A Wiener–Hopf type factorization for the exponential functional of Lévy processes

J. C. Pardo, P. Patie and M. Savov

ABSTRACT

For a Lévy process $\xi = (\xi_t)_{t\geqslant0}$ drifting to $-\infty$, we define the so-called exponential functional as follows:

$$
I_{\xi} = \int_0^{\infty} e^{\xi t} dt.
$$

Under mild conditions on ξ , we show that the following factorization of exponential functionals:

$$
\mathbf{I}_\xi \stackrel{d}{=} \mathbf{I}_{H^-} \times \mathbf{I}_Y
$$

holds, where \times stands for the product of independent random variables, H^- is the descending ladder height process of ξ and Y is a spectrally positive Lévy process with a negative mean constructed from its ascending ladder height process. As a by-product, we generate an integral or power series representation for the law of I_{ξ} for a large class of Lévy processes with two-sided jumps and also derive some new distributional properties. The proof of our main result relies on a fine Markovian study of a class of generalized Ornstein–Uhlenbeck processes, which is itself of independent interest. We use and refine an alternative approach of studying the stationary measure of a Markov process which avoids some technicalities and difficulties that appear in the classical method of employing the generator of the dual Markov process.

1. *Introduction and main results*

We are interested in studying the law of the so-called exponential functional of Lévy processes, which is defined as follows:

$$
I_{\xi} = \int_0^{\infty} e^{\xi_t} dt,
$$

where $\xi = (\xi_t)_{t\geqslant 0}$ is a Lévy process starting from 0 and drifting to $-\infty$. Recall that a Lévy process ξ is a process with stationary and independent increments and its law is characterized completely by its Lévy–Khintchine exponent Ψ , which takes the following form:

$$
\log \mathbb{E}[e^{z\xi_1}] = \Psi(z) = bz + \frac{\sigma^2}{2}z^2 + \int_{-\infty}^{\infty} (e^{zy} - 1 - zy \mathbb{I}_{\{|y| < 1\}}) \Pi(dy), \quad \text{for any } z \in i\mathbb{R}, \tag{1.1}
$$

where $\sigma \geq 0, b \in \mathbb{R}$ and Π is a Lévy measure satisfying the condition $\int_{\mathbb{R}} (y^2 \wedge 1) \Pi(dy) < \infty$; see $\left[1\right]$ $\left[1\right]$ $\left[1\right]$ for more information on Lévy processes.

The exponential functional I_{ξ} has attracted the interest of many researchers over the last two decades. This is mostly due to the prominent role played by the law of I_{ξ} in the study of important processes such as self-similar Markov processes, fragmentation and branching processes but also in various settings ranging from astrophysics, biology to financial and insurance mathematics; see the survey paper [**[5](#page-27-1)**].

Received 28 April 2011; revised 7 February 2012.

The third author wishes to acknowledge the support of foundation The Philippe Wiener-Maurice Anspach which enabled to develop this work during his visit at Université Libre de Bruxelles.

So far there have been two main approaches which have been developed and used to derive information about the law of the exponential functional. The first one uses the fact that the Mellin transform of I_{ξ} is a solution to a functional equation (see [\(4.1\)](#page-17-0)), and is due to Carmona *et al.* [**[9](#page-27-2)**] and has been extended by Maulik and Zwart [**[20](#page-27-3)**]. It is important to note that (4.1) is useful only under the additional assumption that ξ possesses some finite, positive exponential moments as then it is defined on a strip in the complex plane. This equation can be solved for exponential functionals of the negative of subordinators and spectrally positive Lévy processes yielding some simple expressions for their positive and negative integer moments, respectively, which, in both cases, determine the law. Recently, Kuznetsov and Pardo [**[15](#page-27-4)**] have used some special instances of Lévy processes, for which the solution of the functional equation can directly be guessed and verified from (4.1) , to derive some information concerning the law of I_{ξ} . It is worth pointing out that, in general, it is not an easy exercise to invert the Mellin (or moments) transform of I_f since a fine analysis of its asymptotic behaviour is required. This Mellin transform approach relies on two difficult tasks: to find a solution of the functional equation and to provide a general criterion to ensure the uniqueness of its solution. For instance, this approach does not seem to successfully cope with the whole class of spectrally negative Lévy processes.

The second methodology, which has been developed recently by the second author in [**[23](#page-27-5)**, **[25](#page-28-0)**], is based on the well-known relation between the law of I_f and the distribution of the absorption time of positive self-similar Markov processes, which were introduced by Lamperti [**[17](#page-27-6)**] in the context of limit theorems for Markov processes. Indeed, in [**[25](#page-28-0)**], it is shown that the law of I_{ϵ} can be expressed as an invariant function of a transient Ornstein–Uhlenbeck companion process to the self-similar Markov process. Using some potential theoretical devices, a power series and a contour integral representation of the density are provided when ξ is a possibly killed spectrally negative Lévy process.

In this paper, starting from a large class of Lévy processes, we show that the law of I_{ϵ} can be factorized into the product of independent exponential functionals associated with two companion Lévy processes, namely the descending ladder height process of ξ and a spectrally positive Lévy process constructed from its ascending ladder height process. It is well known that these two subordinators appear in the Wiener–Hopf factorization of Lévy processes. The laws of these exponential functionals are uniquely determined by either their positive or their negative integer moments. Moreover, whenever the law of any of these can be expanded in series, we can, in general, develop the law of I_{ξ} in series. Thus, for example, the requirements put on the Lévy measure of ξ in [[15](#page-27-4)] can be relaxed to conditions only on the positive jumps (the Lévy measure on the positive half-line) of ξ , thus enlarging considerably the class of Lévy processes ξ for which we can obtain a series expansion of the law of I_{ξ} .

Although our main result may have a formal explanation through the Wiener–Hopf factorization combined with the functional equation [\(4.1\)](#page-17-0), the proof is rather complicated and involves a careful study of some generalized Ornstein–Uhlenbeck (for short GOU) processes, different from the ones mentioned above. For this purpose, we deepen a technique used by Carmona *et al.* [[9](#page-27-2), Proposition 2.1] and further developed in [[16](#page-27-7)], which relates the law of I_f to the stationary measure of a GOU process. More precisely, we show that the density function of I_{ξ} , say m_{ξ} , is, under very mild conditions, the unique function satisfying the equation $\mathcal{L}m_{\xi} = 0$, where $\mathcal L$ is an 'integrated infinitesimal' operator, which is strictly of an integral form. The latter allows for a smooth and effortless application of Mellin and Fourier transforms. We believe that this method itself will attract some attention as it removes generic difficulties related to the study of the invariant measure via the dual Markov process such as the lack of smoothness properties for the density of the stationary measure and also the application of transforms, which usually requires the use of the Fubini theorem, which is difficult to verify when dealing with non-local operators.

Before stating our main result, let us introduce some notation. First, since in our setting ξ drifts to $-\infty$, it is well known that the ascending (descending) ladder height process H^+ $(H^+(t))_{t\geqslant 0}$ (respectively, $H^- = -H^{-, *} = (-H^{-, *} (t))_{t\geqslant 0}$) is a killed (respectively, proper) subordinator. Then, we write, for any $z \in i\mathbb{R}$,

$$
\phi_+(z) = \log \mathbb{E}[\exp(zH^+(1))] = \delta_+ z + \int_{(0,\infty)} (e^{zy} - 1)\mu_+(dy) - k_+, \tag{1.2}
$$

where $\delta_+ \geq 0$ is the drift and $k_+ > 0$ is the killing rate. Similarly, with $\delta_- \geq 0$, we have

$$
\phi_{-}(z) = \log \mathbb{E}[\exp(zH^{-}(1))] = -\delta_{-}z - \int_{(0,\infty)} (1 - e^{-zy})\mu_{-}(dy). \tag{1.3}
$$

We recall that the integrability condition $\int_0^\infty (1 \wedge y) \mu_{\pm}(dy) < \infty$ holds. The Wiener–Hopf factorization then reads as follows:

$$
\Psi(z) = -c\phi_+(z)\phi_-(z) = -\phi_+(z)\phi_-(z), \quad \text{for any } z \in i\mathbb{R},\tag{1.4}
$$

where we have used the convention that the local times have been normalized in a way that $c = 1$; see [[12](#page-27-8), (5.3.1)]. We avoid further discussion as we assume [\(1.4\)](#page-4-0) holds with $c = 1$.

DEFINITION 1.1. We denote by P the set of positive measures on \mathbb{R}_+ that admit a nonincreasing density.

Before we formulate the main result of our paper, we introduce the two main hypotheses:

 (\mathcal{H}_1) Assume that $-\infty < \mathbb{E}[\xi_1]$ and that one of the following conditions holds:

 $\mathbf{E}_+ \mu_+ \in \mathcal{P}$ and there exists $z_+ > 0$ such that, for all z with $\Re(z) \in (0, z_+)$, we have $|\Psi(z)| < \infty;$ $P+ \Pi_+ \in \mathcal{P}$.

 (\mathcal{H}_2) Assume that

 \mathbf{P}_{+} $\mu_{+} \in \mathcal{P}, k_{+} > 0$ and $\mu_{-} \in \mathcal{P}.$

Then the following result holds.

THEOREM 1.2. Assume that ξ is a Lévy process that drifts to $-\infty$ with characteristics of *the ladder height processes as in* [\(1.2\)](#page-4-1) *and* [\(1.3\)](#page-4-2)*. Let either* (\mathcal{H}_1) *or* (\mathcal{H}_2) *hold. Then, in both cases*, *there exists a spectrally positive L´evy process* Y *with a negative mean whose Laplace* \exp *exponent* ψ_+ *takes the form*

$$
\psi_{+}(-s) = -s\phi_{+}(-s) = \delta_{+}s^{2} + k_{+}s + s^{2} \int_{0}^{\infty} e^{-sy} \mu_{+}(y,\infty) dy, \quad s \ge 0,
$$
\n(1.5)

and the following factorization holds:

$$
\mathbf{I}_{\xi} \stackrel{d}{=} \mathbf{I}_{H^-} \times \mathbf{I}_Y,\tag{1.6}
$$

where $\stackrel{d}{=}$ stands for the identity in law and \times for the product of independent random variables.

REMARK 1.3. We mention that the case when the mean is $-\infty$ together with other problems will be treated in a subsequent study as it demands techniques different from the spirit of this paper.

The result in Theorem 1.2 can be looked at from another perspective. Let us have two subordinators with Lévy measures μ_{\pm} such that $\mu_{+} \in \mathcal{P}, k_{+} > 0$ and $\mu_{-} \in \mathcal{P}$. Then, according to Vigon's theory of philanthropy (see [[30](#page-28-1)]), we can construct a process ξ such that its ladder height processes have exponents as in (1.2) and (1.3) and hence ξ satisfies the conditions of Theorem 1.2. Therefore, we will be able to synthesize examples starting from the building blocks, that is, the ladder height processes. We state this as a separate result.

COROLLARY 1.4. Let μ_+ be the Lévy measures of two subordinators and $\mu_+ \in \mathcal{P}$, k⁺ > 0 *and* μ[−] ∈ P*. Then there exists a L´evy process that drifts to* −∞, *whose ascending and descending ladder height processes have the Laplace exponents* [\(1.2\)](#page-4-1) *and* [\(1.3\)](#page-4-2), *respectively. Then all the claims of Theorem* 1.2 *hold and*, *in particular*, *we have the factorization* [\(1.6\)](#page-4-3)*.*

We postpone the proof of the theorem to Section 4. In the next section, we provide some interesting consequences whose proofs will be given in Section 5. Finally, in Section 3, we state and prove several results concerning some GOU processes. They will be useful for our main proof and, since they have an independent interest, we present them in a separate section.

2. *Some consequences of Theorem* 1.2

Theorem 1.2 allows for multiple applications. In this section, we discuss only a small number of them but we wish to note that almost all results that have been obtained in the literature under restrictions on all jumps of ξ can now be strengthened by imposing conditions only on positive jumps. This is due to [\(1.6\)](#page-4-3) and the fact that on the right-hand side of the identity the law of the exponential functionals has been determined by its integral moments which admit some simple expressions; see Propositions 4.6 and 4.7.

The factorization allows us to derive some interesting distributional properties. For instance, we can show that the random variable I_f is unimodal for a large class of Lévy processes. We recall that a positive random variable (or its distribution function) is said to be unimodal if there exists $a \in \mathbb{R}^+$, the mode, such that its distribution function $F(x)$ and the function $1-F(x)$ are convex, on $(0,a)$ and $(a,+\infty)$ respectively. It can be easily shown (see, for example, $[27]$ $[27]$ $[27]$), that the random variable I_Y , as defined in Theorem 1.2, is self-decomposable and thus, in particular, unimodal. It is natural to ask whether this property is preserved or not for I_ε. We emphasize that this is not necessarily true even if I_H- is unimodal itself. Cuculescu and Theodorescu [**[11](#page-27-9)**] provide a criterion for a positive random variable to be multiplicative strongly unimodal (MSU), that is, its product with any independent unimodal random variable remains unimodal. More precisely, they show that either the random variable has a unique mode at 0 and the independent product with any random variable has also a unique mode at 0 or the law of the positive random variable is absolutely continuous with a density m having the property that the mapping $x \to \log m(e^x)$ is concave on R. We also point out that it is easily seen that the MSU property remains unchanged under rescaling and power transformations and we refer to the recent paper [**[29](#page-28-3)**] for more information about this class of random variables.

We proceed by recalling that, as a general result on the exponential functional, Bertoin *et al.* [[2](#page-27-10), Theorem 3.9] have shown that the law of I_{ξ} is absolutely continuous with a density that we denote throughout by m_{ξ} .

