyclic trans $\beta$-amino ester $194{ }^{123}$

In 2000, both enantiomers of benzocispentacin were obtained by enzymatic resolution of the corresponding $N$-hydroxymethylated $\beta$-lactams $195 .{ }^{124}$ The kinetic resolution methodology used a lipase catalysed esterification step to generate enantiopure
tricyclic $\beta$-lactams 189a and 189b as shown in Scheme 66. ${ }^{125}$ The $\beta$-lactams 195b and 196a were obtained in $42 \%$ and $44 \%$ yields respectively and were easily hydrolysed and deprotected to afford the corresponding $\beta$-amino acids. ${ }^{124}$

Reagents \& Conditions: (i) Lipase PS, vinyl butyrate in acetone, RT, 4hrs; (ii) HCl (aq)
Scheme 66- Lipase PS catalysed $\boldsymbol{\beta}$-lactam opening ${ }^{124}$

Further to this, an improved enzymatic kinetic resolution method based on hydrolysis of NH- $\beta$-lactam 198 was reported, ${ }^{126}$ that offered a more direct route to benzocispentacin and its six and seven membered ring analogues. Lipolase catalysed enantioselective ring opening of 3,4-benzo-6-azabicyclo-[3.2.0]heptan-7-one provided access to both the $(1 R, 2 R)-\beta$-amino acid 189a and the ( $1 S, 8 S$ )- $\beta$-lactam 198b. The $(R, R)$ - $\beta$-amino acid 189a was easily isolated with good yields of $40 \%$ and an ee of greater than $96 \%$. Using aqueous HCl the remaining $\beta$-lactam 198b was ring opened to afford 199b in a $75 \%$ yield and an enantiomeric excess of $99 \%$, resulting in a highly efficient enzymatic synthesis of benzocispentacin (Scheme 67). ${ }^{126}$ More recently this synthesis has been shown to be successful using a solvent-free method using 0.5 equivalents of water as the only reagent. ${ }^{127}$

Reagents \& Conditions: (i) a) Chlorosulfonyl isocyanate; b) $\mathrm{Na}_{2} \mathrm{SO}_{3}$; (ii) $\mathrm{H}_{2} \mathrm{O}$, Lipolase, $60{ }^{\circ} \mathrm{C}$; (iii) $18 \%$ HCl

Scheme 67- Synthesis of enantiopure benzocispentacin ${ }^{126}$

Although both these methods allow access to both benzocispentacin enantiomers, there are several drawbacks with this enzymatic based methodology. For example, if a specific enantiomer is required then a maximum yield of only $50 \%$ can be obtained. Further to this, enzymes are very temperature, pH and substrate specific which can be problematic when preparing a series of structural analogues. More recently, a nonenzymatic kinetic resolution protocol has been developed that involves the use of the amidine, (S)-CI-PIQ 200, as a nucleophilic catalyst for the $N$-acylation of 4 -aryl $\beta$ lactams. ${ }^{128}$ The $\beta$-lactam 198a gave a moderate $42 \%$ conversion, with a relatively low selectivity factor compared to other polycyclic $\beta$-lactams in the study (Scheme 68). ${ }^{128}$

Reagents \& Conditions: (i) $10 \mathrm{~mol} \%$ of 200, $\left({ }^{i} \mathrm{PrCO}\right)_{2} \mathrm{O},{ }^{i} \mathrm{Pr}_{2} \mathrm{NEt}$, tert-amyl alcohol, $0^{\circ} \mathrm{C}$, 30 hrs
Scheme 68- Kinetic resolution of $\boldsymbol{\beta}$-lactams via an organocatalytic $\boldsymbol{N}$-acylation strategy

### 2.4 Background- Intramolecular Enolate-Imine Cyclisation Reactions Generating Multiple Stereocentres

Andrews et al. have previously reported the significance of changing alkali metal counterions from lithium to sodium in ( $S$ ) $-N$-( $\alpha$-methylbenzyl)allylamine complexes. ${ }^{129}$ Unlike the stable lithium amide, the respective sodium complex was seen to undergo a 1,3-sigmatropic rearrangement to generate the corresponding 1-aza allyl species 202 (Scheme 69).

Reagents \& Conditions: (i) ${ }^{n} B u N a, T M E D A$
Scheme 69- Sodium amide 1,3-sigmatropic rearrangement ${ }^{130}$

Such aza-allyl species were shown to undergo conjugate additions with $\alpha, \beta-$ unsaturated esters with high stereoselectivity, ${ }^{131}$ for the construction of a highly functionalised cyclohexylamine containing six contiguous stereocentres in a one-pot reaction. The reported conjugate addition involves addition of one equivalent of ( $E$ )-aza-allyl amide 202 to two equivalents of ( $E$ )-tert-butyl cinnamate. The aminocyclohexane 205 was isolated in $44 \%$ yield as a single major product, ${ }^{132}$ with the absolute configuration of the stereocentres being determined using X-ray crystallography (Scheme 70).

Reagents \& Conditions: (i) tert-butyl cinnamate ( 2.0 equiv.), THF, $-78^{\circ} \mathrm{C}, 12 \mathrm{hrs}$
Scheme 70- One-pot cascade for the asymmetric synthesis of cyclohexylamine $205{ }^{132}$

The proposed mechanism suggests a cis-selective conjugate addition of the sodium aza-allyl species 202 to the first equivalent of the ( $($ ) -tert-butyl cinnamate generating a (Z)-tert butyl ester enolate 203 via an eight membered cyclic transition state. The enolate then undergoes a cis selective Michael addition onto the second equivalent of ( $($ )-tert-butyl cinnamate to give an (Z)-tert-butyl ester enolate 204. In the final step of this reaction cascade a 6-exo-trig ring closure reaction of the enolate fragment of 204 on to its imino functionality occurs with high diastereoselectivity, ${ }^{132}$ as shown in Scheme 70. The ability to generate six new contiguous stereocentres, all with excellent stereocontrol, based on a single ( $S$ ) $-N$-( $\alpha$-methylbenzyl)allylamine fragment is remarkable. ${ }^{132}$

More recently there have been further reports of $\beta$-amino acid derivatives with multiple contiguous stereocentres having been formed from one-pot reactions. ${ }^{133}$ For instance in 2009, Davies et al. reported a tandem conjugate addition/cyclisation reaction that generates a cyclic $\beta$-amino ester 207 with three contiguous stereocentres as shown in Scheme 71. ${ }^{134}$ The conjugate addition of lithium ( $R$ )- $N$-benzyl- $N$-( $\alpha$-methylbenzyl)amide

208 results in an enolate that undergoes a subsequent 6-endo-trig cyclisation reaction to produce a series of 2-aryl-4-aminotetrahydroquinoline-3-carboxylic acids 207 in 98\% de. ${ }^{134}$

Reagents \& Conditions: (i) THF, $-78{ }^{\circ} \mathrm{C}, 3 \mathrm{hrs}$

## Scheme 71- A tandem conjugate addition/cyclisation reaction ${ }^{134}$

These examples demonstrate the potential for new intramolecular enolate-imine cyclisation protocols to be used for the asymmetric synthesis of cyclic $\beta$-amino acids with multiple stereocentres. In light of this, the initial goal of this project was to further explore the final enolate-imine cyclisation step of the cascade reaction shown in Scheme 70, by using simple substrates in the presence of a chiral auxiliary to synthesise a range of chiral cyclic $\beta$-amino acids.

### 2.5 Retrosynthesis of Cyclisation Substrate

In order to adapt the intramolecular enolate-imine methodology (Scheme 70) to produce cyclic $\beta$-amino acids, the first aim was to devise a retrosynthetic route that would enable the desired cyclisation substrates to be prepared (Figure 11).

Therefore, based on simplicity of synthesis, it was decided that the first pathway to be explored would involve using a chiral amine auxiliary for stereocontrol. The starting material of 2-bromobenzaldehyde 209 would have a C3-saturated ester side chain attached to the ortho position of the aryl ring and then the aldehyde functionality would be converted into an imine using the chiral amine. An enolate-imine cyclisation reaction could then be carried out in order to generate the desired cyclic $\beta$-amino ester, which could be deprotected as required.

Figure 11 - Retrosynthetic analysis of a cyclic $\boldsymbol{\beta}$-amino acid

With this in hand, the next step was to devise an appropriate methodology in order to synthesise the required chiral $\omega$-imino ester.

### 2.6 Synthesis of (S)-N-( $\alpha$-methyl- $p$-methoxybenzyl)- $\omega$-iminoesters

The imino-ester in Figure 12 was chosen as an initial substrate to carry out investigations into using the enolate-imine cyclisation methodology for the synthesis of cyclic $\beta$-amino esters.

Figure 12- Target substrate for enolate-imine cyclisation

This target structure had many benefits as a starting point for the development of a stereoselective enolate-imine cyclisation reaction. Firstly, the benzylic $(E)$-imine is configurationally stable, while there is no potential for competing enamine formation. Secondly, the aryl ring should predispose the conformation of the derived enolate towards 5 -exo-trig cyclisation on to its imino functionality. Finally, ( $S$ )- $\alpha$-methyl-pmethoxybenzylamine was chosen as the chiral auxiliary over the cheaper ( $S$ )- $\alpha$ -
methylbenzylamine, because it could be subsequently removed under either hydrogenolytic ( $\mathrm{Pd} / \mathrm{C}, \mathrm{H}_{2}$ ), or oxidative $\left(\mathrm{CAN}, \mathrm{MeCN} / \mathrm{H}_{2} \mathrm{O}\right)$ conditions.

To obtain the target substrate using the retrosynthesis shown in Figure 11, the first step of our synthesis required protection of the aldehyde functionality of 2 bromobenzaldehyde 209 to afford its corresponding acetonide 210. This was achieved via treatment of 209 with propan-1,3-diol, in the presence of a catalytic amount of $p$ toluenesulfonic acid at reflux for three hours (Scheme 72). A Dean-Stark trap was used to remove the water produced and drive the equilibrium of the reaction towards acetonide formation. The resultant 2-(2-bromophenyl)-1,3-dioxane 210 was obtained as a white crystalline solid in $80 \%$ yield.

Reagents \& Conditions: (i) Propan-1,3-diol, pTSA (cat.), Toluene, reflux, 3 hrs
Scheme 72- Synthesis of 2-(2-bromophenyl)-1,3-dioxane

The Mizoroki-Heck reaction is an efficient method that couples an aromatic halide and an electron deficient alkene using a palladium catalyst and a strong base. ${ }^{135-136}$ Therefore, treatment of acetonide 210 and methyl acrylate with a catalytic amount of palladium(II) acetate and the ligand tri(o-tolyl)phosphine gave the $\alpha, \beta$-unsaturated ester 211 in 84\% yield (Scheme 73). ${ }^{137}$

210

211
84\% Yield

Reagents \& Conditions: $(i)$ Methyl acrylate, $\mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{P}(o-\mathrm{Tol})_{3}, \mathrm{DIPEA}, \mathrm{MeCN}, 12 \mathrm{hrs}$
Scheme 73- Synthesis of methyl 3-(2-(1,3-dioxan-2-yl)phenyl)acrylate

The next stage was removal of the alkene functionality of $\alpha, \beta$-unsaturated ester 211. Initially, a hydrogenation reaction using palladium on carbon was attempted on the methyl $\alpha, \beta$-unsaturated ester 211 at atmospheric pressure, which gave only recovered starting material. Subsequently the hydrogen pressure was increased to 4 atm and left for seven hours, which afforded the desired saturated ester 212 in 82\% yield (Scheme 74).

Reagents \& Conditions: (i) $\mathrm{H}_{2}$ (4 atm), Pd/C, MeOH, 7hrs
Scheme 74- Synthesis of methyl 3-(2-(1,3-dioxan-2-yl)phenyl)propanoate acid by hydrogenation

This hydrogenation reaction was successful on a small scale using 300 mg of acetonide $\mathbf{2 1 1}$ or less. However, when the reaction was scaled up it became apparent that the yield of ester 212 decreased dramatically, with most reactions affording significant amounts of starting material. To counteract this, both the pressure and length of time of the hydrogenation reaction were increased, including leaving the hydrogenation reaction for over 24 hours. Unfortunately, this did not increase the proportion of the desired ester 212 instead, affording competing products such as 213 arising from hydrogenolytic cleavage of the acetal functionality (Scheme 75).

Reagents \& Conditions: (i) $\mathrm{H}_{2}$ (4 atm), Pd/C, MeOH, 24hrs
Scheme 75- Palladium catalysed hydrogenolytic cleavage of acetonide

This resulted in an alternative and improved method for alkene reduction being investigated. In 2008, a chemoselective reaction was reported involving conjugate reduction of $\alpha, \beta$-unsaturated ester 214 using sodium borohydride and cobalt(II)chloride in ethanol. Jagdale et al. ${ }^{138}$ described chemoselective reduction of the alkene functionality of ester 214, which they used as part of their practical synthesis of $(R)$ tolterodine (Scheme 76).

Reagents \& Conditions: (i) $\mathrm{NaBH}_{4}, \mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{EtOH}, 10 h r s$
Scheme 76- Chemoselective conjugate reduction of ethyl cinnamate ${ }^{138}$

These conditions were successfully applied to the conjugate reduction of methyl ester 211, which gave its corresponding ethyl ester 216, arising from alkene reduction as well as an unexpected Lewis acid catalysed transesterification reaction with the solvent ethanol (Scheme 77).

Reagents \& Conditions: (i) $\mathrm{NaBH}_{4}, \mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, EtOH
Scheme 77- Chemoselective reduction of ester 211 using cobalt(II)chloride

To confirm this, the reduction reaction was repeated using methanol as solvent with all other conditions remaining constant, which produced the desired saturated methyl ester 212 in 70\% yield after 72 hours (Scheme 78).

Reagents \& Conditions: (i) $\mathrm{NaBH}_{4}, \mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{MeOH}$
Scheme 78- Chemoselective reduction of ester 211 using cobalt(II)chloride in methanol

In 1982, Heinzman et al. proposed that cobalt boride is formed in sodium borohydride cobaltous chloride reduction reactions, which subsequently coordinates to the alkene and as such catalyses a conjugate reduction reaction. ${ }^{139}$ This method is much milder than using $\mathrm{H}_{2}$ gas under pressure as the $\mathrm{NaBH}_{4}$ provides a source of $\mathrm{H}_{2}$ via decomposition over cobalt boride while possibly following a similar mechanism to the Luche reduction.

Therefore, due to the occurrence of the trans-esterification process and the availability of ethyl acrylate, it was decided to carry out a chemoselective conjugate reduction on the ethyl $\alpha, \beta$-unsaturated ester 217, yielding the saturated ethyl ester in $81 \%$ yield (Scheme 79).

[^0]Scheme 79- Synthesis of ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)acrylate 217

Following the success in obtaining samples of both methyl 3-(2formylphenyl)propanoate 212 and ethyl 3-(2-formylphenyl)propanoate 216, it was now necessary to develop conditions that would allow deprotection of their acetal functionalities. After screening a range of deprotection conditions, it was found that
addition of acetic acid and water for 12 hours resulted in the acetal protecting group being smoothly removed to afford the desired aldehydes 218 and 219 (Scheme 80).

Reagents \& Conditions: (i) $\mathrm{AcOH}, \mathrm{H}_{2} \mathrm{O}, 12 \mathrm{hrs}$
Scheme 80- Hydrolysis of acetals 212 and 216

The desired imines 220 and 221 were then prepared in essentially quantitative yield via addition of (S)- $\alpha$-methyl- $p$-methoxybenzylamine to aldehydes 218 and 219 respectively. The equilibrium of imine formation was driven to completion by the use of magnesium sulphate to remove the water produced in the reaction (Scheme 81).

Reagents \& Conditions: (i) (S)- $\alpha$-Methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}, \mathrm{DCM}$, 5 hrs
Scheme 81- Synthesis of chiral imino- $\omega$-esters 220 \& 221

The chiral imines 220 and 221 were generated in sufficient quantity to be used as substrates to investigate our proposed 5-exo-trig cyclisation methodology for the synthesis of $\beta$-amino acids.

### 2.7 Initial Attempts at Developing an Intramolecular EnolateImine Cyclisation Reaction

With the desired chiral imino ester in hand (Figure 12), the next step was to generate its enolate in order to initiate a 5 -exo-trig cyclisation reaction. At the outset, LiHMDS was chosen as a strong, bulky, non-nucleophilic base, which based on the precedent of Andrews et al. ${ }^{132}$ was predicted to afford an enolate that would cyclise to produce a cis-$\beta$-amino ester such as 222 (Scheme 82).

Scheme 82- Proposed cyclisation reaction

Initially, the generation of the enolate of chiral- $\omega$-imino-esters, $(S)$-ethyl 3-(2-(((1-(4methoxyphenyl)ethyl)imino)methyl)phenyl)propanoate 221, was attempted using 1.1 equivalents of LiHMDS as a base over an eight hour period at $-78{ }^{\circ} \mathrm{C}$, in keeping with the original conditions developed for the one-pot synthesis (Scheme 70). ${ }^{132}$ Unfortunately, only starting material was recovered, so the reaction was repeated, but this time it was allowed to warm from $-78{ }^{\circ} \mathrm{C}$ to room temperature. The crude reaction product still contained largely starting material, but small amounts (<10\%) of major and minor diastereomeric products were present. ${ }^{1} \mathrm{H}$ NMR analysis of the crude product reaction revealed that these diastereomers were not the cyclic $\beta$-amino ester products as expected (Scheme 83).

221

Reagents \& Conditions: (i) LiHMDS (1.1 equiv.), THF, $-78^{\circ} \mathrm{C}$ to rt, 8 hrs
Scheme 83- Initial cyclisation reaction using LiHMDS as a base

An appropriate solvent system was established for the separation of the two diastereomers by flash column chromatography, which enabled the major diastereomer to be isolated. Once isolated, the ${ }^{1} \mathrm{H}$ NMR spectrum of the major diastereomer suggested that the cyclisation had occurred as envisaged, however an absence of peaks for an ethyl ester functionality suggested the potential formation of a cyclic $\beta$ lactam. Inspection of the IR data did not show the expected broad absorption between $2500-3300 \mathrm{~cm}^{-1}$ for a carboxylic acid group. A carbonyl absorption at $1731 \mathrm{~cm}^{-1}$ suggested either an ester ( $1735 \mathrm{~cm}^{-1}$ ) or possibly a $\beta$-lactam ( $1745 \mathrm{~cm}^{-1}$ ). ${ }^{140}$ When examining the ${ }^{13} \mathrm{C}$ spectrum of the major diastereomer a carbonyl peak was observed at 170 ppm , which was slightly lower than expected for a $\beta$-amino acid (usually around $180 \mathrm{ppm})$. However, such values correlate well with those previously reported for the carbonyl of a strained $\beta$-lactam ring (between 167 ppm and 173 ppm ). ${ }^{141}$ Finally, the high resolution mass spectrometry data revealed a clean and well defined $\mathrm{m} / \mathrm{z}$ value of 294.14, consistent with the formation of a $\beta$-lactam 223. Therefore based on the data in hand it was proposed that the products formed were a set of diastereomers of the $\beta$ lactam as shown in Scheme 84.

Reagents \& Conditions: (i) LiHMDS (1.1 equiv.), THF, $-78^{\circ} \mathrm{C}$ to rt, 8 hrs
Scheme 84- Identifcation of unexpected $\boldsymbol{\beta}$-lactam products

The major diastereomer has a diagnostic doublet observed at 1.44 ppm and a quartet at 5.00 ppm whilset the minor diastereomer has a diagnostic doublet observed at 1.71 ppm and a quartet at 4.48 ppm. Subsequently a COSY spectrum (Figure 13) of the major diastereomer was obtained, which helped confirm the structure of the major $\beta$ lactam diastereomer.

Figure 13- COSY spectrum of $\boldsymbol{\beta}$-lactam 223

The COSY spectrum reveals that proton $B$ couples to protons $A, A^{\prime}$ and $C$, with a coupling constant of $\mathrm{J}_{(\mathrm{BC})}=4.5 \mathrm{~Hz}$, which is consistent with that expected for a $\beta$-lactam ring system. The bridgehead protons $B(\delta 3.87 \mathrm{ppm})$ and $C(\delta 4.30 \mathrm{ppm})$ resonate at a lower field than would be expected for a $\beta$-amino acid product. In conjunction with all
the other analytical data it was therefore concluded that the product formed was a tricyclic $\beta$-lactam.

### 2.8 Mechanism of $\beta$-Lactam Formation

There are two possible mechanisms by which $\beta$-lactam formation could have occurred. The first proposed mechanism (in its simplistic form) is the formation of an ( $E$ )-enolate that subsequently attacks the imine fragment in a 5-exo-trig manner, resulting in the generation of a highly nucleophilic aza-anion. Consequently, the nucleophilic aza-anion substituent then undergoes a 4-exo-trig ring closing reaction to form the respective $\beta$ lactams 223a and 223b (Scheme 85).

Scheme 85- Enolate mechanism for $\boldsymbol{\beta}$-lactam formation

An alternative mechanism could be proposed based upon a Staudinger ketene cycloaddition pathway. This reaction manifold was first reported in 1907, when a [2+2] cycloaddition was employed to produce the first synthetic $\beta$-lactam 7 (Scheme 86). ${ }^{6}$

Reagents \& Conditions: (i) $\mathrm{NEt}_{3}$ (ii) N -benzylideneaniline
Scheme 86- Staudinger ketene cycloaddition for the synthesis of $\boldsymbol{\beta}$-lactams

Therefore, an alternative mechanism for $\beta$-lactam 223 would require formation of a ketene intermediate 225. Subsequent nucleophilic attack of the imine lone pair onto the carbonyl of the ketene would then afford a zwitterionic intermediate, whose enolate fragment would then undergo ring closure onto the iminium species to afford the $\beta$ lactams 223a and 223b (Scheme 87).

Scheme 87- Alternative ketene mechanism for $\boldsymbol{\beta}$-lactam formation
A review of the literature reveals that while there are numerous examples of Staudinger cycloaddition reaction using more reactive acid chlorides, ${ }^{142}$ there is no such precedent reported for less reactive ester groups. Bearing this lack of precedent in mind, it was concluded that $\beta$-lactam formation was proceeding via a stepwise enolate-imine cyclisation mechanism. Furthermore, it should be noted that a $\beta$-amino ester product

205 was isolated from Andrew et al.'s original cyclisation reaction (Figure 14), which is not consistent with a ketene based mechanism operating in these reactions. Therefore, in this case, we suggest that an enolate-imine cyclisation reaction occurs to afford a $\beta$ amino ester aza-anion, which is less likely to ring close to afford a $\beta$-lactam because of the presence of its bulky $t$-butyl ester.

205

Figure 14- Cyclohexylamine 205 formed from original enolate-imine cyclisation reaction ${ }^{132}$

Indeed, further reinvestigation of this cyclisation reaction has recently revealed the presence of a small amount of bicyclic $\beta$-lactam 226 present in the crude reaction product of this cyclisation reaction (Figure 15).

226

Figure 15- Minor bicyclic $\beta$-lactam 226 product observed from original cyclisation reaction ${ }^{143}$

The 4-exo-trig cyclisation of metalated $\beta$-amino esters to afford $\beta$-lactams is not entirely unexpected, with a review of the literature revealing good precedent for cyclisation. For example in 1974, it was reported that the treatment of (rac)- $\beta$-amino-ester 227 with MeMgl gave racemic $\beta$-lactam 228, albeit in only $12 \%$ yield (Scheme 88). ${ }^{144}$

Reagents \& Conditions: (i) MeMgI, Et $t_{2} \mathrm{O}, 0^{\circ} \mathrm{C}, 2$ hrs.
Scheme 88- Synthesis of 7-ketobenzo[c]cis-6-azabicyclo[3.2.0]heptanes $\mathbf{2 2 8}^{\mathbf{1 4 4}}$

In 2007, Davies et al. showed that magnesium amides cyclise to afford chiral $\beta$-lactams in a similar manner. ${ }^{145}$ It has also been shown that it is possible to generate $\beta$-lactams via the action of titanium halides ${ }^{146}$ and tin(II)amides ${ }^{147}$ on related precursors; in good yields (Scheme 89).

