Coupled, multifield models of inflation can provide several attractive features unavailable in the case of a single inflaton field. These models have a rich dynamical structure resulting from the interaction of the fields and their associated fluctuations. We present a formalism to study the nonequilibrium dynamics of coupled scalar fields. This formalism solves the problem of renormalizing interacting models in a transparent way using dimensional regularization. The evolution is generated by a renormalized effective Lagrangian which incorporates the dynamics of the mean fields and their associated fluctuations at one-loop order. We apply our method to two problems of physical interest: (i) a simple two-field model which exemplifies applications to reheating in inflation, and (ii) a supersymmetric hybrid inflation model. This second case is interesting because inflation terminates via a smooth phase transition which gives rise to a spinodal instability in one of the fields. We study the evolution of the zero mode of the fields and the energy density transfer to the fluctuations from the mean fields. We conclude that back reaction effects can be significant over a wide parameter range. In particular for the supersymmetric hybrid model we find that particle production can be suppressed due to these effects.

I. INTRODUCTION

In recent years, the study of nonequilibrium dynamics in quantum field theory has received much attention in various areas of physics, and particularly in cosmology. The work has been driven largely by inflation [1], the most successful known mechanism for explaining the large-scale homogeneity and isotropy of the universe *and* the small-scale inhomogeneity and anisotropy of the Universe [2]. With observations for the first time able to directly test the more detailed predictions of specific inflationary models, the efforts in understanding inflation and its dynamics have redoubled.

One area of particular interest is the dynamics of multifield models of inflation in which the inflaton is coupled to another dynamical field during inflation. These models can lead to a variety of features unavailable in the case of a single field. Such multifield scenarios include the well known hybrid inflation models [3].

On top of the dynamics during inflation, the subsequent phase of energy transfer between the inflaton and other degrees of freedom leading to the standard picture of big bang cosmology has been the subject of intense study. The inflaton may decay through perturbative processes [4,5] as well as nonperturbative parametric amplification [6,7]. The latter can lead to explosive particle production and very efficient reheating of the universe.

Hybrid inflation and reheating models share an important common thread. They both involve the coupling of two or more dynamical, interacting scalar fields (or higher spin

fields [8]). An important aspect of such systems is the possibility of mixing between the fields. In Ref. [9] for example the classical inflaton decay is investigated for a two field model by solving the non-linear equations of motions on a grid. In Ref. [10], the authors treat the problem of coupled quantum scalar and fermion fields at the tree level. Because of the small couplings involved in inflationary cosmology, such a tree level analysis is useful in a variety of physical situations.

However, hybrid models as well as the dynamics of reheating typically include processes such as spinodal decomposition [11,12] and parametric amplification which require one to go beyond the tree level by including quantum effects either in a perturbative expansion or by means of nonperturbative mean field techniques such as the Hartree approximation or a large- N expansion [5,13,14].

Going beyond tree level brings in the issue of renormalization. The problem of renormalization of time evolution equations in single field models was understood several years ago. In one of the first papers in this field, Cooper and Mottola showed in 1987 Ref. [15], that it is possible to find a renormalization procedure which leads to counter terms independent of time and initial conditions of the mean field. They used a WKB expansion in order to extract the divergences of the theory. In a later paper Cooper *et al.* also discussed a closely related adiabatic method in order to renormalize the ϕ^4 theory in the large- N approximation. Also Boyanovsky and de Vega, Ref. [11], used a WKB method in order to renormalize time-dependent equations in one-loop order, and later on Boyanovsky *et al.* [12] investigated a ϕ^4 model in the large- N approximation and the Hartree approximation, too. In 1996 Baacke *et al.*, Ref. [16], proposed a slightly different method in order to extract the divergences

*On leave of absence from Dortmund University, Dortmund, Germany.

of the theory, which enabled them to use dimensional regularization. In contrast to the WKB ansatz this method can be extended for coupled system, which was demonstrated in Ref. [17]. This procedure will be used also in this paper. We work in the context of a closed time path formalism [18] appropriate to following the time-dependent evolution of the system. In this formalism, the *in*-vacuum plays a predominant role, as quantities are tracked by their *in-in* expectation values (in contrast to the *in-out* formalism of scattering theory). We construct the *in*-vacuum by diagonalizing the mass matrix of the system at the initial time $t=0$. However, because of the time-dependent mixing, a system initially diagonalized in this way will generally not be diagonalized at later times.

One approach to this problem, taken in Ref. [10], is to diagonalize the mass matrix at each moment in time through the use of a time-dependent rotation matrix. The cost of doing so is the appearance of time derivatives of the rotation matrix into the kinetic operators of the theory. While such a scheme is in principle workable beyond the tree level, the modified kinetic operators introduce complications into the extraction of the fluctuation corrections as well as the divergences that are to be removed via renormalization.

We take an alternative approach where the mass matrix is allowed to be non-diagonal for all times $t>0$ and account for the mixing by expanding each of the fields in terms of *all* of the *in*-state creation and annihilation operators. The cost of doing so in an N -field system is the need to track N^2 complex mode functions representing the fields instead of the usual N . However, this allows standard techniques to be used to properly renormalize the system. For the two-field systems common in inflationary models, this effective doubling of the field content adds a relatively minor cost.

For simplicity and clarity, we will work in Minkowski spacetime and in a one-loop approximation. Extensions both to Friedmann-Robertson-Walker spacetimes and to simple non-perturbative schemes such as the Hartree approximation, while more complicated than the present analysis, present no fundamental difficulties. We note that Minkowski spacetime is a good approximation in the latter stages of certain hybrid inflation models, and it will also allow comparison with much of the original reheating literature [4–6] which often neglects the effects of expansion, allowing us to directly determine the role played by the mixing of the fields in the dynamics.

The outline of the paper is as follows. We begin by considering the Lagrangian for N coupled scalar fields and set up our formalism for the quantization of the system. This is followed by an outline of the renormalization procedure. We then provide a summary of the results for the two-field case. We demonstrate the formalism with two examples: a simple reheating model and a hybrid inflation model motivated by supersymmetry.

In the reheating model we investigate two relevant regimes discussed in detail in the literature [6,7], viz., the narrow resonance regime and the broad resonance regime. These different regimes occur depending on the choice of initial conditions. Usually in these models the mixing effects of the fields were neglected by choosing a vanishing initial

value for one of the mean fields: We are now able to treat the full system and to investigate these mixing effects. For this purpose we concentrate on studying the behavior of the fluctuation integrals for the different fields and the time-dependent mixing angle. Depending on the regime, as the mean fields evolve, the effects of the mixing can be quite different. In the narrow resonance regime the mixing angle is very small and plays a subdominant role, whereas in the broad resonance regime the mixing effects are very important. Therefore, we emphasize that neglecting the mixing could lead to incomplete results.

Supersymmetric hybrid models are a special realization of general hybrid inflationary models (see, e.g., Refs. [19,20]). Based on a softly broken supersymmetry potential, the special feature of these models is the occurrence of only one coupling constant, whereas in nonsupersymmetric hybrid models there are at least two different couplings. Thus, in the supersymmetric case there is only one natural frequency of oscillation for the mean fields as long as fluctuations are neglected. This leads to efficient particle production during the preheating stage in the early universe. However, we show below that, by taking into account the fluctuations and investigating the full mixed system, this feature of supersymmetric hybrid models can be lost in some regimes. This is because the effective mass corrections for the two fields are different in these regimes, which leads to a chaotic trajectory for the renormalized field equations of motion in a phase space which mimics the situation of a nonsupersymmetric hybrid model. It appears, then, that supersymmetric hybrid models can lose some of their attractiveness compared to general hybrid models.

