§S4 Conserved Non-Coding conpats

Method:

To search for conserved non-coding conpats with enriched statistical signals, we started with the set of 4936 ortholog triplets and 1000bp upstream and downstream regions multiply aligned using MLAGAN. The High-scoring Conserved Sequence (HCS) blocks were identified as described in the paper, and aligned all-vs-all to identify the best local alignment between pairs. Local alignments were clustered to identify commonly occurring subconpats (occur >= 4 different HCS) termed conpats. We identified all conpat co-occurrences (where the conpat appears upstream of 3 orthologous genes, or downstream of 3 orthologs) by using MAST with an expect

Co-occurrence Enrichment - conpat occurs more often than random conpats of same length and degeneracy. Pvalue assigned by comparing observed co-occurrences to distribution of 1000 simulated conpats of same length

Upstream vs Downstream - conpat occurs preferentially upstream or downstream of genes. Pvalue assigned by binomial distribution (# upstream occurrence, total occurrences, background probability=0.56). Background

Category Enrichment - conpat occurs preferentially near genes having related functional categories. Pvalue for each category C assigned by hypergeometric distribution (# co-occurrences upstream of genes in category C, total # co-occurrences, # all genes in category C, # all genes) with the Bonferroni correction for multiple testing.

Cell Location Enrichment - conpat occurs preferentially near genes having related cellular location, based on the GO cell location category for the A. nidulans gene's best bi-directional hit (BBH) to S. cerevisiae. Pvalue for each category C assigned by hypergeometric distribution (# co-occurrences upstream of genes in category C, total # co-occurrences, # all genes in category C, # all genes) with the Bonferroni correction for multiple testing. The total number of genes is all A. nidulans genes having a three-way ortholog in Aspergillus, and the number of

Definitions:

Three-way orthologs: Pairwise orthologs are defined as best bidirectional hits (within all-vs-all comparison of genome protein sets) using blastp (e<1e-5) and requiring > 60% coverage of each gene. Three-way orthologs

Tabs:

conpats: 69 conpats showed co-occurrence enrichment (p < 0.01) and either upstream or downstream

conpat_sites: sites of co-occurring conpats, 2 lines per ortholog (for upstream co-occurring conpats, and

conpat_matrices.ace: conpat matrix in ACE file format (multiple alignment HCS subsequences). X=any

factors: sequences of known factors used in similarity searches

an_cats: for all three-way orthologs, the A. nidulans locus, description, COG category, yeast best bi-directional hit (BBH), yeast GO cellular location category

top35: the top 35 conpats sorted by the number of HCS

Data fields:

conpats tab:

ID: unique conpat identifier.

Conpat Consensus: sequence logo (generated by WebLogo program [Crooks GE et all, Genome Research, 2004]) based on HCS multiple alignment.

Similar Sequence: name of known factor with a similar binding sequence, based on CompareACE score > 0.85. Set of known factors in tab "factors".

HCS: number of HCS blocks clustered together to generate conpat

5' Sites: number of ortholog triplets (An, Af, Ao) that the conpat co-occurred upstream of. All ortholog triplets were aligned including 1000 bp upstream. If a neighboring gene is located within 1000bp upstream, the upstream non-coding alignment is split in half, otherwise the entire 1000bp upstream alignment is split in half.

3' Sites: number of ortholog triplets (An, Af, Ao) that the conpat co-occurred downstream of. All ortholog triplets were aligned including 1000 bp downstream. If a neighboring gene is located within 1000bp downstream, the downstream non-coding alignment is split in half, otherwise the entire 1000bp downstream alignment is split in half.

5' /3' Bias? "up" indicates that the conpat preferentially occurrs upstream of genes (pvalue < 0.01 based on binomial distribution). "down" indicates a downstream preference.

% Aligned: percent of upstream co-occurrences that overlap an HCS (if 5'/3' bias="up", use downstream co-occurrences otherwise).

Strand Bias? "yes" indicates that the conpat co-occurred more often on the + strand (same strand as gene) than on the - strand (binomial distribution, pvalue < 0.01). "no" indicates that no such preference was observed. Note: there will be no preference for reverse-complement palindrome conpats.

Sites/Gene: average number of times a conpat is found upstream of the gene (if 5'/3' bias = "up") or downstream of the gene (if 5'/3' bias = "down").

