## ACKNOWLEDGMENTS

The research necessary to prepare this report was funded in part by the Bureau of Indian Affairs, Contract Number EOOC14201592. This report was prepared using data derived from the garden project undertaken by the Kuskokwim Native Association in Aniak, Alaska, for the years 1976 through 1978. Those associated with the project, particularly former manager David Hassinger, the Kuskokwim Native Association Board of Directors, and the residents of the Kuskokwim River area, are acknowledged for their assistance. In those cases where data were not available they were provided by the following resource persons and agencies: Dr. Frank J. Wooding, Associate Professor of Agronomy, and Dr. Donald H. Dinkel, Professor of Plant Physiology, Agricultural Experiment Station, University of Alaska, Fairbanks; Dr. Curtis H. Dearborn, Research Horticulturist, and Dr. Richard H. Washburn (deceased), Research Entomologist, Agricultural Research Service, United States Department of Agriculture, Palmer, Alaska; Edward Kern, Marketing Specialist, Alaska State Division of Agriculture, Palmer, Alaska; and Dr. Charles E. Logsdon, Agresources, Palmer, Alaska. Pat Barker, Cooperative Extension Service, University of Alaska, Bethel, Alaska, is also thanked for helping us to obtain information concerning Bethel area markets.

Particular thanks is given Dr. Wayne C. Thomas, Associate Professor of Economics, Agricultural Experiment Station, University of Alaska, Fairbanks, Alaska, for his comments throughout the project and extensive review of this report.

FIGURE 1: Marketing Area for Middle Kuskokwim Valley Produce.

## CHAPTER 1

## INTRODUCTION

Alaskans are concerned with the production of food. This is evident from the concern which has been expressed over the subsistence issue within the current Alaska lands legislation. The debate ponders who shall harvest the state's natural game resource and how the resource shall be harvested. Although this question is not settled, one point is coming to the fore: the game resource alone is not sufficient to satisfy the food needs of Alaska's growing rural population.

In recent months, interest has been expressed in the agricultural potential of the lands in areas of Alaska which are removed from major population centers and from connecting surface transportation routes. One area in particular in southwestern Alaska has made significant progress in agricultural development. The Kuskokwim Native Association has maintained a community garden since 1976 in Aniak on the Kuskokwim River (Figure 1) (Lewis, Thomas, and Wooding, 1978). This effort could be expanded using existing transportation corridors to supply not only the Kuskokwim River valley, but also several villages located away from the river.

The objective of this study is to provide an economic evaluation of the feasibility of producing and marketing vegetables in the Kuskokwim River valley area. Major considerations were the availability of markets, transportation, and a method of product distribution. All were based on production capability of the area and the capacity and time factors pertaining to vegetable storage.

The Kuskokwim River area is unique in comparison to many other rural areas in Alaska: vegetable production capability has been proven historically (Lewis, Thomas, and Wooding, 1978); transportation and distribution systems have been established by commercial air carriers; the area villages have a major population center; and delivery costs from a central point within the area to outlying villages are much less than those presently encountered in the distribution of agricultural products from Anchorage.

Based on historical production methods, six types of field vegetables can be grown successfully in the middle Kuskokwim Valley: potatoes, cabbages, turnips, rutabagas, broccoli, and cauliflower. Two crops, carrots and onions, have been successful in some years. In addition to the eight field crops, tomatoes have been grown successfully in greenhouses.

Several assumptions concerning physical facilities and management were made in formulating the costs presented in this study:

- Any land clearing which may be necessary and any land preparation such as initial fertilization are completed.
- Support facilities such as heated areas to repair machinery, electrical power, a sales office, and a vegetable packing area are available.
- Fertilization rates, seeding rates, and yields are based on the use of irrigation.
- Storage facilities are adequate to maintain the quality of the vegetables during the winter months and during the warmer period immediately following harvest.
- Vegetables are to be sold at wholesale prices to retail outlets only.
- In charge of both production and marketing, a grower-manager is to be employed with abilities to carry out good farm management practices, manage the vegetable distribution through communication with retail outlets and air carriers, and maintain an orderly marketing system to facilitate the flow of products, payments, and deliveries.
The costs of production in the form of capital budgets, annual budgets, and cash flow are given as is the production cost per pound for each vegetable crop. Market demand has been assessed for an area extending from Bethel and surrounding communities to villages as far upriver as Stony River. Marketing alternatives which include storage facilities, transportation services, method of distribution, and pricing policy are discussed. A complete system of production and marketing of vegetable crops which will satisfy consumer demand, bring vegetables to the retailer at a competitive wholesale price, and bring the producer a reasonable, positive return is presented.

The major portion of this study is concerned with production of field vegetable crops on a medium-size farm. This is not to imply that other agricultural ventures should not be considered in the future (Thomas, 1977). These might include large-scale vegetable production with truck farms specializing in one or two crops (Lewis, Thomas, and Wooding, 1978), controlled-environment crop produc-
tion for vegetables, flowers, and bedding plants with control levels varying from conventional greenhouses to environments using controlled lighting (Lewis, Thomas, and Norton, 1978), large-scale grain and forage production, largely for the export market (Lewis and Wooding, 1978), and livestock enterprises (Husby, 1980; Lewis, 1980). Development of the agricultural potential of the Kuskokwim region to the extent suggested by these alternatives would impact land use and lifestyle. These impacts must be carefully evaluated as plans are made for expansion.

## CHAPTER II

## YIELDS AND UNIT SIZE DETERMINATION

The 1977 market demand for produce in the Kuskokwim River area was used to determine the total poundage and types of crops which will be needed to supply a major portion of this market. The area required to produce this supply, both total acreage and acreage allotted to each crop, is directly related to the yields which can be expected. To determine the marketable yields, data from the Aniak garden project, the Agricultural Experiment Station at Fairbanks, and the Cooperative Extension Service at Fairbanks were used (Dinkel and Epps, 1978; Dinkel and Ginzton, 1976; Epps, 1971; Hassinger, 1977; Lewis, Wooding and Hassinger, 1978).

After determination of the marketable yields, acreages were allotted to each crop according to consumer demand with two exceptions, onions and tomatoes. It is not certain whether onions in marginal years will mature to a size which would be adequate to withstand long storage periods (Wooding, 1978). Therefore, the maximum acreage allotted to onions was 1.7 acres, sufficient to satisfy only $7 \%$ of the market demand. The other exception, tomatoes, is produced in greenhouses. The size of the greenhouses was determined by the number of seedlings required for the field crops. The greenhouse size, therefore, is not designed to meet the tomato market demand.

Even though good field and storage management practices may be followed, losses will be sustained. This will affect the amount of produce which can be marketed. These losses have been estimated from observations of the Aniak garden project and from unpublished data obtained from the Agricultural Experiment Station, Fairbanks, Alaska (Dinkel, 1978), and the Agricultural Research Service, Palmer, Alaska (Dearborn, 1977).

Using estimates of field and storage losses, production potential, and consumer preferences, acreage was allotted to each crop within garden units. Farm units of 24 acres in Aniak and 2 acres in Red

Devil were determined to be sufficient to meet the projected 1977 market demand. The Aniak garden in 1978 produced only 6 acres of vegetable crops. Therefore, acreage allotment to crops on 6 acres was included. Expansion would probably not be directly to a 24 -acre farm. A 12-acre farm was included to allow a gradual increase to the maximum area. The information concerning the 2 -acre area can be used if smaller villages wish to begin a commercial vegetable farm venture. Details of yields, acreage allotment, field and storage losses, and marketable product are summarized in Table 1.

[^1]
## CHAPTER III

## PRODUCTION

In order to determine the cost of production for the vegetable crops, the following factors were considered:
greenhouses, machine storage, irrigation, and fencing
vegetable storage
large equipment
tillage practices
small equipment and miscellaneous field and marketing supplies
labor
seeds and seeding rates
fertilizer
herbicides and insecticides.
After these considerations, budgets were prepared for capitalinvestment cost, start-up cost, and annual operating and owner costs. In additon, a cash-flow chart was prepared for each farm size (Appendix C).

## PRODUCTION FACTORS

Greenhouses and equipment storage are used for each farm unit. The greenhouses are wood-frame construction with double-wall polyethylene covering. The size is determined by the space necessary to accommodate broccoli, cabbage, and cauliflower seedlings. Minimal shelter is provided for machinery using wood-frame construction with a galvanized, sheet-steel exterior. The buildings are not insulated and no flooring is provided (Lewis, Lewis, and Wooding, 1978). Operating costs for these buildings include that for yearly replacement of the polyethylene for the greenhouse and a cost included under miscellaneous repairs of $\$ 100$ to $\$ 300$ depending on unit size for the machinery storage.

Irrigation systems are considered an integral part of each farm unit. A drip-type system fed by river water is less expensive than most
systems and is adequate (Hassinger, 1977; Turner et al., 1971). Repairs should be minimal if the drip hoses are removed in the fall and replaced in spring. Repair costs have been included under miscellaneous repairs.

Fencing was provided for animal predator control for all farm units. The material is $2 \times 4$-inch mesh welded wire with creosote treated wooden posts and gates. Again, repair cost is anticipated to be minimal and is included under miscellaneous repairs.