II. N FIELDS

We work with the following Lagrangian for real scalar fields Φ_i with $i=1 \dots N$:

$$L[\Phi_i] = \sum_{i=1}^N \frac{1}{2} \partial_\mu \Phi_i(x) \partial^\mu \Phi_i(x) - V[\Phi_i(x)], \quad (2.1)$$

where the potential is

$$V(\Phi_i) = \sum_{i,j,k,l=1}^N A_i \Phi_i + \frac{1}{2} m_{ij} \Phi_i \Phi_j + \frac{1}{3!} g_{ijk} \Phi_i \Phi_j \Phi_k + \frac{1}{4!} \lambda_{ijkl} \Phi_i \Phi_j \Phi_k \Phi_l. \quad (2.2)$$

Note that m_{ij} , g_{ijk} , and λ_{ijkl} are symmetric in each index, but are generally non-diagonal resulting in the mixing of the different fields. In what follows, subscripts and superscripts $i \dots n$ run over the values $1 \dots N$ and we use a convention in which summation is assumed over repeated lowered indices, but not raised indices.

We will expand each field about their expectation values (taken to be space translation invariant):

$$\Phi_i(x) = \phi_i(t) + \delta\phi_i(x), \quad \phi_i(t) = \langle \Phi_i(x) \rangle. \quad (2.3)$$

Expanding the equations of motion and keeping terms to quadratic order in the fluctuations yields a one-loop approximation. The equations of motion for the zero modes ϕ_i are determined via the tadpole condition. We have

$$\begin{aligned} \ddot{\phi}_i + A_i + m_{ij}\phi_j + \frac{1}{2}g_{ijk}\phi_j\phi_k + \frac{1}{6}\lambda_{ijkl}\phi_j\phi_k\phi_l \\ + \frac{1}{2}g_{ijk}\langle\delta\phi_j\delta\phi_k\rangle + \frac{1}{2}\lambda_{ijkl}\phi_j\langle\delta\phi_k\delta\phi_l\rangle = 0. \end{aligned} \quad (2.4)$$

To this order, the fluctuations obey the equation

$$\ddot{\delta\phi}_i - \vec{\nabla}^2\delta\phi_i + \mathcal{M}_{ij}\delta\phi_j = 0, \quad (2.5)$$

with the mass matrix

$$\mathcal{M}_{ij} = m_{ij} + g_{ijk}\phi_k + \frac{1}{2}\lambda_{ijkl}\phi_k\phi_l. \quad (2.6)$$

As indicated in the Introduction, the complication that arises is not the fact that the mass matrix (2.6) contains mixing between the various fields, rather that the mixing changes with time as the ϕ_i evolve according to Eq. (2.4). This means that if we diagonalize the mass matrix at one time, it will not generally be diagonal at any other time.

Nonetheless, it is most convenient to quantize in terms of a diagonal system at the initial time $t=0$. We define the matrix

$$\mathcal{D}_{ij} = \mathcal{O}_{ik}\mathcal{M}_{kl}\mathcal{O}_{lj}^T, \quad (2.7)$$

and the corresponding fluctuation fields

$$X_i = \mathcal{O}_{ij}\delta\phi_j, \quad (2.8)$$

where \mathcal{O}_{ij} is an orthogonal rotation matrix. \mathcal{D}_{ij} is diagonal at the initial time:

$$\mathcal{D}_{ij} = D^i\delta_{ij}, \quad (2.9)$$

without summation over the raised index i . The X_i obey the equations of motion

$$\ddot{X}_i - \vec{\nabla}^2 X_i + \mathcal{D}_{ij}X_j = 0. \quad (2.10)$$

We quantize the system by defining a set of creation and annihilation operators $a_\alpha^\dagger(\vec{k})$ and $a_\alpha(\vec{k})$ where $\alpha=1\dots N$ corresponds to the *in*-state quanta of frequency

$$\omega_\alpha = \sqrt{k^2 + D^\alpha}. \quad (2.11)$$

As the mixing changes in time, each of the fields X_i is expanded in terms of all of the *in*-state operators. We have

$$\begin{aligned} X_i = \sum_{\alpha=1}^N \int \frac{d^3k}{(2\pi)^3} \frac{1}{2\omega_\alpha} [a_\alpha(\vec{k})U_i^\alpha(\vec{k},t)e^{i\vec{k}\cdot\vec{x}} \\ + a_\alpha^\dagger(\vec{k})U_i^{\alpha*}(\vec{k},t)e^{-i\vec{k}\cdot\vec{x}}]. \end{aligned} \quad (2.12)$$

The initial conditions for the N^2 complex mode functions are

$$U_i^\alpha(\vec{k},0) = \delta_i^\alpha, \quad \dot{U}_i^\alpha(\vec{k},0) = -i\omega_\alpha U_i^\alpha(\vec{k},0). \quad (2.13)$$

It is convenient to define the fluctuation integrals

$$\langle X_i X_j \rangle = \sum_{\alpha=1}^N \int \frac{d^3k}{(2\pi)^3} \frac{1}{2\omega_\alpha} U_i^{\alpha*}(\vec{k},t) U_j^\alpha(\vec{k},t), \quad (2.14)$$

from which it is straightforward to determine the contributions appearing in the zero mode equations (2.4):

$$\langle \delta\phi_i \delta\phi_j \rangle = \mathcal{O}_{ik}^T \mathcal{O}_{jl}^T \langle X_i X_j \rangle. \quad (2.15)$$

It will also prove convenient to introduce the rotated couplings

$$G_{ijk} = g_{ilm} \mathcal{O}_{lj}^T \mathcal{O}_{mk}^T, \quad (2.16)$$

$$\Lambda_{ijkl} = \lambda_{ijmn} \mathcal{O}_{mk}^T \mathcal{O}_{nl}^T, \quad (2.17)$$

which allows us to write the zero mode equations as

$$\begin{aligned} \ddot{\phi}_i + A_i + m_{ij}\phi_j + \frac{1}{2}g_{ijk}\phi_j\phi_k + \frac{1}{6}\lambda_{ijkl}\phi_j\phi_k\phi_l \\ + \frac{1}{2}G_{ijk}\langle X_j X_k \rangle + \frac{1}{2}\Lambda_{ijkl}\phi_j\langle X_k X_l \rangle = 0, \end{aligned} \quad (2.18)$$

while the mode functions obey the equations

$$\ddot{U}_i^\alpha(\vec{k},t) + (k^2 + \mathcal{D}_{ij})U_j^\alpha(\vec{k},t) = 0. \quad (2.19)$$

In addition to the equations of motion, it is useful to have an expression for the energy density of the system. This is particularly true when one completes numerical simulations of the system, since energy conservation is a powerful check of the accuracy of the simulations. After once again decomposing the fields into their expectation values and fluctuations, the energy density to one loop order is

$$\begin{aligned} \mathcal{E} = \frac{1}{2}\dot{\phi}_i^2 + A_i\phi_i + \frac{1}{2}m_{ij}\phi_i\phi_j + \frac{1}{3!}g_{ijk}\phi_i\phi_j\phi_k \\ + \frac{1}{4!}\lambda_{ijkl}\phi_i\phi_j\phi_k\phi_l + \frac{1}{2}\langle \dot{X}_i^2 \rangle \\ + \frac{1}{2}\langle (\vec{\nabla}X_i)^2 \rangle + \frac{1}{2}\mathcal{D}_{ij}\langle X_i X_j \rangle, \end{aligned} \quad (2.20)$$

where we have defined the integrals

$$\langle \dot{X}_i \rangle = \sum_{\alpha=1}^N \int \frac{d^3k}{(2\pi)^3} \frac{1}{2\omega_\alpha} |\dot{U}_i^\alpha(\vec{k},t)|^2, \quad (2.21)$$

$$\langle (\vec{\nabla}X_i)^2 \rangle = \sum_{\alpha=1}^N \int \frac{d^3k}{(2\pi)^3} \frac{k^2}{2\omega_\alpha} |U_i^\alpha(\vec{k},t)|^2. \quad (2.22)$$

A. Divergence structure and renormalization

The mode integrals in the equation of motion defined by Eq. (2.14) and in the energy density defined by Eqs. (2.21), (2.22) are divergent and have to be regulated, allowing for a renormalization of the theory. We require a method of extracting the divergent terms appearing in the mode integrals, a nontrivial task, since the mode equations vary in time and they are coupled. Our aim is now to find counter terms, which are independent of the initial value of the mean fields in order to formulate a finite theory. The correct choice of the initial condition for the fluctuations guarantees that the theory is renormalizable. One way to extract the divergences of the mode integrals is due to a WKB method which allows for a high momentum expansion of the mode functions. However, when the fields are coupled, as in the present case, the usual formulation of the WKB expansion runs into difficulties which are yet to be resolved.

