(54) **Title**: MICROORGANISMS FOR THE PRODUCTION OF MELATONIN

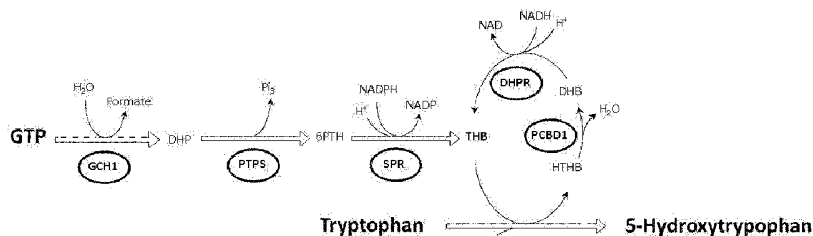

Fig. 1

(57) **Abstract**: Recombinant microbial cells and methods for producing melatonin and related compounds using such cells are described. More specifically, the recombinant microbial cell may comprise exogenous genes encoding one or more of an L-tryptophan hydroxylase, a 5-hydroxy-L- tryptophan decarboxylyase, a serotonin acetyltransferase, an acetylserotonin O- methyltransferase; an L-tryptophan decarboxy-lyase, and a tryptamine-5-hydroxylase, and means for providing tetrahydrobiopterin (THB). Related sequences and vectors for use in preparing such recombinant microbial cells are also described.

WO 2013/127915 A1

MICROORGANISMS FOR THE PRODUCTION OF MELATONIN

FIELD OF THE INVENTION

The present invention relates to recombinant microorganisms and methods for producing melatonin and related compounds, such as serotonin and N-acetylserotonin. More specifically, 5 the present invention relates to a recombinant microorganism comprising heterologous genes encoding at least an L-tryptophan hydroxylase and a serotonin acetyltransferase, and means for providing tetrahydrobiopterin (THB). The invention also relates to a method of producing melatonin and related compounds comprising culturing said microorganism, as well as related compositions and uses thereof.

10 ## BACKGROUND OF THE INVENTION

Serotonin is a naturally occurring amino acid which also plays a significant role as a transmitter substance in the central nervous system in animals, where it is biochemically derived from tryptophan. In a first step, tryptophan is converted to 5-hydroxytryptophan (5HTP) in a reaction catalyzed by tryptophan hydroxylase, which requires both oxygen and 15 tetrahydropterin (THB) as cofactors (Schramek *et al.*, 2001). 5HTP is then converted to serotonin by 5-hydroxy-L-tryptophan decarboxylyase. In plants, serotonin biosynthesis is also carried out in two, albeit different, enzymatic steps. The first step is catalyzed by tryptophan decarboxylase, and converts tryptophan to tryptamine. Tryptamine is then converted into serotonin, in a reaction catalyzed by tryptamine 5-hydroxylase.

20 Serotonin also functions as a metabolic intermediate in the biosynthesis of melatonin. Melatonin is a hormone secreted by the pineal gland in the brain, which, *inter alia*, maintains the body's circadian rhythm, is involved regulating other hormones, and is a powerful anti-oxidant. In both animals and plants, the conversion of serotonin to melatonin is catalyzed by arylserotonin acetyltransferase and acetylserotonin O-methyltransferase, with N-25 acetylserotonin as the metabolic intermediate. Because of, *e.g.*, its role in regulating circadian rhythm, melatonin has been available for many years as an over-the-counter dietary supplement in the U.S. This melatonin is, however, typically chemically synthesized. Thus, there is a need for a simplified and more cost-effective procedure.

U.S. 7,807,421 B2 describes cells transformed with enzymes participating in the biosynthesis 30 of THB and a process for the production of a biopterin compound using the same.

Winge *et al.* (2008) describes recombinant production of tryptophan hydroxylase (TPH2) in *E. coli* for subsequent purification.

U.S. 3,808,101 describes a biological method of producing tryptophan and 5-substituted tryptophans, purportedly by the action of tryptophanase, by cultivation of certain
5 microorganism strains on, *e.g.*, indole and 5-hydroxyindole.

Park *et al.* (2008) describes heterologous expression of tryptophan decarboxylase in rice plants, *E. coli*, and yeast, and serotonin production by the same.

Park *et al.* (2010) describes a recombinant *E. coli* cell comprising nucleic acid sequences encoding a tryptamine 5-hydroxylase and a tryptophan decarboxylase.

10 Park *et al.* (2011) describes dual expression of tryptophan decarboxylase and tryptamine 5-hydroxylase in *E. coli*, and serotonin-production by the same.

Kang *et al.* (2009) reviews the biosynthesis of serotonin derivatives in plants and microbes.

Kang *et al.* (2011) describes cloning of putative N-acetylserotonin methyltransferases from rice into *E. coli*. Melatonin production from N-acetylserotonin was observed.

15 SUMMARY OF THE INVENTION

It has been found that melatonin, as well as its biometabolic intermediates serotonin and N-acetylserotonin, can be produced in a recombinant microbial cell. Advantageously, these compounds can be produced from an inexpensive carbon source, providing for cost-efficient production.

20 The invention thus provides a recombinant microbial cell comprising an exogenous nucleic acid sequence encoding an L-tryptophan hydroxylase, means for providing its co-factor, THB, and exogenous nucleic acid sequences encoding one, two or all of a 5-hydroxy-L-tryptophan decarboxylyase, a serotonin acetyltransferase, and an acetylserotonin O-methyltransferase. Also provided are nucleic acid vectors useful for producing such recombinant microbial cells.

25 In some aspects, the THB is provided by one or more exogenous pathways added to the recombinant microbial cell. For example, the recombinant microbial cell may comprises an enzymatic pathway regenerating THB consumed in the L-tryptophan hydroxylase-catalyzed

production of 5HTP, an enzymatic pathway producing THB from guanosin triphosphate (GTP), or both.

In some aspects, the recombinant cell or vector further comprises nucleic acid sequences encoding a tryptophan decarboxylyase, a tryptamine 5-hydroxylase, or both.

5 In other aspects, the invention provides for methods of producing melatonin or related compounds using such recombinant microbial cells, as well as for compositions comprising melatonin or a related compound produced by such recombinant microbial cells.

These and other aspects and embodiments are described in more details in the following sections.

5 DETAILED DISCLOSURE OF THE INVENTION

As described above, the present invention relates to a recombinant microbial cell capable of efficiently producing melatonin or a related compound, including serotonin or N-acetyl-serotonin, from an exogenously added carbon source.

In a first aspect, the invention relates to a recombinant microbial cell comprising
10 - an exogenous nucleic acid sequence encoding an L-tryptophan hydroxylase (EC 1.14.16.4),
- exogenous nucleic acid sequences encoding enzymes of at least one pathway for producing THB, and
- exogenous nucleic acids encoding one, two or all of a 5-hydroxy-L-tryptophan decarboxy-lyase (EC 4.1.1.28), a serotonin acetyltransferase (EC 2.3.1.87), and an acetylserotonin O-
15 methyltransferase (EC 2.1.1.4). Pathways for producing THB include, but are not limited to, a pathway producing THB from guanosin triphosphate (GTP) and a pathway regenerating THB from 4a-hydroxytetrahydrobiopterin (HTHB). In one embodiment, the recombinant microbial cell is modified, typically mutated, to reduce tryptophan degradation, such as by reducing tryptophanase activity.

20 In a second aspect, the invention relates to a recombinant microbial cell of a preceding aspect or embodiment for use in a method of producing melatonin, N-acetylserotonin or serotonin, which method comprises culturing the microbial cell in a medium comprising a carbon source. The medium may optionally comprise THB.

In a third aspect, the invention relates to a vector comprising nucleic acid sequences
25 encoding an L-tryptophan decarboxylyase, a serotonin acetyltransferase, an acetylserotonin O-methyltransferase, and, optionally, a 5-hydroxy-L-tryptophan decarboxylyase.

In a fourth aspect, the invention relates to a recombinant microbial host cell transformed with the vector of the preceding aspect. The host cell may further be transformed with one or more vectors comprising nucleic acids encoding an L-tryptophan hydroxylase, a GTP

cyclohydrolase I, a 6-pyruvoyl-tetrahydropterin synthase, a sepiapterin reductase, a 4a-hydroxytetrahydrobiopterin dehydratase and/or a dihydropteridine reductase.

In a fifth aspect, the invention relates to a method of producing melatonin, N-acetylserotonin and/or serotonin, comprising culturing a recombinant microbial cell of any preceding aspect
5 or embodiment in a medium comprising a carbon source, and, optionally, isolating one or more of melatonin, N-acetylserotonin and serotonin. In one embodiment, the medium does not comprise a detectable amount of exogenously added THB. In another embodiment, the medium comprises exogenously added THB.

In a sixth aspect, the invention relates to a method for preparing a composition comprising
10 one or more of melatonin, N-acetylserotonin or serotonin comprising the steps of:
(a) culturing a microbial cell comprising an exogenous nucleic acid encoding an L-tryptophan hydroxylase; one or more of a 5-hydroxy-L-tryptophan decarboxy-lyase, a serotonin acetyltransferase, and an acetylserotonin O-methyltransferase; and at least one source of THB in a medium comprising a carbon source, optionally in the presence of tryptophan;
15 (b) isolating melatonin, N-acetylserotonin, or serotonin;
(c) purifying the isolated melatonin, N-acetylserotonin, or serotonin; and
(d) adding any excipients to obtain a composition comprising the desired compound(s). In one embodiment, the microbial cell comprises enzymes of a pathway regenerating THB from 4a-hydroxytetrahydrobiopterin. In one embodiment, the source of THB comprises
20 exogenously added THB. In one embodiment, the source of THB comprises enzymes of a pathway producing THB from GTP.

In a seventh aspect, the invention relates to a method of producing a recombinant microbial cell, comprising transforming a microbial host cell with one or more vectors comprising nucleic acid sequences encoding
25 (a) an L-tryptophan hydroxylase (EC 1.14.16.4);
(b) one, two or all of a 5-hydroxy-L-tryptophan decarboxylyase, a serotonin acetyltransferase, and an acetylserotonin O-methyltransferase ;
(c) a GTP cyclohydrolase I (EC 3.5.4.16);
(d) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12);
30 (e) a sepiapterin reductase (EC 1.1.1.153);
(f) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and
(g) a dihydropteridine reductase (EC 1.5.1.34), each one of said nucleic acid sequences being operably linked to an inducible, a regulated or a constitutive promoter, thereby obtaining the recombinant microbial cell.

In an eighth aspect, the invention relates to a composition comprising melatonin, serotonin and/or N-acetylserotonin obtainable by culturing a recombinant microbial cell comprising exogenous nucleic acid sequences encoding an L-tryptophan hydroxylase and one or more of a 5-hydroxy-L-tryptophan decarboxylyase, a serotonin acetyltransferase, and an
5 acetylserotonin O-methyltransferase and a source of tetrahydrobiopterin (THB) in a medium comprising a carbon source.

In a ninth aspect, the present invention relates to a use of a composition comprising melatonin, serotonin or N-acetylserotonin produced by a recombinant microbial cell or method described in any preceding aspect, in preparing a product such as, *e.g.*, a dietary
10 supplement, a pharmaceutical, a cosmeceutical, a nutraceutical, a feed ingredient or a food ingredient.

Definitions

As used herein, "exogenous" means that the referenced item, such as a molecule, activity or pathway, is added to or introduced into the host cell or microorganism. For example, an
15 exogenous molecule can be added to or introduced into the host cell or microorganism, *e.g.*, via adding the molecule to the media in or on which the host cell or microorganism resides. An exogenous nucleic acid sequence can, for example, be introduced either as chromosomal genetic material by integration into a host chromosome or as non-chromosomal genetic material such as a plasmid. For such an exogenous nucleic acid, the source can be, for
20 example, a homologous or heterologous coding nucleic acid that expresses a referenced enzyme activity following introduction into the host cell or organism. Similarly, when used in reference to a metabolic activity or pathway, the term refers to a metabolic activity or pathway that is introduced into the host cell or organism, where the source of the activity or pathway (or portions thereof) can be homologous or heterologous. Typically, an exogenous
25 pathway comprises at least one heterologous enzyme.

In the present context the term "heterologous" means that the referenced item, such as a molecule, activity or pathway, does not normally appear in the host cell or microorganism species in question.

As used herein, the terms "native" and "endogenous" means that the referenced item is
30 normally present in or native to the host cell or microbal species in question.

As used herein, "vector" refers to any genetic element capable of serving as a vehicle of genetic transfer, expression, or replication for a exogenous nucleic acid sequence in a host

cell. For example, a vector may be an artificial chromosome or a plasmid, and may be capable of stable integration into a host cell genome, or it may exist as an independent genetic element (*e.g.*, episome, plasmid). A vector may exist as a single nucleic acid sequence or as two or more separate nucleic acid sequences. Vectors may be single copy
5 vectors or multicopy vectors when present in a host cell. Preferred vectors for use in the present invention are expression vector molecules in which one or more functional genes can be inserted into the vector molecule, in proper orientation and proximity to expression control elements resident in the expression vector molecule so as to direct expression of one or more proteins when the vector molecule resides in an appropriate host cell.

10 The term "host cell" or "microbial" host cell refers to any microbial cell into which an exogenous nucleic acid sequence can be introduced and expressed, typically via an expression vector. The host cell may, for example, be a wild-type cell isolated from its natural environment, a mutant cell identified by screening, a cell of a commercially available strain, or a genetically engineered cell or mutant cell, comprising one or more other
15 exogenous and/or heterologous nucleic acids than those of the invention.

A "recombinant cell" or "recombinant microbial cell" as used herein refers to a host cell into which one or more exogenous nucleic acid sequences of the invention have been introduced, typically via transformation of a host cell with a vector.

Unless otherwise stated, the term "sequence identity" for amino acid sequences as used
20 herein refers to the sequence identity calculated as $(n_{ref} - n_{dif}) \cdot 100/n_{ref}$, wherein n_{dif} is the total number of non-identical residues in the two sequences when aligned and wherein n_{ref} is the number of residues in one of the sequences. Hence, the amino acid sequence GSTDYTQNWA will have a sequence identity of 80% with the sequence GSTGYTQAWA (n_{dif}=2 and n_{ref}=10). The sequence identity can be determined by conventional methods, *e.g.*, Smith
25 and Waterman, (1981), Adv. Appl. Math. 2:482, by the 'search for similarity' method of Pearson & Lipman, (1988), Proc. Natl. Acad. Sci. USA 85:2444, using the CLUSTAL W algorithm of Thompson *et al.*, (1994), Nucleic Acids Res 22:467380, by computerized implementations of these algorithms (GAP, BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group). The BLAST algorithm (Altschul *et al.*,
30 (1990), Mol. Biol. 215:403-10) for which software may be obtained through the National Center for Biotechnology Information www.ncbi.nlm.nih.gov/) may also be used. When using any of the aforementioned algorithms, the default parameters for "Window" length, gap penalty, etc., are used.

Enzymes referred to herein can be classified on the basis of the handbook Enzyme
35 Nomenclature from NC-IUBMB, 1992), see also the ENZYME site at the internet:

http://www.expasy.ch/enzyme/. This is a repository of information relative to the nomenclature of enzymes, and is primarily based on the recommendations of the Nomenclature Committee of the International Union of Biochemistry and Molecular Biology (IUB-MB). It describes each type of characterized enzyme for which an EC (Enzyme
5 Commission) number has been provided (Bairoch A. The ENZYME database, 2000, Nucleic Acids Res 28:304-305). The IUBMB Enzyme nomenclature is based on the substrate specificity and occasionally on their molecular mechanism; the classification does not in itself reflect the structural features of these enzymes.

In the present disclosure, tryptophan is of L-configuration, unless otherwise noted.

10 The term "substrate", as used herein in relation to a specific enzyme, refers to a molecule upon which the enzyme acts to form a product. When used in relation to an exogenous biometabolic pathway, the term "substrate" refers to the molecule upon which the first enzyme of the referenced pathway acts, such as, *e.g.*, GTP in the pathway shown in Figure 1 which produces THB from GTP (see Figure 1). When referring to an enzyme-catalyzed
15 reaction in a microbial cell, an "endogenous" substrate or precursor is a molecule which is native to or biosynthesized by the microbial cell, whereas an "exogenous" substrate or precursor is a molecule which is added to the microbial cell, via a medium or the like.

The term "yield" as used herein means, when used regarding 5HTP production of a microbial cell, the number of moles of 5HTP per mole of the relevant carbon source in the medium, and
20 is expressed as a percentage of the theoretical maximum possible yield

5 *Specific embodiments of the invention*

As shown in the present Examples, melatonin and related compounds, such as serotonin and N-acetylserotonin, can be produced in a microbial cell transformed with enzymes of a THB-dependent pathway having 5HTP as an intermediate. This pathway comprises a tryptophan hydroxylase, exogenous pathways producing and regenerating its cofactor THB, and a 5-
10 hydroxy-L-tryptophan decarboxy-lyase, which converts 5HTP into serotonin (Figure 1). In some embodiments, the microbial cell can additionally or alternatively be transformed with enzymes allowing for production of these compounds via a tryptamine intermediate. For example, one or more enzymes from the THB-independent tryptamine pathway in plants, comprising tryptamine 5-hydroxylase and L-tryptophan decarboxy-lyase and producing
15 serotonin from L-tryptophan via tryptamine, can be included (Figures 2 and 3). Finally, the microbial cell can also comprise serotonin acetyltransferase, catalyzing the conversion of serotonin to N-acetyl serotonin, and acetylserotonin O-methyltransferase, catalyzing the conversion of N-acetyl serotonin to melatonin. Importantly, production of the desired

compounds can then be achieved from a low-cost exogenous carbon source such as glucose, since all required substrates for the added biosynthetic pathways, L-tryptophan and (for production via a 5HTP intermediate) GTP, are endogenously produced by the recombinant cell.

5 Accordingly, the invention provides a recombinant microbial cell comprising an exogenous nucleic acid sequence encoding an L-tryptophan hydroxylase and one, two or all of a 5-hydroxy-L-tryptophan decarboxy-lyase, a serotonin acetyltransferase, and an acetylserotonin O-methyltransferase, and further comprises means to provide THB.

L-Tryptophan hydroxylase

10 The first step of the THB-dependent pathway is catalyzed by L-tryptophan hydroxylase, also known as tryptophan 5-hydroxylase and tryptophan 5-monooxygenase. This enzyme is typically classified as EC 1.14.16.4, and converts the substrate L-tryptophan to 5HTP in the presence of its cofactors THB and oxygen, as shown in Figure 1.

Sources of nucleic acid sequences encoding an L-tryptophan hydroxylase include any species 15 where the encoded gene product is capable of catalyzing the referenced reaction, including humans, mammals such as, *e.g.*, mouse, cow, horse, chicken and pig, as well as other animals. In humans and, it is believed, in other mammals, there are two distinct TPH alleles, referred to herein as TPH1 and TPH2, respectively. Exemplary nucleic acids encoding L-tryptophan hydroxylase for use in aspects and embodiments of the present invention include, 20 but are not limited to, those encoding *Oryctolagus cuniculus* (rabbit) TPH1 (SEQ ID NO:1); human TPH1 (SEQ ID NO:2; UniProt P17752-2), human TPH2 (SEQ ID NO:3; UniProt P17752-1) as well as those encoding L-tryptophan hydroxylase from *Bos taurus* (cow, SEQ ID NO:4), *Sus scrofa* (pig, SEQ ID NO:5), *Gallus gallus* (SEQ ID NO:6), *Mus musculus* (mouse, SEQ ID NO:7) and *Equus caballus* (horse, SEQ ID NO:8), as well as variants, homologs or 25 active fragments thereof. In one embodiment, the nucleic acid encodes SEQ ID NO:1, or a variant, homolog or catalytically active fragment thereof.

In one embodiment, the nucleic acid sequence encodes an L-tryptophane hydroxylase which is a variant or homolog of any one or more of the aforementioned L-tryptophane hydroxylases, having L-tryptophan hydroxylase activity and a sequence identity of at least 30 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over at least the catalytically active portion, optionally the full-length, of a reference amino acid sequence selected from any one or more of SEQ ID NOS:1 to 9. For example, the sequence identify

between the human TPH1 and TPH2 enzymes is about 65%. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions are considered. These are typically within the group of basic amino acids (arginine, lysine and histidine), acidic amino acids (glutamic acid and aspartic acid), polar amino acids (glutamine and asparagine), hydrophobic amino acids (leucine, isoleucine and valine), aromatic amino acids (phenylalanine, tryptophan and tyrosine), and small amino acids (glycine, alanine, serine, threonine and methionine). Amino acid substitutions which do not generally alter specific activity are known in the art and are described, for example, by H. Neurath and R. L. Hill, 1979, In: The Proteins, Academic Press, New York. The most commonly occurring exchanges are Ala to Ser, Val to Ile, Asp to Glu, Thr to Ser, Ala to Gly, Ala to Thr, Ser to Asn, Ala to Val, Ser to Gly, Tyr to Phe, Ala to Pro, Lys to Arg, Asp to Asn, Leu to Ile, Leu to Val, Ala to Glu, and Asp to Gly. For example, homologs, such as orthologs or paralogs, to TPH1 or TPH2 having L-tryptophan hydroxylase activity can be identified in the same or a related mammalian or other animal species using the reference sequences provided and appropriate activity tests. Assays for measuring L-tryptophan hydroxylase activity *in vitro* are well-known in the art (see, *e.g.*, Winge *et al.* (2008), Biochem. J., 410, 195-204 and Moran, Daubner, & Fitzpatrick, 1998). With the complete genome sequences now available for hundreds of species, most of which available via public databases such as NCBI, the identification of homologous genes encoding the requisite biosynthetic activity in related or distant species, the interchange of genes between organisms is routine and well known in the art.

