#### Abstract

Complexes of $\mathrm{Zn}(\mathrm{II}), \mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ with 2'-[1-(2-pyridinyl)ethylidene]oxamohydrazide (Hapsox) were synthesized and their structures were determined. All the complexes are of a neutral type with two apsox ligands coordinated to $\mathrm{Zn}(\mathrm{II})$ and one apsox ligand coordinated to $\mathrm{Pd}(\mathrm{II})$ or $\mathrm{Pt}(\mathrm{II})$. In each case, the polydentate was coordinated via pyridine and hydrazone nitrogens and $\alpha$-oxyazine oxygen, forming an octahedral geometry around $\mathrm{Zn}(\mathrm{II})$, and a square planar one around $\operatorname{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$. The structure determination was performed by $\mathrm{IR},{ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{13} \mathrm{C}$-NMR spectroscopy, and for the $\mathrm{Zn}(\mathrm{II})$ complex by X-ray structure analysis.

Keywords: Zn (II) complex, $\mathrm{Pd}(\mathrm{II})$ complex, $\mathrm{Pt}(\mathrm{II})$ complex, 2-acetylpyridine derivative, X-ray analysis, NMR spectra.

## INTRODUCTION

As a part of our studies on the influence of the nature of hydrazone/hydrazide ligands and their charge on the structure of transition metal complexes, ${ }^{1-3}$ the synthesis of $\mathrm{Zn}(\mathrm{II}), \mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes with a 2 '-[1-(2-pyridinyl)ethylidene]oxamohydrazide (Hapsox) ligand is reported here.

In previous work, complexes with $2^{\prime} 2^{\prime \prime}$-(2,6-pyridinediyldiethylidyne)dioxamohydrazide $\left(\mathrm{H}_{2} \text { dapsox }\right)^{1,4,5}$ were studied in detail, and some information were gathered on complexes with 2,6-bis[1-(methoxycarbonylmethylhydrazono)ethyl]pyridine

[^0]\# Serbian Chemical Society active member.
$\left(\mathrm{H}_{2}\right.$ dapetha). ${ }^{6}$ The structure of the $\mathrm{H}_{2}$ dapsox ligand, as well as the charges and radii of the central metal ion favour, in most cases, pentagonal bipyramidal (PBP) geometry of the complexes. ${ }^{3}$ On the other hand, with the $\mathrm{H}_{2}$ dapetha ligand, the $\mathrm{Cu}(\mathrm{II})$ and Co (II) complexes have trigonal bipyramidal (TBP) geometry. ${ }^{6}$

Both the above-mentioned ligands are very symmetric, having two identical side chains. In the molecule of 2-acetylpyridine and its hydrazone derivatives, one side chain is missing, so that such ligands are less symmetric. Therefore, it was of interest to establish the mode of coordination of 2'-[1-(2-pyridinyl)ethylidene]oxamohydrazide (Hapsox) as an analogue of dapsox but with only one side chain.

The first synthesized complex with a Hapsox ligand was the octahedral complex of $\mathrm{Co}(\mathrm{III})$ with two apsox ligands in monoanionic form coordinated meridionally as tridentates. The ligand is coordinated via the pyridine and hydrazone nitrogens, as well as the $\alpha$-oxyazine oxygen, as confirmed by X-ray structure analysis. ${ }^{7}$

As a continuation of the study, two $\mathrm{Cu}(\mathrm{II})$ complexes with Hapsox were synthesized and structurally characterized. ${ }^{8}$ In one of them two apsox ligands are coordinated in the same manner as in the $\mathrm{Co}(\mathrm{III})$ complex, giving a distorted octahedral geometry. The only difference between this complex and the Co(III) complex arose as the consequence of the hydrolysis of the terminal amide group in case of the Cu (II) complex, yielding a carboxylic group. ${ }^{8}$ In the second, tetrahedral Cu (II) complex, the ligand is coordinated as a tridentate, forming a six-membered and a five-membered ring around the central metal ion. The fourth coordination site is occupied by a water molecule. ${ }^{8}$