An alternative method has been developed [16,17,21] which relies on a formal perturbative expansion in the effective masses and time derivatives of the masses of the fields. As such, it results in a series expansion of the mode functions in powers of m/ω and \dot{m}/ω^2 , etc. The first few terms in the series include the divergent parts of the integrals that are to be removed via renormalization.

We begin by introducing the following ansatz for the mode functions:

$$U_j^\alpha = e^{-i\omega_{\alpha 0} t} (\delta_j^\alpha + f_j^\alpha). \quad (2.23)$$

The first term on the right-hand side anticipates a quadratic divergence in the quantities $\langle X_i^2 \rangle$. We define the following potential:

$$V_{ij}^\alpha(t) = \mathcal{D}_{ij}(t) - D^\alpha \delta_{ij}. \quad (2.24)$$

The equations of motion for the mode functions Eqs. (2.19) can be written in a suggestive form with the help of Eqs. (2.23), (2.24)

$$\ddot{f}_j^\alpha - i2\omega_{\alpha 0} \dot{f}_j^\alpha = - \sum_{l=1,2} V_{jl}^\alpha (\delta_l^\alpha + f_l^\alpha). \quad (2.25)$$

The terms on the right-hand side of this expression are treated as perturbations to write the f 's order by order in V , with the initial conditions $f_j^i(0) = \dot{f}_j^i(0) = 0$. To first order in V , we have the equations of motion:

$$\dot{f}_j^{\alpha(1)} - 2i\omega_{\alpha 0} f_j^{\alpha(1)} = -V_{j\alpha}^\alpha. \quad (2.26)$$

The corresponding integral solutions for the real part of the f 's are

$$2\Re f_j^{\alpha(1)} = -\frac{V_{\alpha j}^\alpha}{2\omega_{\alpha 0}} + \int_0^t dt' \frac{\dot{V}_{\alpha j}^\alpha(t')}{2\omega_{\alpha 0}} \cos(2\omega_{\alpha 0} t'), \quad (2.27)$$

while the imaginary part is of order $1/\omega^3$ and does not contribute to the divergences [17].

Using these results, we find quadratic and logarithmic divergences:

$$\langle X_i X_j \rangle_{\text{div}} = \int \frac{d^3 k}{(2\pi)^3} \left(\frac{1}{2\omega_j} \delta_{ij} - \frac{1}{4\omega_j^3} V_{ij}^j \right), \quad (2.28)$$

which must be removed via some renormalization procedure while also providing finite corrections to the parameters of the theory.

To make the renormalization scheme explicit, we adopt dimensional regularization. We define the following divergent integrals:

$$\int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\sqrt{k^2 + \mu^2}} = -\mu^2 I_{-3}(\mu) - \frac{\mu^2}{16\pi^2}, \quad (2.29)$$

$$\int \frac{d^3 k}{(2\pi)^3} \frac{1}{4(k^2 + \mu^2)^{3/2}} = I_{-3}(\mu), \quad (2.30)$$

where μ is an arbitrary renormalization point and I_{-3} carries the infinite contributions. In dimensional regularization $I_{-3}(\mu)$ is given by

$$I_{-3}(\mu) = \frac{1}{16\pi^2} \left\{ \frac{2}{\epsilon} + \ln \frac{4\pi\mu^2}{m^2} - \gamma \right\}. \quad (2.31)$$

The infinite part of $\langle X_i X_j \rangle$ is found to be simply

$$\langle X_i X_j \rangle_{\text{infinite}} = -\mathcal{D}_{ij} I_{-3}(\mu). \quad (2.32)$$

This leads to mass and coupling constant counterterms of the following form

$$\delta A_i = \frac{1}{2} I_{-3}(\mu) g_{ijk} m_{jk}, \quad (2.33)$$

$$\delta m_{ij} = \frac{1}{2} I_{-3}(\mu) [g_{ikm} g_{kmj} + \lambda_{ijkl} m_{kl}], \quad (2.34)$$

$$\delta g_{ijk} = \frac{3}{2} I_{-3}(\mu) g_{ilm} \lambda_{lmjk}, \quad (2.35)$$

$$\delta \lambda_{ijkl} = \frac{3}{2} I_{-3}(\mu) \lambda_{ijmn} \lambda_{mnkl}. \quad (2.36)$$

It is important to notice that these counterterms are independent of the initial conditions of the mean fields ϕ_i .

In addition to these counterterms, there are finite corrections of the parameters coming from the finite parts of the integrals (2.28):

$$\langle X_i X_j \rangle_{\text{div,finite}} = -\frac{1}{16\pi^2} D^j \delta_{ij} - \frac{1}{16\pi^2} \mathcal{D}_{ij} \ln \frac{D^j}{\mu^2}. \quad (2.37)$$

From this, we extract the following finite contributions to the couplings and mass:

$$\Delta A_i = -\frac{1}{32\pi^2} \left[G_{ijj} D^j + g_{ijk} m_{jk} \ln \frac{D^k}{\mu^2} \right], \quad (2.38)$$

$$\Delta m_{ij} = -\frac{1}{32\pi^2} \left[\Lambda_{ijkk} D^k + (g_{ikl} g_{klj} + \lambda_{ijkl} m_{kl}) \times \ln \frac{D^k}{\mu^2} \right], \quad (2.39)$$

$$\Delta g_{ijk} = -\frac{1}{8\pi^2} g_{ilm} \lambda_{lmjk} \ln \frac{D^m}{\mu^2}, \quad (2.40)$$

$$\Delta \lambda_{ijkl} = -\frac{3}{32\pi^2} \lambda_{ijmn} \lambda_{mnkl} \ln \frac{D^m}{\mu^2}. \quad (2.41)$$

These finite corrections are also contributing to the energy density. In addition we find a finite part due to the cosmological constant renormalization.

The full, finite equations of motion become

$$\begin{aligned} \ddot{\phi}_i + A_i + \Delta A_i + (m_{ij} + \Delta m_{ij}) \phi_j \\ + \frac{1}{2} (g_{ijk} + \Delta g_{ijk}) \phi_j \phi_k \\ + \frac{1}{6} (\lambda_{ijkl} + \Delta \lambda_{ijkl}) \phi_j \phi_k \phi_l \\ + \frac{1}{2} (G_{ikl} + \Lambda_{ijkl} \phi_j) \sum_{\alpha=1}^N \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\omega_{\alpha 0}} \\ \times \left[f_k^{\alpha*} f_l^\alpha + \delta_k^\alpha f_l^\alpha + \delta_l^\alpha f_k^{\alpha*} + \frac{1}{2\omega_{\alpha 0}^2} \delta_l^\alpha V_{k\alpha}^\alpha \right] = 0. \end{aligned} \quad (2.42)$$

B. Two fields

The two-field case is often encountered, and the physical applications we present in the next section are both in this category. It is therefore worthwhile to pause to look at a few details of such systems. We begin with a system of two real scalar fields Φ and X

$$\mathcal{L} = \frac{1}{2} (\partial_\mu \Phi)^2 + \frac{1}{2} (\partial_\mu X)^2 - V(\Phi, X), \quad (2.43)$$

with the potential

$$\begin{aligned} V(\Phi, X) = \frac{1}{2} m_\phi^2 \Phi^2 + \frac{1}{2} m_\chi^2 X^2 + \frac{\lambda}{4!} \Phi^4 + \frac{\kappa}{4!} X^4 \\ + \frac{g^2}{4} \Phi^2 X^2. \end{aligned} \quad (2.44)$$

This Lagrangian has the same form as that studied in the preceding section with the identifications

$$\Phi_1 \equiv \Phi, \quad \Phi_2 \equiv X,$$

$$m_{11} \equiv m_\phi^2, \quad m_{22} \equiv m_\chi^2, \quad m_{12} = m_{21} = 0,$$

$$\lambda_{1111} \equiv \lambda, \quad \lambda_{2222} \equiv \kappa, \quad \lambda_{1122} \equiv g^2,$$

$$\lambda_{1112} = \lambda_{1222} = 0, A_i = 0, \quad g_{ijk} = 0. \quad (2.45)$$

The remaining components of λ_{ijkl} are determined by the fact that it is symmetric in each of its indices.

