ABSTRACT

In this article we present the first results on domain decomposition methods for nonlocal operators. We present a nonlocal variational formulation for these operators and establish the well-posedness of associated boundary value problems, proving a nonlocal Poincaré inequality. To determine the conditioning of the discretized operator, we prove a spectral equivalence which leads to a mesh size independent upper bound for the condition number of the stiffness matrix. We then introduce a nonlocal two-domain variational formulation utilizing nonlocal transmission conditions, and prove equivalence with the single-domain formulation. A nonlocal Schur complement is introduced. We establish condition number bounds for the nonlocal stiffness and Schur complement matrices. Supporting numerical experiments demonstrating the conditioning of the nonlocal one- and two-domain problems are presented.

1. Introduction

Domain decomposition methods where the subdomains do not overlap are called *substructuring methods*, reflecting their origins and long use within the structural analysis community [1]. These methods solve for unknowns only along the interface between subdomains, thus decoupling these domains from each other and allowing each subdomain to then be solved independently. One may solve for the primal field variable on the interface, generating a Dirichlet boundary value problem on each subdomain (these are Schur complement methods, see [2] and references cited therein), or solve for the dual field variable on the interface, generating a Neumann boundary value problem on each subdomain (these are dual Schur complement methods, see [3–6]). Hybrid dual-primal methods have also been developed [7].

As domain decomposition methods are frequently employed on massively parallel computers, only *scalable* methods are of interest, meaning that the condition number of the interface problem does not grow (or, only grows weakly) with the number of subdomains. Scalable or weakly scalable methods are generated by application of an appropriate preconditioner to the interface problem. This preconditioner requires the solution of a coarse problem to propagate error globally; see any of the Refs. [8–15]. For a general overview of domain decomposition, the reader is directed to the excellent texts [2,16,17].

All of the methods referenced above have in common that they are domain decomposition approaches for *local* problems. In this article, we propose and study a domain decomposition method for the *nonlocal* Dirichlet boundary value problem

$$\mathcal{L}(\mathbf{u}) = \mathbf{b}(\mathbf{x}), \quad \mathbf{x} \in \Omega, \quad (1.1)$$

where

$$\mathcal{L}(\mathbf{u}) := - \int_{\Omega \cup B\Omega} \mathbf{C}(\mathbf{x}, \mathbf{x}') [\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] d\mathbf{x}'. \quad (1.2)$$

Let n and d denote the dimensions of the function space and the spatial domain, respectively. $\Omega \subset \mathbb{R}^d$ is a bounded domain, $B\Omega$ is given in (2.1), \mathbf{b} is given, and $\mathbf{u}(\mathbf{x}) \in \mathbb{R}^n$ is prescribed for $\mathbf{x} \in \mathbb{R}^d \setminus \Omega$. We prescribe the value of $\mathbf{u}(\mathbf{x})$ outside Ω and not just on the boundary of Ω , owing to the nonlocal nature of the problem.

Nonlocal models are useful where classical (local) models cease to be predictive. Examples include porous media flow [18–20], turbulence [21], fracture of solids, stress fields at dislocation cores and cracks tips, singularities present at the point of application of concentrated loads (forces, couples, heat, etc.), failure in the prediction of short wavelength behavior of elastic waves, microscale heat transfer, and fluid flow in microscale channels [22]. These are also cases where microscale fields are nonsmooth. Consequently, nonlocal models are also useful for multiscale modeling. Recent examples of nonlocal multiscale modeling include the upscaling of molecular dynamics to nonlocal continuum mechanics [23], and development of a rigorous multiscale method for the analysis of fiber-reinforced composites capable of resolving dynamics at structural length scales as well as the length scales of the reinforcing fibers [24]. Progress towards a nonlocal calculus is reported in [25]. Development and analysis of a nonlocal diffusion equation is reported in [26–28]. Theoretical developments for general class of integro-differential equation related to the fractional Laplacian are presented in [29–31]. Mathematical and numerical analysis for linear nonlocal peridynamic boundary problems appears in [32,33]. We discuss in Section 2 some specific contexts where the nonlocal operator \mathcal{L} appears, and the assumptions placed upon \mathcal{L} by those interpretations.

To the best of authors' knowledge, this article represents the first work on domain decomposition methods for nonlocal models. Our aim is to generalize iterative substructuring methods to a nonlocal setting and characterize the impact of nonlocality upon the scalability of these methods. To begin our analysis, we first develop a weak form for (1.1) in Section 3. The main theoretical construction for conditioning is in Section 4. We establish spectral equivalences to bound the condition numbers of the stiffness and Schur complement matrices. For that, we prove a nonlocal Poincaré inequality for the lower bound and a dimension dependent estimate for the upper bound. This leads to the novel result that *the condition number of the discrete nonlocal operator can be bounded independently of the mesh size*. In Section 5, we construct a suitable nonlocal domain decomposition framework with special attention to transmission conditions. Then, we prove the equivalence of the boundary value problems corresponding to the single domain and the two-domain decomposition. In Section 6, we first define a *discrete energy minimizing extension*, a nonlocal analog of discrete harmonic extension in the local case, to study the conditioning of the Schur complement in the nonlocal setting. We discretize our two-domain weak form to arrive at a *non-local Schur complement*. We perform numerical studies to validate our theoretical results. Finally in Section 7, we draw conclusions about conditioning and suggest future research directions for nonlocal domain decomposition methods.

2. Interpretations of the operator \mathcal{L}

The operator \mathcal{L} appears in many different application areas, from evolution equations for species population densities [34] to image processing [35]. We review two specific contexts in which the operator \mathcal{L} of (1.1) is utilized, paying special attention to associated assumptions these interpretations place upon \mathbf{C} in \mathcal{L} . In all cases, we find \mathbf{C} to have local support about \mathbf{x} , meaning that we must prescribe Dirichlet boundary conditions only for

$$B\Omega := \text{supp}(\mathbf{C}) \setminus \Omega, \quad (2.1)$$

as depicted in Fig. 2.1. Furthermore, throughout this article we assume an integrable \mathbf{C} .

2.1. Nonlocal diffusion processes

The equation

$$u_t(\mathbf{x}, t) = \mathcal{L}(u(\mathbf{x}, t)) \quad (2.2)$$

Fig. 2.1. Typical domain for (1.1). \mathbf{u} is prescribed in $B\Omega$, and we solve for \mathbf{u} in Ω .

is an instance of a nonlocal p -Laplace equation for $p = 2$, and has been used to model nonlocal diffusion processes, see [36,28] and the references cited therein. In this setting, $u(\mathbf{x}, t) \in \mathbb{R}$ is the density at the point \mathbf{x} at time t of some material, and we assume $C(\mathbf{x}, \mathbf{x}') = C(\mathbf{x} - \mathbf{x}')$ is translation invariant. Then, $\int_{\mathbb{R}^d} C(\mathbf{x}' - \mathbf{x})u(\mathbf{x}', t)d\mathbf{x}'$ is the rate at which material is arriving at \mathbf{x} from all other points in $\text{supp}(C)$, and $-\int_{\mathbb{R}^d} C(\mathbf{x}' - \mathbf{x})u(\mathbf{x}, t)d\mathbf{x}'$ is the rate at which material departs \mathbf{x} for all other points in $\text{supp}(C)$ [37,28].

In this interpretation of (1.1) the following restrictions are placed upon C in \mathcal{L} . It is assumed that $C : \mathbb{R}^d \rightarrow \mathbb{R}$ is a nonnegative, radial, continuous function that is strictly positive in a ball of radius δ about \mathbf{x} and zero elsewhere. Additionally, it is assumed that $\int_{\Omega} C(\xi)d\xi < \infty$.

2.2. Nonlocal solid mechanics

The equation

$$\mathbf{u}_{tt}(\mathbf{x}, t) = \mathcal{L}(\mathbf{u}(\mathbf{x}, t)) + \mathbf{b}(\mathbf{x}) \quad (2.3)$$

is the linearized peridynamic equation [38, Eq. (56)]. The corresponding time-independent (“peristatic”) equilibrium equation is (1.1). Peridynamics is a nonlocal reformulation of continuum mechanics that is oriented toward deformations with discontinuities, see [38–40] and the references therein. In this context, $\mathbf{u} \in \mathbb{R}^n$ is the displacement field for the body Ω , and $\mathbf{C}(\mathbf{x}, \mathbf{x}')$ is a stiffness tensor, also known as a *micromodulus* tensor.