Vegetable storage facilities will be required if crops are to be marketed through the winter months. Those crops which will be stored are potatoes, cabbage, carrots, onions, turnips, and rutabagas. Several types of storage facilities can be used. However, because a large portion of the Kuskokwim River drainage is on a flood plain, aboveground storage is recommended (Epps, 1971). The size of the storage area is determined by the amount of produce which the market can absorb during the storage period. Because the major production and distribution point will be Aniak, this was assumed to be the location of the largest storage facility. As production expands to the upper Kuskokwim valley, additional storage will be needed in the Red Devil area. The storage facility sizes, amounts of produce to be stored, and the location of facilities is shown in Table 2. Storage units $20 \times 20$ feet with a capacity of 50 tons are recommended. In this way, storage capacity can be easily expanded, and, if different storage conditions for various vegetable varieties are needed, these can easily be accommodated. Also, as vegetables are removed from storage, single units can be closed down. Not all vegetable varieties can be stored throughout the winter. The length of time in which the vegetables can be stored and still maintain a high quality will depend on handling and storage conditions as summarized in Table 3. The hand-

Table 2: Size and Location of Storage Areas

| Size of Production <br> Area | Amount of <br> Produce Stored | Location of <br> Storage Facility |
| :---: | :---: | :---: |

| 2 Acres | 12 T | Red Devil |

[^2]Table 3: Parameters for Vegetable Storage and Handling Procedures ${ }^{\text {a }}$

| Crop | Storage Temperature | Humidity | HandlingStorage $^{\mathrm{d}}$ <br> Period <br> (months)$\quad$Storage <br> (by weight) |
| :---: | :---: | :---: | :---: |
| Potatoes | $32-38^{\circ} \mathrm{F}$ | Moderately Moist | Storage in bulk cribs. After harvest, cure by holding in moist air for $1-2$ weeks at $60-75^{\circ} \mathrm{F}$. Before sale, hold for 2 weeks at $50-60^{\circ} \mathrm{F}$ to facilitate sugar conversion to starch. (This holding period will generally be accounted for in the retail store.) |
| Carrots <br> Turnips Rutabagas | $32-38{ }^{\circ} \mathrm{F}$ | Moist | $\begin{array}{lll}\text { Wash and dry thoroughly. The vegetables } & 6 \text { (carrots) } & 10 \% \\ \text { which are to be marketed within a 1-11/2 } & 3 \text { (turnips) } & \\ \text { month period can be stored in open bins. } & 3 \text { (rutabagas) } \\ \text { For longer storage, store in polyethylene, } & \\ \text { ventilated sacks in marketable quantities. Turnips and rutabagas give off } \\ \text { odors but can be stored with other crops.c }\end{array}$ |
| Cabbage | Near $32{ }^{\circ} \mathrm{F}$ | Moderately Moist | Cabbage should not be washed, but should be freed of dirt by removing outer leaves. <br> The heads which are to be marketed within a $1-1 \frac{1}{2}$ month period can be stored in open bins. ${ }^{\text {b }}$ For longer storage, bag individually in polyethylene bags. Cabbage should be trimmed before sale. |
| Onions | $32-38^{\circ} \mathrm{F}$ | Dry | Onions grown from sets are difficult to keep. Bag in net sacks of marketable quantities and keep in dry, well ventilated area, or place in single layer on poultry netting that is suspended in a cold, dry area. Onions should be cleaned but not washed. |

[^3]ling and storage conditions shown assume that the area has been properly cleaned by removing vegetables showing signs of decay, has adequate temperature regulation, ventilation, and moisture control, and that the vegetables have been handled in a manner which precludes spoilage-inducing damage (ARS, 1970). Operating costs include an annual repair cost of $\$ 100$ per unit under miscellaneous repairs and a fuel cost of $\$ 20$ per unit per month for four months. Details for greenhouse, irrigation system, fencing, and storage construction are given in Appendix B.

There is little information available for the Kuskokwim River area concerning use of mechanized tillage equipment. Information was drawn from other areas of Alaska and from areas in the conterminous 48 states in which smaller truck farms are the primary production units (Burlingame, 1970; Dhillon and Nickel, 19'72; Hassinger, 1977a; Wise and Carlin, 1967; Wooding and Dinkel, 1978). Equipment lists vary little for farms up to 24 acres. The major pieces of tillage equipment recommended for the Aniak area are shown in Appendix A, by farm unit size. Equipment costs include both owner and operating costs.

Owner costs for buildings and equipment include: 1) investment cost calculated as shown (Dawson Alaska Insurance Co., 1978).

$$
\text { Investment cost }=\frac{\text { New cost }+ \text { salvage }}{2}(\text { Interest Rate })
$$

with an interest rate of 7\%* and a zero salvage value, and 2) insurance at $\$ 7.00$ per $\$ 1,000$ at new value. Depreciation was calculated over five years with zero salvage value using the straight line method. Repairs and maintenance are calculated at 5\% of new cost.** Details of equipment specifications and costs are given in Appendix A.

It was assumed throughout the calculations that sound management practices will be followed which include: early spring tillage; preparation of a seed bed which is free of debris; proper weed and insect control using herbicides and insecticides applied to maintain a low weed or insect population; and a timely harvest beginning as early as mid-July for early cabbage, broccoli, and cauliflower and continuing into September. The production cost also includes a

[^4]green-manure crop. The green-manure crop recommended is spring rye, oats, common buckwheat, or annual ryegrass. It is used in a three-year rotation with potatoes to reduce losses from disease caused by soil-borne organisms. The crop is turned under while still succulent and will improve the soil's friability and moisture-holding capacity (Lewis, Lewis, and Wooding, 1978).

All small equipment is considered to be replaced at the rate of one-fourth the stock per year. Included as small equipment are field and greenhouse hand tools, vegetable crates, and pots and flats. Miscellaneous crop-care items such as twine, pot stakes, vermiculite, plant-tie ribbon, and wire are assumed to be replaced annually. A complete listing showing number of units required for each farm size, the price per unit, and unit weight is given in Appendix A. Marketing supplies include only packaging. The type, quantity, and price per unit are shown in Table 4. Cleaning equipment for carrots and potatoes was not included. The storage methods recommended and the market demand do not indicate additional cleaning will be required. As the market expands, however, it may be desirable to include a cleaning facility for these crops.

Labor estimates for a medium-size vegetable production operation which is not family owned and operated are not available in Alaska. Therefore, the labor required was calculated by combining data from the Aniak garden project with that from family farms of comparable size in the conterminous 48 states (Burlingame, 1970; Dhillon and

Table 4: Marketing Supplies (Packaging) and Price Per Unit ${ }^{a}$

|  |  | \$ 15 | \$ 39 | \$ 78 | \$ 195 |  |

[^5]Nickel, 1972; Hassinger, 1977; Wise and Carlin, 1967). On a family farm, a family member generally functions as the manager and marketing agent. Because the Kuskokwim River farms will not be family owned and operated, a grower-manager will fill this role, a major function of which will be to act as a marketing agent. Table 5 gives the details of time and wages for labor on the four farm units. Further details of the allocation of labor are shown in the cash-flow tables in Appendix C.

Seed varieties and seeding rates were obtained from local growers, Agricultural Experiment Station, Cooperative Extension Service, and Agricultural Research Service, as well as from the Aniak garden project (Dinkel and Epps, 1978; Dinkel and Ginzton, 1976; Epps, 1971; Hassinger, 1977; Washburn, 1978). The recommended varieties, rate of seeding, and seeding method are shown in Table 6. The amount of seed required for the acreage allotted to each crop within the farm unit and the price per unit are shown in Table 7.

Fertilization rates and methods of application will vary by crop (Burlingame, 1970; Dinkel and Ginzton, 1976; Loynachan, Laughlin, and Wooding, 1978). Three major categories of fertilizer application are used for the field crops. It was assumed irrigation would be available. Greenhouse and field fertilizers are those typically used in the interior of Alaska. Although recommendations have been made which would seem specific, it should be realized that soils will vary and the rates shown may require alteration for each farm location. Soils may also require applications of lime and/or phosphate. Before planting, preferably during the preceding fall, soil samples should be taken and lime requirements estimated (C.E.S., 1977; Epps, 1973; Swan, 1978). Table 8 shows the fertilizers and recommended application rates and methods. The total fertilizer requirements and prices per unit are given in Table 9. The prices quoted include air freight. If barge rates are used, the cost of fertilizer would be reduced by $30-35 \%$.

