Criteria for inclusion in the *Health Technology Assessment* journal

Reports are published in *Health Technology Assessment* (HTA) if (1) they have resulted from work for the HTA programme, and (2) they are of a sufficiently high scientific quality as assessed by the reviewers and editors.

Reviews in *Health Technology Assessment* are termed 'systematic' when the account of the search appraisal and synthesis methods (to minimise biases and random errors) would, in theory, permit the replication of the review by others.

HTA programme

The HTA programme, part of the National Institute for Health Research (NIHR), was set up in 1993. It produces high-quality research information on the effectiveness, costs and broader impact of health technologies for those who use, manage and provide care in the NHS. 'Health technologies' are broadly defined as all interventions used to promote health, prevent and treat disease, and improve rehabilitation and long-term care.

The journal is indexed in NHS Evidence via its abstracts included in MEDLINE and its Technology Assessment Reports inform National Institute for Health and Care Excellence (NICE) guidance. HTA research is also an important source of evidence for National Screening Committee (NSC) policy decisions.

For more information about the HTA programme please visit the website: http://www.nets.nihr.ac.uk/programmes/hta

Background: Self-management (SM) support for patients with chronic obstructive pulmonary disease (COPD) is variable in its coverage, content, method and timing of delivery. There is insufficient evidence for which SM interventions are the most effective and cost-effective.

Objectives: To undertake (1) a systematic review of the evidence for the effectiveness of SM interventions commencing within 6 weeks of hospital discharge for an exacerbation for COPD (review 1); (2) a systematic review of the qualitative evidence about patient satisfaction, acceptance and barriers to SM interventions (review 2); (3) a systematic review of the cost-effectiveness of SM support interventions within 6 weeks of hospital discharge for an exacerbation of COPD (review 3); (4) a cost-effectiveness analysis and economic model of post-exacerbation SM support compared with usual care (UC) (economic model); and (5) a wider systematic review of the evidence of the effectiveness of SM support, including interventions (such as pulmonary rehabilitation) in which there are significant components of SM, to identify which components are the most important in reducing exacerbations, hospital admissions/readmissions and improving quality of life (review 4).

Methods: The following electronic databases were searched from inception to May 2012: MEDLINE, MEDLINE In-Process and Other Non-Indexed Citations, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), and Science Citation Index [Institute of Scientific Information (ISI)]. Subject-specific databases were also searched: PEDro physiotherapy evidence database, PsycINFO and the Cochrane Airways Group Register of Trials. Ongoing studies were sourced through the *meta*Register of Current

Controlled Trials, International Standard Randomised Controlled Trial Number database, World Health Organization International Clinical Trials Registry Platform Portal and ClinicalTrials.gov. Specialist abstract and conference proceedings were sourced through ISI's Conference Proceedings Citation Index and British Library's Electronic Table of Contents (Zetoc). Hand-searching through European Respiratory Society, the American Thoracic Society and British Thoracic Society conference proceedings from 2010 to 2012 was also undertaken, and selected websites were also examined. Title, abstracts and full texts of potentially relevant studies were scanned by two independent reviewers. Primary studies were included if ≈90% of the population had COPD, the majority were of at least moderate severity and reported on any intervention that included a SM component or package. Accepted study designs and outcomes differed between the reviews. Risk of bias for randomised controlled trials (RCTs) was assessed using the Cochrane tool. Random-effects meta-analysis was used to combine studies where appropriate. A Markov model, taking a 30-year time horizon, compared a SM intervention immediately following a hospital admission for an acute exacerbation with UC. Incremental costs and quality-adjusted life-years were calculated, with sensitivity analyses.

Results: From 13,355 abstracts, 10 RCTs were included for review 1, one study each for reviews 2 and 3, and 174 RCTs for review 4. Available studies were heterogeneous and many were of poor quality. Meta-analysis identified no evidence of benefit of post-discharge SM support on admissions [hazard ratio (HR) 0.78, 95% confidence interval (CI) 0.52 to 1.17], mortality (HR 1.07, 95% CI 0.74 to 1.54) and most other health outcomes. A modest improvement in health-related quality of life (HRQoL) was identified but this was possibly biased due to high loss to follow-up. The economic model was speculative due to uncertainty in impact on readmissions. Compared with UC, post-discharge SM support (delivered within 6 weeks of discharge) was more costly and resulted in better outcomes (£683 cost difference and 0.0831 QALY gain). Studies assessing the effect of individual components were few but only exercise significantly improved HRQoL (3-month St George's Respiratory Questionnaire 4.87, 95% CI 3.96 to 5.79). Multicomponent interventions produced an improved HRQoL compared with UC (mean difference 6.50, 95% CI 3.62 to 9.39, at 3 months). Results were consistent with a potential reduction in admissions. Interventions with more enhanced care from health-care professionals improved HRQoL and reduced admissions at 1-year follow-up. Interventions that included supervised or unsupervised structured exercise resulted in significant and clinically important improvements in HRQoL up to 6 months.

Limitations: This review was based on a comprehensive search strategy that should have identified most of the relevant studies. The main limitations result from the heterogeneity of studies available and widespread problems with their design and reporting.

Conclusions: There was little evidence of benefit of providing SM support to patients shortly after discharge from hospital, although effects observed were consistent with possible improvement in HRQoL and reduction in hospital admissions. It was not easy to tease out the most effective components of SM support packages, although interventions containing exercise seemed the most effective. Future work should include qualitative studies to explore barriers and facilitators to SM post exacerbation and novel approaches to affect behaviour change, tailored to the individual and their circumstances. Any new trials should be properly designed and conducted, with special attention to reducing loss to follow-up. Individual participant data meta-analysis may help to identify the most effective components of SM interventions.

Plain English summary

Chronic obstructive pulmonary disease (COPD) is a lung condition that affects about 5% of adults. Patients develop cough and breathlessness, which gets worse over time, and many patients also have 'flare-ups', which can lead to being admitted to hospital for a few days. Patients should try to manage their own health (self-manage) on a daily basis – exercising, eating more healthily, taking medications properly and learning to recognise and self-treat their 'flare-ups' early. The aim is to avoid going to hospital and to maintain better quality of life.

Guidelines recommend that general practitioners and nurses should support patients to self-manage but there is insufficient information about how best to do so. As patients who have just left hospital are at a high risk of being admitted again, one approach would be to introduce a programme of self-management support at this point. However, it is unclear whether this would work or whether it would be efficient financially for the NHS.

In this report, we drew together all available evidence and showed that self-management programmes provided soon after leaving hospital might reduce future hospital admissions and improve patients' quality of life, but the results were inconclusive. However, if better research were undertaken, and programmes were proven to reduce hospital admissions, the approach would be relatively cheap to implement.

We also explored which parts of self-management programmes were the most important, and found that those that included a specific exercise plan appeared to be the most beneficial but it was difficult to be sure about other aspects.

Scientific summary

Background

Systematic reviews have shown that self-management (SM) interventions can lead to improved health-related quality of life (HRQoL) and reduced hospital admissions. However, the content and delivery of SM support varies considerably. There are unanswered questions about whether or not SM support would be effective and cost-effective if started immediately after a hospital admission for an exacerbation, and what is the most effective content and method of delivery of SM programmes.

Objectives

- To undertake a systematic review of the evidence for the effectiveness of SM interventions commencing within 6 weeks of hospital discharge for an exacerbation of chronic obstructive pulmonary disease (COPD) (review 1).
- To undertake a systematic review of the qualitative evidence about patient satisfaction, acceptance and barriers to SM interventions (review 2).
- To undertake a systematic review of the cost-effectiveness of SM support within 6 weeks of hospital discharge for an exacerbation of COPD (review 3).
- To undertake a cost-effectiveness analysis and economic model of post-exacerbation SM support compared with usual care (UC) (economic model).
- To undertake a wider systematic review of the evidence of the effectiveness of SM support including interventions [such as pulmonary rehabilitation (PR)] where there are significant components of SM, to identify which components are the most important in reducing exacerbations, hospital admissions and improving quality of life (review 4).

Methods

Systematic reviews

A comprehensive search strategy of the effectiveness of SM interventions was carried out. The following electronic databases were searched from inception to May 2012, with no language restriction: MEDLINE, MEDLINE In-Process and Other Non-Indexed Citations, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), and Science Citation Index [Institute of Scientific Information (ISI)]. Subject-specific databases were also searched: PEDro physiotherapy evidence database, PsycINFO and the Cochrane Airways Group Register of Trials. Ongoing studies were sourced through the *meta*Register of Current Controlled Trials, International Standard Randomised Controlled Trial Number database, World Health Organization, International Clinical Trials Registry Platform Portal and ClinicalTrials.gov. Specialist abstract and conference proceedings were sourced through ISI's Conference Proceedings Citation Index and British Library's Electronic Table of Contents (Zetoc). Hand-searching through European Respiratory Society, the American Thoracic Society and British Thoracic Society conference proceedings from 2010 to 2012 was also undertaken, and selected websites were also examined.

Study selection was undertaken by two independent reviewers using predefined criteria. Full-text manuscripts were obtained of all abstracts that were likely to meet these criteria.

For review 1, randomised controlled trials (RCTs) and relevant outcomes were included. For review 2, only qualitative studies were included. For review 3, any cost-effectiveness study design was accepted. For the

wider exploratory review (review 4), only RCTs were included and the primary outcomes were pre-specified as HRQoL, hospital admissions and exacerbations.

Studies in which ≈90% of patients had COPD, and where the majority of the patients were moderately/severely affected, were included. For reviews 1–3, patients must have been discharged from hospital with acute exacerbation of their COPD within the previous 6 weeks. For review 4, there were no restrictions around time period.

Self-management was defined as including disease education, medication management, smoking cessation advice, action planning, breathing management, bronchial hygiene techniques, respiratory muscle training (RMT), exercise, correct inhaler technique, advice about nutrition, stress management, relaxation and attendance at patient support groups.

Risk of bias of the selected RCTs was assessed using the Cochrane Risk of Bias tool. The quality of the qualitative study was assessed using the Critical Appraisal Skills Programme tool for qualitative evidence, and the Drummond checklist was used to assess the cost-effectiveness study.

The results of each review were presented descriptively and in forest plots where appropriate. When meta-analysis was undertaken, continuous outcome data were pooled using mean difference with 95% confidence intervals (CIs), and hazard ratios (HRs) with 95% CI for dichotomous events. Owing to the expectation of high levels of heterogeneity, random-effects models were used throughout. The I^2-statistic was used to assess statistical heterogeneity between trials. To explore sources of heterogeneity, subgroup analyses were undertaken. Prediction intervals were calculated to describe the range in which 95% of the distribution of the effects lie. HRQoL measured by the St George's Respiratory Questionnaire (SGRQ) were reversed so that a positive result favoured the intervention group.

Economic model of cost–utility of post-discharge self-management support

A Markov model was developed to consider short-term risks of readmission and mortality, and long-term natural history of COPD. The model compared a SM intervention immediately after a hospital admission for an acute exacerbation with UC. Clinical effectiveness parameters for SM were derived from the clinical effectiveness review, specifically the risk reduction in admissions. The model was speculative; thus, although the clinical review was not conclusive, the model could assess the potential effect and the uncertainty around this assumption. Resource use and costs associated with SM and usual treatment for COPD were taken from a mixture of published and unpublished sources, and expert clinical advice. A clinical cohort of 1000 patients of mixed age, sex, smoking status and disease severity was modelled for a 30-year horizon. Incremental costs and quality-adjusted life-years (QALYs) were calculated. Extensive sensitivity analyses were carried out.

Results

Review of self-management post-discharge (review 1)

The search identified 13,355 citations, of which 836 full-text papers were assessed and 12 were included, reporting 10 RCTs. The interventions included were very heterogeneous, ranging from an exercise-only intervention to intensive integrated care at home. Studies generally had small sample sizes, frequently high risk of bias with poor reporting, high loss to follow-up (particularly for the HRQoL outcomes) and inappropriate analyses in some studies.

Meta-analysis identified no evidence of benefit of early SM support on admissions (HR 0.78, 95% CI 0.52 to 1.17; $I^2 = 70.9\%$), mortality (HR 1.07, 95% CI 0.74 to 1.54; $I^2 = 0\%$) and most other health outcomes. A modest improvement in HRQoL was identified, but this was possibly biased owing to high loss to follow-up in studies. However, the direction of effect for many outcomes (including admissions) favoured the SM intervention.

Review of qualitative studies reporting patient experience of self-management post discharge (review 2)

Only one paper from Australia with a small qualitative component was included. Patients found that the SM programme improved their communication with health-care professionals and access to resources.

Review of cost-effectiveness and costing studies post-discharge (review 3)

Only one trial from Spain met the criteria and was a hospital-at-home intervention with a substantial SM component.

The cost analysis [using 2000 price data in euros (€)] found that the home hospitalisation intervention was significantly less costly than conventional care (average cost per patient: €1255.12 vs. €2033.51; $p = 0.003$).

Economic model of self-management support post discharge

Owing to considerable uncertainty around the impact on readmissions and heterogeneity of the trial results, the model-based analysis should be viewed as speculative and, therefore, only providing estimates of the potential impact of a SM programme delivered in the post-exacerbation period.

The main drivers of the model were the effect on hospital readmissions, duration of the effect, and the cost of a SM programme. The base-case analysis showed that, compared with UC, SM support (delivered within 6 weeks of hospital discharge) was more costly but resulted in better outcomes, with a £683 cost difference and a gain of 0.0831 QALYs. To be cost-effective, a SM programme, post admission for an acute exacerbation, would need to cost no more than £2200 if the relative reduction in admissions was consistent with a HR of 0.82. The sensitivity analysis suggested that SM support had a probability of 68% of being cost-effective at a threshold incremental cost-effectiveness ratio of £20,000 per QALY, demonstrating the uncertainty around the impact of SM on readmissions.

Review of effectiveness of different models and components of self-management (review 4)

A total of 194 papers reporting 174 RCTs reported one of the three primary outcomes. The majority of populations had moderate or severe COPD and recruited participants from secondary care. Trials were generally small (47% had < 50 participants) and had short follow-up (45% up to 3 months). Most trials (163, 96.6%) reported HRQoL, 42 (24.1%) reported hospital readmissions and only 20 (11.5%) reported exacerbations. In the intervention groups, exercise was the most commonly reported component (76.9%), followed by breathing techniques and management of dyspnoea (64.2%), and general education about COPD and its management (47.2%). Seventy-three (31.9%) of the intervention arms had six or more components; 38 (16.6%) were single components, with the vast majority of these being exercise-only interventions.

Sequence generation and allocation concealment were adequate in 66 (37.9%) and 27 (15.5%) studies, respectively. Owing to lack of blinding of participants of their allocation, HRQoL results were considered at high risk of bias, except in trials with an active intervention or sham comparator. A frequent and significant risk of bias was the reporting of the characteristics of only those who completed the study, rather than those randomised.

Studies assessing the effect of individual components were few, but only exercise significantly improved patient outcomes compared with UC, which was restricted to HRQoL in the short term (SGRQ at 3-months' follow-up 4.87, 95% CI 3.96 to 5.79; $I^2 = 0\%$). This is above the minimally clinically important difference of four points for the SGRQ. Multicomponent (at least three individual components) SM interventions were likely to be more effective than UC: at 9–12 months' follow-up, SGRQ = 2.40 (95% CI 0.75 to 4.04; $I^2 = 57.9\%$), hospital admissions HR = 0.79 (95% CI 0.60 to 1.05; $I^2 = 62.6\%$). However, the degree of heterogeneity suggests that there are important features of these interventions that need to be established. Compared with UC, multicomponent SM interventions with supervised exercise (as in a PR

programme) or structured unsupervised exercise (as in a home rehabilitation programme) appear effective. SM programmes that provide an enhanced level of care and support (where there is proactive involvement of health-care professionals) may reduce hospital admissions in the medium term (at 6 months: HR 0.78, 95% CI 0.62 to 0.99; $I^2 = 55.1\%$) and improve HRQoL (SGRQ at 6 months = 4.05, 95% CI 2.23 to 5.87; $I^2 = 8.4\%$). The number of studies included in a range of other analyses which investigated modality of exercise, RMT, duration of programme and person delivering the programme were too limited to provide sufficient evidence to determine their effectiveness. No conclusive findings emerged from direct comparisons between different SM interventions. Notably, there was no evidence that action plans were effective by themselves.

Conclusions

This report provides a thorough evaluation of the available evidence from which to design future research in this area. The reviews of the effectiveness of SM interventions immediately post admission for an exacerbation revealed modest potential benefits to HRQoL, with no other statistically significant effects, but with most other outcomes (excluding mortality) favouring the SM arm. There were no good qualitative papers reporting patient experience of these early SM interventions and only one cost-effectiveness study. A speculative economic model describes the assumptions required for such an intervention to be cost-effective.

The wider exploratory review of SM interventions revealed that although some components of SM interventions were associated with positive effects of HRQoL, such as structured exercise (either within a supervised group or home based) enhanced care and multicomponent interventions, it was not possible to establish the relative roles of individual components in reducing hospital admissions and improving HRQoL.

Implications for health care

The evidence is not consistent with recommending SM support be provided post discharge from hospital after an acute exacerbation of COPD. However, the risk of readmission is so high that further research is needed to establish whether or not some aspects of SM for some patients might be an effective approach.

It is difficult to recommend specific components that should be included in SM support interventions in general. The evidence is most consistent with exercise being an important and effective component, particularly in a supervised or structured unsupervised format. However, the evidence is insufficient to establish the relative importance of other aspects.

Recommendations for research

1. Current interventions to support patient SM delivered post discharge cannot currently be recommended because interventions are heterogeneous and methodology problematic, and, despite there being potential benefit in terms of HRQoL, there is not enough good evidence to be sure that clinical outcomes could be improved. Therefore:

    i. High-quality studies should be undertaken among patients with COPD post discharge.
    ii. This should include qualitative work to explore barriers and facilitators to SM when patients have recently had an exacerbation, exploration of novel approaches to affect behaviour change and exploration of approaches tailored to the individual and their circumstances.
    iii. New approaches should be evaluated by properly designed and conducted trials, with special attention to reducing loss to follow-up.

2. Owing to the heterogeneity and complexity of interventions, it was not possible to unpick the most important components of SM interventions in general, or to confirm whether they improve clinical outcomes. It is clear that action plans alone do not seem to work in their present form, but that structured exercise and more heavily supported interventions (which may not usually be defined as SM) might work better. Therefore:

    i. Further in-depth work using individual participant data (e.g. an individual participant data meta-analysis) should be carried out to try to identify which are the most effective components of interventions and identify patient-specific factors that may modify this. This work is ongoing by other researchers.
    ii. Future studies might try to identify the characteristics of patients who are more likely to be able to self-manage and consider a more targeted approach.
    iii. Further qualitative work is needed to explore patients' barriers and facilitators to SM interventions.
    iv. Novel approaches to influence behaviour change and to help patients manage or prevent exacerbations should be explored, first using qualitative studies and then properly designed and conducted RCTs.
    v. Most trials include a mixture of components; more trials teasing out the individual elements either as lone interventions, or with the addition of one component, would be useful.

3. Recommendations for the design and conduct of future RCTs of interventions to support patient SM:

    i. In general new trials should adhere to modern standards of design, conduct and reporting in order to reduce risks of bias, for example, blinding of outcome assessment, attempts to maximise follow-up or methods to impute this, reporting of the characteristics of all randomised patients.
    ii. The behaviour change theories and strategies that underpin COPD SM interventions need to be better characterised and described.
    iii. A clear framework for describing and classifying SM interventions and their comparators is required.
    iv. Trials need to be adequately powered to detect a clinically relevant difference and long enough to assess changing effects over time. There should be clear reporting of outcomes to include self-efficacy, behaviour change and clinical outcomes, such as hospital admissions and exacerbations.
    v. Given the wide range of HRQoL outcomes available, it would be useful to standardise their use within COPD research and ensure that they are reported accurately within publications.
    vi. Statistical analysis methods should be improved, in particular (1) analysis of HRQoL outcomes should routinely adjust for baseline values to overcome baseline imbalance, account for correlation between final score and baseline score, and increase statistical power; and (2) time-to-event outcomes should be analysed using suitable analyses that allow for differential patient follow-up and summarised using HRs (rather than odds ratios).

Chapter 1 Background

Chronic obstructive pulmonary disease: definition, prognosis and burden

Chronic obstructive pulmonary disease (COPD) is a long-term condition characterised by 'persistent airflow limitation that is usually progressive and associated with an enhanced chronic inflammatory response in the airways and the lung to noxious particles and gases'.[1] The most important cause of COPD is cigarette smoking, although other risk factors are thought to be indoor and outdoor air pollution, occupational exposures and diet.[2] Over time, patients experience increasing breathlessness and more frequent exacerbations of respiratory symptoms, leading to increasing disability, reduced quality of life (QoL) and often repeated hospitalisations.[1]

Chronic obstructive pulmonary disease affects 5–10% of people worldwide,[3] is rising in prevalence,[4] and is a leading cause of death.[5] In the UK it is the second most common cause of emergency admissions,[6] costing the NHS over £800M per year.[7] Increasing recognition of the importance of this disease[8,9] culminated in a new National Clinical Outcomes Strategy in 2011.[6]

Diagnosis and severity of chronic obstructive pulmonary disease

A diagnosis of COPD is suspected among people with breathlessness or cough and is supported by post-bronchodilator spirometry to confirm irreversible airflow obstruction.[10] Although definitions of airflow obstruction are inconsistent and controversial,[11] National Institute for Health and Care Excellence (NICE) guidance for COPD currently defines airflow obstruction when the ratio of forced expiratory volume in 1 second (FEV_1) to forced vital capacity (FVC) is < 0.7 (i.e. $FEV_1/FVC < 0.7$).[10] Despite the requirement for confirmation with spirometry, there are many people with a clinical diagnosis of COPD who do not meet these spirometric criteria.[12] Late-onset asthma, other comorbidities and difficulty obtaining spirometry data may contribute to misdiagnoses.

Severity of airflow obstruction in the UK is graded using categories of FEV_1 as a percentage of predicted normal values of a healthy reference population (*Table 1*),[10] although these definitions may vary across countries, and have changed over time.

Severity of airflow obstruction does not necessarily reflect either the level of disability experienced or the frequency of exacerbation and composite measures to capture the global impact of the disease have been proposed.[1] However, they are not yet widely used as the basis for treatment decisions. Most research

TABLE 1 Current UK categories of airflow limitation

Category	FEV_1% pred
Mild	> 80
Moderate	50–79
Severe	30–49
Very severe	< 30

FEV_1% pred, forced expiratory volume in 1 second percentage predicted.

studies evaluating treatments use FEV_1% pred (forced expiratory volume in 1 second percentage predicted) to select and describe patients. FEV_1 is also often used as an outcome measure to describe prognosis of patients, as are clinical measures (such as dyspnoea and exacerbations), global measures such as health-related quality of life (HRQoL) and health service utilisation (e.g. hospital admissions).

Exacerbations of chronic obstructive pulmonary disease

Exacerbations or 'flare-ups' of COPD occur in approximately 50–60% of moderate/severe patients with COPD, per year, in published cohorts and trials[13,14] and similar rates are also observed in primary care (unpublished data from the Birmingham COPD cohort study). They are a characteristic component of disease progression, often requiring hospitalisation[1] and are associated with long-term poor outcome. Exacerbations are caused primarily by viral respiratory infections, particularly the common cold (associated with about two-thirds of exacerbations).[15] They result in worsening of a patient's symptoms for several days, this being more frequent during winter months.[16]

Approximately 15% of patients with COPD per year have exacerbations that are severe enough to lead to hospital admission,[7] which contributes to over half of the total direct costs of COPD to the NHS.[7] Readmission for an exacerbation within 3 months is high at > 30%,[17] as is 30-day mortality. Exacerbations are often not independent events, and there are a group of people who are frequent exacerbators.[18] Exacerbations are usually treated with an increase in usual medication, a course of antibiotics and/or steroids.[10]

Management of chronic obstructive pulmonary disease

In early-stage disease patients may not display or recognise their symptoms but, as the disease progresses, varying degrees of cough, sputum, wheeze and dyspnoea[1] may develop until eventually patients may require long-term oxygen therapy.[10] Other than the acute treatment of exacerbations, therapy is aimed at reducing progression and managing symptoms and is primarily based around smoking cessation, inhaled medications, pulmonary rehabilitation (PR) and, increasingly, more preventative disease management approaches [including self-management (SM)].[10]

Management of long-term conditions in the UK

More than 15 million people in England are living with long-term conditions such as COPD, diabetes, heart disease and asthma.[19] Long-term conditions represent > 70% of hospital bed-days and more than half of general practitioner (GP) consultations, and account for at least 70% of the total health and social care budget.[19] For patients, long-term conditions reduce QoL and ability to carry out daily tasks, as well as contributing to premature mortality. In the past, treatment of people with long-term conditions would have been more reactive. However, in 2004, the NHS Improvement Plan set out the plans for the future care of these patients by focusing on avoiding admissions and caring for patients at the primary care level, and encouraging patients to manage their own condition (SM).[20]

Patients access health-care professionals relatively infrequently and, therefore, in order to optimise their health patients must be able to manage their own condition successfully on a daily basis. Support should be available to help patients (and their families/carers) manage their own condition and make healthier choices about their diet, physical activity and lifestyle.[20] Since the NHS Improvement Plan was published, this approach has been embedded in subsequent policy documents,[21] which clearly emphasise the important role of SM. However, it is clear that clinicians are often reluctant to take this approach and, therefore, the support for patient SM is likely to be suboptimal.[19]

Surveys indicate that > 90% of patients with long-term conditions would like to become more active self-managers, although in many conditions report insufficient knowledge or support to do so.[22]

Self-management: definition and models

'Self-management' has been defined as the ability of a patient to deal with all that a chronic disease entails, including symptoms, treatment, physical and social consequences and lifestyle changes.[23] The exact nature of SM will vary from condition to condition and person to person. Indeed, there is debate about the interpretation of the goals of SM, which may differ between health-care professionals and patients, and between countries and health-care systems.

There are many factors that may affect a patient's ability to self-manage (e.g. severity, presence of comorbidities, depression, education, psychological factors, ethnicity).[24–27] One behavioural model that describes SM is Patient Activation,[28] which emphasises that patients should have the knowledge, skills and confidence to manage their own health and health care. Interventions to promote SM should aim to address each of these components.

Interventions to support self-management

Self-management support involves collaboration between the health-care professional and the patient so that the patient acquires and demonstrates the knowledge and skills required to manage his/her medical regimens, change their health behaviour, improve control of their disease and improve their well-being.[29] Patient education alone is not sufficient; monitoring and assessment of progress is also essential. SM interventions should teach skills that promote health behaviour modification with the aim of increasing self-efficacy (the belief that one can successfully execute particular behaviours), thus improving clinical outcomes, including adherence.[30] Strategies to promote self-efficacy include personal experience and practice, feedback and reinforcement, analysis of causes of failure and shared experience with successful peers.[30] Indeed, the established NHS Expert Patient Programme for managing chronic diseases is based on Bandura's theory of self-efficacy.[31] Evaluations of SM programmes should therefore first assess patients' self-efficacy, change in behaviour and then patient outcomes and health-care utilisation.

Self-management programmes can be delivered in a number of ways (e.g. series of workshops, written material, by telephone, internet or a mixture) by various professionals or lay personnel, and can have a range of components. Systematic reviews of SM programmes for long-term conditions have concluded that such programmes tend to lead to small improvements in some outcomes for some chronic diseases (but not all) and that further research is needed.[32,33] More recently there have been some unsuccessful high-profile trials in primary care settings,[34–36] some of which suggest that only a subgroup of patients may be able to self-manage.

Self-management of chronic obstructive pulmonary disease: principles and current practice

Self-management for patients with COPD is complex and challenging.[10,25] It requires patients to be able to manage various facets of their condition on a daily basis, including understanding and taking their medications appropriately with good inhaler technique, early recognition of exacerbations of symptoms and early instigation of treatment during an exacerbation, receiving annual influenza vaccinations, managing their breathlessness (including stress management/relaxation) to allow them to undertake activities of daily living, bronchial clearance techniques, taking regular exercise to maintain their lung function and exercise capacity, quitting smoking and maintaining a healthy diet.[29,30,37]

In reality, the true extent to which patients manage these aspects is not well described but it is likely to be suboptimal. A survey published in 2009 in Canada[38] revealed that although patients felt that their knowledge about the disease was good, in reality their knowledge of the causes of COPD, the consequences of not adhering to their medication and how to manage exacerbations was inadequate. A small study in one GP practice in the UK in 2004[39] indicated that only 48% of patients with COPD had discussed levels of exercise with their GP/nurse and only 50% had spare antibiotics/steroids at home in case of exacerbations, although > 80% reported understanding their inhalers, knowing what to do if they had an exacerbation and having given up smoking.

Current self-management support for chronic obstructive pulmonary disease in the UK

Self-management support for COPD is less well developed than in other long-term conditions both in the UK and worldwide. NICE quality standards state that patients with COPD should have a comprehensive, up-to-date personalised management plan, including information/educational material about the condition and its management.[40] NICE guidance also emphasises that patients at risk of having an exacerbation of COPD should be given SM advice/treatment that encourages them to respond promptly to the symptoms of an exacerbation.[10] Other aspects of SM advice include promoting proactive behaviour change, such as smoking cessation and increased exercise. However, the evidence about the exact nature and the effectiveness and cost-effectiveness of potential components of a SM package is acknowledged to be inadequate.[10]

A variety of tools are available, such as the 'Living Well with COPD' programme developed by the Montreal Chest Institute and mentioned in the American Thoracic Society statement,[30] materials provided by the British Lung Foundation,[41] and materials developed by individual hospitals/universities or private health-care companies, but there is no one consistent recommended approach.[6,10] Limited evidence suggests that programmes are patchily provided and unlikely to be individualised.[42] Qualitative studies in the UK and elsewhere suggest that patients report a lack of SM support and a lack of understanding of their condition.[43,44]

This heterogeneity is reflected in the literature describing trials of a wide variety of interventions. It is accepted, however, that the optimum package of care is not known,[10] and this fact is one of the premises upon which this report is based.

There is considerable overlap between programmes that are defined as SM and other more complex supervised programmes, such pulmonary rehabilitation (PR).[37,45] PR is defined as 'an evidence-based, multidisciplinary, and comprehensive intervention for patients with chronic respiratory diseases who are symptomatic and often have decreased daily life activities . . . programs involve patient assessment, exercise training, education, nutritional intervention, and psychosocial support'.[30] A continuum of support is now recognised, which should, ideally, be personalised to reflect an individual patient's needs, including disease severity and other comorbidities.[37,45]

For this reason, in the second study within our evidence report, we have included trials of a wide range of care packages including PR in order to identify which features of SM are most important, as long as they involve one or more of the specified components of SM.

Evidence for the effectiveness and cost-effectiveness of self-management support for chronic obstructive pulmonary disease: existing literature

Current literature on SM for COPD largely addresses the effectiveness of SM support when delivered to patients in a stable state. There are now many trials and overlapping systematic reviews of interventions (such as PR, integrated care), which include a SM component, although to varying degrees.[46–50] A Cochrane systematic review of SM education interventions[48] (excluding studies on PR, updated in 2009) identified 14 randomised controlled trials (RCTs) that showed that SM interventions delivered to patients with COPD in the stable state could significantly reduce hospital admissions compared with usual care (UC) [odds ratio (OR) = 0.64, 95% confidence interval (CI) 0.47 to 0.89], significantly improve some domains of QoL and effect a small improvement in dyspnoea. However, many of the other results were inconclusive, possibly because of the great heterogeneity in the populations studied, nature of the interventions, outcomes measured and length of follow-up. The authors concluded that 'data were still insufficient to formulate clear recommendations regarding the form and contents of SM education programmes in COPD . . . with a need for more large RCTs with long-term follow-up'.[48]

A systematic review of five trials on the effectiveness of action plans only (with only limited education) found that although patients were significantly more likely to recognise exacerbations and initiate treatment, there was no reduction in health-care utilisation, and they concluded that a more significant SM approach might be needed.[50] A further systematic review of COPD disease management programmes,[49] including 10 trials and three before-and-after studies, indicated that such programmes (which often include SM components) may decrease hospital admission and improve QoL, although further exploration of the elements that bring the greatest benefit are needed.

A more recent systematic review of integrated disease management demonstrated a significant improvement in QoL and respiratory admissions,[47] and there are other recent systematic reviews of breathing exercises,[51] outreach nurses[52] and exercise training.[53] These reviews are significantly overlapping in their inclusion but none of them comprehensively reviews all of the latest trials relating to SM interventions/components or attempts to delineate the relative effectiveness of the different components.

One important factor that varies among the trials already reviewed[48] is the nature of the populations involved. It has been suggested that SM programmes should target those patients with more severe COPD and frequent exacerbations in order to be beneficial.[29,30] Patients who are admitted to hospital have a high risk of readmission within 90 days.[17] Thus a focus on patients who are currently hospitalised for COPD (or recently discharged) could have the most potential for health gain and reduction in resource use. Data on such interventions following hospitalisation (other than PR programmes) are limited.[54]

Rationale for evidence review

Although there is a plethora of RCTs published and increasing numbers of systematic reviews on different aspects of SM support for COPD, results are conflicting about which of the many types of interventions, and particularly which components, are the most effective.[10] Furthermore, there remain significant unanswered questions about the timing and delivery of SM support, particularly whether SM support provided soon after discharge from hospital is effective or cost-effective.

In 2010, the National Institute for Health Research (NIHR) Health Technology Assessment (HTA) programme published a commissioning brief: supported SM for patients with moderate to severe COPD. It asked for a wide systematic review of the literature, particularly focusing on patients, around or soon after discharge, to answer: 'What are the elements of supported SM that prevent readmission to hospital and adverse outcomes?' We report a series of systematic reviews and an economic model to address this question.

Chapter 2 Aims and objectives

There were two main aims of this research project. The first was to undertake a systematic review of the effectiveness and cost-effectiveness of supported self-management among people with moderate to severe chronic obstructive pulmonary disease who had recently been discharged from hospital following an acute exacerbation of their condition, and to use this evidence to undertake a model-based cost-effectiveness analysis from the UK NHS perspective. With a wider systematic review, we also planned to identify the features and elements of self-management interventions that are most effective.

Each aim had specific objectives.

Aim 1

Among patients with chronic obstructive pulmonary disease at discharge, or recently discharged from hospital within the last 6 weeks, to undertake:

- a systematic review of:
  - the evidence for the effectiveness of self-management support evaluating health behaviour change, self-efficacy, health service utilisation and patient-reported outcomes such as QoL (review 1)
  - the qualitative evidence about patient satisfaction, acceptance and barriers to self-management support (review 2)
  - the cost-effectiveness of self-management support (review 3)
- a cost-effectiveness analysis and economic model of self-management support compared with usual care (economic model).

Aim 2 (review 4)

Among patients with chronic obstructive pulmonary disease, at any time point, to:

- undertake a wider systematic review of the evidence of the effectiveness of self-management support [including interventions (such as pulmonary rehabilitation) for which there are significant components of self-management] in reducing exacerbations, hospital admissions/readmissions and improving QoL
- describe the features and elements of self-management interventions in relation to their effectiveness by simple categorisation and tabulation
- perform subgroup analysis and meta-regression to explore features such as the effect of study quality, population, setting and nature of intervention on the effectiveness of self-management interventions compared with usual care
- use mixed-treatment comparison meta-analysis methods to explore which components or combinations of components are most effective.

Structure of the report

The following chapters report separately on:

- *Chapter 3*: Aim 1 – clinical effectiveness review (review 1)
- *Chapter 4*: Aim 1 – qualitative evidence review (review 2)
- *Chapter 5*: Aim 1 – cost-effectiveness review (review 3)
- *Chapter 6*: Aim 1 – economic model
- *Chapter 7*: Aim 2 – review of effectiveness of components of self-management (review 4).

Each of the above chapters incorporates methods, results and discussion, and then, finally, *Chapter 8* provides an overall summary.

Chapter 3 A systematic review of the clinical effectiveness of supported self-management interventions delivered shortly after hospital discharge: review 1

The aim of this chapter is to present the findings of a systematic review of the evidence for the effectiveness of SM support evaluating health behaviour change, self-efficacy, health service utilisation and patient-reported outcomes, such as quality of life (QoL).

Methods

A systematic review of published evidence of the effectiveness of interventions to support self-management (SM) among patients with chronic obstructive pulmonary disease (COPD) who had recently been discharged from hospital.

Definition of self-management used for this review

'Self-management' has been defined as the ability of a patient to deal with all that a chronic disease entails, including symptoms, treatment, physical and social consequences and lifestyle changes.[23] SM interventions involve collaboration between the health-care professional and the patient so that the patient acquires and demonstrates the knowledge and skills required to manage their medical regimens, change their health behaviour, improve control of their disease and improve their well-being.[29] This definition of SM was used as a basis to devise a list of SM interventions/components that were considered for this review (*Table 2*). Because SM interventions are so heterogeneous, we specifically chose to include all possible aspects of SM to ensure completeness. However, we excluded interventions of smoking cessation alone, as there is already good evidence of the benefits of smoking cessation in general, and a large number of systematic reviews addressing the effectiveness of smoking cessation interventions (currently 60 Cochrane systematic reviews alone). Most evidence of the effectiveness of smoking cessation relates to general populations, rather than people with a particular condition. Any study that included smoking cessation as one component of a multicomponent package in people with COPD was included. Similarly, there is already a systematic review of pulmonary rehabilitation (PR) at this time point;[55] therefore, it was not considered necessary to repeat it but rather use it for comparison.

Search strategy for effectiveness studies

A comprehensive search strategy was designed and conducted by an experienced information specialist. The searches were kept broad to capture evidence to suit both aims.

Searches for relevant studies were conducted across the following bibliographic databases: MEDLINE, MEDLINE In-Process and Other Non-Indexed Citations and EMBASE (via Ovid), Cochrane Central Register of Controlled Trials (CENTRAL – Wiley) and Science Citation Index (Institute of Scientific Information). Subject-specific databases were also searched: PEDro physiotherapy evidence database, PsycINFO (via Ovid) and the Cochrane Airways Group Register of Trials. Ongoing studies were sourced through the *meta*Register of Current Controlled Trials, International Standard Randomised Controlled Trial Number database, World Health Organization International Clinical Trials Registry Platform Portal and ClinicalTrials.gov. Specialist abstract and conference proceedings were sourced through the Institute of Science Information's Conference Proceedings Citation Index and British Library's Electronic Table of Contents (Zetoc). Hand-searching through European Respiratory Society, the American Thoracic Society and British Thoracic Society (BTS) conference proceedings from 2010 to 2012 was also undertaken, and selected websites were also examined. No language restrictions or methodological filters were applied to the searches.

TABLE 2 Interventions and/or components included or excluded as SM

Intervention/component	Included/excluded	Comments
Adherence to medication	Include	Education about taking treatment correctly, promoting adherence
Ambulatory oxygen	Exclude	Unless it concerns education or support to take prescribed treatments such as ambulatory oxygen
Breathing techniques	Include	For example, pursed lip breathing
Bronchial hygiene techniques	Include	Mucus/airways clearance
Case management	Exclude	Unless elements of SM
Community matrons	Exclude	Unless elements of SM
Complementary therapies	Exclude	Exclude anything on acupuncture and massage, etc.
Early recognition of symptoms/action plans	Include	Must be self-monitoring, not external monitoring by external agency, unless there is a teaching/training element (e.g. patient being taught how to recognise the symptoms and act accordingly)
Education	Include	Any topics
Exercise	Include	Any type of exercise
Hospital at home	Exclude	Unless elements of SM
Inhaler technique	Include	Including assessment of inhaler technique
Integrated care	Exclude	Unless elements of SM
Nutritional programmes	Include	Include anything which encourages/helps people to maintain good nutrition or modify their diet; exclude anything to do with (proprietary) supplements, dietary programmes or trials of effectiveness
Patient empowerment	Include	As recommended by patient advisory group
Relaxation	Include	Any types
Respiratory muscle training	Include	Including both inspiratory and EMT
Smoking cessation	Exclude	Unless as a component of a larger package (not as a single active intervention)
Stress management	Include	Any types including counselling
Support groups	Include	As recommended by patient advisory group
Telecare	Include	Exclude if purely telemonitoring – not just about contact; include if there is an encouragement/support component, e.g. help to promote adherence to medication

EMT, expiratory muscle training.

Electronic database searching was carried out from inception to May 2012, and no updated searches were undertaken beyond this time point. The search strategies used for electronic databases can be found in *Appendix 1*; terms for COPD were combined with those for SM and, where possible, utilised appropriate medical subject headings.