In this interpretation of (1.1) the following restrictions are placed upon \mathbf{C} in \mathcal{L} . It is assumed that \mathbf{C} is integrable and strictly positive definite in the *neighborhood* of \mathbf{x} , $\mathcal{H}_{\mathbf{x}}$, defined as

$$\mathcal{H}_{\mathbf{x}} := \{\mathbf{x}' \in \mathbb{R}^d : \|\mathbf{x}' - \mathbf{x}\| \leq \delta\}, \quad (2.4)$$

where $\delta > 0$ is called the *horizon*. These assumptions are made because they are sufficient to ensure material stability [38, pp. 191–194]. It is also assumed that $\mathbf{C} = \mathbf{0}$ for $\|\mathbf{x}' - \mathbf{x}\| > \delta$. If the material is elastic, it follows that $\mathbf{C}(\mathbf{x}, \mathbf{x}')$ is symmetric (e.g., $\mathbf{C}(\mathbf{x}, \mathbf{x}')^T = \mathbf{C}(\mathbf{x}, \mathbf{x}')$). Further, it is assumed that \mathbf{C} is symmetric with respect to its arguments (e.g., $\mathbf{C}(\mathbf{x}, \mathbf{x}') = \mathbf{C}(\mathbf{x}', \mathbf{x})$). This follows from imposing that the integrand of (1.2) must be anti-symmetric in its arguments, e.g.,

$$\mathbf{C}(\mathbf{x}, \mathbf{x}')[\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] = -\mathbf{C}(\mathbf{x}', \mathbf{x})[\mathbf{u}(\mathbf{x}) - \mathbf{u}(\mathbf{x}')] \quad (2.5)$$

in accordance with Newton’s third law.

3. A nonlocal variational formulation

Here we present a variational formulation of the nonlocal Eq. (1.1). For peridynamics, this was presented by Emmerich and Weckner in [41]. An analogous expression also appears in [38, Eq. (75)], as well as [25].

Our construction takes place on the domain under consideration and its nonlocal boundary, i.e., $\Omega \cup \mathcal{B}\Omega$. We define the *nonlocal closure* of Ω as follows:

$$\overline{\overline{\Omega}} := \Omega \cup \mathcal{B}\Omega.$$

We will utilize the function space

$$V := L_{2,0}^n(\overline{\overline{\Omega}}) = \left\{ \mathbf{v} \in L_2^n(\overline{\overline{\Omega}}) : \mathbf{v}|_{\mathcal{B}\Omega} = \mathbf{0} \right\} \quad (3.1)$$

and the inner product

$$(\mathbf{u}, \mathbf{v}) := \int_{\overline{\overline{\Omega}}} \mathbf{u} \mathbf{v} d\mathbf{x}.$$

The weak formulation of (1.1) is the following: Given $\mathbf{b}(\mathbf{x}) \in L_2^n(\Omega)$, find $\mathbf{u}(\mathbf{x}) \in V$ such that

$$a(\mathbf{u}, \mathbf{v}) = (\mathbf{b}, \mathbf{v}) \quad \forall \mathbf{v} \in V, \quad (3.2)$$

where

$$a(\mathbf{u}, \mathbf{v}) := - \int_{\overline{\overline{\Omega}}} \left\{ \int_{\overline{\overline{\Omega}}} \mathbf{C}(\mathbf{x}, \mathbf{x}')[\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] d\mathbf{x}' \right\} \mathbf{v}(\mathbf{x}) d\mathbf{x}. \quad (3.3)$$

We assume that the iterated integral in (3.3) is finite:

$$- \int_{\overline{\overline{\Omega}}} \left\{ \int_{\overline{\overline{\Omega}}} \mathbf{C}(\mathbf{x}, \mathbf{x}')[\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] d\mathbf{x}' \right\} \mathbf{v}(\mathbf{x}) d\mathbf{x} < \infty$$

and that $\mathbf{C}(\mathbf{x}, \mathbf{x}') [\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})]$ is anti-symmetric in its arguments. Combining these observations with Fubini's Theorem gives the identity

$$-\int_{\bar{\Omega}} \left\{ \int_{\bar{\Omega}} \mathbf{C}(\mathbf{x}, \mathbf{x}') [\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] d\mathbf{x}' \right\} \mathbf{v}(\mathbf{x}) d\mathbf{x} = \frac{1}{2} \int_{\bar{\Omega}} \left\{ \int_{\bar{\Omega}} \mathbf{C}(\mathbf{x}, \mathbf{x}') [\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] [\mathbf{v}(\mathbf{x}') - \mathbf{v}(\mathbf{x})] d\mathbf{x}' \right\} d\mathbf{x}. \quad (3.4)$$

For the proof of well-posedness of the nonlocal BVP (3.2), we utilize the equivalent expression in (3.4) which induces the following bilinear form:

$$a(\mathbf{u}, \mathbf{v}) = \frac{1}{2} \int_{\bar{\Omega}} \int_{\bar{\Omega}} \mathbf{C}(\mathbf{x}, \mathbf{x}') [\mathbf{u}(\mathbf{x}') - \mathbf{u}(\mathbf{x})] [\mathbf{v}(\mathbf{x}') - \mathbf{v}(\mathbf{x})] d\mathbf{x}' d\mathbf{x}. \quad (3.5)$$

In Section 4.1, we will establish the coercivity of $a(u, u)$ in V in the case of scalar functions, i.e., by setting $n = 1$ in (3.1). The continuity of $a(u, v)$ in $L_2(\bar{\Omega})$ follows from (4.22). Furthermore, $R(v) := (b, v)$ is a bounded linear functional on $L_2(\bar{\Omega})$. Therefore, well-posedness of (3.2) follows from the Lax–Milgram Lemma; also see [25, Section 6].

In 1D with $\bar{\Omega} := [-\delta, 1 + \delta]$, the weak form (3.5) becomes

$$a(u, u) = \frac{1}{2} \int_{[-\delta, 1+\delta]} \int_{[x-\delta, x+\delta] \cap [-\delta, 1+\delta]} C(x, x') (u(x') - u(x))^2 dx' dx, \quad (3.6)$$

where the limits of integration have been adjusted to account for the support of $C(x, x')$, which is assumed to vanish if $\|x - x'\| > \delta$. For this problem, the two-dimensional domain of integration is the parallelogram shown in Fig. 3.1. For 2D and 3D problems, the domains of integration are four and six dimensional, respectively.

4. Nonlocal spectral equivalence

The principle result of this section is Theorem 1, a condition number bound for the stiffness matrix arising from a finite element discretization of (3.3). We investigate the conditioning because it determines both the accuracy of the computed numerical solution, as well as the computational effort required by an iterative linear solver to produce the numerical solution. Quantifying the condition number bound is a necessary first step towards developing scalable preconditioners and optimal solvers for nonlocal models.

In the local setting, the classical condition number estimates rely on a Poincaré inequality and an inverse inequality for the lower and upper bound, respectively. Similarly to the local case, we develop a nonlocal Poincaré inequality to be used in the lower bound. We prove a nonlocal Poincaré inequality which is used to establish the coercivity of the underlying bilinear form. However, for condition number analysis, one needs a more refined Poincaré inequality which involves an explicit δ -quantification. Such refined inequality requires substantially more involved analysis, which has been accomplished by the first author in the companion article [42].

The δ -quantification is an essential feature in the nonlocal setting because the lower bound turns out to be dimension dependent, unlike in the local case. This dimensional dependence is induced by the neighborhood \mathcal{H}_x (see (2.4)), which is

Fig. 3.1. Domain of integration for a 1D problem where $\Omega = [0, 1]$ and $B\Omega = [-\delta, 0] \cup [1, 1 + \delta]$. A nonlocal Dirichlet boundary condition is prescribed over $B\Omega$. The grey region indicates the portion of the integration domain where either or both of x, x' lie outside Ω .

d -dimensional in the nonlocal setting but zero-dimensional (a point) in the local setting. Dimension dependence in the Poincaré inequality is captured by δ^m (see Section 4.1) where the power m exhibits a dimensional dependence (i.e., $m = m(d)$).

For the upper bound, we prove a direct estimate instead of an inverse inequality. Neither the upper bound estimate nor the Poincaré inequality requires discrete spaces. Hence, our estimate is valid in infinite dimensional function spaces, a stronger result than that for the local setting.

We investigate the effect of the horizon size δ on the conditioning of the underlying operators. Therefore, we reduce the analysis to the case $\mathbf{C}(\mathbf{x}, \mathbf{x}') = \chi_\delta(\mathbf{x} - \mathbf{x}')$ where $\chi_\delta(\mathbf{x} - \mathbf{x}')$ denotes the *canonical* kernel function whose only role is the representation of the neighborhood in (2.4) by a characteristic function. Namely,

$$\chi_\delta(\mathbf{x} - \mathbf{x}') := \begin{cases} 1, & \|\mathbf{x} - \mathbf{x}'\| \leq \delta, \\ 0, & \text{otherwise.} \end{cases} \quad (4.1)$$

Note that $\chi_\delta(\mathbf{x} - \mathbf{x}')$ is a radial function, which describes isotropic materials [40]. For the remainder of this article, we will restrict our discussion to scalar problems. Namely, we set $n = 1$ in (3.1) which yields, for instance, $\mathbf{u}(\mathbf{x}) = u(\mathbf{x})$, $\mathbf{C}(\mathbf{x}, \mathbf{x}') = C(\mathbf{x}, \mathbf{x}')$, etc. Therefore, the bilinear form under consideration becomes

$$a(u, v) = \frac{1}{2} \int_{\bar{\Omega}} \int_{\bar{\Omega}} \chi_\delta(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] [v(\mathbf{x}') - v(\mathbf{x})] d\mathbf{x}' d\mathbf{x}. \quad (4.2)$$

We state an important property of the canonical kernel which will be used in the upcoming proofs:

$$\int_{\bar{\Omega}} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}' \leq w_d \delta^d, \quad \mathbf{x} \in \bar{\Omega}, \quad (4.3)$$

where w_d is the volume of the unit ball in \mathbb{R}^d . Note that the equality in (4.3) is attained when the neighborhood of \mathbf{x} , $\mathcal{H}_{\mathbf{x}}$ in (2.4), is entirely contained in $\bar{\Omega}$, i.e., when $\mathbf{x} \in \Omega$.