The mass matrix \mathcal{M} is

$$\mathcal{M} = \begin{pmatrix} m_\phi^2 + \lambda \phi^2/2 + g^2 \chi^2/2 & g^2 \phi \chi \\ g^2 \phi \chi & m_\chi^2 + \kappa \chi^2/2 + g^2 \phi^2/2 \end{pmatrix}. \quad (2.46)$$

For two fields, the orthogonal rotation matrix can be written in terms of a single mixing angle θ . The matrix has the form

$$\mathcal{O} = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}, \quad (2.47)$$

where the mixing angle is determined by the $t=0$ mass matrix \mathcal{M} , Eq. (2.46), through the relation

$$\begin{aligned} \tan \theta = \frac{1}{2\mathcal{M}_{12}(0)} [\mathcal{M}_{22}(0) - \mathcal{M}_{11}(0) \\ + \sqrt{[\mathcal{M}_{22}(0) - \mathcal{M}_{11}(0)]^2 + 4\mathcal{M}_{12}^2(0)}]. \end{aligned} \quad (2.48)$$

The eigenvalues of \mathcal{O} are the diagonal elements of the matrix \mathcal{D} , Eq. (2.7), at the initial time:

$$\mathcal{D}(0) = \begin{pmatrix} D^1 & 0 \\ 0 & D^2 \end{pmatrix}, \quad (2.49)$$

with the values

$$\begin{aligned} D^1 = \frac{1}{2} [\mathcal{M}_{11}(0) + \mathcal{M}_{22}(0) \\ + \sqrt{[\mathcal{M}_{22}(0) - \mathcal{M}_{11}(0)]^2 + 4\mathcal{M}_{12}^2(0)}], \end{aligned} \quad (2.50)$$

$$\begin{aligned} D^2 = \frac{1}{2} [\mathcal{M}_{11}(0) + \mathcal{M}_{22}(0) \\ - \sqrt{[\mathcal{M}_{22}(0) - \mathcal{M}_{11}(0)]^2 + 4\mathcal{M}_{12}^2(0)}]. \end{aligned} \quad (2.51)$$

For general times, the mass matrix for the fields X_1 and X_2 , writing $c_\theta = \cos \theta$ and $s_\theta = \sin \theta$, is

$$\mathcal{D}(t) = \begin{pmatrix} c_\theta^2 \mathcal{M}_{11} + 2s_\theta c_\theta \mathcal{M}_{12} + s_\theta^2 \mathcal{M}_{22} & s_\theta c_\theta \mathcal{M}_{22} - s_\theta c_\theta \mathcal{M}_{11} + (c_\theta^2 - s_\theta^2) \mathcal{M}_{12} \\ s_\theta c_\theta \mathcal{M}_{22} - s_\theta c_\theta \mathcal{M}_{11} + (c_\theta^2 - s_\theta^2) \mathcal{M}_{12} & -2c_\theta^2 \mathcal{M}_{22} - 2s_\theta c_\theta \mathcal{M}_{12} + s_\theta^2 \mathcal{M}_{11} \end{pmatrix} \quad (2.52)$$

The zero mode equations, before renormalization, read

$$\ddot{\phi} + m_\phi^2 \phi + \frac{\lambda}{6} \phi^3 + \frac{g^2}{2} \phi \chi^2 + \sum_{ij} Q_{ij}(t) \langle X_i X_j \rangle = 0, \quad (2.53)$$

$$\ddot{\chi} + m_\chi^2 \chi + \frac{\kappa}{6} \chi^3 + \frac{g^2}{2} \chi \phi^2 + \sum_{ij} R_{ij}(t) \langle X_i X_j \rangle = 0, \quad (2.54)$$

where

$$\begin{aligned} Q_{ij} &= \Lambda_{1kij} \phi_k \\ &= \begin{pmatrix} \frac{\lambda}{2} c_\theta^2 \phi + \frac{g^2}{2} s_\theta^2 \phi + g^2 s_\theta c_\theta \chi & -\frac{\lambda}{2} s_\theta c_\theta \phi + \frac{g^2}{2} s_\theta c_\theta \phi + \frac{g^2}{2} (c_\theta^2 - s_\theta^2) \chi \\ -\frac{\lambda}{2} s_\theta c_\theta \phi + \frac{g^2}{2} s_\theta c_\theta \phi + \frac{g^2}{2} (c_\theta^2 - s_\theta^2) \chi & \frac{\lambda}{2} s_\theta^2 \phi + \frac{g^2}{2} c_\theta^2 \phi - g^2 s_\theta c_\theta \chi \end{pmatrix}, \\ R_{ij} &= \Lambda_{2kij} \phi_k \\ &= \begin{pmatrix} \frac{\kappa}{2} s_\theta^2 \chi + \frac{g^2}{2} c_\theta^2 \chi + g^2 s_\theta c_\theta \phi & \frac{\kappa}{2} s_\theta c_\theta \chi - \frac{g^2}{2} s_\theta c_\theta \chi + \frac{g^2}{2} (c_\theta^2 - s_\theta^2) \phi \\ \frac{\kappa}{2} s_\theta c_\theta \chi - \frac{g^2}{2} s_\theta c_\theta \chi + \frac{g^2}{2} (c_\theta^2 - s_\theta^2) \phi & \frac{\kappa}{2} c_\theta^2 \chi + \frac{g^2}{2} s_\theta^2 \chi - g^2 s_\theta c_\theta \phi \end{pmatrix}. \end{aligned} \quad (2.55)$$

The total energy density of the system, including the fluctuations, can be expressed as

$$\begin{aligned} \mathcal{E} &= \frac{1}{2} \dot{\phi}^2 + \frac{1}{2} \dot{\chi}^2 + \frac{1}{2} m_\phi^2 \phi^2 + \frac{1}{2} m_\chi^2 \chi^2 + \frac{\lambda}{4!} \phi^4 + \frac{\kappa}{4!} \chi^4 \\ &\quad + \frac{g^2}{4} \phi^2 \chi^2 + \frac{1}{2} \langle \dot{X}_i^2 \rangle + \frac{1}{2} \langle (\vec{\nabla} X_i)^2 \rangle + \frac{1}{2} \mathcal{D}_{ij} \langle X_i X_j \rangle. \end{aligned} \quad (2.56)$$

Now we have to formulate finite equations of motion and a finite energy density. We adopt the renormalization procedure of Sec. II A for the N field case. By using the identifications (2.45) we derive the appropriate counterterms for the two field case from Eqs. (2.33)–(2.36). We find in particular

$$\begin{aligned} \delta m_\phi^2 &= \frac{1}{2} (\lambda m_\phi^2 + g^2 m_\chi^2) I_{-3}(\mu), \\ \delta m_\chi^2 &= \frac{1}{2} (g^2 m_\phi^2 + \kappa m_\chi^2) I_{-3}(\mu), \\ \delta \lambda &= \frac{3}{2} (\lambda^2 + g^4) I_{-3}(\mu), \\ \delta g^2 &= \frac{g^2}{2} (\lambda + \kappa + 4g^2) I_{-3}(\mu), \\ \delta \kappa &= \frac{3}{2} (g^4 + \kappa^2) I_{-3}(\mu). \end{aligned} \quad (2.57)$$