The citation lists of all included studies and any citations within relevant reviews were scanned for additional relevant studies. Consultations with experts in the field through the investigators identified additional relevant literature.

Reference Manager version 11 (Thomson ResearchSoft, San Francisco, CA, USA) was used to store and manage all search results.

Study selection process

After removal of duplicates, titles and abstracts of the remaining search results were independently reviewed by two reviewers. Full texts were obtained for papers meeting the inclusion criteria or when the abstract was unclear. Full texts were then independently reviewed by two reviewers using detailed and piloted selection criteria concerning study design, populations, interventions, comparators and outcomes for each review. Any discrepancies were resolved by a third reviewer. Any non-English language papers were assessed, based on titles and abstract, but when information was lacking or unclear, translators were used to decide final inclusion. A reviewer worked alongside translators to avoid misinterpretation of the selection criteria. During full-text screening, papers were categorised into their appropriate objectives or were excluded with reasons.

Selection criteria

The selection criteria for this review are summarised in *Table 3*.

Only primary studies were included. Studies concerning patients with moderate to severe COPD were included, and those with patients with mild or very severe COPD were included only if the majority of the study population was moderate/severe. A COPD study population of approximately 90% was required for inclusion unless data on the subset of patients with COPD were provided separately. Studies were included if the intervention was set within either a hospital or a community. Studies of any SM intervention/package or components of SM interventions were included. For example, medication management, action plans, exercise, inhaler technique and stress management (see *Table 2*). Comparators consisting of usual care (UC), control/sham or other SM interventions were accepted.

Risk of bias assessment

All RCTs were assessed using the recommended and validated Cochrane Risk of Bias tool.[56] The following six domains were assessed: sequence generation, allocation concealment, blinding of personnel and participants (by outcome), incomplete outcome data (by outcome), selective outcome reporting and other potential threats to validity. Domains were judged as high risk of bias, low risk of bias and unclear risk of bias. For trials with multiple papers, information from all of the studies was used to judge risk of bias. After a piloting process, all studies were assessed by two independent reviewers with a third reviewer overseeing the process. The GRADE[57] framework was used to denote overall quality of evidence across studies for each of the primary outcomes and also HRQoL, using a scoring system of 4 (high) to 1 (very low) quality. The findings were summarised in a table, incorporating the results but also aspects that led to the final judgement.

Data extraction and manipulation

Approach

Data were extracted into piloted tables by the first reviewer with a second reviewer checking the extraction and a third reviewer overseeing the process. The results of all studies were tabulated and described and considered for combination in meta-analyses. Authors of included studies were contacted to clarify details and provide additional data required for analyses.

TABLE 3 Criteria for selecting studies

Study designs	RCTs
Population	Patients with moderate to severe COPD (defined clinically, with or without spirometry) recruited specifically at discharge or up to 6 weeks post discharge for an acute exacerbation of their condition (patients with mild or very severe COPD were included if they were a minority of the population group)
	Approximately 90% of patients in studies should have COPD
	The setting could be either hospital or community
Intervention	SM packages or important components of SM
	Excluding trials of smoking cessation and PR
Comparator	No intervention, UC, control/sham, other SM intervention
Primary outcomes	Any of:
	Health service outcomes and mortality
	Primary care consultations
	Hospital admissions
	Readmissions
	Duration of admissions
	Mortality
	Emergency department visits
Secondary outcomes	Any considered but to include:
	Behaviour change
	Self-efficacy
	Specific behaviours, e.g. increase in exercise/activity
	Patient-reported outcomes
	Exacerbations
	HRQoL
	Anxiety/depression
	Patient satisfaction
	Dyspnoea
	Other
	Lung function (FEV_1 and FEV_1/FVC)

Types of data extracted

The following types of data were extracted from all papers:

1. *Study characteristics* Including sample size, mean age, severity according to mean FEV_1% pred, place of recruitment, descriptions of intervention and control groups, outcomes, length of intervention and length of follow-up. When multiple papers were derived from the same trial, study characteristics were obtained from the original paper.
2. *Study results* Summary results from baseline and all follow-up times were extracted, including treatment effects, *p*-values, confidence intervals (CIs), mean scores at follow-up and/or mean changes in each group, numbers of events, hazard ratios (HRs), rates, loss to follow-up, etc. If multiple interventions were considered in a study then data were extracted for each pair of interventions compared.

Data manipulation

In order to maximise and prepare the data for statistical analyses, a number of steps were taken:

- Lengths of intervention and follow-up were converted to weeks as a proportion of a 52-week year and rounded to the nearest week.
- For continuous outcomes, for example QoL, reported mean difference (MD) estimates and 95% CIs calculated from an analysis of covariance (ANCOVA) were preferred, as this method adjusts for baseline imbalances. If not reported, the following methods were used in order of priority:
    - MDs reported from an analysis of change scores
    - MDs reported from an analysis of final scores
    - MDs calculated indirectly by ourselves from other information (e.g. mean change score for each group or the mean final score for each group).

If standard errors (SEs) were not reported directly, they were calculated from other information where available (such as *p*-values, 95% CIs, number in each group) at the end of follow-up, and the standard deviation (SD) of values in each group at the end of follow-up.

- For effect estimates for numbers of events over time, for example number of admissions or exacerbations over follow-up, we preferentially used HRs (e.g. from a Cox regression analysis) because they compare the rate of events over the whole follow-up period and account for individuals lost to follow-up (censored). We used only first admissions, as it is not possible to combine different types of measures (e.g. with mean number of admissions per patient) without making very strong assumptions, and this was the most common measure. Where not reported, the following methods were used to estimate the HR and its 95% CI indirectly, used in this priority order:
    - Methods of Parmar *et al.*,[58] which allowed indirect estimation of the HR and its CI from the *p*-value, and the number of patients and outcomes in each group.
    - If numbers of events and sample size were available, the method of Perneger[59] was used. Where there were zero cells then a continuity correction (1/sample size of the opposite group) was added to each cell to allow HRs to be calculable.[60]

- Where necessary, MD results and $\log_e$ HRs presented on the same plots were multiplied by –1 to ensure that all estimates and intervals obtained related to the same direction of effect (e.g. that a MD in HRQoL of < 0 meant the same thing in each study).
- To utilise more results on emergency department (ED) visits, reported mean numbers of visits during follow-up were converted to rate of ED visit by assuming that all patients not lost to follow-up were observed for the full duration of the trial.

Forest plots

Results for each outcome were presented, where relevant, on a forest plot. Interventions were heterogeneous across the studies so results were placed in subgroups most consistent with the intensity and duration of support provided:

(a) more-supported SM package – six or more contacts or unspecified contacts but ≥ 6 weeks' duration
(b) less-supported SM package – fewer than six contacts or unspecified contacts and < 6 weeks' duration
(c) exercise-based intervention.

Within each of these subgroups, studies were displayed in order of length of follow-up except for QoL outcomes, which were also grouped by questionnaire [St George's Respiratory Questionnaire (SGRQ), Chronic Respiratory (Disease) Questionnaire (CRQ), EuroQoL-5 Dimensions (EQ-5D)]. As there were multiple follow-up points, it was decided that for each outcome, only data from the final follow-up period would be displayed in the forest plot and used in any subsequent meta-analysis. The subgroups were specified prior to inspection of the results to allow sensible exploration of the different types of interventions. Meta-regression was not possible owing to the limited number of studies.

Meta-analyses

General approach

For each outcome the core group met to discuss whether or not meta-analysis was appropriate. Meta-analysis was considered only when at least three studies were available.

All analyses were undertaken using Stata statistical software, version 12 (StataCorp LP, College Station, TX, USA). When it was not appropriate to pool data, studies were displayed graphically in a forest plot but without pooling.

Meta-analysis methods

A random-effects meta-analysis model was used to synthesise effect estimates across trials[61] to account for between-trial heterogeneity in intervention effects across the trials. MDs were pooled on the original scale, but HRs were pooled on the $\log_e$ scale.

Heterogeneity across studies was summarised using the I^2-statistic (which gives the percentage of the total variability in the data due to between-trial heterogeneity)[62] and the tau-squared statistic (the between-trial variance).[61]

When two or more interventions from the same study contributed to the same meta-analysis with the same control group, an adjustment was required:

- For continuous outcomes, the SE of each estimate was inflated by first obtaining the pooled SD (assuming equal variances) using the estimates of SE and sample size in each group. An inflated SE was then calculated using the full sample size in the intervention group, and the sample size in the control group divided by the number of comparisons it contributed to within the meta-analysis.
- For one study the same control group appeared twice or more in the analysis when using a HR outcome. As the HRs for this study had been calculated using two-by-two tables,[59] adjustment was made by modifying the number of control events and the total sample size in the control group by dividing by the number of comparisons in which that control group was incorporated. The modified two-by-two tables were then used to calculate new HRs to be used in the meta-analyses where appropriate.[59]

Assessing publication bias

This was not possible as there were fewer than 10 studies for each of the outcomes.

Patient advisory group

A patient advisory group was established from local patients with COPD, chaired by Mr Michael Darby. Meetings were held at the University of Birmingham, and the group provided advice on how COPD affected their lives, their understanding of the importance of SM and different components, and their experiences of

SM programmes. This assisted in the development of the definition of SM for the inclusion criteria of this review. For example, they suggested the need for including peer support groups as an essential component. They also commented on the plain English summary.

Results

Search results

Study identification and flow chart

Initial database searches identified 13,355 records, of which 836 remained after scanning titles and abstracts using the inclusion/exclusion criteria (*Figure 1*). After the same criteria were applied to the full papers, 12 papers reporting 10 trials were finally included in the review.[63–74] *Appendix 2* details the reasons for exclusion at each stage. These were largely because patients were not recruited at the appropriate time point during/after discharge. Overall, 5% of all full texts required arbitration by a third reviewer.

The inclusion of two trials was particularly difficult to assess.[68,75] Both were comparing 'hospital at home' with UC and had substantial SM components. One trial[75] was excluded because all patients were seen in the ED then randomised to home compared with hospital (and therefore patients were not admitted at all unless in the control group). In the second study,[68] although patients were assessed in the ED, a substantial proportion of patients in both arms were initially admitted and then discharged from hospital. The difference between the two arms was (a) the proportion of patients requiring admissions and (b) the intervention arm had ongoing SM support at home, whereas, once discharged, the control group had usual primary care support. Thus, this trial was included.[68]

Conference abstracts meeting the inclusion criteria for this review are listed in *Appendix 3*. There were a further four trials that were ongoing at the time of the search end date (see *Appendix 4*).

Characteristics of included studies

There were 10 RCTs (from 12 papers).[63–74] One study[69] had a limited qualitative element referring to patient satisfaction, which will be discussed in the following chapter (see *Chapter 4*), and one study[68] included a cost analysis, which is presented in *Chapter 5*. *Table 4* details the characteristics of the RCTs.

Characteristics of included randomised controlled trials

Size, setting, recruitment

Randomised controlled trials ranged in size from 33[73] to 464[63] total participants. One[66] was a cluster RCT, based in 45 nursing homes. One paper was the 18-month follow-up of the original study,[64,65] and one paper[72] referred to the Spanish centre of a European study.[71]

Participants were largely recruited in hospital during an exacerbation of COPD or at (or immediately after) discharge. Two papers[67,68] also included patients recruited at the ED who may not have been admitted to hospital.

The definition of COPD for inclusion was generally based on a clinical diagnosis (except for Bucknall *et al.*,[63] which also required patients to meet the spirometric criteria for airflow obstruction). One study[70] included a mixed population of patients with chronic lung disease, although 89% had COPD.

Patient exclusion from trials was usually based on inability to provide consent; terminal illness or extreme comorbidities preventing inclusion in rehabilitation/exercise; or social conditions/lack of access to a telephone. All of the studies were set among patients living at home except for the cluster RCT, which was specifically based in nursing homes.[66]

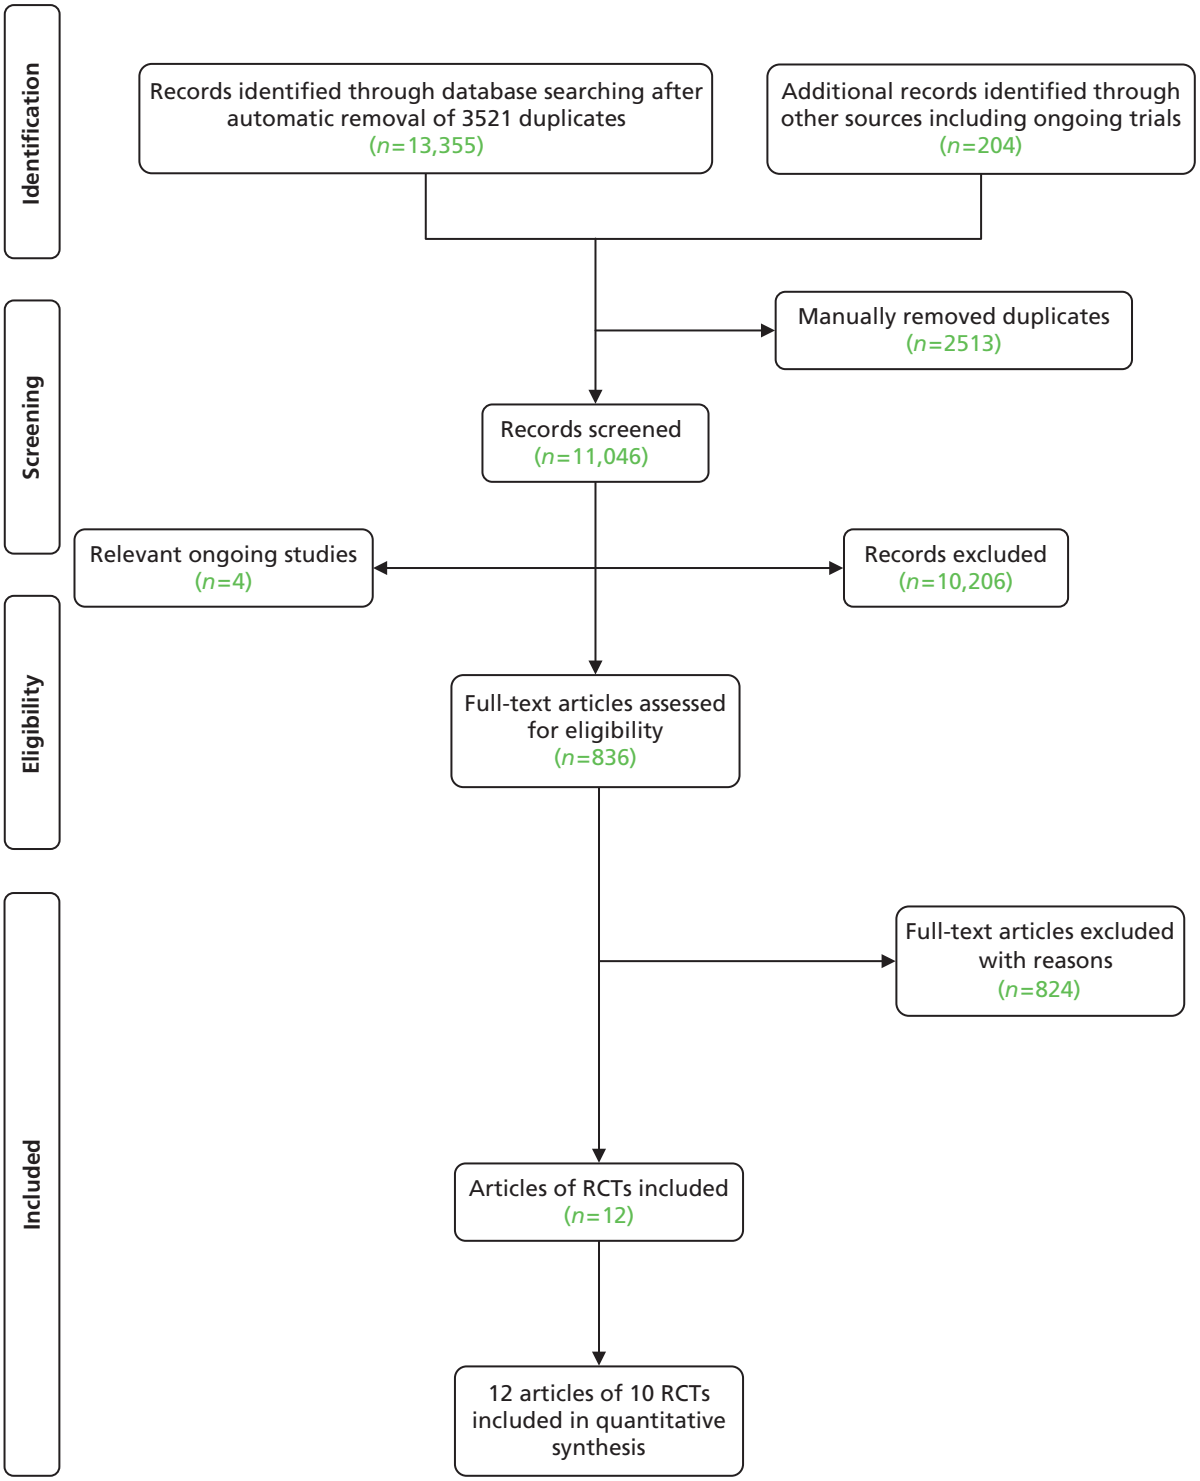

FIGURE 1 The selection process for clinical effectiveness studies.

TABLE 4 Characteristics of included RCTs

Author, year, country, study design	Population inclusion criteria	Participants	Intervention (*n*)	Comparator (*n*)	Outcomes
Behnke, 2000,[64] Germany, RCT	*Inclusion*: Severe COPD; patients admitted owing to acute exacerbation *Exclusion*: Unstable cardiac disease, cor pulmonale or other comorbidities preventing exercise participation, e.g. orthopaedic inabilities or peripheral vascular disease	*N* = 46 Recruited in hospital 4–7 days post hospital admission *Of 30 completers*: Mean age (years) (SD): Int: 64.0 (1.9) Cont: 68.0 (2.2) Sex (male) *n* (%): Int: 12 (80.0) Cont: 11 (73.3) Mean FEV_1% pred (SD): Int: 34.1 (7.4) Cont: 37.5 (6.6)	TRAINING (*n* = 23) Usual medication and 30 minutes daily breathing exercises Ten-day hospital-based training including daily 6-minute treadmill and five self-controlled walking sessions Followed by 6 months individually tailored home-based walking programme, three times a day Diaries of exercise Two-weekly visits for 3 months then monthly telephone calls for 3 months	CONTROL (*n* = 23) Usual medication and 30 minutes' daily breathing exercises Ten-day hospital-based training, including daily 6-minute treadmill and five self-controlled walking sessions Advised to perform exercise at home without specific instruction	Mortality (6 months) QoL – CRQ (3 and 6 months) Exercise capacity: 6-MWT treadmill (1, 2, 3 and 6 months) Dyspnoea: Baseline/Transitional Dyspnoea Index (every visit post discharge) Lung function: FEV_1, FVC, TLC, ITGV, DLCO, RV (days 0 and 11, 3 and 6 months) Blood gas analysis, BP, heart rate (days 1 and 11, and 6 months)

Bucknall, 2012,[63] UK, RCT	*Inclusion*: Patients with COPD admitted to hospital with acute exacerbation; $FEV_1 < 70\%$ pred and $FEV_1/FVC < 0.7$ *Exclusion*: History of asthma or left ventricular failure; active malignant disease; evidence of confusion or poor memory	*N* = 464 During or shortly after hospital admission; six acute hospitals and contributing hospitals with eligible patients; augmented by review of patients attending PR and checking for evidence of hospital admission Mean age (years) (SD): 69.1 (9.3) Sex (male) *n* (%): 170 (37%)	SUPPORTED SM (*n* = 232) Long-term treatment optimised, inhaler techniques checked, offered appropriate smoking cessation advice and PR Symptom daily diaries Supported SM by nurses trained in 'self-regulation theory'; this aims to empower patients to manage COPD by improved knowledge and understanding of the disease and skills to monitor symptoms and carry out appropriate actions, such as altering treatment early in early stages of an exacerbation	UC (*n* = 232) Long-term treatment optimised, inhaler techniques checked, offered appropriate smoking cessation advice and PR Symptom daily diaries UC: continuing management by GP, hospital clinicians or both	Mortality (12 months) Hospital admission with exacerbation of COPD (12 months) Successful SM (initiating treatment during exacerbation) (12 months) QoL: SGRQ, EQ-5D (6 and 12 months) Anxiety/depression – HADS (6 and 12 months) Self-efficacy – COPD Self Efficacy Scale (6 and 12 months)

Author, year, country, study design	Population inclusion criteria	Participants	Intervention (*n*)	Comparator (*n*)	Outcomes
		Mean FEV_1% pred (SD): 40.5 (13.6)	SM material based on 'Living Well with COPD programme' Content included: • Disease knowledge • Events that led to hospital admission • Nature of exacerbations • Recognising early signs of an exacerbation • Managing future exacerbations and monitoring signs and symptoms • How drugs work • Reinforcement of self-management behaviours • SM plan • Four 40-minute individual training sessions delivered at home every 2 weeks for 2 months plus home visits at least every 6 weeks thereafter for 10 months		

6-MWT, 6-Minute Walk Test; ADL, activities of daily living; BMI, body mass index; BP, blood pressure; Cont, control; DLCO, diffusing capacity of the lung for carbon monoxide; GHQ, General Health Questionnaire; GP, general practitioner; HADS, Hospital Anxiety and Depression Scale; ICT, information communication technology; IHD, ischaemic heart disease; Int, intervention; ITGV, intrathoracic gas volume; MRC, Medical Research Council; n/a, not applicable; NR, not reported; $PaCO_2$, partial arterial carbon dioxide tension; PaO_2, partial arterial oxygen tension; SF-12, Short Form questionnaire-12 items; SF-36, Short Form questionnaire-36 items; RV, residual volume; TLC, total lung capacity.

Description of included patients

Mean age of participants was similar across the included RCTs (66–74 years), except in the cluster RCT based in nursing homes,[66] where the mean age was approximately 80 years. Sex distribution, however, was variable across studies (ranging from 37% to 97% males). Where reported, severity of disease was similar with mean FEV_1 ranging from approximately 31% to 42% of predicted values. Most patients were described as having moderate or severe COPD.

Description of self-management interventions and comparators

Interventions were varied and have been described in full in *Table 4*. *Figure 2* provides a summary diagram of the included RCTs, with interventions grouped into three categories:

(a) '*More supported*' Six or more contacts or ≥ 6 weeks' duration if contacts not specified. This category included:

- large RCT in the UK of supported SM (based on the Living Well with COPD materials) for 12 months, compared with UC[63]
- RCT in Spain/The Netherlands of integrated care including supported SM for 12 months,[71,72] compared with UC
- RCT in Hong Kong[70] of a community nurse-supported discharge programme, including SM support, with weekly visits for 4 weeks and then monthly, with additional telephone hotline and a total follow-up of 6 months, compared with UC
- small RCT in the UK[73] of hospital outpatient visit-based SM support over 16 weeks with total 6 months' follow-up, compared with UC
- cluster RCT in Hong Kong[66] of support by community nurses to nursing home staff and patients with a supported SM component, weekly visits for 1 month and thereafter monthly visits for a total of 6 months, compared with UC.

(b) '*Less supported*' Fewer than six contacts or < 6 weeks' duration if contacts not specified. Including:

- RCT in China of telephone-based SM (based on Bandura's theories of self-efficacy[31]), with two telephone calls before week three and total follow-up for 3 months, compared with UC[74]
- RCT in Australia of SM support provided by two visits after 1 week and 1 month, with total 3 months' follow-up, compared with UC[67]
- RCT in Spain of home-based hospitalisation, including SM education and action plans, reinforced during up to five home-visits and telephone contacts over an 8-week period, compared with UC[68]
- RCT in Australia of case management with SM support with review and two telephone calls and follow-up for 3 months in total, compared with UC.[69]

(c) '*Exercise-only intervention*' Home-based exercise-only interventions:

- small RCT of home-based exercise, supervised regularly for 3 months and with 6-month[64] and 18-month[65] follow-up, compared with general exercise advice.

Description of comparators

Comparators were 'UC' [often with little description but focused on usual GP management] except for the exercise trials,[64,65] for which the control group had some initial exercise training in hospital and were then advised to perform exercise at home.

Range of outcomes reported

All included trials measured at least one of the primary outcomes. Mortality was reported in six trials;[63,64,67,68,70–72] hospital admissions (measured in multiple ways) in all 10 trials;[63–74] and other health-care utilisation in six trials.[66–68,70–72,74]

Of the secondary outcomes, HRQoL was assessed in seven trials[63–68,71–73] and was provided as an overall score as well as subdomains. The most common score was the SGRQ.

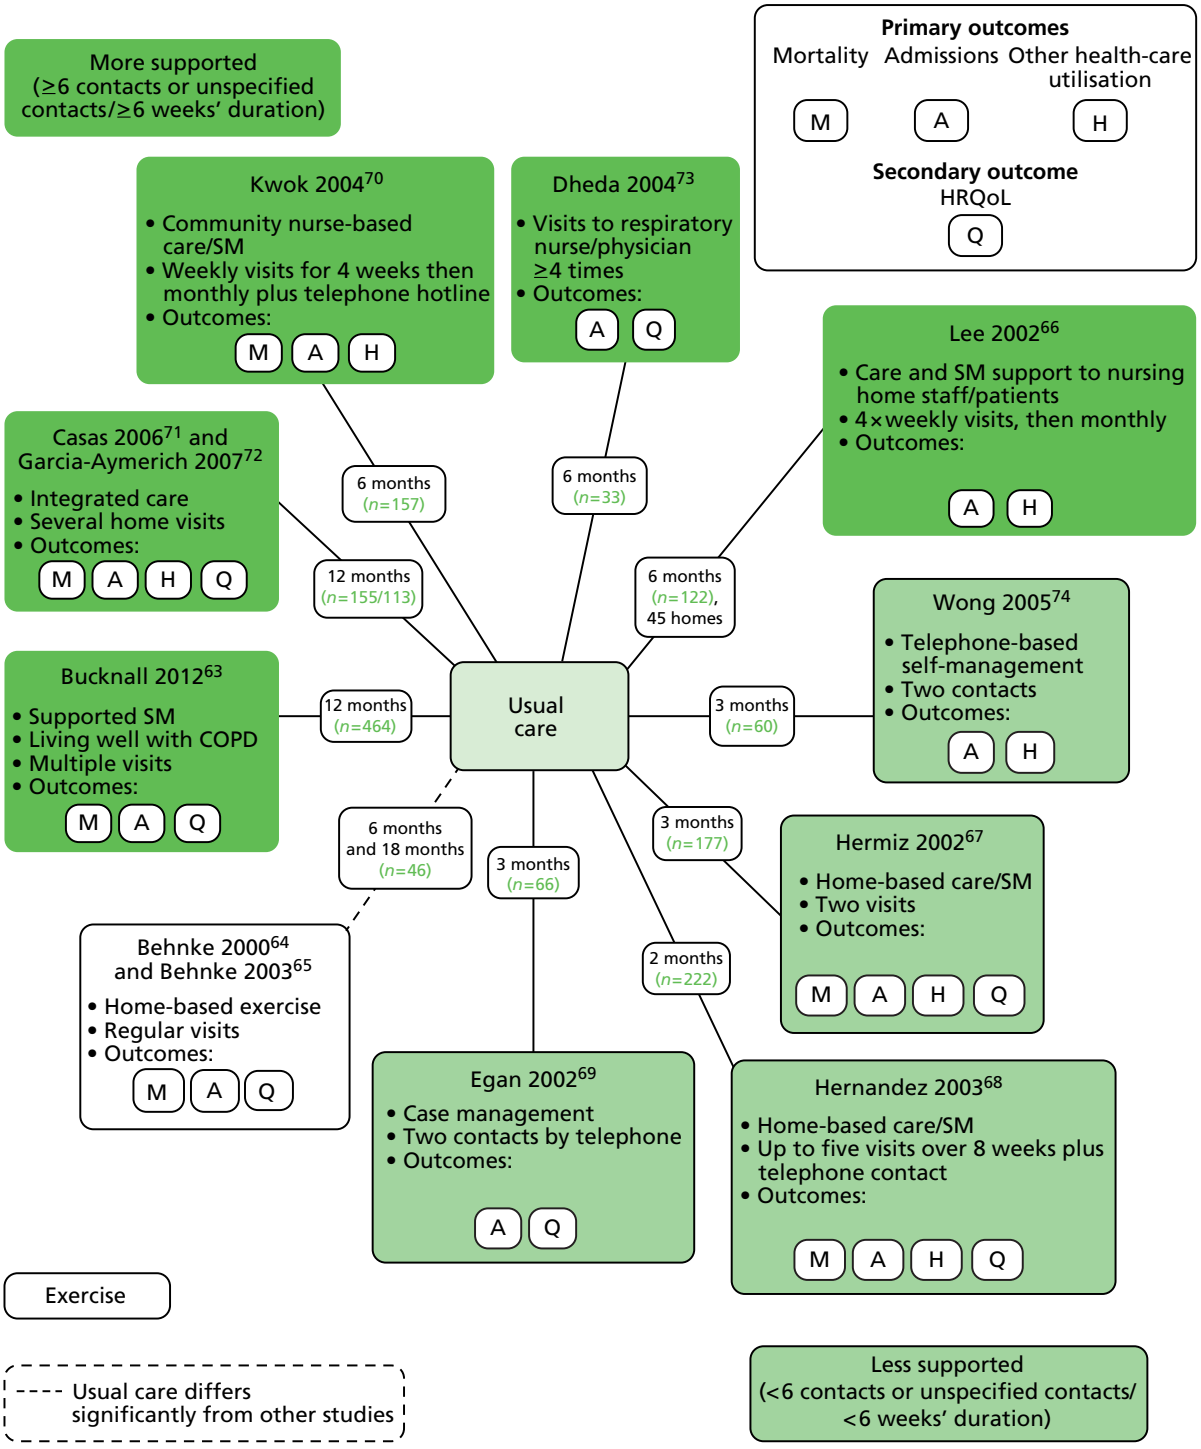

FIGURE 2 Study characteristics of the included RCTs.

Exacerbations were reported in only one trial.[73] Self-efficacy was measured in two trials;[63,74] behaviour change in four trials;[63,67,68,72] anxiety/depression in five trials;[63,66,69,70] exercise capacity in two trials;[64,65,70] dyspnoea in two trials;[64,65,72] and lung function in five trials.[64–66,68,72,73]

Patient satisfaction with the intervention was described in five trials,[66–68,72] one of which is described in full in the next chapter, as it involved qualitative interviews.[69] Costs were described in one trial,[68] but no trials described days lost from work.

Quality of included randomised controlled trials

Risk of bias evaluations are presented in *Table 5* and are described as high, low or unclear risk for each aspect of potential bias.

TABLE 5 Risk of bias assessment of included trials

Sources of bias	[a]Behnke 2000[64]	[a]Behnke 2003[65]	Egan 2002[69]	Hermiz 2002[67]	Lee 2002[66]	Hernandez 2003[68]

Very small study Methods of outcome assessment not described Numerical data not available for lung function Rather limited information provided throughout One patient excluded from analysis owing to visiting GP (not ITT) No table of characteristics Confusion over SEM or SD	Three subjects in control were undergoing PR	Change in sample size calculation External validity of Chinese Self-Efficacy Scale Gender may not be very well balanced across arms	Differences in text and Table 2 for differences in rate of admissions Not well balanced on previous hospitalisations, and receipt of influenza vaccination	No description of lung function test methods Intervention arm seemed to have higher number of admissions in the previous year and possibly worse SGRQ score	

In general, the quality of reporting and conduct of the included studies was low, with some very small, poorly conducted studies.[64,65,73] Out of the 10 RCTs,[63–74] appropriate methods of randomisation (e.g. computer random number generator) were used in six trials[63,68–72,74] suggesting a low risk of bias, although methods were unclear in the remaining four.[64–67,73] Allocation concealment was insufficiently described in all except the largest most recent trial,[63] which used a central telephone method of allocation to reduce the risk of bias.

Blinding of patients and health-care personnel would not have been appropriate for this type of SM and similar such interventions; therefore, the results of any patient-reported outcomes or non-blinded, investigator-assessed outcomes would be potentially subject to bias. In this review, the important patient-reported outcomes were consistently judged to be subject to high risk of bias across all of the trials, including HRQoL, dyspnoea, anxiety and depression, self-efficacy, patient satisfaction and behaviour change.

Measurements of lung function and exercise capacity both rely on assessors' encouragement and could be subject to bias if not blinded. It was usually unclear whether or not investigators were blind to treatment when assessing lung function, although when measured, exercise capacity was judged to have low risk of bias because either the assessors were blind[70] or it was explicitly stated that they did not provide encouragement.[64,65] In general, conduct of outcome measurement were frequently poorly described, with standards and conduct of lung function testing particularly unclear.[64,65,68,72]

However, assessment of hospital admissions, other health-care utilisation and mortality would be likely to have a low risk of bias (either self-reported or obtained from records), as concluded for most of the included trials.

The most obvious flaw in the conduct of some of the included studies was the lack of completeness in follow-up, which was considerably < 70% in some trial arms and would be likely to bias most clinical measures and HRQoL (and other questionnaire) outcomes in particular,[63–65,73] and any other questionnaire/clinical measures. This was even discussed by the authors of the largest, most recent trial with only 61% of randomised patients with HRQoL reported at follow-up,[63] who concluded that the data were therefore unreliable. Several of the studies[64,65] reported characteristics of only the completing participants rather than all randomised participants, or gave no table of characteristics at all.[73] This weakens any attempt to assess baseline imbalance and any bias introduced at this stage.

As is usual, it was difficult to assess selective outcome reporting without availability of protocols. In addition, outcome data were unclearly analysed in several studies,[64–66,69,73] and the older studies (pre 2005) were often limited in their description of methods in general. There were signs of baseline imbalance between arms in some studies, which was not addressed in the analyses.[65] The best conducted and reported trials tended to be the most recent.[63,70–72,74]

Primary outcomes

All-cause mortality: no evidence of effect

Six trials[63,64,67,68,70–72] contributed mortality results (*Figure 3* and *Appendix 5*). There was a wide range of event rates across the trials. Despite the general heterogeneity of interventions, there was no statistical heterogeneity and the overall results indicated that there was no evidence of effect on mortality (HR 1.07, 95% CI 0.74 to 1.54). Using the GRADE system, we would judge that this is moderate-quality evidence (*Table 6*).

Hospital admissions: no evidence of effect

Seven trials[63,65,67,68,70,71,73] contributed data to the admissions results (*Figure 4* and *Appendix 6*). The results of three trials[66,69,74] could not be included in the combined results because they reported mean number of

admissions rather than first admission and one[69] also did not provide sufficient information to calculate a SE.

Overall, statistical heterogeneity was high ($I^2 = 70.9\%$), and subdividing by level of support explained only a fraction of this. Estimates are provided by level of SM support, although there was no evidence of any effect for the non-exercise-based interventions and substantial remaining heterogeneity.

One of the studies that may have contributed to the remaining heterogeneity in the non-exercise-based studies is the small study of 33 participants by Dheda *et al.*,[73] which was poorly reported, had signs of inadequate randomisation and very high loss to follow-up, especially in the intervention arm. This study[73] had the most extreme results in its category.

The trial of home-based exercise[65] demonstrated a large relative reduction on the rate of first admission (HR 0.17, 95% CI 0.05 to 0.66), although this trial was very small and these results were based only on participants who completed the study (< 60% of those randomised), and thus would also be subject to high risk of bias. Furthermore, although subgrouping by intervention category was an a priori identified analysis, care must be taken in the interpretation of results due to multiple comparisons being performed. The evidence above was judged to be of low quality according to GRADE (see *Table 6*).

General practitioner consultations: no evidence of effect

Two trials reported GP-related health-care activity (see *Appendix 7*).[67,71] Neither trial reported any evidence of differences between physician contacts, drug prescriptions or amount of education provided between the intervention arm and the control arm. Note that one trial[67] reported mean number of visits, although it is likely that median values would be more appropriate. The evidence was of very low quality (see *Table 6*).

Emergency department visits: no evidence of effect

The effect on ED visits is displayed in *Figure 5* (see *Appendix 8*), for which five trials[66–68,70,72] contributed data. Four trials[66,68,70,74] reported mean visits per patient and two[67,68] reported first visit. The two trials with a longer follow-up of 6 months[66,70] failed to demonstrate any evidence of an effect on ED visits. This evidence was also of low quality (see *Table 6*).

Secondary outcomes

Health-related quality of life: consistent with improvement although potential bias

Six trials[63–66,67,68,72,73] contributed data on HRQoL using the SGRQ, the CRQ or the EQ-5D (*Figure 6* and *Appendix 9*). The data from one study[69] could not be used as they reported median change only. Five trials[63,67,68,72,73] used the SGRQ, two trials[63,72] reported the EQ-5D and one trial[64] the CRQ.

Overall, SM interventions resulted in an improvement of 3.84 (95% CI 1.29 to 6.40) points on the SGRQ scale compared with control (close to the minimal clinically important difference of four points), although follow-up (where reported) ranged from about 25% to 83% across studies, and, therefore, this result should be treated with caution and contributed to the overall judgement that this evidence was of very low quality (see *Table 6*). In particular, the study by Dheda *et al.*,[73] which produced the most extreme results, had many methodological flaws.

Exercise capacity: possible effect with exercise-based intervention only

Two trials[64,65,70] reported on exercise capacity (see *Appendix 10*). For the study by Behnke *et al.*,[64] we analysed results from the longest follow-up time point (18 months). At this point, the home exercise programme showed strong statistical evidence of a large benefit compared with exercise advice only (MD in treadmill distance in 6 minutes = 355.0 m, 95% CI 269.2 m to 440.9 m). Note that this trial was likely to be biased, as only completing participants were described, and the trial had a loss to follow-up

of > 40%. In neither trial was the substantial baseline imbalance taken into account, which would have exaggerated the effect size. In contrast, the trial of nurse-supported discharge in Hong Kong retained nearly 90% of its patients, and there was no statistical evidence of a difference after 6 months in mean distance walked compared with the UC arm (MD 24 m, 95% CI –7.1 m to 55.1 m).

Lung function: no evidence of effect

Data from four trials[64–66,68,72] were plotted (see *Appendix 11*). Three trials provided results on raw FEV_1 values (*Figure 7*),[64,65,68,72] and two trials the effect on percentage predicted FEV_1 (*Figure 8*).[65,66] There was no evidence of any effect from any of the individual trial results, and it was not deemed appropriate to pool the individual trials due to the small number of studies and heterogeneity of outcomes, follow-up time and methods of analysis. The findings are in agreement with the fifth trial[73] which reported no evidence of effect on FEV_1 but did not provide data. Again, the proportion of patients followed up across the trials was very variable.

Anxiety and depression: possible improvement in scores

Four trials (see *Appendix 12*)[63,66,69,70] reported on psychological health outcomes; however, only two trials[63,66] contributed to the analysis on anxiety (*Figure 9*) because one trial[69] reported only median changes and the other[70] did not provide separate results for anxiety. Although there were data on less than half of the sample in the larger study,[63] the intervention group had a mean reduction of 1.06 points (95% CI 0.04 to 2.08 points) in the 'anxiety' component of the Hospital Anxiety and Depression Scale (HADS) score compared with the control group, and the other trial[66] demonstrated a mean reduction of 1.5 points (95% CI 0.62 to 2.38 points) in the 'anxiety and insomnia' component of the General Health Questionnaire (GHQ) relative to the control group.[66]

One of the above trials[66] also showed some evidence of a reduction in depression score (MD –1.0, 95% CI –1.97 to –0.03), although follow-up rates were not reported, whereas there was no evidence of effect in the larger trial[63] (*Figure 10*).

Exacerbations: no evidence of effect

Only one small, poor-quality trial[73] of hospital outpatient follow-up ($n = 33$) reported on exacerbations. This study reported that there were 'fewer patients with two or more exacerbations within a six-month period (2 v. 3) in the intervention group but the small numbers precluded meaningful statistical analysis'.

Dyspnoea: possible effects in exercise trial

Two RCTs[64,65,70] reported effects on dyspnoea (see *Appendix 13*) reporting a variety of different measures. The Behnke trial[64,65] of home-based exercise reported effects at 1, 2, 3, 6, 12 and 18 months using the Baseline/Transitional Dyspnoea Index and the 'dyspnoea' domain of the CRQ questionnaire. Significant improvements in dyspnoea score in the intervention arm were observed throughout the trial, with all measures. However, > 45% of the 46 original patients had dropped out by the end of the follow-up period.