4.1. Nonlocal Poincaré inequality

In order to establish the coercivity of $a(\cdot, \cdot)$, we prove a nonlocal Poincaré inequality.

Proposition 1. Let $\Omega \subset \mathbb{R}^d$ be a bounded domain and $u \in L_{2,0}(\bar{\Omega})$. Then, there exists $\lambda_{\text{Pncr}} = \lambda_{\text{Pncr}}(\bar{\Omega}, \delta) > 0$ such that

$$\lambda_{\text{Pncr}} \|u\|_{L_2(\bar{\Omega})}^2 \leq a(u, u). \quad (4.4)$$

Proof. The proof is an extension of the one given in [28, Prop. 2.5] for a similar bilinear form. We construct a finite covering for $\bar{\Omega}$ using strips of width $\delta/2$ as follows:

$$S_{-1} := \left\{ \mathbf{x} \in B\Omega : \frac{\delta}{2} \leq \text{dist}(\mathbf{x}, \partial\Omega) \leq \delta \right\}, \quad (4.5)$$

$$S_0 := \left\{ \mathbf{x} \in B\Omega \setminus S_{-1} : \text{dist}(\mathbf{x}, S_{-1}) \leq \frac{\delta}{2} \right\}, \quad (4.6)$$

$$S_1 := \left\{ \mathbf{x} \in \Omega : \text{dist}(\mathbf{x}, \partial\Omega) \leq \frac{\delta}{2} \right\}, \quad (4.7)$$

$$S_j := \left\{ \mathbf{x} \in \Omega \setminus \bigcup_{k=1}^{j-1} S_k : \text{dist}(\mathbf{x}, S_{j-1}) \leq \frac{\delta}{2} \right\}, \quad j = 1, \dots, l, \quad (4.8)$$

where dist denotes the shortest distance in the usual Euclidean sense. The number of strips covering Ω is $l = l(\bar{\Omega}, \delta)$.

We trivially have the following for $j = 0, \dots, l$:

$$\int_{\bar{\Omega}} \int_{\bar{\Omega}} \chi_\delta(\mathbf{x} - \mathbf{x}') |u(\mathbf{x}') - u(\mathbf{x})|^2 d\mathbf{x}' d\mathbf{x} \geq \int_{S_j} \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') |u(\mathbf{x}') - u(\mathbf{x})|^2 d\mathbf{x}' d\mathbf{x}.$$

Using $|u(\mathbf{x})|^2 = |u(\mathbf{x}') - \{u(\mathbf{x}') - u(\mathbf{x})\}|^2 \leq 2\{|u(\mathbf{x}') - u(\mathbf{x})|^2 + |u(\mathbf{x}')|^2\}$, a change in the order of integration, and the following result (obtained from (4.3))

$$\int_{S_j} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}' \leq w_d \delta^d,$$

we obtain the following:

$$\begin{aligned} \int_{S_j} \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') |u(\mathbf{x}') - u(\mathbf{x})|^2 d\mathbf{x}' d\mathbf{x} &\geq \frac{1}{2} \int_{S_j} \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') |u(\mathbf{x})|^2 d\mathbf{x}' d\mathbf{x} - \int_{S_j} \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') |u(\mathbf{x}')|^2 d\mathbf{x}' d\mathbf{x} \\ &= \frac{1}{2} \int_{S_j} \left\{ \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}' \right\} |u(\mathbf{x})|^2 d\mathbf{x} - \int_{S_{j-1}} \left\{ \int_{S_j} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x} \right\} |u(\mathbf{x}')|^2 d\mathbf{x}' \\ &\geq \frac{1}{2} \int_{S_j} \left\{ \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}' \right\} |u(\mathbf{x})|^2 d\mathbf{x} - w_d \delta^d \int_{S_{j-1}} |u(\mathbf{x}')|^2 d\mathbf{x}' \\ &\geq \frac{1}{2} \min_{\mathbf{x} \in \bar{S}_j} \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}' \int_{S_j} |u(\mathbf{x})|^2 d\mathbf{x} - w_d \delta^d \int_{S_{j-1}} |u(\mathbf{x}')|^2 d\mathbf{x}'. \end{aligned}$$

The function

$$F(\mathbf{x}) := \int_{S_{j-1}} \chi_\delta(\mathbf{x} - \mathbf{x}') d\mathbf{x}', \quad \mathbf{x} \in \bar{S}_j$$

is continuous, which follows from continuity of the integral operator and the fact that $\chi_\delta(\mathbf{x} - \mathbf{x}')$ is integrable. By construction of the covering, we have

$$S_{j-1} \cap B(\mathbf{x}, \delta) \neq \emptyset, \quad \mathbf{x} \in S_j,$$

where $B(\mathbf{x}, \delta)$ is a ball of radius δ centered at \mathbf{x} . Hence, we obtain

$$F(\mathbf{x}) = \text{measure} \left(\left\{ \mathbf{x} \in \bar{S}_j : S_{j-1} \cap B(\mathbf{x}, \delta) \right\} \right) > 0, \quad \mathbf{x} \in \bar{S}_j.$$

Therefore by continuity, $F(\mathbf{x})$ attains its infimum in \bar{S}_j and we conclude that

$$\alpha_j := \min_{\mathbf{x} \in \bar{S}_j} F(\mathbf{x}) > 0.$$

Consequently, we have the inequality:

$$\frac{\alpha_j}{4} \int_{S_j} |u(\mathbf{x})|^2 d\mathbf{x} \leq a(u, u) + w_d \delta^d \int_{S_{j-1}} |u(\mathbf{x}')|^2 d\mathbf{x}'. \quad (4.9)$$

From the boundary condition, we get

$$\int_{S_{-1}} |u(\mathbf{x})|^2 d\mathbf{x} = \int_{S_0} |u(\mathbf{x})|^2 d\mathbf{x} = 0.$$

Moreover due to the boundary condition and (4.9), we get

$$\frac{\alpha_1}{4} \int_{S_1} |u(\mathbf{x})|^2 d\mathbf{x} \leq a(u, u). \quad (4.10)$$

For the cases $j = 2, 3$, we respectively have:

$$\frac{\alpha_2}{4} \int_{S_2} |u(\mathbf{x})|^2 d\mathbf{x} \leq a(u, u) + w_d \delta^d \int_{S_1} |u(\mathbf{x}')|^2 d\mathbf{x}' \quad (4.11)$$

$$\frac{\alpha_3}{4} \int_{S_3} |u(\mathbf{x})|^2 d\mathbf{x} \leq a(u, u) + w_d \delta^d \int_{S_2} |u(\mathbf{x}')|^2 d\mathbf{x}'. \quad (4.12)$$

To relate (4.12) to right-hand side of (4.11), multiply (4.11) by $(4w_d \delta^d)/\alpha_2$:

$$\frac{\alpha_3}{4} \int_{S_3} |u(\mathbf{x})|^2 d\mathbf{x} \leq \left(1 + \frac{4w_d \delta^d}{\alpha_2} \right) a(u, u) + \frac{4(w_d \delta^d)^2}{\alpha_2} \int_{S_1} |u(\mathbf{x}')|^2 d\mathbf{x}'. \quad (4.13)$$

Then using (4.10) and (4.13) becomes:

$$\frac{\alpha_3}{4} \int_{S_3} |u(\mathbf{x})|^2 d\mathbf{x} \leq \left(1 + \frac{4w_d \delta^d}{\alpha_2} + \frac{(4w_d \delta^d)^2}{\alpha_1 \alpha_2} \right) a(u, u).$$

Continuing this process, we see the existence of a constant $c(\bar{\Omega}, \delta)$ satisfying:

$$\frac{\alpha_j}{4} \int_{S_j} |u(\mathbf{x})|^2 d\mathbf{x} \leq c(\bar{\Omega}, \delta) a(u, u), \quad j = -1, \dots, l. \quad (4.14)$$

Adding (4.14) for $j = -1, \dots, l$ and using the fact that the covering of $\overline{\overline{\Omega}}$ is composed of disjoint strips, i.e., $\overline{\overline{\Omega}} = \cup_{k=-1}^l S_k$, $S_j \cap S_k = \emptyset$, $j \neq k$, we arrive at the coercivity result. \square

Remark 1. The coercivity proof in [28, Prop. 2.5] assumes a continuous kernel function. The coercivity proof we provide can be generalized to any nonnegative locally integrable radial kernel function which satisfies $C(r) > 0$ on $(0, \delta)$ see the companion article [42, Lemma 2.4].