Of course we get also similar results to Eqs. (2.38)–(2.41) in the N field case finite corrections to the masses and couplings of the form

$$\begin{aligned} \Delta m_\phi^2 &= -\frac{1}{32\pi^2} \{ D^1(\lambda c_\theta^2 + g^2 s_\theta^2) + D^2(\lambda s_\theta^2 + g^2 c_\theta^2) \\ &\quad + g^2 m_\chi^2 L_1 + \lambda m_\phi^2 L_2 \}, \end{aligned} \quad (2.58)$$

$$\begin{aligned} \Delta m_\chi^2 &= -\frac{1}{32\pi^2} \{ D^1(\kappa s_\theta^2 + g^2 c_\theta^2) + D^2(g^2 s_\theta^2 + \kappa c_\theta^2) \\ &\quad + g^2 m_\phi^2 L_2 + \kappa m_\chi^2 L_1 \}, \end{aligned} \quad (2.59)$$

$$\Delta \lambda = -\frac{1}{32\pi^2} \{ \lambda^2 L_2 + g^4 L_1 \}, \quad (2.60)$$

$$\Delta g^2 = -\frac{3}{32\pi^2} \left\{ g^4 (L_1 + L_2) + \frac{1}{2} g^2 \lambda L_2 + \frac{1}{2} g^2 \kappa L_1 \right\}, \quad (2.61)$$

$$\Delta \kappa = -\frac{1}{32\pi^2} \{ g^4 L_2 + \kappa^2 L_1 \}, \quad (2.62)$$

where

$$\begin{aligned}
L_1 &= s_\theta^2 \ln \frac{D^1}{\mu^2} + c_\theta^2 \ln \frac{D^2}{\mu^2}, \\
L_2 &= s_\theta^2 \ln \frac{D^2}{\mu^2} + c_\theta^2 \ln \frac{D^1}{\mu^2}.
\end{aligned} \tag{2.63}$$

As a result of these finite corrections Eqs. (2.58)–(2.62), the total Lagrangian Eq. (2.43) is also modified. This is exactly the renormalized Lagrangian which we needed. We also find an additional finite contribution to the classical Lagrangian given by

$$\begin{aligned}
\Delta \mathcal{L} &= -\frac{g^2 s_\theta c_\theta \phi \chi}{64 \pi^2} \left\{ 4(D^1 - D^2) \right. \\
&\quad + \ln \frac{D^1}{D^2} [(\lambda + g^2) \chi^2 + (\kappa + g^2) \phi^2 \\
&\quad \left. + 2(m_\chi^2 + m_\phi^2)] \right\},
\end{aligned} \tag{2.64}$$

and, the final zero mode equations for ϕ and χ are given by

$$\begin{aligned}
&\ddot{\phi} + (m_\phi^2 + \Delta m_\phi^2) \phi + \frac{1}{6}(\lambda + \Delta \lambda) \phi^3 + \frac{1}{2}(g^2 + \Delta g^2) \phi \chi^2 + \frac{\partial \Delta \mathcal{L}}{\partial \phi} \\
&+ \left\{ \sum_{l\alpha} Q_{ll}(t) \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\omega_{\alpha 0}} \left(2\delta_l^\alpha \Re f_l^\alpha + f_l^\alpha f_l^{\alpha*} + \frac{V_{ll}}{4\omega_{\alpha 0}^3} \right) \right. \\
&\left. + \sum_{\alpha \neq l} Q_{l\alpha} \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\omega_{\alpha 0}} \left(\Re f_l^\alpha + \Re f_\alpha^\alpha \Re f_l^\alpha + \Im f_\alpha^\alpha \Im f_l^\alpha + \frac{V_{l\alpha}}{2\omega_{\alpha 0}^2} \right) \right\} = 0,
\end{aligned} \tag{2.65}$$

and,

$$\begin{aligned}
&\ddot{\chi} + (m_\chi^2 + \Delta m_\chi^2) \chi + \frac{1}{6}(\kappa + \Delta \kappa) \chi^3 + \frac{1}{2}(g^2 + \Delta g^2) \phi \chi^2 + \frac{\partial \Delta \mathcal{L}}{\partial \chi} \\
&+ \left\{ \sum_{l\alpha} R_{ll}(t) \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\omega_{\alpha 0}} \left(2\delta_l^\alpha \Re f_l^\alpha + f_l^\alpha f_l^{\alpha*} + \frac{V_{ll}}{4\omega_{\alpha 0}^3} \right) \right. \\
&\left. + \sum_{\alpha \neq l} Q_{l\alpha} \int \frac{d^3 k}{(2\pi)^3} \frac{1}{2\omega_{\alpha 0}} \left(\Re f_l^\alpha + \Re f_\alpha^\alpha \Re f_l^\alpha + \Im f_\alpha^\alpha \Im f_l^\alpha + \frac{V_{l\alpha}}{2\omega_{\alpha 0}^2} \right) \right\} = 0.
\end{aligned} \tag{2.66}$$

After writing down the finite zero mode equations of motion we also have to renormalize the energy density. Again by using the ansatz (2.23) we can extract the divergent terms of the fluctuation integrals in Eq. (2.56). In addition to the quadratic and logarithmic divergences we find a quartic divergence. This leads to a counterterm which acts as a cosmological constant and has the form

$$\delta \Lambda = \frac{1}{4}(m_\chi^4 + m_\phi^4) I_{-3}(m). \tag{2.67}$$

Altogether the divergent part of the energy density reads

$$\begin{aligned}
\mathcal{E}_{\text{div}} &= -\frac{I_{-3}(m)}{4} \left\{ (g^2 m_\chi^2 + \lambda m_\phi^2) \phi^2 + (g^2 m_\phi^2 \kappa m_\chi^2) \chi^2 \right. \\
&\quad + \frac{1}{2} g^2 (\lambda + \kappa + 4g^2) \phi^2 \chi^2 + \frac{1}{4} (\lambda^2 + g^4) \phi^4 \\
&\quad \left. + \frac{1}{4} (\kappa^2 + g^4) \chi^4 + m_\chi^4 + m_\phi^4 \right\}.
\end{aligned} \tag{2.68}$$

This expression leads of course to the same counterterms we found for the equations of motion, and therefore also to the same finite corrections to couplings and masses. Therefore it is straightforward to formulate a finite energy expression.

Now, we are in a position to discuss the physical applications of our problem. This we shall do in Sec. III, but first we introduce one more quantity that is convenient in discussing the degree to which the mixing plays a role in the dynamics.

C. Time-dependent mixing angle

To better understand how the system evolves in time, it is useful to have a measure of how much the fields ϕ and χ mix at each moment, and how this mixing evolves with the system. To provide us with a measure of the mixing, we introduce a time-dependent mixing angle $\Theta(t)$, which is defined in terms of the time-dependent mass matrix $\mathcal{M}(t)$, Eq. (2.46):

FIG. 1. The logarithm of the fluctuation integrals $\langle X_1^2 \rangle$ (solid), $\langle X_1 X_2 \rangle$ (dashed), and $\langle X_2^2 \rangle$ (dotted) for the narrow resonance regime.

$$\tan \Theta(t) = \frac{1}{2\mathcal{M}_{12}(t)} [\mathcal{M}_{22}(t) - \mathcal{M}_{11}(t) + \sqrt{(\mathcal{M}_{22}(t) - \mathcal{M}_{11}(t))^2 + 4\mathcal{M}_{12}^2(t)}]. \quad (2.69)$$

III. PHYSICAL APPLICATIONS

After setting up the technical framework, we are now in a position to investigate some relevant cosmological multi-field models for inflation. We begin our analysis with a simple two-field model often used for studying the phase of parametric amplification. (This phase occurs just after the completion of inflation in chaotic inflationary models [6,7].) This model provides a useful context to analyze the effects due to field mixing. Next we turn our attention to a supersymmetric hybrid inflationary model, which is of particular interest in cosmology. As discussed in the literature (see, for example, Ref. [19]) particle production (and hence reheating) in these models is much more efficient compared to the non-supersymmetric hybrid models. Until now the mixing effects in these models have not been treated fully, including back reaction effects of the quantum fluctuations in the mean field approximation. This approximation does not take rescattering processes into account and therefore we cannot address the problem of thermalization.

