ABSTRACT

Control laws are designed for stabilization of a chain of integrators of arbitrary degree in finite and fixed time. Presented control laws are obtained with use of Lyapunov function method and homogeneity concept. The present analysis is based on use of explicitly defined Lyapunov function that is the hallmark with respect to similar works. This analysis allows to get simple procedure of parameters tuning and obtain new estimates for settling-time function. The theoretical results are supported by numerical examples.

KEYWORDS

Finite-time stabilization; fixed-time stabilization; homogeneity

1. Introduction

Motivated by modern control applications, the finite-time and fixed-time stabilization feedback design is continuing to be the subject of numerous studies (see, for example, Bacciotti & Rosier, 2005; Bhat & Bernstein, 2000; Cruz-Zavala & Moreno, 2017; Orlov, 2004; Polyakov, Efimov, & Perruquetti, 2015, etc.). Among these studies and many others, particular attention is paid to finite/fixed-time stabilization of integrator chains as a basic model for demonstration and further extension for multi-input multi-output linear plants. Interest to the disturbed integrator chain control systems is additionally motivated by different mechanical and electromechanical applications (see, for example, Chernousko, Ananevskii, & Reshmin, 2008; Utkin, Guldner, & Shi, 2009). However, most of existing control laws are discontinuous (as, for example, in Cruz-Zavala & Moreno, 2017; Harmouche, Laghrouche, Chitour, & Hamerlain, 2016), designed to stabilize the chain of integrators only of a certain order (for second order Orlov, Aoustin, & Chevallereau, 2011; Sua & Zheng, 2015; for third order Sanchez & Moreno, 2013; Trivedi & Bandyopadhyay, 2011, etc.), or even depending directly on the initial conditions (Sanchez & Moreno, 2013).

*A preliminary version of this work (Zimenko, Polyakov, Efimov, & Perruquetti, in press) does not contain proofs and the case of continuous fixed-time control design.

CONTACT K. Zimenko. Email: kostyazimenko@gmail.com

The present paper is devoted to Lyapunov-based controller design which stabilizes the arbitrary order integrator chain in finite/fixed time. Presented control algorithms are obtained with use of Lyapunov function method and homogeneity concept.

The paper (Polyakov et al., 2015) is related to development of robust finite-time and fixed-time stabilization controllers, which depend on implicitly defined homogeneous Lyapunov function. For practical implementation of these control algorithms it is required to use special computational procedures for calculating Implicit Lyapunov Function (ILF). In (Zimenko, Polyakov, & Efimov, 2016) the finite-time control law has been modified to explicit form, where instead of ILF the homogeneous norm is used. Then the difference between ILF and homogeneous norm is considered as additional external disturbance, that has led to a more complex analysis and parameters tuning procedure. In comparison with these works the novelty of the present paper is as follows:

- new finite-time and fixed-time control algorithms are proposed in explicit form for the system of arbitrary order;
- stability analysis is based on the use of a Lyapunov function proposed in explicit form;
- simple procedures of parameters tuning are established;
- new estimates for settling-time function are presented.

It is also shown that fixed-time convergence can be achieved by changing the homogeneity degree in hybrid control algorithm.

In addition, the proposed controllers homogenize the system that implies robustness abilities to external perturbations and time-delays (see, for example, Bernuau, Polyakov, Efimov, & Perruquetti, 2013; Efimov, Polyakov, Perruquetti, & Richard, 2016; Zimenko, Efimov, Polyakov, & Perruquetti, 2017).

The paper is organized in the following way. The problem formulation is presented in Section 2. Section 3 recalls some basics on finite/fixed-time stability and weighted homogeneity. Section 4 presents the main result on finite-time and fixed-time controllers design. Simulation results are shown in Section 5 for performance illustration of proposed control algorithms. Finally, concluding remarks are given in Section 6.

Through the paper the following notation will be used: \mathbb{R} is the set of real numbers; $\mathbb{R}_+ = \{x \in \mathbb{R} : x > 0\}$; $diag\{\lambda_i\}_{i=1}^n$ is a diagonal matrix with elements λ_i ; for $P \in \mathbb{R}^{n \times n}$ the relation $P > 0$ ($P < 0$, $P \geq 0$, $P \leq 0$) means that the symmetric matrix $P = P^T$ is positive (negative) definite (semidefinite); a series of integers $1, 2, \dots, n$ is denoted by $\overline{1, n}$.

2. Problem formulation

Consider a chain of n integrators

$$\dot{x} = Ax + bu, \tag{1}$$

where $x \in \mathbb{R}^n$ is the state vector, $u \in \mathbb{R}$,

$$A = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} \text{ and } b = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}.$$

The objective of the present paper is to design Lyapunov-based controllers, which stabilize the arbitrary order system (1) to the origin in finite/fixed time.