In what follows, we show that when ξ is a spectrally negative Lévy process (that is, $\Pi(dy)\mathbb{I}_{\{y>0\}} \equiv 0$ in [\(1.1\)](#page-2-0) and ξ is not the negative of a subordinator), we recover the power series representation obtained by the second author in $[25]$ $[25]$ $[25]$ for the density of I_{ξ} . We are now ready to state the first consequence of our main factorization.

COROLLARY 2.1. Let ξ be a spectrally negative Lévy process with a negative mean.

(1) *Then we have the following factorization*:

$$
\mathbf{I}_{\xi} \stackrel{d}{=} \mathbf{I}_{H^-} \times G_{\gamma}^{-1},\tag{2.1}
$$

where G_{γ} *is a gamma random variable of parameter* $\gamma > 0$ *, where* $\gamma > 0$ *satisfies the relation* $\Psi(\gamma)=0$. Consequently, if I_H - is unimodal, then I_{ξ} is unimodal.

(2) The density function of I_{ξ} has the form

$$
m_{\xi}(x) = \frac{x^{-\gamma - 1}}{\Gamma(\gamma)} \int_0^{\infty} e^{-y/x} y^{\gamma} m_{H}(-y) dy, \quad x > 0,
$$
 (2.2)

where Γ *stands for the gamma function. In particular*, *we have*

$$
\lim_{x \to \infty} x^{\gamma + 1} m_{\xi}(x) = \frac{\mathbb{E}[\mathcal{I}_{H^-}^{\gamma}]}{\Gamma(\gamma)}.
$$

(3) *Moreover*, *for any* $1/x < \lim_{s\to\infty} (\Psi(s)/s)$,

$$
m_{\xi}(x) = \frac{\mathbb{E}[\Gamma_{H-}^{\gamma}]}{\Gamma(\gamma)\Gamma(\gamma+1)} x^{-\gamma-1} \sum_{n=0}^{\infty} (-1)^n \frac{\Gamma(n+\gamma+1)}{\prod_{k=1}^n \Psi(k+\gamma)} x^{-n}.
$$
 (2.3)

(4) *Finally, for any* $\beta \ge \gamma + 1$, the mapping $x \mapsto x^{-\beta} m_{\xi}(x^{-1})$ is completely monotone on \mathbb{R}^+ , and, consequently, the law of the random variable I_{ξ}^{-1} is infinitely divisible with a *decreasing density whenever* $\gamma \leq 1$ *.*

Remark 2.2. (1) From [**[1](#page-27-0)**, Corollary VII.5], we get that

$$
\lim_{s \to \infty} \frac{\Psi(s)}{s} = \begin{cases} b - \int_{-1}^{0} y \Pi(dy) & \text{if } \sigma = 0 \text{ and } \int_{-\infty}^{0} (1 \wedge y) \Pi(dy) < \infty, \\ +\infty & \text{otherwise.} \end{cases}
$$

Since we excluded the degenerate cases, we easily check that $b - \int_{-1}^{0} y \Pi(dy) > 0$.

(2) We point out that in [**[25](#page-28-0)**] it is proved that the density extends to a function of a complex variable which is analytical on the entire complex plane cut along the negative real axis and admits a power series representation for all $x > 0$.

To illustrate the results above, we consider $\Psi(s) = -(s-\gamma)\phi_-(s), s>0$, with $\gamma > 0$, and where, for any $\alpha \in (0,1)$,

$$
-\phi_{-}(s) = s \frac{\Gamma(\alpha(s-1)+1)}{\Gamma(\alpha s+1)}
$$

=
$$
\int_{0}^{\infty} (1 - e^{-sy}) \frac{(1-\alpha) e^{y/\alpha}}{\alpha \Gamma(\alpha+1) (e^{y/\alpha}-1)^{2-\alpha}} dy = \int_{0}^{\infty} (1 - e^{-sy}) \pi_{\alpha}(y) dy
$$
 (2.4)

is the Laplace exponent of a subordinator. Observing that the density $\pi_{\alpha}(y)$ of the Lévy measure of ϕ_- is decreasing, we readily check that Ψ is the Laplace exponent of a spectrally negative Lévy process. Next, using the identity $I_{H^-} \stackrel{(d)}{=} G_1^{\alpha}$ (see, for example, [[26](#page-28-4)]), we get

$$
I_{\xi} \stackrel{(d)}{=} G_1{}^{\alpha} \times G_{\gamma}^{-1},
$$

which, after some easy computations, yields, for any $x > 0$,

$$
m_{\xi}(x) = \frac{x^{-\gamma - 1}}{\Gamma(\gamma)\Gamma(\gamma + 1)} \sum_{n=0}^{\infty} \Gamma(\alpha(n + \gamma) + 1) \frac{(-x)^{-n}}{n!}
$$
 (2.5)

$$
=\frac{\Gamma(\alpha\gamma+1)x^{-\gamma-1}}{\Gamma(\gamma)\Gamma(\gamma+1)}{}_1F_0((\alpha,\alpha\gamma+1);-x^{-1}),\tag{2.6}
$$

where $_1F_0$ stands for the so-called Wright hypergeometric function; see, for example, **[[6](#page-27-11)**, Section 12.1]. Finally, since G_1^{α} is unimodal, we deduce that I_{ξ} is unimodal. Actually, we have a stronger result in this case since I_{ξ} is itself MSU being the product of two independent MSU random variables, showing in particular that the mapping $x \mapsto {}_1F_0((\alpha, \alpha \gamma + 1); e^x)$ is log-concave on R for any $\alpha \in (0,1)$ and $\gamma > 0$.

We now turn to the second application as an illustration of the situation P_+ of Theorem 1.2. We would like to emphasize that in this case, in general, we do not require the existence of positive exponential moments. We are not aware of general examples that work without such a restriction as [\(4.1\)](#page-17-0) is always crucially used and it is of real help once it is satisfied on a strip.

COROLLARY 2.3. Let ξ be a Lévy process with $-\infty < \mathbb{E}[\xi_1] < 0$ and $\sigma^2 > 0$. Moreover, *assume that*

$$
\Pi(dy)\mathbb{I}_{\{y>0\}}=c\lambda\,e^{-\lambda y}\,dy,
$$

where $c, \lambda > 0$ *. Then we have, for any* $s > -\lambda$,

$$
\psi_{+}(-s) = \delta_{+} s^2 + k_{+} s + c_{-} \frac{s^2}{\lambda + s},
$$

where $c_ = c/\phi_-(\lambda)$ *and* $\delta_+ > 0$ *. Consequently, the self-decomposable random variable* I_Y *admits the following factorization*:

$$
I_Y \stackrel{d}{=} \delta_+ G_{\theta_2}^{-1} \times B^{-1}(\theta_1, \lambda - \theta_1), \tag{2.7}
$$

where $0 < \theta_1 < \lambda < \theta_2$ *are the two positive roots of the equation* $\psi_+(s) = 0$ *and* B *stands for a beta random variable. Then, assuming that* $\theta_2 - \theta_1$ *is not an integer, we have, for any* $1/x < \lim_{s\to\infty} |\phi_-(s)|,$

$$
m_{\xi}(x) = \frac{k_{+} \Gamma(\lambda + 1)x^{-1}}{\Gamma(\theta_{1} + 1)\Gamma(\theta_{2} + 1)} \left(\sum_{i=1}^{2} \frac{\mathbb{E}[\mathcal{I}_{H}^{\theta_{i}}]}{\Gamma(\theta_{i} + 1)} x^{-\theta_{i}} \mathcal{I}_{\phi_{-,i}}(\theta_{i} + 1; -x^{-1}) \right),
$$

where

$$
\mathcal{I}_{\phi_{-,i}}(\theta_i + 1; x) = \sum_{n=0}^{\infty} a_n(\phi_-, \theta_i) \frac{x^n}{n!}
$$
\n(2.8)

and

$$
a_n(\phi_-,\theta_i) = \prod_{\substack{j=1\\j\neq i}}^2 \frac{\Gamma(\theta_j - \theta_i - n)}{\Gamma(\lambda - \theta_i - n)} \frac{\Gamma(n + \theta_i + 1)}{\prod_{k=1}^n \phi_-(k + \theta_i)}, \quad i = 1, 2.
$$

REMARK 2.4. The assumption $\sigma^2 > 0$ and the restriction on $\theta_2 - \theta_1$ have been made in order to avoid dealing with different cases, but they can both be easily removed. The latter will affect the series expansion (5.3) . The computation is easy but lengthy and we leave it out.

Remark 2.5. The methodology and results we present here can also be extended to the case when the Lévy measure $\Pi(dy)\mathbb{I}_{\{y>0\}}$ is a mixture of exponentials as in [[8](#page-27-12), [15](#page-27-4)] but we note that here we have no restrictions on the negative jumps whatsoever.

We now provide an example of Theorem 1.2 in the situation P_{\pm} .

COROLLARY 2.6. *For any* $\alpha \in (0,1)$, *let us set*

$$
\Psi(z) = \frac{\alpha z \Gamma(\alpha(-z+1)+1)}{(1-z)\Gamma(-\alpha z+1)} \phi_+(z), \quad z \in i\mathbb{R},
$$
\n(2.9)

where ϕ_+ *is as in* [\(1.2\)](#page-4-1) *with* $\mu_+ \in \mathcal{P}, k_+ > 0$ *. Then* Ψ *is the Laplace exponent of a Lévy process* ξ *that drifts to* −∞*. Moreover*, *the density of* I^ξ *admits the following representation*:

$$
m_{\xi}(x) = \frac{x^{-1/\alpha}}{\alpha} \int_0^{\infty} g_{\alpha}((y/x)^{1/\alpha}) m_Y(y) y^{1/\alpha - 1} dy, \quad x > 0,
$$
 (2.10)

where g_{α} *is the density of a positive* α *-stable random variable. Furthermore, if* $\lim_{s\to\infty} s^{\alpha-1}\phi_+(-s)=0$, *then*, *for all* $x>0$,

$$
m_{\xi}(x) = \frac{k_{+}}{\alpha} \sum_{n=1}^{\infty} \frac{\prod_{k=1}^{n} \phi_{+}(-k)}{\Gamma(-\alpha n) n!} x^{n}.
$$
 (2.11)

Finally, the positive random variable I_{H-} is MSU if and only if $\alpha \leq \frac{1}{2}$. Hence, I_{ξ} is unimodal *for any* $\alpha \leqslant \frac{1}{2}$ *.*

REMARK 2.7. The fact that I_{H^-} is MSU if and only if $\alpha \leq \frac{1}{2}$ is a consequence of the main result of Simon [**[29](#page-28-3)**].

REMARK 2.8. Note that this is a very special example of the approach of building the Lévy process from ϕ_{\pm} when $\mu_{\pm} \in \mathcal{P}$. One could construct many examples like this and this allows for interesting applications in mathematical finance and insurance; see, for example, [**[24](#page-28-5)**].

As a specific instance of the previous result, we may consider the case when

$$
\phi_{+}(-s) = -\frac{\Gamma(\alpha's + 1)}{\Gamma(\alpha'(s+1) + 1)}, \quad s \geqslant 0,
$$

with $\alpha' \in (0, 1)$. We easily obtain from the identity [\(4.8\)](#page-19-0) that

$$
\mathbb{E}[I_Y^{-m}] = \frac{\Gamma(\alpha' m + 1 - \alpha')}{\Gamma(1 - \alpha')}, \quad m = 1, 2, \dots,
$$

that is, $I_Y \stackrel{d}{=} G_{1-\alpha'}^{-\alpha'}$. Hence, as the product of independent MSU random variables, I_ξ is MSU for any $\alpha' \in (0,1)$ and $\alpha \leq \frac{1}{2}$. Moreover, using the asymptotic behaviour of the ratio of gamma functions given in [\(5.7\)](#page-27-13), we deduce that, for any $\alpha' \in (0, 1 - \alpha)$, we have

$$
m_{\xi}(x) = \frac{1}{\Gamma(1-\alpha')\alpha} \sum_{n=1}^{\infty} \frac{\Gamma(\alpha'n+1)}{\Gamma(-\alpha n)n!} (-1)^n x^n,
$$
\n(2.12)

which is valid for any $x > 0$.

We end this section by describing another interesting factorization of exponential functionals. Indeed, assuming that $\mu_-\in\mathcal{P}$, it is shown in [[26](#page-28-4), Theorem 1] that there exists a spectrally positive Lévy process $\overline{Y} = (\overline{Y}_t)_{t \geq 0}$ with a negative mean and Laplace exponent given by $\bar{\psi}_+(-s) = -s\phi_-(s+1), s>0$, such that the following factorization of the exponential law

$$
I_{H^{-}} \times I_{\bar{Y}}^{-1} \stackrel{d}{=} G_1 \tag{2.13}
$$

holds. Hence, combining (2.13) with (1.6) , we obtain that

$$
\mathcal{I}_{\xi} \times \mathcal{I}_{\bar{Y}}^{-1} \stackrel{d}{=} G_1 \times \mathcal{I}_Y.
$$

Consequently, we deduce from [**[28](#page-28-6)**, Theorem 51.6] the following.

COROLLARY 2.9. If, in one of the settings of Theorem 1.2, we assume further that $\mu_-\in\mathcal{P}$, *then the density of the random variable* $I_{\xi} \times I_{\overline{Y}}^{-1}$, *where* $I_{\overline{Y}}$ *is taken as defined in* [\(2.13\)](#page-8-0), *is*

a mixture of exponential distributions and, *in particular*, *it is infinitely divisible and nonincreasing on* \mathbb{R}^+ .

Considering as above that $I_{H^-} \stackrel{(d)}{=} G_1^{\alpha}$ in Corollaries 2.1 and 2.3, we deduce from [[26](#page-28-4), Section 3.2] that the random variable $S_{\alpha}^{-\alpha} \times I_{\xi}$ is a mixture of exponential distributions, where S_{α} is a positive stable law of index α .

3. *Some results on GOU processes*

The results we present here will be central in the development of the proof of our main theorem. However, they also have some interesting implications in the study of GOU processes, and for this reason we state and prove them in a separate section.