Herbicides will be required for weed control. Recommendations vary dependent on the crop and the type of weed to be controlled. It is anticipated that lambs quarter will present the greatest need for control by use of an herbicide. Table 10 lists the recommended herbicides for the Aniak area, the method and the rate of application (Swan, 1978; Turner et al., 1971). The insect problem may not be severe if levels are initially kept under control (Epps, 1973). Root maggots will probably be a problem however, even on new lands. Good sanitation and cultural practices should eliminate or keep in check undesirable populations. Table 11 contains recommendations

Table 5: Labor Requirements and Wage Rates

| Labor Category | 2 Acres |  | 6 Acres |  | 12 Acres |  | 24 Acres |  |

[^6]Table 6: Seed Varieties and Planting Recommendations

| Crop | Varieties | Spacing, Depth of Planting, Plant and Seed Requirements |
| :---: | :---: | :---: |
| Potatoes | Kennebec | Row width: 36 inches |
|  | Bake King | Seed piece or seed eye spacing within rows: 8 inches |
|  | Green Mountain | Depth of planting: 3-5 inches |
|  | Alaska Red | Seed pieces or seed eyes per acre: 21,780 |
|  |  | Average weight per seed piece: 1.75 ounces |
|  |  |  |
|  |  | Seed piece or seed eye spacing within rows: 8 inches ${ }^{\text {a }}$ |
| Cabbage | Early Marull (early) | Row width: 36 inches |
|  | Golden Acre (early) | Plant spacing within rows: 12 inches |
|  | Earliana (early) | Transplants per acre: 14,520 . |
|  | Tastie (mid-season) | 3,000 seeds per ounce |
|  | Blue Chip (mid-season) | 10 ounces of seed per acre |
|  | Hybrid 15 (mid-season) |  |
| Broccoli | Green Duke | Row width: 36 inches |
|  | Gem | Plant spacing within rows: 15 inches |
|  | Improved Green Comet | Transplants per acre: 11,616 |
|  | Southern Comet | 3,000 seeds per ounce |
|  | Green Comet Waltham 29 | 8 ounces of seed per acre |

| Cauliflower | Super Snowball | Row width: 36 inches |
| :---: | :---: | :---: |
|  | Snow Crown | Plant spacing within rows: 15 inches |
|  | Super Junior Snowball | Transplants per acre: 11,616 |
|  | Whitehorse | 3,000 seeds per ounce |
|  | Snowmound | 8 ounces of seed per acre |
| Carrots | Spartan Bonus | Row width: 15 inches |
|  | Nantes Special Long | Depth of planting: 1/4-1/2 inch |
|  | Spartan Sweet | Seed per acre: 3 pounds |
|  | Royal Chantenay | Thin to 2-3 inches between plants (if necessary). Carrots can be planted in 5 foot strips, spaced 4 foot apart to facilitate application of herbicides by tractor. |
| Onions | Yellow Sets | Row width: 18 inches |
|  |  | Depth of planting: 2 inches. Set spacing within rows: 3 inches. Sets required per acre: 116,160 |
| Turnips | Tokyo Market (Tokyo Cross) Petrowski | Row width: 18 inches |
|  |  | Depth of planting: $1 / 2-3 / 4$ inch |
|  |  | Seed per acre: 3 pounds |
|  |  | Thin to 4-6 inches between plants (if necessary) |
| Rutabagas | York <br> Improved American Purple Top | Row width: 24 inches |
|  |  | Depth to planting: 1/2-3/4 inch |
|  |  | Seed per acre: 2 pounds |
|  |  | Thin to 6-8 inches between plants (if necessary) |

[^7]Table 7: Seed Requirements ${ }^{a}$ and Prices

|  | Crop | 2 Acres | 6 Acres | 12 Acres | 24 Acres | Price Per Unit ${ }^{\text {b }}$ |  | Rate of Seeding ${ }^{\text {c }}$ |

|  | Rutabaga | $1 / 2 \mathrm{lb}$ | $1 / 2 \mathrm{lb}$ | $1 / 2 \mathrm{lb}$ | $1 / 4 \mathrm{lb}$ | $1 / 2 \mathrm{lb}$ | \$3.50 | 12 oz per acre |
|  | Green Manure Oats | 60 lbs | 210 lbs | 420 lbs | 830 lbs | 1 bu | \$10.00 | 100 lbs per acre |
|  | Tomatoes | 1 pkt. | 1 pkt . | 2 pkt . | 3 pkt . | 1 pkt . | \$.50 | 3 seeds per plant |

${ }^{\mathrm{a}}$ The amount of seeds required is for the acreage allotted to each particular crop in a garden unit. For example, the 2 -acre garden contains .6 acres of potatoes requiring $1,437 \mathrm{lbs}$. of seed at the rate of $2,395 \mathrm{lbs}$. per acre. The amounts required are based on packaging quanti$b^{\text {ties, }}$ not on fractions of the per-acre rate. For example, if $1-1 / 2 \mathrm{lbs}$. are required, a $2-\mathrm{lb}$. unit may be allocated.
1978 prices for seeds were obtained from: Stokes Seeds Inc., 737 Main Street, Buffalo, N. Y.; Burpee Seed Company, Warminister, PA.; Anne's Greenhouse, Sheep Creek Road, Fairbanks, AK.
${ }^{c}$ Seeding rates were obtained from: Henry Field Seed and Nursery Company, Shenandoah, Iowa; Agway, Inc., Seed Division, Box 1333 , Syracuse, New York. Direct field seeding rates were taken from grower recommendations. In the case of transplants, seeding rates were $\mathrm{d}^{\text {used }}$ which would give 1-1/2 times the seedlings required (assumeing that losses will occur during production and transplanting).
$\mathrm{d}_{\mathrm{T}}$ The seeding rate of 10,000 eyes per acre was used in Aniak in 1977. This seed rate was used rather than the rate suggested in Table 6 , as was the 1977 price. Yields quoted are based on these results. Seed eyes could be used the first year and potatoes for seed stored for the second year crop. If seed cannot be stored, certified seed can be obtained in Alaska at approximately $\$ .36$ per lb. f.o.b. Aniak for a cost of $\$ 865$ per acre. Caution is advised to exercise care to bring in virus-free seed and to retain seed for the following year on a very selective basis.
$\mathrm{e}_{\text {The onion seeding rate shown is for sets grown from seed in the field and stored over winter. Onions grown from sets would require }}$ approximately 900 lbs . per acre at a price of approximately $\$ 1,000$ per acre f.o.b. Aniak.

# Table 8: Fertilizers and Recommended Application Rates and Methods 

| Crop | Fertilizers |
| :---: | :---: |
| Potatoes ${ }^{\text {a }}$ | 1,250 pounds per acre of 10-20-20 mixed fertilizer (specify that potassium in the $10-20-20$ is supplied as sulphate of potash). Fertilizer is banded 2 inches to each side and slightly below the seed piece with a planter having a fertilizer attachment or when planting by hand. |
| Cabbage | 1,000 pounds per acre of $10-20-20$ mixed fertilizer (specify that potassium in the $10-20-20$ is supplied as sulphate of potash) broadcast in spring and incorporated into the soil during seed bed preparation. 90 pounds per acre of urea (45-0-0) applied as a side dressing 4-5 weeks after transplanting. To avoid leaf burning, immediately follow side dressing with irrigation. |
| Broccoli | Same as for Cabbage. |
| Cauliflower | Same as for Cabbage. |
| Carrots | 900 pounds per acre of 10-20-20 mixed fertilizer (specify that potassium in the 10-20-20 is supplied as sulphate of potash) broadcast in the spring and incorporated into the soil during seed bed preparation. |
| Onions | Same as for Carrots. |
| Turnips | Same as for Carrots. |
| Rutabagas | Same as for Carrots. |
| ${ }^{\mathrm{a}}$ An alternativ remaining be amount of when bandin | banding fertilizer is to broadcast prior to planting. Broadcast fertilizer the rows is then rolled onto the hill during hilling. Furthermore, the applied in this manner could be increased up to twice the amount used no damage to the crop (Logsdon, 1979). |

Table 9: Fertilizer Requirements ${ }^{\mathrm{a}}$ and Prices

| Crop | 2 Acres | 6 Acres | 12 Acres | 24 Acres |  | Price Per Unit ${ }^{\text {b }}$ | Rate of Application |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Potatoes ${ }^{\text {c }}$ |  |  |  |  |  |  |  |
| $10-20-20 \mathrm{w} / \mathrm{K}$ as sulphate of potash | 750 lbs | 2,625 lbs | 5,250 lbs | 10,375 lbs |  | 17.30 per 50 lb | 1,250 lbs/A |
| Cauliflower, Broccoli, Cabbage |  |  |  |  |  |  |  |
| $10-20-20 \mathrm{w} / \mathrm{K}$ as sulphate of potash | 550 lbs | 2,100 lbs | 3,500 lbs | 7,000 lbs | \$ | 17.30 per 50 lb | $1,000 \mathrm{lbs} / \mathrm{A}$ |
| 45-0-0 (Urea) | 50 lbs | 189 lbs | 315 lbs | 630 lbs |  | 480.00 per ton | $90 \mathrm{lbs} / \mathrm{A}$ |
| Carrots, Turnips, |  |  |  |  |  |  |  |
| $10-20-20 \mathrm{w} / \mathrm{K}$ as sulphate of potash | 585 lbs | 1,620 lbs | 3,870 lbs | 7,830 lbs |  | 17.30 per 50 lb | $900 \mathrm{lbs} / \mathrm{A}$ |
| Green Manure |  |  |  |  |  |  |  |
| 45-0-0 (Urea) | 50 lbs | 210 lbs | 420 lbs | 830 lbs |  | 480.00 per ton | $100 \mathrm{lbs} / \mathrm{A}$ |
| Seedlings ${ }^{\text {d }}$ |  |  |  |  |  |  |  |
| 10-52-17 | 3 lbs | 9 lbs | 18 lbs | 361 bs |  | 3.98 per 3 lb . |  |
| Tomatoes ${ }^{\text {e }}$ |  |  |  |  |  |  |  |
| 10-52-17 | 7 lbs | 24 lbs | 48 lbs | 96 lbs |  | 46.83 per 45 lb | $10-3 / 4 \mathrm{lb} / 100 \mathrm{ft}^{2}$ |
| 0-46-0 | 2 lbs | 7 lbs | 14 lbs | 28 lbs |  | 17.90 per 50 lb | $3 \mathrm{lb} / 100 \mathrm{ft}^{2}$ |
| $\mathrm{MgSO}_{4}$ | $1 / 4 \mathrm{lb}$ | $1 / 2 \mathrm{lb}$ | 1 lb | 2 lb | \$ | 3.25 per 5 lb | $1 / 4 \mathrm{lb} / 100 \mathrm{ft}^{2}$ |