In one embodiment, the nucleic acid sequence encoding an L-tryptophan hydroxylase encodes a fragment of one of the full-length L-tryptophan hydroxylases, variants or homologs described herein, which fragment has L-tryptophan hydroxylase activity. Notably, the TPH1 used in Examples 2-4 was a double truncated TPH1 where both the regulatory and interface domains of the full-length enzyme (SEQ ID NO:1) had been removed so that only the catalytic core of the enzyme remained, to increase heterologous expression in *E. coli* and the stability of the enzyme (Moran, Daubner, & Fitzpatrick, 1998). Specifically, the truncation resulted in a fragment corresponding to amino acids Met102 to Ser416 of the full-length enzyme. Accordingly, in one embodiment, the nucleic acid sequence encoding the L-tryptophan hydroxylase encodes the catalytic core of a naturally occurring L-tryptophan hydroxylase or a variant thereof. The fragment may, for example, correspond to Met102 to Ser416 of any one of SEQ ID NOS:2 to 8 or a variant or homolog thereof, when aligned with SEQ ID NO:1. In a particular embodiment, the nucleic acid sequence encodes the sequence of SEQ ID NO:9, or a variant thereof. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:40.

In the recombinant host cell, the L-tryptophan hydroxylase is typically sufficiently expressed so that an increased level of 5HTP production from L-tryptophan can be detected as compared to the microbial host cell prior to transformation with the L-tryptophan xhydroxylase, or to another suitable control. Exemplary assays for measuring the level of 5HTP production from L-tryptophan is provided in Examples 4 and 5. In these Examples, the recombinant strain tested also comprised exogenous pathways for producing and regenerating THB. However, for testing L-tryptophan hydroxylase activity or for actual production of 5HTP, the THB can additionally or alternatively be added to the culture medium at a suitable concentration, for example at a concentration of about 0.1 µM or higher, such as from about 0.01, 0.02, 0.05, or 0.1 mM to about 0.1, 0.25, 1, or 10 mM, such as, *e.g.*, 0.02 to 2 mM, such as 0.05 to 0.25 mM. In one exemplary embodiment, a recombinant microbial cell comprising a tryptophane hydroxylase produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more 5HTP than the corresponding host cell from L-tryptophan which is added to the culture medium at a suitable concentration, *e.g.*, in the range 0.1 to 50 g/L, such as in the range of 0.2 to 10 g/L, or which is endogenously produced from a carbon source. Optionally, the host cell may be one that already has an endogenous capability for producing 5HTP, see, *e.g.*, U.S. 3,808,101, U.S. 3,830,696 and references cited therein, reporting that some microbial strains (*e.g.*, *Proteus mirabilis* (ATCC 15290) and *Bacillus subtilis* (ATCC 21733)) were capable of producing 5HTP from fermentation of a substrate such as 5-hydroxyindole or L-tryptophan.

In one embodiment, the microbial cell is modified, typically mutated, to reduce tryptophanase activity. Tryptophanase or tryptophan indole-lyase (EC 4.1.99.1), encoded by the *tna*A gene in *E. coli*, catalyzes the hydrolytic cleavage of L-tryptophan to indole, pyruvate and NH_4^+. Active tryptophanase consists of four identical subunits, and enables utilization of L-tryptophan as sole source of nitrogen or carbon for growth together with a tryptophan transporter encoded by *tna*C gene. Tryptophanase is a major contributor towards the cellular L-cysteine desulfhydrase (CD) activity. *In vitro*, tryptophanase also catalyzes α, β elimination, β replacement, and α hydrogen exchange reactions with a variety of L-amino acids (Watanabe , 1977). As shown in Example 5, *E. coli* tryptophanase can degrade also 5HTP, thus reducing the yield of 5HTP (Figures 3 and 4). Tryptophan degradation mechanisms are known to also exist in other microorganisms. For instance, in *S. cerevisiae*, there are two different pathways for the degradation of tryptophan (The Erlich pathway and the kynurenine pathway, respectively), involving in their first step the ARO8, ARO9, ARO10, and/or BNA2 genes. Reducing tryptophan degradation, such as by reducing tryptophanase activity, can be achieved by, e.g., a site-directed mutation in or deletion of a gene encoding a tryptophanase, such as the *tna*A gene (in *E. coli* or other organisms such as *Enterobacter aerogenes*), or *kyn*A gene (in *Bacillus* species), or one or more of the ARO8, ARO9, ARO10 and BNA2 genes (in *S. cerevisiae*). Alternatively, tryptophanase activity can be reduced

reducing the expression of the gene by introducing a mutation in, *e.g.*, a native promoter element, or by adding an inhibitor of the tryptophanase.

Tetrahydrobiopterin

In aspects where the recombinant microbial cell of the invention comprises L-tryptophan hydroxylase, it further comprises means to provide or produce THB, such as exogenous nucleic acids encoding at least one pathway for producing THB. THB is native to most animals, where it is biosynthesized from GTP. However, while THB has been found in some lower eukaryotes such as fungi and in particular groups of bacteria such as, *e.g.*, cyanobacteria and anaerobic photosynthetic bacteria of *Chlorobium* species, its presence in microbes is believed to be rare. For example, THB is not native to *E. coli* or *S. cerevisiae*. Accordingly, for aspects and embodiments of the invention where THB is not added to the recombinant cells or not efficiently produced by the microbial host cell itself, THB production capability must be added. For example, the recombinant microbial cell can comprise exogenous nucleic acids encoding enzymes of a pathway producing THB from GTP and/or a pathway regenerating THB from HTHB.

First THB pathway – THB production from GTP

In one embodiment, the recombinant cell comprises a pathway producing THB from GTP and herein referred to as "first THB pathway", comprising a GTP cyclohydrolase I (GCH1), a 6-pyruvoyl-tetrahydropterin synthase (PTPS), and a sepiapterin reductase (SPR) (see Figure 1). The addition of such a pathway to microbial cells such as *E. coli* (JM101 strain), *S. cerevisiae* (KA31 strain) and *Bacillus subtilis* (1A1 strain (TrpC2)) has been described, see, *e.g.*, Yamamoto (2003) and U.S. 7,807,421, which are hereby incorporated by reference in their entireties.

The GCH1 is typically classified as EC 3.5.4.16, and converts GTP to DHP in the presence of its cofactor, water, as shown in Figure 1. Sources of nucleic acid sequences encoding a GCH1 include any species where the encoded gene product is capable of catalyzing the referenced reaction, including humans, mammals such as, *e.g.*, mouse, as well as microbial GCH1 enzymes. Exemplary nucleic acids encoding GCH1 enzymes for use in aspects and embodiments of the present invention include, but are not limited to, those encoding human GCH1 (SEQ ID NO:10), GCH1 from *Mus musculus* (SEQ ID NO:11), *E. coli* (SEQ ID NO:12), *S. cerevisiae* (SEQ ID NO:13), *Bacillus subtilis* (SEQ ID NO:14), *Streptomyces avermitilis* (SEQ ID NO:15), and *Salmonella typhi* (SEQ ID NO:16), as well as variants, homologs and catalytically active fragments thereof. In some embodiments, the microbial host cell

endogenously comprises sufficient amounts of a native GCH1. In these cases transformation of the host cell with an exogenous nucleic acid encoding a GCH1 is optional. In other embodiments, the exogenous nucleic acid encoding a GCH1 can encode a GCH1 which is endogenous to the microbial host cell, *e.g.*, in the case of host cells such as *E. coli*, *S. cerevisiae, Bacillus subtilis* and *Streptomyces avermitilis*. In *E. coli*, for example, the expression of the GCH1 gene is regulated by the SoxS system. Should higher levels of GCH1 be needed, GCH1 from *E. coli* or another suitable source can be provided exogenously. In a particular embodiment, the exogenous nucleic acid sequence encodes *E. coli* GCH1, SEQ ID NO:12. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:41.

The PTPS is typically classified as EC 4.2.3.12, and converts DHP to 6PTH, as shown in Figure 1. Sources of nucleic acid sequences encoding a PTPS include any species where the encoded gene product is capable of catalyzing the referenced reaction, including human, mammalian and microbial species. Exemplary nucleic acids encoding PTPS enzymes for use in aspects and embodiments of the present invention include, but are not limited to, those encoding human PTPS (SEQ ID NO:17), rat PTPS (SEQ ID NO:18), and PTPS from *Bacteroides thetaiotaomicron* (SEQ ID NO:19), *Thermosynechococcus elongates* (SEQ ID NO:20), *Streptococcus thermophilus* (SEQ ID NO:21), and *Acaryochloris marina* (SEQ ID NO:22), as well as variants, homologs and catalytically active fragments thereof. In some embodiments, the microbial host cell endogenously comprises a sufficient amount of a native PTPS. In these cases transformation of the host cell with an exogenous nucleic acid encoding a PTPS is optional. In other embodiments, the exogenous nucleic acid encoding a PTPS can encode a PTPS which is endogenous to the microbial host cell, *e.g.*, in the case of host cells such as *Streptococcus thermophilus*. In a particular embodiment, the exogenous nucleic acid sequence encodes rat PTPS, SEQ ID NO:18. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:42.

The SPR is typically classified as EC 1.1.1.153, and converts 6PTH to THB in the presence of its cofactor NADPH, as shown in Figure 1. Sources of nucleic acid sequences encoding an SPR include any species where the encoded gene product is capable of catalyzing the referenced reaction, including humans, mammalian species such as cow, rat and mouse, and other animals. Exemplary nucleic acids encoding SPR enzymes for use in aspects and embodiments of the present invention include, but are not limited to, those encoding human SPR (SEQ ID NO:23), and SPR from rat (SEQ ID NO:24), mouse (SEQ ID NO:25), cow (SEQ ID NO:26), *Danio rerio* (Zebrafish, SEQ ID NO:27) and *Xenopus laevis* (African clawed frog, SEQ ID NO:28), as well as variants, homologs and catalytically active fragments thereof. Typically, the exogenous nucleic acid encoding an SPR is heterologous to the host cell. In a particular

embodiment, the exogenous nucleic acid encodes SEQ ID NO:24. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:43.

In specific embodiments, one or more of the exogenous nucleic acids encoding GCH1, PTPS and SPR enzymes encodes a variant or homolog of any one or more of the aforementioned GCH1, PTPS and SPR enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over at least the catalytically active portion, optionally over the full length, of the reference amino acid sequence. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do not alter specific activity are considered. Homologs, such as orthologs or paralogs, to GCH1, PTPS or SPR and having the desired activity can be identified in the same or a related animal or microbial species using the reference sequences provided and appropriate activity testing.

In the recombinant host cell, the enzymes of the first THB pathway are typically sufficiently expressed in sufficient amounts to detect an increased level of 5HTP production from L-tryptophan as compared to the recombinant microbial cell without transformation with these enzymes (*i.e.*, the recombinant cell comprising only L-tryptophan hydroxylase), or to another suitable control. Exemplary assays for measuring the level of 5HTP production from L-tryptophan is provided in Examples 4 and 5. In one exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more 5HTP than the recombinant cell without transformation with GCH1, PTPS and/or SPR enzymes. Alternatively, the expression and activity of the enzymes of the first THB pathway, *i.e.*, production of THB or related products, can be tested according to methods described in Yamamoto (2003), U.S. 7,807,421, or Woo *et al.* (2002), Appl. Environ. Microbiol. 68, 3138, or other methods known in the art.

Second THB pathway – THB regeneration

In one embodiment, the recombinant cell comprises a pathway producing THB by regenerating THB from HTHB, herein referred to as "second THB pathway", comprising a 4a-hydroxytetrahydrobiopterin dehydratase (PCBD1) and a 6-pyruvoyl-tetrahydropterin synthase (DHPR). As shown in Figure 1, the second THB pathway converts the HTHB formed by the L-tryptophan hydroxylase-catalyzed hydroxylation of L-tryptophan back to THB, thus allowing for a more cost-efficient 5HTP production.

The PCBD1 is typically classified as EC 4.2.1.96, and converts HTHB to DHB in the presence of water, as shown in Figure 1. Sources of nucleic acid sequences encoding a PCBD1 include any species where the encoded gene product is capable of catalyzing the referenced reaction, including microbial species. Exemplary nucleic acids encoding GCH1 enzymes for use in 5 aspects and embodiments of the present invention include, but are not limited to, those encoding PCBD1 from *Pseudomonas aeruginosa* (SEQ ID NO:29), *Bacillus cereus* var. *anthracis* (SEQ ID NO:30), *Corynebacterium genitalium* (ATCC 33030) (SEQ ID NO:31), *Lactobacillus ruminis* ATCC 25644 (SEQ ID NO:32), and *Rhodobacteraceae bacterium* HTCC2083 (SEQ ID NO:33), as well as variants, homologs and catalytically active fragments 10 thereof. In some embodiments, the microbial host cell endogenously comprises a sufficient amount of a native PCBD1. In these cases, transformation of the host cell with an exogenous nucleic acid encoding a PCBD1 is optional. In other embodiments, the exogenous nucleic acid encoding a PCBD1 can encode a PCBD1 which is endogenous to the microbial host cell, *e.g.*, in the case of host cells from *Bacillus cereus, Corynebacterium genitalium, Lactobacillus* 15 *ruminis* or *Rhodobacteraceae* bacterium. In a particular embodiment, the exogenous nucleic acid sequence encodes *Pseudomonas aeruginosa* PCBD1, SEQ ID NO:29. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:44.

The DHPR is typically classified as EC 1.5.1.34, and converts DHB to THB in the presence of cofactor NADH, as shown in Figure 1. Sources of nucleic acid sequences encoding a DHPR 20 include any species where the encoded gene product is capable of catalyzing the referenced reaction, including humans and other mammalian species such as rat, pig, and microbial species. Exemplary nucleic acids encoding DHPR enzymes for use in aspects and embodiments of the present invention include, but are not limited to, those encoding DHPR from human (SEQ ID NO:34), rat (SEQ ID NO:35), pig (SEQ ID NO:36) cow (SEQ ID NO:37), 25 *E. coli* (SEQ ID NO:38), *Dictyostelium discoideum* (SEQ ID NO:39), as well as variants, homologs or catalytically active fragments thereof. In a particular embodiment, the exogenous nucleic acid encodes *E. coli* DHPR, SEQ ID NO:38. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:45.

In specific embodiments, one or more of the exogenous nucleic acids encoding PCBD1 and 30 DHPR enzymes encodes a variant or homolog of any one or more of the aforementioned PCBD1 and DHPR enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over at least the catalytically active portion, optionally the full length, of the reference amino acid sequence. 35 The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do

not alter specific activity are considered. Homologs, such as orthologs or paralogs, to PCBD1 or DHPR and having the desired activity can be identified in the same or a related animal or microbial species using the reference sequences provided and appropriate activity testing.

In the recombinant host cell, the enzymes of the second THB pathway are typically
5 sufficiently expressed so that an increased level of 5HTP production from L-tryptophan can be detected as compared to the recombinant microbial cell without transformation with these enzymes (*i.e.*, the recombinant cell comprising only L-tryptophan hydroxylase) in the presence of a THB source, or to another suitable control. Exemplary assays for measuring the level of 5HTP production from L-tryptophan is provided in Examples 4 and 5. In one
10 exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more 5HTP than the recombinant cell without transformation with PCBD1 and DHPR enzymes.

Combination of first and second THB pathway

As shown in Figure 1, a successful combination of both the first and second THB pathways in
15 the recombinant cell, introducing pathways for producing THB from GTP and for regenerating THB consumed by L-tryptophan hydroxylase, is especially advantageous, since the addition of THB, as well as the addition of L-tryptophan, can be avoided, allowing for 5HTP production from an inexpensive carbon source. As shown in Example 5, 5HTP production was obtained in a recombinant *E. coli* strain (comprising both the first and second THB pathways) in LB
20 medium supplemented with glucose and/or L-tryptophan. In M9 medium, supplementation with tryptophan produced the highest 5HTP measurements. Accordingly, in one embodiment, the invention provides for recombinant microbial cells, processes and methods where the recombinant host cell comprises both the first and second pathways of any preceding aspect or embodiment.

25 5-hydroxy-L-tryptophan decarboxy-lyase

The last step in the serotonin biosynthesis via a 5HTP intermediate, the conversion of 5HTP to serotonin, is in animal cells catalyzed by a 5-hydroxy-L-tryptophan decarboxy-lyase (DDC), which is an aromatic L-amino acid decarboxylase typically classified as EC 4.1.1.28. See Figure 1. Suitable DDCs include any tryptophan decarboxylase (TDC) capable of
30 catalyzing the referenced reaction. TDC likewise belongs to the aromatic amino acid decarboxylases categorized in EC 4.1.1.28, and can be able to convert 5HTP to serotonin and carbon dioxide (see, *e.g.*, Park *et al.*, 2008, and Gibson *et al.*, J. Exp. Bot. 1972;23(3):775-786), and thus function as a DDC.

Sources of nucleic acid sequences encoding a DDC include any species where the encoded gene product is capable of catalyzing the referenced reaction as described above, including humans, other mammalian species, microbial species, and plants. Exemplary nucleic acids encoding DDC enzymes for use in aspects and embodiments of the present invention include, but are not limited to, those from *Acidobacterium capsulatum* (SEQ ID NO:62), rat (SEQ ID NO:63), pig (SEQ ID NO:64), humans (SEQ ID NO:65), *Capsicum annuum* (bell pepper, SEQ ID NO:66), *Drosophila caribiana* (SEQ ID NO:67), *Maricaulis maris* (strain MCS10; SEQ ID NO:68), *Oryza sativa* subsp. Japonica (Rice; SEQ ID NO:69), *Pseudomonas putida* S16 (SEQ ID NO:70) and *Catharanthus roseus* (SEQ ID NO:71), as well as variants, homologs or catalytically active fragments thereof. In some embodiments, particularly where it is desired to also promote serotonin formation from a tryptamine substrate in the same recombinant cell, an enzyme capable of catalyzing both the conversion of tryptophan to tryptamine and the conversion of 5HTP to serotonin can be used. For example, rice TDC and tomato TDC can function also as a DDC, an activity which can be promoted by the presence of pyridoxal phosphate (*e.g.*, at a concentration of about 0.1 mM) (Park *et al.*, 2008; and Gibson *et al.*, 1972). In a particular embodiment, the exogenous nucleic acid encodes rice TDC, SEQ ID NO:69. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:109.

In specific embodiments, one or more of the exogenous nucleic acids encoding DDC enzymes encodes a variant or homolog of any one or more of the aforementioned DDC enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over at least the catalytically active portion, optionally the full length, of the reference amino acid sequence. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do not alter specific activity are considered. Homologs, such as orthologs or paralogs, to a DDC and having the desired activity can be identified in the same or a related animal or microbial species using the reference sequences provided and appropriate activity testing.

Suitable assays for testing serotonin production by a DDC in a recombinant microbial host cell are provided in, or can be adapted from, *e.g.*, Park *et al.* (2008) and (2011). For example, these assays can be adapted to test serotonin production by a TDC or DDC, either from 5HTP or, in case the microbial cell comprises an L-tryptophan hydroxylase, from L-tryptophan (or simply a carbon source). In one exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at

least 50%, such as at least 100% or more serotonin than the recombinant cell without transformation with DDC/TDC enzymes, *i.e.*, a background value.

Tryptamine pathway

In one aspect, the recombinant microbial cell additionally or alternatively comprises a
5 pathway for producing serotonin from L–tryptophan via a tryptamine intermediate. For example, Park *et al.* (2011) describes the production of serotonin in *E. coli* by dual expression of tryptophan decarboxylase (TDC) and tryptamine 5-hydroxylase (T5H), the latter in the form of a fusion construct with a glutathione S transferase (GST).

The first step of the metabolic pathway is the conversion of L-tryptophan to tryptamine. In
10 plants, this is catalyzed by a TDC, which is an aromatic L-amino acid decarboxylase typically classified as EC 4.1.1.28. See Figure 2. Suitable TDCs include DDCs capable of catalyzing the referenced reaction.