Reagents \& Conditions: (i) $\mathrm{MeMgBr}, \mathrm{Et}_{2} \mathrm{O}, 0^{\circ} \mathrm{C}$
Scheme 89- Synthesis of a $\beta$-lactam using MeMgBr to facilitate cyclisation ${ }^{145}$

More directly related, Ha et al. have shown that treatment of $\beta$-amino ester 231 with LiHMDS in THF at $-78^{\circ} \mathrm{C}$, resulted in cyclisation to afford $\beta$-lactam 232 in $97 \%$ yield (Scheme 90). ${ }^{148}$ In conclusion, this evidence suggests that formation of $\beta$-lactam 223 occurs via an enolate-imine cyclisation mechanism.

Reagents \& Conditions: (i) LiHMDS, THF, $-78{ }^{\circ} \mathrm{C}$ to $0{ }^{\circ} \mathrm{C}, 2 \mathrm{hrs}$
Scheme 90- Lactamisation reaction using LiHMDS as a base to induce cyclisation ${ }^{148}$

### 2.9 Determination of the Configuration of $\beta$-Lactam 223

In light of the discovery of this $\beta$-lactam forming reaction and the ability to isolate the major diastereomer, the next step was to confirm the stereochemistry of the $\beta$-lactam 223.

As the protected tricyclic $\beta$-lactam 223 has been reported previously, ${ }^{126}$ it was decided to deprotect the major diastereomer 223 and use the sign of the specific rotation to assign its configuration. Davies et al. have previously shown that the treatment of $\beta$ lactam 233 with ceric ammonium nitrate (CAN) results in oxidative deprotection to afford the $\beta$-lactam 234 (Scheme 91). ${ }^{149}$

Reagents \& Conditions: (i) CAN (3.0 equiv.), $\mathrm{MeCN}-\mathrm{H}_{2} \mathrm{O}$ (5:1), rt, 16 hrs.
Scheme 91- CAN deprotection reaction of $\beta$-lactam $233{ }^{149}$

With an appropriate deprotection precedent in hand, the next step was to apply this oxidative cleavage methodology to the unknown major diasteromer obtained from the initial cyclisation reaction (Scheme 84). This deprotection strategy was successfully applied to $N$-aryl- $\beta$-lactam 223 yielding the free NH- $\beta$-lactam 198 in $76 \%$ yield.

Reagents \& Conditions: (i) CAN (3.0 equiv), $\mathrm{MeCN}-\mathrm{H}_{2} \mathrm{O}$ (5:1), rt, 16 hrs
Scheme 92- Deprotection of unknown $\beta$-lactam diastereomer 223 using CAN

The free radical mechanism for the deprotection of tricyclic $\beta$-lactam 223 is shown in Scheme 93.

223

Scheme 93- Mechanism of CAN mediated deprotection reaction of $\boldsymbol{\beta}$-lactam 223

Once purified, the $\beta$-lactam 198 was characterized and the identification of the major diastereomer confirmed by comparing the negative sign of its specific optical rotation with the positive values previously reported for its $(S, S)$-enantiomer. ${ }^{126}$ Therefore, the specific rotation of the $(S, S)$ - $\beta$-lactam diastereomer 198a was measured as +224 which compares with the previously reported value of -214 for the $(R, R)-\beta$-lactam 198b. ${ }^{126}$

Figure 16- Comparison of specific rotation values of 198 with literature values ${ }^{126}$

This configurational assignment was further confirmed via hydrolysis of $\beta$-lactam 198a with aqueous hydrochloric acid to give the known $\beta$-amino ester salt hydrochloride salt 199a (Scheme 94). This $\beta$-amino acid salt 199a was isolated in an $83 \%$ yield giving a specific rotation of -2.5 which further correlates with the literature value of -5.7 reported previously for the same enantiomer of this amino acid. ${ }^{126}$

Reagents \& Conditions: (i) $18 \% \mathrm{HCl}$, reflux, 3 hrs
Scheme 94- $\beta$-Amino acid synthesis from $\beta$-lactam 198a

A successful route had now been devised to prepare one of the model $\beta$-amino acid targets; however the 5-exo-trig intramolecular enolate-imine cyclisation required optimization to enable the major diastereomer to be isolated in good yield and high de.

### 2.10 Optimisation of Enolate-Imine Cyclisation Conditions

Initial attempts at developing the intramolecular enolate-imine reaction (Scheme 84) had shown that the cyclisation reaction proceeded to afford $\beta$-lactam 223b. However, a yield of less than $10 \%$ and a diasteromeric excess of $50 \%$ were far from ideal and did not represent a useful synthesis of this type of tricylic $\beta$-lactam. As such, an attempt to optimize these conditions was undertaken in order to not only improve the diastereoselectivity and yield, but also to provide a better insight into rationalising the stereoselectivity of the cyclisation reaction.

The first variable to be selected was the base used to generate the enolate for cyclisation, with all reactions initially carried out at room temperature. A range of bases varying in $\mathrm{pK}_{\mathrm{a}}$, steric bulk and reactivity were investigated in order to see how readily the enolate-imine cyclisation reaction would occur, and determine which base would provide the best yield and diastereoselectivity.

As can be seen from Table 4 the trend suggested that the enolate-imine cyclisation reaction requires a strong sterically hindered base to proceed with good levels of stereocontrol. Initially, the use of LiHMDS gave a low $37 \%$ yield and also a moderate $46 \%$ de (Table 4, Entry 1). Therefore, the reaction was attempted with the more reactive NaHMDS which showed a marked improvement in the $56 \%$ yield and $54 \%$ de (Table 4, Entry 2). As such, due to the positive correlation between reactivity and improved results, KHMDS was trialed as a base; however this was unsuccessful, with only a small amount of $\beta$-lactam being formed in $0 \%$ de (Table 4, Entry 3). Potassium tert-butoxide, a weak base which has previously been reported to synthesise $\beta$-lactams in intermolecular enolate-imine condensations, ${ }^{150}$ successfully generated $\beta$-lactam 223a but in a low yield of $20 \%$ and a poor de of $30 \%$ (Table 4, Entry 4). Finally, sodium ethoxide, triethylamine and sodium hydride were all trialed but did not yield any $\beta$ lactam, with only starting material being recovered (Table 4, Entries 5-7).

Table 4- Effects of choice of base on yield and diastereoselectivity of $\boldsymbol{\beta}$-lactam 223

The non-metallic phosphazene base, also known as a "Schwesinger base", ${ }^{151}$ has previously been shown to generate enolates from isopropyl acetate, ${ }^{152}$ with phosphazene base classed as 'naked' because their counterions are considered to be non-coordinating. ${ }^{153}$ Sadly, despite repeated attempts using phosphazene bases under various conditions no $\beta$-lactam was ever observed with only starting material being recovered. In light of these results, the base chosen for further reaction optimization steps was NaHMDS (Scheme 95).

Reagents \& Conditions: $P_{4}$-t-Bu (1M in Hexanes), THF, $-78^{\circ} \mathrm{C}$ to rt, 8 hrs
Scheme 95- $\beta$-lactam synthesis using phosphazene base 236

The next variable that was examined was the reaction solvent. Toluene was chosen as a potential alternative as this non-coordinating, non-polar solvent has been successfully shown to improve the stereoselectivity in many enolate generating reactions. ${ }^{154}$ In comparison with THF, the cyclisation reaction in toluene gave the $\beta$-lactam 223a in a slightly lower de of $48 \%$, but the main effect was on the yield which was considerably reduced to only $14 \%$. Therefore, THF was chosen as the solvent of choice for further reactions (Table 5, Entry 2).

Table 5- Effects of solvent on yield and diastereoselectivity on $\boldsymbol{\beta}$-lactam 223

The next factor to be investigated was to include an additive in the reaction such as a crown ether. Crown ethers are cyclic compounds that contain ether groups which can bind strongly to specific cations depending on their size. In this case, as the base being
used was NaHMDS, the corresponding crown ether required was 15-crown-5. Due to the strong binding of the crown ether to the metal cation, the sodium counterion should not be involved in the transition state, thus generating a highly reactive "naked" enolate that might have a significant impact on the yield and diastereoselectivity.

At the outset, the addition of 15 -crown- 5 to the reaction was investigated at room temperature. It was found that addition of 15 -crown- 5 had a significant impact on the de increasing it from $54 \%$ to $88 \%$ (Table 6, Entry 2). The effect of the quantity of base employed were also investigated, both with and without the crown ether. The aim was firstly to prove whether increasing the equivalents of the base (and the crown ether) had an impact on the yield and de of the cyclisation reaction, and to subsequently show whether the crown ether was as effective under these conditions.

Table 6- Effects of crown ether additive on yield and diastereoselectivity of $\boldsymbol{\beta}$-lactam 223

As Table 7 shows - the crown ether was as effective at increasing the yield and de using 2.0 equivalents of base as it was with 1.1 equivalents. However, the increase in the equivalents of base (and crown ether) showed a negligible difference in yield and the same de. Therefore, optimal conditions were established as the used of 1.1 equivalents of base in THF in the presence of a stoichiometric amount of 15-crown-5 that gave an $85 \%$ yield of the major diastereomer in $88 \%$ de.

Table 7 - Effects of equivalents of base on the yield and diastereoselectivity of $\boldsymbol{\beta}$-lactam 223

| Entry | Equiv of Base | Crown Ether | Yield (\%) | de (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 1.1 | No | 56 | 54 |
| 2 | 2.0 | No | 66 | 56 |
| 3 | 1.1 | Yes | 85 | 88 |
| 4 | 2.0 | Yes | 86 | 88 |

The final and possibly most important factor to be investigated was temperature. All previous optimization reactions had been carried out at room temperature and so the effect of cooling the reaction was then examined. The temperature at which the enolate is formed could determine whether the thermodynamic or kinetic enolate was formed, as well as improving the facial selectivity of the cyclisation reaction. Therefore, a range of cryogenic temperatures were screened to see what trend between temperature and diastereoselectivity would be observed.

The first step was to perform the cyclisation reaction at $-78^{\circ} \mathrm{C}$ for 2 hours and gradually allow it to warm to room temperature. Although this gave a poor 5\% yield it did produce excellent diastereoselectivity ( $99 \%$ de; Table 8, Entry 2) which was not completely unexpected as stereoselectivity is normally improved at cryogenic temperatures. Therefore, in an attempt to improve the yield, but not to compromise the diastereoselectivity, the cyclisation reaction was carried out at $-45^{\circ} \mathrm{C}$ for 2 hours before warming to room temperature. This gave a very good and much improved yield of $73 \%$ while not affecting the diastereoselectivity which remained at $99 \%$ de (Table 8, Entry 3). The cyclisation was then attempted at $0{ }^{\circ} \mathrm{C}$ for 2 hours before warming to room temperature to see if the yield could be increased even further, this gave only a $67 \%$
yield and a drop in de to $90 \%$ (Table 8, Entry 2). Finally the reaction was carried out at room temperature and these conditions saw a slight drop in the yield but the main drawback was the substantial decrease in the de from $99 \%$ to $88 \%$ de (Table 8, Entry 1). These finding suggested that the optimal temperature profile for this enolate-imine cyclisation reaction is to start at $-45{ }^{\circ} \mathrm{C}$ for 2 hours and allow the reaction to slowly warm to room temperature.

Table 8- Effects of temperature on the yield and diastereoselectivity of $\boldsymbol{\beta}$-lactam synthesis

| Entry | Temp ( $\left.{ }^{\circ} \mathrm{C}\right)$ | Yield (\%) | de (\%) |
| :---: | :---: | :---: | :---: |
| 1 | rt | 86 | 88 |
| 2 | -78 to rt | 5 | 99 |
| 3 | -45 to rt | 73 | 99 |
| 4 | 0 to rt | 67 | 90 |

In conclusion, the optimization process had allowed a set of conditions to be identified that enabled the asymmetric synthesis of $\beta$-lactam 223a to be carried out in good yield and with excellent levels of stereocontrol. The most significant modifications included the addition of a crown ether and reducing the temperature of the reaction to $-45^{\circ} \mathrm{C}$, which allowed $\beta$-lactam 223a to be formed in an excellent de of $99 \%$ and a good $73 \%$ isolated yield.

Reagents \& Conditions: (i) NaHMDS (2.0 equiv.), 15-crown-5, THF, $-45{ }^{\circ} \mathrm{C}$ to rt, 8 hrs
Scheme 96- Optimised conditions for $\boldsymbol{\beta}$-lactam synthesis

Not only did this generate a suitable methodology for the synthesis of $\beta$-lactam 223a, but also the possibility of using it to generate a range of $\beta$-lactam analogues.

### 2.11 Occurrence of a Minor $\beta$-Amino Ester Side Product

Upon further inspection of the ${ }^{1} \mathrm{H}$ NMR spectra of the crude reaction products of some of the enolate-imine cyclisation reactions described in the previous section, there were a few examples where a minor side product was present. This was significant as it could provide further understanding of the mechanism of the enolate-imine cyclisation reaction.

Consequently, it was found that treatment of ester 221 with KHMDS in THF at room temperature resulted in a crude reaction product that was purified by chromatography to afford a small amount of a $\beta$-amino ester side product. The ${ }^{1} \mathrm{H}$ NMR spectrum of this side product contained a triplet at 1.24 ppm and a quartet at 4.19 ppm suggesting that the ethyl ester group was still present. Further to this, the presence of multiplets at 3.18 ppm and 3.36 ppm of its bridgehead ring protons indicated that the initial 5-exo-trig cyclisation had also taken place. In addition, the high resolution mass spectrometry data reported a clean and well defined $\mathrm{m} / \mathrm{z}$ value of 340.19 , consistent with the presence of a $\beta$-amino ester shown in Figure 17.

Figure 17- $\beta$-amino ester isolated from the enolate-imine cyclisation reaction

Analysis of the ${ }^{1} \mathrm{H}$ NMR spectra of the crude products revealed that using LiHMDS and KHMDS in THF at room temperature afforded the minor $\beta$-amino ester in the best yield. In comparison, using NaHMDS as a base does not generate the $\beta$-amino ester, with no $\beta$-amino ester being present in the ${ }^{1} \mathrm{H}$ NMR spectra for any of the optimization reactions carried out in Table 9.

The appearance of a minor $\beta$-amino ester is not completely unexpected when the work by Andrews et al. is considered, ${ }^{132}$ where their original conditions using LiHMDS resulted in $\beta$-amino ester 205 being formed as the major product.

Table 9- Ratio of $\boldsymbol{\beta}$-lactams and $\boldsymbol{\beta}$-amino esters products in enolate-imine cyclisation reactions

With the identification of a minor $\beta$-amino ester side product established, the next step was to establish its stereochemistry. There are four possible diastereomers which could potentially be assigned to $\beta$-amino ester 237 (Figure 18), so therefore the next step was to prepare authentic samples of all of these isomers for comparative purposes.

238 Cis 1

239 Cis 2

240 Trans 1

241 Trans 2

Figure 18- Possible diastereomers of unknown $\boldsymbol{\beta}$-amino ester 237

At the outset, the major diastereomer of ( $S, \alpha R, \beta R$ ) - $\beta$-lactam 223a was subjected to acidic conditions in ethanol, which resulted in a ring opening reaction to form the HCl salt of $(S, \alpha R, \beta R) \beta$-amino ester 242 shown in Scheme 97.

Reagents \& Conditions: $\mathrm{HCl}\left(1 \mathrm{M}\right.$ in $\left.\mathrm{Et}_{2} \mathrm{O}\right)$, EtOH, reflux, 3 hrs
Scheme 97- Ring opening of (S, $\alpha R, \beta R$ )- $\beta$-lactam 223a

In order to obtain the trans isomer $(S, \alpha S, \beta R) 241$ an epimerization reaction was performed on the cis- $\beta$-amino ester 242 using the methodology reported by Fulop et al. that had been used previously to epimerise a similar benzocispentacin structure. ${ }^{126}$ Therefore, the HCl salt of the trans diastereomer was synthesised by stirring with NaOEt in EtOH followed by acidification with 1 M HCl for 30 minutes which gave the ( $S, \alpha S, \beta R$ )-diastereomer 243 (Scheme 100).

Reagents \& Conditions: (i) NaOEt, EtOH, reflux, 7 hrs ; (ii) $\mathrm{HCl}\left(1 \mathrm{M}\right.$ in $\mathrm{Et}_{2} \mathrm{O}$ ), rt, 0.5 hrs
Scheme 98- Synthesis of $\boldsymbol{\beta}$-amino ester 243

Next, the alternative $\beta$-amino ester cis diastereomer ( $S, \alpha S, \beta S$ ) 244 was synthesised from the $(S, \alpha S, \beta S)$ minor $\beta$-lactam diastereomer 223b, that was isolated from an unselective cyclisation reaction. Previously established conditions using KHMDS as a base to carry out the enolate-imine cyclisation reaction on 221 had given an equal ratio of the two major and minor diastereomeric $\beta$-lactams 223a and 223b (Table 4). Therefore, the cyclisation reaction was repeated on a larger scale and the crude product purified by chromatography to afford an authentic sample of ( $S, \alpha S, \beta S$ ) - $\beta$ lactam 223b. With the $(S, \alpha S, \beta S)$ - $\beta$-lactam in hand the subsequent acid catalysed ring opening reaction was carried out to afford the corresponding ( $S, \alpha S, \beta S$ ) - $\beta$-amino ester 244 (Scheme 99). ${ }^{126}$

## Scheme 99- Ring opening of minor diastereomer of $\beta$-lactam 223b

Lastly, to obtain the fourth and final diastereomer of the $\beta$-amino ester, the cis ( $S, \alpha S, \beta S$ )- $\beta$-lactam 244 was epimerized using NaOEt in EtOH, followed by stirring in 1 M HCl for 30 minutes to afford the trans- $(S, \alpha R, \beta S)-\beta$-amino ester 245 (Scheme 100). ${ }^{126}$

Reagents \& Conditions: (i) NaOEt, EtOH, reflux, 48 hrs; (ii) $\mathrm{HCl}\left(1 \mathrm{M} \mathrm{in} \mathrm{Et}_{2} \mathrm{O}\right.$ ), rt, 0.5 hrs
Scheme 100- Epimerisation of $\beta$-amino ester 244

With all four possible diastereomers in hand it was possible to compare their ${ }^{1} \mathrm{H}$ NMR spectra, focusing on the three diagnostic protons of their 5-membered rings (Figure 19).

Figure 19- ${ }^{1} \mathrm{H}$ NMR spectrum of four $\boldsymbol{\beta}$-amino ester diastereomers

Comparison of the four ${ }^{1} \mathrm{H}$ NMR spectra (Figure 19) showed that each diastereomer exhibited distinct resonances between 2.5 ppm and 5 ppm , with the ${ }^{1} \mathrm{H}$ NMR spectrum of $(S, \alpha S, \beta R)$ - $\beta$-amino ester 245 being identical to the ${ }^{1} H$ NMR spectrum of the minor diastereomer isolated from the KHMDS enolate-imine cyclisation reaction. Therefore, based upon the ${ }^{1} \mathrm{H}$ NMR data we can revise the scheme shown in Table 9 to include the stereochemistry of the minor $\beta$-amino ester by-product (Scheme 101).

Scheme 101- All possible cyclisation products with relevant stereochemistry

To conclude, the structure of the $\beta$-amino ester side product was determined as (1S,2R)-ethyl-1-(((S)-1-(4-methoxyphenyl)ethyl)amino)-2,3-dihydro-1H-indene-2carboxylate, which enabled a complete picture of the stereochemical outcome of this cyclisation reaction to be obtained.

### 2.12 Rationale for the Stereochemistry of the Enolate-Imine Cyclisation Reaction

The formation and geometry of the enolate generated in these cyclisation reactions is a crucial factor in explaining the stereochemical outcome of $\beta$-lactam formation. There are two possible geometries when generating substituted enolates; either a ( $Z$ )-enolate or an $(E)$-enolate. Whereas the chiral auxiliary fragment determines the facial selectivity of the cyclisation reaction, the geometry of the enolate formed is highly significant since it determines the cis/trans diastereoselectivity of the initial stereodefining cyclisation reaction.

Literature precedent suggests that deprotonation of an ester with NaHMDS in THF (Scheme 96) should result in the formation of an ( $E$-enolate. In 1976, Ireland et al. ${ }^{155}$
described how an appropriate base and solvent selection determines the geometry of the ester enolate formed, as part of their attempts to control the stereoselectivity of a subsequent $[3,3]$ sigmatropic rearrangement. By trapping enolates of esters with tertbutyldimethylsilyl (TBDMS) groups it was shown that an ( $E$ )-isomer 247 was formed using LDA in THF ( $\sim 95 \%) .{ }^{156}$ However, when the solvent system was altered to include hexamethylphosphoramide (HMPA), the (Z)-enolate ester 248 was formed ( $\sim 85 \%$ ). ${ }^{156}$ These findings were later confirmed by crystallographic data (Scheme 102). ${ }^{157}$

Scheme 102- Formation of $(Z) /(E)$-lithium ester enolates ${ }^{155}$

Further to this, research by Heathcock et al. showed that the percentage of ( $Z$ )-ester enolates generated by strong bulky bases like LDA is very low, with less than $5 \%$ of any (Z)-enolate being formed. ${ }^{158}$ Therefore it can be concluded that an ( $(\Sigma)$-ester enolate should be generated during our intramolecular enolate-imine cyclisation reactions.

It has been demonstrated (Table 6) that the cyclisation of the sodium enolate onto the $\omega$-imino ester produces the same $\beta$-lactam regardless of the presence of 15 -crown-5. Therefore, this suggests that the initial 5-exo-trig reaction proceeds via a non-chelated open transition state (Scheme 103).

Scheme 103- Mechanism of enolate-imine cyclisation via an (E)-ester enolate

The next step was to consider the diastereomeric intermediates that could be formed in this cyclisation reaction and provide an explanation for the selective formation of the $(S, \alpha R, \beta R)-\beta$-lactam 223a as the major product. There are four possible diastereomeric N -anions that could potentially be formed in this 5 -exo-trig cyclisation reaction (Figure 20).

Figure 20- Possible $N$-anion intermediates after 5-exo-trig cyclisation

These diastereomeric intermediates will have different transition state energies of formation; with the epimerisation studies carried out in Scheme 98 clearly demonstrating that trans cyclic $\beta$-amino esters are more thermodynamically stable than their corresponding cis $\beta$-amino esters. In order to further understand the relative
energies some computational modeling was carried out on all four possible diastereomeric intermediates whose structures are presented in Figure 21-Figure 24, in an orientation viewed down the forming bond. The computational modeling and theoretical calculations were carried out by Dr. Andrew Leach at AstraZeneca with the programme "Gaussian09" being applied to the methyl ester diastereomers to minimize the number of calculations required.

In Figure 21, the lowest energy transition state conformation of the aza-anion 250 is shown which affords the observed ( $S, \alpha R, \beta R$ ) $\beta$-lactam 223a. The key feature of this conformation is that the small benzylic hydrogen atom is presented towards the azaanion fragment. This enables this conformation to minimise steric hindrance with the ester fragment, which results in an orientation whereby the methyl group of the chiral auxiliary fragment pointed downwards, with the more sterically demanding phenyl group pointing upwards. In comparison, Figure 22 illustrates the relatively disfavoured conformation of aza-anion 251 that leads to the formation of the minor ( $S, \alpha S, \beta S$ ) $\beta$ lactam 223b. This intermediate 251 is largely disfavoured on steric grounds due to the chiral auxiliary phenyl group clashing with the ester fragment. Figure 23 shows the lower energy transition state leading to the trans- $(S, \alpha R, \beta S)-N$-anion 252 where a staggered conformation is observed, in which the phenyl group of the auxiliary fragment has rotated so that it is staggered along the bond with the methyl substituent in the same plane as the methoxy group. In contrast, the disfavoured transition state in Figure 24 leading to trans- $N$-anion 253 results in its phenyl group being placed close to the methoxy group, and is therefore less likely to form.