3. Preliminaries

3.1. Finite-time and fixed-time stability

Let us consider the system

$$\dot{x} = f(t, x), \quad x(0) = x_0, \quad (2)$$

where $x \in \mathbb{R}^n$ is the state vector, $f \in \mathbb{R}_+ \times \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a vector field. If the vector field f is discontinuous with respect to x , then the solutions of (2) fall into the area of differential inclusions and need to be understood in the sense of Filippov (1988). For any $x_0 \in \mathbb{R}^n$ denote a corresponding solution by $\tilde{X}(t, x_0)$ for the instants $t \geq 0$ for which it exists, $\tilde{X}(0, x_0) = x_0$.

Definition 3.1 (Bhat & Bernstein, 2000; Orlov, 2004). The origin of (2) is said to be globally finite-time stable if it is globally asymptotically stable and any solution $\tilde{X}(t, x_0)$ of (2) reaches the equilibrium point at some finite time moment, i.e., $\tilde{X}(t, x_0) = 0, \forall t \geq T(x_0)$, where $T: \mathbb{R}^n \rightarrow \mathbb{R}_+ \cup \{0\}$ is the settling-time function.

Definition 3.2 (Polyakov, 2012). The origin of (2) is said to be fixed-time stable if it is globally finite-time stable and the settling-time function $T(x_0)$ is bounded, i.e., $\exists T_{\max} > 0: T(x_0) \leq T_{\max}, \forall x_0 \in \mathbb{R}^n$.

Definition 3.3 (Polyakov, 2012). The set M is said to be globally finite-time attractive for (2) if any solution $\tilde{X}(t, x_0)$ of (2) reaches M in some finite time moment $t = T(x_0)$ and remains there $\forall t \geq T(x_0)$, $T: \mathbb{R}^n \rightarrow \mathbb{R}_+ \cup \{0\}$ is the settling-time function.

Definition 3.4 (Polyakov, 2012). The set M is said to be fixed-time attractive for (2) if it is globally finite-time attractive and the settling-time function $T(x_0)$ is globally bounded by some number $T_{\max} > 0$.

Theorem 3.5 (Bhat & Bernstein, 2000; Harmouche et al., 2016). *Suppose there exists a positive definite C^1 function V defined on an open neighborhood of the origin $D \subset \mathbb{R}^n$ and real numbers $C > 0$ and $\sigma \geq 0$, such that the following condition is true for the system (2)*

$$\dot{V}(x) \leq -CV^\sigma(x), \quad x(t) \in D \setminus \{0\}.$$

Then depending on the value σ the origin is stable with different types of convergence:

- if $\sigma = 1$, the origin is exponentially stable;
- if $0 \leq \sigma < 1$, the origin is finite-time stable and

$$T(x_0) \leq \frac{1}{C(1-\sigma)} V_0^{1-\sigma},$$

where $V_0 = V(x_0)$;

- if $\sigma > 1$ the origin is asymptotically stable and, for every ϵ , the set $B(0, \epsilon) = \{x \in D: V(x) < \epsilon\}$ is fixed-time attractive with

$$T_{\max} = \frac{1}{C(\sigma-1)\epsilon^{\sigma-1}}.$$

If $D = \mathbb{R}^n$ and function V is radially unbounded, then the system (2) is globally stable with respect to the equilibrium point.

3.2. Weighted homogeneity

For $r_i \in \mathbb{R}_+$, $i = \overline{1, n}$, $\rho > 2 \max_i r_i$ and $\lambda > 0$ define vector of weights $r = (r_1, \dots, r_n)^T$, dilation matrix $D_r(\lambda) = \text{diag}\{\lambda^{r_i}\}_{i=1}^n$ and homogeneous norm

$$\|x\|_r = \left(\sum_{i=1}^n |x_i|^{\frac{\rho}{r_i}} \right)^{\frac{1}{\rho}}. \quad (3)$$

Note that under introduced restriction on ρ the homogeneous norm is a continuously differentiable function out of the origin.

Definition 3.6 (Zubov, 1958). A function $g: \mathbb{R}^n \rightarrow \mathbb{R}$ (vector field $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$) is said to be r -homogeneous of degree d if $g(D_r(\lambda)x) = \lambda^d g(x)$ ($f(D_r(\lambda)x) = \lambda^d D_r(\lambda)f(x)$) for fixed r , all $\lambda > 0$ and $x \in \mathbb{R}^n$.

Obviously, homogeneous norm is r -homogeneous of degree 1. Introduce the following compact set (homogeneous sphere) $\mathbb{S}_r = \{x \in \mathbb{R}^n: \|x\|_r = 1\}$, then for any $x \in \mathbb{R}^n$ there is $y \in \mathbb{S}_r$ such that $x = D_r(\lambda)y$ for $\lambda = \|x\|_r$.