For the present invention, sources of nucleic acid sequences encoding a TDC include any species where the encoded gene product is capable of catalyzing the referenced reaction as
15 described above, including humans, other mammalian species, and plants. Exemplary nucleic acids encoding TDC enzymes for use in aspects and embodiments of the present invention include, but are not limited to, TDC from *Acidobacterium capsulatum* (SEQ ID NO:62), rat (SEQ ID NO:63), pig (SEQ ID NO:64), humans (SEQ ID NO:65), *Capsicum annuum* (bell pepper, SEQ ID NO:66), *Drosophila caribiana* (SEQ ID NO:67), *Maricaulis maris* (strain
20 MCS10; SEQ ID NO:68), *Oryza sativa* subsp. *Japonica* (rice; SEQ ID NO:69), *Pseudomonas putida* S16 (SEQ ID NO:70) and *Catharanthus roseus* (SEQ ID NO:71), as well as variants, homologs or catalytically active fragments thereof. In a particular embodiment, the exogenous nucleic acid encodes *Catharanthus roseus* TDC, SEQ ID NO:71. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:86
25 (*Catharanthus roseus* TDC). In another particular embodiment, the exogenous nucleic acid encodes rice TDC, SEQ ID NO:69. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:109 (rice TDC).

Following the decarboxylation of L-tryptophan, the second reaction is a tryptamine 5-hydroxylase (T5H, EC 1.14.16.4), which is a cytochrome P450 enzyme, catalyzing the
30 conversion of tryptamine into serotonin with oxygen, hydrogen ions, and NADPH as co-factors. See Figure 2.

For the present invention, sources of nucleic acid sequences encoding a T5H include any species where the encoded gene product is capable of catalyzing the referenced reaction as described above, including plant species. Exemplary nucleic acids encoding T5H enzymes for use in aspects and embodiments of the present invention include, but are not limited to, T5H from *Oryza sativa* (rice; SEQ ID NO:72), as well as variants, homologs or catalytically active fragments thereof. In one embodiment, the T5H or a catalytically active fragment thereof is expressed as a fusion protein, *e.g.*, with a GST, as described in Park *et al.*, (2011). In a particular embodiment, the exogenous nucleic acid encodes a GST fusion construct with aT5H fragment, encoded by SEQ ID NO:87. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:87.

In specific embodiments, one or more of the exogenous nucleic acids encoding TDC and T5H enzymes encodes a variant or homolog of any one or more of the aforementioned TDC or T5H enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over at least the catalytically active portion, optionally the full length, of the reference amino acid sequence. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do not alter specific activity are considered. Homologs, such as orthologs or paralogs, to TDC or T5H and having the desired activity can be identified in the same or a related animal, plant, or microbial species using the reference sequences provided and appropriate activity testing.

Suitable assays for testing serotonin production by TDC-T5H in a recombinant microbial host cell are provided in, or can be adapted from, *e.g.*, Park *et al.* (2011), which is hereby specifically incorporated by reference in its entirety. In one exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more serotonin than the recombinant cell without transformation with TDC/T5H enzymes, *i.e.*, a background value.

Combination of TPH-dependent and tryptamine pathways

In one aspect, the recombinant microbial cell comprises both a THB-dependent and a tryptamine exogenous pathways according to any combination of preceding aspects and embodiments (Figure 3).

Accordingly, in one embodiment the recombinant microbial cell comprises exogenous nucleic acid sequences encoding an L-tryptophan hydroxylase, a GCH1, a PTS, an SPR, a PCBD1, a DHPR, a TDC, a T5H, and, in case DDC activity is not already provided by a TDC; a DDC, each enzyme according to one or more preceding specific embodiments. Optionally, the 5 recombinant microbial cell further comprises exogenous nucleic acids encoding an AANAT, an ASMT, or both.

As described above, some TDCs are also capable of functioning as a DDC, and vice versa, so that DDC and TDC activities are provided by the same enzyme. Accordingly, in one embodiment the recombinant microbial cell comprises exogenous nucleic acid sequences 10 encoding an L-tryptophan hydroxylase, a GCH1, a PTS, an SPR, a PCBD1, a DHPR, a T5H, and an enzyme capable of both TDC and DDC activity, each enzyme according to one or more preceding specific embodiments. Optionally, the recombinant microbial cell further comprises exogenous nucleic acids encoding an AANAT, an ASMT, or both.

The recombinant microbial cell can further comprises exogenous nucleic acids encoding an 15 AANAT, an ASMT, or both.

Serotonin acetyltransferase

In one aspect, the recombinant microbial cell further comprises an exogenous nucleic acid sequence encoding a serotonin acetyltransferase, also known as serotonin –N-acetyltransferase, arylalkylamine N-acetyltransferase and AANAT, and typically classified as 20 EC 2.3.1.87. AANAT catalyzes the conversion of acetyl-CoA and serotonin to CoA and N-Acetyl-serotonin (Figures 1-3).

Sources of nucleic acid sequences encoding a AANAT include any species where the encoded gene product is capable of catalyzing the referenced reaction as described above, including humans, other mammalian species, and plants. Exemplary nucleic acids encoding AANAT 25 enzymes for use in aspects and embodiments of the present invention include, but are not limited to, AANAT from the single celled green alga *Chlamydomonas reinhardtii* (SEQ ID NO 73) (Okazaki *et al.*, 2009), *Bos taurus* (SEQ ID NO:74), *Gallus gallus* (SEQ ID NO:75), *Homo sapiens* (SEQ ID NO:76), *Mus musculus* (SEQ ID NO:77), *Oryctolagus cuniculus* (SEQ ID NO:78), and *Ovis aries* (SEQ ID NO:79), as well as variants, homologs or catalytically active 30 fragments thereof. In a particular embodiment, the exogenous nucleic acid encodes *Chlamydomonas reinhardtii* AANAT, SEQ ID NO:73. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:88 (*Chlamydomonas reinhardtii* AANAT).

In a specific embodiment, the exogenous nucleic acids encoding an AANAT encodes a variant or homolog of any one or more of the aforementioned AANAT enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over the full length of the reference amino acid sequence. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do not alter specific activity are considered. Homologs, such as orthologs or paralogs, to AANAT and having the desired activity can be identified in the same or a related animal, plant, or microbial species using the reference sequences provided and appropriate activity testing.

Suitable assays for testing N-acetylserotonin production by an AANAT in a recombinant microbial host cell are described in, *e.g.*, Thomas *et al.*, Analytical Biochemistry 1990;184:228-34. In one exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more N-acetylserotonin than the recombinant cell without transformation with AANAT enzyme.

<u>Acetylserotonin O-methyltransferase</u>

In one aspect, the recombinant cell further comprises an exogenous nucleic acid encoding an acetylserotonin O-methyltransferase or ASMT, typically classified as EC 2.1.1.4. ASMT catalyzes the last reaction in the production of melatonin from L-tryptophan, the conversion of N-acetyl-serotonin and S-adenosyl-L-methionine (SAM) to Melatonin and S-adenosyl-L-homocysteine (SAH). As described in the Examples, SAH can then be recycled back to SAM via the S-adenosyl-L-methionine cycle in microbial cells where the S-adenosyl-L-methionine cycle is native (or exogenously added) and constitutively expressed, such as, *e.g.*, in *E.coli.*.

Sources of nucleic acid sequences encoding an ASMT include any species where the encoded gene product is capable of catalyzing the referenced reaction as described above, including humans, other mammalian species, and plants. Exemplary nucleic acids encoding ASMT enzymes for use in aspects and embodiments of the present invention include, but are not limited to, ASMT from *Oryza sativa* (rice, SEQ ID NO:80), *Homo sapiens* (SEQ ID NO:81), *Bos Taurus* (SEQ ID NO:82), *Rattus norvegicus* (SEQ ID NO:83), *Gallus gallus* (SEQ ID NO:84), and *Macaca mulatta* (SEQ ID NO:85), as well as variants, homologs or catalytically active fragments thereof. In a particular embodiment, the exogenous nucleic acid encodes

rice ASMT, SEQ ID NO:80. In another particular embodiment, the nucleic acid sequence comprises the sequence of SEQ ID NO:89 (rice ASMT).

In a specific embodiment, the exogenous nucleic acids encoding an ASMT encodes a variant or homolog of any one or more of the aforementioned ASMT enzymes, having the referenced activity and a sequence identity of at least 30%, such as at least 50%, such as at least 60%, such as at least 70%, such as at least 80%, such as at least 90%, such as at least 95%, such as at least 99%, over the full length of the reference amino acid sequence. The variant or homolog may comprise, for example, 2, 3, 4, 5 or more, such as 10 or more, amino acid substitutions, insertions or deletions as compared to the reference amino acid sequence. In particular conservative substitutions and/or amino acid substitutions which do not alter specific activity are considered. Homologs, such as orthologs or paralogs, to ASMT and having the desired activity can be identified in the same or a related animal, plant, or microbial species using the reference sequences provided and appropriate activity testing.

Suitable assays for testing melatonin production by an ASMT in a recombinant microbial host cell have been described in, *e.g.*, Kang *et al.* (2011), which is hereby incorporated by reference in its entirety. In one exemplary embodiment, the recombinant microbial cell produces at least 5%, such as at least 10%, such as at least 20%, such as at least 50%, such as at least 100% or more melatonin than the recombinant cell without transformation with ASMT enzyme.

Vectors

The invention also provides a vector comprising a nucleic acid sequence encoding an L-tryptophan hydroxylase and a DDC as described in any preceding embodiment, and a nucleic acid sequence encoding one or more enzymes of the first and/or second THB pathways, as described in any preceding embodiment and as shown in Figure 1. The specific design of the vector depends on whether the intended microbial host cell is to be provided with one or both THB pathways, as well as on whether host cell endogenously produces sufficient amounts of one or more of the enzymes of the THB pathways. For example, for an *E. coli* host cell, it may not be necessary to include a nucleic acid sequence encoding a GCH1, since the enzyme is native to *E. coli*. Additionally, for transformation of a particular host cell, two or more vectors with different combinations of the enzymes used in the present invention can be applied.

The vector may, for example, comprise a nucleic acid sequence encoding an L-tryptophan hydroxylase and one or more enzymes of the first THB pathway. In one embodiment, the

nucleic acid encodes an SPR, and optionally one or both of a GCH1 and a PTPS. In one embodiment, the vector comprises a nucleic acid sequence encoding an SPR and a PTPS, and optionally a GCH1. In one embodiment, the nucleic acid encodes an SPR, a PTPS and a GCH1. Examples of nucleic acids encoding each of these enzymes are provided herein, and
5 specifically include variants, homologues and catalytically active fragments thereof.

Also or alternatively, the vector may, for example, comprise a nucleic acid sequence encoding an L-tryptophan hydroxylase and one or both enzymes of the second THB pathway. In one embodiment, the nucleic acid encodes a DHPR, and optionally a PCBD1. In one embodiment, the vector comprises a nucleic acid sequence encoding a DHPR and a PCBD1. Examples of
10 nucleic acids encoding each of these enzymes are provided herein, and specifically include variants, homologues and catalytically active fragments thereof.

In one embodiment, the vector comprises a nucleic acid sequence encoding an L-tryptophan hydroxylase, a DDC, an SPR and a DHPR, and optionally a GCH1, a PTPS, a PCBD1 or a combination of any thereof. In one embodiment, the vector comprises a nucleic acid
15 sequence encoding an L-tryptophan hydroxylase, a DDC, an SPR and a DHPR, and a combination of at least two of a GCH1, a PTPS, and a PCBD1.

The invention also provides a vector comprising nucleic acid sequences encoding an AANAT, an ASMT, a TDC or TDC/DDC (*e.g.*, a TDC capable of DDC activity), and, optionally, a T5H. In one embodiment, the vector comprises nucleic acid sequences encoding AANAT, ASMT,
20 TDC/DDC, and T5H (Figure 5). In one embodiment, the vector comprises nucleic acid sequences encoding an AANAT, and ASMT, and a TDC (Figure 6). In a particular embodiment, any one of these vectors may further comprise nucleic acid sequences encoding one or more of an L-tryptophan hydroxylase, a DDC, an SPR, a DHPR, a GCH1, a PTPS and a PCBD1.

The vector can be a plasmid, phage vector, viral vector, episome, an artificial chromosome or
25 other polynucleotide construct, and may, for example, include one or more selectable marker genes and appropriate regulatory control sequences.

Regulatory control sequences are operably linked to the encoding nucleic acid sequences, and include constitutive, regulatory and inducible promoters, transcription enhancers, transcription terminators, and the like which are well known in the art. The encoding nucleic
30 acid sequences can be operationally linked to one common expression control sequence or linked to different expression control sequences, such as one inducible promoter and one constitutive promoter.

The procedures used to ligate the various regulatory control and marker elements with the encoding nucleic acid sequences to construct the vectors of the present invention are well known to one skilled in the art (see, *e.g.*, Sambrook *et al.*, 2001, supra). In addition, methods have recently been developed for assembling of multiple overlapping DNA molecules (Gibson *et al.*, 2008) (Gibson *et al.*, 2009) (Li & Elledge, 2007), allowing, *e.g.*, for the assembly multiple overlapping DNA fragments by the concerted action of an exonuclease, a DNA polymerase and a DNA ligase.

Examples 2 and 11 describe the construction of 12,737bp BACs comprising nucleic acid sequences encoding a GCH1, a PTPS, an SPR, a TPH1, a DHPR, and a PCBD1, all under the control of a single promoter (T7 RNA polymerase). Example 2 also describes the construction of pTHB and pTHBDP vectors comprising some of these components but under the control of lac promoter. These are schematically depicted in Figures 10 and 9, respectively. Accordingly, in one embodiment, the vector of the invention may comprise (a) nucleic acid sequences encoding an L-tryptophan hydroxylase and a DDC, (b) nucleic acid sequences encoding one or more enzymes of the first and/or second THB pathways, as described in any preceding embodiment, (c) regulatory control sequences such as, *e.g.*, promoter and termination sequences, and (d) one or more marker genes. In one embodiment, the elements (with the exception of DDC) are arranged in the order shown in Figure 4, which is a schematic description of plasmid p5HTP. In one embodiment, the vector comprises the components of any one of pTHB, pTHBDP or pTRP, as described in any one of Examples 2 and 11, optionally in the same order as in pTHB, pTHBDP or pTRP, respectively. For example, the vector may comprise nucleic acid sequences corresponding to (a) an L-tryptophan hydroxylase and GCH1, PTPS, and SPR enzymes, one or more ribosomal binding sites, and T7 or lac promoter and T7–terminator, or (b) an L-tryptophan hydroxylase, PCBD1 and DHPR enzymes, one or more ribosomal binding sites, and T7 or lac promoter and T7-terminator. In one embodiment, the vector comprises the nucleic acid sequence of any one of pTHB (SEQ ID NO:51 or 110 or 150), pTHBDP (SEQ ID NO:149, pTRP (SEQ ID NO:52 or 111) or p5HTP (SEQ ID NO:61).

The Examples also describe the construction of a BAC DNA construct for THB-dependent production of melatonin comprising nucleic acid sequences encoding a TDC from rice, an AANAT and an ASMT, all under the control of T7 RNA polymerase promoters. Accordingly, in one embodiment, the vector of the invention may comprise (a) nucleic acid sequences encoding a TDC (rice), an AANAT and an ASMT, (c) regulatory control sequences such as, *e.g.*, promoter and termination sequences, and (d) one or more marker genes. In one embodiment, the elements are arranged in the order shown in Figure 6, which is a schematic description of plasmid pMELT. Also provided is a vector such as a BAC DNA construct for THB-independent production of melatonin, comprising nucleic acid sequences encoding a T5H, a

TDC/DDC, an AANAT and an ASMT, all under the control of T7 RNA polymerase or lac promoters. Accordingly, in one embodiment, the vector of the invention may comprise (a) nucleic acid sequences encoding a T5H, TDC/DDC, an AANAT and an ASMT, (c) regulatory control sequences such as, *e.g.*, promoter and termination sequences, and (d) one or more
5 marker genes. In one embodiment, the elements are arranged in the order shown in Figure 5, which is a schematic description of plasmid pMELR. In one embodiment, the vector comprises the nucleic acid sequence of any one of pMELT (SEQ ID NO:117), or pMELR (SEQ ID NO:104).

The promoter sequence is typically one that is recognized by the intended host cell. For an
10 *E.coli* host cell, suitable promoters include, but are not limited to, the lac promoter, the T7 promoter, pBAD, the tet promoter, the Lac promoter, the Trc promoter, the Trp promoter, the recA promoter, the λ (lamda) promoter, and the PL promoter. For Streptomyces host cells, suitable promoters include that of *Streptomyces coelicolor* agarase (dagA). For a *Bacillus* host cell, suitable promoters include the sacB, amyL, amyM, amyQ, penP, xylA and
15 xylB. Other promoters for bacterial cells include prokaryotic beta-lactamase (Villa-Kamaroff *et al.*, 1978, Proceedings of the National Academy of Sciences USA 75: 3727-3731), and the tac promoter (DeBoer *et al.*, 1983, Proceedings of the National Academy of Sciences USA 80: 21-25). For an *S. cerevisiae* host cell, useful promoters include the ENO-1, GAL1, ADH1, ADH2, GAP, TPI, CUP1, PHO5 and PGK promoters. Other useful promoters for yeast host cells
20 are described by Romanos *et al.*, 1992, Yeast 8: 423-488. Still other useful promoters for various host cells are described in "Useful proteins from recombinant bacteria" in Scientific American, 1980, 242: 74-94; and in Sambrook *et al.*, 2001, supra.

A transcription terminator sequence is a sequence recognized by a host cell to terminate transcription, and is typically operably linked to the 3' terminus of an encoding nucleic acid
25 sequence. Suitable terminator sequences for *E. coli* host cells include the T7 terminator region. Suitable terminator sequences for yeast host cells such as *S. cerevisiae* include CYC1, PGK, GAL, ADH, AOX1 and GAPDH. Other useful terminators for yeast host cells are described by Romanos *et al.*, 1992, supra.

A leader sequence is a non-translated region of an mRNA which is important for translation
30 by the host cell. The leader sequence is typically operably linked to the 5' terminus of a coding nucleic acid sequence. Suitable leaders for yeast host cells include *S. cerevisiae* ENO-1, PGK, alpha-factor, ADH2/GAP.

A polyadenylation sequence is a sequence operably linked to the 3' terminus of a coding nucleic acid sequence which, when transcribed, is recognized by the host cell as a signal to
35 add polyadenosine residues to transcribed mRNA. Useful polyadenylation sequences for yeast

host cells are described by Guo and Sherman, 1995, Molecular Cellular Biology 15: 5983-5990.

A signal peptide sequence encodes an amino acid sequence linked to the amino terminus of an encoded amino acid sequence, and directs the encoded amino acid sequence into the cell's secretory pathway. In some cases, the 5' end of the coding nucleic acid sequence may inherently contain a signal peptide coding region naturally linked in translation reading frame, while a foreign signal peptide coding region may be required in other cases. Useful signal peptides for yeast host cells can be obtained from the genes for *S. cerevisiae* alpha-factor and invertase. Other useful signal peptide coding regions are described by Romanos *et al.*, 1992, supra. An exemplary signal peptide for an *E.coli* host cell can be obtained from alkaline phosphatase. For a Bacillus host cell, suitable signal peptide sequences can be obtained from alpha-amylase and subtilisin. Further signal peptides are described by Simonen and Palva, 1993, Microbiological Reviews 57: 109-137.

It may also be desirable to add regulatory sequences which allow the regulation of the expression of the polypeptide relative to the growth of the host cell. Examples of regulatory systems are those which cause the expression of the gene to be turned on or off in response to a chemical or physical stimulus, including the presence of a regulatory compound. Regulatory systems in prokaryotic systems include the lac, tec, and tip operator systems. For example, one or more promoter sequences can be under the control of an IPTG inducer, initiating expression of the gene once IPTG is added. In yeast, the ADH2 system or GAL1 system may be used. Other examples of regulatory sequences are those which allow for gene amplification. In eukaryotic systems, these include the dihydrofolate reductase gene which is amplified in the presence of methotrexate, and the metallothionein genes which are amplified with heavy metals. In these cases, the respective encoding nucleic acid sequence would be operably linked with the regulatory sequence.

The choice of the vector will typically depend on the compatibility of the vector with the host cell into which the vector is to be introduced. The vectors may be linear or closed circular plasmids.

The vector may be an autonomously replicating vector, *i.e.*, a vector which exists as an extrachromosomal entity, the replication of which is independent of chromosomal replication, *e.g.*, a plasmid, an extrachromosomal element, a minichromosome, or an artificial chromosome. The vector may contain any means for assuring self-replication. Alternatively, the vector may be one which, when introduced into the host cell, is integrated into the genome and replicated together with the chromosome(s) into which it has been integrated. Furthermore, a single vector or plasmid or two or more vectors or plasmids which together

contain the total DNA to be introduced into the genome of the host cell, or a transposon may be used.

The vectors of the present invention preferably contain one or more selectable markers which permit easy selection of transformed cells. The selectable marker genes can, for example, provide resistance to antibiotics or toxins, complement auxotrophic deficiencies, or supply critical nutrients not in the culture media, and/or provide for control of chromosomal integration. Examples of bacterial selectable markers are the dal genes from *Bacillus subtilis* or *Bacillus licheniformis*, or markers which confer antibiotic resistance such as ampicillin, kanamycin, chloramphenicol, or tetracycline resistance. Suitable markers for yeast host cells are ADE2, HIS3, LEU2, LYS2, MET3, TRP1, and URA3.