Remark 2. The above Poincaré type inequality can be established for general Dirichlet boundary conditions, i.e., $u \in L_2(\overline{\overline{\Omega}})$ with $u|_{B\Omega} \neq 0$. In this case, the inequality statement reads as follows:

$$\lambda_{Pncr}(\overline{\overline{\Omega}}, \delta) \|u\|_{L_2(\overline{\overline{\Omega}})}^2 \leq a(u, u) + \int_{S_{-1}} |u(\mathbf{x})|^2 d\mathbf{x}, \quad (4.15)$$

where S_{-1} is the outermost strip of the covering of $\overline{\overline{\Omega}}$. Deducing a coercivity estimate from (4.15) seems impossible unless a zero nonlocal boundary condition is assumed. For mixed and Neumann type boundary conditions, see the companion paper [42, Remark 2.5].

Remark 3. Coercivity of the bilinear form has also been established in [25] under the condition (see [25, Eq. (6.1)]) that

$$\int_{B\Omega} C(\mathbf{x}, \mathbf{x}') d\mathbf{x}' \geq c > 0, \quad \mathbf{x} \in \Omega. \quad (4.16)$$

This condition is stringent because it assumes that all interior points interact directly with the nonlocal boundary $B\Omega$, a situation only possible if the horizon δ is on the order of $|\Omega|$. For applications of practical interest especially in peridynamics, horizon is set to be $\delta \ll |\Omega|$ because problems with large δ are computationally intractable. The coercivity proof given in this article does not assume (4.16).

For the condition number analysis, δ -quantification is essential. In the companion article [42], the first author gives a more refined nonlocal Poincaré inequality. Namely, for sufficiently small δ :

$$\lambda_{refined}(\overline{\overline{\Omega}}) \delta^{d+2} \|u\|_{L_2(\overline{\overline{\Omega}})}^2 \leq a(u, u). \quad (4.17)$$

Note that $\lambda_{refined}$ does not depend on δ . In order to see why $\lambda_{Pncr}(\overline{\overline{\Omega}}, \delta)$ can be refined to a constant $\lambda_{refined}(\overline{\overline{\Omega}})$, we proceed with a 1D demonstration.

4.2. Demonstration of explicit δ -dependence in the nonlocal Poincaré inequality

We demonstrate the lower bound in (4.17) by a 1D example. After enforcing a sufficient regularity assumption, we resort to a Taylor series expansion. For that purpose, we assume that $u \in C^4(\overline{\overline{\Omega}})$ with homogenous Dirichlet boundary conditions enforced on the nonlocal boundary $B\Omega$. This demonstration is based on the desire to have the nonlocal bilinear form converge to its corresponding local (classical) bilinear form as $\delta \rightarrow 0$. For discussions of convergence of other nonlocal operators to their classical local counterparts, see [43,44].

For the sake of clarity, we utilize the equivalent bilinear form below given in (3.4) so that the effect of the boundary condition can easily be seen. We accompany this with a change of variable as follows:

$$\begin{aligned} a(u, u) &= - \int_{\overline{\overline{\Omega}}} \left\{ \int_{\overline{\overline{\Omega}} \cap [x-\delta, x+\delta]} [u(x') - u(x)] dx' \right\} u(x) dx = - \int_{\Omega} \left\{ \int_{[x-\delta, x+\delta]} [u(x') - u(x)] dx' \right\} u(x) dx \\ &= - \int_{\Omega} \left\{ \int_{-\delta}^{\delta} [u(x + \varepsilon) - u(x)] d\varepsilon \right\} u(x) dx. \end{aligned}$$

Using the Taylor expansion

$$u(x + \varepsilon) = u(x) + \frac{\varepsilon}{1!} \frac{du}{dx}(x) + \frac{\varepsilon^2}{2!} \frac{d^2u}{dx^2}(x) + \frac{\varepsilon^3}{3!} \frac{d^3u}{dx^3}(x) + \mathcal{O}(\varepsilon^4),$$

the integrand becomes:

$$[u(x + \varepsilon) - u(x)]u(x) = \varepsilon \frac{du}{dx}(x)u(x) + \frac{\varepsilon^2}{2!} \frac{d^2u}{dx^2}(x)u(x) + \frac{\varepsilon^3}{3!} \frac{d^3u}{dx^3}(x)u(x) + \mathcal{O}(\varepsilon^4).$$

Hence, we arrive at the following expression using $u|_{B\Omega} = 0$ (due to $u|_{B\Omega} = 0$):

$$a(u, u) = - \int_{\Omega} \left\{ \frac{\delta^3}{3} \frac{d^3u}{dx^3}(x)u(x) + \mathcal{O}(\delta^5) \right\} dx = \frac{\delta^3}{3} \int_{\Omega} \frac{du}{dx}(x) \frac{du}{dx}(x) dx + \mathcal{O}(\delta^5).$$

Now, denoting the local bilinear form by

$$\ell(u, u) := |u|_{H^1(\Omega)}^2,$$

we connect the nonlocal and local bilinear forms:

$$a(u, u) = \frac{\delta^3}{3} \ell(u, u) + \mathcal{O}(\delta^5).$$

Therefore, the scaled nonlocal bilinear form asymptotically converges to the local bilinear form:

$$3\delta^{-3}a(u, u) = \ell(u, u) + \mathcal{O}(\delta^2). \quad (4.18)$$

Using the nonlocal Poincaré inequality (4.4) and (4.18), we have

$$\lim_{\delta \rightarrow 0} 3\lambda_{\text{Pncr}}(\overline{\Omega}, \delta) \delta^{-3} \|u\|_{L_2(\overline{\Omega})}^2 \leq \ell(u, u).$$

Therefore, for the left hand side to remain finite, we have to enforce that $\lambda_{\text{Pncr}}(\overline{\Omega}, \delta) = c(\overline{\Omega})\delta^m$ with $m \geq 3$. We desire the largest possible lower bound in the nonlocal Poincaré inequality. This implies that $m = 3$, which is in agreement with (4.17) and is observed numerically in 1D; see the experiments in Section 4.5.1.

4.3. An upper bound for $a(u, u)$

We prove the following dimension dependent estimate:

Lemma 1. Let $\overline{\Omega} \subset \mathbb{R}^d$ be bounded and $u \in L_2(\overline{\Omega})$. Then, there exists $\bar{\lambda} > 0$ independent of $\overline{\Omega}$ and δ such that

$$a(u, u) \leq \bar{\lambda} \delta^d \|u\|_{L_2(\overline{\Omega})}^2. \quad (4.19)$$

Proof. Using $(u(\mathbf{x}') - u(\mathbf{x}))^2 \leq 2(u(\mathbf{x}')^2 + u(\mathbf{x})^2)$, we get

$$a(u, u) \leq \int_{\overline{\Omega}} \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') (u^2(\mathbf{x}) + u^2(\mathbf{x}')) d\mathbf{x}' d\mathbf{x}. \quad (4.20)$$

Furthermore, by a change in the order of integration and the fact that $\chi_{\delta}(\mathbf{x} - \mathbf{x}')$ is an even function, one gets

$$\int_{\overline{\Omega}} \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') u^2(\mathbf{x}) d\mathbf{x}' d\mathbf{x} = \int_{\overline{\Omega}} \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') u^2(\mathbf{x}') d\mathbf{x}' d\mathbf{x}. \quad (4.21)$$

Then using (4.21) and (4.20) becomes:

$$a(u, u) \leq 2 \int_{\overline{\Omega}} \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') u^2(\mathbf{x}) d\mathbf{x}' d\mathbf{x}.$$

Using (4.3), we immediately have the upper bound:

$$2 \int_{\overline{\Omega}} \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') u^2(\mathbf{x}) d\mathbf{x}' d\mathbf{x} \leq 2w_d \delta^d \|u\|_{L_2(\overline{\Omega})}^2 =: \bar{\lambda} \delta^d \|u\|_{L_2(\overline{\Omega})}^2. \quad \square$$

Remark 4. The upper bound is *sharp*; see the companion article [42, Section 4]. We also numerically demonstrate the numerical sharpness of the upper bound; see Section 4.5.

Remark 5. A proof similar to that of Lemma 1 can be given to show the boundedness of the bilinear form with an explicit constant. Namely,

$$|a(u, v)| \leq 2w_d \delta^d \|u\|_{L_2(\overline{\Omega})} \|v\|_{L_2(\overline{\Omega})}. \quad (4.22)$$

Also see the companion article [42] for the boundedness of the bilinear form for general kernel functions.

4.4. The conditioning of the stiffness matrix K

Combining the refined nonlocal Poincaré inequality (4.17) and the upper bound (4.19), we arrive at a condition number estimate.

Theorem 1. For sufficiently small δ , the following spectral equivalence holds:

$$\lambda_{\text{refined}}(\overline{\Omega}) \delta^{d+2} \leq \frac{a(u, u)}{\|u\|_{L_2(\overline{\Omega})}^2} \leq \bar{\lambda} \delta^d, \quad u \in L_{2,0}(\overline{\Omega}). \quad (4.23)$$

Let K be the stiffness matrix produced by discretizing $a(u, u)$. Then, the condition number of K has the bound:

$$\kappa(K) \lesssim \delta^{-2}. \quad (4.24)$$

The spectral equivalence (4.23) enables us to construct an h independent upper bound for the condition number.