Theorem 3.7 (Bacciotti & Rosier, 2005). Let $f: \mathbb{R}^n \rightarrow \mathbb{R}^n$ be defined on \mathbb{R}^n and be a continuous r -homogeneous vector field with degree d ($d < 0$). If the origin of the system

$$\dot{x} = f(x) \quad (4)$$

is locally asymptotically stable then it is globally asymptotically stable (globally finite-time stable) and there exists a continuously differentiable Lyapunov function V which is r -homogeneous of degree $v > -d$.

By definition of homogeneity there exist constants $c_1, c_2 > 0$ such that

$$c_1 \|x\|_r^v \leq V(x) \leq c_2 \|x\|_r^v. \quad (5)$$

The r -homogeneity presented in Definition 3.6 is introduced for some r and all

$\lambda > 0$. Restricting the set of admissible values for λ the local homogeneity concept has been introduced in (Andrieu, Praly, & Astolfi, 2008; Bernuau et al., 2013; Zubov, 1958).

4. Main result

For $\mu \in (0, 1]$ and the vector of weights $r = (l + (n - 1)\mu, l + (n - 2)\mu, \dots, l)^T$, $r_{\max} = \max_{1 \leq j \leq n} r_j = l + (n - 1)\mu$, $r_{\min} = \min_{1 \leq j \leq n} r_j = l$ denote the dilation matrix $D_r(\lambda) = \text{diag}\{\lambda^{r_i}\}_{i=1}^n$ and diagonal matrix $\tilde{H} = \text{diag}\{-m + (n + 1 - i)\mu\}_{i=1}^n$, where $l \in \mathbb{R}_+ : l \geq \mu$, $m \in \mathbb{R}_+ : m > n\mu$.

Theorem 4.1. *If the system of matrix inequalities:*

$$X > 0, \quad (6)$$

$$\alpha_{\max}(\tilde{H}X + X\tilde{H}) + AX + XA^T + by + y^T b^T \leq -\gamma X, \quad (7)$$

$$-\alpha_{\max}(\tilde{H}X + X\tilde{H}) + AX + XA^T + by + y^T b^T \leq -\gamma X, \quad (8)$$

is feasible for some $X \in \mathbb{R}^{n \times n}$, $y \in \mathbb{R}^{1 \times n}$, $\gamma \in \mathbb{R}_+$ and

$$\alpha_{\max} = \left(1 + \left(\sum |k_i|^{\frac{\rho}{\rho - r_{\min}}} \right)^{\frac{\rho - r_{\min}}{r_{\min}}} \right)^{\frac{r_{\min}}{\rho}} \left(\sum \left(\frac{1}{r_i} \right)^{\frac{\rho}{r_{\max} - r_{\min}}} \right)^{\frac{r_{\max} - r_{\min}}{\rho}}, \quad (9)$$

$P = X^{-1}$, $k = yX^{-1}$, then the control of the form

$$u = \|x\|_r^{l-\mu} k D_r \left(\frac{1}{\|x\|_r} \right) x \quad (10)$$

stabilizes the origin of the system (1) in a finite time and the settling-time function estimate has the form

$$T(x_0) \leq \frac{2(m + l - \mu)V_0^\mu}{\mu\gamma c_1^\mu}, \quad (11)$$

where $V_0 = \left(x_0^T H \left(\frac{1}{\|x_0\|_r} \right) P H \left(\frac{1}{\|x_0\|_r} \right) x_0 \right)^{\frac{1}{2(m+l-\mu)}}$, $H(\lambda) = \text{diag}\{\lambda^{-m+(n+1-i)\mu}\}_{i=1}^n$ and $c_1 = \min_{\|x\|_r=1} \left\{ (x^T P x)^{\frac{1}{2(m+l-\mu)}} \right\}$.

Proof. Consider the Lyapunov candidate function in the next form:

$$V(x) = \left(x^T H \left(\frac{1}{\|x\|_r} \right) P H \left(\frac{1}{\|x\|_r} \right) x \right)^{\frac{1}{2m+2l-2\mu}}.$$

The function V is continuous, positive definite and radial unbounded on $\mathbb{R}^n \setminus \{0\}$. In addition, since $\lim_{x \rightarrow 0} V = 0^+$ the function V can be continuously prolonged to the origin by setting $V(0) = 0$.

Note, that V is homogeneous of degree 1. The inequality (5) can be rewritten as

$$c_1 \|x\|_r \leq V \leq c_2 \|x\|_r$$

and $\|x\|_r^{-\mu} \geq c_1^\mu V^{-\mu}$. The parameter c_1 can be estimated on some grid, where $c_1 = \min_{\|x\|_r=1} \left\{ (x^T P x)^{\frac{1}{2(m+l-\mu)}} \right\}$.