[^8]Table 10: Herbicide Rates and Methods of Application

| Crop | Herbicide | Method of Application | Rate of Application |
| :---: | :---: | :---: | :---: |
| Potatoes | SENCOR (metribuzin) (cole crops are sensitive) PREMERGEa | Pre- and early post-emergence, broadcast or banded. <br> Preemergence, with conventional sprayer. | $.5-1 \mathrm{lb} / \mathrm{A}$ in $10-40$ gal. water. Avg. half life: 40-50 days. $7.5 \mathrm{qts} / \mathrm{A}$ in $50 / 100 \mathrm{gal}$. water. ${ }^{\text {a }}$ |
| Cabbage <br> Broccoli <br> Cauliflower <br> Turnips <br> Rutabagas | DACTHAL <br> (dimethyl tetrachloroterephthalate) | Preemergence, to weeds, with conventional sprayer. | 4-10 lb/A in 25-50 gal. water. Avg. half life: 100 days. |
| Carrots Onions | LOROX (linuron) | Pre- or postemergence, sprayed on soil without surfactant controls. Emerged grasses to 2 in., broadleaf weeds to 6 in. | .5-3 lbs/A in sufficient water to cover area. Phytotoxic concentrations disappear in 4 months. ${ }^{\text {c }}$ |
| Carrots Onions | TENORAN (chloroxuron) (cole crops may be sensitive) | After weed emergence and before 2 in . high with conventional sprayer. | $6-8 \mathrm{lbs} / \mathrm{A}$ in $25-40 \mathrm{gal}$. water. Breaks down in sandy-loam at $35 \%$ loss in 8 weeks. |
| Cabbage <br> Broccoli Cauliflower | CDEC | Preemergence, soil surface with ground sprayer. Apply to transplants prior to weed emergence. | $2-6 \mathrm{lbs} / \mathrm{A}$ in 25-40 gal. water. Persists generally $3-6$ weeks. ${ }^{\text {a }}$ |

[^9]Table 11: Insecticide Rates and Methods of Application

| Crop and Insect | Insecticide | Method of Application | Rate of Application |
| :---: | :---: | :---: | :---: |
| APHIDS ${ }^{\text {a }}$ <br> Broccoli Cauliflower Cabbage Carrots Tomatoes | Diazinon AG-500 (EC) | Spray at first sign of insects. Repeat as necessary to maintain control. | 1/2-1 pt./A at 7-10 day intervals within 5-7 days of harvest. 1 pt ./A to within 10 days of harvest. <br> 1/2 pt./A. |
| CUTWORMS <br> Broccoli <br> Cauliflower <br> Cabbage | Diazinon AG-500 <br> (EC) | Broadcast just prior to planting. Work into soil 3-4 in. <br> Side dress after planting with directional nozzle. | 2-4 qts./A. ${ }^{\text {b }} 1$ replanting treatment only. |
| ROOT MAGGOTS | Diazinon AG-500 (EC) | Broadcast as for cutworms. | As for cutworms. $1 / 4$ to $1 / 2 \mathrm{pt}$. in 50 gal . of water. |
| Broccoli Cauliflower |  | Transplant water $1 / 2$ to 1 cupful per plant with drop nozzle. |  |
| Cabbage |  | Spray with drop nozzle to plant soil root area. | 1 pt / $/ \mathrm{A}$ at 10 -day intervals. $4-5$ applications per season. |

[^10]from the Agricultural Experiment Station at Fairbanks and Agricultural Research Service at Palmer. Costs of herbicides and insecticides are variable. For example, Premerge and Diazinon are approximately $\$ 30$ per gallon f.o.b. Aniak. However, on new lands there should not be a weed problem for several years if good cultivation practices are followed. There will, however, be a root maggot problem for the cole crops. A cost of $\$ 5$ per acre for insecticides and herbicides should be adequate on new lands for the first several years. However, this could increase to as much as $\$ 50$ per acre for previously cropped lands or for lands on which good cultivation methods are not used.

## PRODUCTION COSTS

All budgets and the yearly cash flow statements (Appendix C) were prepared considering the production inputs discussed in the preceding paragraphs. Even though one tractor and some tillage implements are already available in the Aniak area and more are on order, these were included in the capital costs in order to provide a better indication of the total investment for all farm units.

Five major categories have been included as capital investments. These are: major implements, small implements, buildings, fencing,

Table 12: Capital Investment Cost

|  |  | 2 Acres |  | 6 Acres |  | 12 Acres |  | 24 Acres |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Major implements |  |  |  |  |  |  |  |  |
| Tractor unit | \$ | 3,580.64 | \$ | 5,000.00 | \$ | 5,000.00 |  | 9,971.00 |
| Tillage |  | 3,397.21 |  | 6,618.39 |  | 6,618.39 |  | 9,714.72 |

| TOTAL |  | 19,478.17 |  | 35,925.03 |  | 48,556.84 |  | 72,653.65 |

and irrigation. All costs shown are for new equipment. Prices are f.o.b. Aniak. Table 12 details the capital cost for each farm unit. Start-up costs, shown in Table 13, are those which will be incurred during the first year of operation before production can begin. Details are given in Appendix A.

The annual budgets for a typical year of operation are given in Tables 14 through 17 for each farm unit. The costs are broken down into two major categories: owner costs which would be incurred whether the farm were in production or not, and operating costs which are incurred only if the farms are operating. Each of the categories include both production and marketing costs. It should be noted that a land lease cost has been included under owner cost. Land in Aniak is currently leased at a charge of $\$ 100$ per year for 6 acres. This charge will not continue when Kuskokwim Native Association land is used.

Table 13: Start-Up Costs (excluding capital costs)

|  | 2 Acres | 6 Acres | 12 Acres | 24 Acres |
| :---: | :---: | :---: | :---: | :---: |
| Field |  |  |  |  |
| Seed ${ }^{\text {a }}$ | \$ 308.62 | \$ 881.03 | \$ 1,708.31 | \$ 3,404.33 |

## CHAPTER IV

## SIZE AND EXTENT OF THE MARKET

To determine the size and extent of the market in the Kuskokwim River area, production capability and market potential were considered. There are limitations in both categories. General factors that limit production capability are climate, manpower availability, land availability, transportation, investment capital, and management expertise. The market potential of the Kuskokwim River basin area, from Stony River to Bethel, is limited by population and accessibility. On the other hand, the area has sufficient population to generate a demand for a vegetable production unit larger than that currently located in Aniak.

## MARKET STRUCTURE

The marketing area has been divided into three distinct units due to the difference in anticipated market share, geographic location, transportation, and population. These units will be referred to as the Aniak area, Bethel area, and Red Devil area. The composition of each of these units is shown in Table 18.

The natural separation of the population into up-river and downriver areas indicates that product distribution would be best facilitated if production and storage were located in the Aniak area to service the Aniak and Bethel areas, and in the Red Devil area for upriver distribution. From these locations, $80 \%$ of both the Aniak and Red Devil area markets could be captured. This is not the case in the Bethel area, which is split into two distinct marketing units: 1) the city of Bethel and 2) the outlying communities and villages. The city of Bethel has three main stores serving approximately $60 \%$ of the population. An estimated goal is to capture $50 \%$ of this market. Access to the outlying communities and villages requires transfer of goods in Bethel. A high rate of loss could be incurred during transfer particularly during the winter months. Therefore, it is suggested that

Table 18: Marketing Area Populations, Stores, and Runways

|  | Population $^{\text {a }}$ | Major Stores | Runway |
| :--- | :---: | :---: | :---: |

| Sleetmute | 270 | $\frac{1}{3}$ | yes |
| Red Devil |  |  | 3 |
| TOTAL |  |  |  |

${ }^{\text {a }}$ Approximate, Orth, 1971.
no attempt be made to meet more than $35 \%$ of the market demand in the outlying areas. The two marketing units within the Bethel area represent a potential market for $44 \%$ of the produce from Aniak. Total market estimates indicate the gardens in the Aniak and Red Devil areas would supply approximately $50 \%$ of the vegetable market in the Kuskokwim River basin. The size of each market area and the market goals are shown in Table 19.

Table 19: Size and Extent of Market by Area

|  | Population (est.) | Market Goal (\% of product) |
| :--- | :---: | :---: |
| Aniak Area | 986 | 80 |
| Bethel Area | 5,833 | 44 |
| Red Devil Area | 272 | 80 |

Tables 20a and 20b show the supply for all areas for each farm size indicated. It should be noted that to generate the maximum market supply two units are used, 24 acres in Aniak and 2 acres in Red Devil.

## PRODUCT PREFERENCES OF CONSUMERS

Since consumption patterns and consumer demand within the Kuskokwim River region may be somewhat unique, demand patterns as related to other areas prove to be of little value. Therefore, a survey of stores in the Aniak and Bethel areas, discussions with the Aniak garden project manager, residents of the three areas, and information from the Cooperative Extension Service in Bethel were used to determine preference patterns. These preference patterns are shown in Table 21.

The consumer ranking of vegetables by preference is not the same as the amount of each crop produced. For example, cabbage is preferred by consumers over carrots, but more carrots were produced. The rank of products purchased also differs from those preferred. Some products are either not available in area stores or are of such poor quality that they are not purchased. Table 22 illustrates the total consumption of each vegetable type in number of pounds consumed.