## EXPERIMENTAL

## Synthesis of the $\left[\mathrm{Zn}(\text { apsox })_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ complex

$\mathrm{Zn}(\mathrm{OAc})_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(0.11 \mathrm{~g}, 0.5 \mathrm{mmol})$ and Hapsox ligand $(0.21 \mathrm{~g}, 1.0 \mathrm{mmol})$ were dissolved in $100 \mathrm{~cm}^{3}$ of methanol and the solution was refluxed until it was clear (approx. 15 min ). After 48 h , pale yellow crystals precipitated from the solution in $60 \%(0.16 \mathrm{~g})$ yield. IR spectrum ( KBr ; $\left.v / \mathrm{cm}^{-1}\right): 3654(m), 3393(v s), 3283(s), 1700(s), 1681(v s), 1629(s), 1593(s), 1573(s), 1546(v s), 1516(v s)$, $1469(s), 1436(m), 1374(m), 1325(m), 1283(s), 1166(w), 1145(w), 1100(w), 1072(m), 1050(w)$, 1018(w), 781 (m), 743(m), 689(s), 656(s), 569(m). Elemental analysis: Found: C $41.06 \%, \mathrm{H} 4.31 \%$, $\mathrm{N} 21.52 \%$, Calcd. for $\left[\mathrm{Zn}(\text { apsox })_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{18} \mathrm{H}_{24} \mathrm{~N}_{8} \mathrm{O}_{7} \mathrm{Zn}\left(M_{\mathrm{r}}=529.82\right)$ : C $40.80 \%, \mathrm{H} 4.57 \%$, N 21.15 \%.

## Syntheses of the $[\mathrm{Pd}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$ and $[\mathrm{Pt}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$ complexes

Hapsox ligand $(0.14 \mathrm{~g}, 0.7 \mathrm{mmol})$ was dissolved in a minimum amount of ethanol and an aqueous solution containing an equimolar amount of $\mathrm{K}_{2}\left[\mathrm{PdCl}_{4}\right](0.23 \mathrm{~g}, 0.7 \mathrm{mmol})$ or $\mathrm{K}_{2}\left[\mathrm{PtCl}_{4}\right](0.29 \mathrm{~g}$, 0.7 mmol ) was added. The mixture was refluxed until it was clear (approx. 2 h ).
$[\mathrm{Pd}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$. The microcrystalline product precipitated after cooling the reaction mixture to room temperature. After filtering, the crystals were washed with ethanol. Yield: 0.13 g ( 51 \%). IR spectrum ( $\mathrm{KBr} ; v / \mathrm{cm}^{-1}$ ): 3411 ( $\left.v s\right), 3293(m), 3235(m), 3169(m), 1708(v s), 1598(s), 1520(v s)$, 1463(m), 1438(m), 1381(w), 1335(w), 1276(s), 1154(w), 1079(w), 1038(w), 783(w), 759(w), 708(m), $585(m), 551(m), 456(w)$. Elemental analysis: Found: C $30.03 \%$, H $2.84 \%$, N $15.34 \%$, Calcd. for $[\operatorname{Pd}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{4} \mathrm{O}_{3} \mathrm{ClPd}\left(M_{\mathrm{r}}=365.09\right)$ : C $29.61 \%$, H $3.04 \%$, N $15.35 \%$.
$[\mathrm{Pd}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$. An orange microcrystalline precipitate separated after keeping the reaction mixture in a refrigerator for 24 h . After filtration, the crystals were washed with ethanol. Yield: 0.18 g ( $58 \%$ ). IR spectrum ( $\mathrm{KBr} ; \mathrm{v} / \mathrm{cm}^{-1}$ ): 3414(s), 3307(m), 3237(m), 3168(m), 1709(s), 1645(w), 1599(m), $1512(s), 1465(m), 1437(m), 1381(w), 1272(s), 778(w), 712(m), 594(w), 556(m)$. Elemental analysis: Found: C $24.25 \%$, H $2.03 \%$, N $12.67 \%$, Calcd. for $[\mathrm{Pt}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{4} \mathrm{O}_{3} \mathrm{ClPt}\left(M_{\mathrm{r}}=453.78\right)$ : C $23.82 \%$, H $2.45 \%$, N $12.35 \%$.