Therefore based on computational calculations, the transition state energies leading to the $N$-anions of the diastereomeric $\beta$-amino esters 250-253 based upon their thermodynamic stability is as follows:

$$
\text { trans- }(S, \alpha S, \beta R) \mathbf{2 5 3} \text { < trans- }(S, \alpha R, \beta S) 252 \text { < cis- }(S, \alpha R, \beta R) 250<\operatorname{cis}-(S, \alpha S, \beta S) 251
$$

Pleasingly, this result is consistent with the fact that ( $S, \alpha R, \beta S$ ) $-\beta$-amino ester 240 was isolated as a minor component of the KHMDS and LiHMDS mediated cyclisation reactions. However, these relative energies lead to the question as to why we see formation of the $(S-\alpha R, \beta R) \beta$-lactam 223a as the major product of these cyclisation reactions?

Figure 21- Favoured cis- $N$-anion structure enabling $\beta$ lactam formation 250

Figure 23-Favoured trans- N -anion structure 253

Figure 22- Disfavoured cis- $N$-anion structure enabling $\beta$ lactam formation 251

Figure 24-Disfavoured trans- N -anion structure 252

It is proposed that the answer to this question lies in the fact that the reaction must generate a dynamic equilibrium whereby a reversible enolate-imine cyclisation reaction occurs to afford a rapidly interconverting mixture of trans/cis- N -anions under thermodynamic control (Scheme 104).

Scheme 104- Molecular modelling of ( $S-\alpha R, \beta R$ ) $\beta$-lactam formation

Regardless of which of the thermodynamically stable trans- N -anions are formed there is no further ring closure pathway that the trans- $N$-anions ( $\mathrm{pK}_{\mathrm{a}} \mathrm{NH} \sim 35$ ) can undergo, therefore these intermediates can revert back to the enolate ( $\mathrm{pK}_{\mathrm{a}}$ enolate $=25$ ) unless an adventitious proton source is present. Therefore, even though the cyclic cis- N anions have a higher energy barrier of formation to overcome, the fact that they can undergo a subsequent rapid 4-exo-trig pathway, to irreversibly afford their corresponding $\beta$-lactams, leads to their selective formation. The formation of the
subsequent $\beta$-lactam, means that the equilibrium of the cyclisation reaction is then driven to produce more of the cis- $N$-anions until the reaction is complete. Therefore, ( $S$ $\alpha R, \beta R$ ) $\beta$-lactam 223a is formed preferentially over the ( $S-\alpha S, \beta S$ )- $\beta$-lactam 223b, as formation of the cis- $N$-anion 251 is calculated to be several kcals higher, therefore less than $1 \%$ of this diastereomer would be expected to be observed. All computational calculations are based upon the assumption that the rate determining step is the enolate formation/cyclisation and not the rapid 4 -exo-trig cyclisation affording the $\beta$ lactam. This assumption agrees with previously reported modeling studies on related intermolecular ester enolate-imine cyclisation reactions to afford $\beta$-lactams. ${ }^{13}$ There are also several examples in the literature where lithium ester enolates have been reported to undergo intermolecular cyclisation reactions on to imines resulting in the selective formation of cis- $\beta$-lactams as seen in Scheme 105. ${ }^{30,49-50,52}$

Reagents \& Conditions: (i) LDA, THF, $-70^{\circ} \mathrm{C}$ to rt; (ii) N-benzylidene-4-methoxyaniline
Scheme 105- Intermolecular lithium ester enolate reaction forming cis- $\beta$-lactams ${ }^{49}$

To summarise, the intramolecular 5-exo-trig cyclisation reaction of $(E)$-enolate occurs under kinetic control to afford four possible $N$-anion intermediates under thermodynamic control. Despite the higher relative energies required for the formation of cis- N -anions, they are the only diastereomers that can undergo a subsequent 4-exotrig ring closure, which then drives the equilibria of the reaction to give $\beta$-lactam products.

### 2.13 Benzocispentacin Conclusion

In conclusion, a chiral auxiliary strategy has been developed that enables an intramolecular ester enolate-imine cyclisation reaction to be used for the asymmetric synthesis of a tricyclic $\beta$-lactam 223a with excellent levels of stereocontrol. The ( $E$ )-
enolate of an $N$-( $\alpha$-methyl- $p$-methoxybenzyl)- $\omega$-imino ester undergoes intramolecular 5-exo-trig cyclisation to afford a cis- N -anion, which subsequently undergoes a 4-exo-tet ring closure to furnish a tricyclic $(S, \alpha R, \beta R)$ - $\beta$-lactam 223a in good yield and excellent de. An optimized protocol has been established using NaHMDS and a crown ether in THF, with potential side products in this reaction having been identified and their stereochemistry assigned. In the following section, application of this methodology for the asymmetric synthesis of a range of structurally related cyclic $\beta$-lactams will be described.

### 2.14 Development of Benzocispentacin Analogues

### 2.14.1 Previous Synthesis of Indane Derived Amino Acids

The availability of a versatile methodology to synthesise a range of highly functionalized cyclic $\beta$-amino acids is highly desirable. In particular, there is a large amount of interest in the synthesis of indane amino acid derivatives due to their potential biological properties. For example, certain substituted indanes have been shown to be mechanism-based inhibitors of dopamine $\beta$-hydroxylase. ${ }^{159}$ In addition $\alpha$-amino acids of substituted indanes, AIDA and APICA, have been shown to be antagonists of metabotropic glutamate receptors which are associated with neurological diseases (Figure 25). ${ }^{160}$

256

257

Figure 25- Structures of AIDA 256 and APICA 257

Due to their important biological activities there have been several attempts at preparing substituted indane amino acids, including an organocatalytic enantioselective synthesis using (R)-proline for the synthesis of both (S)-AIDA and (S)-APICA in 2005 (Scheme 106). . ${ }^{161}$

## Scheme 106- Synthesis of ( $\boldsymbol{S}$ )-AIDA and ( $\boldsymbol{S}$ )-APICA

More recently in 2011, methodology for the synthesis of angularly fused indane amino acids was established, ${ }^{162}$ with addition of ethyl isocyanoacetate to dibromoarene 258 resulting in construction of the new ring system of the tricyclic indane amino acid structure (Scheme 109). ${ }^{162}$ These types of $\alpha$-amino acids scaffolds have been widely used in recent years and the ability to access similar highly functionalized enantiopure analogues for benzocispentacin would be a welcome development.

Reagents \& Conditions: i) Ethyl isocyanoacetate, $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{MeCN}$; (ii) a) EtOH, dil. HCl ; b) $\mathrm{Ac} 2_{2} \mathrm{O}, \mathrm{DMAP}$, DCM

Scheme 107- Synthesis of fused indane $\alpha$-amino acid derivatives ${ }^{162}$

Previously, it had been reported that the addition of enolates onto chiral imines does not provide good methodology for accessing highly substituted $\beta$-amino acids. ${ }^{163}$ Despite this, there have been several other reported methods to generate substituted indane $\beta$-amino acids (benzocispentacin). This includes the cyclisation of radical species onto oxime ethers with tributyltin hydride being used as a radical initiator to afford the cis-alkoxyamine 263 in $68 \%$ yield (Scheme 108). ${ }^{164}$

Reagents \& Conditions: (i) MeONH $2 \cdot H C l$, pyridine, rt; (ii) $\mathrm{Bu}_{3} S n H$, AIBN, benzene, reflux
Scheme 108- Synthesis of alkoxyamino-3-methylidene-chromanes ${ }^{164}$
Furthermore in 2005, diastereoselective addition of an aryl anion to a chiral isoxazoline fragment generated benzocispentacin structures containing four contiguous stereocentres was reported. ${ }^{163}$ In particular, the generation of a quaternary centre in 266 is highly valuable and therefore these types of highly functionalized structures have great potential as peptidomimetic scaffolds (Scheme 109).

Reagents \& Conditions: (i) a) ${ }^{t} \mathrm{BuLi}, \mathrm{THF},-78^{\circ} \mathrm{C}$; b) $\mathrm{HCl} / \mathrm{H}_{2} \mathrm{O}, 0^{\circ} \mathrm{C}$ to rt
Scheme 109- Synthesis of disubstituted $\boldsymbol{\beta}$-amino acids from chiral isoxazolines ${ }^{163}$

As discussed earlier, one of the most useful methodologies for the synthesis of polycyclic $\beta$-amino acids has been developed by Fulop et al., who have successfully managed to use the enzyme Lipolase to catalyse the kinetic resolution of racemic $\beta$ lactam 268 as shown in Scheme 110. ${ }^{126}$ Such work has provided a range of cyclic structures, but this methodology could not be used to prepare chiral $\beta$-lactams containing aryl substituents due to the substrate specific nature of the enzymes active site.

Reagents \& Conditions: (i) CSI, $\mathrm{Na}_{2} \mathrm{SO}_{3}$; (ii) $\mathrm{H}_{2} \mathrm{O}$, Lipolase, $60^{\circ} \mathrm{C}$
Scheme 110- Synthesis of benzocishexacin using enzymatic resolution ${ }^{126}$

Another highly researched area is the synthesis of fluorinated $\beta$-amino acids that are important medicinal chemistry targets. ${ }^{165}$ There are many examples of the incorporation of fluorine into cyclic $\beta$-amino acids which has recently been the subject of a large review. ${ }^{165}$ For example, the synthesis of a difluorinated analogue of cispentacin $2711^{166}$ and substituted $\beta$-lactam $273^{167}$ has generated a large amount of research interest (Scheme 111).

Reagents \& Conditions: (i) a) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}$; b) LDA, THF, $-78{ }^{\circ} \mathrm{C}$; (ii) $\mathrm{BrCH}_{2} \mathrm{COEt}, \mathrm{Zn}, \mathrm{THF}$, reflux
Scheme 111- Examples of fluorinated $\beta$-amino acids/ $\boldsymbol{\beta}$-lactams ${ }^{166-167}$

Therefore, it was the aim of this work to develop our enolate-imine cyclisation reaction to prepare highly functionalized benzocispentacin analogues that incorporated methyl, methoxy and fluoro substituents as well as an angularly fused naphthyl indane $\beta$ -
lactams which could mirror products previously shown to be valuable for $\alpha$-amino acid research.

### 2.14.2 Synthesis of Benzocispentacin Analogues

Six commercially available substituted 2-bromobenzaldehydes were subjected to the previously developed 5 -step methodology to furnish their corresponding chiral $\omega$-iminoesters in moderate to good yields. These cyclisation substrates were derived from 2-bromo-4-methylbenzaldehyde 274a, 2-bromo-5-(trifluoromethyl)benzaldehyde 274b, 2-bromo-6-fluorobenzaldehyde 274c, 2-bromo-5-methoxybenzaldehyde 274d, 2-bromo-4,5-dimethoxybenzaldehyde $\mathbf{2 7 4 e}$ and 1-bromo-2-naphthaldehyde 274f. The most significant alteration to the synthetic protocol was the conjugate reduction of the double bond of the naphthyl derivative 277f that required 72 hours instead of the 48 hours employed for the other analogues. Apart from this exception, all of the other reactions proceeded effectively to afford the desired cyclisation substrates (Scheme 112).

Reagents \& Conditions: (i) Propan-1,3-diol, pTSA, Toluene, (ii) Ethyl Acrylate, $\mathrm{Pd}(\mathrm{OAc})_{2},(\mathrm{o}-\mathrm{Tol})_{3} \mathrm{P}$, DIPEA, MeCN (iii) $\mathrm{NaBH}_{4}, \mathrm{CoCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, Ethanol (iv) Acetic acid and water (v) (S)-(-)-4-methoxy- $\alpha$ methylbenzylamine, $\mathrm{MgSO}_{4}, \mathrm{DCM}$

Scheme 112- Synthesis of $\omega$-imino esters ( $S$ )-279a-f

The yields obtained for each step of the synthetic protocol used to prepare six $\omega$-imino esters 279a-f can be seen in Table 10, which ranged from good to excellent.

Table 10- Yields obtained for the synthesis of chiral imino esters 279a-f

|  | Acetal <br> $275(\%)$ | $\alpha, \beta$-unsaturated <br> ester 276 (\%) | Saturated Ester <br> 277 (\%) | Aldehyde 278 <br> (\%) |
| :---: | :---: | :---: | :---: | :---: |
| $\mathbf{2 7 9}$ (\%) |  |  |  |  |

The intramolecular enolate-imine cyclisation conditions were then applied to the range of chiral $\omega$-imino esters (279a-f) with the resulting de's and yields obtained shown in Table 18. The de's were determined from the integration of the diagnostic resonances for the major and minor $\beta$-lactam diastereomers (280a-f) in the ${ }^{1} \mathrm{H}$ NMR spectra of the crude reaction products. Cyclisation substrates containing a range of electron donating (Table 10, Entries 1, 4 and 6) and electron withdrawing (Table 10, Entries 2, 3 and 6) substituents in various ring positions, afforded a range of $\beta$-lactams using this methodology. As can be seen from Table 11, the majority of the substrates gave cyclised $\beta$-lactams with excellent de's ( $>95 \%$ ) and moderate to good yields. One exception is Entry 3 which had a notably lower de of $90 \%$ when the fluorine is ortho to the imine substituent, although this reaction does benefit from a much higher yield.

The X-ray crystallographic structure of one of the analogues, trifluoro-aryl- $\beta$-lactam 280b, was obtained after successful recrystallisation from a mixed solvent of
dichloromethane and hexane. As shown in Figure 26, the X-ray crystal structure of the protected $\beta$-lactam 280b shows that the major diastereomer of the enolate-imine cyclisation reaction is the $(S, \alpha R, \beta R)-\beta$-lactam, where the methyl group on the auxiliary (C13) lies in the same plane as the $\beta$-lactam ring (C3-N1 and C2-C1) with the three hydrogen atoms on C2, C3 and C12 all pointing out of the plane of the paper in the same direction (as drawn, Figure 26).

Figure 26- X-ray crystal structure of ( $S, \alpha R, \beta R$ )-trifluoro-aryl- $\beta$-lactam 280b with ellipsoids drawn at the $\mathbf{5 0 \%}$ probability level

Oxidative cleavage of the chiral auxiliary fragment of $N$-aryl- $\beta$-lactams 280a-f was then carried out using CAN in $\mathrm{MeCN} / \mathrm{H}_{2} \mathrm{O}$ to afford the deprotected $\beta$-lactams 281a-c in good yields under mild conditions (Figure 27).

66\% Yield

61\% Yield

62\% Yield

Figure 27-Synthesis of tricyclic $\boldsymbol{\beta}$-lactam analogues

Attempts to remove the chiral auxiliary of the remaining three protected $\beta$-lactams 280d-f proved unsuccessful. Firstly, treatment of the protected $\beta$-lactam 280d with CAN gave a ${ }^{1} \mathrm{H}$ NMR spectrum that showed a number of products with the main component
from the deprotection reaction being identified as a keto- $\beta$-lactam. This product is formed from benzylic oxidation, instead of cleavage of the chiral auxiliary from the $\beta$ lactam ring. A similar benzylic oxidation was also observed for the structurally related $N$-aryl- $\beta$-lactam 280e (Scheme 113).

Reagents \& Conditions: (i) CAN (3.0 equiv.), $\mathrm{MeCN}-\mathrm{H}_{2} \mathrm{O}$ (5:1), rt, 16 hrs.
Scheme 113- Formation of keto- $\beta$-lactam 282

A review of the literature revealed that the formation of such keto- $\beta$-lactams was not entirely unexpected, since CAN mediated benzylic oxidations of indane systems have been reported previously (Scheme 114). ${ }^{168}$

Reagents \& Conditions: (i) $\mathrm{CAN}, \mathrm{HNO}_{3}, 30^{\circ} \mathrm{C}, 1.5 \mathrm{hrs}$
Scheme 114- Partial oxidation with CAN ${ }^{168}$

The naphthyl analogue $280 f$ was also not deprotected successfully, yielding only small amounts of starting material and a range of other unidentifiable products. Therefore, the current methodology for the removal of the chiral auxiliary is not suitable for N -aryl protected $\beta$-lactams 280d-f and further work will be required to investigate alternative deprotection conditions for these analogues. Alternatively, a different auxiliary might be used to control the stereoselectivity of the cyclisation reaction.

### 2.14.3 Synthesis and Optimization of the Asymmetric Synthesis of Benzocishexacin

With a range of benzocispentacin derived analogues having been prepared the next step was to attempt to increase the acyclic ring size of the $\omega$-imino ester that would cyclise to afford a six membered $\beta$-lactam. In order to prepare the desired $\omega$-imino ester the design of an alternative synthetic protocol was required, such as an extra methylene group which would need to be included in the ester side chain (Figure 28).

Figure 28- Target starting material for benzocishexacin synthesis

Whereas previously a Heck cross coupling reaction of 2-bromobenzaldehyde had been used to install the ester $\mathrm{C}_{3}$ side-chain, an alternative cross coupling methodology was required for addition of a longer $\mathrm{C}_{4}$ side-chain. To address this problem a review of the literature revealed there was precedent for such a transformation, whereby Sase et al. had reported a one pot Negishi cross coupling reaction of aryl halides with alkyl zinc reagents. ${ }^{169}$ In a two step reaction that involved the use of a PEPPSI ligand, a high yielding cross coupling procedure was used to furnish ethyl 4-(4formylphenyl)butanoate 288 in an 87\% yield (Scheme 115). ${ }^{169}$

Reagents \& Conditions: (i) LiCl, Zn, dibromoethane, trimethylsilylchloride, iodine, $\mathrm{THF}, 5{ }^{\circ} \mathrm{C}$, 12 hrs ; (ii) 4-bromobenzaldehyde, PEPPSI, DMI, rt, 1 hr

Scheme 115- One pot Negishi reaction using alkyl zinc intermediates ${ }^{169}$

PEPPSI 289 (Pyridine-Enhanced Precatalyst Preparation, Stabilisation and Initiation), is a particularly useful ligand for these types of cross-coupling reactions, as it is easily synthesized, air stable and highly active, and has shown an increase in the scope and reliability of the Negishi reaction (Figure 29). ${ }^{170}$

Figure 29- Structure of PEPPSI ligand ${ }^{170}$

It was proposed that this methodology could be utilized to obtain the desired orthosubstituted ester. If possible, this technique would reduce the number of steps required for its synthesis when compared with benzocispentacin, since there would be no need to reduce a double bond or to protect the aldehyde functionality. As such, the one pot Negishi cross coupling was attempted using 2-bromobenzaldehyde 209 (Scheme 116), successfully affording ethyl 4 -(2-formylphenyl)butanoate 291 in $51 \%$ yield. The only alteration to the original methodology was to extend the reaction time of the cross coupling reaction to 12 hours.

Reagents \& Conditions: (i) Lithium chloride, zinc, dibromoethane, trimethylsilylchloride, iodine, THF, 50
${ }^{\circ} \mathrm{C}$, 12 hrs ; (ii) 2-bromobenzaldehyde 209, PEPPSI 289, DMI, rt, 12 hrs
Scheme 116- Synthesis of ethyl 4-(2-formylphenyl)butanoate from Negishi cross coupling

This cross coupling reaction starts with the active $\operatorname{Pd}(0)$ complex which adds to the aryl halide 209 via an oxidative addition, with the resulting $\mathrm{Pd}(\mathrm{II})$ complex subsequently undergoing transmetalation with the zinc activated ethyl 4-bromobutanoate. This is then
followed by a reductive elimination reaction which gives the desired product 291, while regenerating the $\mathrm{Pd}(0)$ complex, as shown in Scheme 117.

Scheme 117- Proposed Negishi cross coupling reaction ${ }^{169}$

The next step was the formation of the chiral imino- $\omega$-ester via reaction of the aldehyde functionality 291 with (S)-(-)-4-methoxy- $\alpha$-methylbenzylamine under our standard conditions (Scheme 118).

Reagents \& Conditions: (i)(S)-(-)-4-methoxy- $\alpha$-methylbenzylamine, $\mathrm{MgSO}_{4}$, DCM, rt, 5 hrs
Scheme 118- Synthesis of (S,E)-ethyl 4-(2-(((1-(4-methoxyphenyl)ethyl)imino)methyl)phenyl) butanoate

With the chiral imino- $\omega$-ester in hand, it was decided that the optimized conditions previously established for the benzocispentacin derivatives (Scheme 96) would be applied to the first synthesis of the benzocishexacin $\beta$-lactam 292. The cyclisation reaction of 285 proved successful, with the $(E)$-enolate undergoing a 6-exo-trig intramolecular cyclisation reaction by nucleophilic attack on to its chiral imine fragment. This gives a cis-aza-anion which subsequently performs a 4-exo-trig ring closing reaction resulting in the formation of $\beta$-lactam 292. The $\beta$-lactam was generated in a moderate yield of $57 \%$ and a good de of $85 \%$. In an attempt to improve the yield and de further a brief optimization screen was then carried out (Table 12).

Reagents \& Conditions: (i) NaHMDS (2.0 equiv.), 15 -crown-5, THF, $-45{ }^{\circ} \mathrm{C}$ to rt, 8 hrs
Scheme 119- Cyclisation reaction of chiral imino- $\omega$-ester 292 to afford $\beta$-lactam 292

Initially, the cyclisation reaction was attempted with both LiHMDS and NaHMDS (Table 12, Entry 1 and 2) without the crown ether to see if this made any improvement. The results show that both the de and conversion were much lower than when compared with the previously optimized conditions (Table 12, Entry 7). When the crown ether was added at room temperature (Table 12, Entry 3) there was a clear increase in the conversion rate and de. Furthermore, when the temperature was decreased (Table 12, Entries 4 and 5) there was a decrease in the conversion rate, but a significant increase in the de, apart from when the reaction was carried out at $-78{ }^{\circ} \mathrm{C}$ which gave only recovered starting material. The increase of base from 1.1 equivalents (Table 12, Entry 5) to 2.0 equivalents (Table 12, Entry 7) showed an impressive increase in the conversion, which may have been due to the presence of water in the reaction media which could have quenched the base when only 1.1 equivalents was used. Therefore, the best conditions established for this reaction are those of Entry 7, which were the initial conditions originally established in benzocispentacin synthesis.

Table 12- Optimisation of a 6-exo-trig intramolecular enolate-imine cyclisation reaction

| Entry | Base | Temp ( $\left.{ }^{\circ} \mathrm{C}\right)$ | Equiv. | Crown | Conversion <br> $(\%)$ | de <br> (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | LiHMDS | rt | 1.1 | No | 74 | 35 |
| 2 | NaHMDS | rt | 1.1 | No | 13 | 28 |
| 3 | NaHMDS | rt | 1.1 | Yes | 100 | 49 |
| 4 | NaHMDS | 0 to rt | 1.1 | Yes | 62 | 58 |
| 5 | NaHMDS | -40 to rt | 1.1 | Yes | 44 | 84 |
| 6 | NaHMDS | -78 to rt | 1.1 | Yes | 0 | - |
| 7 | NaHMDS | -40 to rt | 2.0 | Yes | 73 | 85 |

The explanation for the decrease in the yield and de for the formation of $\beta$-lactam 292 must be due to the presence of the extra methylene unit. Once the $(E)$-enolate has been formed there must be more conformational mobility between the enolate fragment and the imine substituent, resulting in less stereocontrol of the initial 6-exo-trig cyclisation reaction, which results in a poorer facial selectivity and a lower de.

After purification by chromatography, the final step in the synthesis involved removal of the chiral auxiliary from $N$-aryl- $\beta$-lactam 292 by applying the CAN mediated oxidative deprotection shown in Scheme 92. The free $\beta$-lactam 293 was obtained in a $72 \%$ yield (Scheme 120), which may then undergo subsequent acidic hydrolysis to generate the corresponding $\beta$-amino acid as required.