## Market Outlets

There is no wholesale outlet for produce in the Kuskokwim River region. All produce is shipped from either Anchorage or Seattle. It is suggested that the produce from the Aniak and Red Devil areas be marketed at wholesale only. Operating either as or through a wholesale distribution outlet, the farm manager could establish and maintain an orderly flow of product, more easily forecast future demand, and minimize handling of the produce. Retail outlets could be serviced not only through standing orders but on an immediate demand basis.

There may be only one exception to sales only to retailers. In some cases, damaged produce or harvest from experimental crops could be cleared by selling direct to the consumer. However, retail outlets should be given the option to accept this type of product at a lower cost before such disposal is made.

## CHAPTER V

## TRANSPORTATION

The mode of transportation used in delivering the produce from the point of production or storage into the hands of the retail outlets will be an important influencing factor not only in scheduling but also in the determination of type of storage crops marketed during the winter months. Aircraft are the main source of transportation in the area. This mode of transportation is the most economically desirable, in terms of expediency, price, and dependability. However, the limitations as well as the benefits of air transport must be realized. The factors to consider in air transportation are temperature, scheduling and area location, load capacity, and transportation cost.

There are very few villages that are not accessible by air. Some of these areas require double handling of the product in transfer from larger to smaller aircraft. This increases the possibility of damage as well as cost. To minimize damage as much as possible, retail outlets must be made aware of delivery schedules and any deviation which may occur. Carriers as well must be aware of the perishability of the product.

Capacity of the different types of prop-type aircraft used within the Kuskokwim valley area varies from 1,000 to 1,400 pounds. Freight is generally carried on a space-available basis. An understanding with the carrier concerning acceptable poundage and packaging must be reached in order to schedule regular deliveries.

Land transportation is available during the winter months from the closer outlying communities and may substitute for air deliveries to a limited extent. This may eliminate some of the handling problems associated with air transportation and provide savings which, hopefully, will be passed on to the consumer. However, if produce is not protected, freezing may induce spoilage and greater damage than transport by air freight.

Because there is a risk of damage to the produce whether it is shipped by air or overland, there must be a clear policy concerning
responsibility for damage. Traditionally, in wholesale operations, when the produce leaves the wholesale outlet it is the responsibility of the purchaser. The wholesaler, however, should accept responsibility if the packaging is found faulty. All freight costs will be paid by the retail outlets and eventually passed on to the consumer. Applicable freight rates are shown in Table 23. The main purpose for calculating these rates is to aid the retailer in establishing a pricing policy and indicate to the producer a possible forward price.

## CHAPTER VI

## PRICING POLICY

The continued operation of any business is dependent upon a return which covers the costs of production. If returns fall below operating cost for several consecutive years and predictions for future years do not indicate a change, the business will, by necessity, shut down. On the other hand, if the returns do exceed operating cost, the excess will be applied to owner cost. If returns cover both owner and operating cost, the business will break even. It is only when returns exceed operating and owner cost that a return on investment will be realized.

With these points in mind, several questions must be considered when establishing a market price:

- Is it possible to establish and receive a market price which will generate a positive cash flow and provide a reasonable return on investment?
- If a return on investment cannot be realized, can the revenue received cover operating costs?
- Can a price be established which will, at least, cover operating cost and stimulate demand for the product to such an extent that the target market share will be realized?
- Can pricing policy be structured in such a way that a savings to the consumer can be realized?
Considering these questions, suggested wholesale prices plus transportation were established for each vegetable crop (Table 24).

The operating cost per pound of produce is reduced as the size of farms increases. The 24 -acre farm was used to establish a product cost. The Bethel area, with its large population, several retail outlets with established pricing policies, and an additional transportation cost for produce shipped to these retail outlets was selected for use in establishing wholesale prices for the Kuskokwim River area farms. The Bethel area was also used to suggest prices for retail outlets which will be selling produce from the Kuskokwim River area farms.

[^20]
## ESTABLISHING PRODUCT COSTS

Costs for producing each of the field vegetable types were determined by assuming all inputs would be similar except fertilizers, seeds, market packaging, storage, and labor associated with non automated procedures. The costs of these various inputs were added to the remaining base cost to obtain an operating cost of production for each vegetable type. This cost was then added to the owner cost to obtain a total production cost shown in Table 25. It was assumed that the same percentage of owner cost would be assigned to all vegetable types.

It should be noted that depreciation, a noncash cost, makes up approximately $85 \%$ of the owner cost. An average investment cost which assumes a five-year loan at $7 \%$ interest for equipment and building purchases makes up approximately $14 \%$ of owner costs. If purchases are made without assuming a loan, this cost would be eliminated. The owner cash cost remaining would be the land lease which was charged at the rate of $\$ 16.67$ per acre ( $\$ 100$ per 6 acres). Therefore, if noncash costs (depreciation) are not considered and no loans are assumed, the owner cost would be approximately $1 \%$ of that shown in Table 25.

## Suggested Wholesale Prices

Wholesale prices for Kuskokwim River produce were established using 1977 average Anchorage wholesale prices as baseline data. Anchorage wholesale prices and suggested prices f.o.b. Aniak are shown in Table 26. If the production costs are assumed to be cash

Table 26: Anchorage Wholesale Prices and Suggested Wholesale Prices F.O.B. Aniak (\$/b)

| Product | Aniak | Anchorage |
| :--- | ---: | :---: |
| Potatoes | $\$ .15$ | $\$ .13$ |
| Carrots | $\$ .25$ | $\$ .28$ |
| Cabbage | $\$ .25$ | $\$ .25$ |
| Onions | $\$ .25$ | $\$ .16$ |
| Turnips | $\$ .25$ | $\$ .26$ |
| Rutabagas | $\$ .25$ | $\$ .29$ |
| Broccoli | $\$ .40$ | $\$ .40$ |
| Cauliflower | $\$ .50$ | $\$ .50$ |
| Tomatoes | $\$ .95$ | $\$ .69$ |

Table 27: Expected Gross Sales and Returns for a 24-Acre Farm

| Product | Suggested Selling Price (\$) | Marketable Produce (lbs.) | Expected Gross Sales ( $\$$ ) |
| :---: | :---: | :---: | :---: |
| Potatoes | \$. 15 | 183,763 | \$ 27,564 |
| Carrots | \$. 25 | 90,356 | 22,589 |
| Cabbage | \$. 25 | 86,244 | 21,561 |
| Onions | \$. 25 | 16,660 | 4,166 |
| Turnips | \$. 25 | 32,110 | 8,027 |
| Rutabagas | \$. 25 | 34,505 | 8,626 |
| Broccoli | \$. 40 | 35,125 | 14,050 |
| Cauliflower | \$. 50 | 28,272 | 14,136 |
| Tomatoes | \$. 95 | 2,646 | $\begin{array}{r} \$ 120,719 \\ 2,514 \end{array}$ |
|  |  |  | \$123,233 |
| Less operating cost |  |  | 86,988 |
| Return |  |  | \$ 36,245 |

costs only and purchases of equipment and buildings do not necessitate loans, the suggested Aniak prices result in a $14 \%$ return on investment. Table 27 shows the return which could be expected from a 24-acre farm using the suggested wholesale prices f.o.b. Aniak.

It is of interest to determine if the suggested Aniak wholesale price would result in a savings to the consumer. To make this determination, it was assumed that the Bethel merchants who would be handling Kuskokwim River produce would maintain the mark-ups over wholesale cost plus freight which are now being used for Anchorage produce. Table 24 illustrates Bethel retail prices, retail margins, suggested future retail prices and possible savings to consumers.

## CHANGES IN EXPECTED REVENUES

There are two major changes which could alter the expected gross revenue. The onion crop may be eliminated, and a 2 -acre farm in the Red Devil area could be producing vegetables at the same time a $24-$ acre farm in the Aniak area were in production.

Onion production costs are high because of the small acreage allotted to production of this crop. If, due to storage and product maturity limitations, onion production does not prove feasible, it is suggested that the area allotted for onion production be switched to broccoli. This would increase the return by approximately $\$ 5,274$ for a total of $\$ 41,519$.

Table 28: Red Devil Area Suggested Wholesale Prices and Expected Returns for 2 Acres, 24 Acres, and 2 Plus 24 Acres

| Product | Suggested <br> Wholesale Price <br> $(\$ / \mathrm{lb})$ | Marketable <br> Produce <br> $(\mathrm{lb})$ | Expected <br> Returns |
| :--- | ---: | ---: | ---: |
| Potatoes | .23 | 13,284 | $\$ 3,055$ |
| Carrots | .33 | 5,893 | 1,945 |
| Cabbage | .33 | 5,096 | 1,682 |
| Onions | .33 | 1,960 | 647 |
| Turnips | .33 | 1,975 | 652 |
| Rutabagas | .33 | 1,882 | 621 |
| Broccoli | .48 | 3,763 | 1,806 |
| Cauliflower | .58 | 1,697 | 948 |
| Total Sales for 2 Acres |  |  | $\$ 11,356$ |
| Production Cost for 2 Acres |  |  | $\underline{25,302}$ |
| Returns for 2 Acres |  |  | $\mathbf{( \$ 1 3 , 9 4 6 )}$ |
| Returns for 24 Acres |  |  | $\$ 22,245$ <br> Returns for 2 plus 24 Acres |

${ }^{\mathrm{a}}$ Suggested wholesale price is the Aniak wholesale price plus freight at $\$ .08$ per pound.
If the 2 -acre farm in the Red Devil area is operated in conjunction with the 24 -acre farm in the Aniak area and vegetables are sold in the Red Devil area at Aniak wholesale price plus transportation ( $\$ .08$ per pound), the gross revenue for the combined operation will be reduced (see Table 28). As indicated in Table 25, production costs on the 2-acre plot exceed the anticipated wholesale price received in Aniak for all vegetable types.