Enriched in COG categories: categories showing enrichment (pvalue < 0.01 as described above), after multiple category testing. The number of genes in this category are

Enriched in cell location: categories showing enrichment (pvalue < 0.01 as described above), after multiple category testing. The number of genes in this category are

Bits / Base: average number of information content bits contained in the weight matrix.

Conpat Consensus: ASCII representation of the conpat weight matrix. BE VERY CAREFUL if you use this as it's much better to use the underlying weight matrix representation (see conpat_matrices.ace). The ASCII representation has capital letters representing bases with > 1 bit of information from the weight matrix, and lowercase

conpat_sites tab:

conpat ID: unique conpat identifier.

Conpat Consensus: see above

Similar Sequence: see above

conpat 5' / 3' Bias: upsteam/downstream bias of the conpat, see above

Site 5' / 3' of Locus: "up" if the site is upstream of the given gene, "down" if the site is downstream of the given gene

AF Locus: locus of the A. fumigatus ortholog

AN Locus: locus of the A. nidulans ortholog

AO Locus: locus of the A. oryzae ortholog

Locus Description: name of the A. nidulans locus

COG Category: COG category for AN locus (multiple letters indicate locus is in multiple categories)

COG Cat Enriched: 1 if the conpat in enriched in this category (p<0.01)

(Bonferonni correction).

 # AF sites: number of conpat sites upstream/downstream of this gene in A. fumigatus

 # AN sites: number of conpat sites upstream/downstream of this gene in A. nidulans

 # AO sites: number of conpat sites upstream/downstream of this gene in A. oryzae

Overlap HCS: 1 if any of the sites overlaps an HCS

conpat start.

conpat start.

conpat start.

AN 5' UTR Len: if "Site 5'/3' of Locus"="up", then report the length of the EST alignment that overlaps a gene to the 5' end (indicating a lowerbound for the 5' UTR length) or "No EST" if no EST aligns to this gene. NOTE: just the maximum aligned length is given and introns may be present within the 5' UTR.

In AN 5' UTR: 1 if "AN 5' UTR Len">0 and the "AN dist from gene" < "AN 5' UTR Len"

downstream of this gene

In AN 3' UTR: 1 if "AN 3' UTR Len">0 and the "AN dist from gene" < "AN 3' UTR Len"

§S5. Transposable Elements

A number of unusual features were also observed in *Aspergillus* TEs. First, in *A. fumigatus*, one subfamily of I-1_AF non-LTR retrotransposons has a unique target-site, and was found in long terminal repeats of the Afut2 *Gypsy*-like LTR retrotransposon. Second, the *Aspergillus Helitrons* have 5’-TT and CTTG-3’ termini, which differ from the canonical 5’-TC and CTRR-3’ termini[70]. Moreover, Aspergillus *Helitrons* do not contain 3’ palindromic structures, which are present in other eukaryotes[70,71], indicating that 3’ palindromes are not essential for rolling-circle transpositions. Third, all three genomes possess unusual *Mariners*, 7-9 kb in length, that encode a conserved protein of unknown function in addition to a transposase. Finally, we identified families of SINE elements derived from the 5’-half of 5S rRNA containing an internal pol III promoter. They are the first examples of SINE elements present in fungi. Moreover, such 5s RNA derived SINE elements have been found previously in the zebrafish genome only.

§S6.2. Genetic Map Description and Integration

Around 260 known genetic markers, which have associated sequences, exist for *Aspergillus nidulans*[4,5]. These 260 genetic markers were filtered to a set of 196 unambiguous sequences with accessions in GenBank. Of these 196 markers, 103 are ordered on the linkage group map whereas the remaining 93 are unordered. The file of genetic markers is available for download at http://www.broad.mit.edu/cgi-bin/annotation/aspergillus/download_license.cgi .

These markers were compared to the current assembly using BLASTN. Where these matches were unique, were of high quality, and contained most or all the gene, we assigned a marker position in one of our contigs. A total of 187 markers were placed uniquely within the assembly and only 14 of the markers showed discrepancies (see below). We used the 187 unique marker alignments to correlate contigs with linkage groups, creating the correlated genetic maps displayed here.

- 28.5 Mb (18 supercontigs) of the 30 Mb assembly or 95% of the assembly, are anchored to the genetic map.
- 26.8 Mb (12 supercontigs) or 89% of the assembly are ordered and oriented.
- 1.7 Mb can only be placed on a linkage group without specifying order or orientation

More detail is available at http://www.broad.mit.edu/annotation/fungi/aspergillus/markers.html.