The vectors of the present invention may also contain one or more elements that permit integration of the vector into the host cell genome or autonomous replication of the vector in the cell independent of the genome. For integration into the host cell genome, the vector may rely on an encoding nucleic acid sequence or other element of the vector for integration into the genome by homologous or nonhomologous recombination. Alternatively, the vector may contain additional nucleotide sequences for directing integration by homologous recombination into the genome of the host cell at a precise location(s) in the chromosome(s). To increase the likelihood of integration at a precise location, the integrational elements should preferably contain a sufficient number of nucleic acids, such as 100 to 10,000 base pairs, preferably 400 to 10,000 base pairs, and most preferably 800 to 10,000 base pairs, which have a high degree of identity with the corresponding target sequence to enhance the probability of homologous recombination. The integrational elements may be any sequence that is homologous with the target sequence in the genome of the host cell. Furthermore, the integrational elements may be non-encoding or encoding nucleotide sequences. On the other hand, the vector may be integrated into the genome of the host cell by non-homologous recombination.

For autonomous replication, the vector may further comprise an origin of replication enabling the vector to replicate autonomously in the host cell in question. The origin of replication may be any plasmid replicator mediating autonomous replication which functions in a cell. The term "origin of replication" or "plasmid replicator" is defined herein as a nucleotide sequence that enables a plasmid or vector to replicate in vivo. Examples of bacterial origins of replication are the origins of replication of plasmids pBR322, pUC19, pACYC177, and pACYC184 permitting replication in *E. coli*, and pUB1 10, pE194, pTA1060, and pAMβi permitting replication in *Bacillus*. Examples of origins of replication for use in a yeast host cell are the 2 micron origin of replication, ARS1, ARS4, the combination of ARS1 and CEN3, and the combination of ARS4 and CEN6.

More than one copy of the nucleic acid sequence encoding the L-tryptophane hydroxylase, DDC, TDC, T5H, AANAT, ASMT, SPR and a DHPR, and optionally GCH1, a PTPS, a PCBD1 may be inserted into the host cell to increase production of the gene product. An increase in the copy number of the encoding nucleic acid sequence can be obtained by integrating at least 5 one additional copy of the sequence into the host cell genome or by including an amplifiable selectable marker gene with the nucleic acid sequence where cells containing amplified copies of the selectable marker gene, and thereby additional copies of the sequence, can be selected for by cultivating the cells in the presence of the appropriate selectable agent.

Recombinant host cells

10 The present invention also provides a recombinant host cell, into which one or more vectors according to any preceding embodiment is introduced, typically via transformation, using standard methods known in the art (see, *e.g.*, Sambrook *et al.*, 2001, supra. For example, the host cell may be transformed, separately or simultaneously, with p5HTP and pMELT or pMELR. The introduction of a vector into a bacterial host cell may, for instance, be effected 15 by protoplast transformation (see, *e.g.*, Chang and Cohen, 1979, Molecular General Genetics 168: 111-115), using competent cells (see, *e.g.*, Young and Spizizen, 1961 , Journal of Bacteriology 81 : 823-829, or Dubnau and Davidoff-Abelson, 1971 , Journal of Molecular Biology 56: 209-221), electroporation (see, *e.g.*, Shigekawa and Dower, 1988, Biotechniques 6: 742-751), or conjugation (see, *e.g.*, Koehler and Thome, 1987, Journal of 20 Bacteriology 169: 5771-5278).

As described above, the vector, once introduced, may be maintained as a chromosomal integrant or as a self-replicating extra-chromosomal vector.

The transformation can be confirmed using methods well known in the art. Such methods include, for example, nucleic acid analysis such as Northern blots or polymerase chain 25 reaction (PCR) amplification of mRNA, or immunoblotting for expression of gene products, or other suitable analytical methods to test the expression of an introduced nucleic acid sequence or its corresponding gene product, including those referred to above and relating to measurement of 5HTP production. Expression levels can further be optimized to obtain sufficient expression using methods well known in the art and as disclosed herein.

30 Tryptophan production takes place in all known microorganisms by a single metabolic pathway (Somerville, R. L., Herrmann, R. M., 1983, Amino acids, Biosynthesis and Genetic Regulation, Addison-Wesley Publishing Company, U.S.A.: 301-322 and 351-378; Aida *et al.*, 1986, Bio-technology of amino acid production, progress in industrial microbiology, Vol. 24,

Elsevier Science Publishers, Amsterdam: 188-206). The recombinant microbial cell of the invention can thus be prepared from any microbial host cell, using recombinant techniques well known in the art (see, *e.g.*, Sambrook *et al.*, Molecular Cloning: A Laboratory Manual, Third Ed., Cold Spring Harbor Laboratory, New York (2001); Ausubel *et al.*, Current Protocols in Molecular Biology, John Wiley and Sons, Baltimore, Md. (1999).). Preferably, the host cell is tryptophan autotrophic (*i.e.*, capable of endogenous biosynthesis of L-tryptophan), grows on synthetic medium with suitable carbon sources, and expresses a suitable RNA polymerase (such as, *e.g.*, T7 polymerase).

The microbial host cell for use in the present invention is typically unicellular and can be, for example, a bacterial cell, a yeast host cell, a filamentous fungal cell, or an algeal cell. Examples of suitable host cell genera include, but are not limited to, *Acinetobacter, Agrobacterium, Alcaligenes, Anabaena, Aspergillus, Bacillus, Bifidobacterium, Brevibacterium, Candida, Chlorobium, Chromatium, Corynebacteria, Cytophaga, Deinococcus, Enterococcus, Erwinia, Erythrobacter, Escherichia, Flavobacterium, Hansenula, Klebsiella, Lactobacillus, Methanobacterium, Methylobacter, Methylococcus, Methylocystis, Methylomicrobium, Methylomonas, Methylosinus, Mycobacterium, Myxococcus, Pantoea, Phaffia, Pichia, Pseudomonas, Rhodobacter, Rhodococcus, Saccharomyces, Salmonella, Sphingomonas, Streptococcus, Streptomyces, Synechococcus, Synechocystis, Thiobacillus, Trichoderma, Yarrowia and Zymomonas*.

In one embodiment, the host cell is bacterial cell, *e.g.*, an *Escherichia* cell such as an *Escherichia coli* cell; a *Bacillus* cell such as a *Bacillus alkalophilus, Bacillus amyloliquefaciens, Bacillus brevis, Bacillus circulans, Bacillus clausii, Bacillus coagulans, Bacillus lautus, Bacillus lentus, Bacillus licheniformis, Bacillus megaterium, Bacillus stearothermophilus, Bacillus subtilis*, or a *Bacillus thuringiensis* cell; or a *Streptomyces* cell such as a *Streptomyces lividans* or *Streptomyces murinus* cell. In a particular embodiment, the host cell is an *E. coli* cell. In another particular embodiment, the host cell is of an *E. coli* strain selected from the group consisting of K12.DH1 (Proc. Natl. Acad. Sci. USA, volume 60, 160 (1968)), JM101, JM103 (Nucleic Acids Research (1981), 9, 309), JA221 (J. Mol. Biol. (1978), 120, 517), HB101 (J. Mol. Biol. (1969), 41, 459) and C600 (Genetics, (1954), 39, 440).

In one embodiment, the host cell is a fungal cell, such as, *e.g.*, a yeast cell. Exemplary yeast cells include *Candida, Hansenula, Kluyveromyces, Pichia, Saccharomyces, Schizosaccharomyces* and *Yarrowia* cells. In a particular embodiment, the host cell is an *S. cerevisiae* cell. In another particular embodiment, the host cell is of an *S. cerevisie* strain selected from the group consisting of *S. cerevisiae* KA31, AH22, AH22R-, NA87-11A, DKD-5D and 20B-12, *S. pombe* NCYC1913 and NCYC2036 and *Pichia pastoris* KM71.

Production of melatonin or related compounds

The invention also provides a method of producing melatonin, serotonin and/or N-acetyl-serotonin, comprising culturing the recombinant microbial cell of any preceding aspect or embodiment in a medium comprising a carbon source. The desired compound can then
5 optionally be isolated or retrieved from the medium, and optionally further purified. Importantly, using a recombinant microbial cell according to the invention, the method can be carried out without adding L-tryptophan, THB, or both, to the medium.

Also provided is a method of preparing a composition comprising one or more compounds selected from serotonin and/or N-acetyl-serotonin, comprising culturing the recombinant
10 microbial cell of any preceding aspect or embodiment, isolating and purifying the compound(s), and adding any excipients to obtain the composition.

Suitable carbon sources include carbohydrates such as monosaccharides, oligosaccharides and polysaccharides. As used herein, "monosaccharide" denotes a single unit of the general chemical formula $C_x(H_2O)_y$, without glycosidic connection to other such units, and includes
15 glucose, fructose, xylose, arabinose, galactose and mannose. "Oligosaccharides" are compounds in which monosaccharide units are joined by glycosidic linkages, and include sucrose and lactose. According to the number of units, oligosacchardies are called disaccharides, trisaccharides, tetrasaccharides, pentasaccharides etc. The borderline with polysaccharides cannot be drawn strictly; however the term "oligosaccharide" is commonly
20 used to refer to a defined structure as opposed to a polymer of unspecified length or a homologous mixture. "Polysaccharides" is the name given to a macromolecule consisting of a large number of monosaccharide residues joined to each other by glycosidic linkages, and includes starch, lignocellulose, cellulose, hemicellulose, glycogen, xylan, glucuronoxylan, arabinoxylan, arabinogalactan, glucomannan, xyloglucan, and galactomannan. Other suitable
25 carbon sources include acetate, glycerol, pyruvate and gluconate. In one embodiment, the carbon source is selected from the group consisting of glucose, fructose, sucrose, xylose, mannose, galactose, rhamnose, arabinose, fatty acids, glycerine, glycerol, acetate, pyruvate, gluconate, starch, glycogen, amylopectin, amylose, cellulose, acetate, cellulose nitrate, hemicellulose, xylan, glucuronoxylan, arabinoxylan, glucomannan, xyloglucan, lignin, and
30 lignocellulose. In one embodiment, the carbon source comprises one or more of lignocellulose and glycerol.

The culture conditions are adapted to the recombinant microbial host cell, and can be optimized to maximize production or melatonin or a related compound by varying culture conditions and media components as is well-known in the art.

For a recombinant *Escherichia coli* cell, exemplary media include LB medium and M9 medium (Miller, Journal of Experiments in Molecular Genetics, 431-433, Cold Spring Harbor Laboratory, New York, 1972), optionally supplemented with one or more amino acids. When an inducible promoter is used, the inductor can also be added to the medium. Examples
5 include the lac promoter, which can be activated by adding isopropyl-beta-thiogalactopyranoside (IPTG) and the GAL promoter, in which case galactose can be added. The culturing can be carried out a temperature of about 10 to 50 °C for about 3 to 72 hours, if desired, with aeration or stirring.

For a recombinant *Bacillus* cell, culturing can be carried out in a known medium at about 30
10 to 40 °C for about 6 to 40 hours, if desired with aeration and stirring. With regard to the medium, known ones may be used. For example, pre-culture can be carried out in an LB medium and then the main culture using an NU medium.

For a recombinant yeast cell, Burkholder minimum medium (Bostian, K. L., *et al.* Proc. Natl. Acad. Sci. USA, volume 77, 4505 (1980)) and SD medium containing 0.5% of Casamino acid
15 (Bitter, G. A., *et al.*, Proc. Natl. Acad. Sci. USA, volume 81, 5330 (1984) can be used. The pH is preferably adjusted to about 5-8. Culturing is preferably carried out at about 20 to about 40 °C, for about 24 to 84 hours, if desired with aeration or stirring.

In one embodiment, the production method further comprises adding THB exogenously to the culture medium, optionally at a concentration of 0.01 to 100 mM, such as a concentration of
20 0.05 to 10 mM, such as about 0.1 mM or 1 mM. This may be done, for example, when the recombinant host cell has been transformed with the second (regenerating) THB pathway but not the first THB pathway. In another embodiment, both L-tryptophan and THB are added exogenously, with L-tryptophan at a concentration of 0.01 to 10 g/L, optionally 0.1 to 5 g/L, such as 0.2 to 1.0 g/L. In one embodiment, no L-tryptophan is added. In another
25 embodiment, no L-tryptophan or THB is added to the medium, so that the production of melatonin or its precursors or related compounds rely on endogenously biosynthesized substrates.

Using the method for producing melatonin, serotonin or N-acetyl-serotonin according to the invention, a melatonin yield of at least about 0.5%, such as at least about 1%, such as at
30 least5%, such as at least 10%, such as at least 20%, at least 30%, at least 40%, at least 50%, at least 60%, at least 70%, at least 80% or at least 90% of the theoretically possible yield can be obtained from a suitable carbon source, such as glucose.

Isolation of melatonin, N-acetylserotonin or serotonin from the cell culture can be achieved, *e.g.*, by separating the compound from the cells using a membrane, using, for example,

centrifugation or filtration methods. The product-containing supernatant is then collected. Further purification of the desired compound can then be carried out using known methods, such as, *e.g.*, salting out and solvent precipitation; molecular-weight-based separation methods such as dialysis, ultrafiltration, and gel filtration; charge-based separation methods
5 such as ion-exchange chromatography; and methods based on differences in hydrophobicity, such as reversed-phase HPLC; and the like. In one embodiment, ion-exchange chromatography is used for purification of serotonin. An exemplary method for serotonin purification using cation-exchange chromatography is described in Chilcote (1974) (Clin Chem 20(4):421-423). In one embodiment, reverse-phase chromatography is used for
10 separation and/or purification of serotonin, N-acetylserotonin, or melatonin. An exemplary method for purification of these indolamines using reversed-phase chromatography is described in Harumi *et al.*, (1996) (J Chromatogr B 675:152-156).

Once a sufficiently pure preparation has been achieved, suitable excipients, stabilizers can optionally be added and the resulting preparation incorporated in a composition for use in
15 preparing a product such as, *e.g.*, a dietary supplement, a pharmaceutical, a cosmeceutical, or a nutraceutical. For a dietary supplement comprising melatonin, each serving can contain, *e.g.*, from about 0.01 mg to about 100 mg melatonin, such as from about 0.1 mg to about 10 mg, or about 1-5 mg, such as 2-3 mg. Emulsifiers may be added for stability of the final product. Examples of suitable emulsifiers include, but are not limited to, lecithin (*e.g.*, from
20 egg or soy), and/or mono- and di-glycerides. Other emulsifiers are readily apparent to the skilled artisan and selection of suitable emulsifier(s) will depend, in part, upon the formulation and final product. Preservatives may also be added to the nutritional supplement to extend product shelf life. Preferably, preservatives such as potassium sorbate, sodium sorbate, potassium benzoate, sodium benzoate or calcium disodium EDTA are used.

25 EXAMPLE 1

EXAMPLE 1: A Metabolic Pathway for producing 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism

This example describes the introduction of a pathway for producing 5-Hydroxy-L-tryptophan from L-tryptophan, into *E. coli*. 5-Hydroxy-L-tryptophan is derived from the native
30 metabolite L-tryptophan in one enzymatic step as shown in Figure 1. The enzyme that catalyzes this reaction is tryptophan hydroxylase (EC 1.14.16.4), which requires both oxygen and Tetrahydropterin (THB) as cofactors. Specifically, the enzyme catalyzes the conversion of L-tryptophan and THB into 5-Hydroxy-L-tryptophan and 4a-hydroxytetrahydrobiopterin (HTHB). We used TPH genes from variant organisms such as, a double truncated TPH1 from

Oryctolagus cuniculus (rabbit) having the sequence of SEQ ID NO:1 (encoded by SEQ ID NO:40), TPH2 from *Homo sapiens* having the sequence of SEQ ID NO:2, and TPH1 from *Gallus gallus* having the sequence of SEQ ID NO:6. The rationale for using the truncated form rather than the wild-type enzyme was to increase the heterologous expression and stability
5 of the enzyme by removing both the regulatory and interface domains (Moran, Daubner, & Fitzpatrick, 1998). In addition, this mutant enzyme has been shown to be soluble in *E.coli*, and have high specific activity.

THB is not native to *E.coli*, so any THB production capability needs to be added to the bacteria. A previous study reported the production of THB in *E. coli* from the native
10 metabolite Guanosine triphosphate (GTP) in a 3-enzymatic process (Yamamoto, 2003). For the synthesis of THB, the first enzymatic step is GTP cyclohydrolase I (GCH1, EC 3.5.4.16), which catalyzes the conversion of GTP and water into 7,8-dihydroneopterin 3'-triphosphate and formate. For the following examples, a GCHI that is native to *E. coli* (SEQ ID NO:41) is used, which has many aspects of its enzymatic kinetics and reaction mechanisms uncovered
15 (NARP *et al.*, 1995) (Schramek *et al.*, 2002) (Schramek & *et al.*, 2001) (Rebelo & *et al.*, 2003). The second reaction in the production of THB from GTP is a 6-pyruvoyl-tetrahydropterin synthase (PTPS, EC 4.2.3.12), which catalyzes the synthesis of 7,8-dihydroneopterin 3'-triphosphate(DHP) into 6-pyruvoyltetrahydropterin (6PTH) and triphosphate (Figure 1). For the following examples, a PTPS from *Rattus norvegicus* (Rat) is
20 used (SEQ ID NO:42), which was used in the Yamamoto (2003) study mentioned above to produce THB from GTP in *E.coli*. The final reaction in the production of THB from GTP, is the conversion of 6PTH into THB, via NADPH oxidation (Figure 1), and is carried out by the NADPH-dependent Sepiapterin reductase (SPR, EC:1.1.1.153). Similar to the PTPS enzyme above, for this example, an SPR from Rat is used (SEQ ID NO:43), which was also used in a
25 previous study to produce THB from GTP in *E.coli* (Yamamoto, 2003).

As mentioned above, when producing 5-Hydroxy-L-Tryptophan from L-Tryptophan using a TPH1, THB is converted to HTHB. Due to the high price of THB, addition to the media is not cost-efficient, thus HTHB must be converted back to THB, and for the following examples, a 2-step enzymatic process is used. The first enzymatic step is 4a-hydroxytetrahydrobiopterin
30 dehydratase (PCBD1, EC: 4.2.1.96), which catalyzes the conversion of HTHB into Dihydrobiopterin (DHB) and water. A PCBD1 from *Pseudomonas aeruginosa* is used (SEQ ID NO:44), which has been previously expressed in *E. coli*, and purified for characterized (Köster *et al.*, 1998). The second enzymatic step is a NADH-dependent dihydropteridine reductase (DHPR, EC: 1.5.1.34), which catalyzes the conversion of DHB into THB, via the oxidation of
35 NADH. For this example, a DHPR that is native to *E. coli* (SEQ ID NO:45) is used (Vasudevan *et al.*, 1988).

EXAMPLE 2: Construction of DNA constructs for producing 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism

Methods have recently been developed for assembling of multiple overlapping DNA molecules (Gibson *et al.*, 2008) (Gibson *et al.*, 2009) (Li & Elledge, 2007). One of these methods allows 5 the assembly multiple overlapping DNA fragments by the concerted action of an exonuclease, a DNA polymerase and a DNA ligase. The DNA fragments are first recessed using an exonuclease; yielding single-stranded DNA overhangs that can be specifically annealed. This assembly is then covalently joined using a DNA polymerase and DNA ligase. This method was used to assemble DNA molecules the complete synthetic 583kb genitalium genome, and 10 has also produced products as large as 900kb. For the production of 5-Hydroxy-L-tryptophan from L-tryptophan, we used this method to generate a 12,737bp BAC that contains the enzymes GCH1, PTPS, SPR, TPH1, DHPR, and PCBD1, all under the control of T7 promoter or lac promoter.

A DNA operon for the production of THB from GTP was synthesized containing SEQ ID NOS:2, 15 3, and 4 under control of the T7 promoter region (SEQ ID NO:46) or lac promoter region (SEQ ID NO:119) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon were separated by an 18bp intragenic region, which contained an optimized ribosomal binding site (SEQ ID NO:48). Furthermore, a linker region 1 (SEQ ID NO:49) was added upstream of the T7 or lac RNA polymerase promoter site, which had 20 homology to the last ~200 bases on the 3' end of PCR amplified pCC1BAC. A linker region 2 (SEQ ID NO:50) was added downstream of the T7 RNA polymerase terminator site, and had homology to the last ~200 bases on the 5' end TRP operon described below. Furthermore, the Linker regions had NotI restriction digest sites on the ends, and the entire construct was cloned into the plasmid. Thus, a final construct pTHB (SEQ ID NO:51) was generated, which 25 contained the following sequences, and in the following order: SEQ ID NO:49, 46, 41, 48, 42, 48, 43, 47, 50. In order to release the operon for the anneal/repair reaction below, 500ug of pTHB was digested, purified of salts using ethanol precipitation, and then stored at -20C.