Define $\alpha(x) = \left| \|x\|_r^{-1+\mu} \nabla_x (\|x\|_r) \dot{x} \right|$. Since $\nabla_x (\|x\|_r) \dot{x} = \frac{1}{\rho} \|x\|_r^{1-\rho} \sum \frac{\rho}{r_i} |x_i|^{\frac{\rho-r_i}{r_i}} \text{sign}(x_i) \dot{x}_i = \|x\|_r^{1-\rho} \sum \frac{1}{r_i} |x_i|^{\frac{\rho-2r_i}{r_i}} x_i \dot{x}_i$ it can be easily checked that α is homogeneous of degree 0, $\|x\|_r$ is differentiable everywhere for $\rho > 2 \max_i r_i$ and $0 \leq \alpha(x) \leq \alpha_{\max}$. Then the parameter α_{\max} can be found on the set $x \in \mathbb{S}_r$ using Hölder's inequality as follows:

$$\begin{aligned} |\nabla_x (\|x\|_r) \dot{x}| &= \frac{1}{\rho} \left| \sum \frac{\rho}{r_i} |x_i|^{\frac{\rho-r_i}{r_i}} \text{sign}(x_i) \dot{x}_i \right| \leq \sum \frac{1}{r_i} |x_i|^{\frac{\rho-r_i}{r_i}} |\dot{x}_i| \leq \\ &\leq \left(\sum |x_i|^{\frac{\rho(\rho-r_i)}{(\rho-r_{\max})r_i}} \right)^{\frac{\rho-r_{\max}}{\rho}} \left(\sum \left(\frac{1}{r_i} |\dot{x}_i| \right)^{\frac{\rho}{r_{\max}}} \right)^{\frac{r_{\max}}{\rho}} \leq \\ &\leq \left(\sum |\dot{x}_i|^{\frac{\rho}{r_{\min}}} \right)^{\frac{r_{\min}}{\rho}} \left(\sum \left(\frac{1}{r_i} \right)^{\frac{\rho}{r_{\max}-r_{\min}}} \right)^{\frac{r_{\max}-r_{\min}}{\rho}} \leq \\ &\leq \left(1 + |u|^{\frac{\rho}{r_{\min}}} \right)^{\frac{r_{\min}}{\rho}} \left(\sum \left(\frac{1}{r_i} \right)^{\frac{\rho}{r_{\max}-r_{\min}}} \right)^{\frac{r_{\max}-r_{\min}}{\rho}} \leq \\ &\leq \left(1 + \left(\sum |k_i|^{\frac{\rho}{\rho-r_{\min}}} \right)^{\frac{r_{\min}}{r_{\min}}} \right)^{\frac{r_{\min}}{\rho}} \left(\sum \left(\frac{1}{r_i} \right)^{\frac{\rho}{r_{\max}-r_{\min}}} \right)^{\frac{r_{\max}-r_{\min}}{\rho}} = \alpha_{\max}. \end{aligned}$$

Then by applying the inequalities (6)-(8) the time derivative of Lyapunov function V along the trajectories of the system (1) can be estimated as follows

$$\begin{aligned} \dot{V} &= \frac{V^{1-2(m+l-\mu)}}{2(m+l-\mu)} 2x^T H \left(\frac{1}{\|x\|_r} \right) P \left(\dot{H} \left(\frac{1}{\|x\|_r} \right) x + H \left(\frac{1}{\|x\|_r} \right) \dot{x} \right) = \\ &= \frac{V^{1-2(m+l-\mu)}}{2(m+l-\mu)} 2x^T H \left(\frac{1}{\|x\|_r} \right) P \left(-\|x\|_r^{-1} \nabla_x (\|x\|_r) \dot{x} \tilde{H} H \left(\frac{1}{\|x\|_r} \right) x + \right. \\ &\quad \left. + (\|x\|_r)^{-\mu} \left(AH \left(\frac{1}{\|x\|_r} \right) x + bkH \left(\frac{1}{\|x\|_r} \right) x \right) \right) = \\ &= \frac{V^{1-2(m+l-\mu)}}{2(m+l-\mu)} \|x\|_r^{-\mu} 2x^T H \left(\frac{1}{\|x\|_r} \right) P \left(-\|x\|_r^{-1+\mu} \nabla_x (\|x\|_r) \dot{x} \tilde{H} + A + bk \right) H \left(\frac{1}{\|x\|_r} \right) x \leq \\ &\leq -\frac{\gamma c_1^\mu V^{1+\mu-2(m+l)}}{2(m+l-\mu)} x^T H \left(\frac{1}{\|x\|_r} \right) P H \left(\frac{1}{\|x\|_r} \right) x = -\frac{\gamma c_1^\mu}{2(m+l-\mu)} V^{1-\mu} \end{aligned}$$

and

$$T(x_0) \leq \frac{2(m+l-\mu)V_0^\mu}{\mu\gamma c_1^\mu},$$

where $V_0 = V(x_0)$.