A trial of integrated care[72] also reported dyspnoea among 62 of 113 completers using the Medical Research Council (MRC) dyspnoea scale, finding no evidence of effect after 12 months (MD between two arms –0.38, 95% CI –1.1 to 0.34).

Behaviour change: improvement in knowledge but inconsistent evidence of effects on behaviour

Three trials[67,68,72] reported effects of the intervention on a range of health behaviours (see *Appendix 14*). None of the studies used validated questionnaires.

All three trials[67,68,72] reported significantly better knowledge about the disease and how to recognise and treat exacerbations among patients receiving the SM intervention, and two trials[68,72] reported significantly better adherence to inhaler treatment and inhaler technique. This was not matched by improvements in smoking behaviours or uptake of vaccines. Effects on physical activity were inconsistent.

Self-efficacy: inconsistent effects

Two trials[63,74] reported effects on self-efficacy (see *Appendix 15*). Significant improvements in self-efficacy were observed in the trial[74] of a community nurse-supported discharge programme in Hong Kong after 3 months ($p = 0.009$), which was most marked in the physical exertion and weather/environment domains. Despite a high loss to follow-up, a much larger and more intensive trial[63] of supported SM reported no evidence of improvement in self-efficacy after 12 months.

Patient satisfaction: inconsistent results

Four trials[66–68,72] reported effects on patient satisfaction with the intervention using different questionnaires (often with little detail provided; see *Appendix 16*). Two[66,68] of the trials[66–68,72] indicated increased satisfaction with their care compared with the control arm. However, loss to follow-up was generally high.

Discussion

Key results

Despite a rigorous search we identified only 10 RCTs[63–74] that evaluated the effectiveness of interventions providing SM support to patients shortly after being discharged from hospital with an acute exacerbation of their COPD.

Few of the trials had consistently low risk of bias. Many studies were small and suffered from inadequate reporting and high loss to follow-up, particularly affecting patient-reported outcomes such as HRQoL.

Although the participants seemed relatively homogeneous, interventions were very heterogeneous, with some trials[67–69,74] providing low-intensity, short-term support of 2–3 months and others[63] a very intensive package lasting for 12 months.

Overall, there was limited evidence of effect on health-related behaviours and outcomes. There was some evidence of improvement in patient knowledge, treatment of exacerbations and inhaler technique,[68,69,73] but there was inconsistent evidence of effect on other health-promoting behaviours[68,73] or on self-efficacy.[64,75]

In terms of health outcomes, the most consistent effects were observed on patients' QoL, with an overall improvement with data from five trials[63,67,68,72,73] of 3.8 points on the SGRQ score (close to the minimally clinically important difference of four points). Notably, though, this estimate should be treated with caution because, although reaching statistical significance, there was substantial and differential loss to follow-up in both arms, which could bias the results in favour of a positive effect. The authors of the largest trial[63] indicated, themselves, that the results from their trial could be unreliable. The reduction in anxiety exhibited in two trials,[63,66] however, supports some potential effect on patients' psychological health (although it is not clear whether or not this would be clinically important).

An important outcome for these patients is whether the SM package had any effect on subsequent hospital admissions. We were able to use data that reported time to first all-cause admission. Despite subdividing by intensity of intervention, we were unable to explain the substantial heterogeneity observed, but, overall, there was no clear evidence of effect on hospitalisation (HR 0.78, 95% CI 0.52 to 1.17; $I^2 = 71\%$). Post hoc inspection of the data suggested a possibility of a greater effect with the exercise-based intervention but would require more data to be explored in depth. It is possible, however, that the effects on admissions would be diluted because we extracted admissions due to any cause (although in our analysis the majority were for respiratory causes).

There was no apparent evidence of effect on mortality and no clear patterns with duration of intervention.

In general, the most positive results across the outcomes were observed in the small trial of home-based exercise[64,65] but, given the multiple methodological limitations of the trial in terms of reporting and analysis, the results have to be interpreted with caution.

How this fits with other literature

This is the first systematic review that addresses the effectiveness of SM support provided to patients with COPD soon after hospital discharge. The only other review related to this time point is a Cochrane review of PR,[76] which identified nine trials and showed significant reduction in hospital admissions [pooled odds ratio (OR) 0.22, 95% CI 0.08 to 0.58], over 25 weeks and mortality (OR 0.28, 95% CI 0.10 to 0.84) over 107 weeks. Effects of PR on HRQoL were well above the minimal important difference when measured by the CRQ and the SGRQ total score (MD –9.88, 95% CI –14.40 to –5.37). However, in common with our review, trials were small and methodologically inadequate, and, although loss to follow-up was not discussed or assessed in the risk of bias section, a large proportion did not complete the rehabilitation. There was also significant heterogeneity across many of the outcomes. The authors discussed the possibility of publication bias and possible overestimate of effect with small trials but suggested this would not account for the whole effect. The results would fit with our tentative observation that trials with an exercise component might be more effective.

The majority of the studies and reviews of SM support are set among patients who have COPD in a stable state. Our results, although showing few significant effects, are consistent with some of the other systematic reviews. For example, a systematic review of SM education[48] showed evidence of a significant reduction in respiratory admissions (OR 0.64, 95% CI 0.47 to 0.89; $n = 8$ RCTs) and a significant mean improvement of 2.6 points (95% CI 0.2 to 5.0 points) on the SGRQ score ($n = 7$ trials). A review of PR[46] reported an overall mean improvement in SGRQ score of 6 points (95% CI 3 to 9 points; $n = 6$ trials) and a review of integrated disease management[47] found a similar improvement in HRQoL: SGRQ 3.71 points (95% CI 1.6 to 5.8 points; $n = 13$); CRQ 1.02 points (95% CI 0.67 to 1.36 points; $n = 4$) and respiratory admissions (OR 0.68, 95% CI 0.47 to 0.99; $n = 7$) and a similar lack of effect on mortality. Conversely, a review of action plans found little evidence of benefit on HRQoL or health-care utilisation.[50]

In the last couple of years, and particularly since the completion of our searches, there have also been a number of individual trials and commentaries that question whether patients are actually able to self-manage.[34,36,77,78] Two of these among patients with COPD[35,62] identify a group of successful self-managers in post hoc exploratory analyses. The first of these[63] is included in our review but no other studies have explored these subgroups so we were unable to examine this point further.

Strengths and weaknesses

A strength of this review was the comprehensive search and selection process, which made it unlikely that we would have missed relevant studies. In addition, we followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidance with respect to study selection, data extraction, risk of bias assessment, reporting and analysis.

The main limitation relates to the paucity of evidence and methodological weaknesses of many of the available studies, which limits our conclusions, and the heterogeneous nature of the interventions that makes comparisons hard and conclusions difficult to draw. The particular problems with these studies, especially the older ones, include generally inadequate reporting of important items, particularly methods of randomisation and limited data on baseline characteristics. Many studies were small, with data reported only for participants completing the trial and had substantial loss to follow-up of > 30% in some arms, which is likely to bias all self-reported items and HRQoL in particular. There was a lack of information about the assessment of some outcomes, especially lung function measurements and analyses were often unclear or inappropriate. In addition, the admission results were reported in several different ways, for example first admission, mean admissions, etc. Although ideally we would like to be able to capture all of this information – especially as some patients may have multiple admissions – current methodologies are

inadequate to do so. We chose rate of first admission because there were more data available; however, it is unclear how the effect of the interventions would vary if all admissions could be considered.

With the limited number of trials it was not possible to assess publication bias, but it is possible that because of the small size of the studies showing positive effects this would be a potential problem.

Another issue is that of generalisability, as only two RCTs[63,73] were set in the UK health-care setting. Studies in China and other areas of Europe may not necessarily be relevant; the feasibility and effectiveness of different types of support may be dependent on both financial and practical issues in individual settings. With the limited data available it was not possible to explore the effect of different settings.

Implications for research and practice

It is difficult to recommend any type of SM support to be provided immediately after discharge with the evidence available as there is no clear evidence of effect across most of the outcomes. This conclusion is in contradiction to the current recommendations in the COPD discharge care bundle.[79] Notwithstanding, the point estimate is consistent with ≈20% reduction in admissions which has been observed in other systematic reviews.

However, to move forward with this area of research, there should be:

- more in-depth work to explore the needs/views of patients with regard to SM support after a recent discharge from hospital before designing novel interventions aimed at behaviour change
- an adequate standard of reporting ensured in future trials, and they should be conducted to modern standards with an adequate number of participants
- a clear framework for describing and classifying SM interventions and their comparators
- an exercise component included in future studies
- clear reporting of outcomes to include self-efficacy, behaviour change and clinical outcomes, including separate reporting of COPD-related and all-cause admissions
- consideration that patients may be too ill at this point (both physically and psychologically) to take up the more rigorous parts of SM interventions until they are in a more stable state; the difficulty in recruitment and retention in the included studies bears this out.

Conclusions

- Self-management support delivered shortly after an acute exacerbation may have some benefit in terms of HRQoL and possibly admissions but the evidence is thin and unconvincing.
- Exercise may play an important role but there are not enough data to explore this.
- Any future trials should address issues of bias, particularly loss to follow-up, but this may be inherent in the nature of the intervention and the fact that patients are still trying to recover from an exacerbation.
- The evidence is not in support of SM interventions to be put into practice for patients with COPD at, or recently after, hospital discharge.

Chapter 4 A systematic review of the qualitative evidence about patient satisfaction, acceptance and barriers to supported self-management interventions delivered shortly after hospital discharge: review 2

The aim of this chapter is to present the findings of a systematic review of the qualitative evidence about patient satisfaction, acceptance and barriers to self-management (SM) support.

Methods

A systematic review of published evidence of the qualitative evidence about patient satisfaction, acceptance and barriers to SM support programmes among patients with chronic obstructive pulmonary disease (COPD) recently discharged from hospital.

Definition of self-management

As described for review 1 and tabulated in *Table 2*.

Search strategy

A comprehensive search strategy was undertaken as described as for review 1. The search was broad and covered many databases and no study design filters were applied. Search terms related to qualitative evidence included 'patient-centred' and 'patient focus'.

Study selection process

As described for review 1.

Selection criteria

Selection criteria were as described for review 1, with the difference of two elements: study design and outcomes. Only qualitative study designs (interviews and focus groups) were sought and outcomes relating to patient satisfaction, acceptance and barriers to SM were assessed.

Study quality, data extraction and synthesis

Study quality was assessed using the Critical Appraisal Skills Programme (CASP) checklist for qualitative research.[80] As well as extracting data related to study and patient characteristics, any quotes, key themes and concepts identified were extracted. As outlined in the protocol, an interpretive analysis (meta-ethnography)[81] was planned if findings allowed. This involved looking for similarities (reciprocal translation), differences (refutational translation) or creating a line of argument using concepts proposed in included primary studies. However, as only one study described a small element of qualitative interviewing, this was not undertaken.

Results

Search results

Figure 11 outlines the flow of included studies. One of the included randomised controlled trials (RCTs)[69] from review 1 had a limited qualitative element referring to patient satisfaction and was therefore included in this review. There was also one ongoing study (see *Appendix 4*).

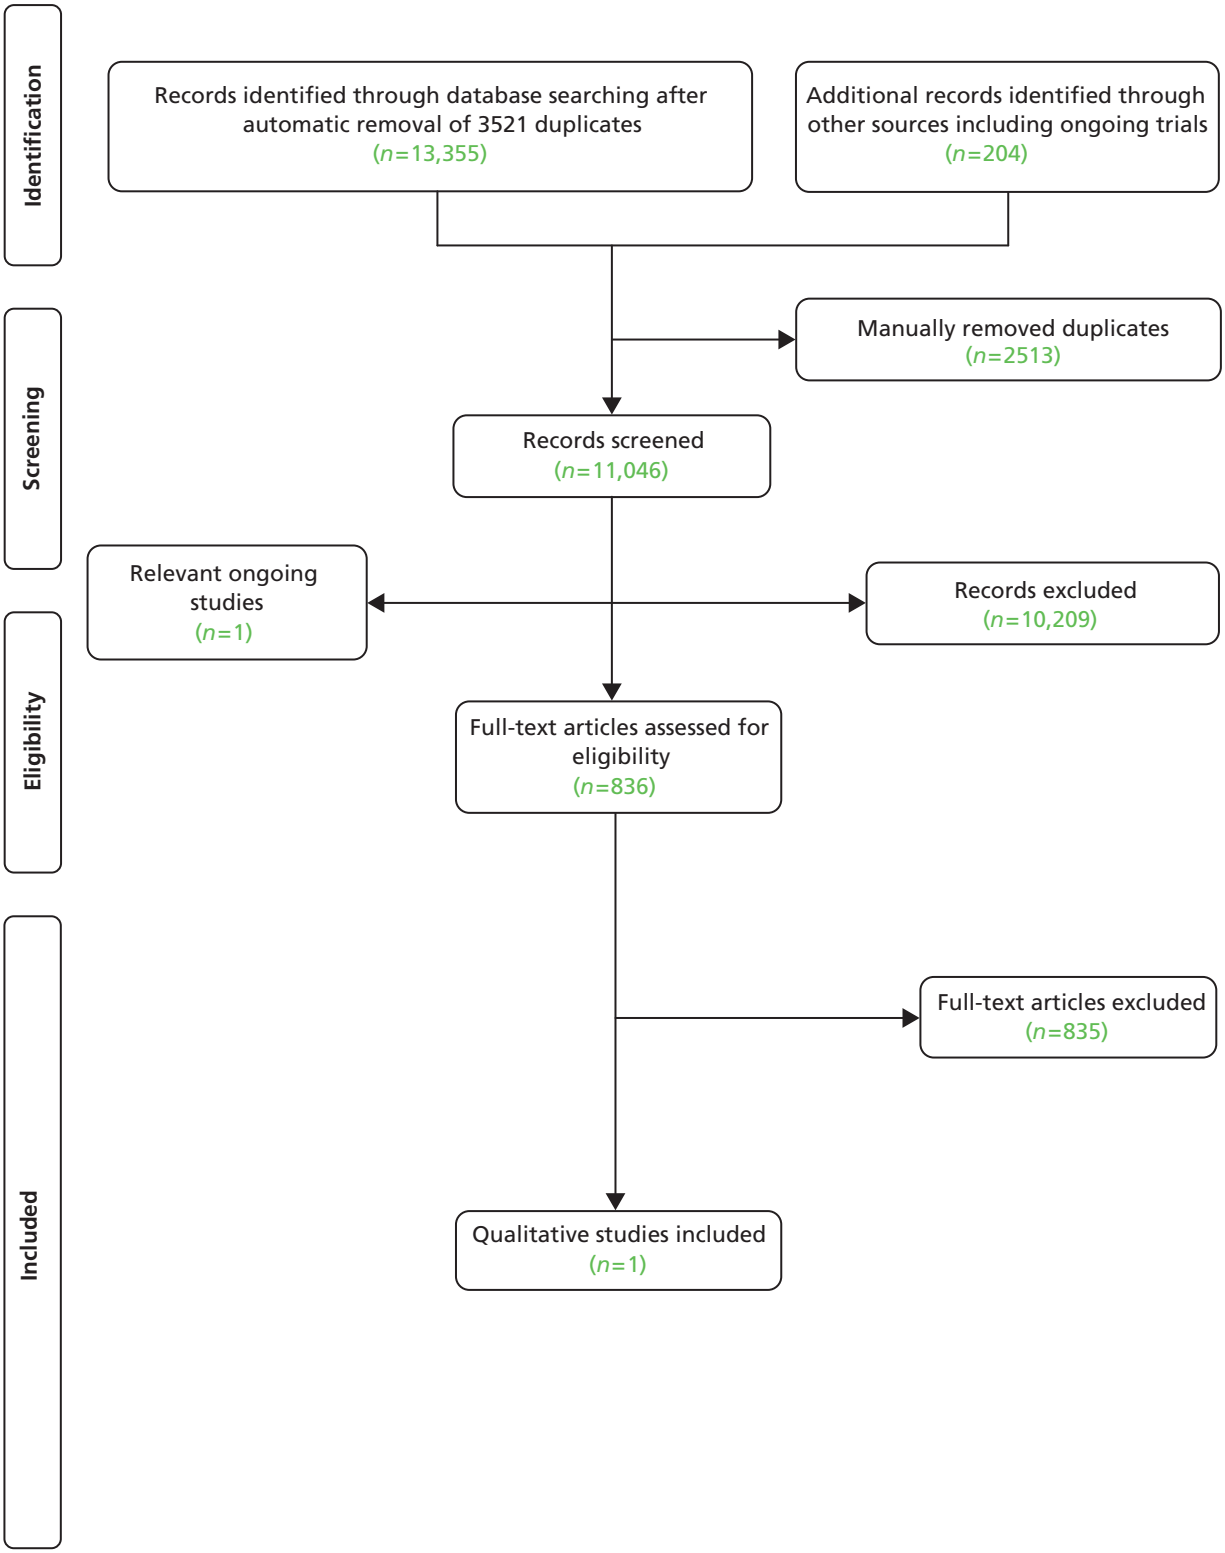

FIGURE 11 Selection process for qualitative studies.

Characteristics of included study

The included trial was a trial of nursing-based case management among 66 patients in Australia admitted to hospital with COPD. The intervention comprised SM support with review and two telephone calls and follow-up for 3 months in total, compared with usual care.[69] A subgroup of 18 patients and their carers from both arms of the trial were interviewed in more depth using semistructured interviews focusing on issues associated with patients and caregiver satisfaction with care. The interviews were recorded, and then transcribed and coded to identify themes. These interviews revealed that patients were very satisfied with their care in hospital and, for those in the intervention arm, ongoing contact with the community nurse was very helpful in improving their access to resources and communication with the health professionals. For those in the control arm, those with family support or medical contact were satisfied but those without were not. *Table 7* describes the patient and caregiver quotes in relation to case managers.

Quality of included studies

Table 8 presents an assessment of the quality of this study. The aims of the study were not very clear from the outset, which means that it was difficult to assess which methodology would be appropriate. It was possible to infer that patients'/carers' views and satisfaction with the intervention would be sought, which would mean that these semistructured qualitative interviews would be appropriate. However, although the authors mentioned that patients were selected to maximise variability, the only factor that they mention is about representing both intervention and control groups.

There is mention of the home setting, although not the justification for it, but they do not mention a topic guide, any modification of the methods, details of any interviewer biases, how the themes were identified or whether or not saturation was reached. Thus, the findings are really not very valuable.

TABLE 7 Patient and caregiver quotes from included qualitative study

Context	Quotation
The caregiver of a patient in the control group without support – such as extensive family, medical support from health-care professionals	*It is absolutely hopeless*
A patient from the intervention group who received a CM talking about benefits of having a CM	*I became more involved with (the CM) and it was good to know that she cared . . . kept on your hammer all the time . . . So I think that . . . it will give some peace of mind to the patients, you know. The big thing is to know what is happening*
A patient from the intervention group commenting on benefits that a CM provides	*(The CM) made me aware of things that were available that I didn't bother to want to know about before*
A caregiver of a patient of the intervention group commenting on benefits that a CM provides	*(The CM) helped me organize (a nebulizer); she pointed out a lot of things to me, different things that should be done (for the patient)*

CM, case manager.

TABLE 8 Risk of bias assessment of included qualitative study using CASP checklist for qualitative research

CASP checklist questions	Judgement and comments/quotes
Was there a clear statement of the aims of the research?	Unclear Aims of the RCT made clear Authors state a lot of focus is around economic outcomes rather than patient-focused outcomes; no clear aim relating to qualitative research
Is a qualitative methodology appropriate?	Unclear *This is an RCT which has both quantitative and qualitative analyses* Unclear as the research goal is not clearly stated although they mention focusing on issues to do with patient and caregiver satisfaction
Was the research design appropriate to address the aims of the research?	Unclear Very little detail of qualitative methodology reported, although semistructured interviews seem appropriate
Was the recruitment strategy appropriate to the aims of the research?	Unclear *Participants were selected to maximise variability and to represent both intervention and control groups* Variability not detailed; subgroup of 18 patients from RCT selected for qualitative
Were the data collected in a way that addressed the research issue?	Unclear Audiotaped interviews Patient interviews – semistructured Patients and caregivers interviewed at home No topic guide, no mention of any modifications during study, no justifications for setting for data collection
Has the relationship between researcher and participants been adequately considered?	Unclear No details of biases; not clear who led interviews
Have ethical issues been taken into consideration?	Unclear 'The study received ethical clearance from the participating hospital' – This is in reference to the RCT; no other details regarding ethics
Was the data analysis sufficiently rigorous?	Unclear Not enough detail to permit judgement *All interviews, including those with the respiratory physicians were audiotaped then transcribed and coded to identify recurring themes and patterns*
Is there a clear statement of findings?	Unclear Not particularly adequate *Based on the qualitative interviews, all patients were very satisfied with their care in hospital*
How valuable is the research?	Not very valuable as it stands with limited details

Discussion

Key results

A comprehensive search of the literature revealed only one RCT[69] with a limited qualitative aspect and limited conclusions.

Strengths and weaknesses

The search strategy was broad, conducted across several databases and with no study design filters applied. Additionally, reviewers adhered to a systematic methodology with two independent reviewers assessing studies for inclusion and exclusion against a prespecified selection criteria; therefore, it was unlikely that any relevant qualitative evidence will have been overlooked. However, after a thorough search and identification process, only one study[69] was included.

How this fits with the findings of the effectiveness review (review 1)

Unfortunately, the included study[69] only gave scant information regarding the qualitative aspects, and it is difficult to be sure of the true purpose of the interviews and how they were actually conducted. The study,[69] however, reported that patients who received a case manager were very satisfied with their care, and were made aware of resources available to them and how to use them. Those in the control arm without family support were more concerned about their situation, although those in the control arm with family support seemed reasonably satisfied. This reflects the evidence from the quantitative studies for which the evidence was inconsistent (two studies[66–68,72] showed better satisfaction with the intervention and two did not) but does not really gain much further insight.

Conclusions

There is almost no qualitative evidence about patients' views on SM support programmes that are delivered post discharge, and, given that the quantitative evidence reveals uncertainty about the effectiveness of such interventions in their current form, it is therefore a potential area of research need.

Chapter 5 A systematic review of the cost-effectiveness of supported self-management interventions delivered shortly after hospital discharge: review 3

The aim of this chapter is to present the findings of a systematic review of the cost-effectiveness of self-management (SM) interventions delivered post discharge in patients with chronic obstructive pulmonary disease (COPD) compared with usual care (UC).

Methods

A systematic review of the literature was conducted to identify all published studies assessing the cost-effectiveness of SM interventions delivered to patients with COPD within 6 weeks of hospital discharge following an acute exacerbation.

Search strategy

A comprehensive search strategy was undertaken by an experienced information specialist from inception to May 2012. Three electronic databases were searched: MEDLINE and EMBASE via Ovid and Cochrane NHS Economic Evaluation Database (Wiley). Searches were not limited by date nor were any language restrictions applied. The search strategies used for each database can be found in *Appendix 17*. Relevant literature from the clinical effectiveness searches were also identified and included for review, if they had not already been captured in the searches for cost-effectiveness.

Reference Manager version 11 was used to store and manage all references.

Study selection process

The inclusion and exclusion criteria outlined below were used to select studies. A two-stage review process was applied by two independent reviewers: first, screening titles and abstracts, and then reviewing full papers. Discrepancies were resolved by a third reviewer with expertise/knowledge in the field of health economics.

Selection criteria

Study design

Full and partial economic studies, costing studies and costing models were included.

Population

Studies including patients admitted to hospital with an acute exacerbation of COPD, who were recruited at the point of discharge or within 6 weeks after discharge were included (see *Chapter 3*, *Methods*).

Intervention

Any SM programme, package or intervention including adherence to medication, inhaler technique, breathing techniques, exercise, education and support groups among others. Pulmonary rehabilitation was not included for this review.

Comparator

Comparators considered were UC, other SM interventions or no intervention.

Outcomes

Cost-related outcomes included health service utilisation, hospital admissions and readmissions, duration of admissions, ED visits, days lost from work, drug utilisation and cost-effectiveness. Effectiveness outcomes were as reported for the clinical effectiveness review (see *Chapter 3*).

Risk of bias assessment

Risk of bias of included studies was assessed using the Drummond checklist, as suggested in the *Cochrane Handbook*.[56] Risk of bias assessment was undertaken by two reviewers independently, one of whom had expertise in the field of health economics.

Data extraction

Study characteristics and results were extracted independently by two reviewers. Meta-analysis was not considered appropriate for this review because of the paucity of evidence.

Results

Search results

Figure 12 outlines the study identification process. A total of 1611 references were imported into Reference Manager, and 240 duplicates were removed automatically and manually. Overall, 1131 titles and abstracts were screened, with 129 articles being identified for full-text review. Only one study[68] met the inclusion criteria for this review, which also formed part of the clinical effectiveness review. A further four studies met initial inclusion criteria but were ongoing and so have been listed in *Appendix 4*.

A number of other studies ($n = 27$) were identified as potentially useful to inform the independent economic analysis (see *Chapter 6*). These studies included relevant primary or secondary data on the cost or utilisation of health care associated with SM in patients with COPD; however, the intervention was not delivered to patients in hospital at the point of discharge or within 6 weeks of hospital discharge. Data from some of these studies were used to estimate the costs of SM in the model (see *Chapter 6*).

Characteristics of included studies

The single included trial by Hernandez *et al.*[68] was conducted in two tertiary hospitals in Barcelona, Spain, with a total sample size of 222 patients: 121 patients were randomised to the home hospitalisation group and 101 were randomised to conventional care. The hospital-at-home intervention included four phases: assessment by a specialist team during admission to the emergency room; treatment at discharge; home hospitalisation with follow-up; and assessment after 8-week follow-up. Specific SM components implemented as part of the hospital-at-home service included 2 hours of the following delivered at the point of discharge and later reinforced during home visits (along with action plan reinforcement):

- education on disease, adherence to medication and recognition/prevention of triggers of exacerbations
- selecting appropriate equipment at home and training on the correct administration of pharmacological therapy
- smoking cessation
- patient empowerment for daily life activities, including hygiene, dressing, household tasks, leisure activities, breathing exercises and skeletal muscle activity
- nutrition recommendations
- socialisation and changes in lifestyle.

The following outcomes were reported: mortality, readmissions or ED visits, hospitalisation, HRQoL, lung function, patient satisfaction, disease knowledge, inhaler technique, medication prescriptions, and home rehabilitation and costs.

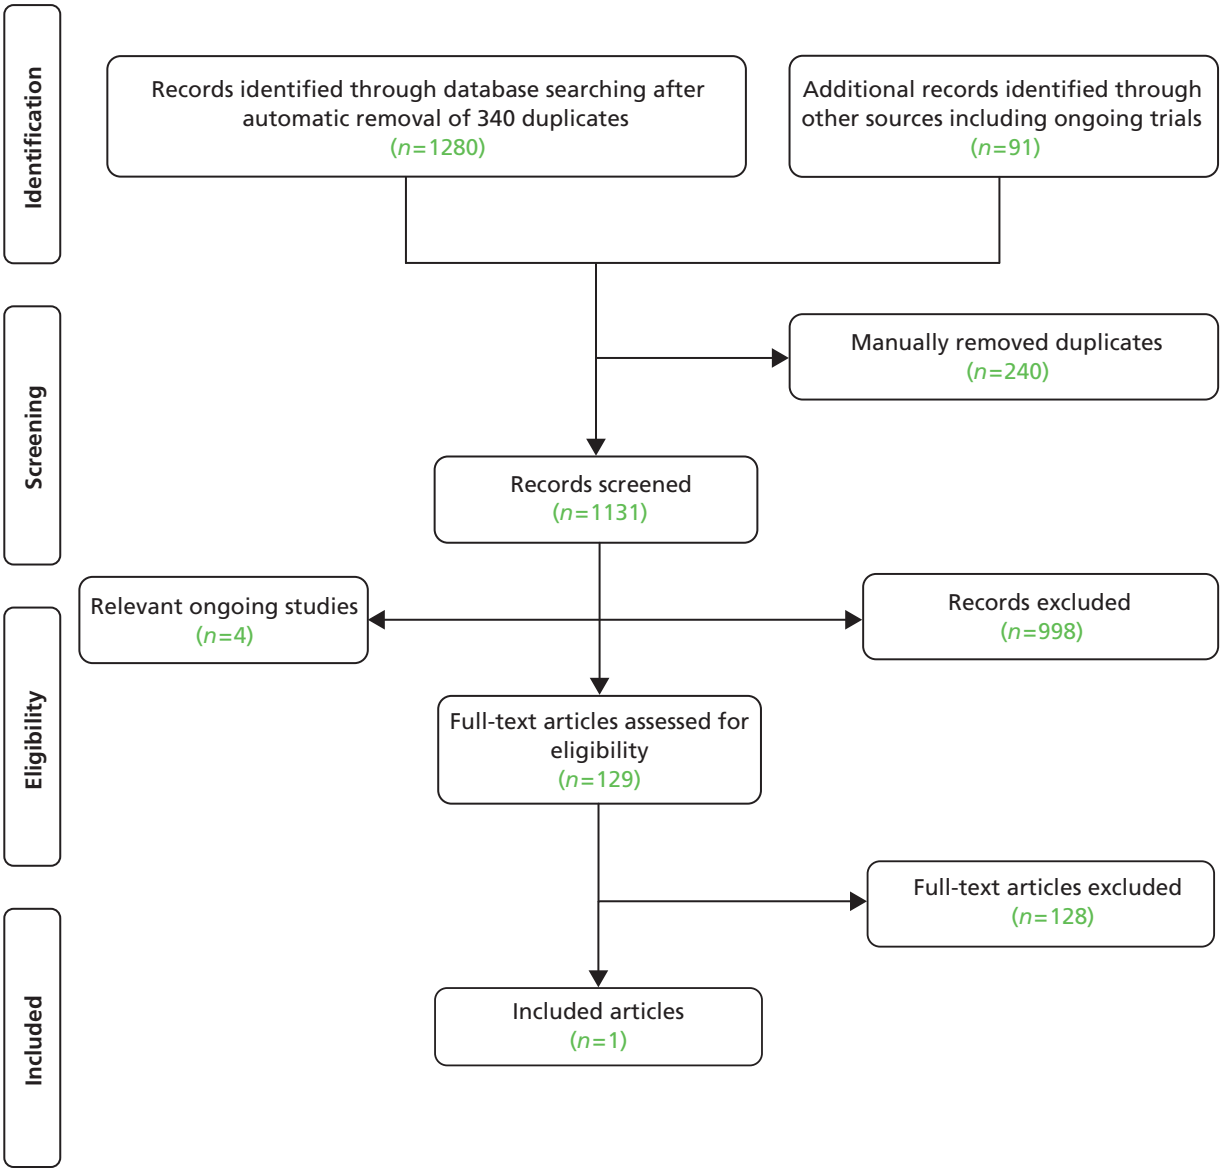

FIGURE 12 Selection process for cost-effectiveness studies.

Quality of included studies

The details of a cost analysis economic evaluation[68] were described and are summarised in *Table 9*. The research question was stated with reasons for its importance as well as for the rationale for the intervention and control under comparison. A public insurer perspective was taken but not justified; however, the limitations of taking this viewpoint were highlighted. The source of effectiveness estimates was stated and details of the design and results of the effectiveness study were provided. Outcome measures were clearly outlined and quantities of resource use (per patient) were given separately from unit costs. Details of direct and indirect costs were provided with nurse home visits, prescriptions, telephone calls and transport being calculated directly and inpatient hospital stay, emergency room visits, outpatient visits, primary care consultations and social support visits being calculated indirectly. Costs incurred by patients or carers were not considered. Currency and price data were reported using 2000 price data (euros); however, no details were provided regarding any price adjustments for inflation or currency conversions. The time horizon for the study was 1 year; thus, discount rates were not applied. Tariff prices were applied to resource-use data that were collected to calculate an average annual health-care cost per patient in both arms. Although differences in both costs and outcomes were reported, they did not conduct a full economic evaluation by presenting the relative cost-effectiveness. As the costs for the intervention were lower and outcomes better, this study[68] suggests the intervention dominated UC. Sensitivity analyses, and the details thereof, were discussed only briefly.

TABLE 9 Summary of study included in cost-effectiveness review

Author	Hernandez *et al.*[68]
Date	2003
Type of economic evaluation	Cost analysis
Currency used	Euros (€)
Year to which costs apply	2000
Perspective used	Public insurer
Comparators	Home hospitalisation compared with conventional care
Source(s) of effectiveness data	Clinical effectiveness data from RCT
Source(s) of resource-use data	Based on data from RCT
Sources of unit cost data	Directly calculated from data from trial, as well as indirectly calculated from tariffs for patients with COPD in a public insurance company
Modelling approach used	Not applicable
Summary of effectiveness results	Mortality: HR = 0.59 (95% CI 0.19 to 1.85)
	First ED visit: HR = 0.41 (95% CI 0.20 to 0.85)
	All ED visits: HR = 0.44 (95% CI 0.24 to 0.79)
	Hospital admission: HR = 0.71 (95% CI 0.40 to 1.24)
	QoL: MD = 4.50 (95% CI 0.66 to 8.34)
	Lung function: MD = 0.20 (95% CI –0.04 to 0.44)
Summary of cost-effectiveness results	Intervention dominates UC
Sensitivity analysis	Intervention dominates UC when resources released by the intervention were 75% or 50% of the average cost

Cost-effectiveness

As only one study met inclusion criteria for this review, no meta-analysis was undertaken; instead, the cost analysis results from the included study[68] are reported.

Costs were reported for the following outcomes (categories) following an 8-week follow-up period: length of hospital stay, emergency room visits (excluding visits that required further hospital admission), outpatient visits, primary care consultations, social support visits, home visits by nurse, prescriptions, telephone calls (both to the nurse from the patient and from the nurse to the patient) and transport costs. Details of the costs reported for each outcome are provided in *Table 10*.

The cost analysis found the home hospitalisation intervention to be significantly less costly than conventional care (average cost per patient: €1255.12 vs. €2033.51; $p = 0.003$). Hospital stay, emergency room visits, outpatient and social support visits were at a greater cost per patient for the conventional care group than for the home hospitalisation group, with the difference for hospital stay and emergency room visits reaching significance ($p < 0.001$ and $p = 0.01$, respectively). Prescription costs were significantly higher in the intervention group than in the control group (cost per patient: €217.21 vs. €172.06; $p = 0.001$). Primary care visits were also greater in the intervention group, although the difference was not reported to be statistically significant.

A sensitivity analysis based on resources for home hospitalisation at 50% and 75% of the average cost per patient (to capture intervention costs in the longer term) was undertaken. Cost savings in favour of home hospitalisation were conserved across each assumption.

TABLE 10 Costs associated with home hospitalisation and conventional care

Resource-use item	Cost per patient (€)		*p*-value[a]
	Home hospitalisation	Conventional care	
Inpatient hospital stay	941.40	1795.47	< 0.001
Emergency room visits	10.31	24.59	0.01
Outpatient visits	5.49	22.04	–
Primary care physician visits	8.19	7.57	–
Prescriptions	217.21	172.06	0.001
Nurse home visits	41.94	–	–
Social support visits	1.62	2.19	–
Telephone calls	20.99	–	–
Transport	7.97	9.59	–
Average cost (€) per patient (95% CI)	1255.12	2033.51	0.003

CI, confidence interval.
a Non-parametric Mann–Whitney *U*-test.

Discussion

Summary of results

A comprehensive search strategy identified one study[68] that met the inclusion criteria for this review. The overall quality of the study was high, with some issues related to reporting. Meta-analysis was not possible. The study[68] revealed that home hospitalisation is less costly than conventional care [£1041.75 vs. £1687.81 (conversion rate €1 = £0.83)].

How this fits with other literature

One relevant study[82] published after the search strategy had been completed was subsequently identified. Xin Lie *et al.*[82] developed a Markov model to evaluate the impact of a hypothetical exacerbation management programme that could detect the risk of exacerbation and divert the risk of hospitalisation. In patients without prior history of exacerbation, they estimated that this would result in savings of US$2900 per patient over 12 years, and in higher-risk patients – with a history of one or two exacerbations per year – this estimate increased to US$16,000 per patient.

Strengths and limitations

This is the first systematic review of the cost-effectiveness literature of SM interventions for patients who have recently been discharged from hospital after an acute exacerbation of COPD. The methods used throughout this cost-effectiveness review were systematic. A comprehensive search strategy was undertaken and the results were reviewed independently by two reviewers, including a health economist. The recommended quality assessment checklist was used.

It should be noted that the patients in this study were recruited from the emergency room rather than after discharge post hospital admission, which may or may not cause variations in the applicability of the results. A scarcity of evidence of the cost-effectiveness of SM interventions was evident. The identified study included the cost of implementing a hospital-at-home programme with components of SM, thus the SM components reflect only a proportion of the costs and cost savings incurred.

Implications for research

There is a need for more economic evaluations, alongside randomised controlled trials, specifically addressing patients who have recently been discharged from an inpatient hospital admission stay after an acute exacerbation of COPD, and who have been treated with SM interventions or components of SM, such as education, action plans, breathing techniques, relaxation and stress management amongst others.

Chapter 6 Economic evaluation

Methods

This section provides a detailed description of the economic model that was developed and used to evaluate the cost-effectiveness (cost–utility) of self-management (SM) support delivered within 6 weeks of hospital discharge compared with usual care (UC) in a patient population with chronic obstructive pulmonary disease (COPD) who have been admitted for an exacerbation. The evidence for the effectiveness of SM programmes (see *Chapter 3*) demonstrated that there was considerable uncertainty for the outcome measures of mortality, quality of life (QoL) and admissions. The model presented here considers the potential impact of reduced admissions due to a SM programme, in terms of costs, mortality and QoL. However, owing to the uncertainty around the point estimate of reduction in admission and the considerable heterogeneity between studies, this effect must be considered with some caution. Therefore, the economic model should be viewed as speculative, with the aim of estimating the potential cost–utility of SM if it is truly effective at reducing hospital admissions for exacerbations.

Model description

A Markov decision model, built in TreeAgePro 2014 (TreeAge Software, Inc., Williamstown, MA, USA) was structured to consider short-term increased risks of readmission and mortality, and the long-term natural history of the disease, taking into account exacerbations, increasing COPD severity and mortality (*Figure 13*). This structure was an adapted version of other COPD Markov models[83] with health states linked to GOLD (Global Initiative for Chronic Obstructive Lung Disease) severity. It incorporated additional health states to capture the higher risks reported in patients immediately after discharge in audits of patients admitted to hospital.[84] The model had a time cycle of 1 month and a lifetime time horizon (30 years) was used. All costs and outcomes were considered from a NHS perspective for a price year of 2012.

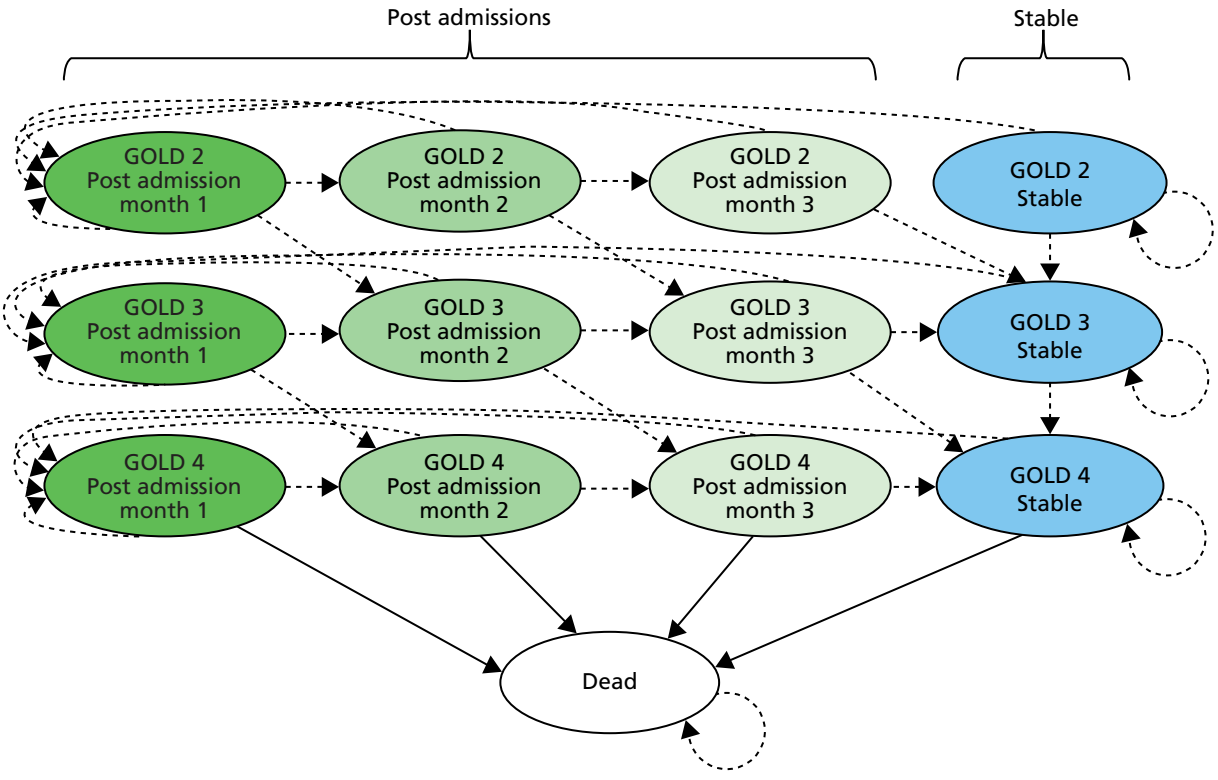

FIGURE 13 Markov model structure.