Reagents \& Conditions: (i) CAN (3.0 equiv.), $\mathrm{MeCN}-\mathrm{H}_{2} \mathrm{O}$ (5:1), rt, 16 hrs
Scheme 120- Oxidative cleavage of chiral auxiliary

To summarise, an alternative methodology has been devised for the synthesis of the 6membered $\beta$-lactam 293. The synthetic route to the cyclisation precursor is much shorter than the one used for the synthesis of its 5 -membered analogues due to the use of a Negishi cross coupling reaction. This approach directly incorporates the ester side chain onto the aryl ring without the need for any protecting groups and the removal of a double bond. Although the 6-exo-trig enolate-imine cyclisation reaction occurs in acceptable yield and a good de, it does not proceed with the same level of diastereocontrol previously demonstrated for the 5-membered benzocispentacin analogues.

### 2.14.4 Conclusion

The application of the newly developed intramolecular enolate-imine cyclisation reaction for the synthesis of tricyclic $\beta$-lactams has been achieved to furnish seven novel polycyclic $\beta$-lactam analogues. The yields obtained range from moderate to high and the de's range from good to excellent. There is a problem with the oxidative removal of the chiral auxiliary fragment for a few N -aryl- $\beta$-lactams but ultimately this novel enolate-imine cyclisation methodology was shown to be successful for the asymmetric synthesis of polycyclic $\beta$-lactam ring systems.

## 3 Results \& Discussion- Acyclic Substrates

### 3.1 Introduction

The original aim of developing stereoselective methodology for carrying out an intramolecular enolate-imine cyclisation reaction had been achieved for a series of benzocispentacin substrates. An exciting application of this research would be to apply this methodology for the asymmetric synthesis for a range of chiral monocyclic $\beta$-amino acids. The most commonly reported monocyclic $\beta$-amino acids used for foldamer synthesis are cispentacin 294 and transpentacin 295, which are also known as 2aminocyclopentanecarboxylic acids (ACPCs) (Figure 30).

Figure 30- Examples of cispentacin (ACPC) 294, transpentacin 295 \& cishexacin (ACHC) 296

Due to the high demand for short and efficient asymmetric syntheses of these type of chiral building blocks it was decided to apply our cyclisation methodology to simple aliphatic $\omega$-imino ester starting materials, with the aim of using it for the asymmetric synthesis of cispentacin and related analogues.

### 3.2 Synthetic Approaches to Cispentacin Derivatives

In the past decade interest in monocyclic $\beta$-amino acids has increased significantly with the first and most widely researched target being cispentacin 294. Cispentacin (also referred to as cis-ACPC) exhibits potent antifungal activity and has found a broad range of applications including incorporation into $\beta$-peptides. In all cyclic $\beta$-amino acids, the carboxyl group is vicinal to the amine group, and consequently there are four possible stereoisomeric forms (Scheme 121).

294a

294b

295a

295b

Scheme 121- All four stereoisomers of ACPC

The ability to access all four stereoisomers of ACPC is a challenge that has been targeted by a number of synthetic groups. Access to enantiopure cispentacins is particularly important when incorporating them into $\beta$-peptides due to their ability to induce different folding properties. For example, transpentacin results in $\beta$-peptides that exhibit a 12-helical conformation ${ }^{171}$ whereas cispentacin forms an extended strand type structure. ${ }^{172}$

Initially, a range of methods for the synthesis of racemic cispentacin were reported. The first synthesis of rac-cispentacin $\mathbf{3 0 0}$ was reported in 1972 by Nativ et al. They demonstrated that rac-cispentacin could be synthesised using a [2+2] cycloaddition reaction of chlorosulfonyl isocyanate with cyclopentene 297 to afford $\beta$-lactam 299, followed by subsequent hydrolytic ring opening (Scheme 122). ${ }^{173}$

Reagents \& Conditions: (i) $\mathrm{ClSO}_{2} \mathrm{NCO}$; (ii) $\mathrm{KI}, \mathrm{NaHSO}_{4}$; (iii) $\mathrm{NaOH}, \mathrm{pH} 7$; (iv) conc. $\mathrm{HCl}, 3 \mathrm{hrs}$
Scheme 122- Racemic synthesis of cispentacin via a [2+2] cycloaddition reaction ${ }^{173}$

Several other methods for the synthesis of racemic acyclic $\beta$-amino acids include protocols that rely on the selective reduction of enamines, ${ }^{174-175}$ Diels-Alder reactions, ${ }^{176}$ Michael additions to cycloalkanecarboxylic acids ${ }^{177}$ and via 1,2-dicarboxylic acid rearrangements. ${ }^{178}$ There are now a number of routes for producing enantiopure pentacin derivatives using asymmetric synthetic protocols, including strategies that employ the chiral pool, chiral auxiliaries, chiral catalysts or kinetic resolution.

Cispentacin 294 was first prepared in enantiopure form by Davies et al. ${ }^{179}$ via conjugate addition of lithium $(S)$-( $\alpha$-methylbenzyl)benzylamide to an $\alpha, \beta$-unsaturated ester to afford ( $1 R, 2 S$ )-cispentacin tert-butyl ester 302 in $98 \%$ de and $65 \%$ yield. Research by Davies et al. using chiral lithium salts to prepare both aliphatic and cyclic $\beta$-amino acids has continued to be developed and was the subject of a large review in 2005 (Scheme 123). ${ }^{180}$

Reagents \& Conditions: (i) 2,6-Di-tert-butylphenol, THF; (ii) a) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, \mathrm{AcOH}$; b) HCl ; c) Dowex 50XB-200

Scheme 123- Synthesis of (1R,2S)-Cispentacin using lithium (S)- $\alpha$-methylbenzyl)benzylamide ${ }^{179}$

The initial work by Davies et al. on the asymmetric synthesis of cispentacin using enantiomerically pure lithium amides has continued to be developed for the synthesis of substituted cispentacin derivatives via parallel kinetic resolution. ${ }^{181}$ In this case, treatment of (rac)-tert-butyl-cyclopentene-1-carboxylate with a mixture of ( $S$ )- N -benzyl-$N$-( $\alpha$-methylbenzyl)amide and ( $R$ )- $N$-3,4-dimethoxybenzyl- $N$-( $\alpha$-methylbenzyl) amide results in enantiorecognition via a mutual kinetic resolution process, to give the enantiomeric addition products 306 and 308. This kinetic resolution enables the synthesis of a variety of C3-alkyl substituted cispentacin derivatives. In addition, epimerisation of the carboxylate centre enables access to alkyl substituted transpentacin derivatives ${ }^{182}$ which have since been successfully incorporated into $\beta$ peptides (Scheme 124). ${ }^{183}$

Reagents \& Conditions: (i) Lithium (S)-N-benzyl-N( $\alpha$-methylbenzyl)amide, lithium (R)-N-3,4-dimethoxybenzyl- N -( $\alpha$-methylbenzyl)amide (50:50), 2,6-di-tert-butylphenol THF, $-78^{\circ} \mathrm{C}$, 3 hrs ; (ii) DDQ, DCM: $\mathrm{H}_{2} \mathrm{O}$ (3:1); (iii) $\mathrm{Pd}(\mathrm{OH})_{2} / \mathrm{C}, \mathrm{MeOH}, \mathrm{H}_{2}$, (5 atm), rt

Scheme 124- Synthesis of $\gamma$-alkyl substituted cispentacin ${ }^{181}$

Since the initial asymmetric synthesis of cispentacin in 1993, a number of new methods have been developed for the synthesis of chiral monocyclic $\beta$-amino acids. One approach involves utilization of the chiral pool for the synthesis of a substituted cishexacin $\beta$-lactam from (+)- $\alpha$-pinene 309 (Scheme 125), ${ }^{184}$ whilst another example
involves the use of a D-glucose derivative to access polyhydroxylated transpentacins (Scheme 126). ${ }^{185}$

Reagents \& Conditions: (i) $\mathrm{CSI}, \mathrm{lhr}, \mathrm{rt}$; (ii) $\mathrm{KOH}, \mathrm{Na}_{2} \mathrm{SO}_{3}$
Scheme 125- Synthesis of cishexacin $\beta$-lactam using (+)- $\alpha$-pinene

The key steps in the formation of polyhydroxylated transpentacins involve the peptide coupling of lactone 313 with benzyloxycarbonylglycine, ethyl chloroformate and triethylamine to give the dipeptide 314 and the subsequent ring opening reaction using hydrazine to give the protected D-glucose derivative 315.

Reagents \& Conditions: (i) TBAF, THF; (ii) $\mathrm{H}_{2}$, Raney-Ni, MeOH; (iii) $\mathrm{ClCO}_{2} \mathrm{Et}, \mathrm{Z}-\mathrm{Gly}, \mathrm{Et}_{3} \mathrm{~N}$, (iv) $\mathrm{H}_{2} \mathrm{NNH}_{2}, \mathrm{MeOH} ;$ (v) t -BuNO $2, ~ \mathrm{HCl}, \mathrm{DMF}$, dioxane; (vi) Gly-CO $2{ }_{2} \mathrm{Me}, E t_{3} \mathrm{~N}, \mathrm{DMF}$

Scheme 126- Synthesis of substituted transpentacin from a derivative of D-glucose ${ }^{185}$

Although these examples show how the chiral pool can be used to provide access to some monocyclic $\beta$-amino acids, this type of methodology has several drawbacks such as long synthetic routes, high expense and the configuration of the product being limited to the availability of naturally occurring chiral starting materials.

The catalytic reduction of enamines to afford $\beta$-amino acids has been well documented ${ }^{103}$ with the first asymmetric synthesis of monocyclic $\beta$-amino ester via enantioselective reduction of an enamine using a chiral ruthenium catalyst being reported in 2003 (Scheme 127). ${ }^{186}$ Zhang et al. reported that $N$-acyl- $\beta$-amino ester 319 could be produced in $99 \%$ ee and $100 \%$ conversion using $(S)$-BINAP as a chiral ligand, with a variety of other chiral ligands having also been investigated. ${ }^{186}$ The use of this chiral ruthenium catalyst provides an excellent way of converting a prochiral $\beta$-amino ester into an enantiopure cis- $\beta$-amino ester, with the corresponding transpentacin being obtained by epimerization. ${ }^{186}$

Reagents \& Conditions: (i) Ru(COD)(Methallyl) $)_{2}$, (S)-BINAP, $\mathrm{HBF}_{4}, \mathrm{H}_{2}, \mathrm{MeOH}$, rt
Scheme 127-Enantioselective hydrogenation reaction to form a $\boldsymbol{\beta}$-amino ester ${ }^{186}$

The stereoselective synthesis of $\beta$-amino acid derivatives using enzymatic kinetic resolution is well documented and such methods have been investigated extensively. ${ }^{115,124,126,187-189}$ In 2003, Fulop et al. devised an efficient and simple methodology for the lipase-catalysed enantioselective ring opening of alicyclic fused $\beta$ lactams. ${ }^{190}$ This enantioselective ring opening reaction furnished enantiopure ( $1 R, 2 S$ )cispentacin and the corresponding ( $1 S, 5 R$ )- $\beta$-lactam in high yield and excellent ee that could be easily separated. The ( $1 S, 5 R$ )- $\beta$-lactam was subsequently ring opened using acid hydrolysis to obtain the other cispentacin enantiomer. This enzymatic methodology has recently been employed for the synthesis of fluorinated alicyclic $\beta$-amino esters ${ }^{191}$ and key intermediates for the Taxol side chain. ${ }^{192}$ Therefore, while the significance of
this enzymatic process has been established, the main drawbacks of this approach are the substrate specific nature of the enzymes employed (Scheme 128).

In 2003, desymmeterisation of meso-anhydrides was achieved using either quinidine or quinine as nucleophilic catalysts to mediate the addition of benzyl alcohol to give mono benzyl esters 322 or $\mathbf{3 2 4}$. Subsequent Curtius degradation of these monobenzyl ester acids afforded the corresponding benzyl cispentacin esters in high ee. ${ }^{193}$ The (S)benzyl hemiester can be obtained using a quinidine mediated desymmetrisation, whereas the ( $R$ )-benzyl hemiester can be generated using a quinine additive. This allows access to either cispentacin enantiomer in up to $97 \%$ ee and $93 \%$ yield (Scheme 129). ${ }^{193}$

Scheme 129- Synthesis of cispentacin via desymmetrisation of a meso-anhydride

More recently a quinine-mediated parallel kinetic resolution has been used to synthesise the antifungal Icofungipen. Icofungipen, also referred to as BAY 10-888, has a dual mode of action as a novel antifungal and is currently in phase II clinical studies as a treatment for yeast infections. ${ }^{194}$ For example, Mittendorf et al. have developed a synthesis that enables $(1 R, 2 S)$-Icofungipen 239 to be prepared on a multi-kilogram scale. ${ }^{195}$

As illustrated in Scheme 130 the substituted cyclopentanone diester 326 is synthesised from tetra-acid 325 using a Dieckmann cyclisation followed by acid catalysed decarboxylation and esterification with ethanol. The alkene functionality is installed using a methylene Wittig reaction and the dicarboxylic acid is converted into mesoanhydride 327. A quinine mediated alcoholysis of the anhydride 327 was carried out using trans-cinnamyl alcohol, which generated the enantiomer 328 in $>99 \%$ ee. Lastly,
a Curtius rearrangement furnished the protected $\beta$-amino ester, which was subsequently deprotected to give ( $1 R, 2 S$ )-Icofungipen 329 in an overall $23 \%$ yield (Scheme 130). ${ }^{195}$

Scheme 130- Quinine mediated synthesis of (1R,2S)-Icofungipen $329{ }^{195}$

Research in this area continues and more recently in 2007 all four enantiomerically pure isomers of Icofungipen 329 have been synthesised using a quinine-mediated parallel kinetic resolution protocol. ${ }^{196}$

Another asymmetric process for the synthesis of cispentacin involves an intramolecular nitrone cycloaddition onto a $\mathrm{C}_{2}$-symmetric ketene bis-sulfoxide. ${ }^{197}$ The facial selectivity of the [3+2] cycloaddition reaction of the nitrone $\mathbf{3 3 0}$ onto the alkene functionality is controlled by diastereoselective steric interactions that occur within the transition state. This results in a defined tricyclic product that was subsequently reduced to form ( $1 R, 2 S$ )-cispentacin 294a. More recently this methodology has been utilized to generate the cispentacin analogue cis-(3R,4R)-4-amino-pyrrolidine-3-carboxylic acid (Scheme 131). ${ }^{198}$

Scheme 131- Intramolecular nitrone cycloaddition for the asymmetric synthesis of cispentacin ${ }^{197}$

In summary, there are a number of methodologies that have been devised in order to prepare enantiopure cispentacin analogues, including the use of chiral catalysts, kinetic resolutions, intramolecular nitrone cycloadditions as well as lithium amide conjugate additions. Despite attempts at functionalisation of the cispentacin ring, many of these methodologies are substrate specific and as such only give access to a limited range of derivatives. Therefore, it was the aim of the research described in this chapter to employ our intramolecular enolate-imine cyclisation methodology for the efficient asymmetric synthesis of cispentacin, as well as some of its analogues.

### 3.3 Chiral Imino Ester Synthesis

The aim of employing an intramolecular enolate-imine cyclisation reaction to generate cispentacin in high yields and diastereoselectivity required a simpler synthetic route compared with that used for the synthesis of the benzocispentacin substrates. The proposed retrosynthesis shown in Scheme 132 reveals that the asymmetric synthesis of cispentacin could potentially be prepared using a short and potentially high yielding methodology.

Scheme 132- Retrosynthesis of cispentacin

In devising the cheapest and most efficient synthetic route, it was found that ethyl 6hydroxyhexanoate 332 was commercially available. Its alcohol fragment was easily oxidised to its corresponding aldehyde, using pyridinium chlorochromate (PCC) to afford ethyl 6-oxohexanoate 333 in 89\% yield (Scheme 133).

Reagents \& Conditions: (i) PCC, DCM; (ii) (S)- $\alpha$-methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}, \mathrm{DCM}, 2 \mathrm{hrs}$
Scheme 133- Synthesis of (S,E)-ethyl 6-((1-(4-methoxyphenyl)ethyl)imino)hexanoate

The chiral imine 334 was formed in a $90 \%$ yield via treatment of aldehyde 333 with (S)-$\alpha$-methyl- $p$-methoxybenzylamine with its formation being established by the presence of an imine proton as a triplet at 7.71 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude reaction product.

The initial imine reaction was reanalyzed after a few hours, which revealed the emergence of an impurity over time. In fact after 48 hours there was none of the original imine 334 left in the reaction, with only a new imine product present, as well as residual amine in a 1:1 ratio. This observation required further investigation as it was important to understand what effect the formation of this new imine might have on the overall success of the enolate-imine cyclisation reaction. The unknown impurity was subjected to a series of 1D and 2D NMR experiments with the ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}, \mathrm{COSY}, \mathrm{HSQC}$ and HMBC spectra (Appendix 5.1-5.2) enabling the structure of the dimeric imine 335 to be determined (Figure 31).

335

Figure 31- Proposed structure of impurity 335

The key correlations in the HMBC spectrum which helped in the identification of 335 showed that the imine proton ( 7.82 ppm ) of this "imine dimer" was interacting with the carbon atoms of the adjacent double bond ( 139.9 ppm and 141.5 ppm ), as well as to a methylene group at 25.2 ppm . The ( $(E)$-geometry of the double bond was confirmed using the NOESY spectrum which reported correlation between the protons at 2.48 ppm and 2.29 ppm , and another correlation between the imine proton at 7.82 ppm and the alkene proton at 5.84 ppm . Furthermore, the high resolution mass spectrometry data reported a clean and well defined $\mathrm{m} / \mathrm{z}$ value of 432.2744 consistent with the formation of a dimer 335 (Figure 32).

335

Figure 32- Correlations observed in HMBC spectrum of 335

A mechanism for the proposed formation of dimer 335 is shown in Scheme 134. Initially, (S,E)-ethyl 6-((1-(4-methoxyphenyl)ethyl)imino)hexanoate 334 is in equilibrium with its enamine tautomer, this enamine attacks a second equivalent of the imine 334 resulting in the formation of a dimer. The amino group is then protonated and undergoes an E2-elimination reaction to form imine-diene, thus releasing $\alpha$-methyl $p$ methoxybenzylamine.

Imine 334

Enamine

Dimer 335

Scheme 134- Proposed mechanism for formation of dimer 335

In summary, the chiral imino ester ( $S, E$-ethyl 6-((1-(4-methoxyphenyl)ethyl)imino) hexanoate 334 which was required as a starting material for the enolate-imine cyclisation reaction could be prepared and isolated. However, this chiral imino ester

334 proved to be very unstable, with dimerisation occuring readily to form a conjugated imine substrate 335. This fact would need to be taken into account when attempting subsequent cyclisation reactions.

### 3.4 Cispentacin Cyclisation and Optimisation

The intramolecular enolate-imine cyclisation methodology was then tested on (S,E)ethyl 6-((1-(4-methoxyphenyl)ethyl)imino)hexanoate 334. Initial reactions were carried out using the optimized conditions developed for benzocispentacin, with the exception that the reactions were carried out at room temperature. As seen previously, carrying out the cyclisation reaction at room temperature should result in a lower de, but was predicted to maximise the yield of 336, thus enabling confirmation that the enolateimine cyclisation was viable for this substrate. Using these initial conditions the protected $\beta$-lactam 336 was isolated in $44 \%$ yield and $92 \%$ de. The success of this reaction was determined by the presence of a diagnostic peak at 3.32 ppm in its ${ }^{1} \mathrm{H}$ NMR spectrum (seen in Appendix 5.1). Further to this, the de could be determined by comparing the two sets of quartets from the chiral auxiliary in the major and minor diastereomers; observed at 4.81 ppm for the major diastereomer, and at 4.70 ppm for the minor diastereomer fragments (Scheme 135).

Reagents \& Conditions: (i) NaHMDS (2.0 equiv), 15 -crown-5, THF, rt, 18 hrs.
Scheme 135- Initial cyclisation reaction of (S,E)-ethyl 6-((1-(4-methoxyphenyl)ethyl)imino)hexanoate 334

The next step was to optimise the reaction in order to increase the yield for formation of the $(S, 1 R, 2 S)$ - $\beta$-lactam 336. It was decided that due to its instability, it might be beneficial to form imine 334 in situ so that there would insufficient time for dimerisation to take place. In light of this, it was decided to carry out the imine formation in THF
rather than DCM, with molecular sieves added to remove any water produced during the imine formation.

As can be seen in Table 13, the length of time employed for formation of the imine in situ has a marked affect on the isolated yield of the $\beta$-lactam product 336 . To summarise, if imine 334 is isolated and left for any length of time it distinctly reduces the yield of $\beta$-lactam 336 (Table 13, Entries 1 and 2), which is to be expected as once the imine has dimerised it is no longer able to cyclise. Upon further inspection it became clear that imine formation was extremely rapid resulting in complete consumption of aldehyde 333 in less than 10 minutes. Therefore, as confirmed by Entry 4, imine 334 can be generated in situ and the cyclisation reaction carried out after 10 minutes via addition of NaHMDS and 15-crown-5 ether, which gave a much improved yield of $\beta$-lactam 336 of $64 \%$ and a good $92 \%$ de.

Table 13- Effect of imine 334 formation

|  | i) (S)-p-methoxy- $\alpha$-methylbenzylamine, THF, time <br> ii) NaHMDS (2.0 equiv.) 15-crown-5 |  |  |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
| Entry | Imine Formation | Isolated Yield (\%) | de (\%) |
| 1 | Stored-96 hours | 24 | 92 |
| 2 | Stored- 2 hours | 44 | 92 |
| 3 | Insitu - 45 mins | 63 | 92 |
| 4 | Insitu - 10 mins | 64 | 92 |

The second variable addressed was the temperature of the reaction, since previous results had shown that lower temperatures could improve the de of these types of cyclisation reactions. The cyclisation reaction was attempted at a range of lower temperatures in order to find the highest de, and in addition, the effect of refluxing the
reaction was also investigated. As predicted, lowering the temperature improved the de but at the same time resulted in a decrease in yield. In terms of stereoselectivity, carrying out the cyclisation reaction at $-45{ }^{\circ} \mathrm{C}$ and allowing it to warm to room temperature gave $N$-aryl- $\beta$-lactam 336 in $50 \%$ yield and $98 \%$ de (Table 14, Entry 3). Interestingly, when the reaction was attempted at reflux (entry 5) the yield was lower than at room temperature, but there was also a significant decrease in the diastereoselectivity, potentially due to competing formation of a thermodynamic ( $Z$ )enolate (Table 14, Entry 5).

Table 14- Effect of temperature on cyclisation reaction

| Entry | Temp ( $\left.{ }^{\circ} \mathrm{C}\right)$ | Isolated Yield <br> $(\%)$ | de (\%) |
| :---: | :---: | :---: | :---: |
| 1 | rt | 64 | 92 |
| 2 | 0 to rt | 57 | 94 |
| 4 | -45 to rt | 50 | 98 |
| 5 | -78 to rt | 26 | 99 |

A factor not previously investigated was the concentration of the cyclisation substrate, as prior experiments had previously been carried out at a standard concentration of 0.05 M . Consequently, the effect of increasing and decreasing the concentration of the substrate was examined since this had the potential to reduce potential oligomerisation pathways and minimize the amount of imine 325 produced from the unwanted enamine-imine dimerisation pathway. Increasing the substrate concentration to 0.5 M resulted in a much lower yield with the de only affected slightly. By increasing the substrate concentration the chance of competing intermolecular enolate-imine
oligomerisation reactions and/or imine dimerisation reactions increases, resulting in unwanted products of polymerisation or dimerisation. In comparison, decreasing the substrate concentration to 0.005 M also gave an extremely poor yield and lowered the de to $81 \%$. This reaction required a large amount of solvent and it was very difficult to uniformly maintain $-45^{\circ} \mathrm{C}$ throughout the reaction flask which may have resulted in the lower de. Therefore, our original concentration of 0.05 M for carrying out these cyclisation reactions was deemed optimal.