§S6.3. Discrepancies between Assembly and Genetic Map

There are a few cases where marker order on the linkage group map conflicts with the locations of markers in supercontigs. The discrepancies may be due to:

1. Errors in assembly of sequence into contigs or supercontigs

2. Errors in order of markers on the linkage group map
3. Correct but incomplete assembly data: for example, one supercontig may lie within a gap between contigs in another supercontig

The following discrepancies were noted and corrected when related to an error in assembly (see also (http://www.gla.ac.uk/Acad/IBLS/molgen/aspergillus/). *All discrepancies that could be associated with errors in the assembly were corrected prior to analysis.* The order and orientation of contigs within supercontigs in this corrected assembly used for analysis is provided below.

1. **Re-orient Supercontig 9, on LG IV**: uvsH and bimD map distally while uvsB is centromere-proximal
2. **Supercontig 15 should be on LG VI not LG IV**: Supercontig 15 is shown as relating to linkage group IV on the basis of the pacA marker. However the clone labelled "pacA" has been found to encode a suppressor of pacA, and has been renamed "suApacA". SuApacA maps on VI, as does cnxG, located in contig 169. Telomeric repeats located at the end of contig 170 determine that supercontig 15 is the short left arm of linkage group VI, with contig 170 distal to contig 169.
3. **Supercontig 14 should be on LG VII**: The alcA gene is genetically mapped to the short left arm of linkage group VII, and therefore locating supercontig 14 to that position (orientation unknown).
4. **Supercontig 16 should be on LG VIII**: supercontig 16 probably relates to the right arm of linkage group VIII, on the basis of a tentative identification of AN9403.1 as "pdhA" (encoding a pyruvate dehydrogenase subunit).
5. **Telomeric simple repeats** are found at:
    - the start of contig 1.134: LG II left end.
    - as stated in item 2, 1.170 (supercontig 15) is clearly the LEFT arm of VI because cnxG (meiotically at the left end of VI) locates to 1.169.
    - the start of contig 1.1: right end of LG VIII.
    - on unattached contigs 1.200 and 1.216

§S6.4. *A. nidulans* Assembly Contig Order and Orientation

The following provides the order and orientation of contigs within supercontigs in the corrected *A. nidulans* assembly used for analysis. Supercontigs are ordered from the end of one arm of each chromosome to the end of the other arm although the selection of which arm to start from was arbitrary for each chromosome.

Notes

[a] The genes shown represent a minimal set. There are additional probable orthologs for most classes of enzyme. Of particular interest is the finding of a large number of enoyl-CoA hydratases (PFAM00378-15 in *A.oryzae*, 10 in *A.fumigatus* and 12 in *A.nidulans* with either mitochondrial or peroxisomal locations predicted) and hydroxyacyl-CoA dehydrogenases (PFAM02737

and 00725 – 5 in *A.oryzae*,3 in *A,fumigatus* and 4 in *A.nidulans* none of which have predicted peroxisomal targetting.

[b] Assignment of proteins to mitochondria was based on TargetP (http://www.cbs.dtu.dk/services/TargetP/ Olof Emanuelsson, Henrik Nielsen, Søren Brunak, and Gunnar von Heijne: "Predicting subcellular localization of proteins based on their N-terminal amino acid sequence", J. Mol. Biol. 300, 1005-1016 (2000) and PSORT II (http://psort.nibb.ac.jp/).

[c] Peroxisomal location was based on the presence of a C-terminal PTS-1 consensus of the form(S/A R/K L/M) or a PTS-2 consensensus (R/K L/V/I X5 H/Q L/A/F/I). The PTS-2 consensus was only found in the ketoacyl-CoA thiolases.

[d] Inactivation of AN5916.2 and AN7111.2 has been shown to affect fatty acid utilisation (Maggio- Hall and Keller (ref 77 in previous version) and a mutation in AN4179.2 results in loss of growth on short chain fatty acids (M.J.Hynes, unpublished).

[e] *Saccharomyces cerevisiae* contains a mitochondrial Lon protease (Pim1/Lon1) but lacks a peroxisomal enzyme.