Severity of COPD was defined according to the GOLD classification. GOLD stage 2 was defined as having a forced expiratory volume in 1 second (FEV_1) of ≥ 50%, < 80% predicted; GOLD stage 3, a FEV_1 of ≥ 30%, < 50% predicted; and GOLD stage 4, a FEV_1 of < 30% predicted. GOLD stage 1 (mild COPD) was excluded, as < 16% of patients admitted to UK hospitals with COPD had a FEV_1 of ≥ 80% predicted.

A patient started in the model in one of three health states representing their first month post admission, taking into account their current GOLD severity stage. Those who continued to recover without further exacerbations moved to health states to represent the second and third month of recovery, again related to their GOLD stage. Within this 3-month recovery period, a patient could die from COPD or other causes or have a further exacerbation requiring readmission, which could be fatal. If the patient survived, they were discharged to restart the 3-month recovery period in a 'first month post-admission' health state. The patient pathway within each post-admission health state (*Figure 14*) was similar for each month and severity stage. The post-admission health states allowed the model to consider the immediate increased risk of readmission and COPD-related mortality for 3 months after discharge. Once a patient survived 3 months of recovery with no readmissions, they moved into a stable health state for their GOLD stage.

Once in the stable GOLD stage 2, 3 or 4, a patient could remain in that health state, deteriorate to the next more severe health state, have an exacerbation or die. An exacerbation could be moderate (managed in primary care) or severe (admitted to hospital). Patients who recovered from moderate exacerbations either remained in the same health state or deteriorated. Severe exacerbations could result in death, and surviving patients moved to the relevant 'first month post-admission' health state. It was assumed that no patients could improve into a better GOLD stage health state. *Figure 15* illustrates the patient pathway in a stable health state.

Base-case cohort

For the base-case analysis, the characteristics of the cohort were taken from the 2011 report by the European Audit[84] of UK patients with COPD admitted to hospital (*Table 11*). The proportions of men and current smokers were assumed to remain constant. The baseline distribution of patients entering the model was 35% in GOLD stage 2, 35% in GOLD stage 3 and 30% in GOLD stage 4.

Estimation of model parameters

This section outlines the assumptions applied, and sources used, to populate the base-case, usual-care arm.

Transition probabilities within post-admission health states

Published data on exacerbation rates in patient cohorts who had been admitted to hospital demonstrated an elevated risk of readmission and mortality immediately after discharge.[84,85] In addition, exacerbation rates and severity of exacerbations increased with disease severity. The risk of a mild or moderate exacerbation was not considered in the post-admission health states.

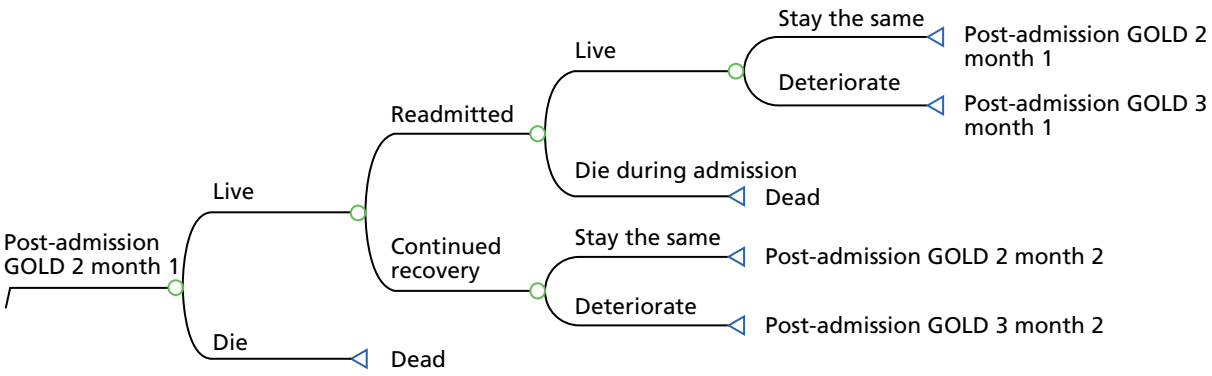

FIGURE 14 Pathways within post-admission states.

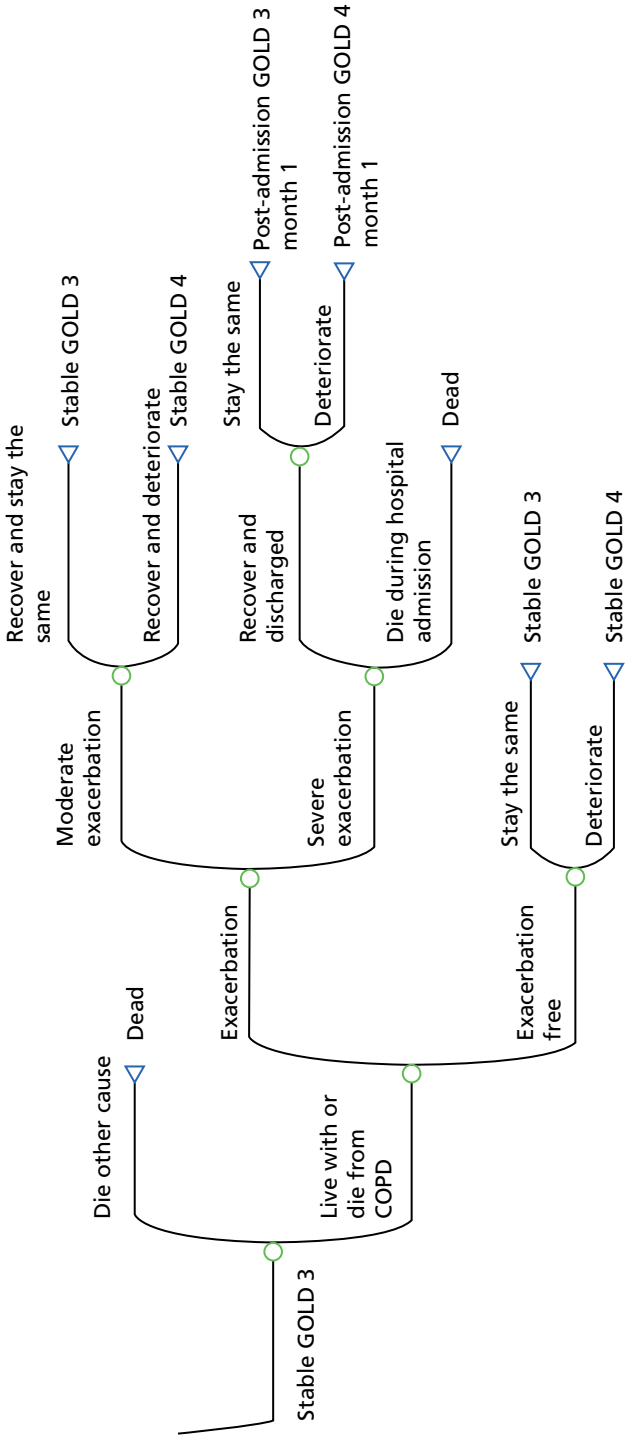

FIGURE 15 Pathways within stable health states.

TABLE 11 Base-case characteristics

Characteristic	Median or %
Age (median)	72
Sex (% male)	47.4
Smoking status (% current smokers)	39.4
GOLD stage (%): 2; 3; 4	35; 35; 30

Source: European Audit 2012.[84]

The majority of the transition probabilities for post-admission health states were obtained from the European Audit[84] and are reported in *Table 12*. Risks of readmission and mortality were the same for each of the three post-admission months and did not differ by GOLD stage. Post-admission COPD-related mortality and readmission risks were assumed to be evenly distributed over the 3-month period.

Age- and sex-specific all-cause mortality rates were obtained from Office for National Statistics life tables and adjusted to avoid double counting of COPD-related mortality. *Appendix 18* lists the COPD adjusted all-cause mortality rates applied in the economic model. Age- and smoking-related disease progression rates were obtained from a published model[86] (see *Appendix 19*). All annual rates were converted to monthly probabilities.

Transition probabilities within stable health states

The patient pathways for each GOLD stage health state were assumed to be the same (see *Figure 15*); however, the probabilities, costs and utilities differed by COPD severity. The probability of progressing to a more severe GOLD stage was not assumed to vary by exacerbation history; thus, the transition probabilities for movement between stable health states were the same as those described above.

The probabilities for exacerbations and hospitalisations were obtained from the TORCH (TOwards a Revolution in COPD Health)[85] and ECLIPSE (Evaluation of COPD Longitudinally to Identify Predictive Surrogate Endpoints)[13] studies, respectively. Patients who survived, exacerbation free, for the 3-month

TABLE 12 Mortality and exacerbation risks applied in post-admission states

Definition	Probability	Beta distribution[a]
COPD-related death during admission[b]		
Men	0.050	$\alpha = 118$, $\beta = 2243$
Women	0.051	$\alpha = 133$, $\beta = 2490$
90-day COPD-related death post admission[b]		
Men	0.047	$\alpha = 104$, $\beta = 2097$
Women	0.049	$\alpha = 120$, $\beta = 2324$
90-day COPD-related readmission[b]		
Men	0.323	$\alpha = 705$, $\beta = 1496$
Women	0.295	$\alpha = 721$, $\beta = 1723$

a A beta distribution is a family of continuous probability distributions defined on the interval (0,1) denoted by α and β, where 'α' is the number of successes in a trial and 'β' is the number of failures.
b Mortality and readmission rates were adjusted to include only those for which the primary cause was COPD or respiratory failure. These were not differentiated by GOLD stage in the post-admission health states.
Source: European Audit 2012.[84]

post-admission period were assumed to have exacerbation and hospitalisation rates similar to those reported in stable cohorts for each severity stage. As the exacerbation rates from the TORCH trial[85] were reported by type of treatment, assumptions were required in the model regarding the proportion of patients on each type of treatment in each GOLD stage health state. These proportions were obtained from unpublished data collected from a cohort of UK patients with COPD who were recruited as part of BLISS (Birmingham Lung Improvement Studies) in the West Midlands. Exacerbation rates were then weighted by the proportion of patients on each treatment in each GOLD stage severity group. As the TORCH study[85] did not report the proportion actually admitted to hospital for an exacerbation, this was obtained from the ECLIPSE study.[13]

The base-case proportions on each type of treatment, annual exacerbation rates and the proportion resulting in a hospital admission are reported in *Tables 13* and *14*. Probabilities for inpatient mortality, all-cause mortality and disease progression are as described previously for the post-admission states.

Estimate for effectiveness of self-management support

Data and assumptions regarding the effectiveness of SM were based on the results of the review presented in *Chapter 3*. As previously highlighted, although evidence suggested a potential reduction in readmissions, there was considerable uncertainty around the point estimate of effect as the 95% CI crossed 1 (see *Chapter 3*, *Hospital admissions: no evidence of effect*). The HR used for the base-case model was the weighted ratio of the more intense SM interventions. Two alternative HRs reported were subsequently applied in a one-way sensitivity analysis. The estimate of effect was applied to all monthly probabilities for readmission for severe exacerbation in the SM strategy in the model (*Table 15*).

TABLE 13 Proportion of each type of treatment and exacerbation rate

	Treatment type			
Severity stage	Other[a]	ICS	LABA	ICS/LABA

Proportion on treatment (%) (BLISS)	16.28	4.65	2.33	76.74
Annual exacerbation rate (TORCH)[85]	1.79	1.53	1.40	1.54

ICS, inhaled corticosteroids; LABA, long-acting beta-agonist; ICS/LABA, combined therapy (combined ICS and LABA).
a Patients may have been on other treatments, such as long-acting muscarinic antagonists (LAMAs) and short-acting muscarinic antagonists (SAMAs).

TABLE 14 Exacerbation and hospitalisation rates applied in stable health states

		Proportion of exacerbations hospitalised[13]	
Severity stage	Overall weighted exacerbation rate[85]	%	Beta distributions
GOLD 2	0.68	11	$\alpha = 104$, $\beta = 841$
GOLD 3	1.00	25	$\alpha = 225$, $\beta = 675$
GOLD 4	1.57	54	$\alpha = 158$, $\beta = 135$

TABLE 15 Adjusted HRs applied to admissions for the SM strategy

Analysis		HR	95% CI	Meta-analysis inclusion criteria
Base case		0.83	0.50 to 1.36	Review 1: More supported SM interventions
One-way sensitivity analysis	Low	0.96	0.49 to 1.90	Review 1: Less supported SM interventions
	High	0.78	0.52 to 1.17	Review 1: All studies, including those with an exercise component

Source: outcomes reported in *Chapter 3* (review 1).

Although the effectiveness estimate was estimated over a short period of time in the trials, the model assumed that the effect of the SM intervention would last for 2 years.

The results of the review indicated no evidence of higher all-cause mortality associated with SM, as the HR reported was very close to 1. As the model takes into account a reduced risk of readmission, which leads to improved survival, no further adjustment to mortality was undertaken.

Estimation of quality-adjusted life-years

Utility values were required for all health states and exacerbation events, and were combined with information on survival in order to calculate quality-adjusted life-years (QALYs). The model health states were based on COPD severity defined by GOLD stages 2–4. Utility values for these health states were calculated from unpublished data collected from the BLISS cohort. Utility scores for GOLD stages 2–3 were derived from the EQ-5D-5L (a revised version of the EQ-5D questionnaire). The five dimensions (mobility, self-care, usual activities, pain and discomfort, and anxiety and depression) have five levels, compared with the older version, which used three levels. The addition of two more levels may have made the EQ-5D more sensitive to differences in health states and avoid ceiling effects.[87]

The EQ-5D-5L was completed by 917 participants enrolled in the BLISS study, with a confirmed diagnosis of COPD, at GOLD stage 2, 3 or 4, and converted to utility scores using the interim crosswalk value set for a UK population reported by EuroQoL.[88] Data from this cohort were deemed suitable for stable health states in the model for two reasons. First, participants were not recovering from an exacerbation at the time of questionnaire completion, therefore the utility scores were expected to reflect QoL in the stable condition. Second, > 80% of patients in each GOLD stage had been admitted to hospital at least once in the past year, therefore presenting a population who suffered exacerbations. EQ-5D-5L responses were converted to utility scores and are reported in *Table 16*.

The utility scores were compared with values applied in other COPD models that defined health states by GOLD severity stage. The utility values obtained from the BLISS cohort study were similar to those reported in other studies.[83,89–91] Data on utility loss suffered immediately after a moderate or severe exacerbation were extracted from previously published models; however, estimates varied greatly and the evidence underpinning these was poor.[83,89,92–94] It was assumed that there was a loss of utility for 1 month for moderate exacerbations and a utility loss for 3 months for severe exacerbations due to full recovery taking a longer period of time.[95–97] However, in line with other studies, the utility loss for severe exacerbations

TABLE 16 Utility scores for stable GOLD health states

Descriptor	GOLD 2	GOLD 3	GOLD 4
Sample size (*n*)	650	229	38
Mean utility score (SE)	0.7041 (0.0102)	0.6765 (0.0174)	0.6014 (0.0415)

SE, standard error.

was assumed to be greatest in the first month, with improvement in QoL in the second and third months post admission.

The utility loss estimate of 15% for moderate exacerbation and 50% for severe exacerbation was obtained from Rutten-van Mölken *et al.*[89] This was applied to the mean utility score across all three severity stages (as opposed to each individually) to ensure that the utility loss suffered in stage 2 or 3 was not greater than loss experienced by stage 4 patients. The mean utility score found in the BLISS cohort across stages 2–4 was 0.693; therefore, a moderate exacerbation was assumed to result in a loss of 0.104 QALYs for 1 month and a severe exacerbation was assumed to result in a 0.346 loss of QALYs in the first month, reducing to a loss of 0.173 QALYs for months 2 and 3. A summary of all the utilities applied in the base-case analysis is provided in *Table 17*.

The review presented in *Chapter 3* found evidence that SM may have a positive impact on QoL; however, the results were highly uncertain. As the model takes into account reduced rates of readmissions in the SM strategy, which leads to reduced loss of QoL, no further utility gains were applied in the model.

Resource use and costs

The resource use considered within the model was broadly concerned with the SM intervention, primary and secondary health-care professional contacts, and pharmacotherapy. Health-care contacts for each GOLD severity group were estimated with reference to National Institute of Health and Care Excellence (NICE) guidelines and expert opinion. Use of pharmacotherapy was estimated from data provided by the BLISS cohort. Unit costs were primarily obtained from NHS Reference costs[98] and Unit Costs of Health and Social Care.[99] When appropriate, unit costs were inflated to 2012 prices using NHS Health Index inflation rates. Annual costs were divided by 12 to derive a monthly cost. Moderate and severe exacerbations were treated as additional one-off costs and assumed to be the same, irrespective of the underlying GOLD stage.

Routine health-care visits

It is recommended by NICE[10] that stable patients with COPD are followed up at least once a year and those with very severe COPD at least twice a year, with rapid access to hospital assessment as necessary. Based on these guidelines it was assumed that patients at GOLD stages 2, 3 and 4 would attend 1, 2 and 2.5 assessments per year, respectively, and that spirometry tests were conducted once per year in GOLD stage 2 and twice in GOLD stage 3 and 4 patients. As follow-up arrangements in primary or secondary care were not specified within the guidelines, an even split between both types of services was assumed for each severity group.

The cost of follow-up and spirometry in secondary care were obtained from NHS Reference Costs.[98] Costs for follow-up in primary care were based on the cost of a home visit by a community nurse, as published by the Personal Social Services Research Unit (PSSRU)[99] and the cost of spirometry was extracted from a costing document published by NHS Commissioning Support for London.[100] Additional health-care costs

	0.5311 (months 2 and 3)	0.5035 (months 2 and 3)	0.4284 (months 2 and 3)

a Source: BLISS cohort; assumptions extracted from Rutten-van Mölken *et al.*[89] and applied to mean scores obtained from BLISS.

included were the provision of annual influenza vaccinations, home oxygen therapy and the cost of prescribing. As the median age of the population was > 70 years, it was assumed that 75%[101] of patients in each severity group received the vaccination at the current estimated cost of £6.21.[101] The average number of days and cost of home oxygen therapy received in each severity group was obtained from estimates reported in Hertel *et al.*,[92] derived from expert opinion.

Smoking cessation advice and pulmonary rehabilitation are also recommended by NICE as UC for patients with COPD.[10] However, these costs were assumed to be the same for both strategies, thus cancelling each other out, and were omitted from the model.

The total annual costs of health-care visits in GOLD stages 2, 3 and 4 were estimated to be £180, £332 and £453, respectively. A summary of the assumptions and reference costs applied to derive these estimates is provided in *Table 18*.

Routine pharmacotherapy

The NICE guidance is not prescriptive for each GOLD stage, and suggests that the number and type of treatments prescribed should be determined by patient symptoms and response. Therefore, the model utilised data from the previously described BLISS cohort for the proportion of patients on each line of therapy, by GOLD stage (*Table 19*).[10] As 100% of patients were reported to be on an inhaled short-acting β_2-agonist (SABA), assumptions on the number of delivery devices in each severity stage were made by clinical experts. Drug reference costs reported by NICE 2011[102] (*Table 20*) were compared with current unit costs listed on the NHS Drug Tariff database[103] in 2014. Most of the drug prices were consistent with those listed in the NICE 2011 report; however, some were higher and some were lower.[102] As there did not appear to be a consistent drug inflation rate during this period (2011–14), it was not appropriate to inflate the 2011 prices or deflate the 2014 prices to estimate the costs in 2012 prices, thus the prices listed in the NHS Drug Tariff database[103] for 2014 were applied. Annual and monthly costs were calculated by applying the same unit cost to annual costs reported by NICE. When there was more than one drug in each treatment class, an overall average cost was applied.

TABLE 18 Annual routine health-care utilisation and costs by GOLD stage

Health care	GOLD 2	GOLD 3	GOLD 4	Unit cost (£)	Source

Cost of exacerbations

Moderate exacerbations were assumed to be predominantly managed in primary care through GP appointments, with a proportion attending accident and emergency (A&E) without admission. As no data were found on the split between GP and A&E visits, assumptions were derived from expert opinion reported in Hertel *et al.*,[92] which assumed that two out of three patients would see a GP, and one out of three patients would attend A&E. Prescribed additional medication for a moderate exacerbation was assumed to be a course of prednisolone (5 mg tablets, six times per day for 5 days) and antibiotics when exacerbations were associated with a history of purulent sputum (NICE[10]). The total cost of treating a moderate exacerbation was estimated to be £114, and a breakdown of how this cost was calculated is presented in *Table 21*.

The majority of severe exacerbations were assumed to be managed in hospital but 20% were assumed to be managed through hospital-at-home or early discharge schemes. The 2011 NICE[102] costing study estimated the average cost of a COPD hospital admission to be £1978. These costs were not inflated as the NHS tariff prices[98] applied appeared similar to those listed in 2012. No data were available on the tariffs for hospital-at-home or early discharge schemes; however, a UK-based cost analysis estimated the costs incurred in a similar scheme to be £1653 in 2009 prices,[104] inflated to £1769 for 2012. Following discussion with our clinical experts, it was assumed that 20% of those who suffered an exacerbation requiring admission accessed the non-inpatient type of service.

Guidance from NICE also recommends that patients should be followed up after discharge therefore this cost was included in the average cost of a severe exacerbation and was assumed to include one follow-up visit, 30% seen by a community nurse, 30% attending a GP appointment and 40% attending an outpatient appointment. The total cost of managing a severe exacerbation was estimated to be £2053 (*Table 22*).

TABLE 21 Cost of moderate exacerbation

Resource-use item	% requiring resource	Unit cost (£)	Source of cost estimate
GP visit (12 minutes)	66.7	44.40	PSSRU[99]

Cost of self-management

The cost of providing a SM programme to patients with COPD post discharge was estimated with reference to the activities described in a sample of studies selected from review 1 in *Chapter 3*. Studies were chosen to reflect different levels of intensity of SM. The estimated cost of delivering a SM programme of low, moderate/high and high intensity is detailed in *Tables 23–25*. The costs estimated for Wong *et al.*[74] and Bucknall *et al.*[63] were estimates based on the resource use described.

TABLE 23 Cost estimates for low-intensity SM

Description of activity	Resource required	Unit cost (£)	Total cost per patient (£)	Source
Two 10- to 20-minute telephone calls within 4 weeks of discharge; each telephone call was assumed to take 45 minutes of staff nurse time, taking into account missed calls and processing information before and after	Staff nurse time	43	64.50	Hour of staff nurse time (PSSRU 2012[99])
A senior nurse specialist supervised this service; this was 15 minutes of time per patient	Senior staff nurse time	81	20.25	Hour of senior nurse specialist (PSSRU 2012[99])

Seven home visits every 6 weeks for 12 months (each visit takes an hour of community nurse specialist time)	Community nurse	61.00	427.00	Hour of community nurse home visiting time (PSSRU 2012[99])
Total cost			671.00	

Source: Bucknall *et al.*[63]

Calculated costs were compared with estimates of other SM programmes that are targeted at patients with COPD but not delivered at discharge (see *Appendix 20*).The majority of SM programmes cost between £500 and £600, and are therefore similar to the estimate of the SM programme described by Casas *et al.*;[71] thus this was chosen for the base case for the moderate- to high-intensity programme. Sensitivity analyses were conducted to evaluate the cost-effectiveness of SM assuming low- and high-intensity programmes and are outlined in the sensitivity analysis subsection.

Assessment of cost-effectiveness

The incremental analysis was designed to generate the cost per additional QALY gained for SM delivered within 6 weeks of discharge when compared with UC in a cohort of patients with COPD. In summary, the key assumptions for the base case were as follows:

- The starting cohort was assumed to be aged 72 years, 47.4% male with 39.4% current smokers (see *Chapter 6*, *Base-case cohort*).
- The starting distribution of COPD severity was 35% GOLD stage 2, 35% GOLD stage 3 and 30% GOLD stage 4 (see *Chapter 6*, *Base-case cohort*).
- Mortality and readmission risks during admission and immediately after discharge were taken from the European Audit[84] and applied for 3 months' post-admission (see *Chapter 6*, *Transition probabilities within post-admission health states*).
- Long-term exacerbation, hospitalisation risk and disease progression were taken from large cohort studies of three years or more (see *Chapter 6*, *Transition probabilities within stable health states*).
- The estimate for reduction in risk of admission with SM was taken from moderate- to high-intensity programmes (see *Chapter 6*, *Estimate for effectiveness of self-management report*).
- Utility values were obtained from the BLISS cohort and an estimate was applied for the utility loss associated with exacerbation (see *Chapter 6*, *Estimation of quality-adjusted life-years*).
- The cost of UC was estimated with reference to pharmacotherapy use amongst the BLISS cohort, best practice guidance, expert opinion and NHS reference prices (see *Chapter 6, Resource use and costs*).
- The cost of SM was estimated to be £597, incurred in the first month and the effect was assumed to last for 2 years (see *Chapter 6*, *Cost of self-management*).

Where available, data were entered into the model as distributions so as to fully incorporate the uncertainty around parameter values in order that a probabilistic sensitivity analysis could be undertaken. Beta distributions were applied to the proportion on different treatments and accessing services in primary and secondary care; they were also applied to annual exacerbation rates and the proportion resulting in hospital admissions, as well as the risk reduction expected in the SM arm. Normal distributions were applied to utilities and utility losses. The probabilistic sensitivity analysis was run with 1000 simulations, and cost-effectiveness planes and acceptability curves were produced.

Sensitivity analysis

Additional model runs were undertaken to determine the impact of changing key parameters on the model results. Those parameters for which the incremental cost-effectiveness ratio (ICER) was demonstrated to be particularly sensitive to change were explored in more detail. The following analyses were undertaken:

1. The time horizon was varied, changing from the base-case assumption of 30 years to 6 months, 2 years, 10 years and 20 years.
2. The effect of SM on admissions was varied by substituting the base-case HR of 0.83 (95% CI 0.50 to 1.36) with two alternative HRs reported in *Chapter 3*. This included a HR derived from a meta-analysis of two low-intensity programmes of 0.96 (95% CI 0.49 to 1.90) and a meta-analysis that included exercise interventions representing a high-intensity programme of 0.78 (95% CI 0.52 to 1.17).
3. The duration of effect was tested for the base-case moderate-high-intensity SM programme, assuming the effect lasted for only (1) 6 months and (2) the lifetime of the cohort (see *Chapter 6*, *Duration of effect*).
4. The cost of SM was tested applying a low estimate of £85 and a high estimate of £671 (see *Chapter 6*, *Cost of self-management*).
5. An alternative set of utility scores obtained from Borg *et al.*[83] were applied (higher utility scores for GOLD stages 2 and 3, lower utility scores for GOLD stage 4 and a proportional deduction in utility for each severity stage lasting for 1 month in both moderate or severe exacerbation); see *Table 26* (see also *Utility values for chronic obstructive pulmonary disease*).
6. Subgroup analysis was conducted to test if the decision rules changed if targeted at different subpopulations. This was tested by assuming that (1) all patients were GOLD stage 2; (2) all patients were GOLD stage 3; (3) all patients were GOLD stage 4; (4) there were different start ages; (5) all of the cohort were male; (6) all of the cohort were female; (7) all were smokers; (8) and all were non-smokers (see *Chapter 6*, *Subgroup analysis*).
7. Two scenario analyses were conducted: scenario 1 applied the highest estimate of effect 0.78 (95% CI 0.52 to 1.17) and the highest estimate of SM costs, £671; scenario 2 applied the lowest estimate of effect 0.96 (95% CI 0.49 to 1.90) and the lowest estimate of costs of £85 (see *Chapter 6*, *Scenario analysis*).

TABLE 26 Alternative utility values applied in one-way sensitivity analysis

Sensitivity analysis 1			
Stable condition	0.7551	0.7481	0.5493
Moderate exacerbation	0.6418 (1 month)	0.6359 (1 month)	0.4669 (1 month)
Severe exacerbation	0.378 (1 month)	0.374 (1 month)	0.2747 (1 month)

Assumptions on proportion effect for utility loss during exacerbation taken from Rutten-van Mölken[89] and applied to mean utilities found in Borg *et al.*[83]

Results

Base-case analysis

The base-case results presented in *Table 27* show that, compared with UC, SM (delivered within 6 weeks of discharge) was more costly and resulted in better outcomes, with a £683 cost difference and gain of 0.0831 QALYs. The ICER was £8218 per QALY gained – well below the threshold values of £20,000–30,000 per QALY gained as recommended by NICE.[10]

Results from the probabilistic sensitivity analysis are shown in the cost-effectiveness plane in *Figure 16*, which shows the distribution of 1000 resampled cost–effect difference pairs. The probabilistic sensitivity analysis clearly shows that SM is the more expensive strategy; however, the effectiveness is less certain, with a number of points indicating that SM may give fewer QALYs. The cost-effectiveness acceptability curve in *Figure 17* shows that the intervention has a 68% probability of being cost-effective at £20,000 per QALY gained and 71% at a £30,000 threshold.

TABLE 27 Base-case results

Strategy	Mean cost (£)	Cost difference (£)	Mean QALYs	QALY difference	ICER (£/QALY)	Probability cost-effective at a specified threshold (%)[a]	
						£20,000/QALY	£30,000/QALY
UC	18,872		5.767				
SM	19,556	683	5.850	0.0831	8218	68	71

a Refers to the proportion of samples drawn from the probabilistic sensitivity analysis that could be considered cost-effective, based on what NICE is willing to pay for an additional QALY gained.

Sensitivity analysis

Alternative model time horizon

Table 28 presents the results of the model when varying the time horizon of the model. At a short time horizon of 6 months, when the intervention has been effective for 6 months, the ICER was £52,487 – above the NICE thresholds for cost-effectiveness; however, this is unlikely to represent a realistic time frame. At 2 years, the ICER reduces to £5954 as a result of most of the additional cost of implementing a SM programme being offset by savings from a reduction in hospital admissions. This changes over time, as higher costs are incurred in the surviving arm as a result of lower mortality. The probability of SM being cost-effective at £20,000/QALY remains > 62% beyond 2 years but no longer dominates UC.

Alternative hazard ratios for readmissions in the self-management strategy

Owing to the considerable uncertainty around the effectiveness estimate (HR) for readmissions, this model parameter was expected to be the biggest driver of the cost-effectiveness results. To test this, two alternative HRs reported in the meta-analysis for review 1 were applied in the model and the results are shown in *Table 29*. The first alternative HR applied was a higher estimate of the effect. This was derived from a meta-analysis that included SM interventions with an exercise component. Applying the higher estimate of effect, the ICER decreased to £6249, and the likelihood of SM being cost-effective at a

TABLE 28 Sensitivity analysis: alternative model time horizons

Time horizons	Cost difference (£)	QALY difference	ICER (£/QALY)	Probability cost-effective at £20,000/QALY (%)	Probability cost-effective at £30,000/QALY (%)
6 months	175	0.0033	52,487	32	39
2 years	95	0.0160	5954	62	65
10 years	489	0.0624	7838	65	72
20 years	664	0.0812	8180	68	71
Base case (30 years)	683	0.0831	8218	68	71

TABLE 29 Sensitivity analysis: alternative HRs for admissions in SM support

HR	Cost difference (£)	QALY difference	ICER (£/QALY)	Probability cost-effective at £20,000/QALY (%)	Probability cost-effective at £30,000/QALY (%)
Base case (0.83, 95% CI 0.50 to 1.36)	683	0.0831	8218	68	71
High estimate (0.78, 95% CI 0.52 to 1.17)	676	0.1082	6249	82	84
Low estimate (0.96, 95% CI 0.49 to 1.90)	703	0.0184	38,265	41	45

threshold value of £20,000 per QALY increased to 82%. The second alternative HR applied was a lower estimate of effect derived from a meta-analysis of two low-intensity SM programmes. This increased the ICER to £38,265. This was above the threshold value of £30,000/QALY and hence the probability of SM being cost-effective at £30,000/QALY reduced to 45%.

Figure 18 illustrates the relationship between changing the point estimates of the HR and the mean ICER. At values of < 1 the ICERs are positive, and at all values of < 0.95 the ICERs are below the threshold of £30,000 per QALY. As the HR approaches 0.5, the ICER decreases and the benefits increase. At all values of > 1, SM is a less favourable option. If SM has no effect or increases the risk of hospital admission, it is dominated by UC (negative ICERs in *Figure 18*) hence why the ICER drops sharply. As the ratio increases to 1.5 the ICER decreases as UC becomes less cost-effective due to lower mortality in the UC arm. The 95% CIs for all three reported estimates crossed 1.

Duration of effect

Table 30 presents the results applying different assumptions regarding the duration of effect of SM support. In the base case it was assumed that the effect of SM would last for 2 years. The values were varied in the sensitivity analysis from 6 months to 30 years. When a shorter duration of effect was applied, the ICER increased and the probability of SM being cost-effective decreased. Conversely, applying a higher duration of effect decreased the ICER and increased the likelihood of SM being cost-effective.

Figure 19 illustrates the relationship between changing the duration of effect and the ICER. At between 6 and 24 months the ICERs drop sharply and the decision rule changes. Most of the studies identified in the effectiveness review were short term in nature, resulting in uncertainty on the duration of this effect.

Cost of self-management

The impact of changing the cost of SM is presented in *Table 31*. Applying the high estimate of £671 increases the ICER to £9257 and the probability of SM being cost-effective at a threshold of £20,000 per QALY is similar at 69%. Applying the low estimate of £85 decreases the ICER to £1033 and increases the probability that SM is cost-effective at a threshold of £20,000 per QALY to 76%.

Figure 20 shows the relationship between SM costs and the ICER. At all values for the cost of SM between £50 and £2200 the ICER is below a willingness-to-pay threshold of £30,000. At costs above £2200 the mean ICER in the base-case scenario is not cost-effective.

Utility values for chronic obstructive pulmonary disease

The effect of applying alternative utility scores and assumptions is shown in *Table 32*, demonstrating that QALYs are gained in both strategy arms, irrespective of the changes in utility values for stable health states and utility loss associated with exacerbation changes. Therefore, there is little impact on QALY differences between strategies, and all estimates of the utility values for stable and exacerbating health states give similar results.

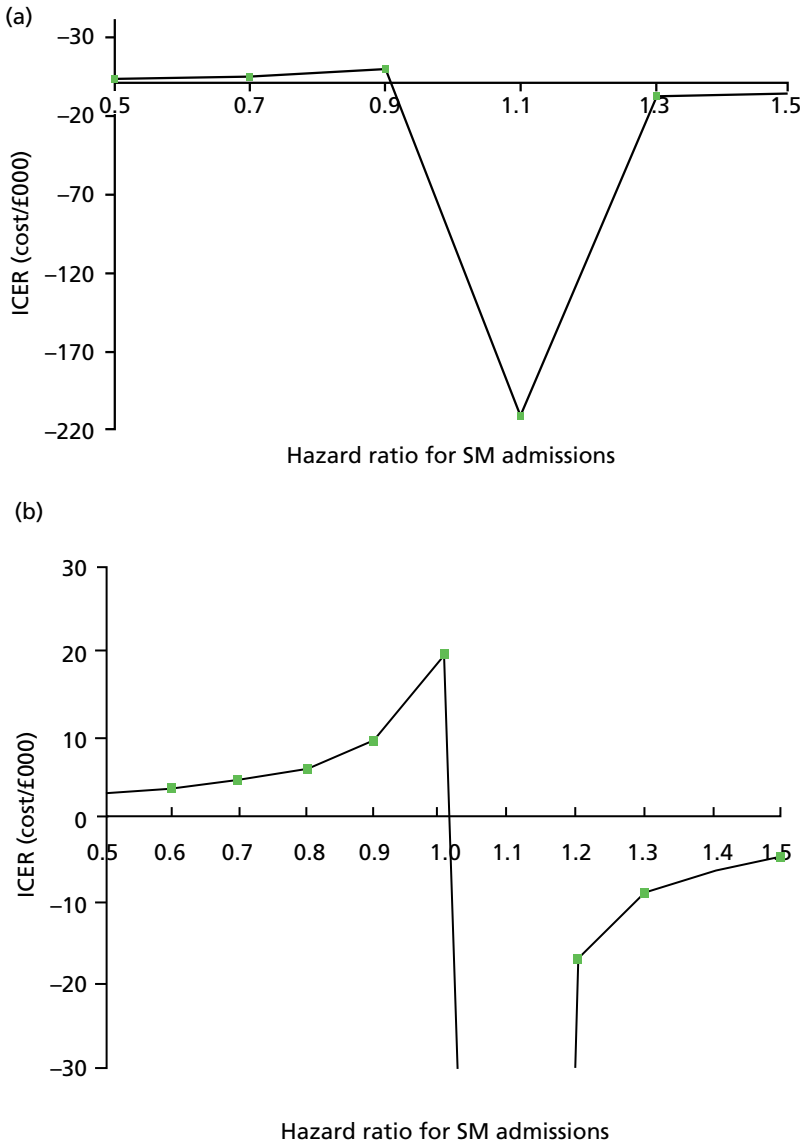

FIGURE 18 Sensitivity analysis: relationship between HR for readmissions and ICER. a, Illustration of how the ICER changes by varying the HR between 0.5 and 1.5; and (b) magnification of how the ICER changes within the boundaries of a threshold of plus or minus £30,000 per QALY.

TABLE 30 Sensitivity analysis: alternative durations of effect

Duration of effect	Cost difference (£)	QALY difference	ICER (£/QALY)	Probability cost-effective at £20,000/QALY (%)	Probability cost-effective at £30,000/QALY (%)

Analysis	Cost difference (£)	Mean QALYs		QALY difference	ICER (£/QALY)
		SM + UC	UC		
Base case	683	5.850	5.767	0.083	8218
Values obtained in Borg *et al.*[83]	680	6.126	6.044	0.082	8304

Subgroup analysis

GOLD severity stage

Table 33 presents the ICERs when assuming that only one GOLD stage severity group entered the model. The mean difference (MD) in QALYs gained between SM and UC increased in more severe groups. The lowest ICER is £3323 per QALY gained in GOLD stage 4, with a 73% likelihood that SM is cost-effective at £20,000 per QALY. There is greater uncertainty around the cost-effectiveness of SM in patients entering the model at GOLD stage 2 or 3, with the probability of being cost-effective at £20,000 per QALY 64% or 62%, respectively.

TABLE 33 Subgroup analysis: alternative GOLD stage cohorts

Cohort enter at:	Mean cost (£)		Cost difference (£)	Mean QALYs		QALY difference	ICER (£/QALY)	% cost-effectiveness at:	
	SM	UC		SM	UC			£20,000/QALY	£30,000/QALY
GOLD 2	15,835	15,245	591	7.437	7.367	0.069	8511	64	68
GOLD 3	21,078	19,989	1089	5.783	5.697	0.086	12,629	62	68
GOLD 4	22,120	21,803	317	4.078	3.983	0.0955	3323	73	75

Age

The starting age of the model cohort was varied and results are presented in *Table 34*. The probability of SM being cost-effective does not change by age but the ICERs are lower in the older cohort. Therefore, although the ICERs are different for different start ages, the decision rules are similar at all start ages and the probability of being cost-effective is similar.

Gender

The results for separate male and female cohorts are shown in *Table 35*. There was very little difference in the ICERs or probability of SM being cost-effective when targeted at solely men or women.

Smoking status

Table 36 presents the results for current smokers and ex-/non-smokers. Again, there was very little difference in the ICERs or probability of SM being cost-effective when targeted at only smokers or ex-smokers.

Scenario analysis

Table 37 presents the results of the scenario analysis. The first scenario applied the highest effect on reducing admissions (HR 0.78) and the highest cost estimate of SM (£671). The second scenario applied the lowest effect (HR 0.96) and the lowest estimate of the cost of SM (£85). This suggests that the likelihood of SM being cost-effective is greater in the higher cost, higher-effect scenario, relative to the lower-cost, lowest-effect scenario, but still < £20,000 per QALY.