Table 15- Effect of the substrate concentration on cyclisation reaction

| Entry | Substrate Conc <br> $(\mathbf{M})$ | Isolated Yield <br> (\%) | de (\%) |
| :---: | :---: | :---: | :---: |
| 1 | 0.05 | 50 | 98 |
| 2 | 0.5 | 15 | 99 |
| 3 | 0.005 | 4 | 81 |

In order to obtain the highest yield the reaction had previously been left overnight for 18 hours, but to improve the efficiency of the overall synthesis the optimum reaction time was explored. As can be seen from Entry 2 the cyclisation reaction gave identical results after 6 hours to those obtained after 18 hours - giving a slightly higher yield and a $99 \%$ de. However, if the reaction time was decreased further to only 1 hour the cyclisation reaction was found not to have proceeded to completion and therefore the yield was lower.

Table 16- Effect of reaction time on the cyclisation reaction

Entry $\quad$ Time (hrs) | Isolated Yield |
| :---: |
| $(\%)$ |$\quad$ de (\%)

| 1 | 18 | 50 | 98 |
| :--- | :--- | :--- | :--- |
| 2 | 6 | 52 | 99 |
| 3 | 1 | 38 | 99 |

The highest yield of $\beta$-lactam 336 observed in the optimization process was $64 \%$, but this posed the question of where the rest of the starting material 334 was going? When the crude product was isolated after work up (using $\mathrm{NH}_{4} \mathrm{Cl}$ and water) only the $\beta$-lactam 336 was observed in the ${ }^{1} \mathrm{H}$ NMR spectrum. Occasionally a small amount of starting material could be seen in the ${ }^{1} \mathrm{H}$ NMR depending on the conditions. In contrast to the benzocispentacin substrates (Scheme 101), none of the corresponding $\beta$-amino esters were ever observed.

In order to determine what was happening to the rest of the starting material the reaction was monitored directly by LCMS. A sample from the reaction mixture was taken at 1 and 6 hours to identify what components were present in solution. The two main components in the LCMS traces had an m/z value of 246 and 135, corresponding to the $\beta$-lactam 336 and a fragment of free amine 337 respectively (Figure 33). This suggests that either the imine 334 is unstable and adventitious water can convert back into its parent aldehyde and amine, or that excess base may be causing E2-elimination of the chiral auxiliary fragment of the $\beta$-lactam product. Furthermore, the high resolution mass spectrometry data for the dimer 325, also revealed peaks at 135.08 , supporting the theory that the imine 334 was dimerising during the reaction.

337
Formula: $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{O}$
Exact Mass: 134.07
$[\mathrm{M}+\mathrm{H}]^{+}: 135.08$

Figure 33- Fragments observed in LCMS analysis

Therefore, based upon the data collected, the optimal reaction conditions required the imine to be generated in situ at room temperature for 10 minutes, the reaction then cooled to $-45{ }^{\circ} \mathrm{C}$, before NaHMDS and 15 -crown- 5 were added to initiate enolate cyclisation. This enabled ethyl-6-oxohexanoate 333 to be converted into the ( $S, \alpha R, \beta S$ )-$\beta$-lactam of cispentacin in $52 \%$ isolated yield after purification by chromatography.

Reagents \& Conditions: (i) (S)- $\alpha$-Methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}, \mathrm{THF}$, rt, 10 mins; (ii) NaHMDS (2.0 equiv.), $15-$ Crown- $5, \mathrm{THF},-45^{\circ} \mathrm{C}$ to rt, 6 hrs .

Scheme 136-Synthesis of (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-6-azabicyclo[3.2.0]heptan-7-one

### 3.5 Synthesis of Cispentacin and Transpentacin Ethyl Ester

Having developed a successful synthesis of (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)6 -azabicyclo[3.2.0]heptan-7-one 336, the next stage was to deprotect it to its corresponding $\beta$-amino acid and $\beta$-amino ester for use as foldamer monomers. The first step was removal of the chiral auxiliary using the previously described CAN mediated conditions. ${ }^{149}$ The deprotected $\beta$-lactam (1R,5S)-6-azabicyclo[3.2.0]heptan-7-one 338 was isolated as a white solid in $71 \%$ yield (Scheme 137). The configuration of the $(S, \alpha R, \beta S)$ - $\beta$-lactam 338 was confirmed by comparing its specific rotation value of
$[a]_{D}^{17}-33.3$ (c 0.87, $\mathrm{CHCl}_{3}$ ) to the reported literature value of $[a]_{D}^{25}-35.9$ (c 0.5, $\left.\mathrm{CHCl}_{3}\right) .{ }^{190}$

Reagents \& Conditions: (i) CAN (4.0 equiv), MeCN- $\mathrm{H}_{2} \mathrm{O}$ (1:1), rt, 4 hrs
Scheme 137- Deprotection of (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-6-azabicyclo[3.2.0]heptan-7one 338

The hydrochloride salt of the corresponding $\beta$-amino acid 300a (cispentacin) was then prepared by acidic hydrolysis of ( $1 R, 5 S$ )-6-azabicyclo[3.2.0]heptan-7-one 338 in $97 \%$ yield (Scheme 138). A specific rotation of $[\alpha]_{\mathrm{D}}^{19}-5.0$ (c 0.5, $\mathrm{H}_{2} \mathrm{O}$ ) was obtained for $\beta$ amino acid 300a, which compares favourably with the literature value of $[a]_{D}^{25}-5.1$ (c $\left.0.5, \mathrm{H}_{2} \mathrm{O}\right) .{ }^{190}$

Reagents \& Conditions: (i) $18 \% \mathrm{HCl}$, reflux, 3 hrs
Scheme 138- Synthesis of (1R,2S)-2-aminocyclopentanecarboxylic acid hydrochloride 300a

Alternatively, the hydrochloride salt of cis- $\beta$-amino ethyl ester 339 could also be synthesised by ring opening of the $\beta$-lactam 338 in the presence of ethanol in $96 \%$ yield (Scheme 139). The (1R,2S)-2-aminocyclopentanecarboxylic acid ethyl ester 339 has been employed for the synthesis of a promising polymerase inhibitor. ${ }^{199}$ The literature method requires recrystallisation of the selected enantiomer resulting in a low overall yield of $29 \%$, ${ }^{199}$ compared with the $35 \%$ overall yield using our methodology.

Reagents \& Conditions: $\mathrm{HCl}\left(1 \mathrm{M}\right.$ in $\left.\mathrm{Et}_{2} \mathrm{O}\right)$, EtOH, reflux, 3 hrs
Scheme 139- Synthesis of (1R,2S)-ethyl 2-aminocyclopentanecarboxylate hydrochloride 339

Another target for our methodology was the synthesis of transpentacin. Gellman et al. have reported that transpentacin is one of the most competent subunits for the formation of helical foldamers. ${ }^{105}$ In 2001, they reported that reductive amination of a $\beta$ ketoester could be used to form the ( $\alpha S, \beta S$ ) $\beta$-amino ester salt 341 using ( $S$ )- $\alpha$ methylbenzylamine in a $29 \%$ overall yield. ${ }^{200}$ Following this, the ( $\alpha S, \beta S$ ) - $\beta$-amino ester salt 341 was subjected to reductive removal of the auxiliary, saponification and protection with Fmoc. ${ }^{200}$ This produced the trans-Fmoc-ACPC residue 342 in an $85 \%$ yield which was a useful building block for the solid phase synthesis of $\beta$-peptides (Scheme 140). ${ }^{200}$

Reagents \& Conditions: (i) (S)- $\alpha$-Methylbenzylamine; (ii) $\mathrm{NaBH}_{3} \mathrm{CN}$; (iii) HCl ; (iv) Recrystallisation; (v) LiOH. $\mathrm{H}_{2} \mathrm{O}$; (vi) $\mathrm{H}_{2}$, $10 \% \mathrm{Pd} / \mathrm{C}$; (vii) Fmoc-OSu

Scheme 140-Synthesis of trans-Fmoc-ACPC 342 ${ }^{200}$

Therefore, it was decided that our intramolecular enolate-imine cyclisation protocol would be expanded in an attempt to produce a more efficient synthesis of a precursor to the trans-Fmoc-ACPC residue 342. The synthesis was modified to use (S)- $\alpha$ methylbenzylamine as a chiral auxiliary to allow for its subsequent removal by hydrogenation as shown in Scheme 141.

The required imine was generated in situ, which was followed by the enolate cyclisation step to give the $\beta$-lactam 343 in $53 \%$ yield and $99 \%$ de. This $\beta$-lactam 343 was subsequently ring opened to form the cis- $\beta$-amino ester salt 344 in $95 \%$ yield. The final step involved epimerization of the ester group to give ( $\alpha S, \beta S$ ) - $\beta$-amino ester 345, giving diastereotopic protons that correlated to those reported by Gellman et al., ${ }^{200}$ this produced the (1S,2S)-ethyl 2-(((S)-1-phenylethyl)amino)cyclopentanecarboxylate 345 in an overall yield of $28 \%$, with this derivative having previously been converted into the Fmoc-derivative 342. ${ }^{200}$

Reagents \& Conditions: (i) (S)- $\alpha$-Methylbenzylamine, THF, rt, 10 mins; (ii) NaHMDS, 15-Crown-5, THF, $-45^{\circ} \mathrm{C}$ to rt, 6 hrs ; (iii) $\mathrm{HCl}, \mathrm{EtOH}$, reflux, 3 hrs ; (iv) $\mathrm{KO}^{\mathrm{t}} \mathrm{Bu}, \mathrm{EtOH}$, reflux, 4 hrs

Scheme 141-Synthesis of (1S,2S)-ethyl 2-(((S)-1-phenylethyl)amino)cyclopentanecarboxylate

These results provide evidence that (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-6-azabicyclo[3.2.0]heptan-7-one 345 can be rapidly prepared using our intramolecular enolate-imine cyclisation methodology, thus enabling access to a range of useful scaffolds for $\beta$-peptide foldamer formation.

### 3.6 Attempted Synthesis of $\alpha$-Methyl-Substituted Cispentacin Synthesis

Another desirable building block for $\beta$-peptide formation would be (1R,2S)-2-amino-1methylcyclopentanecarboxylic acid 349 which contains a quaternary $\alpha$-stereocentre. A search of the literature showed that the synthesis of the racemate of 2-amino-1methylcyclopentanecarboxylic acid was reported in 1983, based on the selective reduction of an oxime (Scheme 142). ${ }^{201}$ Therefore our methodology could potentially afford the first asymmetric synthesis of this $\alpha, \alpha$-disubstituted $\beta$-amino acid 349.

Reagents \& Conditions: (i) a) KOH , ethanol; b) methyl iodide, toluene, 6 hrs, reflux; (ii) $\mathrm{HONH}_{2} \cdot \mathrm{HCl}$, KOH , ethanol; (iii) NaOH , ethanol, lhr, reflux

Scheme 142- Racemic synthesis of $\boldsymbol{\beta}$-amino acid target containing a quaternary $\alpha$-centre ${ }^{201}$

The cheap and readily available ethyl 6-hydroxyhexanoate 332 was chosen as the starting material and in its alcohol functionality would need to be protected as a silyl group. Consequently, treatment of 332 with TES-triflate and 2,6-lutidine in DCM was used to form the TES-protected alcohol 350 in $77 \%$ yield. In order to introduce the methyl substituent, the ester enolate was generated using NaHMDS in THF at $-78^{\circ} \mathrm{C}$, followed by alkylation with methyl iodide to afford (rac)-ethyl ester 351 in $65 \%$ yield (Scheme 143).

Reagents \& Conditions: (i) TES-triflate, 2,6-lutidine, DCM; (ii) NaHMDS, methyl iodide, THF, $-78^{\circ} \mathrm{C}$
Scheme 143- $\alpha$-Alkylation of ethyl 6-hydroxyhexanoate

The triethylsilyl group of $\mathbf{3 5 1}$ was then removed using TBAF to give ethyl 6-hydroxy-2methylhexanoate 352 in $67 \%$ yield, whose alcohol group was then oxidized via treatment with PCC in DCM to give ethyl 2-methyl-6-oxohexanoate 353 in $60 \%$ yield (Scheme 144).

Reagents \& Conditions: (i) TBAF, THF; (ii) PCC, DCM
Scheme 144- Synthesis of ethyl 2-methyl-6-oxohexanoate 353

Due to the previously reported problem with the dimerisation of imine 334 it was decided to generate ethyl 6-(((S)-1-(4-methoxyphenyl)ethyl)imino)-2-methylhexanoate 354 in situ, with the progress of the reaction being monitored by TLC to ensure complete imine formation. Imine formation was complete after 1 hour and the cyclisation reaction was attempted via addition of NaHMDS and 15-crown-5 at room temperature. Unfortunately after 18 hours analysis revealed no presence of any $\beta$ lactam 355 in the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude products. The reaction was repeated numerous times to no avail; therefore it was proposed that the introduction of the methyl substituent must affect the orientaton of the enolate so that it is unable to cyclise effectively onto its imino functionality (Scheme 145).

Reagents \& Conditions: (i) (S)- $\alpha$-Methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}$, THF 1 hr ; (iv) NaHMDS, 15-crown-5, THF, rt, 18 hrs

Scheme 145- Attempted cyclisation of 354 to form (1R,2S)-2-amino-1-methylcyclopentanecarboxylic acid 355

### 3.7 Synthesis of Cishexacin

It was decided that the next step in the project was to attempt to increase the size of the aliphatic chain in order to produce cishexacin 360 using our enolate-imine cyclisation reaction. Trans-2-aminocyclohexanecarboxylic acid (ACHC) has been widely reported as a monomer for incorporation into $\beta$-peptides that display 14 helical conformations. ${ }^{202}$ Therefore, an efficient route for the asymmetric synthesis of the analogous cishexacin 360 (Figure 30) would prove invaluable. Once an improved route to cishexacin 360 had been established then the corresponding $\beta$-amino ester could be epimerized to give trans-ACHC. As can be seen in Scheme 146, the first step was the Baeyer-Villiger oxidation of cycloheptanone 356 with potassium persulphate and subsequent ring opening using ethanol to afford ethyl 7-hydroxyheptanoate 357 in a $74 \%$ yield. ${ }^{203}$ This was followed by a successful PCC oxidation to furnish the corresponding aldehyde 358 in $98 \%$ yield (Scheme 146). During the formation of imine 359, it was found that after two hours ( $S, E$ )-ethyl 7-((1-(4-methoxyphenyl)ethyl)imino)heptanoate 359 had started to dimerise due to emergence of a triplet at 5.79 ppm and a singlet at 7.78 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum. In light of this, it was decided that the imine would be prepared in situ, before cyclisation of its enolate was attempted, as previously carried out for cispentacin.

Once the imine 359 had been formed in situ the initial cyclisation conditions of NaHMDS and 15-crown-5 at room temperature were applied, however no $\beta$-lactam 360 was observed in the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude reaction. Despite several attempts the enolate-imine cyclisation of this substrate was unsuccessful, only affording fragments of recovered starting material fragments. Therefore, it appears that the extra methylene group in the aliphatic chain prevents 6 -endo-trig cyclisation of the enolate from occurring. In comparison, the synthesis of benzocishexacin 292 was successful, but this might be due to the aryl ring predisposing the derived enolate to cyclise onto its imino functionality.

Reagents \& Conditions: (i) $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}, \mathrm{H}_{2} \mathrm{SO}_{4}$, ethanol, rt, 12 hrs ; (ii) PCC, DCM; (iii) (S)- $\alpha$-methyl-pmethoxybenzylamine, $\mathrm{MgSO}_{4}, \mathrm{DCM}, 2 \mathrm{hrs}$; (iv) NaHMDS (2.0 equiv.), 15-crown-5, THF, rt, 6 hrs

Scheme 146- Attempted synthesis of (1R,6S)-7-((S)-1-(4-methoxyphenyl)ethyl)-7-azabicyclo[4.2.0]octan-8-one 360

### 3.8 Gem-Dimethyl Substituted Cispentacin Synthesis

One of the first type of cispentacin analogues prepared was (1R,2S)-2-amino-4,4dimethylcyclopentanecarboxylic acid, more commonly referred to as dm-ACPC. ${ }^{204}$ To date, a review of the literature suggests there are only a few examples of trans-4,4disubstitued ACPC residues having been reported (Figure 34).

361

362

363

Figure 34- Previously synthesised 4,4-disubstituted-ACPC monomers ${ }^{\mathbf{2 0 5}}$

The trans-dm-ACPC residue has recently been incorporated into $\beta$-peptides resulting in a 12-helical scaffold, ${ }^{204}$ that contains hydrogen bond orientations comparable to those seen in $\alpha$-peptide helicies. ${ }^{204}$ At present there is currently only one reported stereoselective methodology for the synthesis of dm-ACPC 368, which is shown in Scheme 147.

19\% Yield

Reagents \& Conditions: (i) $\mathrm{KMnO}_{4}, \mathrm{NaOH}, \mathrm{H}_{2} \mathrm{O}, \mathrm{rt}, 40 \mathrm{hrs}$; (ii) MeOH, benzene, $\mathrm{H}_{2} \mathrm{SO}_{4}$; (iii) $\mathrm{KO}^{t} \mathrm{Bu}$, THF; (iv) (R)- $\alpha$-methylbenzylamine, $\mathrm{AcOH}, \mathrm{MeOH}$; (v) $\mathrm{NaBH}_{3} \mathrm{CN}$

Scheme 147- Asymmetric synthesis of $\boldsymbol{d m}$-ACPC $\mathbf{3 6 8}{ }^{205}$

This current method for the synthesis of dm-ACPC 368 requires 5 steps, is lengthy ( $\sim 105$ hours) and very low yielding ( $\sim 9 \%$ overall). ${ }^{205}$ Therefore, in an effort to improve the existing route, our intramolecular enolate-imine methodology was employed in order to provide an alternative synthesis of $d m$-ACPC.

It was first necessary to synthesise the starting cyclisation substrate from 4,4dimethylcyclohexanone 364. A Baeyer Villiger reaction had previously been employed to generate ethyl 7-hydroxyheptanoate 356 from cycloheptanone 357 and was applied to the 4,4-dimethylcyclohexanone 364 generating alcohol 369 (Scheme 148). ${ }^{203}$

Reagents \& Conditions: (i) $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}, \mathrm{H}_{2} \mathrm{SO}_{4}$, Ethanol, rt, 12 hrs
Scheme 148- Synthesis of ethyl 6-hydroxy-4,4-dimethylhexanoate 369

The corresponding aldehyde 370 was prepared via oxidation with PCC in $87 \%$ yield, followed by formation of the imine 371 in $87 \%$ yield. Imine 371 was left for 72 hours, with ${ }^{1} \mathrm{H}$ NMR analysis revealing it was remarkably stable, with no signs of any new imine products from the enamine-imine dimerisation pathway being formed (Scheme 149).

Reagents \& Conditions:(i) PCC, DCM; (ii) (S)- $\alpha$-Methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}, \mathrm{DCM}, 2 \mathrm{hrs}$
Scheme 149- Synthesis of (S,E)-Ethyl 6-((1-(4-methoxyphenyl)ethyl)imino)-4,4-dimethylhexanoate

Therefore, with the chiral imino ester 371 in hand, the intramolecular enolate-imine cyclisation reaction was attempted in order to generate the protected $\beta$-lactam 372. As with all previous reactions, the cyclisation reaction of 371 was first undertaken at room temperature to maximize the chances of the reaction being successful. It was found that (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-3,3-dimethyl-6-azabicyclo[3.2.0]heptan-7-one 372 was produced in high $78 \%$ yield, but also in $99 \%$ de. This was dissimilar to the optimum methodology for previous substrates which required the reaction to be cooled to $-45^{\circ} \mathrm{C}$ and warmed to room temperature to obtain a very high de (Scheme 150).

Reagents \& Conditions: (i) NaHMDS (2.0 equiv), 15-Crown-5, THF, rt, 6 hrs
Scheme 150- Cyclisation of imine 371 to afford $N$-aryl- $\beta$-lactam 372

The yield observed for the gem-dimethyl $\beta$-lactam 372 was much higher than the yield obtained for cispentacin 336, which was attributed to the Thorpe-Ingold effect helping cyclisation to occur. In 1915, it was proposed that the introduction of a gem-dimethyl group resulted in compression of the internal angle of the nucleophile which favours intramolecular cyclisation reactions. ${ }^{206}$ The literature contains many examples where the Thorpe-Ingold effect has had a significant effect on the success of cyclisation reactions. Therefore, it is proposed that the yield of the intramolecular enolate-imine cyclisation is improved due to geminal methyl substituents stabilizing the reactive conformer that leads to enolate cyclisation, and/or due to the fact that the parent imine does not undergo dimerisation.

The removal of the chiral auxiliary fragment from 372 was then carried out using the previously devised CAN methodology (Scheme 151).

Reagents \& Conditions: (i) CAN (4.0 equiv.), MeCN $-\mathrm{H}_{2} \mathrm{O}$ (1:1), rt, 4 hrs
Scheme 151- Deprotection of $\boldsymbol{\beta}$-lactam 372

The $\beta$-lactam ( $1 R, 5 S$ )-3,3-dimethyl-6-azabicyclo[3.2.0]heptan-7-one 373 was purified by recrystallisation from dichloromethane and hexane to afford a white solid in $87 \%$
yield, which gave the X-ray crystallographic structure shown in Figure 35, clearly revealing the bicylic $\beta$-lactam ring structure.

Figure 35- X-ray crystal structure of (1R,5S)-3,3-dimethyl-6-azabicyclo[3.2.0]heptan-7-one 373 with ellipsoids drawn at the $\mathbf{5 0 \%}$ probability level

In addition, the substituted $\beta$-lactam 373 could be ring opened using acidic conditions in the presence of ethanol to synthesise ( $1 R, 2 S$ )-ethyl 2-amino-4,4-dimethylcyclopentane carboxylate hydrochloride 374 in $90 \%$ yield with a specific rotation value of $[\alpha]_{D}{ }^{17}-2$ (c 1.01, $\mathrm{CHCl}_{3}$ ) (Scheme 152).

Reagents \& Conditions: (i) $\mathrm{HCl}\left(1 \mathrm{M}\right.$ in $\left.\mathrm{Et}_{2} \mathrm{O}\right), \mathrm{EtOH}$, reflux, 3 hrs
Scheme 152- Synthesis of $\boldsymbol{\beta}$-amino ester 374

Therefore, our enolate-imine cyclisation methodology can be used to rapidly prepare $\beta$ amino ester 374 in an overall yield of $37 \%$ in around 25 hours. Also, unlike previous methodologies chromatographic purification was not required to separate any mixtures of diastereomers.

### 3.9 Cyclisation of Acetal Substituted Cispentacin

In light of the success of the cyclisation reaction to form $\beta$-lactam 373 that contains a gem-dimethyl substituent it was decided to introduce an acetonide group into the same position. Firstly, it was hoped that the acetonide functionality would function in a similar manner to the gem-dimethyl substituent 373, giving high yields and an excellent de for its cyclisation reaction due to the Thorpe-Ingold effect. Also, once enolate cyclisation had taken place, the acetonide group could be removed under mild conditions allowing access to the corresponding ketone (Scheme 153). The ability to generate a $\beta$-lactam with a ketone functional group would be highly advantageous as this could potentially allow introduction of a plethora of highly valuable functional groups.