Note that the condition number of the stiffness matrix also depends upon the mesh size h . As an illustration, consider that the nonlocal bilinear form $a(u, u)$ must converge to the corresponding local bilinear form in the limit $\delta \rightarrow 0$, as demonstrated in Section 4.2, and that the condition number of the associated local stiffness matrix varies with h^{-2} . Thus, the bound in (4.24) is not tight in this limit, but allows us to investigate the highly nonlocal regime $h \ll \delta$, which is our principle interest. For an alternative approach to quantifying mesh-dependence in the conditioning of nonlocal models, see [33].

4.5. Numerical verification of condition number by a finite element formulation

For all computational results in this article, we let $\Omega = [0, 1]^d$ be the unit d -cube, where d is the spatial dimension, with $\overline{\Omega} = [-\delta, 1 + \delta]^d$ the nonlocal closure. We impose the Dirichlet boundary condition $u = 0$ on $\partial\Omega = \overline{\Omega} \setminus \Omega$. We use a conforming triangulation \mathcal{T}_h where each element E of \mathcal{T}_h is a d -cube with a side length $h > 0$. Consequently, each element in 1D, 2D, and 3D is a line segment of length h , a square of area h^2 , and a cube of volume h^3 , respectively. Let $V_h \subset V$ be a finite dimensional subspace of V from (3.1). We use a Galerkin finite element formulation of (3.2):

$$a(u_h, v_h) = (b, v_h) \quad \forall v_h \in V_h \quad (4.25)$$

with Dirichlet boundary condition $u_h = 0$ on $\partial\Omega$, where V_h is the space of piecewise constant or piecewise linear shape functions on the mesh \mathcal{T}_h , and where we employ the canonical kernel function χ_δ from (4.1). We denote by K the stiffness matrix arising from the left-hand side of (4.25). To verify our theoretical results we numerically determine the ratio of the largest and smallest eigenvalues of K , defining the condition number of the problem.

4.5.1. Results in one dimension

Results in this section appear in Table 4.1 and Fig. 4.1, where we consider the $h \ll \delta$ regime. We show results for both piecewise constant and piecewise linear shape functions to verify that the choice of shape function apparently does not influence the conditioning of the discrete system. We first compute the condition number of K for different h while holding δ fixed, and observe that the condition number of K is only weakly h -dependent. The minimum and the maximum eigenvalues depend linearly on h , with a slope of nearly unity. We then compute the condition number of K for different values of δ while holding h fixed, and observe that the condition number varies with δ^{-2} . Further, the maximum eigenvalue is proportional to δ , in agreement with Lemma 1. Lastly, the minimum eigenvalue varies as δ^3 , in agreement with (4.17) and our finding of $m = 3$ in Section 4.2. This suggests that, in one dimension, we should redefine $C(x, x')$ in (4.1) as

$$C(x, x') = \begin{cases} \delta^{-3}, & \|x - x'\| \leq \delta, \\ 0, & \text{otherwise} \end{cases}$$

for consistency with the weak form of the classical (local) Laplace operator in the limit $\delta \rightarrow 0$.

4.5.2. Results in two dimensions

Results in this section appear in Table 4.2 and Fig. 4.2. We consider only piecewise constant shape functions in 2D. We first compute the condition number of K for different h while holding δ fixed, and observe that minimum and maximum

Table 4.1

Condition number for K in 1D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary, for both piecewise constant and linear shape functions. We see that the conditioning is apparently not strongly influenced by the choice of shape function. This data is plotted in Fig. 4.1.

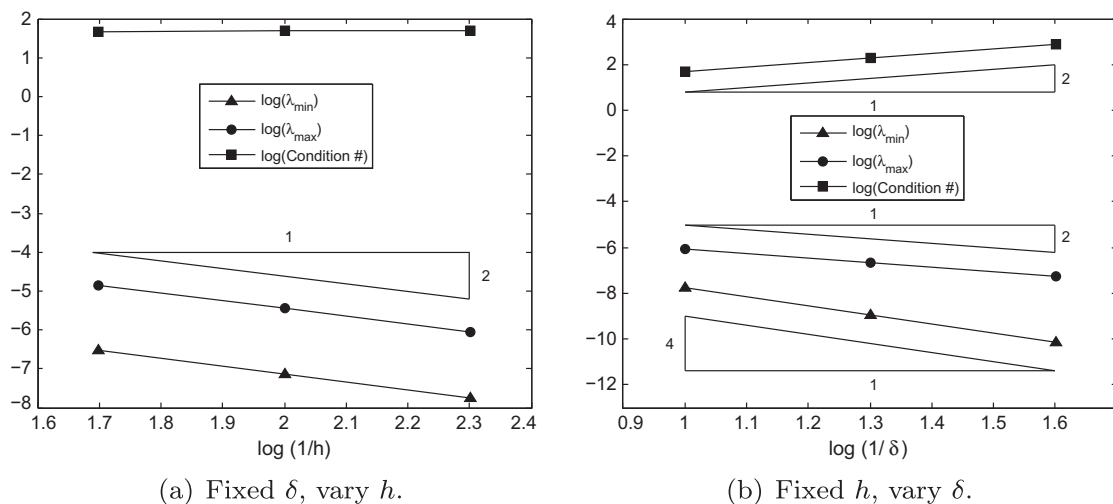

Fig. 4.2. Condition number for K in 2D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary. The condition number is only weakly h -dependent, but varies with δ^{-2} . These figures are plotted from data in Table 4.2.

eigenvalues depend linearly on h with a slope of approximately two, and again the condition number of K depends only weakly upon the mesh size. We then compute the condition number of K for different values of δ while holding h fixed, and observe that the condition number again varies as δ^{-2} , in agreement with (4.24). Further, the maximum eigenvalue is proportional to δ^2 in agreement with Lemma 1, and the minimum eigenvalue is proportional to δ^4 in agreement with (4.17).

5. A nonlocal two-domain problem

We will construct a weak (variational) formulation for nonlocal domain decomposition. We first identify the pieces of the domain for this decomposition. Consider the domain in Fig. 5.1. The nonlocal boundary of Ω , $\mathcal{B}\Omega$, is defined to be the closed region of thickness δ surrounding Ω . Let Γ be the open region corresponding to the interface between the two overlapping open subdomains $\Omega^{(1)}$ and $\Omega^{(2)}$. We define the overlapping subdomains $\Omega^{(i)}$, $i = 1, 2$, as the following:

$$\Omega^{(i)} := \Omega_i \cup \Gamma \cup \Gamma_i,$$

where Γ_i is the open line segment adjacent to Ω_i and Γ . Let $\mathcal{B}\Omega_i$ be the nonlocal closed boundary of Ω_i that intersects $\mathcal{B}\Omega$. The main domain decomposition contributions of this article, namely, the equivalence of the one-domain weak and two-domain weak forms will be proved next.

5.1. Two-domain variational form

We present a two-domain weak formulation of (3.2) and prove its equivalence to the original single-domain formulation (3.2). We define the spaces, $i = 1, 2$,

$$\begin{aligned} V^{(i)} &:= \left\{ v \in L_2(\overline{\Omega^{(i)}}) : v|_{\mathcal{B}\Omega_i} = 0 \right\}, \\ V^{(i),0} &:= \left\{ v \in L_2(\overline{\Omega^{(i)}}) : v|_{\mathcal{B}\Omega_i \cup \Gamma \cup \Gamma_i} = 0 \right\}, \\ \Lambda &:= \left\{ \mu \in L_2(\Gamma) : \mu = v|_{\Gamma} \text{ for suitable } v \in L_{2,0}(\overline{\Omega}) \right\}. \end{aligned} \quad (5.1)$$

We can reduce the outer domain of integration in the bilinear form from $\overline{\Omega}$ to Ω by taking advantage of the zero Dirichlet boundary condition. Namely,

$$a(u, v) = - \int_{\overline{\Omega}} \left\{ \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x} = - \int_{\Omega} \left\{ \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x}, \quad v \in V. \quad (5.2)$$

Therefore, our construction is based on the reduced bilinear form (5.2). We further define a bilinear form $a_{\Omega^{(i)}}(u, v) : V \times V \rightarrow \mathbb{R}$ as follows:

$$a_{\Omega^{(i)}}(u, v) := - \int_{\Omega_i} \left\{ \int_{\Omega^{(i)} \cup \mathcal{B}\Omega_i} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x} - \frac{1}{2} \int_{\Gamma} \left\{ \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x}. \quad (5.3)$$

We utilize the following notation to suppress the integrals in (5.3):

$$a_{\Omega_i}(u, v) := - \int_{\Omega_i} \left\{ \int_{\Omega^{(i)} \cup \mathcal{B}\Omega_i} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x}, \quad (5.4)$$

$$a_{\Gamma}(u, v) := - \int_{\Gamma} \left\{ \int_{\overline{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x}. \quad (5.5)$$

Fig. 5.1. A nonlocal two-domain problem. This is a decomposition of the domain Ω in Fig. 2.1 into overlapping subdomains $\Omega^{(1)}$, $\Omega^{(2)}$, and $\mathcal{B}\Omega$ into overlapping nonlocal boundaries $\mathcal{B}\Omega_1$, $\mathcal{B}\Omega_2$. Note that the interface Γ is $d = 2$ -dimensional.