Although the returns from a combined operation are lower than those from the 24-acre unit, there is justification for the 2 -acre farm in the Red Devil area. Transportation services to this up-river community are such that high losses of produce may be sustained in shipment from Aniak. This physical limitation is considered adequate reason for producing and storing vegetables in Red Devil. If the 2acre farm is regarded as the beginning phase of a development of larger acreage in the Red Devil area, this would also provide a justification for sustaining lower returns to the combined operation during the development years.

## CHAPTER VII

## FINAL THOUGHTS AND SUGGESTED DEVELOPMENT APPROACH

This evaluation of the agricultural development of the middle Kuskokwim River valley has been concerned with field production of vegetable crops on medium-sized truck farms. The objective of the study was to provide as many answers as possible to questions concerning cost of producing vegetables; location and size of farms; location, type, and size of storage facilities; products preferred by consumers; size and extent of the market; transportation of produce; and pricing and marketing policy. The final question: Will the market price established be such that a reasonable market share can be captured and a positive cash flow and reasonable return on investment be realized?

The following answers are derived from an analysis of data collected in the Kuskokwim area, from other regions of Alaska applicable to the Kuskokwim valley, and from the conterminous 48 states which apply to farm size, labor availability, and production practices.

## FINAL THOUGHTS

As can be seen from Table 29, the costs of production decrease as farm size and automation level increase. Using this information, crop production information, 1977 population distribution in the Kuskokwim River valley, and schedules and routes of air carriers, the most favorable locations for vegetable farms were termed to be in the Aniak and the Red Devil areas. The Aniak farm could be expanded to 24 acres while the Red Devil area farm would best be limited to 2 acres. The Red Devil area farm should be regarded as the beginning of a vegetable production development program for the upper Kuskokwim River region. Therefore, the lower returns realized by operating the 2 - and 24 -acre farms will be sustained only over the development period.

Table 29: Cost of Producing Crops (\$/lb)

| Crop | 2 Acres | 6 Acres | 12 Acres | 24 Acres |
| :--- | :---: | :---: | :---: | :---: |
| Potatoes | .50 | .35 | .24 | .13 |
| Carrots | .71 | .50 | .35 | .20 |
| Cabbage | .33 | .23 | .16 | .10 |
| Onions | 1.30 | .91 | .64 | .40 |
| Turnips | .49 | .34 | .24 | .16 |
| Rutabagas | .38 | .27 | .19 | .14 |
| Broccoli | 1.14 | .79 | .56 | .28 |
| Cauliflower | .86 | .60 | .42 | .22 |
| Tomatoes | 1.83 | 1.46 | 1.17 | .94 |

Storage facilities will be needed for potatoes, carrots, cabbage, onions, rutabagas, and turnips. Because much of the Kuskokwim area is on a flood plain, above-ground storage is recommended. Storage would be in the form of $20 \times 20$-foot module units, each with a capacity of 50 tons. The storage units should be located at the sites of vegetable production with a 200 -ton (4-unit) capacity at Aniak and a 50 -ton (1-unit) capacity in the Red Devil area.

The marketing area for the Kuskokwim region extends along the Kuskokwim River from Stony River to Bethel and surrounding communities. Geographic location, population distribution, and transportation routes serve to divide the area into three distinct marketing units: the Aniak area, the Bethel area, and the Red Devil area. It was assumed that Kuskokwim River produce sold through retail outlets would capture only a part of the market in each area. The Bethel area could be supplied at a rate of $44 \%$ by weight of the produce now imported. Both the Aniak and Red Devil areas, on the other hand, could be supplied up to $80 \%$ by weight. Some vegetable varieties which cannot be produced in these two areas would still be imported.

Consumers in the Kuskokwim region showed distinct product preferences, which however, varied from those actually purchased. The lack of good-quality produce of various types in local markets was given as the major reason for this discrepancy. With a reasonable size truck farm in the area, the available produce should come closer to satisfying the demands of the consumer in terms of preference as well as quality.

Aircraft are the main source of transportation in the Kuskokwim basin. All but five villages have airstrips accessible by either regularly scheduled commercial air service or by small, private carriers operating on a demand basis. Because of existing scheduled service, air trans-
port is most appropriate for delivery of produce. In addition, losses due to spoilage or damage would undoubtedly be less than if some other form of carrier were used.

Production from the Aniak and Red Devil farms can be most effectively handled through a wholesale outlet. Local truck farms could provide a steady flow of high-quality, selected products to area retailers through 8 months of the year. A transportation cost advantage could be realized through purchases from a local wholesaler. The 24-acre truck farm can be used to supply retailers at wholesale prices comparable to Anchorage wholesale price. Production costs for the 24-acre farm, suggested prices f.o.b. Aniak, and 1977 Anchorage wholesale prices are shown in Table 30.

If retail stores maintain their present mark-up over Anchorage wholesale prices plus freight when pricing Kuskokwim River produce, consumers should realize a slight benefit in lower market price. Therefore, a reasonable market share should be attained by Kuskokwim River producers. At the wholesale prices suggested, a return to investment of approximately $14 \%$ can be anticipated. Assuming that a schedule of closing of accounts receivable from produce marketed is maintained, farms and the wholesale outlet should operate with a positive cash flow.

The assumption is made that the goal when entering the vegetableproduction industry is to attain the largest appropriate production area as rapidly as possible. It is cautioned that a grower-manager, new to the area, will need time to gain experience, that new lands must be brought into production, and that there will be a period during which soil conditions will not be stable. Expansion of production should not be so rapid that quality of the produce is sacrificed or that the marketing system and marketing experience is over-extended.

## SUGGESTED DEVELOPMENT APPROACH

It has been shown by the estimates made in this report that production and marketing of vegetable crops is economically feasible in the Kuskokwim River basin. Although other industries unrelated to agriculture may also be feasible, this discussion will be limited to those alternatives which are within the agricultural category.

Development of the agricultural potential of the Kuskokwim region would have a large impact on land use and on the current lifestyle of area residents. Because land use and lifestyle are very important factors in planning development alternatives, those alternatives

Table 30: Suggested Wholesale Price

| Crop | Production Cost <br> 2 Acres <br> Red Devil | Production Cost <br> 24 Acres <br> Aniak | Wholesale Price F.O.B. Aniak | Wholesale <br> Price F.O.B. <br> Red Devil | Wholesale <br> Price F.O.B. <br> Anchorage |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Potatoes | \$ . 50 | \$. 13 | \$. 15 | \$ . 23 | \$. 13 |
| Carrots | \$ . 71 | \$. 20 | \$. 25 | \$ . 33 | \$. 28 |
| Cabbage | \$ . 33 | \$. 10 | \$. 25 | \$ . 33 | \$. 25 |
| Onions | \$1.30 | \$.40 | \$. 25 | \$ . 33 | \$.16 |
| Turnips | \$ . 49 | \$. 16 | \$. 25 | \$ . 33 | \$.26 |
| Rutabagas | \$ . 38 | \$. 14 | \$. 25 | \$ . 33 | \$. 29 |
| Broccoli | \$1.14 | \$. 28 | \$. 40 | \$ . 48 | \$. 40 |
| Cauliflower | \$ . 86 | \$.22 | \$. 50 | \$ . 58 | \$.50 |
| Tomatoes | \$1.83 | \$.94 | \$.95 | \$1.83 | \$. 69 |

having the greatest impact on these factors must be carefully evaluated. The agricultural alternatives considered here are large-scale vegetable production, controlled-environment crop production, grain and forage production, and livestock enterprises.

## Large-Scale Vegetable Production

The 24-acre production area detailed in this report is a diversified operation which is centrally located and relies on existing transportation corridors. Expansion into larger areas would imply the use of truck farms which specialize in one or two crops. There would be a need for a more complex agribusiness infrastructure including equipment service centers, storage facilities, a wholesale marketing agency, and a labor pool. The crops produced would be directed toward specific markets, a large portion of which would be outside the Kuskokwim River basin. Therefore, except for high value, perishable vegetable products, modes of transport other than air freight would have to be utilized.

Based on these premises, a large-scale vegetable production operation would require the development of service centers in urban areas with farming operations in close proximity. In the Kuskokwim area, these would in all probability be located in Bethel and Aniak with farming development up-river from Aniak. Entry to markets outside the Kuskokwim area for specific vegetable crops would be necessary. Immediate market expansion would most likely be to Holy Cross and St. Mary's which would present a diversified market. However, the Seward Peninsula, the McGrath-Galena area, and the Anchorage area would be possible outlets for field lettuce, broccoli, cauliflower, and potatoes. Additional transportation corridors including surface routes would have to be utilized. Potatoes in large quantities should be transported by surface carriers. Broccoli and cauliflower, although higher-value crops, could also be carried by surface transportation. Lettuce, a high-value, perishable crop could be transported on existing air carriers.

## Controlled-Environment Crop Production

The controlled-environment crop-production industry includes greenhouses ranging from simple polyethylene-covered frame houses to heated and supplementally lighted houses. Also included are totally controlled environments using no sunlight and controlled air
quality. Produced in these environments are generally high-value crops such as salad vegetables, flowers, and bedding plants. The infrastructure requirements for the industry include scheduled transportation services for perishable products, storage facilities emphasizing controlled cooling, and provision of power at rates comparable to or less than average rates in Alaskan urban communities. Off-peak lighting would be a potential where rates are substantially higher than feasible for operation around the clock.