We recall that, for a given Lévy process ξ , the GOU process U^{ξ} is defined, for any $t \geqslant 0$, $x \geqslant 0$, by

$$
U_t^{\xi}(x) = x e^{\xi_t} + e^{\xi_t} \int_0^t e^{-\xi_s} ds.
$$
 (3.1)

This family of positive strong Markov processes has been intensively studied by Carmona *et al.* [**[9](#page-27-2)**] and we refer to [**[22](#page-27-14)**] for some more recent studies and references. The connection with our current problem is explained as follows. From the identity in law $(\xi_t - \xi_{(t-s)}-)_{0\leq s\leq t}$ $(\xi_s)_{s\leq t}$, we easily deduce that, for any fixed $t\geqslant 0$,

$$
U_t^{\xi}(x) \stackrel{d}{=} x e^{\xi_t} + \int_0^t e^{\xi_s} ds.
$$

Thus, if $\lim_{t\to\infty} \xi_t = -\infty$ almost surely (a.s.), we have that

$$
U^{\xi}_{\infty}(x)\stackrel{d}{=} {\rm I}_{\xi},
$$

and hence the law of I_{ξ} is the unique stationary measure of U^{ξ} ; see [[9](#page-27-2), Proposition 2.1].

In what follows, we use the standard notation $C_b(\mathbb{R})$ or $C_b(\mathbb{R}_+)$ to denote the set of bounded and continuous functions on \mathbb{R} or on \mathbb{R}_+ , respectively. Furthermore, we set $\mathcal{V}' = C_b^2(\mathbb{R})$, where $C_b^2(\mathbb{R})$ is the set of twice continuously differentiable bounded functions which together with its first two derivatives are continuous on $\mathbb{R} = [-\infty, \infty]$. Then, we recall that (see, for example, [[9](#page-27-2)] for the special case when ξ is the sum of a Brownian motion and an independent Lévy process with bounded variation and finite exponential moments and [**[16](#page-27-7)**] for the general case) the infinitesimal generator $L^{U^{\xi}}$ of U^{ξ} takes the form

$$
L^{U^{\xi}}f(x) = L^{\xi}f_e(\ln x) + f'(x), \quad x > 0,
$$
\n(3.2)

whenever $\mathbb{E}[\xi_1] < \infty$ and $f_e(x) = f(e^x) \in \text{Dom}(L^{\xi})$, where L^{ξ} stands for the infinitesimal generator of the Lévy process ξ , considered in the sense of Itô and Neveu (see [[19](#page-27-15), pp. 628–630]). Recall that in this sense $\mathcal{V}' \subset \text{Dom}(L^{\xi})$ and hence $\mathcal{V} = \{f : \overline{\mathbb{R}}_+ \mapsto \overline{\mathbb{R}} | f_e \in \mathcal{V}'\} \subset \text{Dom}(L^{U^{\xi}})$.

In what follows, we often appeal to the quantities defined for $x > 0$ by

$$
\bar{\Pi}(x) := \int_{|y|>x} \Pi(dy); \quad \bar{\Pi}_{\pm}(x) := \int_{y>x} \Pi_{\pm}(dy),
$$
\n(3.3)

$$
\overline{\overline{\Pi}}(x) := \int_{y>x} \overline{\Pi}(y) dy; \quad \overline{\overline{\Pi}}_{\pm}(x) := \int_{y>x} \overline{\Pi}_{\pm}(y) dy,
$$
\n(3.4)

where $\Pi_+(dy) = \Pi(dy)1_{\{y>0\}}$ and $\Pi_-(dy) = \Pi(-dy)1_{\{y>0\}}$. Note that the quantities in [\(3.4\)](#page-9-0) are finite when $\mathbb{E}[\xi_1] < \infty$. Moreover, when $\mathbb{E}[\xi_1] < \infty$, [\(1.1\)](#page-2-0) can be rewritten, for all $z \in \mathbb{C}$, where it is well defined, as follows:

$$
\Psi(z) = \mathbb{E}[\xi_1]z + \frac{\sigma^2}{2}z^2 + z^2 \int_0^\infty e^{zy} \bar{\Pi}_+(y) \, dy + z^2 \int_0^\infty e^{-zy} \bar{\Pi}_-(y) \, dy. \tag{3.5}
$$

For the proof of our main theorem, we need to study the stationary measure of U^{ξ} and, in particular, $L^{U^{\xi}}$ in detail. To this end, we introduce the following functional space:

$$
\mathcal{K} = \left\{ f : \overline{\mathbb{R}}_+ \longmapsto \overline{\mathbb{R}} | f_e \in \mathcal{V}'; \lim_{x \to -\infty} (|f'_e(x)| + |f''_e(x)|) = 0; \int_{\mathbb{R}} (|f'_e(x)| + |f''_e(x)|) dx < \infty \right\},\
$$

where $f_e(x) = f(e^x)$.

PROPOSITION 3.1. Let U^{ξ} be a GOU process with $\mathbb{E}[|\xi_1|] < \infty$. Then $\mathcal{K} \subset \text{Dom}(L^{U^{\xi}})$. *Moreover, for any* $f \in \mathcal{K}$ *we have, for all* $x > 0$,

$$
L^{U^{\xi}}f(x) = \frac{g(x)}{x} + \mathbb{E}[\xi_1]g(x) + \frac{\sigma^2}{2}x g'(x)
$$

+
$$
\int_x^{\infty} g'(y)\overline{\bar{\Pi}}_+\left(\ln\frac{y}{x}\right)dy + \int_0^x g'(y)\overline{\bar{\Pi}}_-\left(\ln\frac{x}{y}\right)dy,
$$
(3.6)

where $g(x) = xf'(x)$. Finally, for any function h such that $\int_0^\infty (y^{-1} \wedge 1) |h(y)| dy < \infty$ and $f \in$ K, *we have*

$$
(L^{U^{\xi}}f, h) = (g', \mathcal{L}h),\tag{3.7}
$$

where $(f_1, f_2) = \int_0^\infty f_1(x) f_2(x) dx$ and

$$
\mathcal{L}h(x) = \frac{\sigma^2}{2}xh(x) + \int_x^{\infty} \left(\frac{1}{y} + \mathbb{E}[\xi_1]\right)h(y) dy
$$

+
$$
\int_x^{\infty} \bar{\bar{\Pi}}_{-} \left(\ln \frac{y}{x}\right)h(y) dy + \int_0^x \bar{\bar{\Pi}}_{+} \left(\ln \frac{x}{y}\right)h(y) dy.
$$
 (3.8)

REMARK 3.2. There are certain advantages when using the linear operator $\mathcal L$ instead of the generator of the dual GOU. Its integral form allows for minimal conditions on the integrability of $|h|$ and requires no smoothness assumptions on h. Moreover, if h is positive, then Laplace and Mellin transforms can easily be applied to $\mathcal{L}h(x)$ since the justification of the Fubini theorem is straightforward.

Proof. Let $f \in \mathcal{K}$; then, by the very definition of \mathcal{K} , we have that $f_e \in \mathcal{V}'$ and, from [\(3.2\)](#page-9-1), we get that $\mathcal{K} \subset \text{Dom}(L^{U^{\xi}})$. Next, (3.6) can be found in [[16](#page-27-7)] but can equivalently be recovered from [\(3.2\)](#page-9-1) by simple computations using the expression for L^{ξ} , which can be found in [[1](#page-27-0), p. 24]. To get [\(3.7\)](#page-10-1) and [\(3.8\)](#page-10-2), we recall that $g(x) = xf'(x) = f'_e(\ln x)$ and use [\(3.6\)](#page-10-0) combined with a formal application of the Fubini theorem to write

$$
(L^{U^{\xi}}f, h) = \int_0^{\infty} \frac{g(y)}{y} h(y) dy + \frac{\sigma^2}{2} \int_0^{\infty} yg'(y)h(y) dy + \mathbb{E}[\xi_1] \int_0^{\infty} g(y)h(y) dy
$$

+
$$
\int_0^{\infty} \int_0^y g'(v) \overline{\bar{\Pi}} - (\ln \frac{y}{v}) dvh(y) dy + \int_0^{\infty} \int_y^{\infty} g'(v) \overline{\bar{\Pi}} + (\ln \frac{v}{y}) dvh(y) dy
$$

=
$$
\int_0^{\infty} g'(v) \int_v^{\infty} \frac{h(y)}{y} dy dv + \mathbb{E}[\xi_1] \int_0^{\infty} g'(v) \int_v^{\infty} h(y) dy dv + \frac{\sigma^2}{2} \int_0^{\infty} v g'(v)h(v) dv
$$

+
$$
\int_0^{\infty} g'(v) \int_v^{\infty} \overline{\bar{\Pi}} - (\ln \frac{y}{v}) h(y) dy dv + \int_0^{\infty} g'(v) \int_0^v \overline{\bar{\Pi}} + (\ln \frac{v}{y}) h(y) dy dv
$$

=
$$
(g', \mathcal{L}h).
$$
 (3.9)

To justify the Fubini theorem, note that $f \in \mathcal{K}$ implies that $\lim_{x\to 0} g(x) = \lim_{x\to 0} f'_e(\ln x) = 0$, $g(x) = \int_0^x g'(v) dv$ and

$$
\int_0^\infty |g'(v)| \, dv = \int_{\mathbb{R}} |f''_e(y)| \, dy \leq C(g) < \infty,
$$
\n
$$
|g(x)| + x|g'(x)| = |f'_e(\ln x)| + |f''_e(\ln x)| \leq C(g) < \infty,
$$
\n(3.10)

where $C(q) > 0$. Note that [\(3.10\)](#page-11-0) and the integrability of $(1 \wedge y^{-1})|h(y)|$ imply that

$$
\int_0^{\infty} \left| \frac{g(y)}{y} \right| h(y) \, dy \leqslant \int_0^{\infty} \int_0^y |g'(v)| dv y^{-1} |h(y)| \, dy \leqslant C(g) \int_0^{\infty} y^{-1} |h(y)| \, dy < \infty,
$$

and so the Fubini theorem applies to the first term in (3.9) . The second term in (3.9) remains unchanged, whereas for the third term we do the same computation noting that only y^{-1} is not present. From [\(3.10\)](#page-11-0) and the fact that $\bar{ \bar{\Pi}}_+(1) + \bar{ \bar{\Pi}}_-(1) < \infty$ as $\mathbb{E}[|\xi_1|] < \infty$, we note that, for the other two terms, we have, with the constant $C(g) > 0$ in (3.10) ,

$$
\int_0^x |g'(v)| \overline{\overline{\Pi}}_{-} \left(\ln \frac{x}{v} \right) dv = \int_0^\infty |x e^{-w} g'(x e^{-w})| \overline{\overline{\Pi}}_{-}(w) dw
$$

$$
\leq \overline{\overline{\Pi}}_{-}(1) \int_0^\infty |g'(v)| dv + C(g) \int_0^1 \overline{\overline{\Pi}}_{-}(w) dw < \infty,
$$

$$
\int_x^\infty |g'(v)| \overline{\overline{\Pi}}_{+} \left(\ln \frac{v}{x} \right) dv = \int_0^\infty |x e^{w} g'(x e^{w})| \overline{\overline{\Pi}}_{+}(w) dw
$$

$$
\leq \overline{\overline{\Pi}}_{+}(1) \int_0^\infty |g'(v)| dv + C(g) \int_0^1 \overline{\overline{\Pi}}_{+}(w) dw < \infty.
$$

Therefore, we can apply the Fubini theorem, which completes the proof of Proposition 3.1. \Box

The next result is known and can be found in [**[16](#page-27-7)**] but we include it and sketch its proof for the sake of completeness and for further discussion.

THEOREM 3.3. Let U^{ξ} be a GOU, where $-\infty < \mathbb{E}[\xi_1] < 0$. Then U^{ξ} has a unique stationary *distribution which is absolutely continuous with density* m *and satisfies*

$$
\mathcal{L}m(x) = 0 \quad \text{for a.e. } x > 0. \tag{3.11}
$$

REMARK 3.4. Note that, due to the discussion in Section 3, $m = m_{\epsilon}$, that is, it equals the density of the law of I_ξ. Therefore, all the information we gathered for m_{ξ} in Section 2 is valid here for the density of the stationary measure of U^{ξ} , that is, m.

REMARK 3.5. Equation (3.11) can be very useful. In this instance, it is far easier to be studied than an equation coming from the dual process which is standard when stationary distributions are discussed. It does not presuppose any smoothness of m, only its existence. Moreover, as noted above, [\(3.11\)](#page-11-1) is amenable to various transforms, and difficult issues such as interchanging integrals using the Fubini theorem are effortlessly overcome.

REMARK 3.6. It is also interesting to explore other cases when a similar equation to (3.11) can be obtained. It seems the approach is fairly general but requires special examples to reveal its full potential. For example, if L is an infinitesimal generator, $\mathcal N$ is a differential operator, $\mathcal L$ is an integral operator and it is possible, for all $f \in C_0^{\infty}(\mathbb{R}_+)$, that is, infinitely differentiable

functions with compact support, and a stationary density u , to write

$$
(Lf, u) = (\mathcal{N}f, \mathcal{L}u) = 0,
$$

then we can solve the equation in the sense of Schwartz to obtain

$$
\tilde{\mathcal{N}}\mathcal{L}u=0,
$$

where $\tilde{\mathcal{N}}$ is the dual of \mathcal{N} . If we show that necessarily for probability densities $\mathcal{L}u = 0$, then we can use $\mathcal L$ to study stationarity.