We can now represent the bilinear form (5.3) as:

$$a_{Q^{(i)}}(u, v) = \frac{1}{2} a_r(u, v) + a_{\Omega_i}(u, v).$$

Remark 6. The test function $v_i = v|_{\Omega_i} \in V^{(i),0}$, $i = 1, 2$ has its support only in Ω_i not $\Omega^{(i)}$. Hence, we may reduce the bilinear form (5.3) to

$$a_{Q^{(i)}}(u^{(i)}, v_i) = a_{\Omega_i}(u^{(i)}, v_i). \quad (5.6)$$

Although, $a_r(u^{(i)}, v_i)$ may appear to create a coupling between the subdomains, no such coupling exists because v_i vanishes on Γ . Therefore, subdomain condition (5.7a) is an expression only for subdomain $\Omega^{(i)}$.

Now, we state the two-domain weak form following the notation of [16]: Find $u^{(i)} \in V^{(i)}$, $i = 1, 2$:

$$a_{Q^{(i)}}(u^{(i)}, v_i) = (b, v_i)_{\Omega_i} \quad \forall v_i \in V^{(i),0}, \quad (5.7a)$$

$$u^{(1)} = u^{(2)} \quad \text{on } \bar{\Gamma}, \quad (5.7b)$$

$$\sum_{i=1,2} a_{Q^{(i)}}(u^{(i)}, \mathcal{R}^{(i)}\mu) = (b, \mu)_{\Gamma} + \sum_{i=1,2} (b, \mathcal{R}^{(i)}\mu)_{\Omega_i} \quad \forall \mu \in \mathcal{A}. \quad (5.7c)$$

where $\mathcal{R}^{(i)}$ denotes any possible extension operator from $L_2(\Gamma)$ to $V^{(i)}$. An extension operator $\mathcal{R}^{(i)} : L_2(\Gamma) \rightarrow V^{(i)}$ is defined to be an operator which satisfies $(\mathcal{R}^{(i)}\eta)|_{\Gamma} = \eta$ for $\eta \in L_2(\Gamma)$. Next, we will show that the one- and two-domain weak forms are equivalent. The proof for the local case can be found in [16, Lemma 1.2.1].

Lemma 2. The problems (3.2) and (5.7) are equivalent.

Proof. (3.2) \Rightarrow (5.7):

Let $u^{(i)} = u|_{Q^{(i)}} \in V^{(i)}$ and $v_i = v|_{\Omega_i} \in V^{(i),0}$, $i = 1, 2$. Extend these functions by zero extension;

$$\theta^{(i)} u^{(i)} := \begin{cases} u^{(i)}, & \text{in } \Omega^{(i)} \\ 0, & \text{otherwise,} \end{cases}$$

$$\theta_i v_i := \begin{cases} v_i, & \text{in } \Omega_i \\ 0, & \text{otherwise.} \end{cases}$$

By LHS of (3.2) and using $v_i|_{\Gamma} = 0$:

$$\begin{aligned} a(\theta^{(i)} u^{(i)}, \theta_i v_i) &= - \int_{\Omega} \left\{ \int_{\bar{\Omega}} \chi_{\delta}(\mathbf{x} - \mathbf{x}') [\theta^{(i)} u^{(i)}(\mathbf{x}') - \theta^{(i)} u^{(i)}(\mathbf{x})] d\mathbf{x}' \right\} \theta_i v_i(\mathbf{x}) d\mathbf{x} = a_{\Omega_i}(u^{(i)}, v_i) = \frac{1}{2} a_r(u^{(i)}, v_i) + a_{\Omega_i}(u^{(i)}, v_i) \\ &= a_{Q^{(i)}}(u^{(i)}, v_i). \end{aligned}$$

By RHS of (3.2),

$$(b, \theta_i v_i) = (b, v_i)_{\Omega_i}.$$

Hence, (5.7a) is satisfied. (5.7b) is trivially satisfied.

Further, for $\mu \in \mathcal{A}$ define the function $\mathcal{R}\mu$ as:

$$\mathcal{R}\mu := \begin{cases} \mathcal{R}^{(1)}\mu, & \text{in } \Omega^{(1)} \\ \mathcal{R}^{(2)}\mu, & \text{in } \Omega^{(2)}. \end{cases}$$

Since $\mathcal{R}\mu$ lives only in $\Omega_1 \cup \Gamma_1 \cup \Gamma \cup \Gamma_2 \cup \Omega_2$, it vanishes on $\mathcal{B}\Omega$. Therefore, $\mathcal{R}\mu \in V$.

From (3.2), partitioning the outer integral and using $\mathcal{R}^{(1)}\mu = \mathcal{R}^{(2)}\mu = \mu$ on Γ , we obtain the LHS of (5.7c):

$$\begin{aligned} a(u, \mathcal{R}\mu) &= \frac{1}{2} a_r(u^{(1)}, \mu) + \frac{1}{2} a_r(u^{(2)}, \mu) + \sum_{i=1,2} a_{\Omega_i}(u^{(i)}, \mathcal{R}^{(i)}\mu) = \frac{1}{2} a_r(u^{(1)}, \mathcal{R}^{(1)}\mu) + \frac{1}{2} a_r(u^{(2)}, \mathcal{R}^{(2)}\mu) + \sum_{i=1,2} a_{\Omega_i}(u^{(i)}, \mathcal{R}^{(i)}\mu) \\ &= a_{Q^{(1)}}(u^{(1)}, \mathcal{R}^{(1)}\mu) + a_{Q^{(2)}}(u^{(2)}, \mathcal{R}^{(2)}\mu). \end{aligned}$$

Likewise, from (3.2) and partitioning the integral, we obtain the RHS of (5.7c):

$$(b, \mathcal{R}\mu)_{\Omega} = (b, \mathcal{R}^{(1)}\mu)_{\Omega_1} + (b, \mathcal{R}^{(2)}\mu)_{\Omega_2} + (b, \mu)_{\Gamma}.$$

Hence, we obtain the transmission condition (5.7c).

(5.7) \Rightarrow (3.2):

Let $u_\Gamma := u^{(1)}|_\Gamma$ (due to (5.7b), we also have $u_\Gamma = u^{(2)}|_\Gamma$) and

$$u := \begin{cases} u^{(1)}, & \text{in } \Omega_1 \\ u^{(2)}, & \text{in } \Omega_2 \\ u_\Gamma, & \text{in } \Gamma. \end{cases} \quad (5.8)$$

We partition the outer integral, use (5.8) and the transmission condition (5.7b). Then, for $v \in V$, LHS in (3.2) becomes the following:

$$\begin{aligned} a(u, v) &= \frac{1}{2} a_\Gamma(u, v) + \frac{1}{2} a_\Gamma(u, v) + \sum_{i=1,2} a_{\Omega_i}(u, v) = \frac{1}{2} a_\Gamma(u_\Gamma, v) + \frac{1}{2} a_\Gamma(u_\Gamma, v) + \sum_{i=1,2} a_{\Omega_i}(u^{(i)}, v) \\ &= \frac{1}{2} a_\Gamma(u^{(1)}, v) + \frac{1}{2} a_\Gamma(u^{(2)}, v) + \sum_{i=1,2} a_{\Omega_i}(u^{(i)}, v) = \sum_{i=1,2} a_{\Omega^{(i)}}(u^{(i)}, v). \end{aligned} \quad (5.9)$$

Let $\mu := v|_\Gamma$. Then, $v - \mathcal{R}^{(i)}\mu \in V^{(i),0}$. First, we add and subtract $\mathcal{R}^{(i)}\mu$ to the second slot of the bilinear form in (5.9) and apply the domain conditions (5.7a) for $v - \mathcal{R}^{(i)}\mu$. Then, we apply the transmission condition (5.7c) and use $v|_\Gamma = \mu$. Hence, we arrive at the RHS in (3.2):

$$\begin{aligned} \sum_{i=1,2} a_{\Omega^{(i)}}(u^{(i)}, v) &= \sum_{i=1,2} a_{\Omega^{(i)}}(u^{(i)}, v - \mathcal{R}^{(i)}\mu) + \sum_{i=1,2} a_{\Omega^{(i)}}(u^{(i)}, \mathcal{R}^{(i)}\mu) = \sum_{i=1,2} (b, v - \mathcal{R}^{(i)}\mu)_{\Omega_i} + \sum_{i=1,2} a_{\Omega^{(i)}}(u^{(i)}, \mathcal{R}^{(i)}\mu) \\ &= \sum_{i=1,2} (b, v - \mathcal{R}^{(i)}\mu)_{\Omega_i} + (b, \mu)_\Gamma + \sum_{i=1,2} (b, \mathcal{R}^{(i)}\mu)_{\Omega_i} = (b, \mu)_\Gamma + \sum_{i=1,2} (b, v)_{\Omega_i} = (b, v). \quad \square \end{aligned}$$

6. Towards nonlocal substructuring

Here we write out the linear algebraic representations arising from the two-domain weak form (5.7), identifying the discrete subdomain equations and transmission conditions. We then construct a nonlocal Schur complement, discuss its condition number as a function of h , δ , and provide supporting numerical experiments.