## Physical measurements

Elemental C, H, N analysis was performed by the standard micromethod in the Centre for Instrumental Analysis, Faculty of Chemistry, University of Belgrade. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra were recorded on a Varian Gemini 2000 spectrometer at 200 MHz , and ${ }^{13} \mathrm{C}$-NMR spectra were recorded on the same instrument at 50 MHz . The IR spectra were recorded on a Perkin-Elmer FTIR 1726X spectrophotometer using the KBr technique. The molar conductivity of a DMF solution of the complex $\left(1 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}\right)$ was measured at room temperature on a Jenway -4009 digital conductivity meter.

## X-Ray structure determination of the Zn(II) complex*

Single-crystal diffraction data was collected using MoK $\alpha$ radiation on a Bruker SMART APEX system with a 2 K resolution CCD deterctor. The data collection was computed using the SMART software; ${ }^{10}$ integration of the collected frames and cell refinement were done using SAINT. ${ }^{11}$ Space-group determination, numerical absorption correction and structure solution/refinement were all performed using the SHELXL-97 program package. ${ }^{12}$ All H atoms were found in the difference Fourier map and were refined isotropically. Determination of hydrogen bonds was performed using the program PLATON. ${ }^{13}$ Data were collected first at 293 K and then at 110 K due to problems with refining the crystal water. For the data collection at 110 K , the crystal had to be "shock cooled" since it dried and cracked within minutes if exposed to a dry gas flow at room temperature. There were no significant structural changes between the two temperatures.

The crystal data for the $\left[\mathrm{Zn}(\operatorname{apsox})_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ complex are shown in Table I.

## RESULTS AND DISCUSSION

The first complex described in this work is the $\mathrm{Zn}(\mathrm{II})$ complex with 2'-[1-(2-pyridinyl)ethylidene]oxamohydrazide (Hapsox). The complex was obtained in methanol solution from $\mathrm{Zn}(\mathrm{OAc})_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and Hapsox ligand (mole ratio 1:2) in $60 \%(0.16$ g) yield, as a yellow single crystal product. The structure was assumed on the basis of elemental microanalysis, IR and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra, and confirmed by X-ray structure analysis.

In the IR spectrum of the $\mathrm{Zn}(\mathrm{II})$ complex, bands at $3393 \mathrm{~cm}^{-1}(v s)$ and 3283 $\mathrm{cm}^{-1}(s)$ attributed to the $v(\mathrm{NH})$ vibrations of the primary amide are observed. The most significant feature of the spectrum is the presence of only one band at 1700 $\mathrm{cm}^{-1}(s)$ due to $v(\mathrm{C}=\mathrm{O})$ vibrations, in contrast to two such bands in the spectrum of the free ligand $\left(1729 \mathrm{~cm}^{-1}(v s)\right.$ and $\left.1706 \mathrm{~cm}^{-1}(v s)\right)$. The loss of one band is attributed to the deprotonation of $-\mathrm{NH}-\mathrm{CO}-$ group and electron delocalization in the corresponding anion. The absorption band of the coordinated $-\mathrm{N}=\mathrm{C}-\mathrm{O}^{-}$group is at $1283 \mathrm{~cm}^{-1}(s)$. Bands between 1600 and $1400 \mathrm{~cm}^{-1}$ are attributed to skeletal vibrations of the pyridine ring and $v(\mathrm{C}-\mathrm{N})$ vibrations.
${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of the $\left[\mathrm{Zn}(\text { apsox })_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ complex was recorded in $\mathrm{DMSO}-\mathrm{d}_{6}$ with TMS as an internal standard. The spectral data of the free ligand (Hapsox) ${ }^{7}$ and the complex are given in Table II. The ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectrum of the complex was not recorded because of the low solubility of the complex.