Proof. From [\(3.7\)](#page-10-1) and the fact that m is the stationary density, we get, for all $g(x) = xf'(x)$, with $f \in C_0^{\infty}(\mathbb{R}_+) \subset \mathcal{K}$,

$$
(g', \mathcal{L}m) = 0.
$$

Then, from Schwartz theory of distributions, we get $\mathcal{L}m(x) = C \ln x + D$ a.e. Integrating (3.8) and the right-hand side of this from 1 to z, multiplying the resulting identity by z^{-1} , subsequently letting $z \to \infty$ and using the fact that m is a probability density, we can show that necessarily $C = D = 0$. The last part requires some work, but it is mainly technical. \Box

THEOREM 3.7. Let \bar{m} be a probability density function such that $\int_0^\infty \bar{m}(y)y^{-1} dy < \infty$ and (3.11) *holds for* \bar{m} ; *then*

$$
m(x) = \bar{m}(x) \text{ a.e.,}
$$
\n
$$
(3.12)
$$

where *m* is the density of the stationary measure of U^{ξ} .

REMARK 3.8. This result is very important in our studies. The fact that we have uniqueness on a large class of probability measures allows us, by checking that [\(3.11\)](#page-11-1) holds, to pin down the density of the stationary measure of U^{ξ} , which is of course the density of I_{ξ} . The requirement that $\int_0^\infty \bar{m}(y)y^{-1}dy < \infty$ is in fact no restriction whatsoever as the existence of a first negative moment of I_{ξ} is known from the literature; see [**[3](#page-27-16)**].

REMARK 3.9. Also it is well known that if $L^{\hat{U}}$ is the generator of the dual Markov process, then $L^{\hat{U}}\bar{m}=0$ does not necessarily have a unique solution when $L^{\hat{U}}$ is a non-local operator. Moreover, one needs assumptions on the smoothness of \bar{m} so as to apply $L^{\hat{U}}$. Using $\mathcal L$ circumvents this problem.

Proof. Let $(P_t)_{t\geqslant0}$ be the semigroup of the GOU U^{ξ} , that is, for any $f \in C_b(\bar{\mathbb{R}}_+)$,

$$
P_t f(x) = \mathbb{E}[f(U_t^{\xi}(x))], \quad x \geq 0, \ t \geq 0.
$$

If [\(3.11\)](#page-11-1) holds for some probability density \bar{m} , then [\(3.7\)](#page-10-1) is valid; that is, for all $f \in \mathcal{K}$,

$$
(L^{U^{\xi}}f,\bar{m})=(g',\mathcal{L}\bar{m})=0.
$$

Assume for a moment that

$$
P_s \mathcal{K} \subset \mathcal{K}, \quad \text{for all } s > 0,
$$
\n
$$
(3.13)
$$

and there exists a constant $C(f, \xi) > 0$ such that, for all $s \leq t$,

$$
|L^{U^{\xi}} P_s f(x)| \leq C(f, \xi)(x^{-1} \wedge 1). \tag{3.14}
$$

Then integrating out with respect to $\bar{m}(x)$ the standard equation

$$
P_t f(x) = f(x) + \int_0^t L^{U^{\xi}} P_s f(x) ds,
$$

we get, for all $f \in \mathcal{K}$,

$$
\int_0^\infty P_t f(x) \bar{m}(x) dx = \int_0^\infty f(x) \bar{m}(x) dx.
$$

Since $C_0^{\infty}(\mathbb{R}_+) \subset \mathcal{K}$ and $C_0^{\infty}(\mathbb{R}_+)$ is separating for $C_0(\mathbb{R}_+)$, the last identity shows that \bar{m} is a density of a stationary measure. Thus, by the uniqueness of the stationary measure, we conclude [\(3.12\)](#page-12-0). Let us prove [\(3.13\)](#page-12-1) and [\(3.14\)](#page-12-2). For $f \in \mathcal{K}$ write

$$
g_s(x) := P_s f(x) = \mathbb{E}[f(U_s^{\xi}(x))] = \mathbb{E}\left[f\left(x e^{\xi_s} + \int_0^s e^{\xi_v} dv\right)\right].
$$

Put $\tilde{g}_s(x) = g_s(e^x) = (g_s)_e(x)$. Note that, since $f \in \mathcal{K}$ and $0 < e^{x+\xi_s} \le e^{x+\xi_s} + \int_0^s e^{\xi_v} dv$, we have the following bound:

$$
\left| e^{x+\xi_s} f'\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv \right) \right| + \left| e^{2(x+\xi_s)} f''\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv \right) \right| \leqslant C(f), \tag{3.15}
$$

which holds uniformly in $x \in \mathbb{R}$, $s \geqslant 0$. In view of [\(3.15\)](#page-13-0), the dominated convergence theorem gives

$$
\tilde{g}'_s(x) = \mathbb{E}\left[e^{x+\xi_s}f'\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv\right)\right],
$$

\n
$$
\tilde{g}''_s(x) = \mathbb{E}\left[e^{x+\xi_s}f'\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv\right)\right] + \mathbb{E}\left[e^{2(x+\xi_s)}f''\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv\right)\right],
$$

\n
$$
\max\{|\tilde{g}'_s(x)|, |\tilde{g}''_s(x)|\} \leq C(f).
$$
\n(3.16)

Clearly then, from [\(3.15\)](#page-13-0) and [\(3.16\)](#page-13-1), the dominated convergence theorem and the fact that $f \in \mathcal{K}$, which implies the existence of $\lim_{x \to \infty} f''_e(x) = b$, we have

$$
\lim_{x \to \infty} \tilde{g}'_s(x) = \mathbb{E}\left[\lim_{x \to \infty} \left(e^{x+\xi_s}f'\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv\right) + e^{2(x+\xi_s)}f''\left(e^{x+\xi_s} + \int_0^s e^{\xi_v} dv\right)\right)\right] = b.
$$

Similarly, we show that $\lim_{x\to\infty} \tilde{g}'_s(x) = \lim_{x\to\infty} f'_e(x)$ and trivially $\lim_{x\to\pm\infty} \tilde{g}_s(x) =$ lim_{x→±∞} $f_e(x)$. Finally, using [\(3.15\)](#page-13-0) and [\(3.16\)](#page-13-1), $f \in \mathcal{K}$, the dominated convergence theorem and the fact that, for all $s > 0$, a.s. $\int_0^s e^{\xi_v} dv > 0$, we conclude that

$$
\lim_{x \to -\infty} |\tilde{g}'_s(x)| + |\tilde{g}''_s(x)| \le 2 \mathbb{E} \left[\lim_{x \to -\infty} \left| e^{x + \xi_s} f' \left(e^{x + \xi_s} + \int_0^s e^{\xi_v} dv \right) \right| + \left| e^{2(x + \xi_s)} f'' \left(e^{x + \xi_s} + \int_0^s e^{\xi_v} dv \right) \right| \right],
$$

which together with the limits above confirms that $\tilde{g}_s \in \mathcal{V}'$ and proves that

$$
\lim_{x \to -\infty} |\tilde{g}_s'(x)| + |\tilde{g}_s''(x)| = 0.
$$

Finally, since $f \in \mathcal{K}$ and (3.15) holds we check that

$$
\int_0^\infty |\tilde{g}'_s(y)| dy \leqslant \mathbb{E}\left[\int_{\int_0^s e^{\xi v} dv}^\infty |f'(u)| du\right] \leqslant \int_0^\infty |f'(u)| du = \int_{\mathbb{R}} |f'_e(u)| du < C(f)
$$

and

$$
\int_0^\infty |\tilde{g}_s''(y)| dy \le E \left[\int_{\int_0^s e^{\xi v} dv}^\infty \left(u - \int_0^s e^{\xi v} dv \right) |f''(u)| du \right] \le \int_0^\infty u |f''(u)| du
$$

$$
\le 2 \int_{\mathbb{R}_+} |f'_e(\ln x)| + |f''_e(\ln x)| \frac{dx}{x} = 2 \int_{\mathbb{R}} (|f'_e(y)| + |f''_e(y)|) dy < C(f),
$$

where $C(f)$ is chosen to be the largest constant in all the inequalities above and we have used the trivial inequality $u^2|f''(u)| \leq |f'_e(\ln u)| + |f''_e(\ln u)|$. Thus, using all the information above, we conclude that $g_s = P_s f \in \mathcal{K}$ and [\(3.13\)](#page-12-1) holds. Next we consider [\(3.14\)](#page-12-2) keeping in mind that all the estimates on \tilde{g}_s that we used to show that $g_s \in \mathcal{K}$ are uniform in s and x. We use [\(3.6\)](#page-10-0) with $g(x) = x g'_{s}(x) = \tilde{g}'_{s}(\ln x)$, the bounds on \tilde{g}_{s} and its derivatives to get

$$
\left|\frac{g(x)}{x} + \mathbb{E}[\xi_1]g(x) + \frac{\sigma^2}{2}x g'(x)\right| \leqslant C(f)x^{-1} + C(f)|\mathbb{E}[\xi_1]| + C(f)\frac{\sigma^2}{2}
$$

$$
\leqslant C(f, \sigma, \mathbb{E}[\xi_1])(1 \wedge x^{-1}).
$$

Moreover, as in the proof of Proposition 3.1, we can estimate

$$
\left| \int_0^x g'(v) \overline{\overline{\Pi}}_- \left(\ln \frac{x}{v} \right) dv \right| + \left| \int_x^\infty g'(v) \overline{\overline{\Pi}}_+ \left(\ln \frac{v}{x} \right) dv \right|
$$

\$\leqslant (\overline{\overline{\Pi}}_-(1) + \overline{\overline{\Pi}}_+(1)) \int_0^\infty |g'(s)| ds + C(f) \left(\int_0^1 \overline{\overline{\Pi}}_-(s) ds + \int_0^1 \overline{\overline{\Pi}}_+(s) ds \right) \$
= (\overline{\overline{\Pi}}_-(1) + \overline{\overline{\Pi}}_+(1)) \int_{-\infty}^\infty |\tilde{g}''(y)| dy + C(f) \left(\int_0^1 \overline{\overline{\Pi}}_-(s) ds + \int_0^1 \overline{\overline{\Pi}}_+(s) ds \right) < C\$,

and therefore [\(3.14\)](#page-12-2) holds since

$$
L^{U^{\xi}}g_s(x) = \frac{g(x)}{x} + \mathbb{E}[\xi_1]g(x) + \frac{\sigma^2}{2}xg'(x) + \int_0^x g'(v)\overline{\bar{\Pi}}_-\left(\ln\frac{x}{v}\right)dv + \int_x^\infty g'(v)\overline{\bar{\Pi}}_+\left(\ln\frac{v}{x}\right)dv.
$$

his concludes the proof.

This concludes the proof.

THEOREM 3.10. Let $(\xi^{(n)})_{n\geqslant 1}$ be a sequence of Lévy processes with negative means *such that*

$$
\lim_{n\to\infty}\xi^{(n)}\stackrel{d}{=}\xi,
$$

where ξ *is a Lévy process with* $\mathbb{E}[\xi_1] < 0$ *. Moreover, if, for each* $n \geq 1$ *,* $m^{(n)}$ *stands for the law of the stationary measure of the GOU process* $U^{\xi^{(n)}}$ defined, for any $t \geq 0, x \geq 0$, by

$$
U_t^{\xi^{(n)}} = x e^{\xi_t^{(n)}} + e^{\xi_t^{(n)}} \int_0^t e^{-\xi_s^{(n)}} ds,
$$

and the sequence $(m^{(n)})_{n\geqslant 1}$ *is tight*, then $(m^{(n)})_{n\geqslant 1}$ *converges weakly to* $m^{(0)}$ *, which is the unique stationary measure of the process* U^{ξ} , *that is*,

$$
\lim_{n \to \infty} m^{(n)} \stackrel{w}{=} m^{(0)}.
$$
\n(3.17)

Proof. Without loss of generality, we assume, using the Skorohod–Dudley theorem (see [**[14](#page-27-17)**, Chapter 3, Theorem 3.30]), that the convergence $\xi^{(n)} \to \xi$ holds a.s. in the Skorohod space $\mathcal{D}((0,\infty))$. Owing to the stationarity properties of $m^{(n)}$, for each $t > 0$, we have, for any $f \in C_b(\mathbb{R}_+),$

$$
(f, m^{(n)}) = (P_t^{(n)}f, m^{(n)}) = (P_t^{(n)}f - P_tf, m^{(n)}) + (P_tf, m^{(n)}),
$$

where $P_t^{(n)}$ and P_t are the semigroups of $U_t^{\xi^{(n)}}$ and U_t^{ξ} . For any $x > 0$, $|(P_t^{(n)}f - P_tf, m^{(n)})| \leq 2||f||_{\infty}m^{(n)}(x, \infty) + \sup_{y \leq x}|P_t^{(n)}f(y) - P_tf(y)|$ $\leq 2||f||_{\infty}m^{(n)}(x,\infty)+\mathbb{E}\left|\sup$ $y \leqslant x$ $|f(U_t^{\xi^{(n)}}(y)) - f(U_t^{\xi}(y))|$ (3.18)

Taking into account that $(m^{(n)})_{n\geqslant 1}$ is tight, we may fix $\delta > 0$ and find $x > 0$ big enough such that

$$
\sup_{n\geqslant 1} m^{(n)}(x,\infty) < \delta.
$$

Also, since $f \in C_b(\overline{\mathbb{R}}_+)$, it follows that f is uniformly continuous on \mathbb{R}_+ . Therefore, to show that

$$
\lim_{n \to \infty} \mathbb{E} \left[\sup_{y \leq x} |f(U_t^{\xi^{(n)}}(y)) - f(U_t^{\xi}(y))| \right] = 0,
$$

owing to the dominated convergence theorem, all we need to show is that

$$
\lim_{n \to \infty} \sup_{y \leq x} |U_t^{\xi^{(n)}}(y) - U_t^{\xi}(y)| = 0.
$$
\n(3.19)