6.1. Linear algebraic representations

We consider a finite element discretization of (5.7). Letting $V_h^{(i)}$ denote the finite element space corresponding to $\Omega^{(i)}$, we define:

$$V_h^{(i),0} := \left\{ v_h \in V_h^{(i)} : v_h|_{\partial\Omega_i \cup \Gamma \cup \Gamma_i} = 0 \right\}$$

$$\mathcal{A}_h := \{ \mu_h \in L_2(\Gamma) : \mu_h = v_h|_\Gamma \text{ for some suitable } v_h \in V_h \}.$$

Here, \mathcal{A}_h denotes a finite element discretization of $L_2(\Gamma)$. We see that the finite element formulation of (5.7) can be written as:

$$a_{\Omega^{(i)}}(u_h^{(i)}, v_{i,h}) = (b, v_{i,h})_{\Omega_i} \quad \forall v_{i,h} \in V_h^{(i),0}, \quad (6.1a)$$

$$u_h^{(1)} = u_h^{(2)} \quad \text{on } \bar{\Gamma}, \quad (6.1b)$$

$$\sum_{i=1,2} a_{\Omega^{(i)}}(u_h^{(i)}, \mathcal{R}_h^{(i)}\mu_h) = (b, \mu_h)_\Gamma + \sum_{i=1,2} (b, \mathcal{R}_h^{(i)}\mu_h)_{\Omega_i} \quad \forall \mu_h \in \mathcal{A}_h. \quad (6.1c)$$

where $\mathcal{R}_h^{(i)}$ denotes any possible extension operator from Γ_h to $V_h^{(i)}$. Following standard practice, we take these extension operators to be the finite element interpolant, which is defined to be equal to μ_h at the nodes in the thick interface Γ and zero on the internal nodes of Ω_i . If we number nodes in Ω_1 first, nodes in Ω_2 second, and nodes in Γ last, we will arrive at a global stiffness matrix that takes the traditional block arrowhead form:

$$K = \begin{bmatrix} K_{11} & 0 & K_{1\Gamma} \\ 0 & K_{22} & K_{2\Gamma} \\ K_{\Gamma 1} & K_{\Gamma 2} & K_{\Gamma\Gamma} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \\ u_\Gamma \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \\ f_\Gamma \end{bmatrix}. \quad (6.2)$$

The first two block rows of the matrix in (6.2) arise from discretizing (6.1a), and the last block row arises from discretizing (6.1c).

6.2. Discrete energy minimizing extension and the Schur complement conditioning

In order to study the conditioning of the Schur complement in the nonlocal setting, we define an analog of the discrete harmonic extension in the local case.

Definition 1. For a given $q \in \mathcal{A}_h$, $E_i : \mathcal{A}_h \rightarrow V_h^{(i)}$ defines a discrete energy minimizing extension into Ω_h if

$$\begin{aligned} E_i(q)|_\Gamma &= q, \\ a_i(E_i(q), v) &= 0, \quad v \in V_h^{(i),0}, \end{aligned} \quad (6.3)$$

where $a_i(\cdot, \cdot)$ denotes the bilinear form restricted to $\overline{\Omega^{(i)}}$. Namely,

$$a_i(u, v) = \int_{\overline{\Omega^{(i)}}} \left\{ \int_{\overline{\Omega^{(i)}}} \chi_\delta(\mathbf{x} - \mathbf{x}') [u(\mathbf{x}') - u(\mathbf{x})] d\mathbf{x}' \right\} v(\mathbf{x}) d\mathbf{x}.$$

The energy minimizing extension $E_i(q)$ of q defines a canonical bilinear form $s_i(q, q) : \mathcal{A}_h \times \mathcal{A}_h \rightarrow \mathbb{R}$ that is associated to the interface Γ whose discretization corresponds to the subdomain Schur complement matrix $S^{(i)}$ below. Let \underline{q} denote the vector representation of q .

$$s_i(q, q) := a_i(E_i(q), E_i(q)) \quad (6.4)$$

$$\underline{q}^t S^{(i)} \underline{q} = a_i(E_i(q_h), E_i(q_h)). \quad (6.5)$$

Let us denote the restriction of $u \in V_h^{(i)}$ to Γ by $u_\Gamma := u|_\Gamma$. The following discussion will reveal the reason why $E_i(u_\Gamma)$ is called an energy minimizing extension. Let us consider the following decomposition of u :

$$u = [u - E_i(u_\Gamma)] + E_i(u_\Gamma). \quad (6.6)$$

Since $(u - E_i(u_\Gamma))|_\Gamma = 0$, by Definition 1 we have:

$$a_i(u - E_i(u_\Gamma), E_i(u_\Gamma)) = 0. \quad (6.7)$$

Using (6.6) and (6.7), we have the energy minimizing property of $E_i(u_\Gamma)$ among $u \in V_h^{(i)}$ with $u|_\Gamma = u_\Gamma$:

$$a_i(u, u) = a_i(u - E_i(u_\Gamma), u - E_i(u_\Gamma)) + 2a_i(u - E_i(u_\Gamma), E_i(u_\Gamma)) + a_i(E_i(u_\Gamma), E_i(u_\Gamma)) \geq a_i(E_i(u_\Gamma), E_i(u_\Gamma)). \quad (6.8)$$

Therefore, using (6.8), (6.4) and (4.19), we have:

$$s_i(u_\Gamma, u_\Gamma) \leq a_i(u, u) \leq \bar{\lambda} \delta^d \|u\|_{L_2(\overline{\Omega^{(i)}})}^2,$$

for all $u \in V_h^{(i)}$, in particular, for $u = u_\Gamma$. Hence,

$$s_i(u_\Gamma, u_\Gamma) \leq \bar{\lambda} \delta^d \|u\|_{L_2(\Gamma)}^2. \quad (6.9)$$

For the lower bound, we simply use (6.3) and (4.17):

$$\lambda_{\text{refined}} \delta^{d+2} \|u\|_{L_2(\Gamma)}^2 \leq \lambda_{\text{refined}} \delta^{d+2} \|E_i(u_\Gamma)\|_{L_2(\overline{\Omega^{(i)}})}^2 \leq a_i(E_i(u_\Gamma), E_i(u_\Gamma)) = s_i(u_\Gamma, u_\Gamma). \quad (6.10)$$

We have proved the following spectral equivalence result:

Theorem 2. For any $q \in \mathcal{A}_h \subset L_2(\Gamma)$, we have:

$$\lambda_{\text{refined}} \delta^{d+2} \leq \frac{s_i(q, q)}{\|q\|_{L_2(\Gamma)}^2} \leq \bar{\lambda} \delta^d. \quad (6.11)$$

Thus, the condition number of the Schur complement matrix $S_\Gamma := S^{(1)} + S^{(2)}$ has the following bound:

$$\kappa(S_\Gamma) \lesssim \delta^{-2}.$$

Remark 7. The preceding condition number estimate indicates that the condition number of the Schur complement is no greater than that of the corresponding stiffness matrix; see (4.24). This estimate is not tight. In fact, we numerically observe smaller condition numbers for the Schur complement; see Table 6.1.

6.2.1. The nonlocal Schur complement matrix

When the contributions from each subdomain are accounted separately, we can write $K_{\Gamma\Gamma}$ in (6.2) as $K_{\Gamma\Gamma} = K_{\Gamma\Gamma}^{(1)} + K_{\Gamma\Gamma}^{(2)}$. Then, $S^{(i)}$ in (6.5) can be written as follows:

$$S^{(i)} := K_{\Gamma\Gamma}^{(i)} - K_{\Gamma i} K_{ii}^{-1} K_{i\Gamma}.$$

Table 6.1

Condition number for S_Γ in 1D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary. This data is plotted in Fig. 6.1.

The solution across the whole of Γ is determined by solving $S_\Gamma u_\Gamma = \tilde{f}$ for u_Γ , where

$$\tilde{f} := f_\Gamma - K_{\Gamma 1} K_{11}^{-1} f_1 - K_{\Gamma 2} K_{22}^{-1} f_2.$$

We observed in Section 4.5 that the condition number of the stiffness matrix K depends only weakly upon the mesh size h . Therefore, we expect that the condition number of the Schur complement matrix S_Γ should at most depend only weakly upon h . We will examine this conjecture in Section 6.3.