Validity of Theorem 4.1 is thus concluded. \square

Remark 1. The finite-time control law (10) for $l = 1$ coincides with the control presented in (Zimenko et al., 2016). In comparison with (Zimenko et al., 2016), presented analysis allows to relax obtained LMIs and simplify the procedure of parameters tuning. Also, new estimates for settling-time function are obtained.

Remark 2. Since the inequalities (7), (8) are feasible at least for sufficiently small α (can be achieved by choosing sufficiently big $l \in \mathbb{R}_+$) the presented control scheme implies simple control parameters tuning: it requires to solve LMIs (6) and

$$\tilde{\alpha}(\tilde{H}X + X\tilde{H}) + AX + XA^T + by + y^T b^T \leq -\gamma X,$$

$$-\tilde{\alpha}(\tilde{H}X + X\tilde{H}) + AX + XA^T + by + y^T b^T \leq -\gamma X,$$

for some $\tilde{\alpha} \in \mathbb{R}_+$ and then choose such l for which $\alpha_{\max} \leq \tilde{\alpha}$.

Remark 3. The parameter m can be chosen large enough to have $\tilde{H}X + X\tilde{H} \leq 0$. In this case the inequality (7) can be ignored.

Remark 4. Parameters l , m , μ and γ allows the upper bound of the settling time function (11) to be adjusted.

Remark 5. For $l = \mu \leq 1$ the control (10) is continuous outside the origin and globally bounded for all $x \in \mathbb{R}^n$:

$$\begin{aligned} u^2 &= x^T D_r \left(\frac{1}{\|x\|_r} \right) k^T k D_r \left(\frac{1}{\|x\|_r} \right) x \leq \varsigma \|x\|_r^{-2m} x^T H \left(\frac{1}{\|x\|_r} \right) P H \left(\frac{1}{\|x\|_r} \right) x = \\ &= \varsigma \|x\|_r^{-2m} V^{2m} \leq \varsigma c_2^{2m}, \end{aligned}$$

where $\varsigma \in \mathbb{R}_+$: $k^T k \leq \varsigma P$.

For $\mu < \min\{l, 1\}$ the control (10) is continuous in the state variable x . If $\mu \rightarrow 0$ then the feedback (10) becomes a linear $u = kx$. If $\mu = l \leq 1$ the control is discontinuous at the origin and continuous outside. For practical realization of the control, the discontinuous feedback law can be replaced with a high-gain linear feedback if the system state is close to the origin as in (Polyakov et al., 2015).

Remark 6. It can be easily checked that the system (1), (10) is homogeneous of degree $-\mu$. Thus, the system has such qualitative stability properties of homogeneous systems as Input-to-State Stability with respect to additive perturbations in the right-hand side of (1) and measurement noises in the feedback (see, for example, Bernuau et al., 2013).

Remark 7. Since the closed-loop system is r -homogeneous with negative degree, then in presence of any delay the system (1), (10) is globally asymptotically stable with respect to a compact set containing the origin independently of delay (see, for example, Zimenko et al., 2017).

Remark 8. The controller (10) can also be treated as the weighted homogeneous version of the unit sliding mode control (Dorling & Zinober, 1986; Utkin et al., 2009).

Note that in presented control scheme instead of homogeneous norm (3) another homogeneous function of degree 1 can be used. In this case the main difference is in calculating the parameter α . Also if we choose instead of homogeneous norm implicitly defined homogeneous function equal to V , then for $m = l = 1$ we obtain implicitly defined Lyapunov function

$$Q = x^T D_r(V^{-1}) P D_r(V^{-1}) x - 1$$

and control $u = V^{1-\mu}kD_r(V^{-1})x$, $V \in \mathbb{R}_+$: $Q(V, x) = 0$ as in (Polyakov et al., 2015; Polyakov, Efimov, & Perruquetti, 2016).

Convergence within a fixed interval of time irrespectively of its initial conditions can be achieved by changing the degree of homogeneity in hybrid control algorithm. The following discontinuous fixed-time controller is based on time dependent switching scheme for the first time presented in (Angulo, Moreno, & Fridman, 2013) for an observer.