The greenhouses discussed in this report are primarily used for seedling production. A tomato crop is recommended for production to utilize the available greenhouse space after the bedding plant season and to provide a high-quality product to local buyers. The facilities are not of a size which would allow production of tomatoes at a cost low enough to provide a positive margin over operating cost. It has been shown, however, that facilities approaching an acre in size can operate with a positive return over total cost of production of a tomato crop (Lewis and Thomas, 1977). The market in the Kuskokwim River basin could support an operation of this size producing largely tomatoes, with a minimal crop mix of cucumbers and peppers. The facility suggested for use is a double-wall, polyethylene-covered wood- or tubular steel-frame structure. Heating would have to be provided to extend the growing season to five to eight months. In addition, cooling facilities which could maintain temperatures near $50^{\circ} \mathrm{F}$ would be necessary for crop storage (Dinkel, 1978). In combination with the greenhouse, field lettuce could be grown. This crop would utilize the same storage and transportation facilities. The existing air-freight service is considered adequate for the system outlined.

If expansion beyond a one-acre, greenhouse-field lettuce operation is considered, the infrastructure requirements would include the development of service centers which would be similar to and located in the same areas as those for the large-scale truck farms. Markets outside the area would be necessary for salad crops. These would undoubtedly differ little from those for large-scale truck farms. A heavy emphasis on regular transportation schedules for perishable products is an important requirement as is available power at commercial rates if any form of lighting is to be used in production of the crops.

## Grain and Forage Production

Historically, grain and forage production have been considered either as large-scale units producing in an area large enough to make processing, storage, and marketing of the product an economically feasible operation (Lewis and Wooding, 1978; Thomas and Carney, 1978) or, smaller units producing grain and forage for a livestock industry which is located with a reasonable proximity to this feed base (Burton, 1971). In terms of land availability, either type of production is conceivable in the Kuskokwim River drainage. However, before such development can begin, the required support services must be considered.

Projections have been made for utilizing land blocks up to 2.3 million acres in the Yukon-Porcupine region (Lewis, Thomas, and Wooding, 1978). The product is intended largely for export to the Pacific Rim countries. The Yukon-Porcupine report summarizes the necessary support services, including: a road system connecting producers to country and terminal elevators, grain elevators, and dryers for processing and storage; power service for farmsteads; service support for machinery sales and service; and a transport system to bring the processed grain to tidewater.

The Kuskokwim region, with a deepwater port at Bethel could provide ready access to tidewater. Not as much land is available as in the Yukon-Porcupine flats. However, it is estimated that 50,000 acres in dryland grain production is a sufficient land mass to produce marketable quantities of grain for export once a marketing system is in place (Lewis and Wooding, 1978). Although markets are available for Alaskan grain, it is doubtful that market prices balanced against production and transportation costs will attract investors to remote areas which do not have existing transportation corridors to tidewater ports (Thomas and Carney, 1978).

Grains and forage produced for local consumption as feed or as food may be a viable enterprise for the Kuskokwim basin. Production costs for grains on 200 and 800 acres in remote areas have been calculated and the operations would seem viable when the costs are compared to prices of imported feed (Lewis, Thomas, and Wooding, 1978). The Stony River area of the upper Kuskokwim could provide up to 10,000 acres which could be used for small-grain and forage production. The Kuskokwim River provides a natural transport system to all points including Bethel. Markets for the grain and
forage would certainly include any livestock producers. However, the market for food barley should not be ignored.

Before a venture of this type is considered, it must be realized that grain-drying and holding facilities will be needed; barley-pearling, rolling, or grinding equipment will be required for the food barley market; and forage-handling equipment and storage should be available. With these realizations, the grain and forage production industry may be a viable venture for consideration in the near future.

## Livestock Enterprises

No attempt has been made to evaluate thoroughly the potential for livestock production in the Kuskokwim basin. Burton (1971) discusses livestock production in southwestern Alaska and presents 1967 cost data. However, this information applies only to Kodiak, Kenai, and the Aleutian chain. More relevant, perhaps, is the interest shown by the Kuskokwim Native Association for development of the Stony River area as an area for livestock production. Historical information indicates that hogs were the most successful as a meat animal in the area. Cattle were raised, but overwintering was a problem. In recent years, a community of homesteaders has also been successful with small numbers of poultry. There is an indication that a heavier reliance on imported meat products will be a trend in the future. Therefore, a local source of these products would be an advantage to area residents both in price and fresh quality.

Although there is no quantitative data available concerning animalcarrying capacity of the range in the Stony River area, animal production (hogs, cattle, sheep and goats) using this range in combination with locally produced grains and forage may be a success. Indications are that a major factor in the success of a meat production venture would be the availability of a good quality feed during the winter months. This could be provided if adequate drying and storage facilities are available.

The question of processing for a meat industry will not be addressed here except to mention that economies of scale do not indicate the viability of a full-scale processing plant in the near future. However, the sale of live animals would be within state of Alaska meat-processing requirements, and a custom-exempt slaughter facility in which purchaser owned animals are slaughtered without inspection
could be used. The minimal facilities used require Division of Agriculture approval and products must be labeled "not for sale."

Indications are that agriculture will play a major role in the development scenario of the Kuskokwim River valley. If development takes place in an haphazard manner, the impact may not be positive. The considerations for the future presented here certainly do not encompass the entire spectrum of possible enterprises. On the other hand, a diversified agribusiness economy can be begun with orderly development of the four enterprises discussed.

A suggested sequence of events might be to begin with a controlledenvironment crop production center consisting of a one-acre greenhouse area complementing the medium-size truck farm outlined in this study. A natural second step would then be expansion to largescale, specialty truck farms and the opening of new market areas. Livestock and grain could be developed conjunctively, but on a small scale to evaluate the quality of production as well as to build management expertise. As agricultural production increases, transportation corridors may expand and diversify, opening the door to large-scale grain production or further expansion of vegetable and larger crop and livestock enterprises.

[^21]
## APPENDIX B

## DETAILS AND MATERIALS LISTS FOR ALL BUILDINGS, IRRIGATION SYSTEM, AND FENCING

## BUILDINGS

Three types of structure are included in the truck farming enterprise. For each, lumber was assumed to be available from local sources in commercial cut lengths and sizes. Labor used for construction was capitalized and charged at $\$ 7.00$ per hour.

## Greenhouses

The greenhouses are primarily used for seedling production. The space required for seedlings was used to determine the house size. Two basic units have been used, a $10^{\prime} \times 12^{\prime}$ house and a $12^{\prime} \times 20^{\prime}$ house. The seedlings are grown on removable shelves, three high at the sides, back and center of the houses. The tomato crop is grown in pots in the available space after the shelves are removed. The houses are wood frame with a double wall, 6 mil polyethylene covering which is replaced every year. The tomato crop is irrigated and fertilized with a Gewa injector through a Chapin spaghetti tube system.* Seedlings are cared for with the Gewa and hand sprayers. Greenhouse space, materials required and prices are shown in Table B. 1

## Machine Storage

Table B. 2 shows the materials list and prices for the machinery storage. Storage for machinery and equipment will be necessary during the winter months. There is no necessity for heating or flooring. The structure is wood frame with galvanized sheet metal covering. No insulation is used.

| TOTAL |  | \$1,336.16 |  | \$1,807.97 |

## Vegetable Storage*

Because most of the Kuskokwim River area is a flood plain, aboveground storage for potatoes, carrots, cabbage, turnips, rutabagas and onions is necessary. A storage building $20^{\prime} \times 20^{\prime}$ in size will store 50 ton of vegetables, the approximate tonnage available from a 2 -acre area. The $20^{\prime}$ x $20^{\prime}$ modules can be added as the fields are expanded to reach a 200 -ton (four unit) capacity for the 24 acre farm. It is necessary to maintain temperatures between $32^{\circ} \mathrm{F}$ and $38^{\circ} \mathrm{F}$ in the storage units. Therefore, minimal heating will be required. To minimize heat loss, the roof, walls and floor contain 6 inches of insulation. Bins are provided for vegetable storage to hold the produce away from the walls and floors. Ventilation is provided in the floors and roof to maintain continuous air circulation. With these additions, required temperatures can be maintained with no more than 5,000 to 10,000 BTU heating capacity. The materials list and prices for the vegetable storage units for each farm size are given in Table B.3.

## IRRIGATION

A minimal irrigation system has been provided. The system uses river water pumped to the field location through polyvinyl-chloride (PVC) flexible pipe. Pumps have been provided with appropriate screens for river water sediment. Water is supplied to the field through a PVC mainline and Chapin twin-wall, drip-irrigation hose feeders.**

[^24]
## APPENDIX B

## Table B.3: Vegetable Storage Units Materials List and Materials Price

| Supplies | 50T, 20'x20' Unit |  |
| :---: | :---: | :---: |
| Lumber |  | \$2,246.36 |
| 2 "x4" | 1,168' |  |
| 2"x6" | $300{ }^{\prime}$ |  |
| 1 "x8" | 1,200' |  |
| 2 "x2" | 2,400' |  |
| 8"x8" | 80' |  |
| Insulation ${ }^{\text {a }}$ | 1,340'-54 rolls | 1,098.00 |
| Vapor Barrier | 20'100'-6 mil | 64.30 |
| Roofing | 20 2'x12' galvanized | 185.00 |
| Hardware | miscellaneous | 300.00 |
| Labor | 4 man weeks | 1,120.00 |
| TOTAL |  | \$5,014.26 |

${ }^{\mathrm{a}}$ Commercial insulation can be replaced with sawdust available from local lumber mills. This will reduce cost by $\$ 1,098.00$.