Scheme 153- Retrosynthesis for acetal substituted $\beta$-lactam

An alternative set of conditions for the Baeyer-Villiger and ring opening reactions needed to be established that were more basic and compatible with the presence of the acid sensitive acetal protecting group. ${ }^{207}$ The use of mCPBA as an oxidant proved successful and the seven-membered lactone 376 was obtained in an $80 \%$ yield. The ring opening reaction of the lactone 376 was carried out under basic conditions using $\mathrm{K}_{2} \mathrm{CO}_{3}$ and ethanol to furnish ethyl 3-(2-(2-hydroxyethyl)-1,3-dioxolan-2-yl)propanoate 377 in an $87 \%$ yield (Scheme 154).

Reagents \& Conditions: (i) mCPBA, DCM; (ii) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{EtOH}$

## Scheme 154- Synthesis of ethyl 3-(2-(2-hydroxyethyl)-1,3-dioxolan-2-yl)propanoate 377

From this point, our established methodology was applied involving oxidation of the alcohol 377 using PCC, followed by subsequent imine formation to form 379 in $98 \%$ yield. Once again, stability studies revealed that this imine was stable over a period of 48 hours (Scheme 155).

Reagents \& Conditions: (i) PCC, DCM; (ii) (S)- $\alpha$-Methyl-p-methoxybenzylamine, $\mathrm{MgSO}_{4}$, THF, 2 hrs
Scheme 155- Synthesis of (S,E)-Ethyl 3-(2-(2-((1-(4-methoxyphenyl)ethyl)imino)ethyl)-1,3-dioxolan-
2-yl)propanoate 379
With the imine in hand, the intramolecular enolate-imine cyclisation was attempted both at room temperature, and $-45{ }^{\circ} \mathrm{C}$ to room temperature, to afford the desired acetalprotected $\beta$-lactam 380. A good $77 \%$ yield of the $\beta$-lactam 380 was obtained at room temperature in $86 \%$ de. The optimum conditions of $-45{ }^{\circ} \mathrm{C}$ to room temperature were then applied and the yield again decreases slightly to $59 \%$ but this generated an excellent diastereoselectivity of $98 \%$ de (Table 17, Entry 2). In comparison with the gem-dimethyl cyclisation, it can be seen that the de obtained was not as high as observed for the gem-dimethyl $\beta$-lactam 380 at room temperature. However, when the temperature was reduced to $-45^{\circ} \mathrm{C}$ the de was significantly improved, which was more in line with the results that were observed for cispentacin 336.

Table 17- Attempted intramolecular enolate-imine cyclisation on imine 379

The removal of the chiral auxiliary proved unsuccessful, with only fragments of the starting material being observed in ${ }^{1} \mathrm{H}$ NMR spectra of the crude products.

Reagents \& Conditions: (i) CAN (4.0 equiv.), MeCN $-\mathrm{H}_{2} \mathrm{O}$ (1:1), rt, 4 hrs
Scheme 156- Removal of chiral auxiliary on $\beta$-lactam 380

There is literature precedent for the use of CAN as a mild deprotection reagent for the removal of acetonide groups, which suggested that two competing reactions might be taking place. ${ }^{208}$ As such, it was decided to selectively remove the acetal first, to give the ketone functionality, before removal of the chiral auxiliary using an alternative methodology. The use of iodine as a mild deprotection reagent enabled the acetal protecting group to be selectively removed while retaining the $\beta$-lactam ring, yielding $\beta$ lactam 382 in 79 \% yield (Scheme 157). ${ }^{209}$

Reagents \& Conditions: (i) Iodine, acetone, rt, 30 mins
Scheme 157-Synthesis of (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-6-azabicyclo[3.2.0]heptane-3,7-
dione 382

The removal of the auxiliary using CAN was attempted on $\beta$-lactam 382, again this proved unsuccessful with the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude product showing cleaved 1-(4-methoxyphenyl)ethanone but the isolation of any $\beta$-lactam was unsuccessful. The problematic removal of the auxiliary suggests that for the synthesis of both $\beta$-lactam 381 and $\beta$-lactam 382 that an alternative auxiliary would be preferred such as ( $S$ )- $\alpha$ methylbenzylamine that could be removed using a hydrogenolytic strategy. Previously, $(S)$ - $\alpha$-methylbenzylamine was avoided due to the symmetry within the tricyclic $\beta$-lactam structures, in these bicyclic $\beta$-lactams there is no such symmetry (Scheme 158).

Reagents \& Conditions: (i) $H_{2}, P d / C, r t, 24$ hrs
Scheme 158- Proposed deprotection of $\beta$-lactam 383 containing an ( $S$ )- $\alpha$-methylbenzylamine auxiliary

In conclusion, it has been demonstrated that our enolate-imine cyclisation methodology can also be used to rapidly prepare $\beta$-lactams 381 and 382 in high yield and excellent de. The removal of the current chiral auxiliary has proved unsuccessful; therefore further work is required in order to successfully generate the free $\beta$-lactams of 381 and 382.

### 3.10 Future Work - Enantioselective Cyclisation

The final work into the intramolecular enolate-imine cyclisation for the synthesis of cispenatcin involved an attempt to control the facial selectivity of the enolate-imine cyclisation reaction in an enantioselective manner. This involved employing an asymmetric Lewis acid catalyst, with the aim of generating cis $\beta$-lactams in high ee. It was decided to employ Tomioka's methodology that had utilised chiral bisoxazoline (BOX) ligands 154 (Figure 36) for the asymmetric synthesis of $\beta$-lactams using an intermolecular enolate-imine condensation. ${ }^{81}$

154

Figure 36- Isopropyl chiral bisoxazoline ligand

Both high yields and good ee's for $\beta$-lactams have been reported using both catalytic and stoichiometric amounts of the copper BOX ligands. ${ }^{83}$ In particular, a chiral BOX ligand was shown to mediate an intermolecular cyclisation reaction between lithium ester enolates and a benzylic imine, to afford the corresponding $\beta$-lactam in $70 \%$ ee (Scheme 159).

Reagents \& Conditions: (i) i-Pr-BOX ligand 154(0.2 equiv.), LDA, DCM, $-20{ }^{\circ} \mathrm{C}$
Scheme 159- Asymmetric Mannich reaction using (R)-iPr-BOX ${ }^{83}$

In order to apply this enantioselective methodology for the asymmetric synthesis of a cispentacin derivative, an achiral imino-ester substrate without a chiral auxiliary group was synthesised. Due to the instability of such imine substrates, the imine 387 was generated in situ and an enolate-imine cyclisation reaction carried out, to afford the racemic $\beta$-lactam 388 in an unoptimised $30 \%$ yield (Scheme 160).

Reagents \& Conditions: (i) Benzylamine, mol. sieves, THF, 15 mins; (ii) NaHMDS, rt, 18 hrs.
Scheme 160-Synthesis of racemic cispentacin $\beta$-lactam 388

This allowed appropriate chiral HPLC conditions (AS-3, 90\% iso-hexane, 10\% ethanol) to be developed that gave well resolved peaks for its enantiomers.

Tomioka's conditions were then applied to the cyclisation of imino ester 387 whose enolate was generated in the presence of 0.2 equivalents of the isopropyl-BOX ligand 154. This reaction was analysed by ${ }^{1} \mathrm{H}$ NMR and showed only the presence of starting material, with no $\beta$-lactam having been formed. Therefore, the original cyclisation conditions using NaHMDS in THF at $-45{ }^{\circ} \mathrm{C}$ to room temperature were applied with the addition of a stoichiometric amount of the chiral BOX ligand 154, which produced the $\beta$ lactam 388, albeit in a poor 6\% yield, which was shown to be racemic by chiral HPLC analysis. The main problems with using this methodology is that when the reaction is carried out in an intermolecular fashion the lithium enolate is first generated, and then the chiral BOX ligand is added, which allows for its complexation to the enolate before the addition of the imine. Unfortunately, for the intramolecular reaction the enolate is always generated in the presence of the imine, so cyclisation can potentially occur before the BOX ligand can have any control over the cyclisation reaction. Enantioselective control of both direct and indirect Mannich reactions has been the subject of several major reviews ${ }^{210-211}$ and therefore there are many more approaches that could be taken in this area of work. For example, the enantioselective reaction could be potentially attempted using a silyl ketene acetal as shown in Scheme 161.

Reagents \& Conditions: (i) TMS-Cl, LDA, THF, $-78{ }^{\circ} \mathrm{C}$
Scheme 161- Potential synthesis of silyl ketene acetal for an indirect Mannich reaction

### 3.11 Conclusion

In conclusion, our previously developed intramolecular enolate-imine cyclisation reaction has been applied to the asymmetric synthesis of four acyclic $\beta$-lactam analogues. An asymmetric synthesis of cispentacin has been developed that also enables the rapid access to the highly desirable transpentacin. An improved methodology for the synthesis of (1R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-3,3-dimethyl-6-azabicyclo[3.2.0]heptan-7-one 372 has been developed, $g$ which is not only quicker but also higher yielding than previous syntheses. Furthermore, the limitations of this methodology have been established by unsuccessfully attempting the cyclisations of acyclic enolates of 6 -membered and $\alpha$-methyl substituted $\omega$-imino-esters. Finally, unsuccessful approaches towards an enantioselective intramolecular enolate-imine cyclisation reaction were attempted in order to synthesise a range of $\beta$-amino acids enantiomers without the need for a chiral auxiliary.

## 4 Experimental

## General Experimental Details

All reactions were performed under a nitrogen atmosphere in oven-dried apparatus, unless otherwise stated. Anhydrous acetonitrile, dichloromethane and tetrahydrofuran were obtained from an Innovative Technology Inc. PS-400-7 solvent purification system. Petrol refers to the fraction of petroleum ether boiling at $40-60{ }^{\circ} \mathrm{C}$. All other commercially available compounds were used as obtained from the chemical suppliers. Analytical thin layer chromatography was performed using commercially available aluminium backed plates coated with Merck G/UV254 neutral silica. Plates were visualised under UV light (at 254 nm ) or by staining with phosphomolybdic acid followed by heating. Flash chromatography was performed using chromatography grade silica, 60 A particle size 35-70 microns from Fisher Scientific. ${ }^{1}$ H NMR spectra were recorded at $500 \mathrm{MHz}, 400 \mathrm{MHz}$ or 300 MHz and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ spectra were recorded at 125 MHz or 75 MHz on a Brüker Avance 500, 400 or 300 spectrometer respectively. Chemical shifts, $\delta$, are quoted in parts per million and are referenced to the residual solvent peak. The following abbreviations are used: s, singlet; d, doublet; t, triplet; q, quartet; dd, doublet of doublets; dt, doublet of triplets; hep., heptet; m, multiplet; pent., pentet; td, triplet of doublets; app., apparent and br., broad. Coupling constants, J, are quoted to the nearest 0.5 Hz . High resolution mass spectra were recorded on a Brüker Daltonics microTOF spectrometer with an electrospray source and external calibration. Masses were recorded in positive electrospray ionisation mode and were introduced by flow injection. Masses are accurate to 5 ppm and data was processed using DataAnalysis software from Brüker Daltonics. Infrared spectra were recorded on a Perkin Elmer Spectrum 100 FT-IR spectrometer, using a Universal ATR accessory for sampling, with only selected absorbances quoted as $v$ in $\mathrm{cm}^{-1}$. Optical rotations were recorded on an Optical Activity Ltd AA-10 automatic polarimeter with a path length of 1 dm ; concentrations (c) are quoted in $\mathrm{g} / 100 \mathrm{~mL}$. All capillary melting points were measured using Stuart digital SMP10 melting point apparatus with 1 degree resolution. X-ray data was collected at 150K on a Nonius KappaCCD area detector diffractometer using Mo-K $\alpha$ radiation ( $\lambda=0.71073 \AA$ ). All structures were solved by direct methods and refined on all F2 data using SHELXL-97 suite of programs, with hydrogen atoms included in idealised positions and refined using the riding model.

### 4.1 General Procedures

### 4.1.1 General Procedure 1: Acetal Formation ${ }^{212}$

To a stirred substituted 2-bromobenzadehyde ( 1.0 equiv.) in toluene ( 50 mL ), 1,3propanediol ( 1.5 equiv.) and $p$-toluene sulphonic acid (PTSA) ( 0.1 equiv.) were added and the resulting solution was heated at reflux under Dean-Stark conditions for 3 hours. After cooling to room temperature, the reaction mixture was washed with water, the organic extract dried using $\mathrm{MgSO}_{4}$ and the solvent evaporated under reduced pressure. The crude compounds were purified by recrystallisation using a suitable solvent system.

### 4.1.2 General Procedure 2: Heck Reaction of Protected 2-Bromobenzaldehydes ${ }^{137}$

To a solution of substituted 2-(2-bromophenyl)-1,3-dioxolan (1.0 equiv.) in acetonitrile, palladium(II) acetate ( 0.05 equiv.) and tri(o-tolyl)phosphine ( 0.10 equiv.) were added. Diisopropylethylamine ( 3.0 equiv.) and the appropriate acrylate ( 1.0 equiv.) were added and the mixture was heated at reflux for 24 hours. After cooling to room temperature, the reaction was diluted with water ( 50 mL ) and the aqueous layer extracted with toluene ( $2 \times 50 \mathrm{~mL}$ ). The combined organic extracts were washed with water ( $2 \times 50$ mL ) and brine ( 30 mL ) and then dried over $\mathrm{MgSO}_{4}$. The mixture was filtered through a plug of Celite $®$ and then the solvent was removed under reduced pressure. Crude compounds were purified by flash column chromatography.

### 4.1.3 General Procedure 3: Chemoselective Conjugate Reduction of Esters ${ }^{138}$

Substituted ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)propanoates (2.0 equiv.) were stirred in ethanol ( 10 mL ) for 30 minutes prior to the addition of cobalt(II) chloride hexahydrate ( 0.02 equiv.). The solution was then cooled to $0^{\circ} \mathrm{C}$ and sodium borohydride ( 4.0 equiv.) was added. The solution was allowed to warm to room temperature and stirred for up to 48 hours. The reaction was quenched with water ( 50 mL ) and diluted with ethyl acetate $(30 \mathrm{~mL})$. The organic layer was separated, washed with brine $(50 \mathrm{~mL})$, dried with $\mathrm{MgSO}_{4}$ and the solvent evaporated under reduced pressure. Crude compounds were purified by flash column chromatography.

### 4.1.4 General Procedure 4: Acetal Deprotection

Substituted ethyl-3-(2-formylphenyl)propanoates were added to a solution of acetic acid: water ( $7 \mathrm{~mL}: 3 \mathrm{~mL}$ ) and left to stir open to the air overnight. The residue was
partitioned between water ( 50 mL ) and diethyl ether ( 50 mL ). The aqueous layer was extracted with diethyl ether ( $2 \times 30 \mathrm{~mL}$ ) and the organic layers were combined and washed with a saturated solution of $\mathrm{NaHCO}_{3}(2 \times 30 \mathrm{~mL})$ and then brine $(30 \mathrm{~mL})$. The organics were dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure to yield analytically pure products.

### 4.1.5 General Procedure 5: Imine-Enolate Cyclisation Reaction

Substituted (S,E)-ethyl-3-(2-((1-(4-methoxyphenyl)ethylimino)methyl)phenyl)propaneates ( 1.0 equiv.) were dissolved in THF. 15-Crown-5 (1.1 equiv.) and NaHMDS (1.1 equiv.) were added and the mixture was stirred for 8 hours at $-40^{\circ} \mathrm{C}$. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$. The aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 30 \mathrm{~mL})$ and the organic layers were combined and washed with water ( 50 mL ). The organics were dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure. Crude compounds were purified by flash column chromatography.

### 4.2 Synthesis of (S)-N-( $\alpha$-methyl-p-methoxybenzyl)- $\omega$-iminoesters

## 2-(2-Bromophenyl)-1,3-dioxane 210

The title compound was prepared according to General Procedure 1 from 2bromobenzadehyde 209 ( $10.0 \mathrm{~g}, 54 \mathrm{mmol}$ ), 1,3-propanediol ( $6.16 \mathrm{~g}, 81 \mathrm{mmol}$ ) and PTSA ( $0.86 \mathrm{~g}, 5.0 \mathrm{mmol}$ ). The crude product was purified by recrystallisation from diethyl ether, yielding a white solid ( $10.47 \mathrm{~g}, 80 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.59(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=8.0$ and $1.5 \mathrm{~Hz}, \mathrm{CBrCH}), 7.40(1 \mathrm{H}, \mathrm{d}$, $J=8.0 \mathrm{~Hz}, \operatorname{Ar}), 7.20(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{Ar}), 7.04(1 \mathrm{H}, \mathrm{td}, \mathrm{J}=8.0$ and $1.5 \mathrm{~Hz}, \mathrm{Ar}), 5.63$ $(1 \mathrm{H}, \mathrm{s}, \mathrm{ArCH}), 4.10\left(2 \mathrm{H}, \mathrm{dd}, \mathrm{J}=11.0\right.$ and $\left.5.0 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 3.85(2 \mathrm{H}, \mathrm{td}, \mathrm{J}=12.5$ and 2.0 $\mathrm{Hz}, \mathrm{OCH}_{2}$ ), 2.16-1.98 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), $1.24\left(1 \mathrm{H}, \mathrm{br} . \mathrm{d}, \mathrm{J}=13.5 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=137.6,132.6,130.4,128.2,127.6,122.4,100.9$, 67.6, 25.7; IR (film / $\mathrm{cm}^{-1}$ ) $v=2846$ (O-CH-O); HRMS: m/z (ES) 243.0018, $\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{O}_{2} \mathrm{Br}$ $[\mathrm{M}+\mathrm{H}]^{+}$requires 243.0021 ; mp $53-55^{\circ} \mathrm{C}$.

## Methyl-3-(2-(1,3-dioxan-2-yl)phenyl)acrylate 211

The title compound was prepared according to General Procedure 2 from 2-(2-bromophenyl)-1,3-dioxolan 210 ( $2.67 \mathrm{~g}, 11.0 \mathrm{mmol}$ ), methyl acrylate ( $0.99 \mathrm{~mL}, 11$ mmol ), palladium (II) acetate ( $0.12 \mathrm{~g}, 0.55 \mathrm{mmol}$ ), tri(o-tolyl)phosphine ( $0.33 \mathrm{~g}, 1.1$ mmol ) and diisopropylethyl amine ( $5.7 \mathrm{~mL}, 33.0 \mathrm{mmol}$ ). The crude product was purified using flash column chromatography [Petrol : EtOAc (85:15), $\mathrm{R}_{f} 0.28$ ] yielding a yellow oil ( $2.29 \mathrm{~g}, 84 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=8.16(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=16.0 \mathrm{~Hz}, \mathrm{ArCHCH}), 7.57-7.48(2 \mathrm{H}, \mathrm{m}$, Ar), 7.35-7.23 (2H, m, Ar), 6.28 ( $1 \mathrm{H}, \mathrm{d}, \mathrm{J}=16.0 \mathrm{~Hz}, \operatorname{ArCHCH}$ ), 5.63 ( $1 \mathrm{H}, \mathrm{s}, \operatorname{ArCHO}$ ), $4.21\left(2 \mathrm{H}, \mathrm{ddd}, \mathrm{J}=12.0,5.0\right.$ and $\left.1.5 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 3.94(2 \mathrm{H}, \mathrm{td}, \mathrm{J}=12.5$ and 2.5 Hz , $\left.\mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 3.74(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 2.30-2.12\left(1 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 1.44-1.34(1 \mathrm{H}, \mathrm{m}$, $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ ); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=167.8,142.9,137.6,133.2,129.5$, $128.5,127.4,127.2,119.9,100.6,67.9,52.1,26.1$; $\mathrm{IR}\left(\right.$ film $\left./ \mathrm{cm}^{-1}\right) v=1712$ ( $\mathrm{C}=\mathrm{O}$ ), 1635 (C=C); HRMS: m/z (ES) 249.1116, $\mathrm{C}_{14} \mathrm{H}_{16} \mathrm{O}_{4}[\mathrm{M}+\mathrm{H}]^{+}$requires 249.1127

## Methyl-3-(2-(1,3-dioxan-2-yl)phenyl)propanoate 212

The title compound was prepared according to General Procedure 3 from methyl 3-(2-(1,3-dioxan-2-yl)phenyl)acrylate 211 ( $1.46 \mathrm{~g}, 5.9 \mathrm{mmol}$ ) and cobalt(II) chloride hexahydrate $(0.01 \mathrm{~g}, 0.06 \mathrm{mmol})$ in methanol $(30 \mathrm{~mL})$ with the addition of sodium borohydride ( $0.44 \mathrm{~g}, 11.8 \mathrm{mmol}$ ) and was stirred at room temperature for 48 hours. The crude product was purified using flash column chromatography [Petrol: EtOAc (80:20), $\mathrm{R}_{f} 0.79$ ] yielding a brown oil ( $1.01 \mathrm{~g}, 70 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.33-7.16(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 5.68\left(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}_{2}\right), 4.33-4.24$ $\left(2 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 4.02\left(2 \mathrm{H}, \mathrm{td}, \mathrm{J}=2.5\right.$ and $\left.12.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 3.71\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right)$, 3.14-3.05 (2H, m, $\operatorname{ArCH}_{2} \mathrm{CH}_{2}$ ), 2.71-2.62 (2H, m, $\mathrm{ArCH}_{2} \mathrm{CH}_{2}$ ), 2.37-2.17 (1H, m, $\left.\mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 1.47\left(1 \mathrm{H}\right.$, app d of hep., $\mathrm{J}=13.5$ and $\left.1.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$.

## (E)-Ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)acrylate 217

The title compound was prepared according to General Procedure 2 from 2-(2-bromophenyl)-1,3-dioxane 210 ( $10.8 \mathrm{~g}, 44.4 \mathrm{mmol}$ ), ethyl acrylate ( $4.82 \mathrm{~mL}, 44.4$ mmol ), palladium (II) acetate ( $0.49 \mathrm{~g}, 2.2 \mathrm{mmol}$ ), tri(o-tolyl)phosphine ( $1.35 \mathrm{~g}, 4.5$
mmol ) and diisopropylethyl amine ( $23.2 \mathrm{~mL}, 133.4 \mathrm{mmol}$ ) in acetonitrile ( 120 mL ). The crude product was purified by flash column chromatography [Petrol : EtOAc (80:20), $\mathrm{R}_{f}$ 0.39 ] yielding a yellow oil ( $11.2 \mathrm{~g}, 96 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=8.16(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=16.0 \mathrm{~Hz}, \mathrm{ArCHCH}), 7.53(2 \mathrm{H}$, app. td, $J=2.0 \mathrm{~Hz}, \operatorname{Ar}), 7.35-7.24(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 6.28(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=16.0 \mathrm{~Hz}, \operatorname{ArCHCH}), 5.63(1 \mathrm{H}, \mathrm{s}$, $\mathrm{CHO}), 4.25-4.16\left(4 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right.$ and $\left.\mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 4.00-3.89\left(2 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$, 2.30$2.13\left(1 \mathrm{H}\right.$, diastereotopic m., $\left.\mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 1.40(1 \mathrm{H}$, app. d of hep., $\mathrm{J}=13.5$ and 1.5 Hz , $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), $1.27\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \quad \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=$ 167.0, 142.2, 137.1, 132.9, 129.8, 129.1, 127.0, 126.7, 119.9, 100.3, 67.6, 60.5, 25.7, 14.3; IR (film / $\mathrm{cm}^{-1}$ ) $v=2851$ ( $\mathrm{O}-\mathrm{CH}-\mathrm{O}$ ), $1728(\mathrm{C}=\mathrm{O}), 1608(\mathrm{C}=\mathrm{C})$; HRMS: m/z (ES) 287.1259, $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{4}[\mathrm{M}+\mathrm{Na}]^{+}$requires 287.1259.

## Ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)propanoate 216

The title compound was prepared according to General Procedure 3 from ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)acrylate 217 ( $1.91 \mathrm{~g}, 7.7 \mathrm{mmol}$ ), cobalt(II) chloride hexahydrate $(0.02 \mathrm{~g}, 0.08 \mathrm{mmol})$ in ethanol $(30 \mathrm{~mL})$ with the addition of sodium borohydride $(0.58 \mathrm{~g}$, $15.4 \mathrm{mmol})$. The crude product was purified using flash column chromatography [Petrol : EtOAc (80:20), $\mathrm{R}_{\mathrm{f}} 0.74$ ] yielding a yellow oil ( $1.65 \mathrm{~g}, 81$ \%).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.62-7.57(1 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 7.31-7.16(3 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 5.67(1 \mathrm{H}$, s, ArCHO), 4.27 ( 2 H , ddd, $\mathrm{J}=10.5,5.0$ and $1.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), $4.16(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\left.\mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 4.01\left(2 \mathrm{H}, \mathrm{td}, \mathrm{J}=2.5\right.$ and $\left.12.5 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$, 3.12-3.03 (2H, m, $\mathrm{ArCH}_{2} \mathrm{CH}_{2}$ ), 2.69-2.59 (2H, m, $\mathrm{ArCH}_{2} \mathrm{CH}_{2}$ ), 2.35-2.17 (1H, m, OCH2CH2), 1.50-1.41 (1H, $\mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), $1.27\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=$ 173.6, 138.9, 136.8, 129.9, 129.3, 127.0, 126.8, 100.6, 67.7, 60.7, 36.5, 28.3, 26.1, 14.6; IR (film / $\mathrm{cm}^{-1}$ ) $v=1729(\mathrm{C}=\mathrm{O})$; HRMS: $\mathrm{m} / \mathrm{z}(\mathrm{ES}) 287.1247, \mathrm{C}_{15} \mathrm{H}_{20} \mathrm{NaO}_{4}[\mathrm{M}+\mathrm{Na}]^{+}$ requires 287.1259.

## Methyl-3-(2-formylphenyl)propanoate 218

The title compound was prepared according to General Procedure 4 from methyl 3-(2-(1,3-dioxan-2-yl)phenyl)propanoate 212 ( $1.01 \mathrm{~g}, 4.1 \mathrm{mmol}$ ), which was added to a solution of acetic acid : water ( $7 \mathrm{~mL}: 3 \mathrm{~mL}$ ) and stirred open to the air overnight. The crude product was purified using flash column chromatography [Petrol : EtOAc (75:25), $\mathrm{R}_{f} 0.70$ ] yielding a yellow oil ( $0.57 \mathrm{~g}, 73 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=10.14$ ( $1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}$ ), 7.80-7.77 (1H, m, Ar), 7.48-7.27 (3H, m, Ar), $3.59\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 3.29\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{CH}_{2}\right), 2.58(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5$ $\left.\mathrm{Hz}, \mathrm{ArCH}_{2} \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=193.1,173.5,143.2,134.2,134.0$, 132.3, 127.5, 52.0, 35.7, 28.5; IR (film / $\mathrm{cm}^{-1}$ ) $v=1733$ (C=O), 1693 (C=O); HRMS: m/z (ES) 193.0854, $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$requires 193.0864.

## Ethyl 3-(2-formylphenyl)propanoate 219

The title compound was prepared according to General Procedure 4 from ethyl 3-(2-(1,3-dioxan-2-yl)phenyl)propanoate 216 ( $0.55 \mathrm{~g}, 2.2 \mathrm{mmol}$ ), which was added to a solution of acetic acid : water ( $7 \mathrm{~mL}: 3 \mathrm{~mL}$ ) and stirred open to the air overnight. The crude was purified using flash column chromatography [Petrol : EtOAc (75:25), R $\mathrm{R}_{f} 0.63$ ] yielding a colourless oil ( $0.32 \mathrm{~g}, 75 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $250 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=10.25$ ( $1 \mathrm{H}, \mathrm{s}, \mathrm{ArCHO}$ ), 7.89-.7.80 (1H, m, Ar), 7.607.27 (3H, m, Ar), $4.14\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.89\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{ArCH}_{2} \mathrm{CH}_{2}\right)$, $2.67\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \operatorname{ArCH}_{2} \mathrm{CH}_{2}\right), 1.25\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (75 MHz, $\mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=192.7,172.6,142.9,133.8,133.8,133.4,131.2,127.0,60.5$, 35.6, 28.0, 14.2; IR (film $/ \mathrm{cm}^{-1}$ ) $v=1728(\mathrm{C}=\mathrm{O}), 1694$ ( $\mathrm{C}=\mathrm{O}$ ) HRMS: m/z (ES) 207.1009, $\mathrm{C}_{12} \mathrm{H}_{14} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$requires 207.1021.
(S,E)-Methyl-3-(2-(((1-(4-methoxyphenyl)ethyl)imino)methyl)phenyl)propanoate 220

Methyl 3-(2-formylphenyl)propanoate 218 ( $0.036 \mathrm{~g}, 0.19 \mathrm{mmol}$ ) was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$ with $\mathrm{MgSO}_{4}$ and stirred under a nitrogen atmosphere. After 5 minutes, $(S)-(-)-4$-methoxy- $\alpha$-methylbenzylamine ( $0.28 \mathrm{~mL}, 0.19 \mathrm{mmol}$ ) was added and the solution was stirred for 5 hours. The solution was filtered and the solvent was evaporated under reduced pressure, yielding a yellow oil ( $0.058 \mathrm{~g}, 96 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=8.60(1 \mathrm{H}, \mathrm{s}, \mathrm{CHN}), 7.79(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=1.5$ and 7.5 Hz , Ar), 7.37-7.18 (5H, m, Ar), 6.91-6.84 (2H, m, Ar), $4.49\left(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right), 3.80$ $\left(3 \mathrm{H}, \mathrm{s}, \mathrm{ArOCH}_{3}\right), 3.67\left(3 \mathrm{H}, \mathrm{s}, \mathrm{COOCH}_{3}\right), 3.25\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=8.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 2.61(2 \mathrm{H}, \mathrm{t}, \mathrm{J}$ $=8.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), $1.56\left(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right)$; $\mathrm{IR}\left(\right.$ film $\left./ \mathrm{cm}^{-1}\right) v=1735(\mathrm{C}=\mathrm{O})$, $1639(\mathrm{C}=\mathrm{N})$; HRMS: m/z (ES) 326.1755, $\mathrm{C}_{20} \mathrm{H}_{23} \mathrm{O}_{3} \mathrm{~N}[\mathrm{M}+\mathrm{H}]^{+}$requires 326.1756.
(S,E)-Ethyl-3-(2-((1-(4-methoxyphenyl)ethylimino)methyl)phenyl)propanoate 221

Ethyl 3-(2-formylphenyl)propanoate 219 ( $4.07 \mathrm{~g}, 19.8 \mathrm{mmol}$ ) was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(150 \mathrm{~mL})$ with $\mathrm{MgSO}_{4}$ and stirred under a nitrogen atmosphere. After 5 minutes, (S)-(-)-4-methoxy- $\alpha$-methylbenzylamine ( $2.92 \mathrm{~mL}, 19.8 \mathrm{mmol}$ ) was added and the solution was stirred for 5 hours. The solution was filtered and the solvent was evaporated under reduced pressure yielding a yellow oil ( $6.34 \mathrm{~g}, 95 \%$ ).

### 4.3 Initial Attempts at Developing an Intramolecular EnolateImine Cyclisation

(2aR,7bR)-1-((S)-1-(4-Methoxyphenyl)ethyl)-2a,3-dihydro-1H-indeno[1,2-b]azet-2(7bH)-one 223a

The title compound was prepared according to General Procedure 5 from ( $S, E$ )-ethyl 3-(2-((1-(4-methoxyphenyl)ethylimino)methyl)phenyl)propanoate 221 (0.144 g, 0.42 mmol ), which was dissolved in THF ( 10 mL ) under a nitrogen atmosphere. 15-Crown-5 ( $0.09 \mathrm{~mL}, 0.46 \mathrm{mmol}$ ) and NaHMDS ( 1 M in THF, $0.46 \mathrm{~mL}, 0.46 \mathrm{mmol}$ ) was added and the mixture was stirred for 8 hours at $-40^{\circ} \mathrm{C}$ and allowed to warm to room temperature. The crude product was purified using flash column chromatography [Petrol: EtOAc ( $60: 40$ ), $R_{f} 0.47$ ] yielding a white crystalline solid ( $0.088 \mathrm{~g}, 73 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.34-7.28(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 7.22-7.14\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{3} \mathrm{OCHCH}\right)$, 6.98-6.94 (2H, m, CH3OCH), $5.00\left(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right), 4.83(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=4.5 \mathrm{~Hz}$, CHCHN ), 3.92-3.89 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CHCH}_{2}$ ), 3.88 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}$ ), 3.41 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=17.5$ and $\left.2.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}\right), 3.03\left(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=17.5\right.$ and $\left.10.5 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}\right), 1.44(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\left.\mathrm{CHCH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=169.8,159.1,145.1,139.7,132.0$, 128.8, 128.4, 126.5, 126.4, 126.2, 114.0, 61.4, 55.4, 51.7, 51.2, 30.1, 18.9; IR (film / $\left.\mathrm{cm}^{-1}\right) v=1731$ (C=O) HRMS: m/z (ES) 316.1308, $\mathrm{C}_{19} \mathrm{H}_{19} \mathrm{O}_{2} \mathrm{~N}[\mathrm{M}+\mathrm{Na}]^{+}$requires 316.1313; mp 90-92 ${ }^{\circ} \mathrm{C} ;[\alpha]_{\mathrm{D}}^{25}=-52\left(c 1.15, \mathrm{CHCl}_{3}\right)$.

## (2aS,7bS)-1-((S)-1-(4-Methoxyphenyl)ethyl)-2a,3-dihydro-1H-indeno[1,2-b]azet2(7bH)one 223b

(S,E)-Ethyl 3-(2-((1-(4-methoxyphenyl)ethylimino)methyl)phenyl)propanoate 221 (0.24 $\mathrm{g}, 0.7 \mathrm{mmol}$ ) was dissolved in THF ( 23 mL ). KHMDS ( 0.5 M in toluene, 1.5 mL , 0.78 mmol ) was added and the mixture was stirred for 8 hours at room temperature. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$. The aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 50 \mathrm{~mL})$ and the organic layers were combined and washed with $\mathrm{NH}_{4} \mathrm{Cl}(50 \mathrm{~mL})$ and water ( 50 mL ). The organics were then dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure. The crude product was purified using flash column chromatography [Hexane: $\mathrm{Et}_{2} \mathrm{O}(1: 1), \mathrm{R}_{f} 0.15$ ] yielding a white crystalline solid ( $0.031 \mathrm{~g}, 15 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.33-7.28(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar})$, 7.24-7.19 (2H, m, Ar), 7.15-7.10 (1H, m, Ar), 6.93-6.86 (3H, m, Ar), $4.82(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=4.5 \mathrm{~Hz}, \mathrm{CHCH}$ ), $4.48(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=$ $\left.7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right)$, 3.92-3.89 (1H, m, CHCH 2 ), $3.86\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 3.40(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=17.5$ and $2.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}$ ), $3.07\left(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=17.5\right.$ and $\left.10.5 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}\right), 1.71(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0$ $\mathrm{Hz}, \mathrm{CHCH}_{3}$ ) ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=170.3,159.0,144.9,138.9,133.4$, 128.8, 128.1, 126.5, 126.4, 125.8, 114.1, 61.1, 55.4, 53.9, 51.5, 30.3, 20.8; IR (film / $\left.\mathrm{cm}^{-1}\right) v=1737(\mathrm{C}=\mathrm{O})$; HRMS: m/z (ES) 294.1502, $\mathrm{C}_{19} \mathrm{H}_{19} \mathrm{O}_{2} \mathrm{~N}[\mathrm{M}+\mathrm{H}]^{+}$requires 294.1494; $\mathrm{mp} 93-95^{\circ} \mathrm{C} ;[\alpha]_{\mathrm{D}}^{17}=+37.3\left(c 0.375, \mathrm{CHCl}_{3}\right)$.

### 4.4 Determination of the Configuration of $\beta$-Lactam 223 (2aR,7bR)-2a,3-Dihydro-1H-indeno[1,2-b]azet-2(7bH)-one 198a

(2aR,7bR)-1-((S)-1-(4-Methoxyphenyl)ethyl)-2a,3-dihydro-1H-indeno[1,2-b]azet-2(7bH)one ( $0.035 \mathrm{~g}, 0.12 \mathrm{mmol}$ ) 223a was added to a solution of acetonitrile : water ( 7.5 mL : 1.5 mL ). Ammonium cerium(IV) nitrate ( $0.19 \mathrm{~g}, 0.35 \mathrm{mmol}$ ) was added portion-wise and the solution was left to stir for 16 hours. The reaction was then quenched with a saturated solution of $\mathrm{NaHCO}_{3}(30 \mathrm{~mL})$ and diluted with diethyl ether ( 30 mL ). The aqueous layer was extracted with diethyl ether ( $2 \times 30 \mathrm{~mL}$ ) and the organic layers combined and washed with a saturated solution of $\mathrm{NaHCO}_{3}(2 \times 30 \mathrm{~mL})$ The organics were dried using $\mathrm{MgSO}_{4}$ and filtered, before being evaporated under reduced pressure. The crude product was purified by recrystallisation from dichloromethane and hexane yielding a white crystalline solid ( $0.14 \mathrm{~g}, 76$ \%).
${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.35-7.21(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 6.25(1 \mathrm{H}, \mathrm{br} . \mathrm{s}, \mathrm{NH}), 5.03(1 \mathrm{H}$, d, J = 4.5 Hz, NCHCH), 4.06-4.00 (1H, m, CHCH2), $3.35\left(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=17.5 \mathrm{~Hz}, \mathrm{CHCH}_{2}\right)$, $3.07\left(1 \mathrm{H}\right.$, dd, $\mathrm{J}=17.5$ and $\left.10.5 \mathrm{~Hz}, \mathrm{CHCH}_{2}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=$ 170.5, 143.2, 139.5, 128.1, 126.1, 125.3, 124.1, 57.5, 53.2, 29.3; IR (film $/ \mathrm{cm}^{-1}$ ) $v=$ $3164(\mathrm{~N}-\mathrm{H}), 1695(\mathrm{C}=\mathrm{O})$; HRMS: m/z (ES) 182.0581, $\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{ON}[\mathrm{M}+\mathrm{Na}]^{+}$requires 181.0582; mp 191-192 ${ }^{\circ} \mathrm{C} ;[\propto]_{\mathrm{D}}^{21}=-214\left(c 0.69, \mathrm{CHCl}_{3}\right)$.
(1 R,2R)-1-Amino-2,3-dihydro-1H-indene-2-carboxylic acid hydrochloride 189a

(2aR,7bR)-2a,3-Dihydro-1H-indeno[1,2-b]azet-2(7bH)-one 198a ( $0.020 \mathrm{~g}, 0.13 \mathrm{mmol}$ ) was added to $18 \% \mathrm{HCl}(5 \mathrm{~mL})$ and the solution was heated at reflux for 3 hours. The solvent was then evaporated under reduced pressure. The crude product was purified by recrystallisation from ethanol and diethyl ether yielding a white crystalline solid ( 0.022 g, 83 \%).
${ }^{1} \mathrm{H} \operatorname{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.45(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=8.0 \mathrm{~Hz}, \mathrm{Ar}), 7.40-7.34(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar})$, $7.31(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \operatorname{Ar}), 4.94(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.5 \mathrm{~Hz}, \mathrm{NCH}), 3.69(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=8.0 \mathrm{~Hz}$, NCHCH), $3.30\left(2 \mathrm{H}, \mathrm{d}, \mathrm{J}=8.5 \mathrm{~Hz}, \mathrm{CHCH}_{2}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(125 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=175.4$, 142.1, 136.6, 130.3, 127.7, 125.4, 125.3, 55.3, 45.5, 33.3; IR (film / cm ${ }^{-1}$ ) $v=3384$ ( $\mathrm{O}-$ H ), 1715 (C=O); HRMS: m/z (ES) 200.0680, $\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{O}_{2} \mathrm{~N}[\mathrm{M}+\mathrm{Na}]^{+}$requires 200.0687; mp $210-214^{\circ} \mathrm{C} ;[\propto]_{\mathrm{D}}^{25}=-2.5(c 0.4, \mathrm{MeOH})$.

### 4.5 Occurrence of a Minor $\boldsymbol{\beta}$-Amino Ester Side Product (1 R,2R)-Ethyl-1-((S)-1-(4-methoxyphenyl)ethylamino)-2,3-dihydro-1H-indene-2carboxylate hydrochloride 242

(2aR,7bR)-1-((S)-1-(4-Methoxyphenyl)ethyl)-2a,3-dihydro-1H-indeno[1,2-b]azet-2(7bH)one 223b ( $0.12 \mathrm{~g}, 0.40 \mathrm{mmol}$ ) was heated at reflux in ethanol $(21 \mathrm{~mL})$ with dry $\mathrm{HCl}(1 \mathrm{M}$ in $\mathrm{Et}_{2} \mathrm{O}, 9 \mathrm{~mL}$ ) for 2 hours. The solvent was then evaporated under reduced pressure. The crude product was purified by recrystallisation from ethanol and diethyl ether yielding a white crystalline solid ( $0.13 \mathrm{~g}, 94 \%$ ).

### 4.7 Synthesis and Optimization of Benzocishexacin

## Ethyl 4-(2-formylphenyl)butanoate $291{ }^{169}$

To a Schlenk flask flushed with nitrogen, anhydrous LiCl ( $0.75 \mathrm{~g}, 17.6 \mathrm{mmol}$ ) was added and dried under vacuum. Zinc dust ( $1.15 \mathrm{~g}, 17.6 \mathrm{mmol}$ ) was added and the resultant mixture was further dried under high vacuum. THF ( 10 mL ) was added and the suspension was stirred for 10 minutes before dibromoethane $(0.076 \mathrm{~mL}, 0.58$ $\mathrm{mmol}), \mathrm{Me}_{3} \mathrm{SiCl}(0.015 \mathrm{~mL}, 0.12 \mathrm{mmol})$, iodine ( $0.09 \mathrm{~g}, 0.35 \mathrm{mmol}$ ) and ethyl $4-$ bromobutyrate ( $1.68 \mathrm{~mL}, 11.8 \mathrm{mmol}$ ) were added and the solution was stirred for 12 hours at $50^{\circ} \mathrm{C}$. The resultant grey suspension was cooled to room temperature and 2 bromobenzaldehyde ( $1.10 \mathrm{~mL}, 9.4 \mathrm{mmol}$ ), PEPPSI ( $0.04 \mathrm{~g}, 0.06 \mathrm{mmol}$ ) and DMI ( 5 mL ) were added to the solution, which was stirred at room temperature for 12 hours. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(20 \mathrm{~mL})$ and then filtered through cotton wool. The aqueous layer was extracted with diethyl ether ( $2 \times 10 \mathrm{~mL}$ ). The combined organics were collected, washed with brine ( $2 \times 10 \mathrm{~mL}$ ) and dried over $\mathrm{MgSO}_{4}$. The solution was then filtered and the solvent evaporated under reduced pressure. The crude compound was purified using flash column chromatography [Petrol : EtOAc (90:10), $\mathrm{R}_{f} 0.50$ ] yielding a yellow oil ( $0.90 \mathrm{~g}, 51 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=10.19(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}), 7.77(1 \mathrm{H}$, app. dd, $\mathrm{J}=7.5$ and 1.5 $\mathrm{Hz}, \mathrm{Ar}), 7.45(1 \mathrm{H}, \mathrm{td}, \mathrm{J}=7.5$ and $1.5 \mathrm{~Hz}, \mathrm{Ar}), 7.32(1 \mathrm{H}, \mathrm{td}, \mathrm{J}=7.5$ and $1.5 \mathrm{~Hz}, \mathrm{Ar}), 7.28-$ $7.20(1 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 4.06\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.01(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}$, $\mathrm{ArCH}_{2} \mathrm{CH}_{2}$ ), $2.31\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.93-1.82(2 \mathrm{H}$, pent., $\mathrm{J}=7.5 \mathrm{~Hz}$, $\mathrm{ArCH}_{2} \mathrm{CH}_{2}$ ), $1.19\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{c}}=$ 192.5, 173.3, 144.3, 133.8, 133.7, 132.5, 131.2, 126.8, 60.4, 33.8, 31.8, 27.0, 14.3; IR (film $/ \mathrm{cm}^{-1}$ ) $v=1728$ ( $\mathrm{C}=\mathrm{O}$ ), 1695 ( $\mathrm{C}=\mathrm{O}$ ), 1600 (C-O); HRMS: m/z (ES) 243.0984, $\mathrm{C}_{13} \mathrm{H}_{16} \mathrm{O}_{3}[\mathrm{M}+\mathrm{Na}]^{+}$requires 243.0997.
(S,E)-Ethyl 4-(2-((1-(4-methoxyphenyl)ethylimino)methyl)phenyl)butanoate 285

Ethyl 4-(2-formylphenyl)butanoate ( $0.84 \mathrm{~g}, 3.8 \mathrm{mmol}$ ) 291 was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(50 \mathrm{~mL})$ with $\mathrm{MgSO}_{4}$ and stirred under a nitrogen atmosphere. After 5 minutes, (S)-(-)-4-methoxy- $\alpha$-methylbenzylamine ( $0.56 \mathrm{~mL}, 3.8 \mathrm{mmol}$ ) was added and stirring was continued for 5 hours. The solution was then filtered and the solvent evaporated under reduced pressure yielding a colourless oil ( $1.10 \mathrm{~g}, 82 \%$ ).

## (1S,2S)-Ethyl 2-(((S)-1-phenylethyl)amino)cyclopentanecarboxylate 345

(1R,2S)-Ethyl 2-(((S)-1-phenylethyl)amino)cyclopentanecarboxylate 344 ( $0.16 \mathrm{~g}, 0.55$ mmol ) was dissolved in dry ethanol ( 8 mL ) under a nitrogen atmosphere. Potassium tert-butoxide ( $0.12 \mathrm{~g}, 1.10 \mathrm{mmol}$ ) was added and the reaction was heated at reflux for 4 hours. After cooling, the reaction was quenched with $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$ and the aqueous layer extracted with dichloromethane ( $2 \times 30 \mathrm{~mL}$ ). The combined organics were collected and washed with water ( $2 \times 30 \mathrm{~mL}$ ) and then dried over $\mathrm{MgSO}_{4}$. The solvent was then evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol: EtOAc (90:10), $\mathrm{R}_{f} 0.15$ ] yielding a colourless oil $(0.79 \mathrm{~g}, 55 \%)$ in accordance with the literature. ${ }^{213}$
${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.33-7.30(4 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 7.26-7.21$ (1H, m, Ar), 4.16-4.08 $\left(2 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.86\left(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right), 3.23(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHNH})$, $2.60(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCHNH})$, 2.01-1.92 ( $1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CHNH}$ ), $1.81(2 \mathrm{H}$, hep., J = $7.5 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), 1.72-1.57 (2H, m, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), $1.36(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.5 \mathrm{~Hz}$, $\left.\mathrm{CHCH}_{3}\right), 1.33-1.27\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.24\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=176.0,128.3,126.9,126.7,61.6,60.3,56.8,51.3,34.3$, 28.9, 24.6, 23.7, 14.1; IR (film / cm ${ }^{-1}$ ) $v=1727$ (C=O); HRMS: m/z (ES) 262.1562, $\mathrm{C}_{16} \mathrm{H}_{23} \mathrm{O}_{2} \mathrm{~N}[\mathrm{M}+\mathrm{H}]^{+}$requires 262.1807; $[\propto]_{\mathrm{D}}^{21}=-1.4\left(c 0.71, \mathrm{CHCl}_{3}\right)$.

