were a major influence
on my interest in biology

ABSTRACT

The published information regarding the biology and pest status of Graphognathus leucoloma Boheman is summarized.

A study was made of egg development at temperatures ranging from 4 to 37.8°C and relative humidities ranging from 40 to 100%. Egg hatch was frequently very low and showed considerable variability. Median duration of development ranged from about 14 days at 31.5°C to 95-97 days at 15°C, with the developmental-hatching threshold between 12.1 and 13.5°C. Sub-threshold temperatures were lethal. Virtually no hatching occurred below 100% RH but the eggs could withstand considerable desiccation and would hatch when moistened. Possible effects of humidity on the duration of development and of parental age on egg viability are also discussed. Some reasons for the very low egg viability are suggested, along with modifications to the experimental design to eliminate them.

Studies were made of adult and pupal size, and of longevity, pre-oviposition period and reproductive output. Some reasons for unexpectedly low fecundity and long pre-oviposition period are discussed.

The structure of the egg envelopes and the cement in which the eggs are laid was studied, using scanning and transmission electron microscopy, and Nomarski differential interference microscopy. A histochemical study of these structures, supplemented by some simple chemical tests, was also made, to elucidate in part their composition. The chorion is 4-9µm thick and composed entirely of protein; some 250,000 aeropyles are scattered over the surface, and its structure is such that it could probably act as a plastron when the egg is submerged. There is no micropyle. Disulphide linkages are probably important in the structure of the chorion, as in many other species, but unlike other beetles so far studied, no crystalline proteins were found. The vitelline membrane was found to be a three-layered structure 0.3-0.5µm thick composed of protein and acid mucopolysaccharides, and to be highly resistant to chemical attack. Waterproofing is probably provided by a layer of lipid on the outer surface of the vitelline membrane. The cement was found to be a complex, variable and heterogeneous mixture of protein and up to five acid mucopolysaccharides, which is unlike that of any other species reported. Some possible functions of the cement and the significance of its composition are suggested.

A note on the citation of publications, and the referral to species and their systematic status.

Any publication by three joint authors is cited in full the first time it is referred to and thereafter is abbreviated to the form: senior author et al. Publications with more than three joint authors are cited in the form: senior author et al. each time they are cited, including the first. The specific name of any organism is given in full only on the first time it is referred to, and the names of insect species and genera and their taxonomic status are listed in Appendix Five.

ACKNOWLEDGEMENTS

I would like to thank Mr. I.A.N. Stringer, who supervised the major part of this work, for his constant advice and helpful suggestions, and Dr. J. Crofton for his supervision in its early stages.

Thanks are also due to Dr. M.J. Merrilees, who offered helpful advice during the early stages and on histochemistry; to Mr. M. Mannering and Dr. J. Riddle for advice regarding histological methods; to Dr. W.M. Kain who made a number of helpful suggestions during the planning stages of both seasons' work; and to Mr. M.J. Esson for his constant advice.

I am indebted to Mr. M.J. Esson and Dr. W.M. Kain for the loan of equipment without which this work would not have been possible; to Professor Bacon for the use of a constant temperature room; to Mr. E. Roberts for the loan of a refrigerator; and to Mr. W. Thomas for constructing much of the other equipment. I am also grateful to Mr. P. Couchman for supplying a sample of basic fuchsin that worked; to Messrs. C. Fletcher and R. Hanson for many of the chemicals used in the histochemistry, and to Dr. M.J. Merrilees for a sample of cetylpyridinium chloride. The ever helpful and patient staff of Chemistry Stores have also earned my gratitude.

Thanks to Mr. D. Hopcroft who prepared the material for electron microscopy and for operating the microscopes, and, together with Mr. I. Simpson, for processing the electron micrographs.

Credit for the frontispiece and Figs. 3.1, 3.2 and 3.3 must go to the staff of the Central Photographic Unit, who also processed the light micrographs. Miss A. Turner drew Figs. 2.1 to 2.6.

I wish to thank Dr. P. Elliott, Mr. M.J. Esson, Mr. P.G. Fenemore and Mr. N. Pomeroy who read parts of the manuscript and who made many useful suggestions; Mr. C.G. Arnold and Dr. B.S. Weir, who advised me on statistical methods; and Di Machin for assistance with the final preparation and for a translation from the French text. Thanks are due also to Glenis Mobberley for typing references on to cards; to my sister, Diana Cloud, for sending several references from Canada and for her constant encouragement; and Mrs. J. Parry for typing the final manuscript.

CHAPTER ONETHE STUDY ANIMAL1.1 ORIGINS AND OCCURRENCE

The white-fringed weevil, Graphognathus leucoloma Boheman (Coleoptera, Curculionidae, Brachyderinae), is a native of South America, where it occurs in Argentina, Brazil, Chile, Peru and Uruguay (Berry, 1947; Young et al., 1950). Its known range now includes many south-eastern states of the U.S.A. as far north as Maryland (Anonymous, 1969), all five mainland Australian states (Chadwick, 1970), South Africa (Joubert, 1951) and New Zealand. In New Zealand, G. leucoloma was found in Northland in 1944, where it was believed to have been introduced with American war equipment about 1940 (Cottier, 1962), but it now occurs throughout the North Island and has been found in Nelson (Perrott, 1964) and Ashburton (Lay, 1975) in the South Island.

Buchanan (1947) recognised three species of Graphognathus: G. leucoloma, G. peregrinus and G. minor, and six races of G. leucoloma, of which five occur in the U.S.A. Only G. leucoloma is recorded outside North and South America, but no details regarding strains appear to have been published.