Discussion

Key results

This is the first economic model to consider the cost-effectiveness of SM support compared with UC in patients with COPD within 6 weeks of discharge from hospital admission for an exacerbation. Owing to the considerable uncertainty on the impact on readmissions, and the heterogeneity of the trial results, this model-based analysis should be viewed as speculative, and therefore providing only estimates of the potential impact of a SM programme.

The base-case model results suggested that SM support was a cost-effective intervention at the threshold at which NICE is willing to pay at £20,000 per QALY gained, if the assumption that the provision of SM support leads to a reduction in hospital admissions is met. The impact of reduced readmissions in the model led to lower mortality and morbidity from severe exacerbations over the long term. There were fewer costly hospital admissions, and intervention costs were relatively low compared with the cost of a readmission.

The probabilistic sensitivity analysis, which considers parameter uncertainty in the model, suggested that SM had a probability of 68% of being cost-effective at a threshold of £20,000/QALY, demonstrating the uncertainty around the impact of SM on readmissions. The remaining probability, when SM was not cost-effective, was due to the intervention potentially having worse outcomes while being more costly. Furthermore, the one-way sensitivity analyses undertaken were informative in highlighting the key drivers of the model results. As expected, cost-effectiveness was affected by the estimate of effect on readmissions, duration of effect and cost of a SM programme. The base case considered the intervention to have an impact for 2 years; however, the data from trials were collected only over the short term, for example 6 months. The results demonstrated that if the effect lasts for only 6 months then at a threshold of £20,000 per QALY gained the SM support was unlikely to be cost-effective. Currently, the model suggests that as long as the cost of the intervention is < £2200 then it is likely to be cost-effective; however, this threshold value will drop if the intervention is less effective.

Subgroup analysis, changing by considering different cohorts with regards to gender, age or smoking status, *found no evidence of effect on the overall result*. There was some evidence that SM might be more cost-effective in GOLD stage 4 patients. This is most likely to be due to a higher baseline risk of exacerbation and a higher proportion of exacerbations resulting in hospital admission. Therefore, a risk reduction is likely to have a greater effect.

Strengths and limitations

A key strength of this analysis is that this is the first economic model to consider the cost-effectiveness of SM in this particular patient group and illustrates the key variables that impact on the results. Although no good-quality, long-term data currently exist on the effectiveness of SM, a model structure exists for reanalysis once additional data become available.

The model structure applied was a further strength of this study. It is a modified version of previously published decision models whereby additional post-admission health states were added to incorporate emerging evidence on the higher risks in patients with COPD immediately after discharge.[13] This was thought to be particularly important for measuring costs and outcomes in this model, as the patient population were assumed to receive the intervention within 6 weeks of discharge.

Although there are concerns about the effectiveness estimates, robust data were included in the model to represent the natural history of the condition. The risks applied in the first 3 months were obtained from the UK cohort included in the European Audit[84] of patients with COPD admitted to hospital. The model also captures long-term outcomes by disease severity, applying data on long-term exacerbation risks, mortality and disease progression from large longitudinal studies – TORCH[85] and ECLIPSE.[13] This study also applies patient-level utility data obtained from a representative sample of UK patients (unpublished data obtained from BLISS cohort). Finally, although there was a great deal of uncertainty around effectiveness data and assumptions applied to this model, distributions were applied to reflect this uncertainty. The probabilistic sensitivity analysis was also supplemented by a one-way sensitivity analysis of all key parameters, thus demonstrating which parameters were mostly likely to influence decisions to implement SM.

There are a number of caveats when considering the results of this economic model. Most importantly, this is a speculative decision model and therefore can be considered as indicative of only the potential cost-effectiveness of SM. As highlighted in the clinical effectiveness and cost-effectiveness review, there is a dearth of high-quality evidence on the long-term costs and outcomes associated with this intervention. This model was based on this weak evidence of effect and thus incorporates considerable uncertainty when assumptions from the literature and estimates from clinical experts were applied in the absence of better-quality data.

In addition to the uncertainty around the effect of SM, there was also some uncertainty around parameters and assumptions applied in the base case for UC. Although the model was able to reflect mortality and readmission risks in the first 3 months after discharge, it was assumed that after those 3 months, those who were not readmitted would move to a stable health state. It is unclear if this really reflects natural history or if the risk of readmissions and mortality remain higher beyond 3 months among those with recent history of exacerbation. Similarly, the data extracted from the TORCH[85] and ECLIPSE[13] studies represent average exacerbation and hospitalisation rates in stable COPD cohorts over a 3-year period and these data were applied over a 30-year time horizon. In reality this may change over time.

The model highlights a number of areas in which further research is required. Crucially, further evidence is needed on the effectiveness of SM support to confirm if it is indeed cost-effective and with greater certainty. Longer-term evidence beyond 6 months is also required. Follow-up data on cohorts of patients admitted to hospital is needed to provide better estimates of long-term outcomes. A review of costs applied of other SM programmes in patients with COPD suggests that the cost of implementing SM support are likely to range somewhere between £85[68] and £671.[63] Although more research is required to develop more accurate cost estimates for implementing SM programmes in this cohort, this is unlikely to change the outcome of this analysis. Finally, better data are required on utility values in COPD populations, particularly the utility loss associated with exacerbation.

Although outside the scope of this report – in light of the uncertainty around the effectiveness and cost-effectiveness of the intervention – it would be beneficial for a value of information analysis to be undertaken in the future. Value of information analysis allows a comparison of the potential benefits of additional research with the costs of further investigation. The value of any further research is based on how much this extra information will reduce the overall decision uncertainty.

Summary

- Currently, there is no published evidence on the cost-effectiveness of SM compared with UC in patients with COPD who have recently been discharged from hospital.
- This is the first economic model to attempt to estimate the cost-effectiveness of SM in this patient group.
- This speculative model indicates that SM is cost-effective if it is assumed that the intervention has a small positive effect on reducing admissions for a minimum of 6 months.
- The model has a number of limitations, the most important related to the large amount of uncertainty around the effectiveness estimate driving the model results.
- The analysis highlights the importance of conducting further research on the effect and duration of effect of the SM intervention delivered post discharge to allow a more robust analysis of cost-effectiveness.

Chapter 7 A systematic review to identify the features and elements of self-management support interventions that are most effective: review 4

The aim of this chapter is to present the findings from a broad systematic review to assess the effectiveness, and identify the most effective components, of self-management (SM) interventions.

Methods

A systematic review of the evidence of effectiveness of interventions to support SM among patients with chronic obstructive pulmonary disease (COPD), at any time point, to identify the features and elements that are most effective.

Definition of self-management

As described for review 1 and tabulated in *Table 2*.

Search strategy

A comprehensive search strategy described as for review 1. Only citation lists of relevant reviews were examined for additional relevant studies.

Study selection process

As described for review 1.

Selection criteria

In contrast with the first review, owing to the likely high volume of relevant studies, the selection criteria included only RCTs and a more limited range of outcomes (*Table 38*). Although RCTs purely of smoking cessation were excluded, trials described as 'pulmonary rehabilitation (PR)' were included, as many PR trials include components of SM and aim to enable participants to self-manage their condition after the PR programme ends. Furthermore, many interventions describe supported SM with a supervised structured exercise programme, which is similar to PR. There is a large overlap of intervention content even with different definitions and we wanted to include as complete a range of evidence as possible.

Risk of bias assessment

As for review 1, all of the RCTs were assessed using the Cochrane Risk of Bias tool.[56] Assessment was limited to primary outcomes. All studies were assessed by one independent reviewer, with a second reviewer independently checking at least 10% of studies, and a third reviewer overseeing the complete process.

Data extraction

Approach

Data extraction of study characteristics was undertaken by a single reviewer, except for key fields such as sample size, duration of intervention and duration of follow-up, which were extracted in duplicate on to a piloted table of characteristics. The components of interventions were mapped by a single reviewer after the research team had each mapped 30 studies and discussed discrepancies and component definitions/criteria. For the results, data were extracted only from papers that reported any of the three primary outcomes (QoL, hospital admissions/readmissions or exacerbations). The reporting in papers of secondary outcomes (mortality, anxiety, depression, exercise capacity, lung function, health-care utilisation, ED visits

TABLE 38 Selection criteria for review 4

Study designs	RCTs
Population	Any patients with moderate to severe COPD (defined clinically with or without spirometry) including those in the stable state (patients with mild or very severe COPD were included if they were a minority of the population group)
	> 90% of patients in studies had COPD
	The setting could be either hospital or community
Intervention	SM packages, larger packages of care that included a significant component of SM (e.g. PR) or important components of SM
	Excluding trials of smoking cessation
Comparator (where appropriate)	No intervention, usual care, control/sham, other SM intervention
Primary outcomes	Exacerbations
	Hospital admissions/readmissions
	HRQoL
Secondary outcomes	Mortality
	Anxiety, depression
	Exercise capacity
	Lung function
	Health service utilisation
	ED visits
	Dyspnoea

and breathlessness) was documented but the results were not extracted. Owing to high volume, one reviewer extracted all of the data on to piloted tables using Microsoft Excel version 2010 (Microsoft Corporation, Redmond, WA, USA), with at least 10% of the extracted data being checked by a statistician. If necessary any differences were resolved via discussion with a third reviewer. When relevant data were lacking or unclear, authors were contacted via e-mail.

Types of data extracted
As described for review 1.

Data manipulation
As described for review 1.

Analyses
Owing to a large volume of literature, only those papers that reported any one of the three primary outcomes were taken forward for further analyses:

(a) HRQoL scores including subdomain scores
(b) numbers of/time to first hospital admissions/readmissions
(c) numbers of/time to first exacerbation/s.

Papers with secondary, but no primary, outcomes were tabulated only.

Analyses consisted of mapping and description of the features and elements of the interventions from the included papers; presentation of the results of various combinations and comparisons of components on forest plots; meta-analysis of the data where appropriate; meta-regression; and subgroup analysis to explore heterogeneity.

Description of the features and elements of self-management interventions by simple categorisation and tabulation

To describe the features and elements of SM interventions, a mapping process was undertaken whereby interventions were broken down into a visual representation of components (defined in *Table 39*). Components included disease knowledge/education, exercise, breathing techniques, smoking cessation

TABLE 39 Definitions of components of SM

Component		Broad inclusion/definition
Disease knowledge		Education about disease, disease management, treatments, SM, chronic illness, activities of daily life, end of life, self-care tips, travel and COPD
SM unspecified		SM education/skills
RMT		IMT, EMT (pressure, threshold, resistance devices)
Action planning		Managing exacerbations, coping plan, management of COPD symptoms, recognising when to call a doctor
Breathing management and techniques		Breathing exercises, breathing retraining, respiratory biofeedback, managing breathlessness and coping with triggers for breathlessness, t'ai chi, vocal exercises
Smoking cessation		Advice, counselling, groups, interventions to help reduce/quit smoking as required
Medication/ adherence		Information about medication and adherence, promoting adherence (pharmacological or non-pharmacological)
Bronchial hygiene techniques		Postural drainage/coughing technique
Nutrition		Advice, counselling, groups, supplements as required
Psychological intervention		Psychosocial support, cognitive–behavioural therapy, cognitive training, relaxation (including exercises, e.g. progressive muscle relaxation), stress management, general goal-setting, mood disturbance, handling emotions (how to cope with the disease), psychosocial problems associated with respiratory disability, self-talk and panic control, health, qigong
Preventative		Avoiding exacerbations, pollution and environmental hazards, managing infections, personal hygiene
Inhaler technique and use		Assessing inhaler technique, teaching correct use and handling of inhalers
Energy conservation		Pacing and good posture, home modifications and ADL, work simplification
Support groups/ patient empowerment		Peer support self-help groups/networks, e.g. Breathe Easy, developing confidence to negotiate with clinicians
Exercise	Strength	Upper limb, lower limb strength/resistance exercises
	Aerobic	Cycling, walking, stair climbing as aerobic/endurance exercises
	Other	Flexibility and balance exercises, sham training, unspecified exercises
Enhanced access/ care		Access to health professionals, access to call centre/hotline, health professional home visits and/or telephone support
Other		Any miscellaneous uncommon components, e.g. sleep or other symptom control
Usual care		Usual medications and visits to GP or routine secondary care

ADL, activities of daily living; EMT, expiratory muscle training; IMT, inspiratory muscle training; RMT, respiratory muscle training.

and inhaler technique among others. Each component was subdivided into either an information element only or a support/training element. All treatment arms of the trials were mapped in this way. The numbers of components within intervention and control arms were identified.

Exploring significant components of self-management interventions in reducing exacerbations, hospital admissions/readmissions and improving quality of life

Planned analyses and comparisons

To explore the effectiveness of different SM components (or groups of components), a series of 18 analyses were planned (*Table 40*) in collaboration with the steering group to ensure clinical relevance. The analysis plan was developed prior to collation of any of the data and followed two main objectives:

To:

i. explore clinically relevant interventions
ii. avoid repeating any recent high-quality systematic review, such as a Cochrane review.

TABLE 40 Analyses planned to explore the effectiveness of SM components and interventions

Intervention	Comparator
1. Multicomponent interventions	UC/control
2. Addition of one component	
3. Exercise-only interventions	UC/control/sham intervention
4. Enhanced care	
5. Multicomponent interventions with supervised exercise	UC/control
6. Multicomponent interventions with structured unsupervised exercise	UC/control
7. Multicomponent interventions with exercise counselling only	UC/control
8. Multicomponent interventions without an exercise element	UC/control
9. Multicomponent interventions including an exercise component consisting of aerobic and strength training	UC/control
10. Strength and aerobic exercise training	Aerobic training only
11. Endurance/aerobic training	Strength/resistance training
12. Upper limb and lower limb training	Lower limb training only
13. Interval training	Continuous training
14. IMT or EMT	UC/control/sham intervention
15. More sessions/longer-duration interventions	Fewer sessions/shorter duration interventions
16. Hospital-based interventions	Home-based interventions
17. Pharmacist-delivered interventions	
18. Maintenance programme post PR	No maintenance programme post PR

EMT, expiratory muscle training; IMT, inspiratory muscle training; UC, usual care.

We explored the effectiveness of any single component interventions that were delivered either alone or as part of a wider package for which the only difference between the two arms was this single component. A multicomponent SM package was included in many analyses and we defined multicomponent as including three or more relevant components. The definition of three components was used because most exercise programmes would require some discussion of managing breathlessness. From a clinical perspective it seemed likely that some interventions would describe both components and others only the exercise component.

To avoid repeating current systematic reviews, we chose not to explore the effectiveness of integrated care but instead explored the effects of 'enhanced care'. We defined 'enhanced care' to be interventions that gave patients access to additional contact with health-care professionals through regular telephone contact or visits. This is distinct from integrated care, which required delivery by a multidisciplinary team.

The effectiveness of exercise-only interventions was explored by examining different combinations of exercise (e.g. strength, aerobic, and combined strength and aerobic exercises). The inclusion of these different modes of exercise is important for professionals developing and delivering SM and rehabilitation programmes for COPD. Exercise as part of multicomponent packages was categorised into groups of supervised exercise (which mirrors PR), unsupervised exercised (mirroring home-based rehabilitation programmes) and exercise education only.

As well as the components, we were also interested in delivery mechanisms. These were discussed and agreed by the steering group before any analyses were undertaken. We considered that the location of the intervention was an important delivery issue, for example hospital or centre-based compared with a home-based programme and the duration or intensity of programmes to be important delivery issues also. To explore these questions we sought trials that had direct comparisons.

Post hoc analyses were decided upon after mapping the content of the SM intervention components. Post hoc analyses included an exploration of the effectiveness of interventions delivered by pharmacists and the effectiveness of maintenance programmes post PR.

Presentation on forest plots

For each analysis, the first stage involved presenting extracted study results on forest plots alongside key study characteristics so that the wider team could determine whether it was sensible to perform meta-analysis. For each intervention, the effectiveness across each outcome was presented. Data were presented in forest plots when there were ≥ 10 studies. As there were multiple follow-up points, results were divided into three time periods: up to and including 3 months; above 3 months to 6 months; and beyond 6 months since the start of the study. If a study had more than one follow-up point within each time period, the latest follow-up within the period was used.

All forest plots were then ordered according to the number of components in the intervention arm, followed by the length of follow-up and then alphabetically by author name.

Owing to a large volume of different QoL measures used, only data from the disease-specific total SGRQ and CRQ were included in the forest plots. In this review, SGRQ is presented on a reversed scale (i.e. higher scores are better).

For QoL data, the numbers of patients followed up were displayed, as well as baseline differences between intervention and control arms, and whether or not ANCOVA was used to adjust for the baseline value. For plots of HRs, details were also displayed of whether or not the effect size was used directly from data within the trials or whether or not they were estimated using other available data.

Meta-analysis methods

As described for review 1, but in addition to the summary estimate and its 95% confidence interval (CI), each random-effects analysis was also summarised by reporting a 95% prediction interval. This predicts how the effectiveness of the intervention could vary from the average in different circumstances, for example for different contexts, populations and lengths of follow-up.[62,105] This is important to ascertain whether the intervention is likely to work in the majority of settings, or whether – due to unexplained heterogeneity – the intervention may work well in some settings but work less well (or not at all) in other settings. Prediction intervals were calculated where there were five or more studies per analysis and were tabulated separately from the forest plots.

Assessing publication bias

For each meta-analysis containing ≥ 10 studies, the likelihood of publication bias was investigated through the construction of funnel plots and Egger's test for 'small-study effects', i.e. the tendency for smaller studies to provide more positive findings. It is important to note that when heterogeneity exists, publication bias may be one of a number of reasons for any small-study effects identified. The restriction of 10 studies was due to the low power of identifying small-study effects with few studies.[106]

Meta-regression and subgroup or sensitivity analyses

For each meta-analysis, if there were sufficient numbers of studies (at least 10 per meta-analysis), meta-regression was considered to explore whether the following prespecified variables explained any of the heterogeneity: severity of disease in the study population, length of intervention, number of components of intervention and study quality.

Mixed-treatment comparisons

Although mixed-treatment comparison meta-analyses were planned, the assumptions to undertake the analysis were not considered to have been met. In particular, the large heterogeneity in follow-up time, the included patient population and the study design suggested that the consistency assumption required was unlikely to be sensible.[107] Therefore, no mixed-treatment comparisons were explored.

Patient advisory group

See review 1 for details.

Search results

Included studies

From 13,355 identified titles, 836 full papers were obtained and 283 papers were finally included. Of these, 174 RCTs from 194 papers reported one of the three primary outcomes: HRQoL, hospital admissions/readmissions and exacerbations (*Figure 21*). A total of 89 papers reported outcomes other than our three primary outcomes and are listed in *Appendix 21* alongside the secondary outcomes that they reported. Overall, 553 papers were excluded (see *Appendix 2* for full list with reasons for exclusion). Arbitration by a third reviewer was required for 5% of all full texts. In total, 40 ongoing studies were identified as relevant (see *Appendix 4*).

Within the 174 trials with primary outcomes several studies had multiple arms. Thus there were 229 comparisons of interventions compared with usual care (UC), control or another active intervention.

Characteristics of studies

The study and population characteristics of the 174 included RCTs with relevant primary outcomes are summarised in *Appendix 22*.

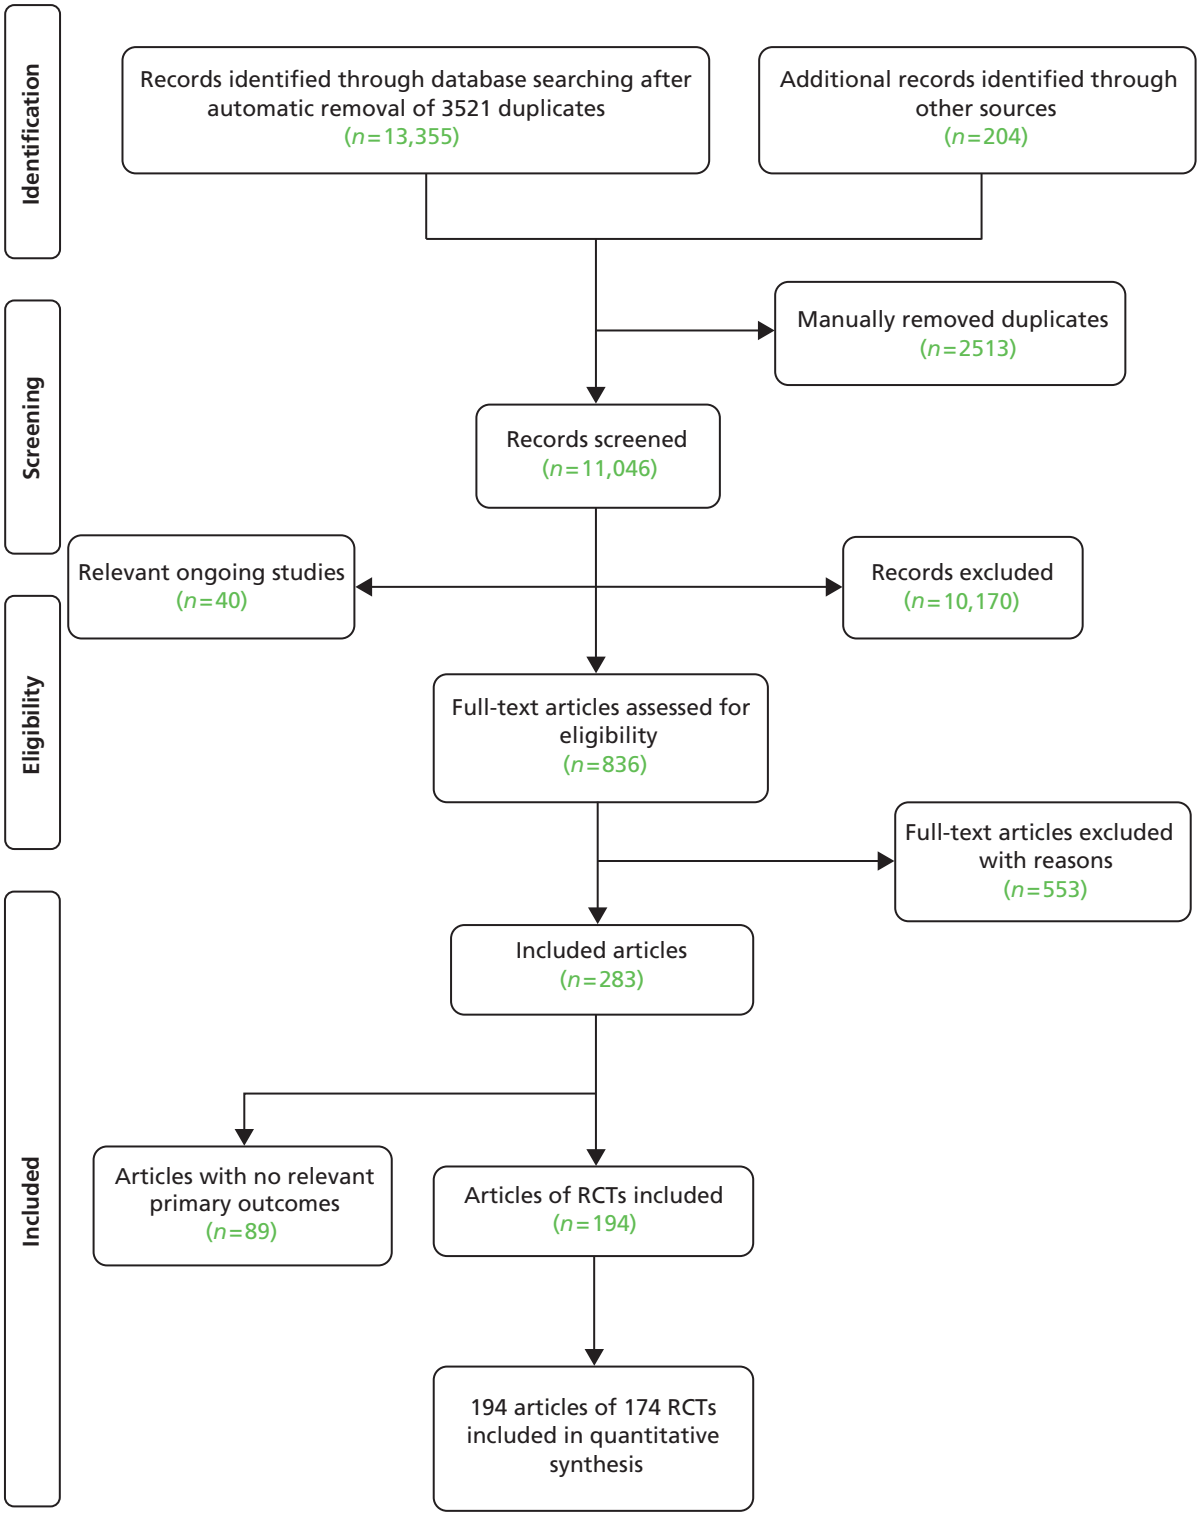

FIGURE 21 Summary of the selection process for clinical effectiveness studies.

Country/setting/recruitment

The majority of the trials were set in high-income countries, with 33 (19%) from the USA and 21 (12.1%) from the UK. However, trials were set in 31 different countries, including eight from China, six from Hong Kong, three from India and two from the Republic of Korea. A breakdown is given in *Table 41*.

TABLE 41 Setting of SM trials

Country	*n*	%
USA[108–140]	33	19.0
UK[63,73,141–159]	21	12.1

Republic of Korea[268]	1	0.6
Spain and Belgium[70]	1	0.6
Venezuela[269]	1	0.6

Note
'*n*' refers to number of trials.

Size

The sample size of the 174 included trials ranged from 10 to 743 [median 53, interquartile range (IQR) 38–100]. Trials were generally small with 81 (46.6%) trials including < 50 participants, 47 (27.0%) with 50–99 participants, 34 (19.5%) with 100–199 participants, and 12 (6.9%) with ≥ 200 participants (*Table 42*).

Population characteristics

Table 43 summarises the characteristics of the populations in the trials. The characteristics reported were frequently of those who completed the trial rather than those who were randomised.

The mean age of the participants was between 52 and 80 years, with the majority of trials (72%) reporting a mean age of between 60 and 69 years. The proportion of male participants ranged from 15% to 100%. In the trials that provided data on the gender of the participants, males tended to be in the majority. Thirty-four trials[66,67,69,70,74,111,112,118,127,133,136,142,144,151–153,168,185,192,195,199,201–205,209,210,212,214,218,238,264,270–272] did not report the FEV_1% pred but reported the proportions within severity groups. Of the trials that did provide these data, the mean FEV_1% pred of the trial participants ranged from 26.3% to 69.0%. More than half of trials had a population mean in the 30–59% range, which is equivalent to GOLD stage 3 – severe COPD.

Recruitment of participants was mainly from secondary care or PR programmes.

Follow-up of trial participants

Length of follow-up ranged from 4 weeks to 2 years from the start of the intervention. In 78 (44.8%), follow-up was ≤ 3 months, in 120 (69.0%) it was ≤ 6 months and in 174 (94.3%) it was ≤ 1 year. Twelve trials[65,116,155,166,172,182,190,248,271,273–277] had follow-up of > 1 year (*Table 44*).

Time from the end of intervention (delivery of last element of SM support) to last follow-up varied considerably (see *Table 44*). A total of 106 (60.9%) of the trials reported follow-up data only at the end of the intervention period (details provided within appendices). Only 18 trials[111,121,141,161,166,170,172,192,195,198,210,213,217,229,250,251,270,271,276–279] (10.9%) reported a follow-up of > 6 months after the end of the intervention.

Interventions

The interventions were very heterogeneous. They included structured group-based PR programmes; more limited one-to-one educational SM interventions delivered in an outpatient setting or at a patient's home, sometimes with telephone follow-up; integrated disease management with multidisciplinary input and often some element of monitoring by health professionals; exercise-only interventions (with some dyspnoea management) and respiratory muscle training (RMT) using threshold devices. Within these various broad categories, there was a range of individual SM components, including some that might be less traditionally part of SM, such as qigong, t'ai chi and singing. *Appendix 23* provides detailed descriptions of the intervention and comparator groups with intensity and frequency of interventions delivered.

Description of self-management components in intervention and comparator arms

Within the arms of the 174 trials we categorised 15 types of components (plus other and unspecified). In the intervention groups exercise was the most commonly reported component (76.9%), followed by breathing techniques and management of dyspnoea (64.2%), and general education about COPD and its management (47.2%). Details of the numbers of individual components for the intervention and comparator groups are shown in *Table 45*. *Appendix 24* displays which components were present within the intervention and comparator groups of each study.

Action planning for self-treating exacerbations	43 (18.8)	9 (3.9)
Smoking cessation advice/support	44 (19.2)	18 (7.9)
Inhaler technique	36 (15.7)	19 (8.3)
Bronchial hygiene/secretion clearance techniques	30 (13.1)	16 (7.0)
Unspecified	24 (10.5)	9 (3.9)
RMT	32 (14.0)	11 (4.8)
Energy conservation	22 (9.6)	7 (3.1)
Other	18 (7.9)	5 (2.2)
Preventative measures to avoid infection	18 (7.9)	11 (4.8)
COPD support groups	7 (3.1)	3 (1.3)

Up to 13 different SM components were included in any one of the intervention arms, and up to 11 in any one of the comparator groups (*Table 46*). Seventy-three (31.9%) of the intervention arm interventions had six or more components. In the intervention group, 38 (16.6%) were single components with the vast majority of these being exercise-only interventions. In contrast, the majority of the comparators had two or fewer described components [167 (72.9%)], with 34.9% not providing any detail about the SM education or support provided to the comparator group as part of UC (see *Table 46*).

The content of the components of the intervention are shown according to the total number of components in the intervention in *Table 47*. Of the single-component interventions, 25 of 38 (65.8%) were exercise only, 9 of 38 (23.7%) were RMT and three (7.9%) were breathing exercises. In the two- and three-component interventions, exercise is frequently combined with breathing/dyspnoea management and disease knowledge. Overall, the most common components were exercise [176 (76.9%) of studies], breathing techniques and dyspnoea management [147 (64.2%)], disease knowledge [108 (47.2%)] and psychological interventions [77 (33.6%)].

In those interventions with six or more components, the most common components were exercise [69 (94.5%) of studies], breathing techniques and dyspnoea management [66 (90.4%)], disease knowledge [65 (89.0%)] and medication advice [60 (82.5%)]. Notably, smoking cessation was mentioned in only 38 (52.1%) of the interventions with six or more components.

Figure 22 displays the range of different interventions included.

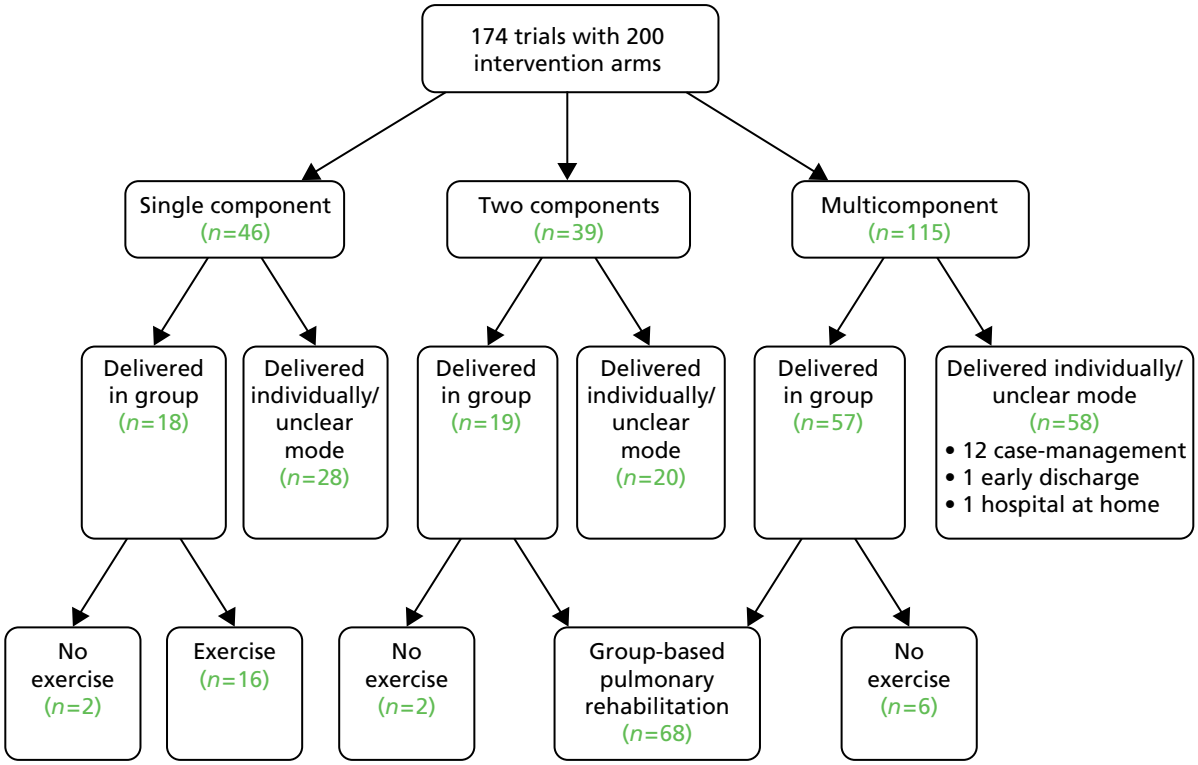

FIGURE 22 Range of interventions included across 174 trials.

Duration of the intervention

The duration of the intervention was measured to the last behavioural or supportive contact and ranged from 1 day to 2 years (*Table 48*). A total of 114 trials (58.8%) reported interventions of ≤ 3 months' duration, with nine trials (4.6%) being longer than 1 year. Five trials[71,72,117,142,215,255,280,281] did not report an intervention duration or had a variable duration intervention (*see Appendix 23*).

TABLE 48 Duration of intervention

Intervention duration (weeks)	No. of studies	%
< 1	2	1.1
4	19	10.9
5–8	59	33.9
9–13	34	19.5
14–26	29	16.7
27–52	22	12.6
53–104	4	2.3
NR/variable duration	5	2.9

NR, not reported.

Mode of delivery of the intervention

The majority of the interventions were delivered by nurses and respiratory physiotherapists. Half of the interventions had a group-based component; 63 (36.2%) were entirely group based; and an additional 24 (13.8%) had a group component followed by individual support. In 20 studies the mode of delivery was unclear. Details of the mode of delivery are in *Table 49* and in the detailed characteristics of intervention table in *Appendix 23*.

Comparator arms

There were 141 comparisons (from 127 trials) of an intervention compared with UC or a control group that was not an active intervention. The UC arm was frequently not described; in other cases it was the standard primary and/or secondary care for people with COPD.

A total of 107 comparisons (from 85 trials) were of two active interventions. Details are provided in *Appendix 23*.

Primary outcome measures

Most trials (163, 96.6%) reported HRQoL; 42 (24.1%) reported hospital admissions or readmissions and only 20 (11.5%) reported exacerbations.

Other outcome measures reported

The included studies reported a wide range of outcomes; 12 reported mortality, 103 dyspnoea, 34 anxiety and 41 depression outcomes. Exercise capacity was reported in 135 studies and lung function in 92 studies. Health service utilisation was reported in 41 trials and ED visits in 29 trials. The details of which trial reported which outcomes are displayed in *Appendix 25*.

Risk of bias of included studies

Table 50 summarises the risk of bias. Details of the risk of bias assessment for all of the included studies are tabulated in *Appendix 26*.

Reporting of the method of generating the randomisation sequence was generally poor, with only 71 (36%) of the trials providing adequate information. Where reported, the randomisation method was adequate to produce a low risk of bias. Similarly, the majority of studies [146 (84%)] did not provide sufficient information about allocation concealment to be able to determine the risk of bias. We considered the risk of bias for self-reported HRQoL to be high unless the participant was blinded to the intervention, either by randomisation to an active intervention in each study arm, or through a sham intervention. This resulted in a high rate of categorisation of high risk of bias for this outcome measure [117 (63%)].

TABLE 49 Mode of delivery of SM interventions

Mode of delivery	*n* (studies)	%
Group based	63	36.2
Individual	63	36.2
Mixed: group and one to one	24	13.8
Remote (internet/telemonitoring)	4	2.3
Unclear	20	11.5
Total	174	100.0

TABLE 50 Summary of risk of bias

Risk of bias	Low, *n* (%)	High, *n* (%)	Unclear, *n* (%)	Total
Sequence generation	66 (37.9)	0 (0)	108 (62.1)	174
Allocation concealment	27 (15.5)	1 (0.6)	146 (83.9)	174
Blinding of HRQoL outcome	34 (19.5)	117 (62.7)	23 (13.2)	174
Blinding of admission outcome	44	0	1	45
Incomplete outcome data	46 (26.4)	83 (47.7)	45 (25.8)	174
Selective outcome reporting	55 (31.6)	2 (1.1)	117 (67.2)	174
Other biases	44 (25.3)	86 (49.4)	44 (25.3)	174

Note
'*n*' refers to number of studies.

We also assumed that reporting of hospital admission would be unlikely to be influenced by knowledge of allocation; thus, the majority of trials reporting this outcome were categorised as at low risk of bias for this outcome. Loss to follow-up was frequently high, and authors often failed to adequately account for those with missing outcome data or did not describe their characteristics. Relatively few trials reported that they had published a protocol or were registered on a clinical trials database, so only 63 (30%) were categorised as at low risk of bias of selective outcome reporting; however, in most cases all the outcome measures described in the methods were reported in the results section.

A significant other potential cause of bias was due to authors reporting in the abstract the numbers completing the trial rather than randomised and the characteristics of only those who completed the trial. Furthermore, baseline imbalances (e.g. caused by small sample sizes) were not routinely adjusted for in statistical analyses, and thus differences at follow-up (e.g. in QoL) might (partly) be due to baseline differences.

Effectiveness results

Appendix 25 gives an overall summary of direction of effects for each trial for reference purposes.

The following sections refer to the results of specific analyses described previously in *Table 40*.

All trials

Figures 23–26 plot the outcomes at all reported time points for all trials for HRQoL measured by the SGRQ and the CRQ, hospital admission and exacerbations. These results have not been combined by meta-analysis due to the heterogeneity of the interventions and comparators.

The trials were ordered by the number of components, and upon visual inspection there does not appear to be any relationship between the size of the effect and the number of components. For HRQoL, many trials reported a large difference between the intervention and comparator group at baseline and, when present, this was rarely adjusted for in the analysis using ANCOVA.

At the last follow-up point, 11 of 56 (19.6%) resulted in a statistically significant reduction in hospital admissions and 4 of 28 (14.3%) a statistically significant reduction in exacerbations. A total of 22 of 87 (25.3%) comparisons showed a statistically significant improvement in total SGRQ score, 16 of 41 (39.0%) in total CRQ, 10 of 24 (41.7%) on the physical components of the Short Form questionnaire-36 items (SF-36) but only 2 of 21 (9.5%) on the mental component of the SF-36. For individual components, the CRQ 'dyspnoea' and 'mastery components had the highest proportions of reported significant improvements (26.4% and 25.8%, respectively).

Multicomponent interventions compared with usual care

Health-related quality of life

Multicomponent interventions were defined as those with three or more components. Forty-one trials reporting 44 interventions compared with UC reported usable total SGRQ or CRQ results; 31 trials reported hospital admissions, of which 18 could be used in meta-analysis; and 12 trials reported exacerbations of which three could be used in the meta-analysis (see *Appendix 25*).

The meta-analysis findings are reported for three time periods: up to and including 3 months, greater than 3 months but up to 6 months (hereafter described as 3–6 months) and greater than 6 months.

For SGRQ followed up to 3 months, most trials reported a greater improvement from baseline to follow-up in favour of the intervention group.[68,121,142,144,148,149,161,186,194,213,214,221,226,227,237–239,257] The summary meta-analysis result reveals that on average the multicomponent arm had a SGRQ score of 6.50 points (95% CI 3.62 to 9.39 points) higher than the UC arm. However, this is the average of a distribution of trial effects and this distribution is wide due to high heterogeneity ($I^2 = 82.4\%$). The prediction interval reports the range in which 95% of the distribution of the effects lies. The majority of the interval is > 0 and thus mainly in favour of multicomponent interventions; however, it does overlap zero (95% CI –4.66 to 17.67) indicating that the interventions are not always effective. At the longer follow-up point of 3–6 months, the estimate of the average effect was 4.47 points on the SGRQ (95% CI 1.93 to 7.02 points; $I^2 = 79.6\%$) and at > 6 months it was 2.40 points (95% CI 0.75 to 4.04 points; $I^2 = 57.9\%$), both favouring the intervention group. There is some suggestion that the size of the effect was smaller as follow-up was longer, but loss to follow-up was also a more significant problem at the longest follow-up point, which may have biased the effect estimate. The upper boundary of the prediction intervals also lowers with the longer follow-up time.