## $4.10 \alpha$-Methyl-Substituted Cispentacin Synthesis

## Ethyl 6-((triethylsilyl)oxy)hexanoate 350

A solution of ethyl 6-hydroxyhexanoate $332(1.5 \mathrm{~mL}, 9.2 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(90 \mathrm{~mL})$ was cooled to $0{ }^{\circ} \mathrm{C}$ under a nitrogen atmosphere. 2,6-Lutidine ( $2.1 \mathrm{~mL}, 18.4 \mathrm{mmol}$ ) was added followed by a dropwise addition of TES-triflate ( $3.1 \mathrm{~mL}, 13.7 \mathrm{mmol}$ ), the resulting solution was then stirred for 3 hours at $0^{\circ} \mathrm{C}$. Following this, the reaction was quenched
with water ( 30 mL ) and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 30 \mathrm{~mL})$, the organic layers were combined and further washed with water ( 30 mL ). The organics were dried using $\mathrm{MgSO}_{4}$ and filtered; the solvent was then removed under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (95:5), $\mathrm{R}_{f} 0.71$ ] yielding a colourless oil ( $1.95 \mathrm{~g}, 77 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=4.09\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.57(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=6.5$ $\left.\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{OSi}\right), 2.27\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{EtOOCCH}_{2}\right), 1.67-1.56(2 \mathrm{H}$, pent., J = 7.5 Hz , $\left.\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}\right)$, 1.54-1.46 (2H, q, J = $\left.7.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}\right)$, 1.40-1.28 (2H, m, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}$ ), $1.22\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 0.92\left(9 \mathrm{H}, \mathrm{t}, \mathrm{J}=8.0 \mathrm{~Hz}, \mathrm{SiCH}_{2} \mathrm{CH}_{3}\right)$, $0.56\left(6 \mathrm{H}, \mathrm{q}, \mathrm{J}=8.0 \mathrm{~Hz}, \mathrm{SiCH}_{2} \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=173.7$, 62.6, 60.1, 34.3, 32.5, 25.4, 24.8, 14.2, 6.7, 4.6; IR (film / $\mathrm{cm}^{-1}$ ) $v=1737$ (C=O) 1095 (Si-O); HRMS: m/z (ES) 297.1724, $\mathrm{C}_{14} \mathrm{H}_{30} \mathrm{O}_{3} \mathrm{Si}[\mathrm{M}+\mathrm{Na}]^{+}$requires 297.1862.

## Ethyl 2-methyl-6-((triethylsilyl)oxy)hexanoate 351

A solution of NaHMDS ( 1 M in THF, $1.5 \mathrm{~mL}, 1.5 \mathrm{mmol}$ ) in THF ( 15 mL ) was cooled to $78^{\circ} \mathrm{C}$, followed by a dropwise addition of ethyl 6-((triethylsilyl)oxy)hexanoate 350 (0.35 $\mathrm{g}, 1.2 \mathrm{mmol})$. The reaction was left for 4 hours and allowed to warm to $-40^{\circ} \mathrm{C}$, methyl iodide ( $0.13 \mathrm{~mL}, 2.04 \mathrm{mmol}$ ) was subsequently added and the resulting solution was left overnight to warm to room temperature. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(20 \mathrm{~mL})$ and the aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \mathrm{x}$ $30 \mathrm{~mL})$. The organic layers were combined and washed with brine ( 30 mL ). The organics were then dried using $\mathrm{MgSO}_{4}$ and filtered before the solvent was removed under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (95:5), $\mathrm{R}_{f} 0.74$ ] yielding a yellow oil ( $0.24 \mathrm{~g}, 65 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=4.12\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.59(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=6.5$ $\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{OSi}$ ), $2.41\left(1 \mathrm{H}\right.$, sextet, $\mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}$ ), 1.73-1.28 ( $6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), $1.24\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 1.13(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH} \mathrm{CH}) 0.95(9 \mathrm{H}, \mathrm{t}, \mathrm{J}=8.0$ $\left.\mathrm{Hz}, \mathrm{SiCH}_{2} \mathrm{CH}_{3}\right), 0.58\left(6 \mathrm{H}, \mathrm{q}, \mathrm{J}=8.0 \mathrm{~Hz}, \mathrm{SiCH}_{2} \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}$
$=176.9,62.7,60.1,39.6,33.6,32.8,23.6,17.0,14.3,6.8,4.4$; $\mathrm{IR}\left(\right.$ film $\left./ \mathrm{cm}^{-1}\right) v=1736$ (C=O) 1096 (Si-O); HRMS: m/z (ES) 289.2186, $\mathrm{C}_{15} \mathrm{H}_{32} \mathrm{O}_{3} \mathrm{Si}[\mathrm{M}+\mathrm{H}]^{+}$requires 289.2199.

## Ethyl 6-hydroxy-2-methylhexanoate 352

TBAF (1M in THF, $1.85 \mathrm{~mL}, 1.85 \mathrm{mmol}$ ) was slowly added to a solution of ethyl 2-methyl-6-((triethylsilyl)oxy)hexanoate 351 ( $0.27 \mathrm{~mL}, 0.92 \mathrm{mmol}$ ) in THF ( 15 mL ) and left for 30 minutes. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(20 \mathrm{~mL})$ and the aqueous layer was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 30 \mathrm{~mL})$. The organics were then dried using $\mathrm{MgSO}_{4}$ and filtered before the solvent was removed under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (95:5), $\mathrm{R}_{f} 0.10$ ] yielding a yellow oil ( $0.11 \mathrm{~g}, 67 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=4.12\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.64(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=6.5$ $\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{OH}$ ), 2.48-2.36 (1H, sextet, J = $7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}$ ), 1.76-1.30 (6H, m, J = 7.0 Hz , $\left.\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.25\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 1.15\left(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right)$; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=176.8,62.7,60.2,39.5,33.4,32.6,23.4,17.1$, 14.3; IR (film $/ \mathrm{cm}^{-1}$ ) $v=3404(\mathrm{O}-\mathrm{H}), 1733(\mathrm{C}=\mathrm{O})$; HRMS: $\mathrm{m} / \mathrm{z}(\mathrm{ES}) 175.1347, \mathrm{C}_{9} \mathrm{H}_{18} \mathrm{O}_{3}$ $[\mathrm{M}+\mathrm{H}]^{+}$requires 175.1334.

## Ethyl 2-methyl-6-oxohexanoate 353

Ethyl 6-hydroxy-2-methylhexanoate $352(0.062 \mathrm{~mL}, 0.35 \mathrm{mmol})$ was added to pyridinium chlorochromate ( $0.11 \mathrm{~g}, 0.51 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ and allowed to stir at room temperature for 3 hours. The reaction mixture was filtered through a pad of Celite $®$ and Fluorosil $®$ and the solvent evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (80:20), $\mathrm{R}_{f}$ 0.80 ] yielding a colourless oil ( $0.037 \mathrm{~g}, 60 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=9.76(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=1.5 \mathrm{~Hz}, \mathrm{CHO}), 4.13(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\mathrm{OCH}_{2}$ ), 2.48-2.38 (3H, m, $\mathrm{CHCH}_{3}$ and $\mathrm{CH}_{2} \mathrm{CHO}$ ), 1.69-1.27 (4H, m, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), 1.22 $\left(3 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 1.16\left(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CHCH}_{3}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}$ $=201.2,175.5,59.4,42.8,38.5,32.2,18.9,16.2,13.4$; $\mathrm{IR}\left(\right.$ film $\left./ \mathrm{cm}^{-1}\right) v=1726(\mathrm{C}=\mathrm{O})$; HRMS: m/z (ES) 173.1191, $\mathrm{C}_{9} \mathrm{H}_{16} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$requires 173.1178.
(E)-Ethyl 6-(((S)-1-(4-methoxyphenyl)ethyl)imino)-2-methylhexanoate 354

Ethyl 2-methyl-6-oxohexanoate $353(0.038 \mathrm{~g}, 0.22 \mathrm{mmol})$ was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(6 \mathrm{~mL})$ with $\mathrm{MgSO}_{4}$. After 5 minutes $(S)-(-)-4-$ Methoxy- $\alpha$-methylbenzylamine ( 0.032 mL , 0.22 mmol ) was added and the reaction was stirred for 3 hours. The solution was then filtered and the solvent evaporated under reduced pressure yielding a pale yellow oil ( 0.061 g, $91 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.71(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=4.5 \mathrm{~Hz}, \mathrm{CHM}$ ), 7.29-7.20 (2H, m, Ar), 6.90-6.83 (2H, m, Ar), $4.23\left(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=6.5 \mathrm{~Hz}, \mathrm{ArCHCH}_{3}\right), 4.11(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\left.\mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.78\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 2.48-2.22\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CHN}\right), 1.73-1.49(4 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CHCH}_{3}\right)$, 1.48-1.43 (3H, d, $\left.\mathrm{ArCHCH}_{3}\right)$, 1.43-1.10 $\left(7 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right.$ and $\left.\mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$.

### 4.11 Synthesis of Cishexacin

## Ethyl 7-hydroxyheptanoate 357

Potassium persulfate $(5.00 \mathrm{~g}, 18.50 \mathrm{mmol})$ was added to a solution of $\mathrm{H}_{2} \mathrm{SO}_{4}(4.60 \mathrm{~mL})$, ethanol ( 10 mL ) and water ( 2 mL ), which had been cooled to $15^{\circ} \mathrm{C}$. A solution of cycloheptanone 356 ( $0.73 \mathrm{~g}, 6.17 \mathrm{mmol}$ ) in ethanol ( 3 mL ) was added dropwise and the reaction was left to stir overnight. The reaction was diluted with water $(30 \mathrm{~mL})$ and the aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 30 \mathrm{~mL})$. The organics were collected, dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure. The crude
product was purified by distillation $\left(\mathrm{bp}_{0.2}=114-116{ }^{\circ} \mathrm{C}\right)$ yielding a colourless oil $(0.838$ $\mathrm{g}, 74 \%)$ in accordance with the literature. ${ }^{203}$
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=4.02\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 3.52(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=6.5$ $\mathrm{Hz}, \mathrm{CH}_{2} \mathrm{OH}$ ), $2.38(1 \mathrm{H}$, br. s, OH$), 2.20\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.5 \mathrm{~Hz}, \mathrm{EtOOCCH}_{2}\right)$, 1.60-1.40 (4H, $\mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), 1.33-1.21 (4H, m, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), $1.51(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\mathrm{OCH}_{2} \mathrm{CH}_{3}$ ); ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=173.9,62.6,60.2,34.2,32.4,28.6$, 25.4, 24.8, 14.2; IR (film / $\mathrm{cm}^{-1}$ ) $v=3389(\mathrm{O}-\mathrm{H}), 1732(\mathrm{C}=\mathrm{O})$; HRMS: m/z (ES) 175.1323, $\mathrm{C}_{9} \mathrm{H}_{18} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$requires 175.1334.

## Ethyl 7-oxoheptanoate 358

Ethyl 7-hydroxyheptanoate 357 ( $0.737 \mathrm{~mL}, 4.23 \mathrm{mmol}$ ) was added to pyridinium chlorochromate ( $1.37 \mathrm{~g}, 6.34 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{~mL})$ and allowed to stir at room temperature for 2 hours. The reaction mixture was filtered through a pad of Celite ${ }^{\circledR}$ and Fluorosil $(®$ and then evaporated under reduced pressure. The crude product was purified by distillation $\left(\mathrm{bp}_{0.2}=96-98^{\circ} \mathrm{C}\right)$ yielding a colourless oil ( $0.714 \mathrm{~g}, 98 \%$ ) in accordance with the literature. ${ }^{203}$
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=9.69(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}), 4.05\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$, $2.38\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{CHO}\right), 2.23\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{EtOCOCH}_{2}\right), 1.66-1.49(4 \mathrm{H}$, $\mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), 1.37-1.23 (2H, m, CH2CH2CH2), $1.18\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=6.5 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=202.5,173.5,60.2,43.6,34.1,28.5,24.7,21.6$, 14.2; IR (film / $\mathrm{cm}^{-1}$ ) $v=1725(\mathrm{C}=\mathrm{O})$.

### 4.12 Gem-Di-Methyl Substituted Cispentacin Synthesis

## Ethyl 6-hydroxy-4,4-dimethylhexanoate 369

Potassium persulfate ( $2.40 \mathrm{~g}, 8.87 \mathrm{mmol}$ ) was added to a solution of $\mathrm{H}_{2} \mathrm{SO}_{4}(5 \mathrm{~mL})$, ethanol ( 10 mL ) and water ( 2 mL ), which has been cooled to $15^{\circ} \mathrm{C}$. A solution of $4,4^{\prime}$ -
dimethylcyclohexanone 364 ( $0.373 \mathrm{~g}, 2.96 \mathrm{mmol}$ ) in ethanol ( 3 mL ) was added dropwise and the reaction was left to stir overnight. The reaction was diluted with water $(30 \mathrm{~mL})$ and the aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 30 \mathrm{~mL})$. The organics were collected, dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc ( $80: 20$ ), $\mathrm{R}_{f} 0.23$ ] yielding a colourless oil ( $0.445 \mathrm{~g}, 80 \%$ ). ${ }^{203}$
${ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=4.05\left(2 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2}\right), 3.61(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\left.\mathrm{CH}_{2} \mathrm{OH}\right), 2.68(1 \mathrm{H}, \mathrm{br} . \mathrm{s}, \mathrm{OH}), 2.25-2.17\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Et}\right), 1.54-1.40(4 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}_{2}\right), 1.19\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 0.83\left(6 \mathrm{H}, \mathrm{s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $75 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=174.4,60.4,59.5,44.0,36.9,31.9,29.6,27.1,14.2$; IR (film $/ \mathrm{cm}^{-1}$ ) $v=3413(\mathrm{O}-\mathrm{H}), 1733(\mathrm{C}=\mathrm{O})$; HRMS: m/z (ES) 189.1486, $\mathrm{C}_{10} \mathrm{H}_{20} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$ requires 189.1490.

## Ethyl 4,4-dimethyl-6-oxohexanoate 370

Pyridinium chlorochromate ( $0.589 \mathrm{~g}, 2.73 \mathrm{mmol}$ ) was added to ethyl 6-hydroxy-4,4dimethylhexanoate 369 ( $0.343 \mathrm{~mL}, 1.82 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15 \mathrm{~mL})$ and allowed to stir at room temperature for 2 hours. The reaction mixture was filtered through a pad of Celite $®^{\circledR}$ and Fluorosil ${ }^{\circledR}$ and then evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (80:20), $\mathrm{R}_{f}{ }^{-}$ 0.79 ] yielding a colourless oil ( $0.295 \mathrm{~g}, 87 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=9.80(1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}), 4.15-4.01\left(2 \mathrm{H}\right.$, br. $\left.\mathrm{s}, \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$, 2.34-2.18 (4H, br. s, $\mathrm{CH}_{2} \mathrm{CHO}$ and $\left.\mathrm{CH}_{2} \mathrm{CO}_{2}\right)$, 1.75-1.59 (2H, br. s, $\left.\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$, 1.30$1.15\left(3 \mathrm{H}\right.$, br. s, $\left.\mathrm{OCH}_{2} \mathrm{CH}_{3}\right), 1.10-0.95\left(6 \mathrm{H}, \mathrm{s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(75 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ : $\delta_{\mathrm{C}}=202.9,173.6,60.5,54.5,37.1,33.1,29.4,27.0,14.2$; $\mathrm{IR}\left(\right.$ film $\left./ \mathrm{cm}^{-1}\right) v=1732$ (C=O); HRMS: m/z (ES) 187.1340, $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}_{3}[\mathrm{M}+\mathrm{H}]^{+}$requires 187.1334.

Ethyl 4,4-dimethyl-6-oxohexanoate 370 ( $0.183 \mathrm{~g}, 0.98 \mathrm{mmol}$ ) was dissolved in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{~mL})$ with $\mathrm{MgSO}_{4}$. After 5 minutes $(S)-(-)-4-M e t h o x y-\alpha$-methylbenzylamine ( $0.145 \mathrm{~mL}, 0.98 \mathrm{mmol}$ ) was added and the reaction was stirred for 3 hours. The solution was then filtered and the solvent evaporated under reduced pressure yielding a pale yellow oil ( $0.272 \mathrm{~g}, 87 \%$ ).

(1 R,5S)-6-((S)-1-(4-Methoxyphenyl)ethyl)-6-azaspiro[bicyclo[3.2.0]heptane-3,2'-[1,3]dioxolan]-7-one 380

The title compound was prepared according to General Procedure 5 from ( $S, E$ )-Ethyl 3-(2-(2-((1-(4-methoxyphenyl)ethyl)imino)ethyl)-1,3-dioxolan-2-yl)propanoate 379 ( 0.12 g , $0.33 \mathrm{mmol})$, which was dissolved in dry THF ( 10 mL ) under a nitrogen atmosphere. 15-crown-5 ( $0.13 \mathrm{~mL}, 0.67 \mathrm{mmol}$ ) and NaHMDS ( 1 M in THF, $0.67 \mathrm{~mL}, 0.67 \mathrm{mmol}$ ) were added and the mixture was stirred for 8 hours at $-40^{\circ} \mathrm{C}$ and allowed to warm to room temperature. The crude product was purified using flash column chromatography [Petrol : EtOAc (40:60), $\mathrm{R}_{f} 0.13$ ] yielding a white crystalline solid ( $0.060 \mathrm{~g}, 59 \%$ ).
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{H}}=7.26(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 6.89(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 4.94(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0$ $\mathrm{Hz}, \mathrm{CHCH}_{3}$ ) 4.03-3.78 (8H, m, $\mathrm{COCH}_{3}, \mathrm{OCH}_{2} \mathrm{CH}_{2}$ and NCH$)$, $3.44(1 \mathrm{H}, \mathrm{ddd}, \mathrm{J}=9.0,4.5$ and $1.0 \mathrm{~Hz}, \mathrm{NCHCH}), 2.20\left(1 \mathrm{H}, \mathrm{dt}, \mathrm{J}=14.0\right.$ and $\left.1.0 \mathrm{~Hz}, \mathrm{O}_{2} \mathrm{CCH}_{2}\right), 2.03(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=$ 14.5 and $1.0 \mathrm{~Hz}, \mathrm{O}_{2} \mathrm{CCH}_{2}$ ), 1.84-1.67 (2H, m, $\mathrm{O}_{2} \mathrm{CCH}_{2}$ ), $1.60(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=7.0 \mathrm{~Hz}$, $\mathrm{CHCH}_{3}$ ) ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=168.4,158.9,132.5,128.4,116.5$, 113.9, 64.6, 64.3, 55.3, 53.5, 51.2, 50.9, 38.0, 34.6, 19.0; IR (film $/ \mathrm{cm}^{-1}$ ) $v=1740$ (C=O); HRMS: m/z (ES) 304.1543, $\mathrm{C}_{17} \mathrm{H}_{21} \mathrm{O}_{4} \mathrm{~N}[\mathrm{M}+\mathrm{H}]^{+}$requires 304.1542; mp $49-51^{\circ} \mathrm{C}$; $[\alpha]_{\mathrm{D}}^{20}=-7.96\left(c 1.01, \mathrm{CHCl}_{3}\right)$.

## (1 R,5S)-6-((S)-1-(4-methoxyphenyl)ethyl)-6-azabicyclo[3.2.0]heptane-3,7-dione $382^{209}$

(1R,5S)-6-((S)-1-(4-Methoxyphenyl)ethyl)-6-azaspiro[bicyclo[3.2.0]heptane-3,2'-[1,3]-dioxolan]-7-one 380 ( $0.043 \mathrm{~g}, 0.14 \mathrm{mmol}$ ) and iodine ( $0.004 \mathrm{~g}, 0.014 \mathrm{mmol}$ ) was stirred in acetone ( 5 mL ) at room temperature for 30 minutes. The acetone was evaporated under reduced pressure and the residue dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic layer was separated, washed with $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(10 \mathrm{~mL})$ and brine $(20 \mathrm{~mL})$, dried with $\mathrm{MgSO}_{4}$ and the solvent evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (20:80), $\mathrm{R}_{f} 0.33$ ] yielding a colourless oil ( 0.029 g, $79 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.22(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 6.88(2 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 4.83(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=8.5$ $\left.\mathrm{Hz}, \mathrm{CHCH}_{3}\right) 4.05(1 \mathrm{H}, \mathrm{m}, \mathrm{NCH}), 3.79\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 3.66(1 \mathrm{H}, \mathrm{ddd}, \mathrm{J}=10.5,5.0$ and $2.0 \mathrm{~Hz}, \mathrm{NCHCH}$ ), $2.62\left(1 \mathrm{H}, \mathrm{m}, \mathrm{COCH}_{2}\right)$, 2.46-2.23 (3H, m, $\mathrm{CH}_{2} \mathrm{COCH}_{2}$ ), 1.58 (3H, d, J $=7.5 \mathrm{~Hz}, \mathrm{CHCH}_{3}$ ) ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{C}}=214.3,167.9$, 159.2, 131.9, 128.4, 114.2, 55.3, 52.0, 51.8, 49.1, 41.7, 37.0, 19.5; IR (film / cm ${ }^{-1}$ ) $v=1738$ (C=O), $1671(\mathrm{C}=\mathrm{O})$; HRMS: $\mathrm{m} / \mathrm{z}(\mathrm{ES}) 282.1078, \mathrm{C}_{15} \mathrm{H}_{17} \mathrm{O}_{3} \mathrm{~N}[\mathrm{M}+\mathrm{H}]^{+}$requires 282.1106; $[\alpha]_{\mathrm{D}}^{20}=$ -30.6 (c 1.18, $\mathrm{CHCl}_{3}$ ).

### 4.14 Future Work - Enantioselective Cyclisation

## 6-Benzyl-6-azabicyclo[3.2.0]heptan-7-one 388

Ethyl 6-oxohexanoate 333 ( $0.95 \mathrm{~g}, 5.97 \mathrm{mmol}$ ) was dissolved in dry THF ( 100 mL ) with $\mathrm{MgSO}_{4}$ and left stirring under a nitrogen atmosphere. After 5 minutes benzylamine ( $0.65 \mathrm{~mL}, 5.97 \mathrm{mmol}$ ) was added to the reaction and stirred for 10 minutes, the solution was subsequently cooled to $-40^{\circ} \mathrm{C}$. NaHMDS ( 1 M in THF, $12.0 \mathrm{~mL}, 12.0 \mathrm{mmol}$ ) was added and the mixture was stirred for 8 hours, allowing to warm to room temperature. The reaction was quenched with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$ and the THF was removed under reduced pressure. The resulting solution was further diluted with a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(20 \mathrm{~mL})$ and the aqueous layer was extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \mathrm{x}$ $30 \mathrm{~mL})$. The organic layers were combined and washed with water ( 50 mL ). The organics were then dried using $\mathrm{MgSO}_{4}$ and filtered before being evaporated under reduced pressure. The crude product was purified using flash column chromatography [Petrol : EtOAc (60:40), $\mathrm{R}_{f} 0.35$ ] yielding a colourless oil ( $0.70 \mathrm{~g}, 58 \%$ ).
${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta_{\mathrm{H}}=7.37-7.24(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}), 4.48(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=15.0$ and 2.0 $\left.\mathrm{Hz}, \mathrm{NCH}_{2}\right), 4.09\left(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=15.0\right.$ and $\left.1.0 \mathrm{~Hz}, \mathrm{NCH}_{2}\right), 3.90(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=5.0 \mathrm{~Hz}, \mathrm{NCH})$, $3.45\left(1 \mathrm{H}\right.$, dd, J= 7.5 and $3.0 \mathrm{~Hz}, \mathrm{NCHCH}$ ), $2.03\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.75(2 \mathrm{H}, \mathrm{m}$, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ), $1.57\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.38\left(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 1.18(1 \mathrm{H}, \mathrm{m}$, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2}$ ) ; ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta_{\mathrm{C}}=169.4,136.2,128.7,128.2,127.6$, $57.5,54.9,44.0,26.8,24.9,22.7$; IR (film $/ \mathrm{cm}^{-1}$ ) $v=1743(\mathrm{C}=\mathrm{O})$.