Comparing the spectrum of the ligand with that of the complex, it can be seen that the chemical shifts of the methyl group (C7) and C3 protons are higher in the complex than in the ligand, due to electron withdrawal from the nitrogens N1 and N 2 by zinc. The electronic effects arising from coordination of the pyridine nitrogen are more prominent for the para (C3) and ortho (C1) hydrogens, than for the meta ( C 2 and C 4 ) ones.

(a)

(b)

(c)

Final confirmation of the structure of the complex was obtained by X-ray structure analysis. The complex is of a neutral type with three molecules of crystal water. Two ligand molecules are coordinated in the monoanionic form, giving a deformed octahedral geometry. The largest distortion is observed for $\mathrm{Zn}-\mathrm{N} 6$ and $\mathrm{Zn}-\mathrm{O} 3$ bonds, the length of which are 2.0663(2) and 2.1262(1) $\AA$, respectively. The apsox ligand is coordinated to $\mathrm{Zn}(\mathrm{II})$ via the pyridine and hydrazone nitrogens as well as via the $\alpha$-oxyazine oxygen. Theoretically, there are four possible geometric isomers (Scheme 1) and the crystal structure of the $\left[\mathrm{Zn}(\operatorname{apsox})_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ complex shows that the apsox ligands are meridionally coordinated (Scheme 1a), as expected since both ligands are tridentates when coordinated in the monoanionic form (Fig. 1). Their coordination in the $\alpha$-oxyazine form results in the formation of four five-membered rings around $\mathrm{Zn}(\mathrm{II})$, which are more planar than in the analogous complexes with the dapsox ligand. ${ }^{9}$ Selected bond lengths and angles are given in Table III. As the geometries of both ligands are almost identical, data are shown for one ligand only. The $\mathrm{C} 8-\mathrm{O} 1, \mathrm{C} 8-\mathrm{N} 3$ and $\mathrm{N} 2-\mathrm{N} 3$ are typical for deprotonation at N3 and the consequential electron delocalization.

The crystal packing is characterized by strong intermolecular hydrogen bonds involving most of the potential donors and acceptors (Table IV). Hydrogen bond
system in the structure is three-dimensional. The amide nitrogens N8 and N4 are double donors, as are the oxygens O 5 and O 7 from molecules of water, while the water oxygen 06 is a single donor. The consequence is that the complete structure is multi-layered. Namely, molecules of the complex and water molecules form layers parallel to the ab-plane.

The mode of coordination of the apsox ligand is identical to that of the $\mathrm{H}_{2}$ dapsox ligand. Namely, the two identical side chains in $\mathrm{H}_{2}$ dapsox are coordinated in the same way as the single side chain in apsox. ${ }^{9}$

The $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes with Hapsox as ligand were prepared by the reaction of the ligand with $\mathrm{K}_{2}\left[\mathrm{PdCl}_{4}\right]$ and $\mathrm{K}_{2}\left[\mathrm{PtCl}_{4}\right]$, respectively.