There were fewer trials reporting the CRQ. At all three time points the estimate of the average effect was in favour of the intervention group, suggesting that, on average, multicomponent SM interventions were more effective than UC at up to 6 months' follow-up. However, heterogeneity was high and the prediction intervals at all three time points included zero. The results for HRQoL are summarised in *Figures 27* and *28* and *Table 51*.

Hospital admissions

The results of 18 studies[63,65,67,68,70,71,73,120,140,142,148,160,168,212,213,227,266,270] of multicomponent interventions compared with UC which reported hospital admissions have been analysed; eight with follow-up at ≤ 3 months,[67,68,70,120,148,160,212,227] four with follow-up to 6 months;[70,73,160,266] and eight with follow-up at ≥ 1 year.[63,65,71,140,142,168,213,270] Although the summary HRs from meta-analysis favoured the intervention groups at all three follow-up periods, there was much uncertainty leading to only weak statistical evidence of an effect and heterogeneity was high at follow-up times of > 3 months. Details are given in *Figure 29* and *Table 52*.

Exacerbations

Exacerbations were reported in an analysable format by only four studies.[73,182,213,284] The multicomponent interventions had no evident effect – details in *Figure 30* and *Table 52*. At the last follow-up point, only 2 of 12 studies that reported exacerbations reported a statistically significant effect in favour of the multicomponent SM intervention.[140,172]

n/a, not applicable.

Summary: multicomponent interventions

Evidence of effectiveness of multicomponent interventions on HRQoL, but considerable uncertainty for hospital admissions and exacerbations.

Exploring specific individual components of self-management interventions

We aimed to explore the effectiveness of specific individual components of SM interventions by examining the trials for which there was a difference in one component between intervention and control arms.

Action plans

Four trials[170,188,229,231] reported the addition of an action plan to a SM package. There was no difference in the average effect on HRQoL of the arms including action plans compared with the comparator groups (SGRQ 0.43, 95% CI –1.69 to 2.54; $I^2 = 0\%$) (*Figure 31*).

McGeoch *et al.*[229] further undertook 1-year follow-up of people who were given an action plan and reported no effect on hospital admissions (HR 0.97, 95% CI 0.33 to 2.89) (*Figure 32*). At 6 months' follow-up, a large trial by Trappenburg *et al.*[188] found no additional effect of action plans on exacerbations (HR 1.12, 95% CI 0.77 to 1.62) (*Figure 33*).

Breathing techniques

Two trials[235,240] reported breathing training or techniques. On average, the breathing training groups had a SGRQ score that was 5.0 points (95% CI 4.06 to 5.94 points) higher than the comparison groups. Although the trials were of a small size, the heterogeneity was low ($I^2 = 0\%$). Van Gestal *et al.*[208] reported no difference in the CRQ at 4 weeks' follow-up (0.17, 95% CI –0.09 to 0.43 points) (*Figure 34*; see also *Figure 31*).

Distraction auditory therapy during exercise

Bauldoff *et al.*[108] reported no significant difference in SGRQ between the group with distraction auditory therapy and a group with an exercise intervention only (see *Figure 31*).

Exercise techniques/dyspnoea management

We did not include the exercise-only interventions in this analysis, as these have been separately analysed and are described in the next section. This analysis investigates the effect of adding exercise to other SM components.

Two trials[141,225] reported HRQoL using the SGRQ, with an average effect of 8.20 points (95% CI –2.28 to 18.67 points). The trial by Petersen *et al.*[225] was small ($n = 19$), with a difference at baseline not accounted for and short follow-up. Three trials[141,204,272] reported the CRQ with the exercise group achieving an average of 0.71 points (95% CI –0.30 to 1.73 points) more improvement than the comparison group (see *Figures 31* and *34*).

A small trial by Moore *et al.*,[271] which investigated exacerbations, reported no evidence of a reduction at 6 weeks' follow-up (see *Figure 33*).

Patient support groups

Brooks *et al.*[193] investigated the effect of the addition of a patient support group to a multicomponent SM package, but although only half of the participants completed the trial, no difference in HRQoL was found at 1-year follow-up (SGRQ 1.40, 95% CI –4.14 to 6.94) (see *Figure 31*).

Exercise-only interventions compared with usual care or a sham intervention

We further examined the effect of individual components by reviewing trials in which exercise was a single component. The exercise could be supervised or unsupervised, but there were no other SM components.

Eight trials[64,183,207,212,240,248,252,282] reported the effects of exercise-only interventions on HRQoL, with no other SM components in a way through which the data could be incorporated in the meta-analyses. The four trials[183,212,240,252] with five comparator groups, which reported SGRQ at up to 3 months, reported a significant benefit from the exercise-only intervention (4.87 points, 95% CI 3.96 to 5.79). The prediction interval (3.39–6.36) provides strong evidence that exercise-only interventions are effective in improving the SGRQ score at up to 13 weeks' follow-up. Only Gohl *et al.*[207] reported the SGRQ at 1-year follow-up with a large but non-significant effect in favour of exercise, although the sample size was very small with only 19 participants. Three trials[64,248,282] reported the CRQ outcome, although all had low rates of follow-up, so results must be interpreted with caution. At 3 months' follow-up there was a modest effect in favour of the exercise group but not statistically significant, and at 6 months there was a larger, non-significant effect, with a high level of heterogeneity. Details are shown in *Figures 35* and *36*, and *Table 53*.

Chan *et al.*[212] compared t'ai chi and exercise to UC in separate comparisons and reported no effects on hospital admission rates (*Figure 37*). Behnke *et al.*[64] undertook follow-up at the end of an 18-month exercise-only intervention and showed a significantly lower hospital admission rate in the intervention group (3/14) compared with 9 of 12 in the UC group (HR 0.17, 95% CI 0.05 to 0.64). In addition, Hernandez *et al.*[282] reported no statistical difference in admission rates between the exercise group and comparator at last follow-up. A small trial by Murphy *et al.*[252] reported exacerbations at 3 and 6 months, with a suggestion of lower rates, but participant numbers were very small (HR at 3 months 0.02, 95% CI 0.00 to 28.17; HR at 6 months 0.34, 95% CI 0.07 to 1.77) (*Figures 37* and *38*). Chan *et al.*[212] reported no difference on exacerbations between groups at 3 months' follow-up.

Summary: individual components

For individual components we are limited by insufficient evidence. There is no evidence of effectiveness of action plans, there was only one trial[193] of support groups showing no difference when added to a multicomponent package; breathing management and techniques may have a positive effect.

There is strong evidence that exercise-only interventions increase HRQoL in the short-term, but limited evidence on hospital admissions and exacerbations.

Enhanced care

We wanted to explore the general effects of providing support to patients over just giving simple information approaches, which we termed 'enhanced care'. It included regular telephone contact to reinforce information or behaviour change techniques, provided encouragement or included scheduled home visits for assessment with reinforcement or encouragement.

Fifteen studies[63–65,67,71,72,110,120,140,155,180,188–190,192,193,206,251,270,271,283] provided information in the form of the total SGRQ or CRQ and were included in the meta-analyses. Only three studies[67,120,193] reported the SGRQ at 3 months' follow-up with very heterogeneous results; estimate of average effect was 1.27 points (95% CI –4.28 to 6.82 points, $I^2 = 73.8$). At 3–6 months' and 12 months' follow-up the enhanced-care arm had a higher SGRQ score than the UC arm – details are given in *Figure 39* and *Table 54*. The estimates of the average CRQ at the three follow-up times all favoured the enhanced-care arm but were not statistically significant and heterogeneity was very high (*Figure 40*).

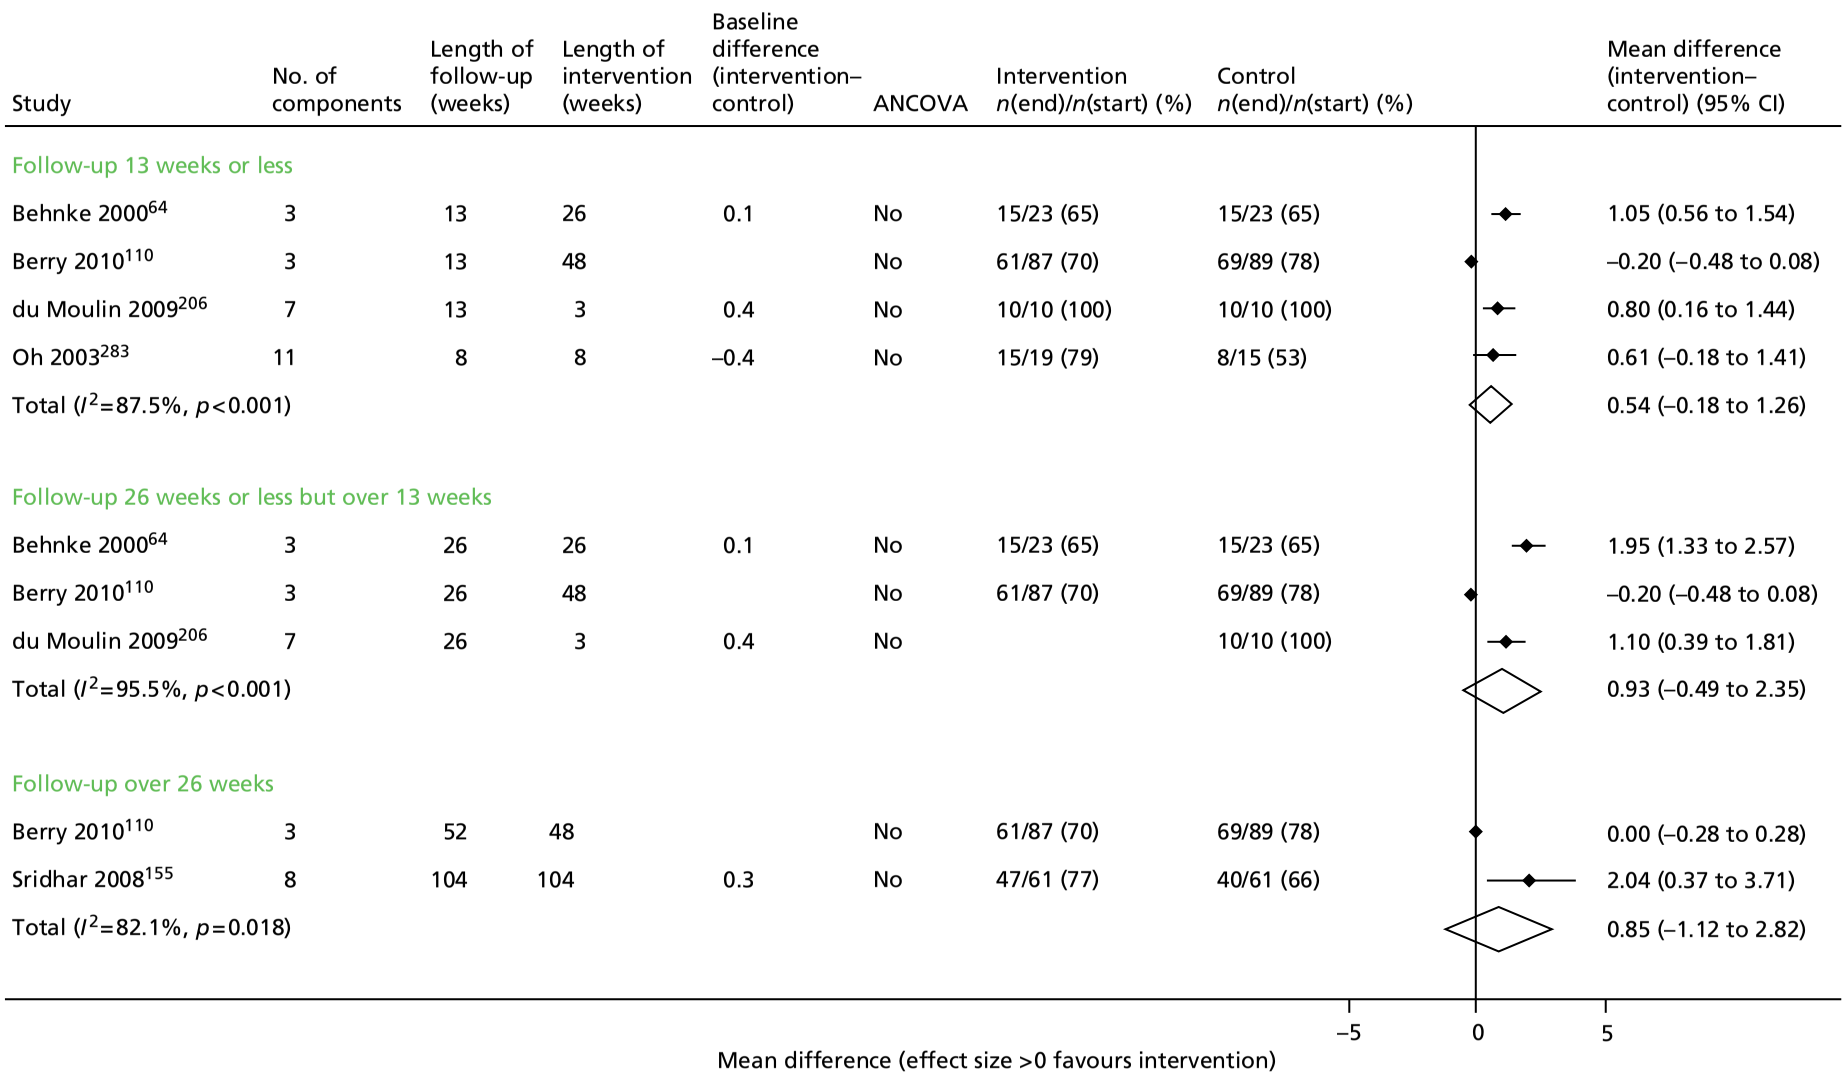

FIGURE 40 Health-related quality-of-life (CRQ) outcomes for enhanced care (±SM package) vs. UC/SM package.

On average, enhanced care had a similar risk of hospital admission at 3 and 6 months (*Figure 41* and *Table 54*), but a lower risk at 1 year or longer (HR 0.78, 95% CI 0.62 to 0.99). However, there was moderate heterogeneity at 1 year and the prediction interval showed that the intervention would frequently not be effective in lowering hospital admissions. Seven studies did not provide data that could be included in the meta-analyses,[69,74,136,140,180,188,251] of which three also reported a statistically significant reduction in hospital admissions at 1-year follow-up.[140,180,251]

Only three trials[155,188,206] were included in the meta-analyses for exacerbations with no evidence of any effect of enhanced care on risk of exacerbation (*Figure 42*). Four other trials[120,140,180,251] reported exacerbation rates at last follow-up, one[140] of which reported a statistically significant reduction.

Summary: enhanced care interventions

Positive effect on HRQoL, particularly at medium-/longer-term follow-up. There may be a reduction in hospital admissions with longer-term follow-up, but there is considerable heterogeneity. There is insufficient evidence to establish the effect on exacerbations.

The contribution of exercise to multicomponent self-management packages

The following analyses explore the contribution of exercise and its mode of delivery as a contributor to the heterogeneity. Multicomponent interventions:

- with a supervised exercise element compared with UC
- a structured, unsupervised exercise element compared with UC
- exercise counselling only compared with UC
- without an exercise element compared with UC.

Multicomponent interventions with a supervised exercise element compared with usual care

Trials were included in this category if the exercise component of a larger package of care was directly supervised. The majority were group, centre-based interventions (generally referred to as PR).

Health-related quality of life

Of the 47 trials that reported HRQoL, 26 trials (27 interventions) reported disease-specific HRQoL using the total SGRQ or CRQ (see *Appendices 13* and *27*). Findings are similar to those for multicomponent interventions overall, with the largest estimate of the average effect in SGRQ at up to 3 months' follow-up (7.75, 95% CI 3.49 to 12.01) points. There was no difference in average effect between the intervention and UC arms in SGRQ at follow-up of > 6 months. Heterogeneity was very high for most outcomes and follow-up times and loss to follow-up variable. Small but significant improvements in the CRQ were seen at 3 and 6 months' follow-up favouring the SM group. Details are given in *Figures 43* and *44* and *Table 55*.

Hospital admissions

We were able to combine the reports of hospital admission rates in six trials.[65,148,160,192,212,213,227] Although the trend was for the average effect on admission rates to be lower in the intervention arms, this was not a significant effect at any of the follow-up time points (*Figure 45*). Four other trials[172,182,212,213] reported hospital admissions at last follow-up; only one reported a statistically significant reduction in hospital admissions.[172]

Exacerbations

Three trials[182,206,213] reported exacerbation rates in such a way that a HR could be computed; heterogeneity was low or moderate but no evidence of effect was observed (*Figure 46* and *Table 55*). Two additional trials[172,212] reported exacerbations at last study follow-up, with Güell *et al.*[172] reporting a statistically significant reduction in favour of the intervention group.

Multicomponent interventions with a structured, unsupervised exercise element compared with usual care

Trials were included in this category if they provided detail about a structured home exercise programme including duration and proposed frequency of exercise within a larger package of care. These were home-based interventions.

Of the eight trials[186,251,255,262,264,270,283,284] that reported HRQoL, five used the total SGRQ[186,251,255,262,270] and one the CRQ.[283] On average, the multicomponent SM package with structured unsupervised exercise had a larger improvement in SGRQ at 3–6 months' follow-up than UC [3.59 points (95% CI 1.28 to 5.91 points; $I^2 = 0\%$)]. However, by 1-year follow-up there was no evidence of effect: SGRQ 0.80 points (95% CI –1.03 to 2.63 points; prediction interval –2.39 to 3.99). Only one trial[283] reported the CRQ at 8 weeks' follow-up (0.61, 95% CI –0.18 to 1.41 points) (*Figures 47* and *48*, and *Table 56*).

Exacerbations	≤ 3 months	1	3.01 (0.31 to 28.96)	n/a

n/a, not applicable.

Of the four trials[182,255,262,270] that reported hospital admissions at last follow-up, two[182,270] reported a statistically significant reduction in the intervention group. A HR could be calculated for only one trial,[270] which reported a significant reduction in hospital admissions (HR 0.55, 95% CI 0.35 to 0.87) (*Figure 49*).[270] Moore *et al.*,[284] who had only 27 participants (and wide CIs), reported exacerbations (HR 3.01, 95% CI 0.31 to 28.96) (see *Figure 50*). An additional two trials[192,251] reported no significant difference in exacerbations at last follow-up point.

Multicomponent interventions with exercise counselling only compared with usual care

Seven trials[67,72,73,140,170,180,266] reported disease-specific HRQoL using total SGRQ or CRQ following multicomponent interventions that included advice about increasing exercise. There were no significant effects on the SGRQ in the combined analyses at any of the three follow-up points and heterogeneity was high (*Figure 51* and *Table 57*). Two trials[72,180] had large differences in the SGRQ score at baseline that were not accounted for, and three trials[72,73,140] had low or imbalanced follow-up rates.

Eight trials reported hospital admissions,[67,70,71,73,75,140,168,266] of which one[168] was not included in the meta-analyses. There were no significant effects on admissions at any of the three follow-up points, and heterogeneity was high at the 6- and 12-month follow-up points. Details are given in *Figure 52* and *Table 57*.

Only Dheda *et al.*[73] reported exacerbation rates at 6 months' follow-up in a form enabling a HR to be calculated, with no difference between study arms (*Figure 53*). Three other trials[140,180,266] reported exacerbations at 6 months[265] or a year,[140,180] with Rice *et al.*[140] reporting a significant reduction in exacerbations at 1 year.

Multicomponent interventions without an exercise element compared with usual care

We included five trials[63,112,120,185,256] of multicomponent interventions that did not include exercise or even advice about exercise as a component in the meta-analyses.

Although the estimates of average effects of QoL (SGRQ) at all three follow-up points were in the direction favouring the intervention, none was statistically significant and heterogeneity was high (*Figure 54* and *Table 58*).

Admissions	≤ 3 months	1	0.32 (0.03 to 3.03)	n/a
	> 6 months	2	0.99 (0.76 to 1.30)	0

n/a, not applicable.

Results were combined for two trials that reported hospital admission rates at 3–6 months.[63,142] Neither reported a statistically significant reduction in admissions (*Figure 55*). Three other trials[112,136,142] that reported hospital admissions at last follow-up did not find any significant difference between study groups. Koff *et al.*[120] reported no significant difference in exacerbations at 3 months' follow-up.

Summary: role of exercise in multicomponent interventions

- Multicomponent interventions with supervised exercise compared with UC have a positive effect on HRQoL and positive trend for hospital admissions but not reaching statistical significance.
- For multicomponent interventions with structured, unsupervised exercise there is evidence of effectiveness on HRQoL in the medium term, but insufficient evidence for hospital admissions and exacerbations.
- For interventions with advice to increase exercise in an unstructured manner there were few trials, but no evidence of overall effect on HRQoL, hospital admissions or exacerbations.
- There were limited numbers of studies of multicomponent interventions without any exercise counselling. There is some evidence that they may lead to short-term improvements in HRQoL, but there was inconclusive evidence for hospital admissions.

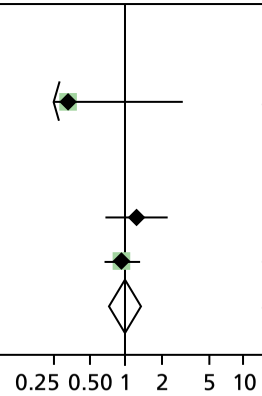

FIGURE 55 Admissions outcomes for multicomponent SM interventions without an exercise element vs. UC/control.

Self-management interventions including an exercise component consisting of aerobic and strength training

Given the possible influence of exercise, we further explored the effect of different types of exercise interventions by first examining the effects of interventions that include both aerobic and strength training.

The summary meta-analysis result indicates that, on average, the combined aerobic/strength exercise arm has a SGRQ score of 7.80 points higher than the UC arm (95% CI 2.82 to 12.79 points). However, this is the average of the distribution of intervention effects and this distribution was wide as a result of high heterogeneity ($I^2 = 81.5\%$). The prediction interval, in which 95% of the distribution of the effects occur, is –10.60 to 26.21, which is mainly in favour of the intervention, but also indicates that the intervention is not always effective. At the mid follow-up point of 3–6 months, the estimate of the average effect was 3.76 points on the SGRQ (95% CI 2.13 to 5.39 points; $I^2 = 0\%$) favouring the intervention group. However, at > 6 months there was no evidence of effect (*Figure 56* and *Table 59*). The CRQ results favoured the intervention group up to 6 months' follow-up (*Figure 57*).

We identified six trials[148,154,160,213,227,270] reporting hospital admissions but at no follow-up time point was the average effect significantly in favour of the intervention arm (*Figure 58* and *Table 59*).

Similarly, the average effects of the four trials reporting exacerbations,[154,182,213,284] showed no evidence of effect of aerobic and strength training (*Figure 59*).

Summary: strength and aerobic exercise interventions

Favourable effect on HRQoL and hospital admissions (although not statistically significant). No evidence of effect on exacerbations.

Strength and aerobic exercise training compared with aerobic training only

To investigate the effect of strength training, we evaluated the effects of studies reporting the addition of strength training over aerobic training. Two trials reported this comparison at 3 months' follow-up.[233,246] On average combined training has a SGRQ 4.23 points (95% CI –8.75 to 17.22 points) higher than aerobic training alone, but this effect is not statistically significant (*Figure 60*).

Summary: strength training

Limited evidence from only two trials;[233,246] no evidence of effect.

Dourado 2009[233] B = strength training and low-intensity general training vs. low-intensity general training; Vonbank 2012[246] B = strength and endurance training vs. endurance training.

Endurance training compared with strength/resistance training

To explore which of the strength or endurance training was more effective we examined trials directly comparing both. Four trials reported HRQoL for this comparison (*Figures 61* and *62*).[216,233,246,247] At none of the follow-up points was there any evidence of a significant difference in average effect (*Table 60*). Only one trial reported hospital admission rates, which showed no evidence of effect (HR 0.68, 95% CI 0.22 to 2.13) (*Figure 63*).[247]

Summary: endurance training compared with strength/resistance training

Limited evidence; no evidence of effect.

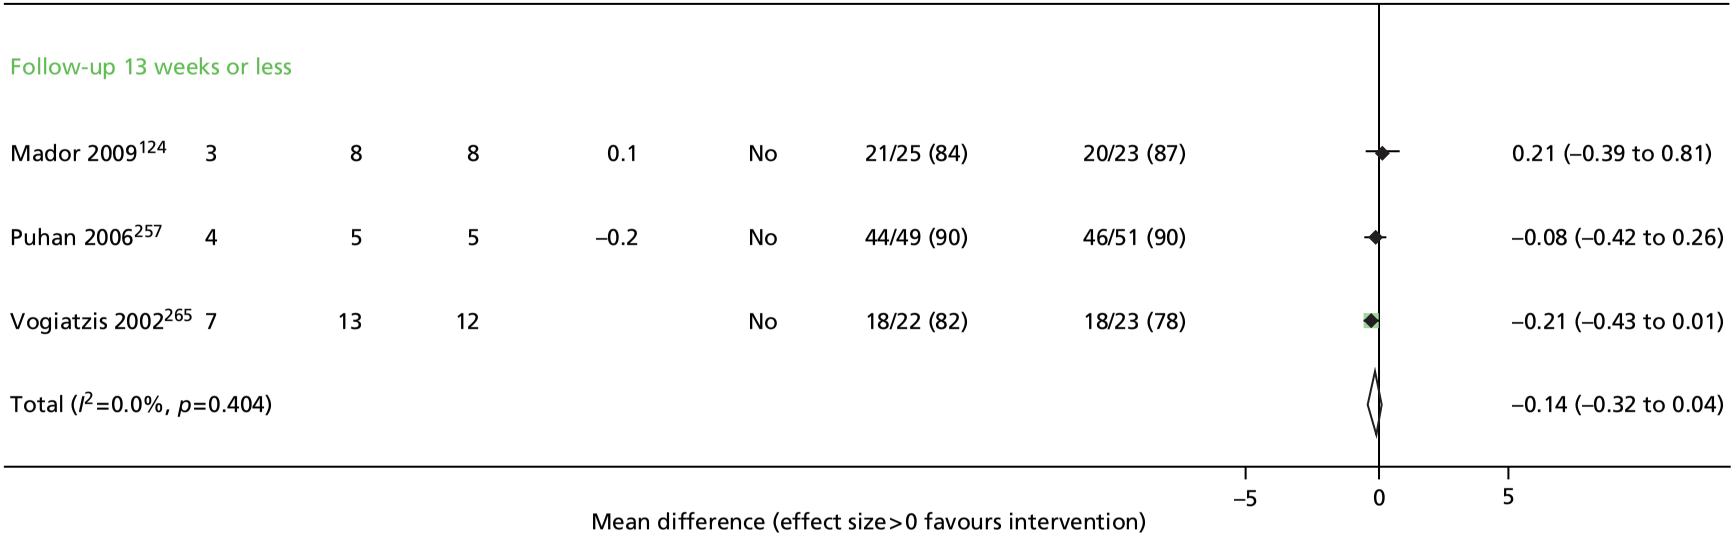

FIGURE 65 Health-related quality-of-life (CRQ) outcomes of interval vs. continuous training.

Inspiratory or expiratory muscle training compared with usual care or a sham intervention

Four trials[163,184,253,254] reported RMT compared with a UC or sham intervention. Two small trials[253,254] reported the SGRQ at three follow-up points but with wide CIs around a non-significant effect. Two small trials[163,184] reported the CRQ immediately post intervention at 5 and 8 weeks, with an average CRQ score of 0.44 points (95% CI –0.27 to 1.15) higher than UC, indicating a non-statistically significant improvement in HRQoL. Only one trial[253] reported hospital admissions, with a non-significantly lower HR in the RMT arm (HR 0.77, 95% CI 0.34 to 1.72) (*Figures 66–68* and *Table 61*).

Summary: inspiratory/expiratory muscle training

Limited evidence. Some evidence of potential effect on HRQoL in mid to longer term.

Direct comparison of more sessions/longer duration with shorter programmes

This analysis investigated the effect of longer programmes: 7 weeks' duration compared with 4 weeks' duration,[144] additional exercise sessions following a course of PR[224] or two compared with one repeat PR sessions.[244] It did not investigate the intensity of exercise undertaken within a session. There is no evidence that longer programmes or more sessions lead to improved SGRQ scores or reduced exacerbations (*Figures 69–71* and *Table 62*).

Summary: more sessions/longer-duration interventions

Limited evidence; no evidence of effect.

Hospital compared with home location

Four trials reported disease-specific HRQoL outcomes in hospital with or without home locations compared with a home-based programme (*Table 63*).[64,169,177,198] There was no evidence of an average effect that differed between the comparison groups in HRQoL at any of the follow-up points except for one small trial at 6 months' follow-up[64] (*Figures 72* and *73*). In Maltais *et al.*[198] both groups received a 4-week outpatient supervised educational package, while the exercise component was either hospital- or home-based.

Summary: hospital-based compared with home-based interventions

Limited evidence; no evidence of effect.

Delivery by pharmacists

We aimed to explore any effects by professional delivering care. The majority of interventions were delivered by nurses or physiotherapists. Three trials[136,251,266,285] had a SM intervention delivered by a pharmacist with a UC comparator. Of these, two trials[251,266] reported the SGRQ, with a higher average effect in favour of the pharmacist-led intervention at 6 months (2.74, 95% CI –1.54 to 7.03; $I^2 = 30.3\%$), but this was not statistically significant (*Figure 74*). At 1-year follow-up, Khdour *et al.*[251] reported a non-significant difference of 3.80 SGRQ points in favour of the pharmacist-led intervention (95% CI –1.95 to 9.55 points). Jarab *et al.*[266] reported a significant reduction in hospital admissions at 6 months (HR 0.26, 95% CI 0.07 to 0.93) (*Figure 75*).

Summary: delivery by pharmacists

Insufficient evidence; no evidence of effect.

Maintenance programme post pulmonary rehabilitation compared with no maintenance programme

No combined analyses were possible for this analysis. Romagnoli *et al.*[244] found no evidence of effect on HRQoL from a maintenance programme following PR at 4, 26 or 52 weeks (*Figure 76*). At 2 years' follow-up, Sridhar *et al.*[155] reported a significantly greater CRQ score (2.04, 95% CI 0.37 to 3.71) but no effect on hospital admissions (HR 1.11, 95% CI 0.65 to 1.91) or exacerbations (HR 1.00, 95% CI 0.68 to 1.46) (*Figures 77–79*).

Exploring heterogeneity using meta-regression

Meta-regression was used to explore the effects of risk of bias within studies, the average severity of COPD in the participants, the number of intervention components and the duration of the intervention. The last analysis is also clearly related to the follow-up time point. No clear pattern emerged. Although at up to 3 months' follow-up the trials of all multicomponent interventions with generally low risk of bias have a significantly higher SGRQ score than trials at higher risk of bias, this effect was not seen at any other time point or for subgroups of interventions. Similarly, increasing numbers of components were associated with significant improvements of SGRQ in analyses of all multicomponent interventions, but a small but opposite effect was seen for the effect of enhanced SM on hospital admissions. For multicomponent interventions, the population with severe COPD had a reduced improvement in SGRQ compared with those with moderate or less severe COPD. Inconsistent results were observed for length of follow-up (*Tables 64* and *65*).

Publication bias

We present funnel plots of the analyses, which included at least 10 studies (see *Appendices 28–33*). The asymmetric distribution apparent in several of the plots is suggestive of publication bias, with an Egger's test for asymmetry showing $p < 0.1$ in five of the six analyses with ≥ 10 trials. These patterns are consistent with an absence of smaller studies with negative outcomes. This would be consistent with biases observed in other literatures, particularly in the context of a comprehensive search of the literature such as the one carried out here. Although the publication bias is thus a genuine concern, the asymmetry may also be due to systematic associations between sample size and other heterogeneous characteristics that impact on outcome.

14–26		–	–	–
27+		0.39	–0.27 to 1.04	0.244

a Reference is higher risk of bias.
b Reference is less severe population.
c Reference is intervention length of ≤ 13 weeks.

Discussion

We report the findings of a large systematic review that has explored the components and delivery of SM interventions in order to try to identify the optimal mode of delivery and make-up of such interventions.

Key results

Overall we found that:

- There were a large number of relevant trials with our primary outcomes of interest but the majority were small, short term (≤ 3 months) and poorly reported.
- Almost half of the trials suffered from incomplete outcome reporting, which was likely to be an important source of bias for the HRQoL results in particular.
- Interventions were very heterogeneous and usually multicomponent.
- Exercise was the most common component, but other common components were breathing management techniques and general education about COPD and its management.
- Overall, the nature and results of the studies were so heterogeneous it was not appropriate to combine them all together.
- Studies assessing the effect of individual components were few but, from the evidence available, only exercise significantly improved patient outcomes, but this was restricted to HRQoL in the short term.
- Multicomponent interventions (with three or more components) produced combined effects which suggested that HRQoL was improved compared with UC. However, there was much statistical heterogeneity that could not be explained by length of follow-up. The results were also consistent with a potential reduction in admissions but, again, data were heterogeneous and the CIs crossing the line of no effect. Further exploration using meta-regression techniques indicated that the results could have been affected by the likely bias introduced in the study, the disease severity of the populations and the number of components in the interventions, although across time points, these findings were not stable.
- Subgroups of the multicomponent studies revealed that interventions with more enhanced care and support were effective in improving HRQoL and reducing admission rates among the studies of ≥ 6 months' duration.
- Furthermore, multicomponent interventions that included supervised exercise, or an unsupervised but structured exercise element, resulted in significant and clinically important improvements in HRQoL up to 6 months, although data were sometimes heterogeneous. There was insufficient evidence to comment on other outcomes.
- Further exploration of exercise did not reveal which type of exercise was more effective or whether duration/intensity was important.
- Insufficient evidence was available to assess the effect of delivery of SM type of health professional.

Comparison of findings with other reviews

Contents of self-management interventions

Through mapping the SM interventions and their individual components we are able to show the huge range of interventions, with differing components, delivered either as brief information/education or in a more supported manner. Exercise was the most frequent component and the most common component of single/two-component interventions. A recent systematic review by Stoilkova *et al.*[286] has mapped educational programmes in COPD management only, including studies published in the English language. This reported that over half of educational interventions had ≥ 10 topics incorporated within a programme. We took a much broader approach to defining SM, searching for studies that might include any of the relevant aspects of SM. Although we also found that a high proportion of trials evaluated multicomponent interventions, about one-fifth were single component, usually exercise only.

Role of behaviour change strategies

From the descriptions of interventions it was frequently not clear to what extent techniques for behaviour change were used in the SM education and support. Most intervention descriptions had no description of underlying behavioural change theory or the individual behaviour change strategies used. Some papers described using self-regulation theory, or Bandura's Social Learning Theory;[31] others described strategies such as self-monitoring, goal-setting, action planning and the use of biofeedback. The use of Abraham and Michie's[287] taxonomy of behaviour change to underpin the descriptions of the SM interventions would enable their relative contributions to be ascertained. Education is an important element of COPD SM interventions, with almost half of the studies in this review including this component. However, education as directly imparted provision of information is generally not effective by itself.[288] Information is effective when accompanied by active, behavioural strategies, and it is not clear to what extent these have been included within the interventions included in this review. Dishman *et al.*[289] identified that knowledge alone did not predict behaviour change, but that self-efficacy is an important cognitive determinant of change, showing that people have at least acquired the confidence and belief that they can self-manage their COPD. Trials that used action planning for an exacerbation generally failed to measure self-efficacy to determine whether they increased self-efficacy for identification of an exacerbation and confidence with commencing treatment. Given that action planning has not been found to be effective,[50] it is vital to explore the mechanisms by which it is proposed to work, to establish whether any lack of effect is due to a failure to commence treatment as a result of lack of confidence.

Behavioural change techniques that have been shown to be most effective in the promotion of physical activity and healthy eating in the general population may also be beneficial to encourage physical activity and exercise in people with COPD.[290] The technique associated with most effects was being prompted to self-monitor behaviour. Other techniques that appeared to be effective when combined with self-monitoring were prompting intention formation, goal-setting and providing feedback on performance. These would all be achievable as part of a SM intervention for people with COPD.

Results of effectiveness of self-management interventions

Overall the effect on HRQoL of multicomponent SM interventions was positive, with an average effect size of greater than four points on the SGRQ, which is considered to be the minimal clinically important difference. The effect of SM on admissions and exacerbations was less clear, possibly as a result of fewer trials in the analyses. Our plan was to explore the expected high levels of heterogeneity to try to identify formats of SM for COPD that looked particularly promising in terms of HRQoL and health service utilisation outcomes. These analyses were developed by the wider project steering group and aimed to have a clinical coherence. We decided not to repeat analyses that were the subject of recent Cochrane systematic reviews.

We have no evidence from our analyses that SM interventions with more components are better than those with fewer. The results from the meta-regression provided inconsistent results in relation to the risk of bias of the study, severity of the population's COPD and number of components.

Role of specific components of self-management

There were few studies that evaluated either single components of SM compared with UC, or the addition of an individual component to a wider package of care. The exploration of single component interventions is important, as it may be the case that it is easier for participants to focus on a single component better than a multicomponent intervention.

Action plans

A Cochrane systematic review investigated the effect of action plans with a brief educational component compared with UC.[50] There was no effect on HRQoL, emergency room visits, general practitioner consultations or hospital admissions, but participants in the action plan group had more treatments for exacerbations. Our review did not identify any additional studies addressing this SM strategy alone. Action planning was a component in over half of the multicomponent interventions.

Smoking cessation interventions

Smoking cessation was a surprisingly low proportion of the SM components (in $< 20\%$ of interventions); however, this may be a result of people with COPD being referred out to a separate smoking cessation service, rather than including it as part of a SM programme. It is possible that the inclusion of smoking cessation within SM programmes may be a source of heterogeneity, which we have not explored. In a systematic review of smoking cessation interventions for COPD five studies were included.[291] There were no comparisons of psychological interventions compared with no interventions. Direct comparisons of two active psychosocial interventions showed no significant difference, but a combination of a psychosocial and pharmacological intervention compared with no treatment showed sustained cessation.

Exercise-only interventions

We have reported the effects of exercise-only/exercise with dyspnoea management interventions compared with UC. At follow-up of ≤ 3 months the average effect of exercise only was –4.87 (95% CI –5.79 to –3.96) SGRQ points in favour of the intervention but, because of small numbers of trials reporting HRQoL with a longer follow-up or admissions or exacerbations, we do not have evidence of an effect after this short period. All but one of these trials included supervised exercise, so we were unable to explore the role of direct supervision compared with unsupervised home-based exercise in the absence of other SM components.

Effect of multicomponent interventions

In the wide range of multicomponent SM interventions and settings evaluated, our meta-analysis indicates that overall (on average) multicomponent SM interventions have a positive effect on HRQoL. Our summary estimates were larger than the minimal clinically important difference for SGRQ at follow-up to 6 months for the multicomponent interventions and at all follow-up points for the CRQ.[292] However, we did find considerable heterogeneity, making it hard to establish which particular interventions and which particular settings work best. Our findings are similar to those of a systematic review by Effing *et al.*,[48] who evaluated the effectiveness of SM education compared with UC. Effing *et al.*[48] included 14 trials, with considerable overlap with our analysis but they excluded trials of PR. Effing *et al.*[48] reported a smaller improvement on the SGRQ (2.6, 95% CI 0.02 to 5.0) than we found, but did report a significant reduction in respiratory admissions, which did not agree with our findings.

Integrated disease management

Several systematic reviews have addressed the effectiveness of disease management.[47,49] This has been defined by Schrijvers[293] as 'Disease management consists of a group of coherent interventions designed to prevent or manage one or more chronic conditions using a systematic, multidisciplinary approach and potentially employing multiple treatment modalities. The goal of chronic disease management is to identify persons at risk for one or more chronic conditions, to promote SM by patients and to address the illness or conditions with maximum clinical outcome, effectiveness and efficiency regardless of treatment setting(s) or typical reimbursement patterns'. The most recent review is a Cochrane review by Kruis *et al.*[47] The Cochrane review[47] included 26 trials and reported a difference of 3.71 points on the SGRQ (95% CI 1.6 to

5.8 points) in favour of the intervention group, a reduction in respiratory admissions (OR 0.68, 95% CI 0.47 to 0.99) and a reduction in all-cause admissions up to 12 months (OR 0.62, 95% CI 0.36 to 1.07). There was no effect on exacerbations. Given this recent review, we have not repeated this analysis in this report.