In this case for $m_1, m_2 \in \mathbb{R}_+$: $m_1 = m_2 + 2\mu$, $m_1 > n\mu$, $l > (n-1)\mu$, $\mu \in (0, 1]$ denote vectors of weights $r_1 = (l + (n-1)\mu, l + (n-2)\mu, \dots, l)^T$, $r_2 = (l - (n-1)\mu, l - (n-2)\mu, \dots, l)^T$, homogeneous norms $\|x\|_{r_1}$, $\|x\|_{r_2}$ and matrices $D_1(\lambda) = \text{diag}\{\lambda^{r_1(i)}\}_{i=1}^n$, $\tilde{H}_1 = \text{diag}\{-m_1 + (n+1-i)\mu\}_{i=1}^n$, $D_2(\lambda) = \text{diag}\{\lambda^{r_2(i)}\}_{i=1}^n$, $\tilde{H}_2 = \text{diag}\{-m_2 - (n+1-i)\mu\}_{i=1}^n$, $H_1(\lambda) = \text{diag}\{\lambda^{-m_1 + (n+1-i)\mu}\}_{i=1}^n$, $H_2(\lambda) = \text{diag}\{\lambda^{-m_2 - (n+1-i)\mu}\}_{i=1}^n$.

Define homogeneous functions of degree 1:

$$V_1(x) = \left(x^T H_1 \left(\frac{1}{\|x\|_{r_1}} \right) P H_1 \left(\frac{1}{\|x\|_{r_1}} \right) x \right)^{\frac{1}{2(m_1 + l - \mu)}},$$

$$V_2(x) = \left(x^T H_2 \left(\frac{1}{\|x\|_{r_2}} \right) P H_2 \left(\frac{1}{\|x\|_{r_2}} \right) x \right)^{\frac{1}{2(m_2 + l + \mu)}}.$$

For V_1 and V_2 according to (5) define c_{11} , c_{21} and c_{12} , c_{22} correspondingly.

Theorem 4.2. *If the system of matrix inequalities (6),*

$$\alpha_1(\tilde{H}_1 X + X \tilde{H}_1) + AX + XA^T + by + y^T b^T \leq -\gamma_1 X, \quad (12)$$

$$-\alpha_1(\tilde{H}_1 X + X \tilde{H}_1) + AX + XA^T + by + y^T b^T \leq -\gamma_1 X, \quad (13)$$

$$\alpha_2(\tilde{H}_2 X + X \tilde{H}_2) + AX + XA^T + by + y^T b^T \leq -\gamma_2 X, \quad (14)$$

$$-\alpha_2(\tilde{H}_2 X + X \tilde{H}_2) + AX + XA^T + by + y^T b^T \leq -\gamma_2 X, \quad (15)$$

is feasible for some $X \in \mathbb{R}^{n \times n}$, $y \in \mathbb{R}^{1 \times n}$, $\gamma_1, \gamma_2 \in \mathbb{R}_+$, where α_1, α_2 are calculated according to (9) with r_1 and r_2 correspondingly, $P = X^{-1}$, $k = yX^{-1}$, then the control of the form

$$u = \begin{cases} \|x\|_{r_2}^{l+\mu} k D_2 \left(\frac{1}{\|x\|_{r_2}} \right) x & \text{for } t \leq T_s, \\ \|x\|_{r_1}^{l-\mu} k D_1 \left(\frac{1}{\|x\|_{r_1}} \right) x & \text{for } t > T_s, \end{cases} \quad (16)$$

for some $T_s \in \mathbb{R}_+$ stabilizes the origin of the system (1) in a fixed time

$$T(x_0) \leq 2(m_1 + l - \mu)\mu^{-1} \left(\frac{c_{22}^\mu}{\gamma_2 E^\mu} + \frac{B^\mu}{\gamma_1 c_{11}^\mu} \right), \quad (17)$$

where $E = \left(\frac{2(m_1+l-\mu)c_{2_2}^\mu}{\mu\gamma_2 T_s} \right)^{\frac{1}{\mu}}$,

$$B = \max_{V_2=E} V_1. \quad (18)$$

Proof. Similarly to the proof of Theorem 4.1 it can be shown that if the inequalities (6), (12)-(15) hold, then

$$\dot{V}_2 \leq -\frac{\gamma_2 V_2^{1+\mu}}{2(m_2+l+\mu)c_{2_2}^\mu} \quad (19)$$

and

$$\dot{V}_1 \leq -\frac{\gamma_1 c_{1_1}^\mu V_1^{1-\mu}}{2(m_1+l-\mu)}.$$

Consider the following sets

$$\mathbb{B}_1 = \{x \in \mathbb{R}^n : V_1 \leq B\}$$

and

$$\mathbb{B}_2 = \{x \in \mathbb{R}^n : V_2 \leq E\}.$$

By (18), it is obvious, that $\mathbb{B}_2 \subset \mathbb{B}_1$. According to Theorem 3.5 and (19) the set \mathbb{B}_2 is fixed-time attractive with $T_{\max} = T_s = \frac{2(m_2+l+\mu)c_{2_2}^\mu}{\mu\gamma_2 E^\mu} = \frac{2(m_1+l-\mu)c_{2_2}^\mu}{\mu\gamma_2 E^\mu}$. When x reaches the set $\mathbb{B}_2 \subset \mathbb{B}_1$, for $t > T_s$ the system will become finite-time stable and it will converge to the origin in a time, bounded by $T_1 = \frac{2(m_1+l-\mu)B^\mu}{\mu\gamma_1 c_{1_1}^\mu}$. Then the control (16) stabilizes the origin of the system (1) in a fixed time $T(x_0) \leq T_1 + T_s$, that is equal to (17). \square

Note, that the parameter $T_s \in \mathbb{R}_+$ can be arbitrarily chosen.