§S10. Gene Prediction Protocol and Accuracy Estimation

§S10.1. Gene Prediction Protocol

Gene structures were predicted using a combination of FGENESH, FGENESH+, and GENEWISE. Both FGENESH and FGENESH+ are gene prediction programs acquired from Softberry.com and GENEWISE is part of the WISE2 package developed by Ewan Birney and is available from the Sanger Center.

Both FGENESH and FGENESH+ utilize a statistical model of gene structure that require training on each organism for accurate prediction. FGENESH+ additionally combines a protein sequence with the statistical model to improve accuracy. We acquired these programs already trained by Softberry on *Aspergillus nidulans* sequences.

GENEWISE (as we ran it), splices and aligns a protein sequence with genomic sequence to predict a gene structure. Although GENEWISE does utilize some species-specific parameters, most notably for intron nucleotide statistics and splice site consensus sequences, these can be set to non-species specific defaults. In this case, GENEWISE essentially produces the best local alignment of a protein assuming that introns start at GT and end at AG most of the time and in some cases this results a full alignment of the protein to the genome. Since we are interested in predicting complete gene structures, we post-processed GENEWISE incomplete protein alignments by moving the first and last exon upstream or downstream to the nearest start and stop codons respectively. If a stop codon was encountered upstream of a gene before a start could be found, the gene call was not used.

Briefly, these three gene callers were combined in the following manner:

1. FGENESH was run on the entire genomic sequence to provide an initial set of predicted genes. Each FGENESH predicted was put into a set of EVIDENCE_GENES.
2. The genome was also searched against the non-redundant protein database using BLASTX
3. Regions of the genome with blastx homology spanning over 80% of a protein (when sub-alignments are stitched together in a consistent fashion) were considered "Homologous Gene Regions" (HGRs).
4. HGRs were clustered into groups of HGRs that all implicated the same gene structure (most often representing groups of essentially orthologous proteins).
5. For each cluster of HGRs, the protein showing the most sequence similarity to the genome was passed to both FGENESH and GENEWISE to produce 2 gene predictions, if the protein had >80% amino acid identity to the translated genome (cumulative across sub-alignments).
6. If the protein used in the previous had >90% amino acid identity to the translated genome (cumulative across sub-alignments), then the GENEWISE call, if valid, was favored over the FGENESH+ call, and was used as the EVIDENCE_GENE for the HGR (see below for the reason why) and added to the set of EVIDENCE_GENES. If this protein had >80% but less than 90% amino acid identity to the translated genome (cumulative across

sub-alignments), then the FGENESH+ call, if valid, was favored over the GENEWISE call, and was used as the EVIDENCE_GENE for the HGR and added to the set of EVIDENCE_GENES.

7. When EVIDENCE_GENES overlapped in their exons, the EVIDENCE_GENE with the least amount of homology support (as measured by the sequence similarity of the protein used to make the call or zero for FGENESH calls) was removed from the set of EVIDENCE_GENES.
8. All remaining EVIDENCE_GENES were then called as our official ANNOTATED_GENES and passed to the next step of gene calling for Gene Naming.

§S10.2. Accuracy Estimation

The accuracy of our gene prediction protocol was assessed by comparing predicted to overlapping EST alignments (aligned using est2genome). Alignments of individual ESTs were grouped into *EST clusters* corresponding to sets of ESTs predicting the identical gene structure at a particular locus.

Table §S10.1 – Estimated Gene Prediction Accuracy

§S12. Two Predicted TPP Riboswitches

Based on conservation, we identified three TPP binding riboswitches[1], one of which has not been described in Aspergillus. Riboswitches are regulatory elements found in untranslated regions of mRNA which fold to bind target metabolites leading to altered gene expression[1-3]. A TPP riboswitch, which binds thiamin pyrophosphate and regulates genes involved in thiamine biosynthesis, was previously identified in the 5' UTR of the *A. oryzae thi4*[1]. We find this element conserved upstream of thi4 in *A. fumigatus* and *A. nidulans*. We also find an element recently shown to be present upstream of orthologous NMT1 thiamine biosynthesis genes (AN8009, 53.m03858, AO70322000058)[4], corresponding to the known *N. crassa* NMT1 riboswitch[1]. A third element was found conserved upstream of orthologous purine-cytosine permease genes (AN4526, 53.m05980, AO70321000134). This element has not been previously characterized in any organism, although evidence linking purine influx to thiamine biosynthesis has been reported[5,6].