A second DNA operon was synthesized for the production of 5-Hydroxy-L-tryptophan from L-tryptophan, in addition to regeneration of THB from HTHB. This operon contained SEQ ID NO: 30 40, 44 and 45 under control of the T7 promoter region (SEQ ID NO:46), or the lac promoter region (SEQ ID NO:119), and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon were separated by an 18bp intragenic region, which contained an optimized ribosomal binding site (SEQ ID NO:48). A linker region 2 (SEQ ID NO:50) was added upstream of the T7 RNA polymerase promoter site, which is the same 35 linker added to the plasmid pTHB, to assist in the assembly of the final plasmid. The DNA construct was cloned into the standard cloning vector pUC57 with flanking NotI restriction

digestion sites, thus allowing extraction of DNA construct when necessary. The final construct pTRP (SEQ ID NO:52) was generated, which contained the following sequences, and in the following order: SEQ ID NO: 49, 46, 40, 48, 44, 48, 45, 47, 50. As in the case with pTHB, in order to release the operon for the anneal/repair reaction below, 500ug of
5 pTRP was digested, purified of salts using ethanol precipitation, and then stored at -20°C.

In order to generate the BAC backbone for the final DNA construct, pCC1BAC (EPICENTRE) was PCR-amplified using primer A (SEQ ID NO:53), and primer B (SEQ ID NO:54), and then gel purified. Assembly reactions (80 µl) wer carried out in 250 µl PCR tubes in a thermocycler and contained 5% PEG-8000, 200 mM Tris-Cl pH 7.5, 10 mM MgCl2, 1mM DTT,
10 100 µg/ml BSA, and 4.8 U of T4 polymerase. All DNA pieces in the assembly reaction must be at equal Molar concentrations. Thus, 500ng of digested plasmids pTHB and pTRP, wer added to the reaction, in addition to 1000ng of the pCC1BAC PCR product using primers A and B. Reactions wer incubated at 37°C for a period of 10 minutes. The reactions were then incubated at 75°C for 20 minutes, cooled at -6°C/ minute to 60°C and then incubated for 30
15 minutes. Following the 30-minute incubation, the reaction was cooled at -6°C/min to 4°C and then held. The assembly reaction was followed by a repair reaction, which repairs the nicks in the DNA. The repair reaction, which was a total of 40 µl, contained 10 µl of the assembly reaction, 40 U Taq DNA ligase, 1.2 U Taq DNA Polymerase, 5% PEG-8000, 50 mM Tris-Cl pH 7.5, 10 mM MgCl2, 10 mM DTT, 25 µg/ml BSA, 200 µM each dNTP, and 1mM NAD. The
20 reaction was incubated for 15 min at 45°C, and then stored at -20°C.

A similar approach was applied for the constructions of DNA vectors for the expression of TPH genes from *Oryctolagus cuniculus* (SEQ ID NO:1, encoded by SEQ ID NO:40), *Homo sapiens* (SEQ ID NO: 2) or *Gallus gallus* (SEQ ID NO 6). A linear DNA was amplified by PCR using cloning vectors pBAD18kan (SEQ ID NO:120) as a template using primers Lin-pBAD-FWD
25 (SEQ ID NO:121) and Lin-pBAD-REV (SEQ ID NO:122). The TPH genes were amplified using the primers TPH-FWD (SEQ ID NO:123) and TPH-REV (SEQ ID NO:124). The PCR amplified DNA fragments were assembled using the above mentioned approach.

A similar approach was applied for the construction of DNA vector for the expression of GCH1, PTPS, SPR, TPH1 genes (SEQ ID NOS:41, 42 and 43) for the synthesis and recycling
30 of THB. A DNA operon for the production of THB from GTP was amplified using primers THB-FWD (SEQ ID NO: 133) and THB-REV (SEQ ID NO: 134) using p5HTP as the template, and the vector backbone was amplified using pTH19cr (SEQ ID NO: 135) as the template using primers pTH19cr-Lin-FWD (SEQ ID NO:136) and pTH19cr-Lin-REV (SEQ ID NO:137). The PCR fragments were assembled using the above mentioned approach, and the final
35 constructed plasmid was designated pTHB (SEQ ID NO:150, FIG. 10), where the THB synthetic pathway genes are under the control of lac promoter.

A similar approach was applied for the construction of DNA vector for the expression of PCBD1, and DHPR genes (SEQ ID NO: 29 and 34, respectively). The genes were PCR amplified using primers DP-FWD (SEQ ID NO:138) and DP-REV (SEQ ID NO:139) using p5HTP as the template. The vector backbone was PCR amplified using pUC18 (SEQ ID NO:140) as the template using primers LinPUC18-FWD (SEQ ID NO:141) and LinPUC18-REV(SEQ ID NO:142). The linearized PCR products were assembled using the above mentioned approach, and the final constructed plasmid was designated pDP, where the PCBD1 and DHPR genes are under the control of lac promoter.

A similar approach was applied for the construction of DNA vector for the expression of the GCH1, PTPS, SPR, TPH1 genes and the PCBD1 and DHPR genes. The operon containing the lac promoter, PCBD1 and DHPR genes was PCR amplified using the pDP as the template and using the primers lac-DP-FWD (SEQ ID NO:143) and lac-DP-REV (SEQ ID NO:144). The operon containing the lac promoter, GCH1, PTPS, SPR, TPH1 genes was PCR amplified using the pTHB as the template and using primers Pa-THB-FWD (SEQ ID NO:146) and Pa-THB-REV (SEQ ID NO:147). The vector backbone was amplified using pBAD33 (SEQ ID NO:148) as the template and primers Lin-pBAD-FWD (SEQ ID NO:121) and Lin-pBAD-REV (SEQ ID NO:122). The amplified linear DNA fragments were assembled using the above mentioned protocol, and the final constructed plasmid was designated pTHBDP (SEQ ID NO:149, Fig 9).

EXAMPLE 3: Transformation of E. coli cells with DNA constructs for producing 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism

In a 2mm cuvette, five microliters of the repair reaction was electroporated into 50 uL of EPI300 *E. coli* cells (EPICENTRE) using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells were transferred to 500uL SOC media (2% peptone, 0.5% Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 2 hours. Cells were then plated onto LB agar supplemented with 15µg/ml chloramphenicol or 50 µg/ml kanamycine depending on the vector backbone sequence, and incubated overnight at 37°C. Yields typically depend on the size of overlapping regions, the size of the final construct, and the number of DNA pieces that are being assembles. Specifically, shorter overlapping regions, larger final constructs, and higher number of assembly pieces all lead to a decrease in yields. In this assembly, there were 3 DNA pieces being assembled with ~60-200bp overlapping regions. It is best to keep the overlapping regions 200bps or more, however, 60pbs is sufficient but leads to low yields. In addition, the final construct was only12,737bps, which is relatively small for this methodology, and thus has little effect on the efficiency and yields. The following day, 10 colonies are selected, and grown overnight in LB medium (1% peptone, 0.5% yeast extract,

and 0.5% NaCl) supplemented with 15μg/ml chloramphenicol or 50 μg/ml of kanamycin depending on the vector backbone sequence. BAC DNA is extracted from each overnight culture using a GeneJET Plasmid Miniprep Kit (Fermentas). BAC DNA constructs were digested with the restriction enzyme SalI (NEB) and subjected to agarose gel electrophoresis using mini sub cell (Bio-Rad) for 30 minutes at 100V. A 7006bp band (pCC1BAC) and 5731bp band (THB-TRP fragment) were observed, ensuring the correct assembly of the DNA construct. In order to confirm correct assembly, ~500bp regions surround the overlapping regions were PCR amplified. The overlapping region of pCC1BAC and THB operon was amplified with primers C (SEQ ID NO:55) and D (SEQ ID NO:56), the assembly region of the THB and TRP operon was amplified with primers E (SEQ ID NO:57) and F (SEQ ID NO:58), and the assembly region of the TRP operon and pCC1BAC was amplified using primers G (SEQ ID NO:59) and H (SEQ ID NO:60). The final DNA construct for producing 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism was thus confirmed and designated p5HTP (Figure 4) (SEQ ID NO:61).

DNA constructs based on pBAD18kan extracted from overnight culture were digested with BamHI and subjected to agarose gel electrophoresis. The clones with expected band sizes were sequenced and confirmed. The plasmid harboring TPH2 from *Homo sapiens* was designated pTPH-H (SEQ ID NO:125), the plasmid harboring TPH1 from *Gallus gallus* was designated pTPH-G (SEQ ID NO:126), and the plasmid harboring TPH1 from *Oryctolagus cuniculus* was designated pTPH_OC (SEQ ID NO:127).

EXAMPLE 4: Transformation of T7 RNA polymerase harboring cells with p5HTP, and fermentation for the production of 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism

The p5HTP DNA construct was then introduced into an *E.coli* host cell harboring the T7 RNA polymerase. The strain chosen was the Origami B (DE3) (EMD Chemicals), which contains a T7 RNA polymerase under the control of an IPTG inducer. Origami B (DE3) strains also harbor a deletion of the lactose permease (lacY) gene, which allows uniform entry of IPTG into all cells of the population. This produces a concentration-dependent, homogeneous level of induction, and enables adjustable levels of protein expression throughout all cells in a culture. By adjusting the concentration of IPTG, expression can be regulated from very low levels up to the robust, fully induced levels commonly associated with T7 RNA polymerase expression. In addition, Origami B(DE3) strains have also been shown to yield 10-fold more active protein than in another host even though overall expression levels were similar.

Origami B(DE3) strains containing p5HTP were evaluated for the ability to produce 5HTP. Given that an industrial process would require the production of chemicals from low-cost carbohydrate feedstocks such as glucose, it is necessary to demonstrate the production of 5HTP from a native compound in *E.coli*. In this example, L-Tryptophan was used as the
5 starting metabolic intermediate compound, and the metabolic pathways for the production of L-Tryptophan are native to *E.coli,* and well-known. Thus, the next set of experiments was aimed to determine whether endogenous L-tryptophan produced by the cells during growth on glucose could fuel the 5HTP pathway. Cells were grown aerobically in M9 minimal medium (6.78 g/L, Na_2HPO_4, 3.0 g/L KH_2PO_4, 0.5 g/L NaCl, 1.0 g/L NH_4 Cl, 1 mM $MgSO_4$, 0.1 mM
10 $CaCl_2$) supplemented with 10 g/L glucose, 1 g/L L-tryptophan, 100 mM 3-(N-morpholino)propanesulfonic acid (MOPS) to improve the buffering capacity, and the 15 mg/L chloramphenicol. In order to determine the optimal Induction level, growth experiments were done with IPTG concentrations of 1000, 100, and 10 µM. IPTG was added when the cultures reached an OD600 of approximately 0.2, and samples were taken for 5HTP analysis at 12
15 hours following induction. Significant amounts of 5HTP were detected at all IPTG concentration, indication that the basal level of expression is quite high. Maximum 5HTP concentrations of almost 1 mg/L were achieved when using 1 mM IPTG induction.

EXAMPLE 5: Knocking out tnaA gene in E. coli to prevent from 5-hydroxytryptophan degradation

20 This Example shows that tryptophanase, apart from degrading tryptophane to indole, can also degrade 5-hydroxytryptophan to 5-hydroxyindole (Figure 7):

E. coli MG1655 wild type strain was streaked out on a LB culture plate. After incubating overnight at 37 °C, a single colony was picked for the inoculation of 5 ml of LB medium supplemented with 1.0 mM of 5-hydroxytryptophan in a 14 ml falcon tube, and the cultures
25 were incubated at 37 °C with a shaking speed of 250 rpm. After 24 hours, a significant portion of 5-hydroxytryptophan was degraded into 5-hydroxyindole, and after 96 hours, all the 5-hydroxytryptophan was degraded (Figure 8a).

We knocked out the *tna*A gene using the Datsenko-Wanner method (Datsenko and Wanner 2000). A replacement DNA fragment was PCR amplified using the primers H1-P1-tnaA (SEQ
30 ID NO:128) and H2-P2-tnaA (SEQ ID NO:129), and pKD4 as template as indicated in the referenced article. The PCR product was digested with DpnI, and then purified. As indicated by the referenced article, the purified DNA product for gene knockout was transformed into *E. coli* MG1655 competent cell carrying a helper plasmid pKD46 expresses λ-red recombinase. The transformants were spread out on kanamycin LB culture plates, and leave at 30 °C
35 overnight. The colonies that grew up on kanamycin plates were restreaked on fresh LB plates

containing kanamycin, and the isolated colonies were checked by colony PCR with primers tnaA-CFM-FWD (SEQ ID NO:130) and K1 (SEQ ID NO:132) to confirm gene knockout.

The confirmed knockout strain *E. coli* MG1655 tnaA::FRT-Kan-FRT was cultured in LB medium supplemented with 50 µg/ml of kanamycin, and then washed with cold glycerol to prepare
5 competent cells. Then another helper plasmid pCP20 was transformed into the knockout strain and the transformants were spread out on LB culture plates with ampicillin as selection marker. The plates were kept at 30 °C till colonies grow up on it. Selected single colonies were grown in LB medium supplemented with ampicillin overnight at 30 °C. Cell pellets were collected by centrifugation and washed twice with fresh LB medium. Then the cell pellets
10 were resuspended in LB medium and cultured at 37 °C for 3 hours so that it may lose the helper plasmid pCP20. After that the cell pellets were collected, washed, and then spread out on LB plates. After incubating at 37 °C overnight, single colonies were restreaked out on LB, LB plus kanamycin, and LB plus ampicillin plates. The colonies that grew on LB plates, but not on LB plus kanamycin or LB plus ampicillin plates, were selected for colony PCR
15 confirmation with tnaA-CFM-FWD (SEQ ID NO:130) and tnaA-CFM-REV (SEQ ID NO:131).

The confirmed *E. coli* MG1655 *tna*A$^-$ mutant strain was then further tested. The strain was inoculated in LB medium supplemented with 1.0 mM of 5-hydroxytryptophan, and then incubated at 37 °C with a shaking speed of 250 rpm. As a control, *E. coli* MG1655 wild type strain was cultured under the same condition. Samples were taken after 48 hours. The
20 results showed that the 5-hydroxytryptophan was completed degraded into 5-hydroxyindole in the culture of wild type strain, while 5-hydroxytryptophan was stable in the culture of *tna*A$^-$ mutant strain (Fig 8b).

EXAMPLE 6: Transformation of E. coli MG1655 *tna*A$^-$ mutant *cell with pTPH-H or pTPH-G together with pTPR, and fermentation for the production of 5-Hydroxy-L-tryptophan*

25 The constructed pTPH-H, pTPH_OC or pTPH-G were co-transformed with pTPR into *E. coli* MG1655 *tna*A$^-$ mutant strain, and the cells were tested for 5-hydroxy-L-tryptophan production in shake flask cultures.

Cell culture conditions. A single colony of the *E. coli* MG1655 *tna*A$^-$ mutant strain carrying the plasmids pTPR and pTPH-H or pTPH-G was used for the inoculation of 5 ml LB medium with
30 15 µg/ml of chloramphenicol and 50 µg/ml of kanamycin. The culture was incubated in a shaker at 37 ºC and a rotation speed at 200 rpm. The cell pellets were collected at exponential phase by centrifugation, and washed twice with fresh LB medium, and then resuspended in 50 ml of LB medium supplemented with 5 g/L of glycerol and 0.2 g/L of

tryptophan. The culture mediums were prepared separately, and 100 µl of resuspended preculture cell solution was used for the inoculation of 5 ml fresh culture medium. The culture tubes were incubated in a shaker at 37 ºC and a rotation speed at 200 rpm. After the cultures grow to OD600 about 0.5, 1 mM of IPTG was added to induce protein expression.
5 Culture broth was collected 24 hours after induction and centrifuged at 8000 rpm for 5 min. Supernatants were collected for HPLC measurements.

HPLC conditions. A Ultimate 3000 HPLC system (Dionex, now Thermo-fisher) was used for this assay. The mobile phase of the HPLC measurement was 80% 10 mM NH_4COOH adjusted to pH 3.0 with HCOOH and 20% acetonitrile. The flow rate was set at 1.0 ml/min. A
10 Discovery HS F5 column (Sigma) was used for the separation, and an UV detection at 254 nm was used for 5-hydroxytryptophan detection. The column temperature was set at 35 ºC. The standard 5-hydroxytryptophan (Sigma, >98% purity) was used to establish a standard curve for 5HTP concentrations.

Results

15 Using *tna*A$^-$ cells, the 5-hydroxytryptophan concentrations measured in the cultures ranged from 0.15 mM to 0.9 mM. The highest production was observed with cells harboring plasmid expressing TPH1 from *Oryctolagus cuniculus,* producing 0.9 mM of 5-hydroxy-L-tryptophan in the cultures.

Table 1 shows the results of a preliminary experiment using *E. coli* MG1655 cells (without
20 *tna*A knock-out) transformed with pTPH-H. Since the analyitcal method used was not at the time fine-tuned, the results were interpreted as qualitative rather than quantitative. The data showed, however, that adding THB did not help 5HTP production, and that the pathway for 5HTP production was functional.

TABLE 1 - Summarized HPLC Data

Culture code	Medium	5HTP (mM)
A	M9 + 10 g/L Glc + 1.0 g/L Trp + MOPS	0.66
B	M9 + 5 g/L Glc	0.28
C	M9 + 5 g/L Glc + 0.2 g/L Trp	0.42
D	M9 + 5 g/L Glc + 1 mM THB	0.13
E	M9 + 5 g/L Glc + 0.2 g/L Trp + 1 mM THB	0.39
F	LB + 0.2 g/L Trp	1.45
G	LB + 5 g/L Glc + 0.2 g/L Trp	1.42
H	LB + 0.2 g/L Trp + 1 mM THB	1.24

I	LB + 5 g/L Glc + 0.2 g/L Trp + 1mM THB	1.89
J	LB + 5 g/L Glc	2.44
K	LB + 5 g/L Glc + 1 mM THB	1.51
M9	M9 + 5 g/L Glc	0.12
MG1655	LB + 5g/L Glc	0.02

EXAMPLE 7: Exemplary Metabolic Pathway for producing Melatonin from L-tryptophan in a microorganism, using a Tetrahydropterin independent pathway.

This example describes an exemplary pathway for producing Melatonin from L-tryptophan, in
5 *E.coli*, using a THB independent pathway. Melatonin can be derived from the native metabolite L-tryptophan in a four-step enzymatic pathway, which is shown in Figure 2. The first enzyme in the metabolic pathway is the tryptophan decarboxylase (TDC, EC 4.1.1.28), which converts L-tryptophan to tryptamine and carbon dioxide. For this example, the TDC from *Catharanthus roseus* TDC is used (SEQ ID NO:86) (GenBank accession no. J04521). The
10 *C. roseus* enzyme has previously been expressed in *E.coli*, and was shown to have significant *in vivo* activity (Sangkyu *et al.*, 2011). Following the decarboxylation of L-tryptophan, the second reaction is a tryptamine 5-hydroxylase (T5H, EC 1.14.16.4), which is a cytochrome P450 enzyme, and catalyzes the synthesis of tryptamine into serotonin, via NADPH oxidation. Previous studies were unable to produce an active native T5H within *E.coli*, and thus
15 generated an active T5H by constructing a number of T5H mutants from *Oryza sativa* (rice) and testing their *in vivo* T5H activity in *E.coli* (Sangkyu *et al.*, 2011). The T5H enzyme used in this example, which has *in vivo* functionality in *E.coli* (Sangkyu *et al.*, 2011), has the first 37 amino acids deleted from the N-terminal, and a glutathione S transferase (GST) translationally fused with the truncated N-terminus (SEQ ID NO:87). The third reaction in
20 the production of Melatonin from L-tryptophan is serotonin acetyltransferase (AANAT, EC 2.3.1.87), which catalyzes conversion of acetyl-CoA and serotonin, to CoA and N-Acetyl-Serotonin. For this example, an AANAT from the single celled green alga *Chlamydomonas reinhardtii* is used (SEQ ID NO:88), which retains function after being expressed and extracted from *E.coli* (Okazaki *et al.*, 2009). The last reaction for the production of
25 Melatonin from L-tryptophan is acetylserotonin O-methyltransferase (ASMT, EC 2.1.1.4), which catalyzes the conversion of N-acetyl-serotonin and S-adenosyl-L-methionine (SAM) to Melatonin and S-adenosyl-L-homocysteine (SAH). About 20% of the L-methionine pool in *E.coli* is used as a building block of proteins, with the remaining converted to S-adenosyl-L-methionine (SAM), the major methyl donor in the cell. When SAM donates its methyl group
30 in the ASMT reaction, it is converted to SAH. SAH can then be recycled back to SAM via the S-adenosyl-L-methionine cycle, which is native and constitutively expressed in *E.coli.* For this example, an ASMT from *Oryza sativa* (rice) is used (SEQ ID NO:89), which has

previously been expressed in *E.coli* and had significant *in vivo* ASMT activity (Kang *et al.*, 2011).

EXAMPLE 7: Construction of an exemplary DNA construct (pMEL) for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway.