Similarly to finite-time case, remarks analogous to 2-6 can be presented for fixed-time control algorithm. For example, the fixed-time controller is constructed by switching homogeneity properties of the system: it is homogeneous with positive degree μ for $t \leq T_s$ and with negative degree $-\mu$ for $t > T_s$.

Remark 9. Analogously to Remark 7, due to the fact that the closed-loop system (1), (16) is homogeneous with negative degree $-\mu$ for $t \geq T_s$ it is globally asymptotically stable with respect to a compact set containing the origin in presence of any delay.

The convergence rate of proposed control algorithms can be accelerated via time-rescaling in similar way, as in (Efimov, Levant, Polyakov, & Perruquetti, 2016; Harmouche et al., 2016; Levant & Dvir, 2014).

Remark 10. For $\lambda > 1$ and $N = \text{diag}\{\lambda^{1-i}\}_{i=1}^n$ rewrite the control (16) (or control (10)) as $\bar{u}(x) = \lambda^n u(Nx)$. Then for $\bar{x} = Nx$, $\bar{t} = \lambda t$, $\bar{T}_s = T_s/\lambda$ we obtain $\dot{\bar{x}} = A\bar{x}(\bar{t}) + b\bar{u}(\bar{x}(\bar{t}))$ and the following estimates of settling-time function: $T(x_0) \leq \frac{T_1+T_s}{\lambda}$ for the control (16) and $T(x_0) \leq \frac{2(m+l-\mu)V(\bar{x}_0)^\mu}{\mu\gamma c_1^\mu \lambda}$ for the control (10).

The result of Theorem 4.2 can be easily transformed for the case of continuous control law as follows.

Theorem 4.3. *If the system of matrix inequalities (6), (12)-(15),*

$$AX + XA^T + by + y^T b^T \leq -\tilde{\alpha}X, \quad (20)$$

is feasible for some $X \in \mathbb{R}^{n \times n}$, $y \in \mathbb{R}^{1 \times n}$, $\gamma_1, \gamma_2, \tilde{\alpha} \in \mathbb{R}_+$, where α_1, α_2 are calculated according to (9) with r_1 and r_2 correspondingly, $P = X^{-1}$, $k = yX^{-1}$, then the control of the form

$$u = \begin{cases} \|x\|_{r_2}^{l+\mu} k D_2 \left(\frac{1}{\|x\|_{r_2}} \right) x & \text{for } \|x\|_{r_2} \geq 1, \\ kx & \text{for } \|x\|_{r_1} \geq 1 \text{ and } \|x\|_{r_2} < 1, \\ \|x\|_{r_1}^{l-\mu} k D_1 \left(\frac{1}{\|x\|_{r_1}} \right) x & \text{for } \|x\|_{r_1} < 1, \end{cases} \quad (21)$$

stabilizes the origin of the system (1) in a fixed time

$$T(x_0) \leq 2(m_1 + l - \mu) \left(\frac{c_{2_2}^\mu}{\mu\gamma_2 c_{1_2}^\mu} + \frac{c_{2_1}^\mu}{\mu\gamma_1 c_{1_1}^\mu} + \frac{\ln(c_{2_2}/c_{1_1})}{\tilde{\alpha}} \right). \quad (22)$$

Proof. Consider the following sets

$$\mathbb{C}_1 = \{x \in \mathbb{R}^n : \|x\|_{r_1} \leq 1\}$$

and

$$\mathbb{C}_2 = \{x \in \mathbb{R}^n : \|x\|_{r_2} \leq 1\}.$$

Since $r_1(i) \geq r_2(i)$ for $i = \overline{1, n}$ we have $\mathbb{C}_1 \subseteq \mathbb{C}_2$. According to Theorem 3.5 and Theorem 4.2 the set \mathbb{C}_2 is fixed-time attractive with $T_2 = T_{\max} = \frac{2(m_1+l-\mu)c_{2_2}^\mu}{\mu\gamma_2 c_{1_2}^\mu}$. When x reaches the set \mathbb{C}_2 , the system will become exponentially stable with $u = kx$, $V = (x^T P x)^{\frac{1}{2(m_1+l-\mu)}}$ and due to (20) will reach the set \mathbb{C}_1 in a time, bounded by $T_{lin} = 2(m_1 + l - \mu) \frac{\ln(c_{2_2}/c_{1_1})}{\tilde{\alpha}}$. Finally, inside the set \mathbb{C}_1 the closed-loop system is finite-time stable with $T_1 = \frac{2(m_1+l-\mu)c_{2_1}^\mu}{\mu\gamma_1 c_{1_1}^\mu}$. Then the control (21) stabilizes the origin of the system (1) in a fixed time $T(x_0) \leq T_1 + T_2 + T_{lin}$, that is equal to (22). \square