A. Reheating

The reheating phase in chaotic inflationary models is characterized by two different regimes, which depend on the chosen initial conditions: the first is the narrow resonance regime, while the second is the case of broad resonance. In order to investigate these regimes we examine two different parameter sets, where only the initial values for the zero modes are varied. We find significant differences in the behavior of the fluctuation integrals as well as the mixing angle in the two regimes.

To make the analysis as simple as possible, we set $\lambda = \kappa = 0$ as well as $m_\chi = 0$. For the remaining parameters, we set $m_\phi = 1$, which just acts as a unit of mass, and $g^2 = 0.01$. With

FIG. 2. The logarithm of the fluctuation integrals $\langle X_1^2 \rangle$ (solid), $\langle X_1 X_2 \rangle$ (dashed), and $\langle X_2^2 \rangle$ (dotted) for the broad resonance regime.

these parameters, the case usually studied in the literature, $\chi(0) = 0$, does not introduce any mixing between the fields since the off-diagonal elements of the ϕ - χ mass matrix are proportional to χ . However, taking $\chi(0) = 0$ may not always be the case. For instance, χ field could take a large vacuum expectation value during inflation, provided χ is treated as a field other than the inflaton. For the purpose of illustration we may consider a non-zero initial condition for χ which is of order its effective mass $g\phi$ at the beginning of the preheating stage and examine the consequences. The initial condition for ϕ in the narrow resonance regime is fixed by the condition $g^2\phi(0)/4m_\phi^2 = 0.1$ (remember, g is fixed to be $g = 0.001$) and for the broad resonance regime by $g^2\phi(0)/4m_\phi^2 = 100$. If we take $\phi(0)$ to be approximately the Planck scale as appropriate to the end of inflation, this would correspond to $m_\phi \sim 10^{17}$ GeV and $m_\phi \sim 10^{14}$ GeV for the two respective cases. Note that these parameters are chosen to depict the phenomena of interest during a time scale that can be accurately simulated. The results are, in any case, representative of two-field mixing in the narrow and broad resonance regimes regardless of the precise parameter values in any particular model.

Figure 1 shows the logarithm of the three fluctuation integrals $\langle X_1^2 \rangle$, $\langle X_1 X_2 \rangle$ and $\langle X_2^2 \rangle$ for the narrow resonance case. These are seen to be dominated by the exponential growth of $\langle X_2^2 \rangle$, while the other contributions grow more slowly. Therefore, the evolution is characterized by production of X_2 particles. We now turn to the broad resonance regime, where things look quite different. Here, each of the fluctuation integrals grows rapidly as shown in Fig. 2. Significant mixing of the species occurs along with copious particle production.

The behavior of the fluctuation integrals is consistent with the behavior of the time-dependent mixing angle Θ . Here, the mixing plays a sub-dominant role in the narrow resonance regime (Fig. 3) with the mixing angle remaining near zero. This means that X_2 predominantly corresponds to the χ field, such that the process is one of χ particle production, which is as expected. Concentrating on the time-dependent mixing angle in the broad resonance regime, Fig. 4, significant mixing between the fields is observed. The rapid variation in the mixing angle indicates that mixing between the

FIG. 3. Time-dependent mixing angle $\Theta(t)$ for the narrow resonance regime.

fields plays a very important role in the evolution of preheating in the broad resonance regime. The large influence this has on the behavior of the system is clear from the evolution of the zero mode components $\phi(t)$ in Fig. 5 and $\chi(t)$ in Fig. 6.

B. Supersymmetric hybrid inflation

We now consider a hybrid inflationary model where the finite coupling of two fields plays an interesting role in the termination of slow roll inflation [3]. The particular model we study is based on softly broken supersymmetry [19] with the potential

$$V(\sigma, N) = \frac{1}{2} m_\sigma^2 \sigma^2 + \frac{1}{4} \kappa_s^2 (N^2 - 2\sigma_c^2)^2 + \kappa_s^2 N^2 \sigma^2. \quad (3.1)$$

The field σ plays the role of an inflaton during inflation while the field N is trapped in a false vacuum $\langle N \rangle = 0$. The inflaton rolls down the potential along the σ direction to reach a critical value $\sigma = \sigma_c$. Once σ reaches its critical value, the effective squared mass for the N field becomes negative and consequently it rolls down from the false vacuum to its global minimum through the mechanism of

FIG. 4. Time-dependent mixing angle $\Theta(t)$ for the broad resonance regime.

FIG. 5. Zero mode evolution with fluctuation (solid line) and without fluctuation (dotted line) for $\phi(t)$ for the broad resonance regime.

spinodal instability [11,12]. Thus, inflation comes to an end and both the fields begin oscillations around their respective minima given by

$$\sigma = 0, \quad N = \sqrt{2} \sigma_c. \quad (3.2)$$

This is the onset of the preheating stage, which has been discussed in the literature [22,19,23]. The difference between the supersymmetric hybrid potential and non-supersymmetric hybrid potentials lies in different coupling constants. In Eq. (3.1), there is only the single coupling parameter κ_s , while in the non-supersymmetric version there can be at least two different coupling constants. The above potential, except for the σ mass term, can be derived very easily from the superpotential for F -term spontaneously supersymmetry breaking:

$$W = \frac{\kappa_s}{2} \sigma (N^2 - \sigma_c^2). \quad (3.3)$$

The appearance of a mass term for σ in Eq. (3.1) is due to the presence of soft supersymmetry breaking. Its presence is essential for slow roll inflation to produce adequate density perturbations and also to provide a correct tilt in the power

FIG. 6. Zero mode evolution with fluctuation (solid line) and without fluctuation (dotted line) for $\chi(t)$ for the broad resonance regime.

spectrum [19]. The height of the potential during inflation is given by $\kappa_s^2 \sigma_c^4$. Similar potentials to Eq. (3.1) can also be derived from D -term supersymmetry breaking as discussed in Refs. [24]. In these models the critical value σ_c and the height of the potential energy are related to the Fayet-Illipoulos term coming from an anomalous $U(1)$ symmetry. As in any inflationary model, hybrid inflation is constrained by the Cosmic Background Explorer (COBE) [25]. This imposes the bound

$$\kappa_s \sigma_c \approx 1.27 \times 10^{15} |\eta| \text{ GeV}, \quad (3.4)$$

where η is one of the slow roll parameters which determines the slope of the power spectral index [25]. For our purpose we fix it to be $|\eta| \sim 0.01$.

In order to discuss the details of the physics we mention here the equivalence between Eq. (3.1) and Eq. (2.2). This helps us to establish direct relationship with our earlier analysis:

$$\begin{aligned} \phi &\equiv \sigma, & \chi &\equiv N, & \delta\phi &\equiv \delta\sigma, & \delta\chi &\equiv \delta N, \\ \lambda &= 0, & \kappa &\equiv 6\kappa_s^2, & g &\equiv 2\kappa_s, & m_\phi &\equiv m_\sigma, \\ m_\chi^2 &\equiv -2\kappa_s^2 \sigma_c^2. \end{aligned} \quad (3.5)$$

Notice that m_χ^2 is negative. An interesting feature of the hybrid model is that irrespective of the values of the parameters κ_s , σ_c , and m_σ , as long as they satisfy the COBE constraints, the behavior of the mean fields follow a common pattern once they begin to oscillate [19]. First of all, the mass term for the σ field, m_σ , becomes less dominant compared to the effective frequency for the two fields, which is given by the effective mass for the two fields during oscillations

$$m_{\text{eff}\sigma} = m_{\text{eff}N} = 2\kappa_s \sigma_c \gg m_\sigma. \quad (3.6)$$