5 For the production of 5 Melatonin from L-tryptophan in a microorganism, using a THB independent pathway, the method described in Example 2 is used to generate a 16,821bp BAC that contains the enzymes TDC, T5H, AANAT, and ASMT, all under the control of T7 RNA polymerase.

A DNA operon for the production of Serotonin from Tryptophan is synthesized containing SEQ 10 ID NO 1 and 2, under control of the T7 promoter region (SEQ ID NO:46) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon are separated by an 18bp intragenic region, which contains an optimized ribosomal binding site (SEQ ID NO:48). Furthermore, a genome integration region (sce1/E.coli gDNA 1)(SEQ ID NO:90), followed by a linker region 3 (SEQ ID NO:91) is added upstream of the T7 RNA 15 polymerase promoter site, which has homology to the last ~200 bases on the 3' end of PCR amplified pCC1BAC. A linker region 4 (SEQ ID NO:92) is added downstream of the T7 RNA polymerase terminator site, and has homology to the last ~200 bases on the 5' end TRP operon described below. The DNA construct is cloned into the standard cloning vector pUC57 with flanking FseI restriction digestion sites, thus allowing extraction of DNA construct when 20 necessary. The final construct pSER (SEQ ID NO:93) is generated, which contains the following sequences, and in the following order: SEQ ID NO:91, 90, 46, 86, 48, 87, 47, 92. In order to release the operon for the anneal/repair reaction below, 500 µg of pSER is digested with FseI, purified of salts using ethanol precipitation, and then stored at -20C.

A second DNA operon is synthesized for the production of Melatonin from Serotonin, in order 25 to complete the synthesis of Melatonin production from Serotonin. This operon contains SEQ ID NO:88 and 89 under control of the T7 promoter region (SEQ ID NO:46) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon are separated by an 18bp intragenic region, which contains an optimized ribosomal binding site (SEQ ID NO:48). A linker region 4 (SEQ ID NO:92) is added upstream of the T7 RNA 30 polymerase promoter site, which is the same linker added to the plasmid pSER, and will assist in the assembly of the final plasmid. Furthermore, a genome integration region (sce1/E.coli gDNA 2)(SEQ ID NO:94) is added downstream of the T7 terminator. The DNA construct is cloned into the standard cloning vector pUC57 with flanking FseI restriction digestion sites, thus allowing extraction of DNA construct when necessary. The final

construct pASM (SEQ ID NO:95) is generated, which contains the following sequences, and in the following order: SEQ ID NO:92, 46, 88, 48, 89, 47, 94. As in the case with pSER, in order to release the operon for the anneal/repair reaction below, 500ug of pASM is digested with FseI, purified of salts using ethanol precipitation, and then stored at -20C.

5 In order to generate the BAC backbone for the final DNA construct, pCC1BAC (EPICENTRE) is PCR-amplified using primer MEL_BAC_F (SEQ ID NO:96), and primer MEL_BAC_R (SEQ ID NO:97), and then gel purified. Assembly reactions (80 µl) are carried out in 250 µl PCR tubes in a thermocycler and contain 5% PEG-8000, 200 mM Tris-Cl pH 7.5, 10 mM MgCl2, 1mM DTT, 100 µg/ml BSA, and 4.8 U of T4 polymerase. All DNA pieces in the assembly 10 reaction must be at equal Molar concentrations. Thus, 500ng of digested plasmids pSER and pASM, are added to the reaction, in addition to 1000ng of the pCC1BAC PCR product using primers A and B. Reactions are incubated at 37°C for a period of 10 minutes. The reactions is then incubated at 75°C for 20 minutes, cooled at -6°C/ minute to 60°C and then incubated for 30 minutes. Following the 30-minute incubation, the reaction is cooled at -6°C/min to 4°C 15 and then held. The assembly reaction is followed by a repair reaction, which repairs the nicks in the DNA. The repair reaction, which is a total of 40 µl, contains 10 µl of the assembly reaction, 40 U Taq DNA ligase, 1.2 U Taq DNA Polymerase, 5% PEG-8000, 50 mM Tris-Cl pH 7.5, 10 mM MgCl2, 10 mM DTT, 25 µg/ml BSA, 200 µM each dNTP, and 1mM NAD. The reaction is incubated for 15 min at 45°C, and then stored at -20°C.

20 *EXAMPLE 8: Transformation of E. coli cells with exemplary DNA construct for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway.*

In a 2mm cuvette, five microliters of the repair reaction is electroporated into 50 uL of EPI300 *E. coli* cells (EPICENTRE) using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells are transferred to 500uL SOC media (2% peptone, 0.5% 25 Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 2 hours. Cells are then plated onto LB agar supplemented with 15µg/ml chloramphenicol, and incubated overnight at 37°C. Yields are typically dependent on the size of overlapping regions, the size of the final construct, and the number of DNA pieces that are being assembles. Specifically, shorter overlapping regions, larger final 30 constructs, and higher number of assembly pieces all lead to a decrease in yields. In this assembly, there are 3 DNA pieces being assembled with ~200bp overlapping regions. It is best to keep the overlapping regions 200bps or more for high yields. In addition, the final construct is only 16,821bps, which is relatively small for this methodology, and thus has little effect on the efficiency and yields. The following day, 10 colonies are selected, and grown 35 overnight in LB medium (1% peptone, 0.5% yeast extract, and 0.5% NaCl) supplemented

with 25μg/ml Kanamycin. BAC DNA is extracted from each overnight culture using a GeneJET Plasmid Miniprep Kit (Fermentas). BAC DNA constructs are digested with the restriction enzyme SceI (NEB) and subjected to agarose gel electrophoresis using mini sub cell (Bio-Rad) for 30 minutes at 100V. A 7400bp band (pCC1BAC) and ~9400bp band (SER-ASM
5 fragment) is observed, ensuring the correct assembly of the DNA construct. Also, In order to confirm correct assembly, ~500bp regions surrounding the overlapping regions are PCR amplified. The overlapping region of pCC1BAC and SER operon is amplified with primers LEFT_BAC_FORWARD (SEQ ID NO:98) and LEFT_BAC_REVERSE (SEQ ID NO:99), the assembly region of the SER and ASM operons is amplified with primers CENTER_FORWARD
10 (SEQ ID NO:100) and CENTER_REVERSE (SEQ ID NO:101), and the assembly region of the ASM operon and pCC1BAC is amplified using primers RIGHT_BAC_FORWARD (SEQ ID NO:102) and RIGHT_BAC_REVERSE (SEQ ID NO:103). The final DNA construct for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway is thus confirmed and designated pMEL (Figure 5) (SEQ ID NO:104).

15 *EXAMPLE 9: Genome integration of exemplary DNA construct (SER-ASM fragment) for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway.*

The exemplary DNA construct (SER-ASM fragment) for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway is then integrated into the
20 bacterial genome, using a modified version of a genome integration method (Herring *et al.*, 2003). Specifically, Origami B (DE3) cells are grown at 37°C to an OD600 of 0.6 and then made electrocompetent by concentrating 100-fold and washing three times with ice-cold 10% glycerol. The cells are then electroporated with 100 ng of plasmid pACBSR, which has the ability of simultaneous arabinose-inducible expression of I-SceI and bacteriophage λ red
25 genes (c, b, and exo). In a 2mm cuvette, 2 microliters of the pACBSR is electroporated into 50 uL of Origami B (DE3) *E. coli* cells using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells are transferred to 500uL SOC media (2% peptone, 0.5% Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 1 hour. Cells are then plated onto LB agar supplemented with 35μg/ml
30 chloramphenicol, and incubated overnight at 37°C. Origami B (DE3) containing the pACBSR plasmid are then made electrocompetent in the same manner as above, and then electroporated with pMEL. Directly following the electroporation, cells are transferred to 500uL SOC and incubated at 37°C for 1 hour. Cells are then plated onto LB agar supplemented with 35μg/ml chloramphenicol and 50μg/ml Kanamycin, and incubated
35 overnight at 37°C. The following day, individual colonies are grown at 37°C for 2h in 2mL of LB medium with 35μg/ml chloramphenicol and 50μg/ml Kanamycin to maintain the pMEL and

pACBSR. Two milliliters of LB containing 1% arabinose, in addition to 35µg/ml chloramphenicol and 50µg/ml Kanamycin, are added to the culture to induce the expression of I-SceI and bacteriophage λ red genes (c, b, and exo) from the pACBSR plasmid. The cells are further incubated 2 more hours at 37°C, which allows cleavage at the I-SceI site and red
5 recombination between homologous regions of the digested pMEL and the bacterial genome. Following the incubation, serial dilutions are spread on agar plates containing kanamycin, and 1% arabinose, and incubated overnight. In order to confirm correct integration, 10 colonies are chosen and the genomic DNA extracted. The genomic DNA is subjected to PCR using primers surrounding the genomic integration site of the SER-ASM fragment. For the upstream
10 region, primers used are primers 1MEL_INT_FOR (SEQ ID NO:105) and 1MEL_INT_REV (SEQ ID NO:106), and for the downstream integration site, primers 2MEL_INT_FOR (SEQ ID NO:107) and 2MEL_INT_REV (SEQ ID NO:108) are used.

Cells with confirmed integration of the SER-ASM fragment are then grown aerobically in M9 minimal medium (6.78 g/L, Na_2HPO_4, 3.0 g/L KH_2PO4, 0.5 g/L NaCl, 1.0 g/L NH4Cl, 1 mM
15 $MgSO_4$, 0.1 mM $CaCl_2$) supplemented with 10 g/L glucose, 1g/L L-tryptophan. In order to determine the optimal Induction level, growth experiments are done with IPTG concentrations of 1000, 100, and 10 µM. IPTG is added when the cultures reached an OD600 of approximately 0.2, and samples are taken for Melatonin analysis at 12 hours following induction.

20 *EXAMPLE 10: Exemplary Metabolic Pathway for producing Melatonin from L-tryptophan in a microorganism, using a THB dependent pathway.*

This example describes an exemplary THB dependent pathway for producing Melatonin from L-tryptophan, in *E.coli*. When THB is available as a cofactor, Melatonin can be derived from the native metabolite L-tryptophan in a four enzymatic pathway, which is shown in Figure 1.
25 The first enzyme in the metabolic pathway catalyzes the conversion of L-tryptophan, into 5-Hydroxy-L-tryptophan. This reaction is catalysed by tryptophan hydroxylase (TPH1, EC 1.14.16.4), which requires both oxygen and THB as cofactors. Specifically, the enzyme catalyzes the conversion of L-tryptophan (Schramek *et al.*, 2001), oxygen, and THB, into 5-Hydroxy-L-tryptophan and 4a-hydroxytetrahydrobiopterin (HTHB). In this example, for the
30 production of 5-Hydroxy-L-tryptophan from L-tryptophan, a double truncated TPH1 from *Oryctolagus cuniculus* (rabbit) encoded by SEQ ID NO:40 was used, which is a mutant protein containing only the catalytic core of TPH1. The rationale for using the truncated form rather then the wild type enzyme is to increase the heterologous expression and stability of the enzyme by removing both the regulatory and interface domains (Moran, Daubner, &

Fitzpatrick, 1998). In addition, this mutant enzyme has been shown to be soluble in *E.coli*, and have high specific activity.

The second enzyme in the metabolic pathway that produces Melatonin from L-tryptophan is the tryptophan decarboxylase (TDC, EC 4.1.1.28), which in some cases can function as a DDC so as to convert 5-Hydroxy-L-tryptophan to serotonin and carbon dioxide. For this example, the TDC from *Oryza sativa* (rice) is used (SEQ ID NO:109), since this enzyme was previously expressed in *E.coli*, and shown to have significant *in vivo* ability to convert 5-Hydroxy-L-tryptophan to serotonin (Park *et al.*, 2008).

The third reaction in the THB dependent production of Melatonin from L-tryptophan is serotonin acetyltransferase (AANAT, EC 2.3.1.87), which catalyzes conversion of acetyl-CoA and serotonin, to CoA and N-Acetyl-Serotonin. For this example, an AANAT from the single celled green alga *Chlamydomonas reinhardtii* is used (SEQ ID NO:88), which retained function after being expressed and extracted from *E.coli* (Okazaki *et al.*, 2009).

The last reaction for the production of Melatonin from L-tryptophan is acetylserotonin O-methyltransferase (ASMT, EC 2.1.1.4), which catalyzes the conversion of N-acetyl-serotonin and S-adenosyl-L-methionine (SAM) to Melatonin and S-adenosyl-L-homocysteine (SAH). About 20% of the L-methionine pool in *E.coli* is used as a building block of proteins, with the remaining converted to S-adenosyl-L-methionine (SAM), the major methyl donor in the cell. When SAM donates its methyl group in the ASMT reaction, it is converted to SAH. SAH can then be recycled back to SAM via the S-adenosyl-L-methionine cycle, which is native and constitutively expressed in *E.coli.* For this example, an ASMT from *Oryza sativa* (rice) is used (SEQ ID NO:89), which has previously been expressed in *E.coli* and had significant *in vivo* ASMT activity (Kang *et al.*, 2011).

THB is not native to *E.coli*, so the production capability needs to be added to the bacteria. A previous study has already accomplished the production of THB in *E.coli*, and they were able to produce it from the native metabolite Guanosine triphosphate (GTP) in a 3-enzymatic process (Yamamoto, 2003). For the synthesis of THB, the first enzymatic step is GTP cyclohydrolase I (GCHI, EC 3.5.4.16), which catalyzes the conversion of GTP and water into 7,8-dihydroneopterin 3'-triphosphate and formate. For this example, a GCHI that is native to *E.coli* (SEQ ID NO:41) is used, which has many aspects of its enzymatic kinetics and reaction mechanisms uncovered (NARP *et al.*, 1995) (Schramek *et al.*, 2002) (Schramek *et al.*, 2001) (Rebelo *et al.*, 2003). The second reaction in the production of THB from GTP is a 6-pyruvoyl-THB synthase (PTPS, EC 4.2.3.12), which catalyzes the synthesis of 7,8-dihydroneopterin 3'-triphosphate(DHP) into 6-pyruvoylTHB (6PTH) and triphosphate (Figure 3). For this example, a PTPS from *Rattus norvegicus* (Rat) is used (SEQ ID NO:42), which

was used in a study mentioned above to produce THB from GTP in *E.coli*. The final reaction in the production of THB from GTP, is the conversion of 6PTH into THB, via NADPH oxidation (Figure 3), and is carried out by the NADPH-dependent Sepiapterin reductase (SPR, EC:1.1.1.153). Similar to the PTPS enzyme above, for this example, an SPR from Rat is used
5 (SEQ ID NO:43), which was also used in a previous study to produce THB from GTP in *E.coli*.

As mentioned above, when producing 5-Hydroxy-L-Tryptophan from L-Tryptophan using a TPH1, THB is converted to HTHB. Due to the high price of THB, addition to the media is not ideal, thus HTHB must be converted back to THB, and for this example, a 2 enzymatic process is used. The first enzymatic step is 4a-hydroxytetrahydrobiopterin dehydratase
10 (PCBD1, EC:4.2.1.96), which catalyzes the conversion of HTHB into Dihydrobiopterin(DHB) and water. A PCBD1 from *Pseudomonas aeruginosa* is used (SEQ ID NO:44), which has been previously expressed in *E.coli*, and purified for characterized (Köster *et al.*, 1998). The second enzymatic step is a NADH-dependent dihydropteridine reductase (DHPR, EC:1.5.1.34), which catalyzes the conversion of DHB into THB, via the oxidation of NADH.
15 For this example, a DHPR that is native to *E.coli* (SEQ ID NO:45) is used (Vasudevan *et al.*, 1988).

EXAMPLE 11: Construction of an exemplary DNA construct for producing 5-Hydroxy-L-tryptophan from L-tryptophan in a microorganism.

A DNA operon for the production of THB from GTP is synthesized containing SEQ ID NO:41,
20 42, and 43 under control of the T7 promoter region (SEQ ID NO:46) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon are separated by an 18bp intragenic region, which contains an optimized ribosomal binding site (SEQ ID NO:48). Furthermore, a linker region 3 (SEQ ID NO:91) is added upstream of the T7 RNA polymerase promoter site, which has homology to the last ~200 bases on the 3' end of
25 PCR amplified pCC1BAC. A linker region 4 (SEQ ID NO:92) is added downstream of the T7 RNA polymerase terminator site, and has homology to the last ~200 bases on the 5' end TRP operon described below. The DNA construct is cloned into the standard cloning vector pUC57 with flanking NotI restriction digestion sites, thus allowing extraction of DNA construct when necessary. The final construct pTHBb (SEQ ID NO:110) is generated, which contains the
30 following sequences, and in the following order: SEQ ID NO 91, 46, 41, 48, 42, 48, 43, 47, 50. In order to release the operon for the anneal/repair reaction below, 500ug of pTHBb is digested, purified of salts using ethanol precipitation, and then stored at -20C.

A second DNA operon is synthesized for the production of 5-Hydroxy-L-tryptophan from L-tryptophan, in addition to regeneration of THB from HTHB. This operon contains SEQ ID NO

40, 44, and 45 under control of the T7 promoter region (SEQ ID NO:46) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon are separated by an 18bp intragenic region, which contains an optimized ribosomal binding site (SEQ ID NO:48). A linker region 4 (SEQ ID NO:92) is added upstream of the T7 RNA
5 polymerase promoter site, which is the same linker added to the plasmid pTHBb, and will assist in the assembly of the final plasmid. The DNA construct is cloned into the standard cloning vector pUC57 with flanking NotI restriction digestion sites, thus allowing extraction of DNA construct when necessary. The final construct pTRPb (SEQ ID NO:111) is generated, which contains the following sequences, and in the following order: SEQ ID NO:91, 46, 40,
10 48, 44, 48, 45, 47, 92. As in the case with pTHB, in order to release the operon for the anneal/repair reaction below, 500ug of pTRP is digested, purified of salts using ethanol precipitation, and then stored at -20C.

In order to generate the BAC backbone for the final DNA construct, pCC1BAC (EPICENTRE) was PCR-amplified using primer A (SEQ ID NO:53), and primer B (SEQ ID NO:54), and then
15 gel purified. Assembly reactions (80 µl) are carried out in 250 µl PCR tubes in a thermocycler and contain 5% PEG-8000, 200 mM Tris-Cl pH 7.5, 10 mM MgCl2, 1mM DTT, 100 µg/ml BSA, and 4.8 U of T4 polymerase. All DNA pieces in the assembly reaction must be at equal Molar concentrations. Thus, 500ng of digested plasmids pTHB and pTRP, are added to the reaction, in addition to 1000ng of the pCC1BAC PCR product using primers A and B. Reactions are
20 incubated at 37°C for a period of 10 minutes. The reactions is then incubated at 75°C for 20 minutes, cooled at -6°C/ minute to 60°C and then incubated for 30 minutes. Following the 30-minute incubation, the reaction is cooled at -6°C/min to 4°C and then held. The assembly reaction is followed by a repair reaction, which repairs the nicks in the DNA. The repair reaction, which is a total of 40 µl, contains 10 µl of the assembly reaction, 40 U Taq DNA
25 ligase, 1.2 U Taq DNA Polymerase, 5% PEG-8000, 50 mM Tris-Cl pH 7.5, 10 mM MgCl2, 10 mM DTT, 25 µg/ml BSA, 200 µM each dNTP, and 1mM NAD. The reaction is incubated for 15 min at 45°C, and then stored at -20°C.

EXAMPLE 12: Transformation of E. coli cells with exemplary DNA construct for producing Melatonin from L-tryptophan in a microorganism, using a THB dependent pathway.

30 In a 2mm cuvette, five microliters of the repair reaction is electroporated into 50 uL of EPI300 *E. coli* cells (EPICENTRE) using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells are transferred to 500uL SOC media (2% peptone, 0.5% Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 2 hours. Cells are then plated onto LB agar supplemented with
35 15µg/ml chloramphenicol, and incubated overnight at 37°C. Yields are typically dependent

on the size of overlapping regions, the size of the final construct, and the number of DNA pieces that are being assembles. Specifically, shorter overlapping regions, larger final constructs, and higher number of assembly pieces all lead to a decrease in yields. In this assembly, there are 3 DNA pieces being assembled with ~200bp overlapping regions. It is best to keep the overlapping regions 200bps or more for high yields. In addition, the final construct is only 16,821bps, which is relatively small for this methodology, and thus has little effect on the efficiency and yields. The following day, 10 colonies are selected, and grown overnight in LB medium (1% peptone, 0.5% yeast extract, and 0.5% NaCl) supplemented with 15µg/ml chloramphenicol and 25µg/ml Kanamycin. BAC DNA is extracted from each overnight culture using a GeneJET Plasmid Miniprep Kit (Fermentas). BAC DNA constructs were digested with the restriction enzyme SceI (NEB) and subjected to agarose gel electrophoresis using mini sub cell (Bio-Rad) for 30 minutes at 100V. A 7400bp band (pCC1BAC) and ~9400bp band (SER-ASM fragment) is observed, ensuring the correct assembly of the DNA construct. Also, In order to confirm correct assembly, ~500bp regions surrounding the overlapping regions is PCR amplified. The overlapping region of pCC1BAC and THB operon is amplified with primers C (SEQ ID NO:55) and D (SEQ ID NO:56), the assembly region of the SER and ASM operons is amplified with primers E (SEQ ID NO:57) and F (SEQ ID NO:58), and the assembly region of the ASM operon and pCC1BAC is amplified using primers G (SEQ ID NO:59) and H (SEQ ID NO:60). The final DNA construct for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway is thus confirmed and designated p5HTP (Figure 4)(SEQ ID NO:61).

