# Zackenberg Valley seen by TerraSAR-X – Land cover and moisture conditions

## Motivation

• Soil moisture is an important variable in the hydrological cycle, as evapotranspiration is highly dependent on the availability of water stored in the soil just beneath the surface.

• Radar remote sensing has been identified as a suitable tool for the detection of spatial and temporal soil moisture variability.

• Ground measurements are difficult to obtain and thus sparse in arctic regions.

### Land Cover classes

Barrens	BA
Boulder Field	BFI
Abrasian plateau	AP
Fell field	FFl
Dryas heath	DY
Cassiope heath	CA
Salix snow bed	SS
Grassland	GR
Fen	FAI
Water	WA

# **Soil Moisture / Land cover classes**

• Soil moisture was measured manually in the field with a Hydrosense 2 device with 12 cm rods randomly or along 100m transects with one measurement each m.

• More than 5000 soil moisture measurements were performed in 2013 and 2014 each.

 The soil moisture values were than compared to the TerraSAR-X backscatter values.

 $\rightarrow$  The results show no relation between the soil moisture and the backscatter values, independent of the land cover on top and the moisture regime on ground.

• Data stacks from Mai – August 2013 (17 images) and April – August 2014 (13 images)

 Spotlight dual-pol HH/VV • Orbits  $80 = 27.4^{\circ}$  and Orbit  $95 = 38,1^{\circ}$ , both descending Spatial resolution after data processing including geocoding and terrain correction: 3.4m in ground and azimuth direction Multi-looking and a 3x3

Lee filter were applied.

### Kennaugh matrix decomposition

- K0: Total intensity of HH and VV
- K3: Loss of polarization during the scattering
- process real part of the conjugation of the complex signals of HH and VV
- K4: change of the relation between two
- amplitude values during reflection difference of the HH and VV intensities
- K7: phase delay during scattering in a particular direction - imaginary part of the conjugation of
- the complex signals of HH and VV

- $\rightarrow$  Water bodies and fan areas could be separated best from their surroundings
- $\rightarrow$  lowest classification performance was found for heath and salix formations.

 $\rightarrow$  TerraSAR-X is valuable to separate land, water, and fen areas in this high arctic tundra landscape, while soil moisture monitoring and further land cover analysis require data from radar sensors operating with longer wavelength.