From the definition of $U^{\xi^{(n)}}$ and U^{ξ} , we obtain that, for $y \leq x$,

$$
|U_t^{\xi^{(n)}}(y) - U_t^{\xi}(y)| \leq x|e^{\xi_t^{(n)}} - e^{\xi_t}| + |e^{\xi_t^{(n)}} - e^{\xi_t}| \int_0^t e^{-\xi_s^{(n)}} ds + e^{\xi_t} \left| \int_0^t e^{-\xi_s^{(n)}} - e^{-\xi_s} ds \right|.
$$

Since $\xi^{(n)} \stackrel{\text{a.s.}}{\rightarrow} \xi$ in the Skorohod topology and

$$
\mathbb{P}(\{\exists n \geq 1 : \xi_t^{(n)} - \xi_{t-}^{(n)} > 0\} \cap \{\xi_t - \xi_{t-} > 0\}) = 0,
$$

the first term on the right-hand side of the last expression converges a.s. to zero as $n \to \infty$. The a.s. convergence in the Skorohod space implies the existence of time changes $(\lambda_n)_{n\geq 1}$ such that, for each $n \geq 1$, $\lambda_n(0) = 0$, $\lambda_n(t) = t$, the mapping $s \mapsto \lambda_n(s)$ is increasing and continuous on $[0, t]$, and

$$
\lim_{n \to \infty} \sup_{s \leq t} |\lambda_n(s) - s| = \lim_{n \to \infty} \sup_{s \leq t} |\lambda_n^{-1}(s) - s| = 0,
$$
\n(3.20)

$$
\lim_{n \to \infty} \sup_{s \leq t} |\xi_{\lambda_n(s)}^{(n)} - \xi_s| = \lim_{n \to \infty} \sup_{s \leq t} |\xi_s^{(n)} - \xi_{\lambda_n^{-1}(s)}| = 0.
$$
\n(3.21)

Hence,

$$
\left| \int_0^t e^{-\xi_s^{(n)}} - e^{-\xi_s} ds \right| \leq \left| \int_0^t e^{-\xi_s^{(n)}} - e^{-\xi_{\lambda_n^{-1}(s)}} ds \right| + \left| \int_0^t e^{-\xi_{\lambda_n^{-1}(s)}} - e^{-\xi_s} ds \right|.
$$

The first term on the right-hand side clearly goes to zero due to (3.21) , whereas (3.20) implies that the second term goes to zero a.s. by the dominated convergence theorem and the fact that pathwise, for $s \leq t$,

$$
\limsup_{n \to \infty} |e^{-\xi_{\lambda_n^{-1}(s)}} - e^{-\xi_s}| > 0
$$

only on the set of jumps of ξ and this set has a zero Lebesgue measure. Thus, we conclude that

$$
\lim_{n \to \infty} e^{\xi_t} \left| \int_0^t e^{-\xi_s^{(n)}} - e^{-\xi_s} ds \right| = 0.
$$

Similarly, we observe that

$$
\lim_{n \to \infty} |e^{\xi_t^{(n)}} - e^{\xi_t}| \int_0^t e^{-\xi_s^{(n)}} ds \le \lim_{n \to \infty} t |e^{\xi_t^{(n)}} - e^{\xi_t} |e^{\sup_{s \le t} (-\xi_s^{(n)})} = 0,
$$
\n(3.22)

where the last identity follows from

$$
\sup_{s\leqslant t}|(-\xi_s^{(n)})|\leqslant \sup_{s\leqslant t}|\xi_{\lambda_n^{-1}(s)}|+\sup_{s\leqslant t}|\xi_s^{(n)}-\xi_{\lambda_n^{-1}(s)}|=\sup_{s\leqslant t}|\xi_s|+\sup_{s\leqslant t}|\xi_s^{(n)}-\xi_{\lambda_n^{-1}(s)}|,
$$

and an application of (3.21) . Therefore, (3.19) holds and

$$
\lim_{n \to \infty} \sup_{y \leq x} |f(U_t^{(n)}(y)) - f(U_t^{\xi}(y))| = 0.
$$

The dominated convergence theorem then easily gives that the right-hand side of [\(3.18\)](#page-15-3) goes to zero and hence

$$
\limsup_{n\to\infty}|(P_t^{(n)}f-P_tf,m^{(n)})|\leqslant 2||f||_{\infty}\sup_{n\geqslant 1}m^{(n)}(x,\infty)\leqslant 2||f||_{\infty}\delta.
$$

As $\delta > 0$ is arbitrary, we show that

$$
\lim_{n \to \infty} | (P_t^{(n)} f - P_t f, m^{(n)}) | = 0.
$$

Since $(m^{(n)})_{n\geqslant1}$ is tight, we choose a subsequence $(m^{(n_k)})_{k\geqslant1}$ such that $\lim_{k\to\infty} m^{(n_k)} \stackrel{d}{=} \nu$ with ν a probability measure. Then, for each $t \geqslant 0$,

$$
(f,\nu) = \lim_{k \to \infty} (f, m^{(n_k)}) = \lim_{k \to \infty} (P_t^{(n_k)} f, m^{(n_k)}) = \lim_{k \to \infty} (P_t f, m^{(n_k)}) = (P_t f, \nu).
$$

Therefore, ν is a stationary measure for U^{ξ} . But since $m^{(0)}$ is the unique stationary measure, we conclude that

$$
\lim_{n \to \infty} m^{(n)} \stackrel{w}{=} \nu = m^{(0)}.
$$

This translates to the proof of [\(3.17\)](#page-14-0).

4. *Proof of Theorem* 1.2

We start the proof by collecting some useful properties in two trivial lemmas. The first one discusses the properties of Ψ.

Lemma 4.1 [**[28](#page-28-6)**, Theorem 25.17]. *The function* Ψ, *defined in* [\(3.5\)](#page-10-4), *is always well-defined on* iR. Moreover, Ψ *is analytic on the strip* $\{z \in \mathbb{C}; -a_{-} < \Re(z) < a_{+}\}$, where $a_{-}, a_{+} > 0$ *if and only if* $\mathbb{E}[e^{(-a_-+\epsilon)\xi_1}] < \infty$ *and* $\mathbb{E}[e^{(a_+-\epsilon)\xi_1}] < \infty$ *for all* $0 < \epsilon < a_- \wedge a_+$ *.*

The second lemma concerns the properties of ϕ_{\pm} and is easily obtained using Lemma 4.1, [\(1.4\)](#page-4-0) together with the analytical extension and the fact that subordinators have all negative exponential moments.

LEMMA 4.2. Let ξ be a Lévy process with $\mathbb{E}[\xi_1] < \infty$. Then ϕ_+ is always analytic on the *strip* $\{z \in \mathbb{C}; \Re(z) < 0\}$ *and is well-defined on i*R. Moreover, ϕ_+ *is analytic on* $\{z \in \mathbb{C}; \Re(z) <$ a_+ } *for* $a_+ \geq 0$, *if and only if* $\mathbb{E}[e^{(a_+-\epsilon)\xi_1}] < \infty$ *for some* $\epsilon > 0$ *. Similarly,* ϕ_- *is always analytic on the strip* $\{z \in \mathbb{C}; \Re(z) > 0\}$ *and is well-defined on* iR*, and* ϕ_{-} *is analytic on* $\{z \in \mathbb{C}; \Re(z) <$ $-a$ [}] *for* $a_-\geqslant 0$, *if and only if* $\mathbb{E}[e^{(-a_-\epsilon)}\zeta_1]<\infty$ *for some* $\epsilon>0$ *. Finally, the Wiener–Hopf factorization* [\(1.4\)](#page-4-0) *holds on the intersection of the strips, where* ϕ_+ *and* ϕ_- *are well-defined.*

4.1. *Proof in the case* E_+

We recall that, in this section, we assume, in particular, that ξ is a Lévy process with a finite negative mean and that there exists $a_+ > 0$ such that $|\Psi(z)| < \infty$ for any $0 < \Re(z) < a_+$.

 \Box

Next, we write $\theta^* = \max(\theta, a_+)$, where $\theta = \inf\{s > 0; \Psi(s) = 0\}$ (with the convention that inf $\emptyset = +\infty$). We also recall from [[9](#page-27-2)] (see also [[20](#page-27-3)]) that the Mellin transform of I_ε, defined by

$$
\mathcal{M}_{m_{\xi}}(z) = \int_0^\infty x^{z-1} m_{\xi}(x) \, dx,
$$

satisfies, for any $0 < \Re(z) < \theta^*$, the following functional equation:

$$
\mathcal{M}_{m_{\xi}}(z+1) = -\frac{z}{\Psi(z)} \mathcal{M}_{m_{\xi}}(z). \tag{4.1}
$$

We proceed by proving the following easy result.

LEMMA 4.3. If $\mu_+ \in \mathcal{P}$, then there exists a spectrally positive Lévy process Y with Laplace $\text{exponent } \psi_{+}(-s) = -s\phi_{+}(-s), s \geq 0, \text{ and a negative finite mean } -\phi_{+}(0).$ Moreover, if ξ has *a* negative finite mean, then $\mathbb{E}[(I_{H} - \times I_Y)^{-1}] = -\phi_+(0)\phi_-'(0^+) < +\infty$.

Proof. The first claim follows readily from [**[1](#page-27-0)**, Theorem VII.4(ii)] and by observing that $\psi'_+(0^-) = \phi_+(0)$. From [\(4.8\)](#page-19-0), we get that $\mathbb{E}[I_Y^{-1}] = k_+$. Next, since $-\infty < \mathbb{E}[\xi_1] < 0$, using the dual version of Doney [[12](#page-27-8), Corollary 4.4.4(iv)], we get that $-\infty < \mathbb{E}[H_1^-] < 0$ and thus $\phi'_{-}(0^+) < \infty$. From the functional equation [\(4.1\)](#page-17-0), we easily deduce that $\mathbb{E}[\mathcal{I}_{H^-}^{-1}] = -\phi'_{-}(0^+),$ which completes the proof since the two random variables are independent.

LEMMA 4.4. Assume that ξ has a finite negative mean and condition E_+ holds. Let η be *a positive random variable with density* $\kappa(x)$, *such that* $\mathbb{E}[\eta^{-1}] < \infty$ *and* $\mathbb{E}[\eta^{\delta}] < \infty$ for *some* $\theta^* > \delta > 0$. Then, for any z such that $\Re(z) \in (0, \delta)$,

$$
\mathcal{M}_{\mathcal{L}\kappa}(z) = \int_0^\infty x^{z-1} \mathcal{L}\kappa(x) dx = \frac{\Psi(z)}{z^2} \mathcal{M}_\kappa(z+1) + \frac{1}{z} \mathcal{M}_\kappa(z),\tag{4.2}
$$

and if $M_{\mathcal{L}\kappa}(z)=0$, for $0 < a < \Re(z) < b < \delta$, then $\mathcal{L}\kappa(x)=0$ a.e.

Furthermore, the law of the positive random variable $I_Y \times I_{H^-}$ *, as defined in Theorem 1.2,* is absolutely continuous with a density, denoted by \bar{m} , which satisfies

$$
\mathcal{L}\bar{m}(x) = 0 \quad \text{for a.e. } x > 0. \tag{4.3}
$$

REMARK 4.5. Note that the proof of this lemma shows that we have uniqueness for the probability measures with a first negative moment that satisfy [\(4.1\)](#page-17-0). This is a rather indirect approach and seems to be more general than the verification approach of Kuznetsov and Pardo [**[15](#page-27-4)**, Proposition 2], where precise knowledge on the rate of decay of the Mellin transform $\mathcal{M}_{m_{\epsilon}}(z)$ is needed. In general, such an estimate on the decay seems impossible to obtain.

Proof. We start by proving [\(4.2\)](#page-17-1). Note that since $\int_0^\infty y^{-1} \kappa(y) dy < \infty$, we can use Proposition 3.1 to get

$$
\mathcal{L}\kappa(x) = \frac{\sigma^2}{2} x \kappa(x) + \int_x^\infty \frac{\kappa(y)}{y} dy + \mathbb{E}[\xi_1] \int_x^\infty \kappa(y) dy + \int_x^\infty \bar{\bar{\Pi}} \left(\ln \frac{y}{x} \right) \kappa(y) dy + \int_0^x \bar{\bar{\Pi}} \left(\ln \frac{y}{y} \right) \kappa(y) dy.
$$
\n(4.4)

As κ is a density, one can use the Fubini theorem to get, after some easy computations, that, for any $\epsilon < \Re(z) < \delta < \theta^*$, with $0 < \epsilon < \delta$,

$$
\mathcal{M}_{\mathcal{L}\kappa}(z) = \int_0^\infty x^{z-1} \mathcal{L}\kappa(x) dx
$$

= $\mathcal{M}_{\kappa}(z+1) \left(\frac{\sigma^2}{2} + \frac{\mathbb{E}[\xi_1]}{z} + \int_0^\infty \overline{\bar{\Pi}}_-(y) e^{-zy} dy + \int_0^\infty \overline{\bar{\Pi}}_+(y) e^{zy} dy \right) + \frac{1}{z} \mathcal{M}_{\kappa}(z)$
= $\frac{\Psi(z)}{z^2} \mathcal{M}_{\kappa}(z+1) + \frac{1}{z} \mathcal{M}_{\kappa}(z).$

Let $\mathcal{M}_{\mathcal{L}\kappa}(z) = 0$ for $\epsilon < \Re(z) < \delta$. We show, using the fact that all terms in [\(4.4\)](#page-17-2) are positive except the negative one due to $\mathbb{E}[\xi_1] < 0$, that, with $u = \Re(z)$,

$$
\int_0^\infty x^{u-1} |\mathcal{L}\kappa(x)| dx \leq \mathcal{M}\kappa(u+1) \left(\frac{\Psi(u)}{u^2} - 2 \frac{\mathbb{E}[\xi_1]}{u} \right) + \frac{1}{u} \mathcal{M}\kappa(u) < \infty.
$$

Given the absolute integrability of $x^{z-1}\mathcal{L}\kappa(x)$ along imaginary lines determined by $\epsilon < \Re(z) < \delta$, we can apply the Mellin inversion theorem to the identity $\mathcal{M}_{\mathcal{L}\kappa}(z) = 0$ to get $\mathcal{L}\kappa(x) = 0$ a.e.; see [[7](#page-27-18), Section 6, Theorem 6].