Hence, there is a single natural frequency of oscillation, thanks to supersymmetry. Since the masses of the fields are the same at the global minima, there exists a particular solution of the equations of motion for the σ and N fields. Their trajectory follows a straight line towards their global minima:

$$N = \pm \sqrt{2}(\sigma_c - \sigma). \quad (3.7)$$

The maximum amplitude attained by the σ field is $\sim \sigma_c$, while the other field attains a larger amplitude $N = \sqrt{2}\sigma_c$. (We remind readers that $\sigma = \sigma_c$ corresponds to the point where the effective mass for N field changes its sign.) This is the point of instability which we need to discuss here. From Eq. (3.1) we notice that prior to the oscillations of the fields, and during the oscillations, the effective mass square for σ is always positive. However, this is not the case for N , and its mass square can be positive as well as negative even during the oscillations of the fields, provided the amplitudes are large enough. If the amplitudes for σ and N are such that they satisfy Eq. (3.7), then the effective mass square for the N field is in fact always negative for $\sigma < \sigma_c$. If the amplitudes are large enough such that after the second order phase

transition the initial amplitude for $\sigma \approx \sigma_c$, it is then quite possible that near the critical point the effective mass for the field N vanishes completely. As far as the motion of the mean field without including fluctuations is concerned this does not provide any new insight. However, if the fields are quantized then the perturbations in the field, especially for δN , grow exponentially because ω_N^2 in Eq. (2.26) becomes negative for sufficiently small momentum k . This shows that the vacuum is unstable near the critical point σ_c .

Another intuitive way to appreciate this point is to consider the adiabatic condition for the vacuum. The adiabatic evolution for the zero mode evolution for N field is given by $|\dot{\omega}_N| \ll \omega_N^2$. This condition is maximally violated at the point where the effective mass square for N becomes zero, and, violation in adiabatic evolution of the zero mode for N suggests that many fluctuations of δN are produced during the finite period when the adiabaticity is broken [23]. This explanation is quite naive because the overall production of particles and fluctuations depends also upon the global behavior of the zero mode fields. The effect of corrections due to fluctuations might affect the production of particles and this is the point we are going to emphasize in our numerical simulations.

In some sense the hybrid model is quite different from chaotic inflationary models. In chaotic models, the inflaton field rolls down with an amplitude $\sim 1/(mt)$, where m is the mass of the oscillating field. However, in the hybrid model the amplitude of the oscillations die down very slowly, allowing many oscillations of the σ and N fields in one Hubble time. Thus, one could expect large amplitude oscillations of the fields for a long time. This crucially depends on the parameter σ_c . If $\sigma_c \ll M_p$, then we notice that effective masses for σ and N fields during oscillations are much larger than the Hubble parameter. The Hubble parameter is given by $H \approx \kappa \sigma_c^2 / M_p$ during inflation, so,

$$\frac{m_{\text{eff}\sigma}}{H} = \frac{m_{\text{eff}N}}{H} \approx \frac{M_p}{\sigma_c} \gg 1, \quad (3.8)$$

provided the scale of σ_c is quite small compared to the Planck mass, we can effectively neglect the expansion of the Universe.

In the supersymmetric hybrid model there are two regimes of interest. Just after the mass square of the N field becomes negative, the fields begin to oscillate with an amplitude which decreases as $\propto 1/t^2$. When the field amplitude drops below $|N(t)/\sqrt{2}\sigma_c - 1| \leq 1/3$, the amplitude of the oscillations decreases as $\propto 1/t$. In this regime, when the expansion of the Universe is neglected, the amplitude of the oscillations remains constant and the oscillations are harmonic:

$$\frac{N(t)}{\sqrt{2}\sigma_c} \approx 1 + \frac{1}{3} \cos(m_{\text{eff}\sigma} t). \quad (3.9)$$

The corresponding evolution equation for the σ field can be found from Eq. (3.7).

FIG. 7. Evolution of σ (solid line) and N (dotted line) without fluctuations for parameter set (3.10).

In this paper we are neglecting the expansion of the Universe. We concentrate upon two regimes—one with large amplitude oscillations which leads to the following parameters:

$$\begin{aligned} \lambda &= 0, \quad \kappa = 24, \quad g = 4, \quad m_\sigma^2 = 0, \\ m_N^2 &= -16 \times 10^{-12}, \\ \sigma(0) &= 1.4 \times 10^{-6}, \\ N(0) &= 1 \times 10^{-15}, \end{aligned} \quad (3.10)$$

and the other with small amplitude oscillations with the parameters

$$\begin{aligned} \lambda &= 0, \quad \kappa = 24 \times 10^{-6}, \quad g = 4 \times 10^{-3}, \\ m_\sigma^2 &= 0, \quad m_N^2 = -4 \times 10^{-12}, \\ \sigma(0) &= 0.24 \times 10^{-3}, \quad N(0) = 0.66 \times 10^{-3}. \end{aligned} \quad (3.11)$$

The coupling constants are dimensionless while the other dimensional parameters are denoted in Planck units. We find below a marked difference in the zero mode behavior of the fields σ and N in these two cases, depending on whether the fluctuations are taken into account or neglected.

In parameter set (3.10), we study the features of the fields with a large amplitude. This can happen when the σ and N fields begin their oscillations just after the end of inflation. As mentioned earlier, after the end of inflation the maximum amplitude attained by the mean fields can be quite large $\sigma = \sigma_c$, and $N = \sqrt{2}\sigma_c$. This is precisely the initial condition we have chosen for the mean fields for our numerics, as shown in Fig. 7. The values for κ_s and σ_c can be evaluated from Eq. (3.5), which yields

$$\kappa_s = 2, \quad \sigma_c = \sqrt{2} \times 10^{-6}. \quad (3.12)$$

We notice that the evolution for σ and N fields without taking into account the fluctuations are anharmonic, see Fig. 7, and, their trajectories in the σ - N plane is a straight line, as shown in Fig. 8. However, switching on the fluctuations leads to a completely chaotic trajectory as shown in Fig. 9. The departure from the straight line trajectory is quite sig-

FIG. 8. Trajectory for the fields σ and N for parameter set (3.10) without fluctuations.

nificant and it tells us that the renormalized zero mode equations have different contributions to the parameter $6\kappa_s^2$ and to the effective mass of the N field. This mismatch in the frequencies of the zero mode equations for σ and N leads to an irregular trajectory.

The other way to interpret this behavior is to think in terms of different effective mass corrections to σ and N fields, such that the effective frequencies of the oscillations for σ and N do not match each other at the bottom of the potential. This is certainly a nontrivial result. Nonetheless, the result is quite expected from the fact that the amplitude of the oscillations are quite large and the effective mass for the N field is zero at each and every oscillation when $\sigma = \sigma_c$.

As we mentioned earlier, the frequencies of the oscillations of the zero modes are different, as can be noticed in Figs. 10 and 11. The zero mode of σ influenced by the fluctuations oscillates around its minimum $\sigma=0$ with a more rapid frequency than when fluctuations are neglected. This suggests that the effective mass correction to the zero mode for σ is coming solely from the finite coupling contribution from the N field. (Note that we have already set the bare mass for $m_\sigma=0$.) The oscillations maintain the regularity with increasing and decreasing amplitude. However, the story is not the same for the zero mode behavior for the N field. The amplitude of N increases gradually and the fre-

FIG. 9. Trajectory for the fields σ and N for parameter set (3.10) with fluctuations.

FIG. 10. Zero mode evolution for $\sigma(t)$ with fluctuations for parameter set (3.10).

quency of the oscillations varies. We mention here that the effective mass for the N field can vanish at a critical point. As a result, the adiabatic condition for the N field is violated at those instants and this is the reason why the amplitude of the N field is enhanced rather than suppressed.