EXAMPLE 13: Construction of an exemplary DNA construct (pMELT) for producing Melatonin from 5-Hydroxy-L-tryptophan in a microorganism, using a THB dependent pathway.

For the production of 5 Melatonin from 5-Hydroxy-L-tryptophan in a microorganism, using a THB dependent pathway, we generate a 13,891bp BAC (pMELT) that contains the enzymes TDC (Rice), AANAT, and ASMT, all under the control of T7 RNA polymerase. A DNA fragment for the production of Serotonin from 5-Hydroxy-L-tryptophan is synthesized containing a L-Tryptophan decarboxylase (TDC) from Rice (SEQ ID NO:109), which has 5-Hydroxy-L-tryptophan decarboxylase activity (Park *et al.*, 2008). The gene is under control of the T7 promoter region (SEQ ID NO:46) and T7 terminator region (SEQ ID NO:47). In order for strong translation, genes within an operon are separated by an 18bp intragenic region, which contains an optimized ribosomal binding site (SEQ ID NO:48). Furthermore, a linker region 3 (SEQ ID NO:91) is added upstream of the T7 RNA polymerase promoter site, which has homology to the last ~200 bases on the 3' end of PCR amplified pCC1BAC. A genome integration region (sce1/E.coli gDNA 2)(SEQ ID NO:94), followed by a linker region 2 (SEQ ID NO:92) is added downstream of the T7 RNA polymerase terminator site, which has homology

to the last ~200 bases on the 5' end TRP operon described below. The DNA construct is cloned into the standard cloning vector pUC57 with flanking FseI restriction digestion sites, thus allowing extraction of DNA construct when necessary. The final construct pTDCR (SEQ ID NO:112) is generated, which contains the following sequences, and in the following order:
5 SEQ ID NO:91, 46, 109, 47, 94, 92. In order to release the operon for the anneal/repair reaction below, 500ug of pTDCR is digested with FseI, purified of salts using ethanol precipitation, and then stored at -20C.

In order to generate the BAC backbone for the final DNA construct, pCC1BAC (EPICENTRE) is PCR-amplified using primer A (SEQ ID NO:96), and primer B (SEQ ID NO:97), and then gel
10 purified. Assembly reactions (80 µl) are carried out in 250 µl PCR tubes in a thermocycler and contain 5% PEG-8000, 200 mM Tris-Cl pH 7.5, 10 mM MgCl2, 1mM DTT, 100 µg/ml BSA, and 4.8 U of T4 polymerase. All DNA pieces in the assembly reaction must be at equal Molar concentrations. Thus, 500ng of digested plasmids pTDCR and pASM, are added to the reaction, in addition to 1000ng of the pCC1BAC PCR product using primers A and B.
15 Reactions are incubated at 37°C for a period of 10 minutes. The reactions is then incubated at 75°C for 20 minutes, cooled at -6°C/ minute to 60°C and then incubated for 30 minutes. Following the 30-minute incubation, the reaction is cooled at -6°C/min to 4°C and then held. The assembly reaction is followed by a repair reaction, which repairs the nicks in the DNA. The repair reaction, which is a total of 40 µl, contains 10 µl of the assembly reaction, 40 U
20 Taq DNA ligase, 1.2 U Taq DNA Polymerase, 5% PEG-8000, 50 mM Tris-Cl pH 7.5, 10 mM MgCl2, 10 mM DTT, 25 µg/ml BSA, 200 µM each dNTP, and 1mM NAD. The reaction is incubated for 15 min at 45°C, and then stored at -20°C.

EXAMPLE 14: Transformation of E. coli cells with exemplary DNA construct for producing Melatonin from 5-Hydroxy-L-tryptophan in a microorganism.

25 In a 2mm cuvette, five microliters of the repair reaction is electroporated into 50 uL of EPI300 *E. coli* cells (EPICENTRE) using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells are transferred to 500uL SOC media (2% peptone, 0.5% Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 2 hours. Cells are then plated onto LB agar supplemented with
30 15µg/ml chloramphenicol, and incubated overnight at 37°C. Yields are typically dependent on the size of overlapping regions, the size of the final construct, and the number of DNA pieces that are being assembles. Specifically, shorter overlapping regions, larger final constructs, and higher number of assembly pieces all lead to a decrease in yields. In this assembly, there are 3 DNA pieces being assembled with ~200bp overlapping regions. It is
35 best to keep the overlapping regions 200bps or more for high yields. In addition, the final

construct is only 13,891 bps, which is relatively small for this methodology, and thus has little effect on the efficiency and yields. The following day, 10 colonies are selected, and grown overnight in LB medium (1% peptone, 0.5% yeast extract, and 0.5% NaCl) supplemented with 15µg/ml chloramphenicol and 25µg/ml Kanamycin. BAC DNA is extracted from each overnight culture using a GeneJET Plasmid Miniprep Kit (Fermentas). For construction conformation, BAC DNA constructs are digested with the restriction enzyme SceI (NEB) and subjected to agarose gel electrophoresis using mini sub cell (Bio-Rad) for 30 minutes at 100V. Also, In order to confirm correct assembly, ~500bp regions surrounding the overlapping regions are PCR amplified. The overlapping region of pCC1BAC and SER operon is amplified with primers LEFT_BAC_FORWARD (SEQ ID NO:98) and LEFT_BAC_REVERSE (SEQ ID NO:99), the assembly region of the SER and ASM operons is amplified with primers CENTER_MEL_FORWARD (SEQ ID NO:113) and CENTER_ MEL_REVERSE (SEQ ID NO:114), and the assembly region of the ASM operon and pCC1BAC is amplified using primers RIGHT_BAC_MEL_FORWARD (SEQ ID NO:115) and RIGHT_BAC_MEL_REVERSE (SEQ ID NO:116). The final DNA construct for producing Melatonin from L-tryptophan in a microorganism, using a THB independent pathway is thus confirmed and designated pMELT (Figure 6) (SEQ ID NO:117).

EXAMPLE 15: Genome integration of exemplary DNA construct (5TS-ASM fragment) for producing Melatonin from 5-Hydroxy-L-tryptophan in a microorganism.

The exemplary DNA construct (5TS-ASM fragment) for producing Melatonin from 5-Hydroxy-L-tryptophan in a microorganism, is integrated into the bacterial genome, using a modified version of a genome integration method (Herring *et al.*, 2003). Specifically, Origami B (DE3) cells are grown at 37°C to an OD600 of 0.6 and then made electrocompetent by concentrating 100-fold and washing three times with ice-cold 10% glycerol. The cells are then electroporated with 100 ng of plasmid pACBSR, which has the ability of simultaneous arabinose-inducible expression of I-SceI and bacteriophage λ red genes (c, b, and exo). In a 2mm cuvette, 2 microliters of the pACBSR is electroporated into 50 uL of Origami B (DE3) *E. coli* cells using a MicroPulser Electroporator (BioRad). Directly following the electroporation, cells are transferred to 500uL SOC media (2% peptone, 0.5% Yeast extract, 10mM NaCl, 2.5mM KCl, 10mM MgCl2, 10mM MgSO4, 20 mM Glucose) and incubated at 37°C for 1 hour. Cells are then plated onto LB agar supplemented with 35µg/ml chloramphenicol, and incubated overnight at 37°C. Origami B (DE3) containing the pACBSR plasmid are then made electrocompetent in the same manner as above, and then electroporated with pMELT. Directly following the electroporation, cells are transferred to 500uL SOC and incubated at 37°C for 1 hour. Cells are then plated onto LB agar supplemented with 35µg/ml chloramphenicol and 50µg/ml Kanamycin, and incubated overnight at 37°C. The following

day, individual colonies are grown at 37°C for 2h in 2mL of LB medium with 35μg/ml chloramphenicol and 50μg/ml Kanamycin to maintain the pMELT and pACBSR. Two milliliters of LB containing 1% arabinose, in addition to 35μg/ml chloramphenicol and 50μg/ml Kanamycin, are added to the culture to induce the expression of I-SceI and bacteriophage λ red genes (c, b, and exo) from the pACBSRplasmid. The cells are further incubated 2 more hours at 37°C, which allows cleavage at the I-SceI site and red recombination between homologous regions of the digested pMELT and the bacterial genome. Following the incubation, serial dilutions are spread on agar plates containing kanamycin, and 1% arabinose, and incubated overnight. From the plates, 10 colonies are chosen and the genomic DNA extracted. The genomic DNA is subjected to PCR using primers surrounding the genomic integration site of the 5TS-ASM fragment. For the upstream region, primers used are 1MEL_INT_FOR (SEQ ID NO:105) and 1MEL_INT_REV (SEQ ID NO:106), and for the downstream integration site, primers 2MELT_INT_FOR (SEQ ID NO:118) and 2MEL_INT_REV (SEQ ID NO:108) are used.

EXAMPLE 16: Transformation of cells harboring 5TS-ASM fragment, with p5HTP and fermentation for the production of Melatonin from L-tryptophan in a microorganism.

The p5HTP DNA construct is then introduced into a *E.coli* host cell harboring the T7 RNA polymerase. The strain chosen was the Origami B (DE3)(EMD Chemicals), which contains a T7 RNA polymerase under the control of an IPTG inducer. Origami B (DE3) strains also harbor a deletion of the lactose permease (lacY) gene, which allows uniform entry of IPTG into all cells of the population. This produces a concentration-dependent, homogeneous level of induction, and enables adjustable levels of protein expression throughout all cells in a culture. By adjusting the concentration of IPTG, expression can be regulated from very low levels up to the robust, fully induced levels commonly associated with T7 RNA polymerase expression. In addition, Origami B(DE3) strains have also been shown to yield 10-fold more active protein than in another host even though overall expression levels were similar.

Origami B(DE3) strains containing p5HTP were evaluated for the ability to produce 5HTP. Given that an industrial process would require the production of chemicals from low-cost carbohydrate feedstocks such as glucose, it is necessary to demonstrate the production of 5HTP from a native compound in *E.coli*. In this example, L-Tryptophan is used as the starting metabolic intermediate compound, and the metabolic pathways for the production of L-Tryptophan are native to *E.col,* and well described. Thus, the next set of experiments is aimed to determine whether endogenous L-tryptophan produced by the cells during growth on glucose can fuel the 5HTP pathway. Cells are grown aerobically in M9 minimal medium (6.78 g/L, Na_2HPO_4, 3.0 g/L KH_2PO_4, 0.5 g/L NaCl, 1.0 g/L NH_4Cl, 1 mM $MgSO_4$,

0.1 mM CaCl 2) supplemented with 10 g/L glucose, 1g/L L-tryptophan, and the 15 mg/L chloramphenicol. In order to determine the optimal Induction level, growth experiments are done with IPTG concentrations of 1000, 100, and 10 μM .

EXAMPLE 17: Transformation of cells harboring 5TS-ASM fragment and 5HTP, with pSER and fermentation for the production of Melatonin from L-tryptophan in a microorganism, using both a THB dependent and independent pathways.

In order to produce Melatonin from L-tryptophan in a microorganism, using both a THB dependent and -independent pathway (Figure 3), the pSER DNA construct is transformed into a *E.coli* host cell harboring the T7 RNA polymerase 5TS-ASM fragment described in example 11 above. The strains are then evaluated for the ability to produce 5HTP. Given that an industrial process would require the production of chemicals from low-cost carbohydrate feedstocks such as glucose, it is necessary to demonstrate the production of 5HTP from a native compound in *E.coli*. In this example, L-Tryptophan is used as the starting metabolic intermediate compound, and the metabolic pathways for the production of L-Tryptophan are native to *E.coli,* and well described. Thus, the next set of experiments is aimed to determine whether endogenous L-tryptophan produced by the cells during growth on glucose could fuel the 5HTP pathway. Cells are then grown aerobically in M9 minimal medium (6.78 g/L, Na 2 HPO 4 , 3.0 g/L KH 2 PO 4 , 0.5 g/L NaCl, 1.0 g/L NH 4 Cl, 1 mM MgSO 4 , 0.1 mM CaCl 2) supplemented with 10 g/L glucose, 1g/L L-tryptophan, 15 mg/L chloramphenicol, and 50 mg/L of ampicillin. In order to determine the optimal Induction level, growth experiments are done with IPTG concentrations of 1000, 100, and 10 μM.

EXAMPLE 7: Constructing melatonin producer in Saccharomyces cerevisiae

Saccharomyces cerevisiae strains do not have native tryptophan hydroxylase or THB synthesis- or recycling pathways. These genes/pathways must be cloned into the *S. cerevisiae* strain in order to produce 5-hydroxytryptophan. Mikkelsen et al. (2012) has introduced a platform for chromosome integration and gene expression in S. cerevisiae strains, which can be used for the construction of 5-hydroxytryptophan producers.

The THB synthetic pathway genes are assigned to be expressed at relatively low levels, and therefore the X3 and X4 sites (Mikkelsen et al., 2012) are chosen for the expression of the GCH1, PTPS and SPR genes (SEQ ID NOS:41, 42 and 43). These three genes can be PCR amplified with using pTHB plasmid (SEQ ID NO:150) as the template and primers GCH1-FWD, GCH1-REV, PTPS-FWD, PTPS-REV, SPR-FWD, and SPR-REV, respectively (SEQ ID NOS:151, 152, 153, 154, 155 and 156, respectively). Then, the amplified PCR products are

fused into the X3 and X4 vectors together with the bidirectional promoter fragment (Mikkelsen et al., 2012) using the USER cloning protocol (Nour-Eldin et al. 2006).

A similar approach can be used for the constructions of the insertion vectors for the THB recycling pathway genes such as DHPR and PCBD1 (SEQ ID NOS: 45 and 44, respectively).
5 The DHPR and PCBD1 genes can be amplified using the primers DHPR-FWD, DHPR-REV, PCBD1-FWD, and PCBD1-REV, respectively (SEQ ID NOS: 157, 158, 159, and 160). The insertion vector XI-4 is chosen as the backbone (Mikkelsen et al. 2012).

A similar approach can be used for the constructions of the insertion vectors for the expression of TPH2 gene from *Homo sapiens* (SEQ ID NO:2), TPH1 from *Gallus gallus* (SEQ
10 ID NO: 6) and TPH1 gene from *Oryctolagus cuniculus* (SEQ ID NO:1). Primers for the amplification of these genes are TPH-H-FWD, TPH-H-REV, TPH-G-FWD, TPH-G-REV, TPH-Oc-FWD, and TPH-OC-REV, respectively (SEQ ID NOS:161, 162, 163, 164, 165 and 166, respectively). The XI-3 insertion vector is used for the construction (Mikkelsen et al. 2012).

A similar approach can be used for the construction of the insertion vector for the expression
15 of DDC, AANAT and ASMT genes for the conversion of 5-hydroxytryptophan into melatonin. The DDC, AANAT and ASMT genes can be amplified using pMELR (SEQ ID NO:65, 74, 85) plasmid as the template using primers DDC-FWD, DDC-REV, AANAT-FWD, AANAT-REV, ASMT-FWD, and ASMT-REV, respectively (SEQ ID NOs:167, 168, 169, 170, 171 and 172, respectively). The DDC and AANAT genes are fused inserted into the XII-3 vector together
20 with the bidirectional promoter segment, and the ASMT gene is fused into the XII-4 vector together with pGAL1 promoter segment (Mikkelsen et al., 2012). The resulted integration vector is used for chromosomal integrations.

Transformation of the above mentioned insertion plasmids are made following the lithium acetate/single-stranded carrier DNA/PEG method (Gietz and Schiestl, 2007). The above-
25 described insertion plasmids for the integration of THB synthesis and recycling pathway genes are transformed iteratively into the yeast strain CEN.PK113-7D in three consecutive transformations. The URA3 marker is eliminated by direct repeat recombination after each integration by selecting colonies grow on plates with 740 mg/L 5-fluoroorotic acid. The colonies grown up on the selection plates are further screened by colony PCR to confirm the
30 insertions. The selected strain(s) are used to prepare competent cells, which are then transformed with one of the TPH insertion plasmids as described above. The transformant mixtures are screened with uracil and 5-fluoroorotic acid, and further confirmed with colony PCR. The final strains are named as CEN.PK-TPHh, CEN.PK-TPHg, and CEN.PK-TPHoc carrying and expressing the TPH genes from *Homo sapiens*, *Gallus gallus,* and *Oryctolagus cuniculus,*
35 respectively.

The CEN.PK-TPHh, CEN.PK-TPHg, or CEN.PK-TPHoc strains are transformed with the integration vectors harboring the DDC, AANAT, and ASMT genes by two consequential transformations as described above. The transformant mixtures are screened with uracil and 5-fluoroorotic acid. The colonies grown up on the screening plates are further confirmed with colony PCR. The final strain harboring the genes for THB synthesis such as GCH1, PTPS and SPR, THB recycling genes such as DHPR and PCBD1, TPH, DDC, AANAT, and ASMT genes can be used for melatonin productions.

Throughout this application, various publications have been referenced. The disclosure of each one of these publications in its entirety is hereby incorporated by reference in this application in order to more fully describe the state of the art to which this invention pertains. Although the invention has been described with reference to the Examples provided above, it should be understood that various modifications can be made without departing from the spirit of the invention.

Embodiments

The following represent specific, exemplary embodiments of the present invention.

1. A recombinant microbial cell comprising
   an exogenous nucleic acid sequence encoding an L-tryptophan hydroxylase (EC 1.14.16.4),
   an exogenous nucleic acid sequence encoding a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28), and
   exogenous nucleic acid sequences encoding enzymes of at least one pathway for producing tetrahydrobiopterin (THB).

2. The recombinant microbial cell of embodiment 1, further comprising an exogenous nucleic acid sequence encoding a serotonin acetyltransferase (EC 2.3.1.87).

3. The recombinant microbial cell of any one of the preceding embodiments, further comprising an exogenous nucleic acid sequence encoding an acetylserotonin O-methyltransferase (EC 2.1.1.4).

4. The recombinant microbial cell of any one of the preceding embodiments, comprising exogenous nucleic acid sequences encoding enzymes of a first and/or a second pathway for producing THB, the first pathway producing THB from guanosin triphosphate (GTP), and the second pathway regenerating THB from 4a-hydroxytetrahydrobiopterin.

5. The recombinant microbial cell of embodiment 4, wherein the enzymes of the first pathway comprise

(a) optionally, a GTP cyclohydrolase I (EC 3.5.4.16);

(b) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12); and

(c) a sepiapterin reductase (EC 1.1.1.153).

6. The recombinant microbial cell of any one of embodiments 4 and 5, wherein the
5 enzymes of the second pathway comprise

(a) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

(b) optionally, a dihydropteridine reductase (EC 1.5.1.34).

7. The recombinant microbial cell of any one of the preceding embodiments, wherein at least one nucleic acid sequence encoding a 6-pyruvoyl-tetrahydropterin synthase and at least
10 one nucleic acid sequence encoding a sepiapterin reductase is heterologous.

8. The recombinant microbial cell of any one of the preceding embodiments, wherein at least one nucleic acid sequence encoding a 4a-hydroxytetrahydrobiopterin dehydratase is heterologous.

9. The recombinant microbial cell of any one of the preceding embodiments, wherein
15 each one of said exogenous nucleic acid sequences is operably linked to an inducible, a regulated or a constitutive promoter.

10. The recombinant microbial cell of any one of the preceding embodiments, wherein each one of said exogenous nucleic acid sequences is comprised in a multicopy plasmid or incorporated into a chromosome of the microbial cell.

20 11. The recombinant microbial cell of any one of the preceding embodiments, which comprises a mutation providing for reduced tryptophan degradation, optionally providing for reduced tryptophanase activity.

12. The recombinant microbial cell of any one of the preceding embodiments, which is derived from a microbial host cell which is a bacterial cell, a yeast host cell, a filamentous
25 fungal cell, or an algeal cell.

13. The recombinant microbial cell of embodiment 12, wherein the microbial host cell is of a genus selected from the group consisting of *Acinetobacter, Agrobacterium, Alcaligenes, Anabaena, Aspergillus, Bacillus, Bifidobacterium, Brevibacterium, Candida, Chlorobium, Chromatium, Corynebacteria, Cytophaga, Deinococcus, Enterococcus, Erwinia, Erythrobacter,* 5 *Escherichia, Flavobacterium, Hansenula, Klebsiella, Lactobacillus, Methanobacterium, Methylobacter, Methylococcus, Methylocystis, Methylomicrobium, Methylomonas, Methylosinus, Mycobacterium, Myxococcus, Pantoea, Phaffia, Pichia, Pseudomonas, Rhodobacter, Rhodococcus, Saccharomyces, Salmonella, Sphingomonas, Streptococcus, Streptomyces, Synechococcus, Synechocystis, Thiobacillus, Trichoderma, Yarrowia,and* 10 *Zymomonas*.