Next it is plain that the law of $I_Y \times I_{H-}$ is absolutely continuous since, for any $x > 0$,

$$
\bar{m}(x) = \int_0^\infty m_Y \left(\frac{x}{y}\right) y^{-1} m_{H-}(y) dy.
$$
\n(4.5)

Furthermore, from the Wiener–Hopf factorization [\(1.4\)](#page-4-0) and the definition of ψ_{+} , we have that

$$
\frac{-z}{\Psi(z)} = \frac{-z}{\phi_-(z)} \frac{-z}{\psi_+(z)},
$$

which is valid for any $0 < \Re(z) < \theta^*$. Thus, we deduce from the functional equation [\(4.1\)](#page-17-0) and the independency of Y and H^- that, for any $0 < \Re(z) < \theta^*$,

$$
\mathcal{M}_{\bar{m}}(z+1) = -\frac{z}{\Psi(z)} \mathcal{M}_{\bar{m}}(z). \tag{4.6}
$$

Next, since, from Lemma 4.3, we have that $\int_0^\infty y^{-1} \bar{m}(y) dy < \infty$, we can use Proposition 3.1, and thus [\(4.4\)](#page-17-2) and subsequently [\(4.2\)](#page-17-1) are valid for \bar{m} . Moreover, owing to the representation [\(3.5\)](#page-10-4) of Ψ and relation [\(4.6\)](#page-18-0), we have that, for any $\epsilon < \Re(z) < \theta^*$ with $0 < \epsilon < \theta^*/4$,

$$
\mathcal{M}_{\mathcal{L}\bar{m}}(z) = \frac{\Psi(z)}{z^2} \mathcal{M}_{\bar{m}}(z+1) + \frac{1}{z} \mathcal{M}_{\bar{m}}(z) = 0,
$$

and we conclude that $\mathcal{L}\bar{m}(x) = 0$ a.e.

We are now ready to complete the proof of Theorem 1.2 in the case \mathbf{E}_{+} . Indeed, since m_{ξ} , the density of I_f, is the density of the stationary measure of U^{ξ} , we have that m_{ξ} is also a solution to [\(3.11\)](#page-11-1). Combining Lemma 4.4 with the uniqueness argument of Theorem 3.7, we conclude that the factorization [\(1.6\)](#page-4-3) holds.

4.2. *Proof of the two other cases:* $P+$ *and* P_{\pm}

We start by providing some results that will be used several times throughout this section.

Proposition 4.6 (Carmona *et al.* [**[9](#page-27-2)**]). *Let* H *be the negative of a* (*possibly killed*) *subordinator with Laplace exponent* ϕ ; *then the law of* I_H *is determined by its positive entire moments as follows*:

$$
\mathbb{E}[I_H^m] = \frac{\Gamma(m+1)}{\prod_{k=1}^m (-\phi(k))}, \quad m = 1, 2, \dots
$$
 (4.7)

 \Box

PROPOSITION [4](#page-27-19).7 (Bertoin and Yor $[4]$). Let Y be an unkilled spectrally positive Lévy *process with a negative mean and Laplace exponent* ψ_+ ; *then the law of* $1/I_Y$ *is determined by its positive entire moments as follows*:

$$
\mathbb{E}[\mathbf{I}_Y^{-m}] = \mathbb{E}[-Y_1] \frac{\prod_{k=1}^{m-1} \psi_+(-k)}{\Gamma(m)}, \quad m = 1, 2, \dots,
$$
\n(4.8)

with the convention that the right-hand side is $\mathbb{E}[-Y_1]$ *when* $m = 1$ *.*

In order to get (1.6) in the case when ξ does not have some finite positive exponential moments, we will develop some approximation techniques. However, the exponential functional is not continuous in the Skorohod topology and therefore we have to find some criteria in order to secure the weak convergence of sequences of exponential functionals. This is the aim of the next result.

LEMMA 4.8. Let $(\xi^{(n)})_{n\geqslant 1}$ be a sequence of Lévy processes with negative means such that

$$
\lim_{n \to \infty} \xi^{(n)} \stackrel{d}{=} \xi,
$$

where ξ *is a Lévy process with* $\mathbb{E}[\xi_1] < 0$. Let us assume further that at least one of the following *conditions holds*:

- (a) for each $n \geq 1$, $\xi^{(n)}$ and ξ are unkilled spectrally positive Lévy processes such that $\lim_{n\to\infty} \mathbb{E}[\xi_1^{(n)}] = \mathbb{E}[\xi_1];$
- (b) for each $n \geq 1$, $\xi^{(n)}$ and ξ are the negative of unkilled subordinators;
- (c) the sequence $(m_{\xi^{(n)}})_{n\geq 1}$ is tight, where $m_{\xi^{(n)}}$ is the law of $I_{\xi^{(n)}}$.

Then, *in all cases*, *we have*

$$
\lim_{n \to \infty} I_{\xi^{(n)}} \stackrel{d}{=} I_{\xi}.
$$
\n(4.9)

Proof. To prove (4.9) in the case (a), we simply observe that writing $\psi_+^{(n)}$ for the Laplace exponent of $\xi_1^{(n)}$, we have, by the Lévy continuity theorem (see, for example, [**[13](#page-27-20)**, Theorem XIII.1.2]), that, for all $s \geq 0$, $\psi^{(n)}_+(-s) \to \psi_+(-s)$ as $n \to \infty$. Next, putting $M_m^{(n)}$ for the sequence of negative entire moments of $I_{\xi^{(n)}}$, we easily deduce, from [\(4.8\)](#page-19-0) for all $m = 1, 2, \ldots$, that $\lim_{n \to \infty} M_m^{(n)} = M_m$, where M_m is the sequence of negative entire moments of I_{ϵ} . These random variables being moment determinate (see Proposition 4.7), we conclude (a) by invoking [**[13](#page-27-20)**, Example (b), p. 269]. The second case follows by applying a similar line of reasoning to the expression (4.7) . Finally, the case (c) is a straightforward consequence of [\(3.17\)](#page-14-0) of Theorem 3.10. \Box

Before stating our next result, we need to introduce the following notation. Let us first recall that the reflected processes $(R_t^+ = \sup_{0 \le s \le t} \xi_s - \xi_t)_{t \ge 0}$ and $(R_t^- = \xi_t - \inf_{0 \le s \le t} \xi_s)_{t \ge 0}$ are Feller processes in $[0, \infty)$ which possess local times $L^{\pm} = (L_t^{\pm})_{t \ge 0}$ at the level 0. The ascending and descending ladder times, i.e. $l^{\pm} = (l^{\pm}(t))_{t \geqslant 0}$, are defined as the right-continuous inverses of L^{\pm} , that is, for any $t \geq 0$, $l^{\pm}(t) = \inf\{s > 0; L_s^{\pm} > t\}$, and the ladder height processes $H^+ = (H^+(t))_{t \geqslant 0}$ and $-H^- = (-H^-(t))_{t \geqslant 0}$ are defined by

$$
H^+(t) = \xi_{l^+(t)} = \sup_{0 \le s \le l^+(t)} \xi_s, \quad \text{whenever } l^+(t) < \infty,
$$

-
$$
H^-(t) = \xi_{l^-(t)} = \inf_{0 \le s \le l^-(t)} \xi_s, \quad \text{whenever } l^-(t) < \infty.
$$

Here, we use the convention $\inf\{\emptyset\} = \infty$ and $H^+(t) = \infty$ when $L^+_{\infty} \leq t$ and $-H^-(t) = -\infty$ when $L_{\infty}^- \leq t$. From [**[12](#page-27-8)**, p. 27], we have, for $\alpha, \beta \geq 0$,

$$
\log \mathbb{E}[e^{-\alpha l^+(1)-\beta H^+(1)}] = -k(\alpha, \beta) = -k_+ - \eta_+ \alpha - \delta_+ \beta
$$

$$
-\int_0^\infty \int_0^\infty (1 - e^{-(\alpha y_1 + \beta y_2)}) \mu_+(dy_1, dy_2), \tag{4.10}
$$

where η_+ is the drift of the subordinator l^+ and $\mu_+(dy_1, dy_2)$ is the Lévy measure of the bivariate subordinator (l^+, H^+) . Similarly, for $\alpha, \beta \geq 0$,

$$
\log \mathbb{E}[e^{-(\alpha l^{-}(1)-\beta H^{-}(1))}] = -k_*(\alpha, \beta) = -\eta_{-\alpha} - \delta_{-\beta}
$$

$$
-\int_0^\infty \int_0^\infty (1 - e^{-(\alpha y_1 + \beta y_2)}) \mu_{-}(dy_1, dy_2), \tag{4.11}
$$

where η_- is the drift of the subordinator l^- and $\mu_-(dy_1, dy_2)$ is the Lévy measure of the bivariate subordinator $(l^-, -H^-)$.

LEMMA 4.9. Let ξ be a Lévy process with triplet (a, σ, Π) and Laplace exponent ψ . Let, *for any* $n \ge 1$, $\xi^{(n)}$ *be the Lévy process with Laplace exponent denoted by* $\psi^{(n)}$ *and triplet* $(a, \sigma, \Pi^{(n)})$ *such that* $\Pi^{(n)} = \Pi$ *on* \mathbb{R}_+ *and on* \mathbb{R}_+

$$
\Pi^{(n)}(dy) = h^{(n)}(y)\Pi(dy),
$$

where, for all $y > 0$, $0 \le h^{(n)}(y) \uparrow 1$ *as* $n \to \infty$ *and uniformly, for* $n \ge 1$ *, we have that, for some* $C \geqslant 0$, $\limsup_{y\to 0} y^{-1}(1-h_n(y)) \leqslant C$. Then,

$$
\lim_{n \to \infty} \xi^{(n)} \stackrel{d}{=} \xi,\tag{4.12}
$$

and, *for all* $\alpha \geq 0, \beta \geq 0$, *we have*, *as* $n \to \infty$,

$$
k^{(n)}(\alpha, \beta) \longrightarrow k(\alpha, \beta),
$$

\n
$$
k^{(n)}_*(\alpha, \beta) \longrightarrow k_*(\alpha, \beta),
$$

\n(4.13)

where $k^{(n)}(\alpha, \beta)$ *and* $k^{(n)}_*(\alpha, \beta)$ *stand for the bivariate Laplace exponents of the ladder processes of* $\xi^{(n)}$, *normalized such that* $k^{(n)}(1,0) = k^{(n)}_*(1,0) = 1$. Also $k(\alpha,\beta)$ and $k_*(\alpha,\beta)$ *stand for the bivariate Laplace exponents of the ladder processes of* ξ , *normalized such that* $k(1, 0) =$ $k_*(1,0) = 1.$

REMARK 4.10. Denote by $(l_{(n)}^+, H_{(n)}^+)$ (respectively $(l_{(n)}^-, -H_{(n)}^-)$) the bivariate ascending (respectively descending) ladder processes of $\xi^{(n)}$ and (l^+, H^+) (respectively $(l^-, -H^-)$) the bivariate ascending (respectively descending) ladder processes of ξ ; then from the Lévy continuity theorem we deduce that, as $n \to \infty$,

$$
(l_{(n)}^+, H_{(n)}^+) \stackrel{d}{\longrightarrow} (l^+, H^+),
$$

$$
(l_{(n)}^-, -H_{(n)}^-) \stackrel{d}{\longrightarrow} (l^-, -H^-),
$$
\n
$$
(4.14)
$$

where in the convergence the sequence of killing rates of the ladder height processes also converges to the killing rate of the limiting process.