The system is designed to apply a uniform water supply adjacent to the plants at soil level. The feeder tubes and pumps can either be left in the field or removed during winter months. Supplies, particularly pump requirements will vary with the proximity of the field to a water source. Estimates of supplies and prices are shown in Table B.4.

## FENCING

Fencing has been provided for all field units. It is anticipated that some degree of control will be needed for animals in the area. All fencing is welded wire, 2 " x 4 " mesh, 6 ' height. Fence posts are 4 " x $4^{\prime \prime}$, wood from local suppliers, creosoted for protection. Gates are 20' width to allow easy access with equipment. Supplies needed and price lists are given in Table B.5.

${ }_{b}$ Small tool cost is $1 / 4$ the total cost.
${ }^{\mathrm{b}}$ Full-time labor @ $\$ 5.00 / \mathrm{hr}$. for 4 months; field boss @ $\$ 7.00 / \mathrm{hr}$. for 7 months; part-time labor @ $\$ 5.00 / \mathrm{hr}$. for 10 months during planting and har${ }^{\text {vest }}$; grower-manager © $\$ 1,500$ /month for 12 months.
${ }_{\mathrm{d}}{ }^{\text {Includes parts used, grease and oil only. }}$
${ }^{\mathrm{d}}$ Time allocated from grower-manager.

[^25]
[^0]:    ${ }^{\text {a }}$ Acreage allotments do not include a green manure crop, which for each unit is equal in size to the acreage allocated to potatoes (Lewis, Lewis, and Wooding, 1978).
    ${ }^{\mathrm{b}}$ Although onions may not mature to a large size, $15 \%$ of the field loss may be recovered as a marketable green onion crop. Market demand was not estimated for greeen onions.
    ${ }^{\text {c }}$ The yields estimated include the turnip tops which make up $1 / 6$ of the weight. This is included in the field loss of $37 \%$. The green could be marketed, however, reducing this loss to $20 \%$. Market demand was not estimated for turnip greens.

[^1]:    ${ }^{\mathrm{d}}$ The yields estimated do not include the tops.
    ${ }^{\mathrm{e}}$ Tomato plants are assumed to bear at the rate of 3 pounds per plant per month for a 3$\mathrm{f}^{\text {month period (Lewis and Thomas, 1977). Market demand was not estimated. }}$
    Totals do not include the tomato crop.

[^2]:    ${ }^{\text {a }}$ Assumes $80 \%$ of the total yield for all crops except broccoli, cauliflower and tomatoes will be stored and assumes there will be a storage loss of $10 \%$ for potatoes, carrots, turnips, rutabagas, and onions and 25\% for cabbage.

[^3]:    ${ }_{\mathrm{b}}^{\mathrm{a}}$ Adapted from Storing Vegetables and Fruits. 1970. Market Quality Research Division, Agricultural Research Service, Washington, D.C. ${ }_{c}$ Open-bin storage recommendations from Dearborn, (1977) and Kern (1978).
    ${ }_{d}$ Storage recommendations are from Dinkel, 1977.
    ${ }^{\mathrm{d}}$ Assumes all vegetables are cleaned using no water with the exception of carrots which can be washed if dried thoroughly.

[^4]:    *A rate of $6 \%$ is charged by the Alaska Agricultural Revolving Loan Fund but this may increase.
    **Does not include labor or a parts inventory and is an average for all equipment. Estimates are from Fairbanks, Alaska, local dealers, 1977.

[^5]:    ${ }_{6}^{a}$ Price and unit size source: Alaska Paper Company, 1978. Anchorage, Alaska.
    ${ }^{\mathrm{b}}$ Assumes cabbages weigh approximately 3 lbs . per head.
    $\mathrm{c}_{\text {Assumes }} 1 / 2$ are in 100 lb . sacks, $1 / 4$ in 20 lb . sacks, and $1 / 4$ in 10 lb . sacks.

[^6]:    ${ }_{b}^{\text {A }}$ salary of $\$ 1500$ per month is paid for 12 months.
    A fee of $\$ 200$ per month is paid for 9 months.

[^7]:    ${ }^{\mathrm{a}}$ Spacing of potatoes will vary by management method and variety. Kennebecs which do not set an excessive amount of potatoes could be spaced as closely as 6 inches in 36 -inch rows while Bake King or Green Mountain would probably require 10-12 inch spacing in rows 38-40 inches apart (Logsdon, 1979).

[^8]:    ${ }^{\mathrm{a}}$ The amount of fertilizer required is for the acreage allotted to each particular crop in a garden unit. The amounts required are based on ${ }_{b}$ packaging quantities.
    1978 prices were obtained from E. C. Geiger, Harleysville, Pennsylvania, and Alaska Mill and Feed Company, Inc., Anchorage, Alaska. ${ }^{c}$ Fertilizer rates assume good management practices are used. The rate applied is to approximate a 20 -ton-per-acre yield. The crop will $\mathrm{d}_{\text {Seedling fertilizer requirements were }}^{\text {require }}$ more rate were applied.
    Seedling fertilizer requirements were obtained from C.E.A., 1977; and Epps, 1971. The amounts were estimated using a rate of approxi$e^{\text {mately }} 1 / 2 \mathrm{oz}$. per 1 gallon water.
    $\mathrm{e}_{\text {Fertilization rates used are from C.E.S., }}^{\text {mat }} 197$.

[^9]:    ${ }^{\mathrm{a}}$ The $7.5 \mathrm{qts} / \mathrm{A}$ rate in $50-100$ gal. of water is used in the Matanuska Valley. A rate of approximately 9 qts/A applied at 40 gal./A has been recommended for the interior of Alaska. $9 \mathrm{qts} / \mathrm{A}$ is recommended for application just as plants begin to emerge to give weed-free
    
    $\mathrm{b}_{\text {Application rates in the Matanuska Valley at } 16 \mathrm{lb} / \mathrm{A} \text { have been used successfully. }}$
    $\mathrm{c}_{\text {An application rate of } 4 \mathrm{lbs} / \mathrm{A} \text { is recommended and used for onions in the Matanuska Valley. A single weeding before application is }}$ drecommended.
    ${ }_{\mathrm{e}}$ Rate used in Matanuska Valley.
    TREFLAN (trifluralin) is a commonly used herbicide for all cole crops. However, its effectiveness was not considered as good as the herbicides listed.
    Table reference except where noted: Dearborn, 1977.

[^10]:    ${ }_{\mathrm{b}}^{\mathrm{a}}$ Malathion and Kelthane are also recommended for control of greenhouse aphids and mites, respectively.
    $\mathrm{b}_{\text {The }} 2-4 \mathrm{qt}$./A rate is for the total season and should be applied at 10 -day intervals.
    Table reference: (Washburn, 1978).

[^11]:    ${ }^{a}$ Excludes seedling production.
    $\mathrm{b}_{1 / 4}$ replaced annually.
    ${ }^{\mathrm{c}}$ Depreciation is a non-cash cost.

[^12]:    ${ }_{b}^{a}$ Excludes seedling production .
    ${ }^{1 / 4}$ replaced annually.
    ${ }^{c}$ Depreciation is a non-cash cost.

[^13]:    ${ }_{b}^{a}$ Excludes seedling production.
    $\mathrm{b}_{1 / 4}$ replaced annually.
    ${ }^{c}$ Depreciation is a non-cash cost.

[^14]:    ${ }_{\mathrm{b}}^{\mathrm{a}}$ Excludes seedling production.
    $\mathrm{b}_{1 / 4}^{1 /}$ replaced annually.
    ${ }^{\mathrm{c}}$ Depreciation is a non-cash cost.

[^15]:    ${ }^{\text {a }}$ Shipping and handling losses are not included in pounds supplied.

[^16]:    a Barker, 1978.
    Not available in local stores.

[^17]:    ${ }^{\text {a }}$ Consumption information obtained from the following sources: Swanson's, Native Store, Alaska Commercial, Bethel, Alaska; Kosko's and Alaska Commercial, Aniak, Alaska. Consumption for the Red Devil Area was estimated using population figures.

[^18]:    ${ }^{\mathrm{b}}$ Minimum freight rate is $\$ 10.50$ for Wien Air Alaska and its subcontractors.
    Flights from Aniak to Red Devil are scheduled three times a week with additional flights when necessary. Freight rates from Red Devil to Sleetmute and Stony River are estimates received from Wien subcontractors.

[^19]:    ${ }^{\text {a }}$ Wholesale prices and transportation as of March, 1978.
    Retail selling price observed in Bethel in January, 1978, Swanson's, Native Store, and Alaska Commercial average.
    ${ }_{\mathrm{d}}$ Determined by local retailer as mark-ups over operating costs.
    Local Aniak consumers will have a possible advantage in retail price of approximately $\$ .07 / \mathrm{lb}$.
    ${ }^{\mathrm{e}}$ No transportation included since production capacity will supply only neighboring markets.

[^20]:    a Operating cost includes both production and marketing.
    Cost of tomatoes was determined using actual production, operating, and marketing costs and owner costs for $1 / 2$ the greenhouse structure and equipment.

[^21]:    ${ }^{\mathrm{a}}$ F.o.B. Aniak; ${ }^{\mathrm{b}}$ in pounds.