Remark 11. In comparison with the control law (16), since the closed-loop system (1), (21) is r -homogeneous with positive degree μ on the set $\{x \in \mathbb{R}^n : \|x\|_{r_2} \geq 1\}$, then it preserves robustness with respect to some delay $\tau \leq \tau_0$, $\tau_0 \in \mathbb{R}_+$ (according to Efimov, Polyakov, et al., 2016; Zimenko et al., 2017).

Remark 12. Presented results can be easily extended to linear MIMO systems using block decomposition like in (Polyakov et al., 2016). Thereby, feedback linearizable nonlinear systems $\dot{x} = f(x) + G(x)u$ can also be stabilized by presented control laws (see, for example, Isidori, 1995).

5. Simulation results

Let us demonstrate the performance of presented control laws using the system of triple integrator. Using Theorem 4.1 the finite-time stabilizing controller is designed for this system in the form (10) with the parameters $l = 45$, $m = 1.21$, $\mu = 0.4$, $\rho = 91.6$, where the matrix $P \in \mathbb{R}^{3 \times 3}$ and the vector $k \in \mathbb{R}^{1 \times 3}$ are obtained from the inequalities (6)-(8):

$$P = \begin{pmatrix} 1.2382 & 0.4564 & 0.0371 \\ 0.4564 & 0.2068 & 0.0202 \\ 0.0371 & 0.0202 & 0.0035 \end{pmatrix},$$

$$k = (-122.7548 \quad -63.2132 \quad -9.4683).$$

Obtained estimation of the settling-time function for $x_0 = (0 \ 0 \ 1)^T$ is $T(x_0) \leq 712.1066$.

The parameters of the fixed-time stabilizing controller (16) were selected solving the LMIs (6), (12)-(15) with the parameters $l = 45$, $m_1 = 1.21$, $m_2 = 0.41$, $\mu = 0.4$, $\rho_1 = \rho_2 = 91.6$:

$$P = \begin{pmatrix} 24.1416 & 16.8444 & 3.0117 \\ 16.8444 & 14.9767 & 3.1131 \\ 3.0117 & 3.1131 & 1.0985 \end{pmatrix},$$

$$k = (-19.9578 \quad -20.9022 \quad -6.7877).$$

The parameter T_s has been chosen equal to 2. Obtained estimation of the settling-time function is $T(x_0) \leq 921.1276$. The simulation has been carried out for $x_0 = (0 \ 0 \ 10)^T$.

The parameters of the fixed-time stabilizing controller (21) were selected solving the LMIs (6), (12)-(15), (20) with the same parameters as in previous example and $\tilde{\alpha} = 2.6966$, $T(x_0) \leq 922.84$. The simulation has been carried out for $x_0 = (0 \ 0 \ 10)^T$.

Simulations for finite-time and fixed-time convergence accelerated with $\lambda = 3$ and the same initial conditions have also been carried out for the control laws (10) and (16) with $T(x_0) \leq 232.7987$ and $T(x_0) \leq 307.0425$, correspondingly. All simulations results are presented in Fig.1-8.

Note, that presented estimations of the settling-time function are quite conservative due to conservative estimation of α_{\max} in (9) and, thus, of the parameter γ . For example, during the simulation presented in Fig.1, the parameter $\alpha(x)$ did not exceed the value 1.257 and using this value as α_{\max} the estimation of the settling-time function $T(x_0) \leq 67.65$ could be obtained. Thus, the search for another r -homogeneous function of degree 1 instead of (3) and/or less conservative estimate of the parameter α_{\max} can be considered as the subject for a future research.

6. Conclusions

The paper is focused on finite-time and fixed-time control for integrator chains of arbitrary order. Obtained finite-time control design method consist in appropriate

Figure 8. System states versus time for accelerated fixed-time control (16)

modification of control law presented in (Zimenko et al., 2016) and use of analysis based on explicitly defined Lyapunov function. Based on this result simple procedure of parameters tuning and new estimates for settling-time function were obtained. The fixed-time control algorithms for chain of integrators are presented. It is shown that fixed-time convergence can be achieved by changing the homogeneity degree in hybrid control algorithms. The performance of obtained control algorithms is demonstrated through simulations.

A detailed study of the presented control algorithms on robustness analysis with respect to disturbances, uncertainties, delays and extension of these results on wider class of systems goes beyond the scope of the paper providing the subject for a future research.