Proof. For the sake of completeness and also to include both the compound Poisson case and the cases when $\alpha = 0$ and/or $\beta = 0$, we must improve the proof of Vigon [[30](#page-28-1), Lemma 3.4.2]. Next, since $\Pi^{(n)}(dx) \stackrel{v}{\rightarrow} \Pi(dx)$, where $\stackrel{v}{\rightarrow}$ stands for vague convergence, we get [\(4.12\)](#page-20-0) from, for

example, [**[14](#page-27-17)**, Theorem 13.14(i)]. We note the identity

$$
\xi \stackrel{d}{=} \xi^{(n)} + \tilde{\xi}^{(n)},\tag{4.15}
$$

where $\tilde{\xi}^{(n)}$ is a subordinator with Lévy measure $\tilde{\Pi}^{(n)}(dy) = (1 - h_n(y))\Pi(dy)$ and no drift, as $1-h_n(y)=O(y)$ at zero. Then, when ξ is a compound Poisson process we have that $\tilde{\xi}^{(n)}$ is a compound Poisson process and, for all $t > 0$,

$$
\mathbb{P}(\xi_t^{(n)} = 0) = \mathbb{P}(\xi_t = 0, t < \tilde{T}^{(n)}) + \mathbb{P}(\xi_t^{(n)} = 0, t \geq \tilde{T}^{(n)}),
$$

where $\tilde{T}^{(n)} = \inf\{s > 0; \tilde{\xi}_s^{(n)} > 0\}$. Since, for all $y > 0$, $h^{(n)}(y) \uparrow 1$, it follows that $\mathbb{P}(t > \tilde{T}^{(n)}) \to$ 0 as $n \to \infty$ and

$$
\mathbb{P}(\xi_t^{(n)} \in dy)\mathbb{I}_{\{y \geq 0\}} \xrightarrow{v} \mathbb{P}(\xi_t \in dy)\mathbb{I}_{\{y \geq 0\}}.
$$

When ξ is not a compound Poisson process, the law of $\xi^{(n)}$ does not charge $\{0\}$ and thus, as $n \to \infty$,

$$
\mathbb{P}(\xi_t^{(n)} \in dy)\mathbb{I}_{\{y>0\}} \xrightarrow{v} \mathbb{P}(\xi_t \in dy)\mathbb{I}_{\{y>0\}}.
$$

Henceforth, from the expression

$$
k^{(n)}(\alpha,\beta) = \exp\left(\int_0^\infty dt \int_0^\infty (e^{-t} - e^{-\alpha t - \beta y}) t^{-1} \mathbb{P}(\xi_t^{(n)} \in dy)\right),\tag{4.16}
$$

which holds for any $\alpha > 0$ and $\beta > 0$ (see, for example, [**[1](#page-27-0)**, Corollary VI.2.10]), we deduce easily that, for both cases,

$$
\lim_{n \to \infty} k^{(n)}(\alpha, \beta) = k(\alpha, \beta). \tag{4.17}
$$

Moreover, we can write

$$
k^{(n)}(\alpha, \beta) = k^{(n)}(0, 0) + \tilde{k}^{(n)}(\alpha, \beta),
$$
\n(4.18)

where $\tilde{k}^{(n)}$ are the Laplace exponents of unkilled bivariate subordinators; see [[12](#page-27-8), p. 27]. Note from (4.16) that

$$
k^{(n)}(0,0) = \exp\left(-\int_0^\infty (1 - e^{-t}) \mathbb{P}(\xi_t^{(n)} \ge 0) \frac{dt}{t}\right).
$$

Next, from [\(4.15\)](#page-21-1) and the fact that $\tilde{\xi}^{(n)}$ is a subordinator, we have that $\mathbb{P}(\xi_t^{(n)} \geq 0) \leq \mathbb{P}(\xi_t \geq 0)$ 0) and, appealing to the monotone convergence theorem, we get that $k^{(n)}(0,0) \downarrow k(0,0)$. Hence, we deduce from [\(4.17\)](#page-21-2) and [\(4.18\)](#page-21-3) that, for any $\alpha, \beta > 0$, $\tilde{k}^{(n)}(\alpha, \beta) \rightarrow \tilde{k}$ Hence, we deduce from (4.17) and (4.18) that, for any $\alpha, \beta > 0$, $k^{(n)}(\alpha, \beta) \to k(\alpha, \beta)$, where $\tilde{k}(\alpha, \beta) = k(\alpha, \beta) - k(0, 0)$. From the Lévy continuity theorem, we have, writing $(\tilde{l}_{(n)}^+, \tilde{H}_{(n)}^+)$ for the unkilled versions of the ascending bivariate ladder processes, that $(\tilde{l}_{(n)}^+, \tilde{H}_{(n)}^+) \stackrel{\widetilde{d}}{\rightarrow} (\tilde{l}^+, \tilde{H}^+)$, where $(\tilde{l}^+, \tilde{H}^+)$ stands also for the unkilled version of $(\tilde{l}^+, \tilde{H}^+)$. These probability distributions being proper, we have that, for all $\alpha, \beta \in \mathbb{R}$, $\tilde{k}^{(n)}(i\alpha, i\beta) \to \tilde{k}(i\alpha, i\beta)$; see [[13](#page-27-20), Theorem XV.3.2]. Hence, $k^{(n)}(0, i\beta) \to k(0, i\beta)$ for all $\beta \in \mathbb{R}$, which completes the proof for the ascending ladder height processes. The proof of the convergence of the Laplace exponent of the bivariate descending ladder process follows readily from the identities

$$
\psi^{(n)}(i\beta) - \alpha = -k^{(n)}(\alpha, -i\beta)k_*^{(n)}(\alpha, i\beta),
$$

$$
\psi(i\beta) - \alpha = -k(\alpha, -i\beta)k_*(\alpha, i\beta),
$$

and the convergence of $\psi^{(n)}$ to ψ and $k^{(n)}$ to k .

4.2.1. The case $P +$. We first consider the case when ξ satisfies both the conditions $P +$ and $\mathbb{E}[\xi_1] > -\infty$. We start by showing that the condition **P**+ implies that $\mu_+ \in \mathcal{P}$. To this

 \Box

end, we shall need the so-called *equation amicale invers* $\acute{e}e$ derived by Vigon, for all $x > 0$,

$$
\bar{\mu}_{+}(x) = \int_{0}^{\infty} \bar{\Pi}_{+}(x+y)\mathcal{U}_{-}(dy),
$$
\n(4.19)

where \mathcal{U}_- is the renewal measure corresponding to the subordinator H^- ; see, for example, [**[12](#page-27-8)**, Theorem 5.16].

LEMMA 4.11. Let us assume that $\bar{\Pi}_+(x)$ has a non-positive derivative $\pi_+(x)$ defined for *all* $x > 0$ *and such that* $-\pi_+(x)$ *is non-increasing. Then* $\bar{\mu}_+(x)$ *is differentiable with derivative* $u(x)$ *such that* $-u(x)$ *is non-increasing.*

Proof. Fix $x > 0$ and choose $0 < h < x/3$. Then we have the trivial bound using the nonincreasing property of $-\pi_+(x)$ and the description [\(4.19\)](#page-22-0) of $\bar{\mu}_+(x)$

$$
\frac{|\bar{\mu}_{+}(x \pm h) - \bar{\mu}_{+}(x)|}{h} \leqslant \int_{0}^{\infty} \frac{|\bar{\Pi}_{+}(x + y \pm h) - \bar{\Pi}_{+}(x + y)|}{h} \mathcal{U}_{-}(dy)
$$

$$
\leqslant \int_{0}^{\infty} (-\pi_{+}(x + y - h)) \mathcal{U}_{-}(dy)
$$

$$
\leqslant \int_{0}^{\infty} \left(-\pi_{+}\left(\frac{2x}{3} + y \right) \right) \mathcal{U}_{-}(dy).
$$

We show now that the last expression is finite. Note that

$$
\int_0^\infty \left(-\pi_+\left(\frac{2x}{3}+y\right)\right) \mathcal{U}_-(dy) \leqslant \sum_{n\geqslant 0} -\pi_+\left(\frac{2x}{3}+n\right) \left(\mathcal{U}_-(n+1)-\mathcal{U}_-(n)\right).
$$

From the trivial inequality $\mathcal{U}_-(n+1) - \mathcal{U}_-(n) \leq \mathcal{U}_-(1)$ (see [[12](#page-27-8), Chapter 2, p.11]) and since $-\pi_+(x)$ is the non-increasing density of $\bar{\Pi}_+(x)$, we have, with $C = \mathcal{U}_-(1) > 0$,

$$
\int_0^\infty -\pi_+ \left(\frac{2x}{3} + y\right) \mathcal{U}_-(dy) \leq C \sum_{n \geq 0} -\pi_+ \left(\frac{2x}{3} + n\right)
$$

$$
\leq -C\pi_+ \left(\frac{2x}{3}\right) + C \sum_{n \geq 1} \left(\bar{\Pi}_+ \left(\frac{2x}{3} + n - 1\right) - \bar{\Pi}_+ \left(\frac{2x}{3} + n\right)\right)
$$

$$
\leq -C\pi_+ \left(\frac{2x}{3}\right) + C\bar{\Pi}_+ \left(\frac{2x}{3}\right) < \infty.
$$

Therefore, for all $x > 0$, the dominated convergence applies and gives

$$
u(x) = \int_0^\infty \pi_+(x+y)\mathcal{U}_-(dy).
$$

As $-\pi_+(x)$ is non-increasing, we deduce that $-u(x)$ is non-increasing as well.

In the case $P+$, in comparison to the case E_+ , we have that ξ does not necessarily have some positive exponential moments. To circumvent this difficulty, we introduce the sequence of Lévy processes $\xi^{(n)}$ obtained from ξ by the following construction: we keep the negative jumps intact and we discard some of the positive ones. More precisely, we to thin the jumps of ξ to get a Lévy process $\xi^{(n)}$ with $\Pi_+^{(n)}$ whose density has the form

$$
\pi_+^{(n)}(x) = \pi_+(x) \left(\mathbb{I}_{\{0 < x \leq 1\}} + e^{-n^{-1}(x-1)} \mathbb{I}_{\{x > 1\}} \right). \tag{4.20}
$$

 \Box

Clearly, $-\pi^{(n)}_+(x)$ is non-increasing and $\mathbb{E}[e^{s\xi^{(n)}_1}] < \infty$ for $s \in (0, n^{-1})$; see [\(4.20\)](#page-22-1). Moreover, since we have only thinned the positive jumps and pointwise $\lim_{n\to\infty} \pi^{(n)}_+(x) = \pi_+(x)$, see (4.20) ,

$$
\lim_{n \to \infty} \xi^{(n)} \stackrel{\text{a.s.}}{=} \xi \tag{4.21}
$$

in the Skorohod space $\mathcal{D}(0,\infty)$. Finally, since $-\infty < \mathbb{E}[\xi_1^{(n)}] < \mathbb{E}[\xi_1] < 0$ and $-\pi_+^{(n)}(x)$ is nonincreasing, it follows that Lemma 4.11 applies and we deduce that the Lévy measure of the ascending ladder height process of $\xi^{(n)}$ has a negative density whose absolute value is nonincreasing in x. Then, since, for each $n \geqslant 1$, $\xi^{(n)}$ has some finite positive exponential moments, we have that

$$
I_{\xi^{(n)}} \stackrel{d}{=} I_{H_{(n)}^-} \times I_{Y^{(n)}}.
$$
\n(4.22)

Since we thinned the positive jumps of ξ , for all $t \geq 0$, $\xi_t^{(n)} \leq \xi_t$ and the monotone convergence theorem together with [\(4.21\)](#page-23-0) imply that

$$
\lim_{n \to \infty} I_{\xi^{(n)}} \stackrel{\text{a.s.}}{=} I_{\xi}.
$$
\n(4.23)

By the choice of the approximating sequence $\xi^{(n)}$, we can first use Lemma 4.9 to get

$$
\lim_{n \to \infty} H_{(n)}^- \stackrel{d}{=} H^-, \tag{4.24}
$$

and then Lemma 4.8(b) to obtain that

$$
\lim_{n \to \infty} I_{H_{(n)}^{-}} \stackrel{d}{=} I_{H^{-}}.
$$
\n(4.25)

Again from Lemma 4.9, we deduce that $k^{(n)}(0,-s) \to k(0,-s)$ for all $s \geq 0$, and $\lim_{n\to\infty} \mathbb{E}[Y_1^{(n)}] = -\lim_{n\to\infty} k^{(n)}(0,0) = \mathbb{E}[Y_1]$, so we can apply Lemma 4.8(a) to get

$$
\lim_{n \to \infty} I_{Y^{(n)}} \stackrel{d}{=} I_Y,
$$

which completes the proof in this case.

4.2.2. The case P_{\pm} . First from the philanthropy theory developed by Vigon [[30](#page-28-1)], we know that the conditions $\mu_+ \in \mathcal{P}$ and $\mu_- \in \mathcal{P}$ ensure the existence of a Lévy process ξ with ladder processes H^+ and H^- and such that the Wiener–Hopf factorization [\(1.4\)](#page-4-0) holds on iR. Since we also assume that $k_{+} > 0$, this Lévy process necessarily drifts to $-\infty$. Next, let us introduce the Laplace exponents

$$
\phi_{+}^{(p)}(z) = \delta_{+}z + \int_{(0,\infty)} (e^{zx} - 1)\mu_{+}^{(p)}(dx) - k_{+},
$$
\n(4.26)

$$
\phi_{-}^{(n)}(z) = -\delta_{-}z - \int_{(0,\infty)} (1 - e^{-zx}) \mu_{-}^{(n)}(dx), \tag{4.27}
$$

where we set $\mu_+^{(p)}(dx) = e^{-x/p}\mu_+(dx), p > 0$, and $\mu_-^{(n)}(dx) = e^{-x/n}\mu_+(dx), n > 0$. Plainly, for any $p > 0, n > 0, \mu^{(p)}_+ \in \mathcal{P}$ and $\mu^{(n)}_- \in \mathcal{P}$, hence there exists a Lévy process $\xi^{(p,n)}$ with Laplace exponent $\Psi^{(p,n)}$ satisfying

$$
\Psi^{(p,n)}(z) = -\phi_+^{(p)}(z)\phi_-^{(n)}(s),\tag{4.28}
$$

which is easily seen to be analytic on the strip $-1/n < \Re(z) < 1/p$. Moreover, from [**[12](#page-27-8)**, Corollary 4.4.4], we have $\mathbb{E}[\xi_1^{(p,n)}] = -k_+ \left(\int_0^\infty x e^{-x/n} \mu_+(dx) + \delta_- \right)$, which is clearly finite and negative. Hence, the conditions E_{+} are satisfied and we have, with obvious notation, that

$$
{\rm I}_{\xi^{(p,n)}}\stackrel{d}{=} {\rm I}_{H_{(n)}^-}\times {\rm I}_{Y^{(p)}},
$$

where, for any $p > 0$, $Y^{(p)}$ is a spectrally positive Lévy process with Laplace exponent $\psi^{(p)}_+(-s) = -s\phi^{(p)}_+(-s), s \geqslant 0.$ Let us first deal with the case $n \to \infty$. Since $\phi^{(n)}_-(s) \to \phi_-(s)$ for all $s \geqslant 0$, we have that

$$
\lim_{n \to \infty} H_{(n)}^- \stackrel{d}{=} H^-,
$$

and from Lemma 4.8(b) we get that

$$
\lim_{n \to \infty} I_{H_{(n)}^-} \stackrel{d}{=} I_{H^-}.
$$

Thus, we deduce that, for any fixed $p > 0$, the sequence $(I_{\xi^{(p,n)}})_{n \geq 1}$ is tight. Moreover, for any fixed $p > 0$, we also have $\xi^{(p,n)} \stackrel{d}{\rightarrow} \xi^{(p)}$, as $n \rightarrow \infty$, where $\xi^{(p)}$ has a Laplace exponent $\Psi^{(p)}$ given by

$$
\Psi^{(p)}(z) = -\phi_+^{(p)}(z)\phi_-(z). \tag{4.29}
$$

Indeed, this is true by the philanthropy theory. Then, from Lemma $4.8(c)$, we have that

$$
\lim_{n\to\infty}{\rm I}_{\xi^{(p,n)}}\stackrel{d}={\rm I}_{\xi^{(p)}}\stackrel{d}={\rm I}_{H^-}\times{\rm I}_{Y^{(p)}},
$$

which provides a proof of the statement in the case P_{\pm} together with the existence of some finite positive exponential moments. Next, as $p \to \infty, \phi^{(p)}_+(s) \to \phi_+(s)$ for all $s \geq 0$, and we have that

$$
\lim_{p \to \infty} Y^{(p)} \stackrel{d}{=} Y,
$$

where Y is a spectrally positive Lévy process with Laplace exponent $\psi_{+}(-s) = -s\phi_{+}(-s)$. As $\mathbb{E}[Y_1^{(p)}] = \phi_+^{(p)}(0) = -k_+$, we can use Lemma 4.8(a) to obtain

$$
\lim_{p\to\infty}{\mathcal I}_{Y^{(p)}}\stackrel{d}{=}{\mathcal I}_Y.
$$

As above, we conclude from Lemma 4.8(c) that

$$
\lim_{p \to \infty} I_{\xi^{(p)}} \stackrel{d}{=} I_{\xi} \stackrel{d}{=} I_{H^-} \times I_Y,
$$

which completes the proof of the theorem.