The composition of the complexes was determined by elemental microanalysis. The IR spectra of the $\mathrm{Pd}(\mathrm{II})$ and the $\mathrm{Pt}(\mathrm{II})$ complexes are similar. The bands corresponding to $v(\mathrm{NH})$ vibrations of the primary amide moiety are at $3411 \mathrm{~cm}^{-1}(v s)$ and $3293 \mathrm{~cm}^{-1}(v s)$ for the $\operatorname{Pd}(\mathrm{II})$ complex and at $3415 \mathrm{~cm}^{-1}(v s)$ and $3307 \mathrm{~cm}^{-1}$ (vs) for the $\mathrm{Pt}(\mathrm{II})$ complex. In the spectral region around $1700 \mathrm{~cm}^{-1}$, there are bands $\left(v(\mathrm{C}=\mathrm{O})\right.$, amide I) at $1708 \mathrm{~cm}^{-1}(v s)$ in the spectrum of the $\mathrm{Pd}(\mathrm{II})$ complex and at $1709 \mathrm{~cm}^{-1}(v s)$ in the spectrum of the $\mathrm{Pt}(\mathrm{II})$ complex. The presence of the bands at $1276 \mathrm{~cm}^{-1}(s)$ and $1272 \mathrm{~cm}^{-1}(s)$ in the spectra of pallatium and platinum complexes, respectively, originating from coordinated $-\mathrm{N}=\mathrm{C}-\mathrm{O}^{-}$groups, indicates deprotonation of the Hapsox ligand in complexes. Finally, the group of bands at 1600-1400 $\mathrm{cm}^{-1}$ corresponds to skeletal pyridine ring and $v(\mathrm{C}-\mathrm{N})$ vibrations.

The ${ }^{1} \mathrm{H}$-NMR spectral data of the $[\mathrm{Pd}($ apsox $) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$ and $[\mathrm{Pt}(a p s o x) \mathrm{Cl}] \cdot \mathrm{H}_{2} \mathrm{O}$ complexes are given in Table II. As with the Zn complex, deprotonation of nitrogen N 3 upon complexation can be seen by loss of the NH signal at 10.82 ppm . By deprotonation, the electron density at oxygen O 1 is increased $\left[-\mathrm{N}^{-}-\mathrm{C}=\mathrm{O} \leftrightarrow-\mathrm{N}=\mathrm{C}-\mathrm{O}^{-}\right.$] making it a better electron donor for coordination. Other changes in the chemical shifts are rather similar to the $\left[\mathrm{Zn}(\mathrm{apsox})_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ complex indicating that the same atoms participate in the coordination.

The significant chemical shift changes of methyl C7, carbonyl C8 and pyridine ring carbon atom signals in the ${ }^{13} \mathrm{C}$-NMR spectrum upon complexation with platinum (Table V) confirm that the coordination sites are pyridine nitrogen, hydrazone nitrogen and $\alpha$-oxyazine oxygen. Based on elemental analysis and the spectral data for the $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes, it can be concluded that the ligand is coordinated as a tridentate and the fourth coordination site is occupied by a chloride ion. The geometry of the complexes is square planar, characteristic for $\mathrm{Pd}(\mathrm{II})$ complexes with coordination number 4. Analogous complexes with $\mathrm{H}_{2}$ dapsox could not be obtained, possibly because of steric reasons.

Since metal complexes of 2-acetylpyridine semicarbazones and thiosemicarbazones are biologically active, , ${ }^{14-17}$ the antimicrobial and antitumor activities of the synthesized complexes will be the subject of further research.

У овом раду описана је синтеза и структурна карактеризација комплекса $\mathrm{Zn}(\mathrm{II})$, $\operatorname{Pd}(\mathrm{II})$ и $\operatorname{Pt}(\mathrm{II})$ са 2'-[1-(2-пиридинил)етилиден]оксамохидразидом (Hapsox). Сва три добијена комплекса су неутралног типа са два координована apsox лиганда у случају комплекса $\mathrm{Zn}(\mathrm{II})$, односно једним арsox лигандом у случају $\operatorname{Pd}(\mathrm{II})$ и $\operatorname{Pt}(\mathrm{II})$ комплекса. Координација полидентата је у свим комплексима остварена преко пиридинског азота, хидразонског азота и $\alpha$-оксиазинског кисеоника градећи октаедарску геометрију око $\mathrm{Zn}(\mathrm{II})$, односно квадратно планарну геометрију око Pd(II) и Pt(II). Потврду за овакве структуре добили смо из ИЦ, ${ }^{1} \mathrm{H}-\mathrm{NMR}$ и ${ }^{13} \mathrm{C}$-NMR спектара, док је за $\mathrm{Zn}(\mathrm{II})$ комплекс урађена и рендгенска структурна анализа.