The evolution of the energy density is shown in Fig. 12. At first instance it seems quite odd that the energy density of the fluctuations does not increase further. One would naively expect a larger contribution of the energy density of $\delta\sigma$ and δN . This is not the case here. The energy density for the mean fields and the fluctuations are equally shared. The reason is the correction due to the fluctuations. These corrections modify the effective mass of the N field and induce corrections to the coupling constants, namely κ and g . The coupling constants are modified in such a way that the trajectory of zero mode fields become irregular. Usually the production of fluctuations is not efficient in this case. This is quite similar to the situation of preheating in non-supersymmetric hybrid models [22]. Even though we started with a supersymmetric hybrid model where at the bottom of the potential there is a single effective frequency, the situation changes completely if the fluctuations are taken into account. Essentially the coupling constants get a large correction which does not preserve an effective single coupling constant for the evolution of the zero mode fields. This is precisely the reason why the zero mode trajectory becomes

FIG. 11. Zero mode evolution for $N(t)$ with fluctuations for parameter set (3.10).

FIG. 12. Energy density stored in $\delta\sigma$ and δN fluctuations (dashed line) and zero mode energy density (dotted line) for parameter set (3.10). The total energy remains constant (solid line).

irregular and also why the production of $\delta\phi$ and δN is so low.

As a next example of the supersymmetric hybrid model we choose parameter set (3.11), with a small coupling κ_s and small σ_c

$$\kappa_s = 2 \times 10^{-3}, \quad \sigma_c = 0.707 \times 10^{-3}. \quad (3.13)$$

In this example, the coupling between the fields is quite small; $g = 4 \times 10^{-3}$, and also the initial conditions for σ and N have been chosen such that the fields oscillate around their respective minima. The maximum amplitude for $\sigma(0) = \sigma_c/3$ and $N(0) = (2\sqrt{2}/3)\sigma_c$ is much below the critical point σ_c . We remind the readers that the chosen initial conditions for the oscillations do not come naturally just after the end of inflation, therefore this example does not represent a real situation. In spite of this we study the particular situation in order to notice the contrast in the behavior of the zero modes and the energy densities in the fluctuations. This particular set of initial conditions for $\sigma(0), N(0)$ offers an alternative example where spinodal instability in the N field does not take place. As a result the effective mass square for the N field never crosses zero and the adiabatic condition for the N field is not strongly broken. The oscillations of the mean fields σ and N are harmonic in nature, as shown in Figs. 13 and 14 by the dotted lines. The amplitudes are constant with a frequency given by Eq. (3.6). The oscillations of the mean fields is governed by Eqs. (3.7) and (3.9). The trajectory in the σ - N plane is a straight line whose slope is governed by Eq. (3.7).

The effect of the fluctuations is also quite expected in this case. The amplitudes of the zero mode for σ and N fields decreases after a while and, in contrast to the preceding example, the frequency of the oscillations do not change very dramatically; see the behavior of zero mode in solid lines in Figs. 13 and 14. The trajectories for the zero mode evolution remain a straight line in this case, as shown in Fig. 15. This is quite reasonable for the parameters we have chosen, but an important observation is that the effect of fluctuations does not alter the straight line trajectory for the zero mode fields. This suggests that for small amplitude oscillations the corrections to the coupling constants, $\Delta\kappa$ and Δg , are such that

FIG. 13. Zero mode evolution for $\sigma(t)$ with fluctuations (solid lines) and the without fluctuations (dotted line) for parameter set (3.11).

the zero mode equations still have a similar oscillating frequency. This can be seen in Figs. 13 and 14. The production of $\delta\sigma$ and δN is not very significant because the energy density stored in $\delta\sigma$ and δN does not grow rapidly. Thus the energy transfer from the zero modes to the fluctuation modes is not favorable for such small amplitude oscillations as can be seen in Fig. 16.

We conclude this section by mentioning that preheating in this supersymmetric hybrid model is quite interesting. Depending on the amplitude of the oscillations of the fields, the behavior of the zero mode can be quite different. As a new feature we noticed that if the amplitude of the oscillations is close to the critical value σ_c , the effective mass square for the N field becomes negative and as a result the fluctuations of the field grows exponentially. However, the effect of fluctuations alters the coupling constants in such a way that the trajectory of the zero modes become irregular. Even though the adiabatic conditions seem to be broken for the N field near the critical value, the energy density transferred from the zero mode to the fluctuations is not sufficient. Our study reveals some interesting messages which we briefly mention here. We emphasize the point that the departure from the straight line trajectory of the zero mode is an essential feature of a supersymmetric hybrid model if the fluctuations are taken into account. Even though, we have not included the

Hubble expansion, the results we have obtained are quite robust because supersymmetric hybrid inflationary models have a unique behavior of the fields which allows a smaller inflationary scale compared to the effective masses of the fields around their global minima. This suggests that during the oscillations, the expansion is felt much later, on a time scale determined by the parameters. This behavior is not shared by models where inflation is governed by a single field as in chaotic inflationary models. This undermines the production of quanta from the vacuum fluctuations. In several ways this affects the post inflationary radiation era of the Universe. Supersymmetric, weakly interacting dark matter formation and generation of baryonic asymmetry in the Universe during preheating are the two most important frontiers which due to our results may warrant a careful reevaluation.

In order to substantiate our claim that a due consideration of fluctuations after the end of inflation is an important feature of any supersymmetric hybrid model, we have chosen an unphysical example which serves the purpose of making a vivid distinction. We stress here that the spinodal instability which is actually responsible for producing an irregular trajectory of the zero mode of the fields in a phase space is completely lacking if the amplitudes of the oscillations for σ, N are small compared to the critical value σ_c . This acts as

FIG. 16. Energy density stored in $\delta\sigma$ and δN (dotted line) along with the zero mode energy density (double dotted line) for parameter set (3.11). The total energy density remains constant (solid line).

a comparative study and shows that after the end of inflation, in a supersymmetric hybrid inflationary model, due to the spinodal instability in a field, a proper renormalization of the masses and the coupling constant have to be taken into account.

IV. CONCLUSION

We have introduced a formalism to address the dynamics of N nonequilibrium, coupled, time varying scalar fields. We have shown that the one-loop corrections to the mean field evolution can be renormalized by dimensional regularization. For the sake of clarity and simplicity we restricted ourselves to Minkowski spacetime while deriving the renormalized equations of motion and the energy density of the system. We applied our formalism to a two-field case where we study the behavior of the quantized mode functions and the effect of fluctuations on the zero mode equations of motion for various parameters, including small and large amplitude oscillations and large and weak coupling between two scalar fields. The varied couplings and amplitudes illustrate various facets of the intertwined dynamics of the two-fields which lead to a deeper understanding of the production of self-quanta and the transfer of energy density between the fields in a cosmological context.

As a special example we have chosen a two-field inflationary model which is genuinely motivated by supersymmetry and thus preserves the effective masses of the fields to be the same in their local minima. The model, as a paradigm, predicts inflation which comes to an end via a smooth phase transition, and the robustness of the model is confirmed by a slightly tilted spectrum of scalar density fluctuations within the COBE limit. The model parameters can be adjusted to give an inflationary scale covering a wide range of energy

scales from TeV to 10^{15} GeV. The phase transition leads to a spinodal instability in one of the fields which leads to coherent oscillations of the fields around their global minima. The instability occurs in one of the fields which demands careful study of the back reaction to an otherwise growing mean field in an intertwined coupled bosonic system. An account of influence of the fluctuations gives rise to uneven contribution to the renormalized masses of the fields. This results in an irregular trajectory of the zero mode in a phase space, which breaks the coherent oscillations of the two fields. This prohibits an excessive production of particles from the vacuum fluctuations. This requires a careful re-evaluation of the successes of the production of weakly interacting massive particles and baryogenesis via out of equilibrium decay in supersymmetric hybrid inflationary models. Our study implies that exciting higher spin particles from the vacuum fluctuations of the coherent oscillations of the fields in a supersymmetric hybrid inflationary model demands careful reconsideration.

Even though we have neglected the effect of expansion in our calculation, our results are robust enough to claim that the fluctuations in a supersymmetric hybrid model do not grow if the back reaction of the fluctuations is taken into account in the mean field evolution. An extension of our formalism to an expanding universe deserves separate attention.