5. *Proof of the corollaries*

5.1. *Corollary* 2.1

First, since ξ is spectrally negative and has a negative mean, it is well known that the function Ψ admits an analytical extension on the right-half plane, which is convex on \mathbb{R}^+ drifting to ∞ , with $\Psi'(0^+) < 0$, and thus there exists $\gamma > 0$ such that $\Psi(\gamma) = 0$. Moreover, the Wiener–Hopf factorization for spectrally negative Lévy processes boils down to

$$
\Psi(s) = \frac{\Psi(s)}{s - \gamma}(s - \gamma), \quad s > 0.
$$

It is not difficult to check that, with $\phi_{+}(s) = s - \gamma$ and $\phi_{-}(s) = -\Psi(s)/(s - \gamma)$, we have $\mu_-, \mu_+ \in \mathcal{P}$. Observing that $\psi_+(s) = s^2 - \gamma s$ is the Laplace exponent of a scaled Brownian motion with a negative drift γ , it is well known (see, for example, **[31](#page-28-7)**) that

$$
I_Y \stackrel{d}{=} G_{\gamma}^{-1}.
$$

The factorization follows then from Theorem 1.2 considered under the condition P_{+} . Since the random variable G_{γ}^{-1} is MSU (see [[11](#page-27-9)]), we have that if I_{H^-} is unimodal, then I_{ξ} is unimodal,

which completes the proof of (1) . Next, (2) follows easily from the identity

$$
m_{\xi}(x) = \frac{1}{\Gamma(\gamma)} x^{-\gamma - 1} \int_0^{\infty} e^{-y/x} y^{\gamma} m_{H}(\mathbf{y}) \, d\mathbf{y}
$$
\n
$$
\tag{5.1}
$$

combined with an argument of monotone convergence.

Further, we recall that Chazal *et al.* [[10](#page-27-21), Theorem 4.1] showed that, for any $\beta \geqslant 0$, $\phi_{\beta}(s)$ = $(s/(s+\beta))\phi_{-}(s+\beta)$ is also the Laplace exponent of a negative of a subordinator and with obvious notation

$$
m_{H_{\beta}^{-}}(x) = \frac{x^{\beta} m_{H^{-}}(x)}{\mathbb{E}[\mathcal{I}_{H^{-}}^{{\beta}}]}, \quad x > 0.
$$
\n(5.2)

Then, assuming that $1/x < \lim_{u\to\infty} \Psi(u)/u$, we have, from [\(4.7\)](#page-18-1), [\(5.1\)](#page-25-0) and [\(5.2\)](#page-25-1),

$$
m_{\xi}(x) = \frac{1}{\Gamma(\gamma)} x^{-\gamma - 1} \sum_{n=0}^{\infty} (-1)^n \frac{x^{-n}}{n!} \int_0^{\infty} y^{n+\gamma} m_{H^-}(y) dy
$$

\n
$$
= \frac{\mathbb{E}[\Gamma_{H^-}^{\gamma}]}{\Gamma(\gamma)} x^{-\gamma - 1} \sum_{n=0}^{\infty} (-1)^n \frac{x^{-n}}{n!} \frac{n!}{\prod_{k=1}^n -(k/(k+\gamma))\phi_-(k+\gamma)}
$$

\n
$$
= \frac{\mathbb{E}[\Gamma_{H^-}^{\gamma}]}{\Gamma(\gamma)\Gamma(\gamma+1)} x^{-\gamma - 1} \sum_{n=0}^{\infty} (-1)^n \frac{\Gamma(n+\gamma+1)}{\prod_{k=1}^n -k\phi_-(k+\gamma)} x^{-n}
$$

\n
$$
= \frac{\mathbb{E}[\Gamma_{H^-}^{\gamma}]}{\Gamma(\gamma)\Gamma(\gamma+1)} x^{-\gamma - 1} \sum_{n=0}^{\infty} (-1)^n \frac{\Gamma(n+\gamma+1)}{\prod_{k=1}^n \Psi(k+\gamma)} x^{-n},
$$

where we used an argument of dominated convergence and the identity $-k\phi_{-}(k+\gamma)=\Psi$ $(k + \gamma)$. Next, again from [\(5.1\)](#page-25-0), we deduce that

$$
x^{-\beta}m_{\xi}(x^{-1}) = \frac{1}{\Gamma(\gamma)}x^{\gamma+1-\beta} \int_0^{\infty} e^{-xy}y^{\gamma}m_{H}(\mathbf{y})\,dy,
$$

from which we easily see that, for any $\beta \geq \gamma + 1$, the mapping $x \mapsto x^{-\beta} m_{\xi}(x^{-1})$ is completely monotone as the product of two Laplace transforms of positive measures. The proof of the corollary is completed by invoking [[28](#page-28-6), Theorem 51.6] and noting that I_{ξ}^{-1} has a density given by $x^{-2}m_{\xi}(x^{-1})$, that is, with $\beta = 2$.

5.2. *Corollary* 2.3

We first observe from equation (4.19) that, in this case,

$$
\bar{\mu}_{+}(x) = c e^{-\lambda x} \int_{0}^{\infty} e^{-\lambda y} \mathcal{U}_{-}(dy)
$$

$$
= c_{-} e^{-\lambda x},
$$

where the last identity follows from [**[12](#page-27-8)**] and we have set $c_ = c/(\phi_-(\lambda))$. From [\(1.5\)](#page-4-4), we deduce that Y is a spectrally positive Lévy process with Laplace exponent given, for any $s < \lambda$, by

$$
\psi_{+}(s) = \delta_{+} s^{2} - k_{+} s + c_{-} \frac{s^{2}}{\lambda - s} \n= \frac{s}{\lambda - s} (-\delta_{+} s^{2} - (\delta_{+} \lambda + k_{+} + c_{-}) s - k_{+} \lambda),
$$

where $\delta_+ > 0$ since $\sigma > 0$; see [[12](#page-27-8), Corollary 4.4.4]. Thus, using the continuity and convexity of ψ_+ on $(-\infty, \lambda)$ and on (λ, ∞) , studying its asymptotic behaviour on these intervals and the identity $\psi'_+(0) = -k_+ < 0$, we easily show that the equation $\psi_+(s) = 0$ has three roots that are real, one is obviously 0 and the two others θ_1 and θ_2 are such that $0 < \theta_1 < \lambda < \theta_2$. Thus,

$$
\psi_+(-s) = \frac{\delta_+ s}{\lambda + s}(s + \theta_1)(s + \theta_2), \quad s > -\lambda.
$$

Next, from [\(4.8\)](#page-19-0), we have, with $C = k_{+}(\Gamma(\lambda + 1)/\Gamma(\theta_1 + 1)\Gamma(\theta_2 + 1))$ and for $m = 2, \ldots$, that

$$
\mathbb{E}[\mathbf{I}_Y^{-m}] = C\delta_+^{m-1} \frac{\Gamma(m+\theta_1)\Gamma(m+\theta_2)}{\Gamma(m+\lambda)},
$$

from which we easily deduce [\(2.7\)](#page-7-0) by moment identification. Note that a simple computation gives $\theta_1 \theta_2 = \delta_+ \lambda k_+$, securing that the distribution of I_Y is proper. Next, the random variable I_Y^{-1} being moment determinate, we have, for $\Re(z) < \theta_1 + 1$, that

$$
\mathbb{E}[I_Y^{z-1}] = C\delta_+^{-z} \frac{\Gamma(-z+\theta_1+1)\Gamma(-z+\theta_2+1)}{\Gamma(-z+\lambda+1)}.
$$

Applying the inverse Mellin transform (see, for example, [**[21](#page-27-22)**, Section 3.4.2]), we get

$$
m_Y\left(\frac{x}{\delta^+}\right) = C \sum_{i=1}^2 x^{-\theta_i - 1} \mathcal{I}_i(-x^{-1}), \quad x > 0,
$$
\n(5.3)

where $\mathcal{I}_i(x) = \sum_{n=0}^{\infty} b_{n,i}(x^n/n!)$, $b_{n,1} = \Gamma(\theta_2 - \theta_1 - n)/\Gamma(\lambda - \theta_1 - n)$ and $b_{n,2} = \Gamma(\theta_1 - \theta_2 - n)/\Gamma(\lambda - \theta_1 - n)$ $\Gamma(\lambda - \theta_2 - n)$. The proof of the corollary is completed by following a line of reasoning similar to the proof of Corollary 2.1.

5.3. *Corollary* 2.6

For any $\alpha \in (0,1)$, let us observe that, for any $s \geqslant 0$,

$$
\phi_{-}(-s) = \frac{\alpha s \Gamma(\alpha(s+1) + 1)}{(1+s)\Gamma(\alpha s + 1)}\tag{5.4}
$$

$$
=\int_0^\infty (1 - e^{-sy}) u_\alpha(y) dy,
$$
\n(5.5)

where $u_{\alpha}(y) = e^{-y}e^{-y/\alpha}/\Gamma(1-\alpha)(1-e^{-y/\alpha})^{\alpha+1}$. We easily check that $u_{\alpha}(y)dy \in \mathcal{P}$ and hence Ψ is a Laplace exponent of a Lévy process that drifts to $-\infty$. Next, we know (see, for example, [**[26](#page-28-4)**]) that

$$
I_{\tilde{H}^-} \stackrel{d}{=} S_{\alpha}^{-\alpha},
$$

where \tilde{H}^- is the negative of the subordinator having Laplace exponent

$$
\tilde{\phi}_{-}(-s) = \frac{\alpha \Gamma(\alpha s + 1)}{\Gamma(\alpha (s - 1) + 1)}.
$$

Observing that $\phi_{-}(-s)=(-s/(-s+1))\tilde{\phi}_{-}(-s+1)$, we deduce, from [\(5.2\)](#page-25-1), that

$$
m_{H^{-}}(x) = \frac{x^{-1/\alpha}}{\alpha} g_{\alpha}(x^{-1/\alpha}), \quad x > 0,
$$
\n(5.6)

from which we readily get the expression [\(2.10\)](#page-8-1). Then we recall the following power series representation of positive stable laws (see, for example, [**[28](#page-28-6)**, Formula (14.31)]),

$$
g_{\alpha}(x) = \sum_{n=1}^{\infty} \frac{(-1)^n}{\Gamma(-\alpha n)n!} x^{-(1+\alpha n)}, \quad x > 0.
$$

Then, by means of an argument of dominated convergence justified by the condition $\lim_{s\to\infty} s^{\alpha-1}\phi_+(-s) = 0$, we get, for all $x > 0$, that

$$
m_{\xi}(x) = \frac{k_+}{\alpha} \sum_{n=1}^{\infty} \frac{(-1)^n}{\Gamma(-\alpha n) n!} x^n \int_0^{\infty} y^{-(n+1)} f_Y(y) dy
$$

=
$$
\frac{k_+}{\alpha} \sum_{n=1}^{\infty} \frac{\prod_{k=1}^n \phi_+(-k)}{\Gamma(-\alpha n) n!} x^n,
$$

where we used the identity [\(4.8\)](#page-19-0), $\mathbb{E}[-Y_1] = k_+$ and $\psi_+(-k) = -k\phi_+(-k)$. The fact that the series is absolutely convergent is justified by using classical criteria combined with the Euler reflection formula $\Gamma(1-z)\Gamma(z)\sin(\pi z) = \pi$ with the asymptotics

$$
\frac{\Gamma(z+a)}{\Gamma(z+b)} = z^{a-b}(1+O(|z|^{-1})) \quad \text{as } z \longrightarrow \infty, \ |\arg(z)| < \pi; \tag{5.7}
$$

see, for example, [**[18](#page-27-23)**, Chapter 1]. We complete the proof by mentioning that Simon [**[29](#page-28-3)**] proved recently that the positive stable laws are MSU if and only if $\alpha \leq \frac{1}{2}$, which implies, from [\(5.6\)](#page-26-1), that I_{H^-} is also MSU in this case.

Acknowledgements. The authors are grateful to the reviewer's valuable comments, which improved the presentation of the manuscript. The two last authors would like to thank A. E. Kyprianou for stimulating discussions while they were visiting the University of Bath.