6.3. Numerical verification of the Schur complement conditioning

To test the conjecture of the previous section, we discretize the Dirichlet boundary value problem

$$S_I(u_h, v_h) = (b, v_h) \quad \forall v_h \in A_h, \quad (6.12)$$

with $u_h = 0$ on $\partial\Omega$, using piecewise constant and piecewise linear shape functions on uniform cartesian mesh, and numerically determine the ratio of the largest and smallest eigenvalues, defining the condition number of the problem.

6.3.1. Results in one dimension

We define the regions $\Omega_1 = (0, 0.5 - \delta/2)$, $\Omega_2 = (0.5 + \delta/2, 1)$, and $\Gamma = (0.5 - \delta/2, 0.5 + \delta/2)$, such that Γ is always a region of width δ centered at $x = 0.5$. We then compute the largest and smallest eigenvalues of S_Γ . We show results for both piecewise constant and piecewise linear shape functions to verify that the choice of shape function does not play a role in the conditioning of the discrete system.

We first compute the condition number of S_Γ for different h while holding δ fixed. Our results appear in Table 6.1 and Fig. 6.1. The minimum and maximum eigenvalues depend linearly on h , with a slope of nearly unity. Consequently, the condition number of S_Γ is only weakly h -dependent. We then compute the condition number of S_Γ for different δ while holding

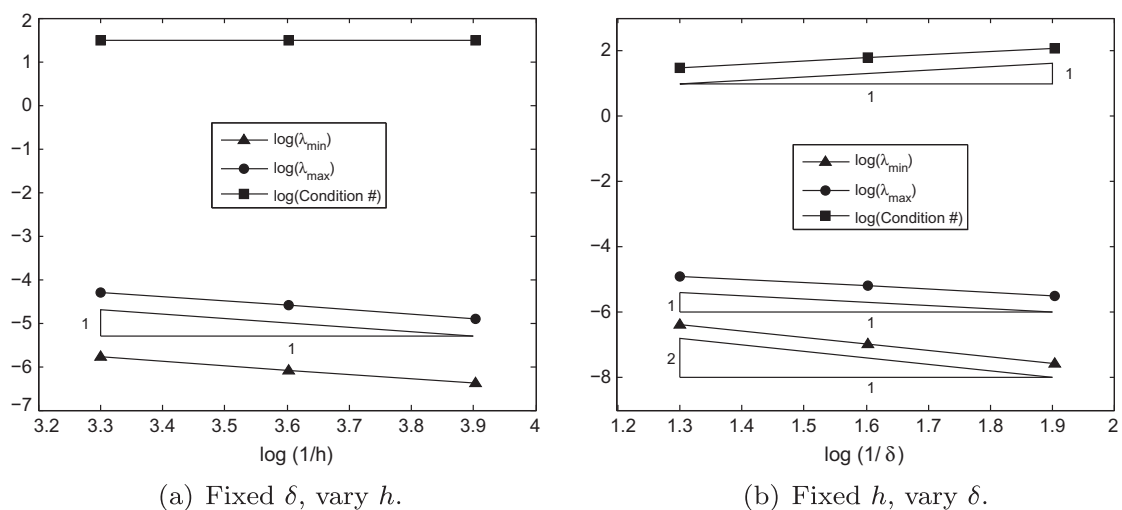

Fig. 6.1. Condition number for S_Γ in 1D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary. The condition number of S_Γ is only weakly h -dependent, but varies with δ^{-1} . These figures are plotted from data in Table 6.1. The plots for piecewise linear and piecewise constant shape functions are identical.

Table 6.2Condition number for S_I in 2D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary. This data is plotted in Fig. 6.2.

$1/h$	$1/\delta$	λ_{\min}	λ_{\max}	Condition #

(a) Fixed δ , vary h .(b) Fixed h , vary δ .**Fig. 6.2.** Condition number for S_I in 2D for (a) fixed δ , allowing h to vary, and (b) fixed h , allowing δ to vary. The condition number of S_I in 2D is only weakly h -dependent, but varies with δ^{-1} . These figures are plotted from data in Table 6.2.**Table 7.1**The δ -quantification of the reported numerical results.

Dim	$\lambda_{\min}(K)$	$\lambda_{\max}(K)$	$\kappa(K)$	$\lambda_{\min}(S_I)$	$\lambda_{\max}(S_I)$	$\kappa(S_I)$
1D	$\mathcal{O}(\delta^3)$	$\mathcal{O}(\delta)$	$\mathcal{O}(\delta^{-2})$	$\mathcal{O}(\delta^2)$	$\mathcal{O}(\delta)$	$\mathcal{O}(\delta^{-1})$
2D	$\mathcal{O}(\delta^4)$	$\mathcal{O}(\delta^2)$	$\mathcal{O}(\delta^{-2})$	$\mathcal{O}(\delta^3)$	$\mathcal{O}(\delta^2)$	$\mathcal{O}(\delta^{-1})$

h fixed, and observe that the condition number varies nearly as δ^{-1} , which is better conditioned than the original stiffness matrix K , whose condition number varied with δ^{-2} .

6.3.2. Results in two dimensions

We define the regions $\Omega_1 = (0, 0.5 - \delta/2) \times (0, 1)$, $\Omega_2 = (0.5 + \delta/2, 1) \times (0, 1)$, and $\Gamma = (0.5 - \delta/2, 0.5 + \delta/2) \times (0, 1)$, such that Γ is always a region of width δ centered at $x = 0.5$. We then compute the largest and smallest eigenvalues of S_I . We consider only piecewise constant shape functions in 2D, having established that the choice of shape function does not affect the conditioning.

We first compute the condition number of S_I for different h while holding δ fixed, and observe that minimum and maximum eigenvalues depend linearly on h with a slope of approximately two, and again the condition number of K depends only weakly upon the mesh size. Our results appear in Table 6.2 and Fig. 6.2. We then compute the condition number of S_I for different δ while holding h fixed, and observe that the condition number again varies as δ^{-1} .

7. Conclusions and future work

We have presented a variational theory for nonlocal problems, such as (1.1). With this theory, we proved the well-posedness of the variational formulation of nonlocal boundary value problems with Dirichlet boundary conditions and practical

kernel functions that are relevant to peridynamics. In addition, we proved a spectral equivalence estimate which leads to a mesh-size independent upper bound for the condition number of the stiffness matrix. The spectral equivalence relies on the upper bound (4.19) and the nonlocal Poincaré inequality (4.17) for the lower bound, where in both the δ -dependence and dimension dependence have been explicitly quantified. Supporting numerical experiments demonstrated the sharpness of the upper bound (4.19) as well as the lower bound (4.17). Explicit δ -quantification in the condition number bound serves to guide preconditioner construction for nonlocal problems. We then constructed a nonlocal domain decomposition framework with associated nonlocal transmission conditions, also proving equivalence between the one-domain and two-domain nonlocal Dirichlet boundary value problems. We defined an energy minimizing extension, analogous to a harmonic extension used in the local case, to analyze the condition number of the nonlocal Schur complement operator. We discretized our two-domain weak form to arrive at a nonlocal Schur complement matrix. Conditioning of the nonlocal Schur complement matrix was explored via numerical studies. We summarize the numerical results in Table 7.1. We observe that $\kappa(K)$ and $\kappa(S_F)$ are only weakly dependent upon the mesh size but vary with δ^{-2} and δ^{-1} , respectively.

It is interesting to compare the conditioning of the discrete nonlocal problem with the conditioning of the (local) discrete Laplace equation. The condition number of the stiffness matrix for the local discrete Laplace equation varies with h^{-2} [17, Theorem B.32], and the corresponding Schur complement matrix condition number varies with h^{-1} [17, Lemma 4.11]. For a fixed mesh size $0 < h \ll \delta$, we see from Table 7.1 that the discrete nonlocal stiffness matrix K varies with δ^{-2} , and the condition number of the corresponding nonlocal Schur complement matrix S_F varies as δ^{-1} .

Application of an appropriate preconditioner, involving the solution of a coarse problem, reduces the condition number of the Schur complement of the weak classical (local) Laplace operator from $\mathcal{O}((Hh)^{-1})$ to $\mathcal{O}((1 + \log(H/h))^2)$, where H is the subdomain size [17, Lemma 4.11], [2, Section 4.3.6]. One unexplored area involves examining the role of a coarse problem in the nonlocal setting, which has not been considered here. A logical direction would be to expand other substructuring methods to a nonlocal setting, such as Neumann–Dirichlet, Neumann–Neumann, FETI-DP (the dual-primal finite element tearing and interconnecting method) [7], or BDDC (balancing domain decomposition by constraints) [15]. Additional opportunities for future research include addressing convergence analysis for alternative domain decomposition methods not based on substructuring in a nonlocal setting. More fundamental concepts in Schwarz theory such as stable decompositions and local solvers need to be reconstructed for nonlocal problems to support convergence analysis for additive, multiplicative, and hybrid algorithms.

Acknowledgements

The first author thanks Dr. Tadele Mengesha of Louisiana State University for many enlightening discussions. The authors also acknowledge helpful discussions with Pablo Seleson of Florida State University, and also Dr. Richard Lehoucq of Sandia National Laboratories, and thank him for pointing out the Ref. [28].