Enhanced care

Our definition of enhanced care included proactive telephone calls from a respiratory health-care professional and helplines available to patients or visits from health-care professionals, all as a means to reinforce information/techniques/strategies and encourage behaviour change. The interventions were generally delivered by a respiratory nurse or physiotherapist/physiologist. This has not been addressed in other systematic reviews. We have identified improvements in HRQoL and reduced hospital admissions after 6 months of follow-up, suggesting that these enhancements should be considered further. The analyses had high levels of heterogeneity, so further exploration of the individual components would be useful.

Role of exercise alone or within larger self-management packages

Group-based self-management with supervised exercise as part of a multicomponent self-management intervention

Our analysis of SM interventions with supervised exercise is similar to that of Lacasse *et al.*'s[46] Cochrane review of PR programmes. Although the Lacasse *et al.* review[46] included six trials in their analysis of total SGRQ, we included 18, and found a similar effect size at our follow-up points up to 6 months, but an attenuated effect after one year follow-up. We had higher heterogeneity than that reported by Lacasse *et al.*,[46] which may reflect our wider inclusion criteria. We have been able to extend the Lacasse review by reporting hospital admissions and exacerbations; however, the number of trials in these analyses was low (five and three, respectively) and no significant effects were seen.

Multicomponent self-management without supervised exercise

We undertook subgroup analyses to explore the effect of the level of supervision and amount of exercise advice and support in multicomponent SM interventions. The unsupervised exercise was structured in terms of frequency, duration and intensity, but did not take place in a centre or group setting. Although we identified an average effect on the SGRQ at 3 months that was significant, evidence of effect in the longer term was absent. Interventions that included exercise advice only or no exercise at all (as part of a multicomponent intervention) had no evidence of effectiveness.

To further explore the role of exercise we investigated the effect of strength and aerobic exercise training compared with UC. These interventions all included at least one other SM component with the exercise. This showed significantly higher HRQoL scores, but no effect on hospital admissions and exacerbations.

In a systematic review, Zainuldin *et al.*[294] explored intensity of leg training and type of training (interval compared with continuous). Three trials compared higher-intensity training with lower-intensity training but the pooled effect showed no significant difference between the groups on 6-Minute Walk Distance. HRQoL and hospital admissions/exacerbations were not reported. There was no significant difference between the interval and continuous training groups in the eight included studies, for any of the outcomes, including HRQoL.[294] In our study we also found no difference between interval and continuous training.

Role of aerobic and resistance exercise

To unpick the relative contributions of resistance (strength) and aerobic exercise on HRQoL, hospital admissions and exacerbations, we undertook direct comparisons. Only two trials[233,246] directly compared resistance and aerobic exercise with aerobic exercise only, with no difference in average HRQoL between the exercise arms. No trials reported hospital admissions.

Four trials compared endurance with resistance exercise showing no effect of HRQoL or hospital admissions.[216,233,246,247]

Respiratory muscle training

Two main groups of interventions came under this category. Sívori *et al.*[263] compared upper limb exercises to UC, with no significant effect on HRQoL. Our findings are similar to those of Costi *et al.*,[295] who reported the HRQoL outcomes individually for three trials, all of which found no significant difference.

We identified a large number of trials that evaluated inspiratory muscle training (IMT) and expiratory muscle training (EMT) using threshold devices (20 trials: see *Appendix 27*). These either had UC or sham devices (set at the lowest setting for resistance) as the comparison group. Only four trials[163,184,253,254] reported disease-specific HRQoL using the SGRQ or CRQ and one trial[253] reported hospital admissions. We did not identify any evidence of effectiveness of RMT on these outcomes.

Our findings can be compared with those of systematic reviews of IMT compared with UC,[296] and IMT or IMT plus PR compared with other rehabilitation interventions.[297] Geddes *et al.*[296] had only two trials that compared IMT to sham treatment and reported the total CRQ (weighted MD 0.33, 95% CI 0.19 to 1.47). The review by O'Brien *et al.*[297] reported only the individual subscales for the CRQ, but found a significantly greater improvement in the dyspnoea subscale for the exercise-only interventions than the interventions that included IMT (CRQ dyspnoea 1.94, 95% CI 1.01 to 2.88).

Interventions delivered by particular professional groups

Three trials[136,251,266,285] reported SM interventions by pharmacists. We hypothesised that the multicomponent interventions that they delivered would have a particular focus on medication management, which was a component of all three trials. The combined effects on HRQoL were not significant, but Jarab *et al.*[266] reported a significant reduction in hospital admissions at 6 months' follow-up.

Other systematic reviews have reported the effects of interventions delivered by physiotherapists[298] and of outreach nursing.[52] The review of outreach nursing[52] has considerable overlap with the concept of integrated disease management. Wong *et al.*[52] reported a significant improvement in HRQoL, but no effect on mortality or hospital admissions.

How the evidence fits with other long-term conditions

All our included trials took a patient-based approach in which the SM was delivered to patients in the form of group-based or individual education and other support. A large UK-based cluster randomised trial (WISE: Whole System informing self-management engagement),[34] published after our search was completed, sought to support primary care practitioners to embed SM support into their everyday practice. The trial recruited 1634 patients with COPD in primary care but did not find statistically significant improvements in self-efficacy, generic HRQoL or shared decision-making. The authors cited difficulties with implementation in a 'real' primary care setting with an unselected group of patients.

Recent studies of note since our searches were undertaken

A recent trial[34] was halted prematurely after interim analysis identified a higher mortality rate in the group that received the SM intervention. The intervention failed to increase knowledge or use of antibiotics as part of action planning, but the findings are otherwise unexplained. An analysis of mortality rates across all of the included studies in our review might help identify whether this was an outlying result.

Strengths and limitations

Strengths

This is the largest systematic review of SM for COPD, with 174 trials reporting our three outcomes in 229 comparisons. We had no exclusions by language or publication date and included 12 trials that were reported in a language other than English. The review was undertaken with two people independently selecting titles, abstracts and full papers for inclusion/exclusion, with a third person reviewing and deciding on papers where there was a disagreement, and group discussion about papers and interventions that were difficult to categorise. We used an extensive data extraction form to extract directly and – when not reported – indirectly calculate statistical results for the intervention effects of interest. This allowed us to incorporate a larger number of studies in the meta-analysis than previous reviews, especially with regard to HRs.

Many of our subgroup analyses cover topics of published systematic reviews and we were able to extend the included papers in a number of these. We have also explored additional groups of interventions, for example in relation to the level of supervision and specification of the exercise component. Although we would have liked to undertake indirect comparisons to explore individual or groups of components further, this was not possible due to the heterogeneity of populations, interventions and comparators.

Heterogeneity was apparent in most meta-analyses but the causes of heterogeneity were difficult to identify due to the small number of studies in most meta-analyses and the potential for trial-level confounding when exploring heterogeneity. Therefore, to help summarise the heterogeneity more clearly, when five or more studies were included in the meta-analysis we reported 95% prediction intervals. These revealed the range of possible intervention effects caused by unexplained heterogeneity. However, this interval may also reflect heterogeneity caused by small-study effects and low-quality primary studies rather than just clinical causes of heterogeneity.

Limitations of studies within the review

The main limitations of our review result from the heterogeneity of both the interventions and the comparison groups, and the general poor standard of reporting and conduct in many of the identified trials. The included trials were often small, with 46% having < 50 participants; few included a power calculation; and the reporting of method of randomisation, allocation concealment and blinding of outcome assessment was often absent or poorly described. When undertaking risk of bias assessment we did not use explicit cut-offs for a certain attrition or imbalance between study groups because so many studies had small sample sizes and these thresholds were easily crossed by one or two more participants lost to follow-up in one study arm compared with the other.

As many of the trials used a ‘UC’ comparator, it was not possible to blind participants to their allocation. This is likely to lead to an attention effect, when the participants in the active intervention arm have a more positive experience and often more social support through group-based activities. As most of the trials reported HRQoL which often includes a mental or social component and follow-up was frequently only undertaken at the end of the intervention period, attention bias is likely.

Limitations of our review methods

In defining SM interventions we took a very broad perspective but tried to exclude those interventions when the intervention was largely provided by a professional. Thus hospital-at-home interventions were included only if they expressly described a SM or educational component. Disease management programmes were excluded if they were telemonitoring without an educational or SM element. Some exercise programmes that were delivered by physiotherapists were short term and appeared to describe something ‘done to’ the patient rather than teaching them to self-manage; these were excluded. Owing to the large number of papers identified and a number of people reviewing abstracts and papers for eligibility, there will inevitably be some inconsistencies in relation to inclusion/exclusion. We tried to minimise this through regular team discussions about papers that we were unsure of including.

We planned to undertake full independent double data extraction on all papers but, owing to the large number of eligible papers, only one person extracted the characteristics and outcomes, with a 20% check of the outcome data and a 100% check for key characteristics such as number of participants, duration of intervention and duration of follow-up. To ensure consistency the same person categorised the components in all trials.

In extracting HRQoL outcome data we focused on the disease-specific measures (SGRQ and CRQ) and have not reported the generic HRQoL outcomes, as a wide variety of these were reported in a small number of trials. We decided not to combine the findings of the SGRQ and CRQ in meta-analysis, as they report different domains. In addition, the reporting of the actual point differences in meta-analysis on the original scales, rather than a standardised MD, makes interpretation easier.

The admission results were reported in several different ways, for example first admission, mean admissions, etc. Although ideally we would like to be able to capture all of this information, especially because some patients may have multiple admissions, current methodologies are inadequate to do so. We chose rate of first admission because there were more data available; however, it is not clear how the effect of the interventions would vary if all admissions could be considered.

The trials reported a large number of outcomes, and trials that met our inclusion criteria in relation to population and intervention – but did not report one of our three primary outcomes (HRQoL, hospital admissions and exacerbations) – are listed but not described. Although we acknowledge the importance of other outcomes, such as exercise capacity, the focus of this review was health service utilisation and patient QoL. Mortality was rarely reported as an outcome but can be obtained from the reasons for loss to follow-up. Papers often did not report the cause of death (respiratory or other cause) and we cannot be sure about completeness, given that few trials specified mortality as an outcome measure. Therefore, we did not include mortality in our analyses.

We have undertaken a large number of comparisons, with the associated risk of identifying significant effects due to chance. However, this review was planned to be exploratory in nature and we are cautious in the interpretation of our findings.

We had planned to undertake indirect comparisons of clusters of intervention components but did not do this owing to considerable heterogeneity of the UC arms and difficulties in identifying potential comparison groups. The heterogeneity and low-quality studies led us to conclude that the consistency assumption (which is required to undertake a mixed-treatment comparison) was unlikely to be plausible, and thus indirect comparisons were not considered.[107]

Generalisability

Our trials were set in 21 different countries, suggesting that our findings can be generalised across a range of different health-care settings. We did not explore the effect of location, and thus the standard level of COPD care as a potential cause of heterogeneity but it may be an important factor. In particular, we did not focus on studies undertaken only in the UK. Most of the trial participants were recruited from secondary care settings – usually hospital outpatients – and $< 6\%$ were from primary care. In addition, the participants generally had moderate or severe COPD, as defined by GOLD criteria. Thus our findings may not be generalised well to populations with milder COPD managed in primary care. In addition, trials may recruit participants who are more affluent or have a higher educational level than the general population. Given the fundamental role of self-efficacy in many SM interventions, the representativeness of the participants is key. Comparisons of the characteristics of recruited participants and people who decline to take part in a trial are rarely reported, so we are unable to comment on the generalisability of the trial participants in these aspects.

Chapter 8 Overall discussion

Introduction

This report had two aims: to evaluate the effectiveness and cost-effectiveness of SM commencing within 6 weeks of hospital discharge for an exacerbation of COPD, and to explore which components or mechanisms of delivery appear most promising in terms of the effectiveness of SM interventions for COPD in general.

Main findings

The review of SM post discharge identified no evidence of benefit of early SM support on admissions, mortality and most other health outcomes, although a modest, but possibly biased, improvement in HRQoL. However, the direction of the effect for many of the outcomes (including admissions) favoured the SM intervention. A speculative economic model was developed to explore the cost-effectiveness of such an intervention – if it were truly effective at reducing hospital admissions. The main drivers of the model were the effect on hospital readmission, the duration of the effect and the cost of a SM programme. To be cost-effective, a SM programme post admission for an acute exacerbation would need to cost no more than £2200 if there was an 18% reduction in readmissions. The sensitivity analysis suggested that SM had a probability of 68% of being cost-effective at a threshold incremental cost-effectiveness ratio of £20,000 per quality-adjusted life-year, demonstrating the uncertainty around the impact of SM on readmissions.

The second study was an exploratory review of the broad SM and PR literature to try to determine the components and mechanisms of delivery that are associated with better outcomes. Multicomponent (at least three individual components) SM interventions are likely to be effective, but the degree of heterogeneity suggests that there are important features of these interventions that need to be established; those with supervised exercise (as in a PR programme) or structured, unsupervised exercise (as in a home rehabilitation programme) appear effective. SM programmes that provide an enhanced level of care and support may reduce hospital admissions in the medium term (6 months).

Except for exercise-only interventions, there were surprisingly few trials of individual SM components, and few for which the difference between study groups was only one component. Notably, there was no evidence that action plans were effective by themselves.

Overall conclusion

It is difficult to recommend any type of SM support to be provided immediately after discharge with the evidence available, as there is no clear evidence of effect across most of the outcomes. Notwithstanding, the point estimate is consistent with ≈20% reduction in admissions, which has been observed in other systematic reviews of COPD SM interventions.

Although some components of SM interventions are associated with positive effects of HRQoL, such as structured exercise (either within a supervised group or home based), enhanced care and multicomponent interventions, it was not possible to establish the relative roles of the individual components in reducing hospital admissions and improving HRQoL.

Recommendations for future research

1. Current interventions to support patient SM that is delivered post discharge cannot currently be recommended because interventions are heterogeneous and methodology is problematic, and, despite there being potential benefit in terms of HRQoL, there is not enough good evidence to be sure that clinical outcomes could be improved. Therefore:

    i. High-quality studies should be undertaken among patients with COPD disease post discharge.
    ii. This should include qualitative work to explore barriers and facilitators to SM when patients have recently had an exacerbation, exploration of novel approaches to affect behaviour change, and exploration of approaches tailored to the individual and their circumstances.
    iii. New approaches should be evaluated by properly designed and conducted trials, with special attention to reducing loss to follow-up.

2. Owing to the heterogeneity and complexity of interventions, it was not possible to unpick the most important components of SM interventions in general or to confirm whether they improve clinical outcomes. It is clear that action plans alone do not seem to work in their present form, but that structured exercise and more heavily supported interventions (which may not usually be defined as SM) might work better. Therefore:

    i. Further in-depth work using individual patient data (e.g. an Individual Patient Data meta-analysis) should be carried out to try to identify which are the most effective components of interventions and identify patient-specific factors that may modify this. This work is ongoing by other researchers.
    ii. Future studies might try to identify the characteristics of patients who are more likely to be able to self-manage, and consider a more targeted approach.
    iii. Further qualitative work is needed to explore patients' barriers and facilitators to SM interventions.
    iv. Novel approaches to influence behaviour change and to help patients manage or prevent exacerbations should be explored, first using qualitative studies and then properly designed and conducted randomised controlled trials (RCTs). Most trials include a mixture of components; more trials teasing out the individual elements, either as lone interventions, or with the addition of one component, would be useful.

3. Recommendations for the design and conduct of future RCTs of interventions to support patient SM:

    i. In general, new trials should adhere to modern standards of design, conduct and reporting in order to reduce risks of bias, for example blinding of outcome assessment, attempts to maximise follow-up or methods to impute this, and reporting of the characteristics of all randomised patients.
    ii. The behaviour change theories and strategies that underpin COPD SM interventions need to be better characterised and described.
    iii. A clear framework for describing and classifying SM interventions and their comparators is required.
    iv. Trials need to be adequately powered to detect a clinically relevant difference and long enough to assess changing effects over time. There should be clear reporting of outcomes to include self-efficacy, behaviour change and clinical outcomes such as hospital admissions and exacerbations.
    v. Given the wide range of HRQoL outcomes available, it would be useful to standardise their use within COPD research and ensure that they are reported accurately within publications.

Statistical analysis methods should be improved: in particular (1) analysis of HRQoL outcomes should routinely adjust for baseline values to overcome baseline imbalance, account for correlation between final score and baseline score, and increase statistical power; and (2) time-to-event outcomes (such as admissions, mortality, etc.) should be analysed using suitable analyses that allow for differential patient follow-up, and summarised using HRs (rather than odds ratios).

Acknowledgements

The authors thank the following:

- Simon Stevens for his invaluable administrative support and excellent organisational skills, and keeping us all going throughout a complex project.
- All of the people who kindly gave their time to help translate articles: Yumiko Akiya, Dom Barkos, Susan Bayliss, Matthew Blackburn, Yumi Chen, Jennifer Choi, Karin Diaconu, Janine Dretzke, Maxwell Feltham, Ditte Hedegaard, Boris Kysela, Antje Lindenmeyer, Kinga Malottki, Cristina Peñaloza and Amanda Zhang.

Contributions of authors

Rachel E Jordan (Senior Lecturer, Public Health/Epidemiology) (co-principal investigator) wrote the protocol, co-directed and developed the review, chaired the team and investigator meetings, liaised with the Public and Patient Participation group, contributed to study selection, undertook and oversaw data extraction and risk of bias assessment for reviews 1 and 2, wrote the background, oversaw and wrote the results for reviews 1 and 2, and commented on and edited all other aspects of the report.

Saimma Majothi (Research Fellow, Systematic Reviews), lead reviewer, led and coordinated the systematic review, led study selection, led the development of risk of bias and data extraction tools, undertook classification of studies, extracted results of studies for reviews 1–4, undertook risk of bias assessment for reviews 1–4, coordinated data analysis, wrote the methods sections, wrote sections for the qualitative review (review 2), wrote the cost-effectiveness review (review 3), drafted interim reports and commented on the final report.

Nicola R Heneghan (Lecturer, Physiotherapy), second reviewer, contributed to review development, study selection, data extraction and risk of bias assessment, and commented on the final report.

Deirdre B Blissett (Research Fellow, Health Economics) led and wrote the section on the economic model, undertook risk of bias for review 3 and commented on the final report.

Richard D Riley (Professor, Biostatistics) advised on methodology of the protocol, advised on statistical and reviewing methods, developed data extraction form for statistical results, undertook initial statistical analyses, supervised statistical analyses, contributed to writing the statistical methods and commented on the final report.

Alice J Sitch (Research Fellow, Biostatistics) undertook analyses for review 4, contributed to methods of analyses and commented on the final report.

Malcolm J Price (Research Fellow, Biostatistics) extracted samples of results, advised and undertook statistical analyses for review 1, wrote analysis methods for review 1, and commented on the final report.

Elizabeth J Bates (Academic Clinical Lecturer, Primary Care) contributed to risk of bias assessment, contributed to data extraction, provided clinical input, advised on costs and commented on the final report.

Alice M Turner (Clinician Scientist and Honorary Consultant Physician) contributed to study selection, provided data and advice on components of cost for the economic modelling, provided clinical input to protocol and review, and commented on the final report.

Susan Bayliss (Information Specialist) advised on, and performed, search strategies.

David Moore (Senior Lecturer, Systematic Reviews) advised on methodology of protocol, provided ongoing advice on conduct of review and methodology, contributed to study selection and risk of bias, provided technical support and commented on the final report.

Sally Singh (Professor and Head of Cardiac and Pulmonary Rehabilitation, University Hospitals of Leicester NHS Trust) provided clinical input at investigator meetings and specific questions in the interim and commented on the final report.

Peymane Adab (Professor, Public Health) contributed to risk of bias assessment, provided epidemiological input and commented on the final report.

David A Fitzmaurice (Professor, Primary Care) commented on the protocol, contributed to the study selection, provided clinical input at the investigator meetings and commented on the final report.

Susan Jowett (Senior Lecturer, Health Economics) commented on the protocol, oversaw the economic model, provided methodological input at the investigator meetings, edited the economic model chapter and commented on the final report.

Kate Jolly (Professor, Public Health) (co-principal investigator) contributed to the protocol, co-directed and developed the review, co-chaired the team and investigator meetings, contributed to the study selection, undertook and oversaw the data extraction and risk of bias assessment for review 4, oversaw the analyses, undertook the descriptive analyses and wrote results for review 4, and commented on/edited all of the other aspects of the report.

Publications

Part of this report has been presented at the International Primary Care Respiratory Group (IPCRG) conference in Stockholm (May 2013) and the British Thoracic Society conference in London (November 2013).

Funding

Rachel Jordan was funded by the NIHR with a post-doctoral research fellowship (pdf/01/2008/023). Kate Jolly is part-funded by the National Institute for Health Research (NIHR) Collaborations for Leadership in Applied Health Research and Care West Midlands.

Y, yes for inclusion.

Appendix 5 Mortality data from randomised controlled trials: review 1

Study year	Brief intervention	Brief control	Mortality outcome, description	Follow-up (months)	Reassessment		Effect size/*p*-value
					Intervention	Control	
Behnke 2000[64]	Home-based walking exercise programme, *N* = 23	Control: advised to exercise, no instruction, *N* = 23	Deaths	6	1/23 (4.3%)	1/23 (4.3%)	NR
Hermiz 2002[67]	Home-based care focused on SM, *N* = 84	UC, *N* = 93	Total deaths	3	9/84 (10.7%)	10/93 (10.8%)	NR
Hernandez 2003[68]	Home hospitalisation, *N* = 121	UC, *N* = 101	Deaths	2	5/121 (4.1)	7/101 (6.9)	NR
Kwok 2004[70]	Community nurse-supported discharge programme, *N* = 77	UC, *N* = 80	Deaths	6	3/77	6/80	NR
Casas 2006[71]	Integrated care with SM intervention, *N* = 65	UC, *N* = 90	Total deaths	6, 12	7/65 (10.8%), 12/65 (18.5%)	11/90 (12.2%), 14/90 (15.6%)	NR
Garcia-Aymerich 2007[72]	Integrated care included supported SM, *N* = 44	UC, *N* = 69	Total deaths	6, 12	6/44 (13.6%), 11/44 (25.0%)	8/69 (11.6%), 10/69 (14.5%)	NR
Bucknall 2012[63]	Supported SM, *N* = 232	UC, *N* = 232	COPD deaths, all-cause deaths	12	23/232 (10%), 30/232 (13%)	16/232 (7%), 22/232 (9%)	HRs: time to death, 1.36 (95% CI 0.71 to 2.61), 1.35 (95% CI 0.77 to 2.38)

NR, not reported.

Appendix 6 Hospital readmissions data from randomised controlled trials: review 1

Study year	Brief		Outcome description	Follow-up (months)	End point		Effect size/*p*-value
	Intervention	Control			Intervention	Control	
Egan 2002[69]	Case management, *N* = 33	UC, *N* = 33	Unscheduled readmissions; no detail	3	*N* = 33/33 Mean (range): 2.1 (1–5)	*N* = 33/33 Mean (range): 2.6 (1–6)	Reported no significant difference

Appendix 18 Chronic obstructive pulmonary disease-adjusted all-cause mortality rates by age and sex: review 3

Appendix 18 lists the COPD-adjusted all-cause mortality rates applied in the economic model. These were derived from all-cause and COPD-related mortality rates by sex and age for a UK population, obtained from the Office for National Statistics.

	All-cause mortality (%)		Deaths caused by COPD (%)		COPD-adjusted mortality (%)	
Age (years)	Male	Female	Male	Female	Male	Female
60	0.8342	0.5361	4.205241	5.111524	0.7828	0.509483

Appendix 20 Cost of other self-management programmes in populations with chronic obstructive pulmonary disease: review 3

Appendix 20 lists cost estimates extracted from SM programmes targeted at patients with COPD, not provided within 6 weeks of discharge. Costs are listed in the year and currency they were reported and also 2012 GB pound sterling (£) prices. Costs were converted using mid-year exchange rates for the reporting year and inflated assuming an average inflation rate of 3.5%.

Author	Type of programme	Main activities	Cost, year, currency (as reported)	Costs 2012, GB£ (estimated)
Khdour 2011[279]	Pharmacy-led SM programme	A consultation with a pharmacist, lasting 1 hour Two follow-up telephone calls lasting 20 minutes Two follow-up consultations	381, 2006, GB£	458
Sridhar 2008[155]	Nurse-led intermediate care programme	A 1-hour group session A home visit by a respiratory nurse A follow-up telephone call	107, 2006, GB£	129
Dewan 2012[299]	Disease management programme	A group session lasting 1.5 hours Development of an action plan Provision of a refillable prescriptions Access to helpline Series of follow-up telephone calls	849, 2011, US$	544
Monninkhof 2004[300]	SM programme	Five group sessions lasting 2 hours Provision of education booklet Two group training sessions lasting 1 hour	642, 2002, euros	508
Tinkelman 2003[301]	Disease management programme	A telephone education session Ongoing access to case management support via telephone service Series of follow-up telephone calls Reassessment at 6 months	635, 2002, US$	573

Appendix 21 Outcomes as reported by studies included for review 4 but not included in analyses

Appendix 22 Summary of characteristics of population and study information: review 4

Author, year, setting	Sample size	Age, mean (SD)	Males%	FEV_1% (SD)	Recruited from	Intervention details	Control details	Follow-up (weeks)
Aimonino Ricauda 2008 Italy[75]	104	79.7 (3.2)	65	42.5	ED	Hospital at home	Inpatient care	26
Arnardottir 2006 Sweden[216]	63	66. 6 (2)	50	37.5 (2.5)	Secondary care outpatient	Endurance, resistance training and calisthenics	Resistance training and calisthenics	52
Arnardottir 2007 Sweden[217]	100	64.5 (7.6)	15	33.4 (11.5)	PR programme	Interval training	Continuous training	16
Barakat 2008 France[249]	80	64.8 (11.1)	84	42.6 (3.1)	Secondary care outpatient	PR	Control	14
Bauldoff 2002 USA[108]	24	68.1 (8.0)	17	41.3 (13.0)	PR programme	Music (distractive auditory stimulation)	Control	8
Bauldoff 2005 USA[109]	30	63.0 (11)	43	41.3 (18)	Secondary care outpatient	(1) Moderate distractive auditory stimulation during exercise; and (2) slow distractive auditory stimulation during exercise	Attention control	4
Beckerman 2005 Israel[253]	42	67.3 (15.8)	76	42.5 (11.7)	Community	IMT	Sham training	52
Behnke 2000, Behnke 2003, Germany[64,65]	46	66.0 (2.1)	77	36.0 (7.0)	Secondary care inpatient	Home-based exercise	Control	26, 78
Bendstrup 1997 Denmark[222]	47	64.5 (2.5)	88	NR	Secondary care	PR	Control	24
Bernard 1999 Canada[191]	45	65.3 (7.9)	78	42.5 (13.8)	NR	Aerobic and strength training	Aerobic training	12
Berry 2010 USA[110]	176	66.0 (10.0)	50	51.8 (19.4)	Mixed	Lifestyle activity intervention	Traditional exercise therapy	52
Bestall 2003 UK[141]	66	68.7 (7.5)	NR	37.5 (11.5)	PR programme	Exercise	Control	52
Bjornshave 2005 Denmark[223]	31	62.6	35	34.8	Secondary care	Middle intensity training	Low-intensity training	4
Blake Jr 1990 USA[111]	94	63.4	81	NR	Secondary care outpatient	Psychosocial intervention	Control	52
Bonilha 2009 Brazil[232]	43	71.7 (7.5)	75	51.1 (20.5)	Mixed	Singing classes	Control	25
Bourbeau 2003, Bourbeau 2006, Gadoury 2005 Canada[192,270,271]	191	69.5 (7.0)	57	NR	Secondary care	SM programme	UC	52, 104, 52
Boxall 2005 Australia[160]	60	76.7 (7.9)	57	39.1 (15.5)	Secondary care outpatient	Home-based PR	Control	26
Breyer 2010 Austria[245]	60	60.3 (8.5)	45	46.3 (17.6)	NR	Nordic walking	Control	39
Brooks 2002 Canada[193]	109	68.0 (7.4)	59	32.0 (12.0)	PR programme	Enhanced follow-up	Conventional follow-up	52
Bucknall 2012 UK[63]	464	69.1 (9.3)	37	40.5 (13.6)	Mixed	Supported SM	UC	52
Busch 1988 Canada[194]	20	65.1 (15.5)	79	26.3 (10.0)	Unclear	Home exercise	Control	18
Cai 2006 China[199]	82	61.0 (9.0)	95	NR	Secondary care	Education	Control	26
Carr 2009 Canada[195]	34	68.0 (8.1)	44	NR	Primary and secondary care	Repeat PR	UC	52

Appendix 23 Characteristics of interventions of studies included in review 4

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Aimonino Ricauda 2008[75]	Hospital at home – multidimensional geriatric assessment, patient and carer education	8	Inpatient control – routine hospital care	0	2	Individual
Arnardottir 2006[216]	Mixed exercise training – endurance training: 30 minutes, 2× per week with either resistance: 30 minutes, 1× per week; or calisthenics: 15 minutes 1× per week plus relaxation: 15 minutes, 1× per week	2	Resistance training: 30 minutes and calisthenics: 15 minutes with relaxation: 15 minutes	2	8	Group
Arnardottir 2007[217]	Interval training: 90 minutes, 2× per week	2	Continuous training: 90 minutes, 2× per week	2	16	Group
Barakat 2008[249]	PR – exercise and education: 1 hour, 3× per week	3	UC	0	14	Group
Bauldoff 2002[108]	Music as a form of distractive auditory stimulation to accompany home walking programme: 20–45 minutes, 2–5× per week	2	Control	1	8	Individual
Bauldoff 2005[109]	(1) Moderate tempo distractive auditory stimulation with upper extremity training: 15 minutes 2–3× per week plus warm-up; (2) slow tempo distractive auditory stimulation: 15 minutes, 2–3× per week plus warm-up	1	Attention control	1	4	Individual
Beckerman 2005[253]	IMT using threshold device: 15 minutes 2× per day, 6 days per week, gradual increase in load; training in centre for 1 month then home with daily telephone call and weekly visit by respiratory therapist	1	Sham training, as intervention group with very low load	1	52	Unclear
Behnke 2000, Behnke 2003[64,65]	Ten-day inpatient walking training programme and breathing exercise; then walking training at home: 3× per day, with fortnightly supervision for 3 months	3	Control – advised to do exercise, without specific instructions	2	26	Individual
Bendstrup 1997[222]	PR: group exercise supervised by physiotherapist 1 hour, 3× per week; 12 educational sessions and 2× occupational therapy sessions	9	Control – UC, waiting list until follow-up	0	12	Group
Bernard 1999[191]	Aerobic and strength training: aerobic – 30 minutes, 3× per week; strength – 45 minutes, 3× per week	1	Aerobic training: 30 minutes, 3× per week plus 45 minutes' relaxation and breathing	4	12	Group
Berry 2010[110]	Behavioural lifestyle activity programme to promote physical activity: centre-based exercise programme 1 hour, 3× per week (reducing in frequency) plus fortnightly educational classes plus discussion about self-regulation and maintenance of exercise, individual counselling and telephone support	3	Exercise programme 1 hour 3× per week plus fortnightly educational classes for 3 months	2	48	Mixed

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Bestall 2003[141]	Exercise and education group programme: 2× per week	11	Education programme: 2× per week	10	8	Group
Bjornshave 2005[223]	Middle-intensity home-based exercise training (steps and walking): 30 minutes, 5× per week	1	Low-intensity home-based exercise: 30 minutes 2× per week	1	4	Unclear
Blake Jr 1990[111]	Psychosocial intervention (stress management strategies – relaxation, guided imagery, breathing exercises): one session of 60–90 minutes Individualised plan developed, audiotape and reading material provided At least 1 telephone contact and 2× follow-up visits, 2–4 weeks apart	5	Control	0	8	Individual
Bonilha 2009[232]	Singing group class with physiotherapist and singing teacher, 1 hour per week (5 minutes' relaxation, 10 minutes' related respiratory exercise, 15 minutes' vocalisation exercises and 30 minutes' singing training)	4	Physiotherapy and handcraft classes, 1× per week (5 minutes' relaxation and 50 minutes' exercises)	2	24	Group
Bourbeau 2003, Bourbeau 2006, Gadoury 2005[192,270,271]	Living Well with COPD programme: 8 × 1-hour home visits by health professional who was case manager	12	UC	0	8	Individual
Boxall 2005[160]	Home-based PR programme: graduated exercise programme 1× per day; physiotherapist visits 1× per week for 6 weeks, then 1× per 2 weeks; education by physiotherapist, nurse and occupational therapy staff Around six education sessions and 11 home visits in total	8	UC	0	12	Individual
Breyer 2010[245]	Initial 2-hour instruction then supervised outdoor Nordic walking 1 hour, 3× per week; educational session 1× per week	7	One educational session per week	6	13	Group
Brooks 2002[193]	Group discussion about home programme and exercise sessions 2 hours per month led by physical therapist; telephone support from physical therapist 1× per month	5	Visit to physical therapist every 3 months to discuss home programme	4	52	Mixed

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Bucknall 2012[63]	Supported self-management – nurse visits: 4 × 40 minutes for 2 months then every 6 months	6	UC	0	52	Individual
Busch 1988[194]	Home exercise programme: endurance and resistance exercise 5× per week, fortnightly visit by physiotherapist	2	No home exercise, but visits by physiotherapist every 3 weeks to monitor activity level	0	18	Individual
Cai 2006[199]	Education – disease and disease management	6	Control	0	26	Group
Carr 2009[195]	9–15 × 2-hour PR-type sessions in 3 weeks (inpatient or outpatient setting)	6	UC	6	3	Mixed
Casas 2006, Garcia-Aymerich 2007[71,72]	Integrated care – comprehensive assessment of patients at discharge; SM education programme by specialised respiratory nurse: 2 hours before discharge, with reinforcement sessions via telephone: 1× per week for 1 month; individually tailored care plan; access to specialised nurse through ICT platform including a web-based call centre	10	UC: scheduled visits from physician usually every 6 months	0	–	Individual
Chan 2010, Chan 2011[212,272]	(1) T'ai chi qigong – 13 movements of breathing regulating led by a qualified t'ai chi qigong master: 60 minutes, 2× per week; patients advised to practise exercises for 1 hour daily, DVD and pictures given;	4	Control – usual activities (arranged to join community activities to ensure consistent attendance)	0	13	Group
	(2) exercise – PLB and diaphragmatic breathing; advised to perform breathing and walking: 1 hour per day; leaflets with instructions/pictures given (arranged to join community activities to ensure consistent attendance)	3				
Cockcroft 1987[142]	Respiratory health worker home visit (health education and support): approximately 1× per month	3	Control	0	–	Individual
Coultas 2005[112]	Nurse-assisted management: 2 × 4-hour sessions		UC	1	26	Mixed
	(1) nurse-assisted collaborative management including self-management skills: additional 8 hours;	5				
	(2) nurse-assisted medical management	5

Puente-Maestu 2000, Puente-Maestu 2003[177,275]	Supervised exercise – treadmill exercise supervised by physiotherapist: 1 hour, 4× per week	3	Self-monitored exercise: walking 3–4 km for 1 hour 4× per week plus clinic visits 1× per week	3	8	Unclear
Puhan 2006[257]	Inpatient PR: 12–15 sessions over 3 weeks plus high-intensity continuous exercise, target workload 70% plus followed by home exercise, 20 minutes per day Physical therapy led	4	Inpatient PR: 12–15 sessions over 3 weeks plus high-intensity (50%) and low-intensity (10%) interval exercise training 20 minutes per day followed by home exercise 20 minutes per day Physical therapy led	4	5	Mixed
Rea 2004[230]	Chronic disease management programme by GP and practice nurse, care plan, assessment by respiratory physician and nurse, offer of PR, flu immunisation, 3-monthly follow-up in primary care	7	Assessment by GP and practice nurse who had guidelines for COPD management and access to PR	0	52	Individual
Regiane Resqueti 2007[178]	Home-based PR: 3 × 1 hour individualised education and physical therapy; 3 × hospital exercise training; with weekly visit and telephone call by therapist for 7 weeks; home exercise for 1.5 hours, 5× per week, plus monthly telephone for 4 months	6	3 × hour individualised education and physical therapy	4	26	Individual
Ren 2011[201]	(1) PR strategy group 1: aerobic exercise training with PLB and abdominal breathing; education: 20 minutes, 5× per week; (2) PR strategy group 2 – strategy 1 plus upper and lower limb training	2 1	Control: PR education, 2× per month	0	20	Group
Rice 2010[140]	1 × 1.5 hours' group education session, individual action plan with rescue medications; monthly telephone support from case manager; telephone number of 24-hour nursing helpline	8	Leaflet with summary of COPD care and telephone number of 24-hour nursing helpline	2	52	Mixed

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Riera 2001[179]	IMT with flow meter device: home training 30 minutes per day, 6× per week with monitoring every 6 weeks	2	Sham training with no load	2	26	Individual
Ringbaek 2000[226]	PR – education and exercise: 2 hours 2× per week	5	Control: conventional community care	0	8	Group
Romagnoli 2006[244]	Two repeat PR programmes of 18 sessions each	4	One repeat PR programme of 18 sessions	4	52	Group
Rooyackers 2003[187]	Inpatient programme: general exercise training (20 minutes) plus eccentric cycle exercise training (15 minutes), 5 days per week	1	Inpatient programme: general exercise training (20 minutes) 5 days per week	1	10	Group
Sassi-Dambron 1995[134]	Weekly group sessions focusing on strategies to manage dyspnoea	4	Six weekly educational sessions not related to COPD	3	6	Group
Scherer 2000[258]	Respiratory muscle endurance training through portable device (using nose clip): 15 minutes, 2× per day, 5× per week, 8 weeks	1	Sham breathing training through incentive spirometer: 15 minutes, 2× per day, 5× per week, 8 weeks	1	8	Individual
Sewell 2005[152]	PR: 2× per week; 1 hour exercise, 1 hour education, daily home walking plus individualised supervised strengthening exercises × 10 and unsupervised home exercise	8	PR 2× per week; 1 hour exercise, 1 hour education, daily home walking plus functional exercise programme based on ADL × 10 and unsupervised at home	8	7	Mixed
Sewell 2006[153]	PR: rolling programme of 14 sessions: relaxation, disease education, chest clearance, etc., plus home exercise programme; 2 hours (1 hour supervised exercise and 1 hour education), 2× per week	8	PR: rolling programme of 14 sessions: relaxation, disease education, chest clearance, etc., plus home exercise programme; 2 hours (1 hour supervised exercise and 1 hour education), 2× per week	8	7	Group
Seymour 2010[154]	PR commencing 1 week post discharge – 2 × 2-hour exercise and education sessions/week	2	UC	1	8	Group
Shao 2003[202]	Rehabilitation behavioural intervention consisting of psychological, somatic and lifestyle interventions	5	Control	0	52	Mixed
Simpson 1992[135]	Weight training: 3× per week	2	Control: no intervention	0	8	Unclear
Singh 2003[241]	Home-based PR: breathing techniques, controlled coughing, energy conservation and walking: 1 hour per day	4	UC	0	4	Individual

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Sívori 1998[263]	Lower limb training: 75% max. capacity ergocycling 45 minutes, 3× per week for 8 weeks Plus upper limb training exercises: five different exercises with ball, bags of sand or wooden bars. 45 minutes' exercise 3× per week for 8 weeks: 24 sessions total Plus respiratory exercises	1	Lower limb training: 75% max. capacity ergocycling 45 minutes, 3× per week for 8 weeks	1	8	Group
Smith 1999[168]	Home-based nursing intervention: case conference between primary and secondary health-care team, home review, visits by specialist nurse every 2–4 weeks, addressed education, fitness advice and early identification of exacerbations	7	UC	1	52	Individual
Soler 2006[180]	Specific programme: monthly clinical visits to specialised clinic and short educational programme; nurse-led group education; an information session for patients and families also provided	6	Conventional management	4	52	Group
Solomon 1998, Gourley 1998[136,285]	Pharmacist intervention – patient assessment, therapeutic and educational interventions, collaboration with health-care team, patient follow-up through clinic visits or telephone follow-up	3	Control	0	26	Individual
Spencer 2010[169]	Supervised outpatient exercise 1 hour 1× per week plus unsupervised exercise 1 hour × 4 days (walking plus strength exercises)	1	Unsupervised exercise 1 hour × 5 days (walking plus strength exercises), booklet and diary	1	52	Group
Spruit 2002[247]	Supervised endurance training at outpatient department: 90 minutes 3× per week	1	Supervised resistance training at outpatient department: 90 minutes 3× per week	1	12	Unclear
Sridhar 2008[155]	PR 2 hours 2× per week for 4 weeks; followed by supported SM by nurse, monthly telephone, and home visit every 3 months	7	PR: 2 hours 2× per week for 4 weeks	4	104	Mixed