14. The recombinant microbial cell of any one of the preceding embodiments, which is a bacterial cell.

15. The recombinant cell of embodiment 14, which is an *Escherichia* cell.

16. The recombinant microbial cell of embodiment 15, which is an *Escherichia coli* cell.

15 17. The recombinant microbial cell of any one of embodiments 15 and 16, which comprises a mutation in or a deletion of the tnaA gene.

18. The recombinant microbial cell of any one of embodiments 1 to 13, which is a fungal cell.

19. The recombinant microbial cell of any one of embodiments 1 to 13, which is a yeast 20 cell.

20. The recombinant microbial cell of embodiment 19, which is a *Saccharomyces* cell.

21. The recombinant microbial cell of embodiment 20, which is derived from a *Saccharomyces cerevisiae* cell.

22. The recombinant microbial cell of any one of the preceding embodiments, wherein the 25 L-tryptophan hydroxylase is an L-tryptophan hydroxylase 1 or a catalytically active fragment thereof.

23. The recombinant microbial cell of any one of the preceding embodiments, wherein the L-tryptophan hydroxylase comprises an amino acid sequence having a sequence identity of at

least 70%, such as at least 80% or at least 90% to the amino acid sequence of at least one of SEQ ID NOS:1 to 8, or to a catalytically active fragment thereof.

24. The recombinant microbial cell of any one of the preceding embodiments, wherein the L-tryptophan hydroxylase comprises the amino acid sequence of SEQ ID NO:9.

5 25. The recombinant microbial cell of any one of the preceding embodiments, wherein the 5-hydroxy-L-tryptophan decarboxy-lyase comprises an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90% to the amino acid sequence of at least one of SEQ ID NOS:62 to 71.

26. The recombinant microbial cell of any one of the preceding embodiments, wherein the 10 5-hydroxy-L-tryptophan decarboxy-lyase comprises the amino acid sequence of SEQ ID NO:69.

27. The recombinant microbial cell of any one of the preceding embodiments, wherein the serotonin acetyltransferase comprises an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90% to the amino acid sequence of at least 15 one of SEQ ID NOS:73 to 79.

28. The recombinant microbial cell of any one of the preceding embodiments, wherein the serotonin acetyltransferase comprises the amino acid sequence of SEQ ID NO:73.

29. The recombinant microbial cell of any one of the preceding embodiments, wherein the acetylserotonin O-methyltransferase comprises an amino acid sequence having a sequence 20 identity of at least 70%, such as at least 80% or at least 90% to the amino acid sequence of at least one of SEQ ID NOS:80 to 85.

30. The recombinant microbial cell of any one of the preceding embodiments, wherein the acetylserotonin O-methyltransferase comprises the amino acid sequence of SEQ ID NO:80.

31. The recombinant microbial cell of any one of embodiments 5-30, wherein

25 (a) the GTP cyclohydrolase I comprises the amino acid sequence of any one of SEQ ID NOS:10-16;

(b) the 6-pyruvoyl-tetrahydropterin synthase comprises the amino acid sequence of any one of SEQ ID NOS:17-22;

(c) the sepiapterin reductase comprises the amino acid sequence of any one of SEQ ID NOS:23-28; or

(d) any combination of (a) to (c).

32. The recombinant microbial cell of any one of embodiments 6 to 31, wherein

5 (a) the 4a-hydroxytetrahydrobiopterin dehydratase comprises the amino acid sequence of any one of SEQ ID NOS:29-33;

(b) the dihydropteridine reductase comprises the amino acid sequence encoded by SEQ ID NO:34-39; or

(c) a combination of (a) and (b).

10 33. The recombinant microbial cell of any one of the preceding embodiments, further comprising an exogenous nucleic acid sequence encoding an L-tryptophan decarboxy-lyase (EC 4.1.1.28), a tryptamine-5-hydroxylase (EC 1.14.16.4), or both.

34. A microbial cell of any one of the preceding embodiments for use in a method of producing serotonin, N-acetylserotonin, melatonin, or any combination thereof, the method
15 comprising culturing the microbial cell in a medium comprising a carbon source.

35. A vector comprising nucleic acid sequences encoding an a serotonin acetyltransferase, an acetylserotonin O-methyltransferase, and a L-tryptophan decarboxy-lyase and/or 5-hydroxy-L-tryptophan decarboxy-lyase.

36. The vector of embodiment 33, wherein the L-tryptophan decarboxy-lyase has an
20 amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90%, to the amino acid sequence of at least one of SEQ ID NOS:62 to 71.

37. The vector of any one of embodiments 35 to 36, wherein the L-tryptophan decarboxy-lyase comprises the amino acid sequence of SEQ ID NO:71.

38. The vector of any one of embodiments 35 to 37, wherein the serotonin
25 acetyltransferase has an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90%, to the amino acid sequence of at least one of SEQ ID NOS:73 to 79.

39. The vector of any one of embodiments 35 to 38, wherein the serotonin acetyltransferase comprises the amino acid sequence encoded by SEQ ID NO:73.

40. The vector of any one of embodiments 35 to 39, wherein the acetylserotonin O-methyltransferase has an amino acid sequence having a sequence identity of at least 70%,
5 such as at least 80% or at least 90%, to the amino acid sequence of at least one of SEQ ID NOS:80 to 85.

41. The vector of any one of embodiments 35 to 40, wherein the acetylserotonin O-methyltransferase comprises the amino acid sequence encoded by SEQ ID NO:80.

42. The vector of any one of embodiments 35 to 41, comprising a 5-hydroxy-L-tryptophan
10 decarboxy-lyase comprising an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90% to the amino acid sequence of at least one of SEQ ID NOS:62 to 71.

43. The vector of any one of embodiments 35 to 42, wherein the 5-hydroxy-L-tryptophan decarboxy-lyase comprises an amino acid sequence encoded by SEQ ID NO:69.

15 44. The vector of any one of embodiments 35 to 43, comprising a nucleic acid sequence encoding a tryptamine 5-hydroxylase.

45. The vector of embodiment 44, wherein the tryptamine 5-hydroxylase comprises an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 90% to the amino acid sequence of SEQ ID NO:72.

20 46. The vector of embodiment 44, wherein the tryptamine 5-hydroxylase comprises an amino acid sequence encoded by SEQ ID NO:87.

47. The vector of any one of embodiments 35 to 46, further comprising one or more operably linked regulatory control elements, selection markers, or both.

25 48. The vector of any one of embodiments 35 to 47, wherein each one of said nucleic acid sequences is operably linked to an inducible, a regulated or a constitutive promoter.

49. The vector of any one of embodiments 35 to 48, which is a plasmid.

50. A vector comprising the sequence of SEQ ID NO: 104 or SEQ ID NO:117.

51. A recombinant microbial host cell transformed with the vector of any one of embodiments 35 to 50.

52. The recombinant microbial host cell of embodiment 51, further transformed with one or more vectors comprising nucleic acids encoding

5 (a) an L-tryptophan hydroxylase (EC 1.14.16.4);

(b) a GTP cyclohydrolase I (EC 3.5.4.16);

(c) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12);

(d) a sepiapterin reductase (EC 1.1.1.153);

(e) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

10 (f) a dihydropteridine reductase (EC 1.5.1.34),

each one of said nucleic acid sequences being operably linked to an inducible, a regulated or a constitutive promoter.

53. The vector of embodiment 52, wherein the L-tryptophan hydroxylase has an amino acid sequence having a sequence identity of at least 70%, such as at least 80% or at least 15 90%, to the amino acid sequence of at least one of SEQ ID NOS:1 to 8, or to a catalytically active fragment thereof.

54. The vector of any one of embodiments 52 and 53, wherein the L-tryptophan hydroxylase comprises the amino acid sequence encoded by SEQ ID NO:9.

55. The recombinant microbial host cell of any one of embodiments 51 to 54, which is 20 derived from a host cell of a genus selected from the group consisting of *Acinetobacter, Agrobacterium, Alcaligenes, Anabaena, Aspergillus, Bacillus, Bifidobacterium, Brevibacterium, Candida, Chlorobium, Chromatium, Corynebacteria, Cytophaga, Deinococcus, Enterococcus, Erwinia, Erythrobacter, Escherichia, Flavobacterium, Hansenula, Klebsiella, Lactobacillus, Methanobacterium, Methylobacter, Methylococcus, Methylocystis, Methylomicrobium,* 25 *Methylomonas, Methylosinus, Mycobacterium, Myxococcus, Pantoea, Phaffia, Pichia, Pseudomonas, Rhodobacter, Rhodococcus, Saccharomyces, Salmonella, Sphingomonas,*

Streptococcus, Streptomyces, Synechococcus, Synechocystis, Thiobacillus, Trichoderma, Yarrowia,and Zymomonas.

56. A method of producing serotonin, comprising culturing the recombinant microbial cell of any one of embodiments 1 to 34 and 51 to 55 in a medium comprising a carbon source,
5 and, optionally, isolating serotonin.

57. A method of producing N-acetyl-serotonin, comprising culturing the recombinant microbial cell of any one of embodiments 2 to 34 and 51 to 55 in a medium comprising a carbon source, and, optionally, isolating N-acetyl-serotonin.

58. A method of producing melatonin, comprising culturing the recombinant microbial cell
10 of any one of embodiments 3 to 34 and 51 to 55 in a medium comprising a carbon source, and, optionally, isolating melatonin.

59. The method of any embodiment 56, comprising isolating serotonin and, optionally, purifying serotonin.

60. The method of embodiments 57, comprising isolating N-acetyl-serotonin and,
15 optionally, purifying N-acetyl-serotonin.

61. The method of embodiments 58, comprising isolating melatonin and, optionally, purifying melatonin.

62. A method for preparing a composition comprising serotonin comprising the steps of:

(a) culturing a microbial cell an exogenous nucleic acid sequence encoding an L-
20 tryptophan hydroxylase (EC 1.14.16.4), an exogenous nucleic acid encoding a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28), and a source of THB in a medium comprising a carbon source, optionally in the presence of tryptophan;

(b) isolating serotonin;

25 (c) purifying the isolated serotonin; and

(d) adding any excipients to obtain a composition comprising serotonin.

63. A method for preparing a composition comprising melatonin comprising the steps of:

(a) culturing a microbial cell comprising an exogenous nucleic acid sequence encoding an L-tryptophan hydroxylase (EC 1.14.16.4), an exogenous nucleic acid encoding a 5-hydroxy-L-tryptophan decarboxy-lyase (EC 4.1.1.28), an exogenous nucleic acid sequence encoding a serotonin acetyltransferase (EC 2.3.1.87), an exogenous nucleic acid sequence encoding an acetylserotonin O-methyltransferase (EC 2.1.1.4), and a source of THB in a medium comprising a carbon source, optionally in the presence of tryptophan;

(b) isolating melatonin;

(c) purifying the isolated melatonin; and

(d) adding any excipients to obtain a composition comprising melatonin.

64. A method for preparing a composition comprising N-acetyl-serotonin comprising the steps of:

(a) culturing a microbial cell comprising exogenous nucleic acid sequences encoding an L-tryptophan hydroxylase (EC 1.14.16.4), a 5-hydroxy-L-tryptophan decarboxy-lyase (EC 4.1.1.28) and a serotonin acetyltransferase (EC 2.3.1.87), and a source of THB, in a medium comprising a carbon source and, optionally, tryptophan;

(b) isolating N-acetyl-serotonin;

(c) purifying the isolated N-acetyl-serotonin; and

(d) adding any excipients to obtain a composition comprising N-acetyl-serotonin

65. The method of any one of embodiments 62 to 64, wherein the microbial cell further comprises exogenous nucleic acid sequences encoding an L-tryptophan decarboxy-lyase (EC 4.1.1.28) and a tryptamine-5-hydroxylase (EC 1.14.16.4).

66. The method of any one of embodiments 62 to 65, wherein the source of THB comprises exogenously added THB.

67. The method of any one of embodiments 62 to 66, wherein the source of THB comprises enzymes of a pathway producing THB from GTP.

68. The method of any one of embodiments 62 to 67, wherein the carbon source is selected from the group consisting of glucose, fructose, sucrose, xylose, mannose, galactose, 5 rhamnose, arabinose, fatty acids, glycerine, glycerol, acetate, pyruvate, gluconate, starch, glycogen, amylopectin, amylose, cellulose, cellulose acetate, cellulose nitrate, hemicellulose, xylan, glucuronoxylan, arabinoxylan, glucomannan, xyloglucan, lignin, and lignocellulose.

69. The method of embodiment 68, wherein the carbon source comprises one or more of lignocellulose and glycerol.

10 70. A method of producing a recombinant microbial cell, comprising transforming a microbial host cell with one or more vectors comprising nucleic acid sequences encoding

(a) an L-tryptophan hydroxylase (EC 1.14.16.4);

(b) a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28);

(c) a GTP cyclohydrolase I (EC 3.5.4.16);

15 (d) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12);

(e) a sepiapterin reductase (EC 1.1.1.153);

(f) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

(g) a dihydropteridine reductase (EC 1.5.1.34),

each one of said nucleic acid sequences being operably linked to an inducible, a regulated or 20 a constitutive promoter, thereby obtaining the recombinant microbial cell.

71. A method of producing a recombinant microbial cell, comprising transforming a microbial host cell with one or more vectors comprising nucleic acid sequences encoding

(a) an L-tryptophan hydroxylase (EC 1.14.16.4);

(b) a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28);

(c) a serotonin acetyltransferase (EC 2.3.1.87);

(d) a GTP cyclohydrolase I (EC 3.5.4.16);

(e) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12);

(f) a sepiapterin reductase (EC 1.1.1.153);

5 (g) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

(h) a dihydropteridine reductase (EC 1.5.1.34),

each one of said nucleic acid sequences being operably linked to an inducible, a regulated or a constitutive promoter, thereby obtaining the recombinant microbial cell.

72. A method of producing a recombinant microbial cell, comprising transforming a
10 microbial host cell with one or more vectors comprising nucleic acid sequences encoding

(a) an L-tryptophan hydroxylase (EC 1.14.16.4);

(b) a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28);

(c) a serotonin acetyltransferase (EC 2.3.1.87);

(d) an acetylserotonin O-methyltransferase (EC 2.1.1.4);

15 (e) a GTP cyclohydrolase I (EC 3.5.4.16);

(f) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12);

(g) a sepiapterin reductase (EC 1.1.1.153);

(h) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

(i) a dihydropteridine reductase (EC 1.5.1.34),

20 each one of said nucleic acid sequences being operably linked to an inducible, a regulated or a constitutive promoter, thereby obtaining the recombinant microbial cell.

73. The method of any one of embodiments 70 to 72, wherein the L-tryptophan hydroxylase is a TPH1.

74. The method of any one of embodiments 70 to 73, further comprising transforming the microbial host cell with one or more vectors comprising nucleic acid sequences encoding an
5 L-tryptophan decarboxy-lyase (EC 4.1.1.28), a tryptamine-5-hydroxylase (EC 1.14.16.4), or both.

75. The method of any one of embodiments 70 to 74, comprising mutating the cell to reduce tryptophanase degradation, optionally to reduce tryptophanase activity.

76. The method of embodiment 75, comprising mutating or deleting a gene encoding a
10 tryptophanase, optionally the *tna*A gene.

77. A composition comprising serotonin, obtainable by culturing the recombinant microbial cell of any one of embodiments 1 to 34 in a medium comprising a carbon source.

78. A composition comprising melatonin, obtainable by culturing the recombinant
15 microbial cell of any one of embodiments 3 to 34 in a medium comprising a carbon source.

CLAIMS

1. A recombinant microbial cell comprising exogenous nucleic acid sequences encoding an L-tryptophan hydroxylase (EC 1.14.16.4), a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28), a serotonin acetyltransferase (EC 2.3.1.87), an acetylserotonin O-methyltransferase (EC 2.1.1.4), and enzymes of at least one pathway for producing tetrahydrobiopterin (THB).

2. A recombinant microbial cell comprising exogenous nucleic acid sequences encoding an L-tryptophan hydroxylase (EC 1.14.16.4), a 5-hydroxy-L-tryptophan decarboxylyase (EC 4.1.1.28), and enzymes of at least one pathway for producing tetrahydrobiopterin (THB), and, optionally, a serotonin acetyltransferase (EC 2.3.1.87).

3. The recombinant microbial cell of any one of the preceding claims, comprising exogenous nucleic acid sequences encoding enzymes of a first and/or a second pathway for producing THB, the first pathway producing THB from guanosin triphosphate (GTP), and the second pathway regenerating THB from 4a-hydroxytetrahydrobiopterin.

4. The recombinant microbial cell of claim 3, wherein the enzymes of the first pathway comprise

(a) optionally, a GTP cyclohydrolase I (EC 3.5.4.16);

(b) a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12); and

(c) a sepiapterin reductase (EC 1.1.1.153).

5. The recombinant microbial cell of any one of claims 3 and 4, wherein the enzymes of the second pathway comprise

(a) a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); and

(b) optionally, a dihydropteridine reductase (EC 1.5.1.34).

6. The recombinant microbial cell of any one of the preceding claims, wherein each one of said exogenous nucleic acid sequences is operably linked to an inducible, a regulated or a constitutive promoter.

7. The recombinant microbial cell of any one of the preceding claims, which comprises a mutation providing for reduced tryptophanase activity.

8. The recombinant microbial cell of any one of the preceding claims, which is derived from a microbial host cell which is a bacterial cell, a yeast host cell, a filamentous fungal cell,
5 or an algeal cell.

9. The recombinant cell of any one of the preceding claims, which is an *Escherichia coli* cell.

10. The recombinant microbial cell of claim 9, which comprises a mutation in or a deletion of the *tna*A gene.

10 11. The recombinant microbial cell of claim 8, which is a *Saccharomyces cerevisiae* cell.

12. The recombinant microbial cell of any one of the preceding claims, wherein the L-tryptophan hydroxylase comprises the amino acid sequence of SEQ ID NO:9.

13. The recombinant microbial cell of any one of claims 4 to 12, wherein

(a) the GTP cyclohydrolase I comprises the amino acid sequence of any one of
15 SEQ ID NOS:10-16;

(b) the 6-pyruvoyl-tetrahydropterin synthase comprises the amino acid sequence of any one of SEQ ID NOS:17-22;

(c) the sepiapterin reductase comprises the amino acid sequence of any one of SEQ ID NOS:23-28;

20 (d) the 4a-hydroxytetrahydrobiopterin dehydratase comprises the amino acid sequence of any one of SEQ ID NOS:29-33;

(e) the dihydropteridine reductase comprises the amino acid sequence encoded by SEQ ID NO:34-39; or

(f) a combination of any one or more of (a) to (e).

14. A vector comprising nucleic acid sequences encoding an a serotonin acetyltransferase, an acetylserotonin O-methyltransferase, and a L-tryptophan decarboxy-lyase and/or 5-hydroxy-L-tryptophan decarboxy-lyase.

15. The vector of claim 14, wherein the 5-hydroxy-L-tryptophan decarboxy-lyase
5 comprises an amino acid sequence encoded by SEQ ID NO:69.

16. A method of producing melatonin, comprising culturing the recombinant microbial cell of any one of claims 1 and 3 to 13 in a medium comprising a carbon source, and, optionally, isolating melatonin.

17. A method of producing serotonin, comprising culturing the recombinant microbial cell
10 of any one of claims 2 to 13 in a medium comprising a carbon source, and, optionally, isolating serotonin.

18. The method of any one of claims 16 and 17, wherein the carbon source is selected from the group consisting of glucose, fructose, sucrose, xylose, mannose, galactose, rhamnose, arabinose, fatty acids, glycerine, starch, glycogen, amylopectin, amylose,
15 cellulose, cellulose acetate, cellulose nitrate, hemicellulose, xylan, glucuronoxylan, arabinoxylan, glucomannan, xyloglucan, lignin, and lignocellulose.

19. A method of producing a recombinant microbial cell, comprising

transforming a microbial host cell with one or more vectors comprising nucleic acid sequences encoding an L-tryptophan hydroxylase (EC 1.14.16.4); a 5-hydroxy-L-
20 tryptophan decarboxylyase (EC 4.1.1.28); a GTP cyclohydrolase I (EC 3.5.4.16); a 6-pyruvoyl-tetrahydropterin synthase (EC 4.2.3.12); a sepiapterin reductase (EC 1.1.1.153); a 4a-hydroxytetrahydrobiopterin dehydratase (EC 4.2.1.96); a dihydropteridine reductase (EC 1.5.1.34), and, optionally, a serotonin acetyltransferase (EC 2.3.1.87) and an acetylserotonin O-methyltransferase (EC 2.1.1.4),

25 wherein each one of said nucleic acid sequences is operably linked to an inducible, a regulated or a constitutive promoter,

thereby obtaining the recombinant microbial cell.