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Stulbarg 2002, Carrieri-Kohlman 2005, Davis 2006[137,394,395]	(1) Dyspnoea SM programme (as control) and training: 24 × 30 minutes' nurse-coached treadmill exercise sessions;	6	Dyspnoea SM programme: 3 hours' individualised dyspnoea SM education over four sessions plus manual, walking prescription, pedometer and instructions to exercise at home for 20 minutes 4× per week	6	8	Unclear
	(2) dyspnoea SM programme (as control) and exposure: 4 × 30 minutes' nurse-coached treadmill exercise sessions	6				
Subin 2010[242]	Exercise training: 5× per week		Upper limb exercise training 5× per week	2	4	Unclear
	(1) Upper and lower limbs; (2) lower limbs	2, 2				
Theander 2009[220]	PR programme: physiotherapist, dietitian (3×), occupational therapist (3×), nurse (2×); 1 hour, 2 days per week	8	UC	0	12	Group
Toshima 1990, Ries 1995[138,276]	Comprehensive PR programme: education, breathing techniques, psychosocial support and exercise, 12 sessions	12	Educational control programme – did not include exercise or behavioural elements or individualised instruction, four fortnightly sessions	4	8	Group
Trappenburg 2011[188]	Individualised action plan: consultation with nurse case manager, telephone follow-up at 1 and 4 months	9	UC plus consultation with nurse case manager	7	17	Individual
Troosters 2000[248]	Exercise training programme: 1.5 hours 3× per week for 3 months, reducing to 2× per week for the next 3 months	1	Usual medical care	0	26	Unclear
Van Gestel 2012[208]	Exercise training plus respiratory feedback training (daily practice of controlled breathing) – 1.5 hours, 3× per week for 3–4 weeks	2	Exercise training: 1.5 hours, 3× per week for 3–4 weeks	1	4	Unclear
Vogiatzis 2002[265]	PR including supervised interval training: cycling 40 minutes per day, 2× per week in supervised groups	7	PR including supervised continuous training: cycling 40 minutes per day, 2× per week in supervised groups	7	12	Group
Vonbank 2012[246]	(1) Strength and endurance training: 2× per week;	1	Strength training: 2× per week	1	12	Unclear
	(2) endurance training, building up to 60 minutes 2× per week	1				
Wadell 2004[221]	(1) Physical aerobic training in water: 45 minutes 3× per week;	1	Control	0	12	Group
	(2) physical aerobic training on land 45 minutes, 3× per week	1

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Wakabayashi 2011[262]	Integrated care: 6 × 30 minutes' individual tailored education	8	UC: standard education	7	26	Individual
Wang 2004[203]	Resistance abdominal breathing exercises: 15–30 minutes, 2× per day	2	Control: simple abdominal breathing exercise	1	13	Individual
Warlies 2006[209]	Specific education programme: Usually 2 × 3 hours week-days or 2 hours on a week-day and 4 hours on Saturday Telephone hotline available after completion of the sessions Materials included brochures, diary, inhalers, peak flow meters, anatomical models	1	Routine advice (approximately 15 minutes) by practice nurse on use of inhalers, description of medication plan, self-help strategies, advice on smoking, explanation of breathing apparatus	4	26	Group
Waterhouse 2010[277]	Hospital rehabilitation: 2 hours 2× per week Half received telephone support: months 3, 4, 5, 6, 9, 12, 15	5	Community rehabilitation: 2 hours 2× per week Half received telephone support: months 3, 4, 5, 6, 9, 12, 15	5	6	Group
Watson 1997[231]	Action plan and booklet from primary care nurse plus antibiotic and prednisolone from GP	2	UC	0	1	Individual
Wedzicha 1998[157]	Exercise training and education programme: 2× per week	10	Education programme: 2× per week	9	8	Unclear
Weekes 2009[158]	Leaflet of nourishing snacks, drinks and food fortification; dietary counselling provided dietitian and supply of milk powder	1	Control: leaflet of nourishing snacks, drinks and food fortification with no discussion	1	26	Individual
White 2002[159]	PR programme with exercise and education: 2 hours 2× per week	9	Individual 1-hour educational session with booklet and exercise advice; advised 30 minutes' exercise 4× per week	9	6	Group
Wijkstra 1994[189]	Visit to physiotherapist 2× per week for exercise, plus twice daily practice; monthly home visit by nurse for education and SM strategies'; monthly visit to GP	6	Control group	0	12	Individual
Wijkstra 1995[190]	Weeks 1–12: 30 minutes' exercise at outpatient department physiotherapist 2× per week plus monthly coaching by GP and nurse; (1) weekly physiotherapy; (2) monthly physiotherapy	7	No rehabilitation	0	78	Individual

Author year	Intervention description	Number of components	Control description	Number of components	Intervention length (weeks)	Mode
Wittmann 2007[210]	As control group, with an additional component of behaviour training in group setting: 90 minutes, 4× per week; discussion with doctor to establish action plan for emergency situations: 30–60 minutes	10	Inpatient rehabilitation programme – including tailoring of medication, learning correct inhaler techniques, physical training, breathing and SM techniques; if necessary smoking cessation support, psychological help, nutritional advice	7	3	Group
Wong 2005[74]	Nurse-initiated telephone follow-up to increase self-efficacy: two telephone calls (weeks 1 and 3)	2	UC	0	3	Individual
Wood-Baker 2006[170]	Information booklet and individual exercise session with specialist nurse, plus SM plan with action plan based on early recognition exacerbation	12	Information booklet and individual exercise session with specialist nurse plus UC	11	1	Individual
Wright 2003[211]	Resistance training – muscle habituation: 2 weeks; hypertrophic training: 5 weeks each, 2× then 3× per week, 60 minutes then 120 minutes	2	Control	0	12	Group
Xu 2010[204]	(1) Integrative rehabilitation (traditional and modern) – qigong, diaphragmatic breathing, PLB, upper and lower limb training;	3	UC	0	52	Individual
	(2) modern rehabilitation – diaphragmatic breathing, PLB, upper and lower limb training;	2				
	and (3) traditional rehabilitation and qigong	2				
Yamaguti 2012[235]	Diaphragmatic breathing training programme: 45 minutes 3× per week supervised by physiotherapist	1	UC	0	4	Individual
Yeh 2010[139]	T'ai chi – warm-up exercise, five simplified t'ai chi movements and meditative breathing all delivered by two certified and experienced instructors: 1 hour, 2× per week; 35 minutes' instructional video to take home and practice at least 3× per week	3	UC	1	12	Group
Zhang 2008[205]	PR 15 minutes, 3× per day: (1) PR with PLB; (2) PR	22	No PR	0	8	Unclear

ADL, activities of daily living; ICT, information communication technology; MBBT, mind–body breathing therapy; PLB, pursed lip breathing.

Appendix 26 Risk of bias assessment for all included studies with primary outcomes: review 4

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Aimonino Ricauda 2008[75]	LOW Computer-generated random numbers	LOW Sealed numbered envelopes	HRQoL: HIGH Hospital admission: UNCLEAR Method not stated	LOW ITT analysis 23% dropout – balanced in number and similar reasons between groups No comment on the baseline characteristics of dropouts vs. completers but only 3% lost to follow-up – remainder were deaths	UNCLEAR No protocol	HIGH Baseline data provided for all participants Gender and percentage on home oxygen imbalanced was between groups – the home oxygen use was greater in the intervention group
Arnardottir 2006[216]	UNCLEAR 'Blindly randomised in block of 4'	LOW 'Blindly randomised'	HIGH 'Self-administered questionnaires'	UNCLEAR Withdrawals reported, but no ITT	LOW All outcomes reported	UNCLEAR Very small sample Baseline line differences for rate of perceived exertion and 12-MWD
Arnardottir 2007[217]	UNCLEAR 'Stratified according to disease severity . . . randomised into blocks of 4'	UNCLEAR 'Closed envelope method'	HRQoL: HIGH	HIGH 40% loss to follow-up – higher functional/residual capacity and lung capacity = more severe disease; no other differences in dropouts; reasons given for dropouts but no numbers per arm	LOW	HIGH No description of baseline characteristics of those lost to follow-up

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Barakat 2008[249]	LOW Randomisation was in blocks of 10, using random numbers	UNCLEAR Not mentioned	HRQoL: HIGH	LOW SGRQ 9/80 missing; provided reasons for dropouts, equal numbers per arm	UNCLEAR	HIGH 'Excluded' participants from analysis after randomisation, including 2/40 who did not adhere to rehabilitation programme Some imbalance in FVC at baseline: 86.1 (17.8) vs. 78.7 (5.5)
Bauldoff 2002[108]	UNCLEAR	UNCLEAR	HRQoL: HIGH	UNCLEAR Mean data given only for outcomes therefore no details on '*n*'; it could be assumed that there was complete follow-up	UNCLEAR HRQoL mentioned in methods and reported in results	UNCLEAR Baseline characteristics seem balanced, (age imbalance, $p < 0.05$ but values not stated); gender not mentioned
Bauldoff 2005[109]	UNCLEAR	UNCLEAR Not clear when allocated to intervention	UNCLEAR No mention	LOW All subjects accounted for	LOW No study protocol but report includes all outcomes	LOW
Beckerman 2005[253]	LOW 'The patients were randomised using a random numbers table into two groups'	UNCLEAR NR	HRQoL: LOW Sham training intervention is control; mode of data collection not reported but blinded assessor Hospital admission/ length of stay: LOW Self-reported but reported on daily by blinded assessor telephone call	HIGH Dropouts – more from control group dropped out and more deaths in control group (2 vs. 4) Characteristics of dropouts not described	UNCLEAR No protocol	LOW Well-matched baseline with all participants reported No discussion of limitations in discussion

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Behnke 2000[64]	UNCLEAR	UNCLEAR	HRQoL: HIGH Questionnaires unblinded	HIGH 16/46 dropped out – 8 from each group; reasons given for each and fairly similar but small numbers; possible that exacerbation may be more of a reason for dropout in the control group; no comparison of those who drop out with those who complete	UNCLEAR HRQoL reported in methods and results	HIGH Baseline data/demographics only given only for completers; seems balanced
Behnke 2003[65]	UNCLEAR Stated randomised, no method given	UNCLEAR	HRQoL: LOW Self-reported intervention vs. UC control Hospital admissions: LOW Exacerbations: LOW	UNCLEAR Only 26 of the 30 previously recruited patients took part in this follow-up study – no reasons given for the dropouts Is an ITT analysis of the 26 patients	UNCLEAR No protocol	HIGH Baseline reported for all 26 patients (but not the 30 previous trial completers) Intervention group average age 5 years younger
Bendstrup 1997[222]	UNCLEAR	UNCLEAR	HRQoL: HIGH Comments indicate that patients were not blind as control group told would get intervention at end of study if it proved effective	HIGH Only 32/47 randomised patients completed Reasons for dropouts stated but not clear for 5/15 dropouts to which group they belonged; four dropped out of intervention and five from control; small number but similar reason	UNCLEAR Method = results section	HIGH Demographics supplied for only those who completed the intervention in each arm Appear balanced but small numbers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Bernard 1999[191]	UNCLEAR	UNCLEAR	HRQoL: HIGH	UNCLEAR 4/19 and 5/26 failed to complete, reasons given but not by group; no comparison with completers	UNCLEAR HRQoL mentioned in the methods and results	HIGH Baseline data only for completers Fairly well balanced Baseline HRQoL not reported; only comparisons of change in each group
Berry 2010[110]	LOW 'Randomisation was performed using a web-based randomisation application'; 'stratified by gender and study period'. Block sizes varied randomly between 4 and 6	LOW 'Only the statisticians were unblinded to the randomisation scheme'	HRQoL: HIGH	Lifestyle activity programme: 24/87 dropped out; traditional exercise therapy: 20/89 Details of reasons for dropout were provided by study group; higher dropouts were due to medical condition in traditional exercise therapy than lifestyle activity programme (6 vs. 2) 'The dropouts were significantly younger and there were a relatively low percentage with comorbid illness'	UNCLEAR	LOW
Bestall 2003[141]	LOW 'Randomisation sequence was computer generated'	UNCLEAR Blocks of eight in sealed envelopes	HRQoL: HIGH	LOW All patients accounted for	LOW All outcomes reported	LOW Baseline balanced

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Bjornshave 2005[223]	UNCLEAR 'After inclusion, the patients were randomised' (p. 103)	UNCLEAR Timing of randomisation is unclear	No information on who performed tests and whether blinded HRQoL: HIGH	HIGH Withdrawals reported – slightly higher in intervention group However, dropouts were excluded in analysis; no imputation or baseline observation carried forward	LOW All prespecified outcomes reported	UNCLEAR None – no adjustments for sex or baseline FEV_1, which differed at baseline – but small numbers and baseline differences not statistically significant
Blake Jr 1990[111]	UNCLEAR Stated randomised but no method detailed	UNCLEAR NR	HRQoL: HIGH Self-reported intervention vs. UC control Admissions: LOW Self-reported at monthly intervals	UNCLEAR ITT analysis < 10% dropout/incomplete data No comparison of those with incomplete data/ attendance with those with complete data/attendance	UNCLEAR No protocol	HIGH Baseline characteristics reported for all participants; unbalanced HRQoL 11.3 vs. 14.4, intervention vs. control Intervention group more educated (40% beyond high school vs. 22%)
Bonilha 2009[232]	UNCLEAR 'The volunteers were then randomised to a Singing Group or to a Control Group' No information on method of randomisation	UNCLEAR	HRQoL: LOW Self-completed comparison of interventions (singing vs. handcrafts) No mention of single blinding of outcome assessors	HIGH ITT analysis – NR Characteristics of patients who dropped out not discussed 30% overall dropout rate (25% from control group, 34% from intervention) Similar reasons and proportions of dropout from each group Characteristics of patients who dropped out not discussed	UNCLEAR No protocol	HIGH Baseline only reported for trial completers Difference in HRQoL at baseline between groups – 10 points on the SGRQ Current smokers excluded

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Bourbeau 2003[192]	LOW 'Patients underwent randomisation with the use of a central computer-generated list of random numbers'	LOW Central allocation in blocks	Independent evaluator HRQoL: HIGH Admissions: LOW Exacerbations: LOW	LOW All patients accounted for; dropout slightly higher in control	LOW All outcomes reported	LOW Baseline balanced
Gadoury 2005[271]	UNCLEAR 'Randomly assigned'	UNCLEAR	LOW Patients unblinded, but outcome data from hospital and insurance database	LOW Withdrawals reported, and ITT performed	LOW All outcomes reported	UNCLEAR Protocol only adhered to strictly for year 1; case manager available for some subjects
Boxall 2005[160]	LOW Computer-generated random numbers	UNCLEAR Coded into opaque envelopes by person blinded	'Neither assessors or patients were blinded' HRQoL: HIGH Admissions: LOW	UNCLEAR Withdrawals reported, but no ITT	LOW All outcomes reported	LOW
Breyer 2010[245]	LOW 'Randomisation . . . was done by a computer-generated algorithm . . .'	UNCLEAR	HRQoL: HIGH	HIGH No ITT analysis Very low dropout rate – 7.6% but no reports of characteristics of dropouts Similar dropout rate for both intervention and control groups But dropout from intervention due to exacerbation; dropout from control as a result of loss to follow-up	LOW Protocol available	HIGH Retired patients or on sick leave? Highly motivated patients – note low dropout Baseline well matched but only reported for trial completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Brooks 2002[193]	LOW Random numbers table	UNCLEAR	HRQoL: HIGH Intervention vs. UC	UNCLEAR Appears to be ITT analysis Similar proportions of dropouts – reasons not detailed Stated no differences in baseline characteristics between groups and details reported	UNCLEAR No protocol	LOW Baseline characteristics reported for all patients
Bucknall 2012[63]	LOW 'We used a minimisation technique to stratify randomisation of participants by demographic factors . . . We constructed a computer-generated sequence by using the method of randomised permuted blocks of length four, with two allocations being made at random and two by minimisation'	LOW 'The researcher did not know whether a participant was being allocated at random or by minimisation and could therefore not determine the next treatment allocation before enrolling each participant'	HRQoL: HIGH Hospital admissions: LOW 'The study team were blind to information on hospital admissions when these classifications were made' 'Participants received monthly telephone calls from an independent researcher, blinded to the patients' randomisation status, to collect information on health service usage and exacerbations'	HRQoL: HIGH Self-completed questionnaires with only 61% returned – failure to complete associated with sicker, more depressed and lower self-efficacy Time to admission or death: LOW 11% dropout rate (low) – but more withdrawals from the control group, – 21 vs. 32 Similar and small (three and four, respectively) numbers lost to follow-up in each treatment group ITT analysis of primary outcome (readmission or death)	UNCLEAR Protocol available Additional subgroup analyses were added during the trial 'Within the first few months, we realised that some participants accepted self-management more readily than others. Therefore, as participants in the intervention group completed their 12-month period of follow-up, we classified them as either a "successful self-manager" or not after case based review by the study team'	UNCLEAR Well matched at baseline across all characteristics Low recruitment rate (47%), but similar recruitment rate to other trials in this field; intervention required high level of commitment so non-participants may not have benefited from the intervention Those who declined more deprived residence area

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Busch 1988[194]	UNCLEAR 'Assigned patients by stratified random sampling to either the control group or exercise group'	UNCLEAR	HRQoL: HIGH	HIGH 20 random 10 : 10; 14 follow-up 7 : 7 Reasons for dropouts documented	UNCLEAR All outcomes in methods reported in results	HIGH Patients excluded from follow-up in exercise group if they did not adhere to exercise regime ($n = 3$); control group if they exercise $n = 2$ Baseline data given for only 14 patients followed up
Cai 2006[199]	Randomly	NR	HIGH			
Carr 2009[195]	UNCLEAR States randomised but randomisation methods not reported	UNCLEAR	Investigator responsible for collection outcome measure data not aware of group allocation HRQoL: HIGH Interviewer delivered CRQ but intervention vs. UC	HIGH Five dropouts due to acute exacerbation 85% completion Report on the characteristics of withdrawn patients – less dyspnoea otherwise similar to completers – no quantification of degree of difference ITT analysis – NR	UNCLEAR No protocol	HIGH 'Comorbidities that might adversely affect outcome measures' excluded – not clear what these are Acute exacerbation removed from follow-up Baseline differences 12% and 24%, respectively, on oxygen in intervention vs. control group – 53% vs. 35% male in intervention vs. control Baseline reported for all completers but only for all participants who did not have an intervening AECOPD between recruitment/baseline and randomisation

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Casas 2006[71]	LOW Computer-generated randomisation	UNCLEAR NR	HRQoL: HIGH Self-reported comparison of intervention vs. UC control Hospital admissions: LOW from records	LOW ITT analysis Similar drop-out rate and reasons between arms 20–26% drop-out rate with death responsible for 17%	UNCLEAR No protocol	UNCLEAR Baseline reported for all patients Gender imbalance (12% vs. 23% female) Difference between type of intervention at the two study sites – GP home visits in Germany; nurse, social worker and physician in Spain
Garcia-Aymerich 2007[72]	LOW 'Assigned using computer-generated random numbers'	LOW 'Blindly assigned'	HRQoL: HIGH Health-care resource use: LOW	HIGH Follow-up intervention 53% Loss to follow-up 3% Follow-up control 60% Loss to follow-up 13% Imbalance in loss to follow-up, high loss	LOW	LOW
Chan 2010[212]	LOW Computer-generated randomisation	UNCLEAR NR	HRQoL: UNCLEAR	LOW ITT analysis; 23% dropout Reasons for dropout similar between groups except loss of interest higher in breathing/exercise group	UNCLEAR No protocol	UNCLEAR Baseline reported for a wide range of characteristics for all participants and gender differences controlled for in analysis

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Chan 2011[272]	LOW Random allocation was done using a randomiser software[21] Both the total number of subjects and number of groups were entered into the computer randomiser, which then generated the random assignment of subjects; this step helped avoid yielding a highly disparate sample size in the study groups; instead, it preserved many positive attributes of simple randomisation	UNCLEAR	Exacerbations: LOW 'The number of COPD exacerbations and hospital admissions during the preceding 6 weeks period was recorded' This study utilised a single-blind, RCT. The research assistants for data collection were blinded to minimise researcher bias	HIGH Overall dropout rate > 10% Total dropout rate = 23% With differences in dropout rates between groups: • 28% control • 14% t'ai chi group • 28% plain exercise	UNCLEAR No protocol	UNCLEAR Very few female patients overall Age: t'ai chi group older average age 69 years vs. 58 years for control and 61 for exercise – also fewer current smokers in t'ai chi group: 17.1% vs. 23.2% vs. 22.4%
Cockcroft 1987[142]	UNCLEAR States randomised but no method described	UNCLEAR NR	HRQoL: HIGH Self-reported intervention vs. UC control Admissions: LOW from records	LOW Low dropout ($n = 2$) from ($n = 75$) sample Not stated as ITT analysis and no comparison of dropouts vs. trial completers, but very low dropout	UNCLEAR No protocol	UNCLEAR Baseline data reported for all participants; limited range of variables reported; well-balanced baseline
Coultas 2005[112]	LOW 'Selected from electronic claims database' 'Computer-generated random list'	UNCLEAR	HRQoL: HIGH 'Self-report health care utilisation' 'Assessors of health care outcomes were blinded'	UNCLEAR Withdrawals reported, but no ITT	LOW All outcomes reported	UNCLEAR Underpowered Baseline line differences for gender

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Covey 2001[113]	UNCLEAR Stated randomised But no details	UNCLEAR NR	HRQoL: LOW Control group is educational intervention Patients blinded to previous responses Stated single blinded	HIGH ITT analysis not reported – appears not to be according to results Larger dropout from IMT group (7 vs. 3) 'Sample characteristics for patients who completed the study and those who did not complete the study were not significantly different' but no detail of this	UNCLEAR NR	HIGH Baseline reported for only the completers BMI higher in educational intervention group Smoking status – NR
de Blok 2006[181]	UNCLEAR 'Randomly assigned'	UNCLEAR	HIGH 'Clinical staff blinded for group assessment'	UNCLEAR Withdrawals reported but no ITT	LOW All outcomes reported	UNCLEAR Very small sample
Dheda 2004[73]	HIGH Stated randomised, no methods described	UNCLEAR NR	HRQoL: HIGH Self-reported UC vs. intervention	UNCLEAR ITT analysis not reported; no comparison of characteristics of dropouts vs. trial completers	UNCLEAR No protocol	UNCLEAR Not clear if baseline reported for all participants or just trial completers; limited range of variables reported at baseline $n = 25$ at completion

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Donesky-Cuenco 2009[114]	UNCLEAR 'Forty-one (41) patients were randomly assigned to the Yoga group or to the UC group' No details of method for assigning	UNCLEAR	HRQoL: HIGH Self-reported Blinding not referred to except – 'Patients were asked about their satisfaction and experiences with the programme during individual exit interviews, which were conducted by the PI, who was not involved with the study operations'	UNCLEAR ITT analysis – stated ITT analysis in flow diagram but numbers stated do not indicate ITT Dropout rate identical, similar reasons – 71% follow-up, all dropouts reported and characteristics compared	No protocol	HIGH Baseline data only reported for trial completers Baseline differences between treatment group and controls – oxygen use higher in treatment group (29% vs. 6%) also mean age higher (4 years older)
Dourado 2009[233]	UNCLEAR 'In groups of 3, patients were randomly assigned to one of the training modalities . . .' No comment on mode of randomisation	UNCLEAR	HRQoL: LOW Self-completed questionnaires and comparison of intervention	HIGH ITT analysis – NR Approximately 25% dropout rate – variable between groups Detail of reasons for dropout provided for only the whole study cohort, not by group 'However, comparisons of these patients (dropouts) with those completing the programs did not show significant differences at baseline' No other details	UNCLEAR No protocol	HIGH $n = 35$ but three groups, so each only small Baseline differences Baseline only reported for completing participants

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
du Moulin 2009[206]	LOW For randomisation purposes, we prepared 20 envelopes, 10 with a plus, indicating intervention group, and 10 with a minus, indicating control group; patients drew these envelopes themselves; if this was not possible, a third person not involved in the study randomised the patient	UNCLEAR Opaque envelopes	HRQoL: HIGH Self-completion with assistance if required Intervention vs. normal care	HIGH ITT analysis Large dropout rate – but balance between two groups and different reasons for dropout No comparison of the characteristics of dropout vs. completers	UNCLEAR No protocol	HIGH Very small study size $n = 20$ with 40% dropout Baseline reported for all patients Average age 5 years younger and 20% more smokers in intervention group
Eaton 2009[227]	LOW 'Randomised . . . using computer-generated randomisation'	UNCLEAR 'Computer-generated randomisation with the allocation being concealed until the intervention was assigned' No details about how	HRQoL: HIGH Intervention vs. UC 'The nature of the intervention precluded blinding of participants and health-care providers' Hospital readmission: LOW 'Data were obtained from hospital and primary health-care records and were reconciled with patient home diary records by assessors blinded to the intervention allocation'	HIGH 'Both intention-to-treat and per-protocol analyses are reported' 82 vs. 90% follow-up intervention vs. control 'There were no significant differences in baseline characteristics between attendees and non-attendees' But not detailed	LOW The study was registered prospectively with the Australian Clinical Trials Registry (ACTRNO12605000372684)	HIGH Baseline: 9% fewer current smokers in intervention group and lower total pack-years (by 5 years) – also more European patients in intervention group (83 vs. 68%)

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Effing 2009[161]	LOW Minimisation programme	UNCLEAR	HRQoL: LOW Self-reported, comparison of two interventions Hospital admission Not entirely clear how these data were collected? From records or from diaries? Exacerbations: LOW Data collected from patient diaries but very clearly defined criteria	UNCLEAR ITT analysis done but only after baseline measurement and substantial number of dropouts between randomisation and baseline measurement Imbalance between numbers and reasons for dropout – more dropouts for lack of motivation in self-treatment group Limited comparison between baseline characteristics of dropouts vs. completers – dropouts less dyspnoeic	UNCLEAR No protocol	UNCLEAR Baseline data reported for all patients but note only limited range of variables reported and substantial number of dropouts after randomisation and before baseline measurements Exacerbations clearly defined as negative change in two major symptoms with duration also clearly defined
Effing 2011[278]	LOW 'Patients were randomised into two study groups, using a minimisation programme, nine minimising differences between groups in gender, current smoking, FEV_1 predicted (or > 50%), use of inhaled corticosteroid, and current participation in a regular physiotherapy programme'	UNCLEAR	HRQoL: HIGH Self-completed questionnaire	HIGH ITT analysis done but no reporting on baseline characteristics of dropouts Low dropout rate of 8 (10.5%) Withdrawals from the control group and only three (4%) from treatment group – lost to follow-up/failure to return only in the control group, but total lost to follow-up only 7% Identical and low numbers of deaths	UNCLEAR No protocol	HIGH Baseline variation between groups in ISWT and endurance walking test – intervention group longer distance

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Efraimsson 2008[218]	LOW Matched pairs, independent person drew lots for allocation of either intervention or control	UNCLEAR	HRQoL: HIGH By questionnaire in undisturbed area of clinic, nurse available to answer questions and check patients had responded to all items	UNCLEAR 100% follow-up in tables, yet says 'the dropout rate' was 10 patients, may refer to eligible patients not recruited	UNCLEAR	LOW
Egan 2002[69]	LOW Random number tables	UNCLEAR NR	HRQoL: HIGH Intervention vs. UC control – not entirely clear if control is UC; however, significantly different level of clinical input between intervention and control group	HIGH Dropout rate not balanced between groups (24% from control; 15% from intervention). Reasons not listed for withdrawal and no comparison of characteristics No ITT analysis	UNCLEAR No protocol	HIGH Baseline data listed for all participants Marked gender imbalance between groups – 60% vs. 30% male, intervention vs. control Also variation in income levels Inclusion criteria includes chronic asthma – diagnosis not listed in baseline data
Elci 2008[236]	LOW Randomly allocated using number tables	UNCLEAR	HRQoL: HIGH	LOW Loss to follow-up 15.4%, equal in each arm No description of *n* by outcome	LOW	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Elliott 2004[162]	UNCLEAR Randomly assigned	UNCLEAR No mention of when measures undertaken in relation to randomisation	HIGH No mention of blinding – unsure who undertook measures	LOW Outcome data reported only on completed; no baseline measure carried forward or imputation; but no systematic difference in withdrawals by group (73% complete in intervention vs. 69% in control) Reason for withdrawal described (table 4)	LOW All outcomes reported	LOW
Emery 1998[115]	LOW 'Patients were randomised to one of three groups … Group assignments were taken from a random number schedule, printed on a piece of paper, and placed in a sealed envelope'	LOW 'Participants were not given the envelope containing their group assignment until after completing the baseline assessment, and technical staff conducting the assessments were not aware of group assignments'	HRQoL: HIGH Using self-reported, validated questionnaire	LOW 79 randomised with 6/79 (7.6%) dropouts, which were all reasoned Group A: 4/29 (illness) Group B: 2/25 (transport issues) Group C: no dropouts Differences between completers vs. dropouts assessed	UNCLEAR Outcomes measures in methods section reported in results section	LOW Baseline data reported for all patients randomised; any baseline imbalances made explicit in text
Engstrom 1999[219]	UNCLEAR	UNCLEAR	HIGH	UNCLEAR 2/28 control plus 3/27 dropped out; reasons were given; no comparisons between dropouts and completers undertaken	UNCLEAR HRQoL (SGRQ and generic) mentioned in methods and results	HIGH Baseline data given for only those followed up; fairly balanced

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Fernandez 2009[171]	UNCLEAR Randomised by block allocation but no indication of how	UNCLEAR	No direct comment on blinding for any of the outcomes HRQoL: UNCLEAR Self-completed questionnaire of intervention vs. normal care	HIGH ITT analysis – NR 84% follow-up Similar dropout numbers Three refused from intervention, one refused in control No comment on characteristics of dropouts	UNCLEAR No protocol	HIGH No female patients but baseline well matched; however, only reported for those who completed the study Control group approximately half of the size of the intervention group
Finnerty 2001[143]	LOW 'In blocks of 10 using random numbers'	UNCLEAR	HRQoL: HIGH Patient completed but supervised by a blinded observer	HIGH Many patients failed to attend assessment at baseline after randomisation. HRQoL – quality of outcome data plus whether balance between groups depends on time point for assessment	UNCLEAR HRQoL mentioned in method and results	HIGH Demographics not given for all randomised patients at baseline
Foy 2001[116]	UNCLEAR	UNCLEAR	HRQoL: HIGH	14/70 did not complete 18 months of study in short-term intervention arm; 8/70 in the long-term intervention arm; reason not reported No mention of difference between dropouts and completers	UNCLEAR CRQ mentioned in methods and results	LOW Baseline characteristics given for all randomised parts and seem fairly balanced

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Gallefoss 1999[255]	UNCLEAR	UNCLEAR	HRQoL: HIGH	UNCLEAR 4/31 and 5/31 in control and intervention lost to follow-up; two of those in the hospital group were due to hospitalisation; no other details given	UNCLEAR HRQoL (HRQoL, SGRQ) mentioned in methods and results	UNCLEAR Baseline characteristics are fairly balanced except more never smoked in the intervention group [13% ($n = 4$) vs. 0%]
Gallefoss 2000[280]	LOW 'Using random number tables'	UNCLEAR	HRQoL: HIGH Self-reported hospitalisations: LOW	UNCLEAR Dropouts of patients with COPD were similar between groups: 4/31 and 5/31. Two of the control patients dropped out due to exacerbations but none in the intervention group	UNCLEAR Hospitalisation appears presented as expected. Was HRQoL measured at baseline? (Appears not.) HRQoL data appear to be presented only as a relationship with hospitalisations/GP visits	LOW Baseline data for patients with COPD only appears balanced for the variables tabulated Demographics are presented for all patients at baseline
Gallefoss 2002[391]	LOW Random number table	UNCLEAR	Hospital admission: LOW Self-reported and checked against hospital records Exacerbations: LOW Measured by use and prescribing of rescue medications from pharmacy records	No ITT analysis Low dropout 13% Balanced number and reasons between groups	UNCLEAR No protocol	LOW Baseline reported for all patients – well balanced and good range of characteristic reported, not BMI
Gallefoss 2004[281]	UNCLEAR Randomly assigned	UNCLEAR No mention	UNCLEAR No mention; unlikely to affect results	LOW Withdrawals discussed; no different in withdrawal by group; no imputation	LOW All outcomes reported	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Ghanem 2010[264]	UNCLEAR 'Randomly allocated' – no details given	UNCLEAR No details given	HRQoL: HIGH 'It was not possible to blind patients or assessors'	LOW No loss to follow-up at 2 months follow-up	UNCLEAR	HIGH Large baseline difference in urban/rural residence; high proportion of those not allocated to rehabilitation were 'rural' 86% vs. 56% Considerable baseline difference in 'respiratory failure', more control group had respiratory failure: 72 vs. 43%
Gilmore 2010[117]	LOW Randomly drawn cards in blocks of four	UNCLEAR Allocation concealment – NR	States non-blinded HRQoL: HIGH Not self-completed (read aloud to participants) Four intervention groups – three intervention variants and one UC control	HIGH 27% dropout Reasons for dropouts not reported by group in text Home visit group appears to have higher dropouts Comparison of characteristics of completers with recruits given	UNCLEAR No protocol	UNCLEAR Baseline reported for all and for all completers But baseline comparison between groups reported for only the completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Gohl 2006[207]	Patients were randomised ('lottery'); no further details	UNCLEAR No details	No details	7/17 dropouts in intervention group [two, peripheral arterial disease; one shoulder fracture; one prostate cancer, exacerbation due to infection during main training period (1) or during final assessment period (2)] 8/17 dropouts in control group (two, bereavement; two peripheral arterial disease; two exacerbation due to infection during final assessment period; two non-compliance) No details on differences between patients dropping out or remaining in study	No obvious selective reporting; all outcomes mentioned in methods also reported in results section	Reasons for dropouts described as atypical for this patient population
Goldstein 1994[196]	UNCLEAR Randomised, stratified by 6-MWD	UNCLEAR No details	HRQoL: HIGH	HIGH Follow-up: 78/89 Intervention dropouts 7/45; control 4/44 Details not provided by study arm	UNCLEAR	HIGH Baseline imbalances in sex, number living alone, years since cessation of smoking and number receiving supplementary oxygen
Gourley 1998[286]	UNCLEAR Stated randomised but not methods described	UNCLEAR NR	HRQoL: HIGH Intervention vs. control, which differs markedly in degree of contact	HIGH Total recruitment, follow-up not reported, reported only elsewhere Not ITT analysis	UNCLEAR No protocol	HIGH No baseline data given in this paper; however, reported elsewhere and only for trial completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Guyatt 1999[393]	UNCLEAR Stated randomised, but no detail of method Full method described in Goldstein 1994[196]	UNCLEAR NR	HRQoL: HIGH Self-reported intervention vs. UC control	HIGH 16% vs. 10% dropout in intervention vs. control; reasons for dropout not reported by group ITT – NR No comparison of baseline characteristics of dropouts vs. trial completers	UNCLEAR No protocol	UNCLEAR Baseline reported in Goldstein, 1994;[196] baseline reported for all participants Gender imbalance 57% vs. 43% male in intervention vs. control Baseline HRQoL well balanced
Green 2001[144]	UNCLEAR NR	UNCLEAR Concealed envelopes; envelopes not numbered	HRQoL: LOW Comparison of interventions	Not ITT analysis	UNCLEAR No protocol	HIGH Baseline reported for all participants Mismatched baseline for pack-years (38 vs. 47 in 4-week rehabilitation vs. 7-week rehabilitation); also significant (> 0.5) differences in baseline HRQoL scores
Güell 2000[172]	LOW	HIGH Unconcealed but consecutive patients enrolled	Technical staff blinded No mention of other groups HRQoL: HIGH Questionnaires Admissions: LOW	LOW 7/30 and 6/30 dropped out. Demographic data for completers and dropouts given for both groups for major variables (but not gender)	UNCLEAR HRQoL/exacerbations/ hospitalisations mentioned in methods and given in results	LOW Baseline data given for all patients, not just completers Groups were fairly balanced

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Güell 2006[173]	UNCLEAR 'Unconcealed randomisation' 'Recruitment of consecutive patients'	UNCLEAR 'Not concealed'	HIGH 'Neither patients or clinicians were blinded' 'Technicians who collected data were blinded to allocation'	UNCLEAR Withdrawals reported, but no detail on management of data	LOW All outcomes reported	HIGH Baseline differences for Millon Behavior Health Inventory (MBHI) (*behaviour*) and Revised Symptom Checklist (SCL-90-R) (*symptoms*)
Guyatt 1992[118]	UNCLEAR Randomisation reported but method not described 'Randomisation in sequence'	UNCLEAR Concealment Reported but method not described	HRQoL: LOW Comparison of interventions and blind assessors 'Other study personnel were blind to allocation. Patients were repeatedly instructed not to mention their impressions of the training procedure to their physician or to anyone concerned with the study'	HIGH No ITT analysis 15% dropout (11/74); however, dropout in run-in period due to illness 'too great a commitment' was 30%); different reasons for dropout given between groups and no comparison of characteristics	UNCLEAR No protocol	HIGH Baseline reported for only those who completed the run-in period Smoking status – NR
Hermiz 2002[67]	UNCLEAR *Site 1*: randomised permuted blocks with a block size of four *Site 2*: 'simple randomisation'	UNCLEAR	HRQoL: HIGH All data collected by project officer, including administration of HRQoL measure No mention of blinding	HIGH Loss to follow-up: intervention 8/84, control 3/93 – more withdrew from intervention group	UNCLEAR	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Hernandez 2000[282]	UNCLEAR Stated randomised but no details	UNCLEAR	HRQoL: UNCLEAR Self-reported: was intervention vs. control; however, both groups attended for check up and treatment supervision greater than normal care	HIGH Not clear if ITT analysis as not stated and *n* not given Dropout rate 39% but balanced between groups	UNCLEAR No protocol	UNCLEAR Only a limited range of baseline characteristics reported – unclear if for all patients or only completers Participants were ex-smokers only; no exacerbations during course of study and no comorbidities
Hernandez 2003[68]	LOW 'Blindly assigned using a set of computer-generated random numbers'	UNCLEAR	HRQoL: HIGH Self-reported intervention vs. UC trial Hospital admission: LOW Self-reported with some verified from records Exacerbations: LOW	UNCLEAR Dropout rate not reported except deaths Unclear if ITT analysis as *n* not reported in data	UNCLEAR No protocol	Baseline given for all patients and a good range of characteristics reported 10% more current smokers in intervention group
Hill 2006[163]	LOW Computer-generated random number sequence	UNCLEAR NR	HRQoL: LOW Double-blind, interviewer-administered comparison of intervention and sham intervention	UNCLEAR Low (6%) dropout after randomisation, but dropouts ($n = 2$) from intervention group	UNCLEAR No protocol	HIGH Baseline reported for only trial completers but, as noted, only 6% dropout Baseline well matched except 6-MWT: > 10% further in intervention group

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Holland 2004[164]	UNCLEAR Not described	UNCLEAR Not clear whether baseline measures were taken prior to randomisation	LOW Data collector was blinded to group allocation	LOW All withdrawals accounted for ITT analysis undertaken	LOW All expected outcomes reported	LOW
Hospes 2009[183]	UNCLEAR 'Patients were randomly assigned to an exercise counselling or a UC group' No mention of methods of randomisation	UNCLEAR	HRQoL: HIGH Self-reported but intervention vs. control	HIGH Only 10% dropout and similar between groups Analysis was not ITT analysis	UNCLEAR No protocol	HIGH $N = 40$ but baseline reported for only the completing participants Baseline difference between groups in GOLD stage of COPD (22% stage 1 in intervention group vs. only 6% in control group) Smoking not reported in baseline characteristics
Hsiao 2003[259]	UNCLEAR Method of randomisation not described	UNCLEAR NR	HRQoL: UNCLEAR Interventions and one UC control; no details of blinding/administration	Dropout 12/42 No reported differences in baseline characteristics but no detail given No ITT analysis	UNCLEAR No protocol	HIGH Baseline given for only study completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Hynninen 2010[256]	UNCLEAR Stated randomly assigned in matched pairs but no details on method	LOW Numbered sealed containers, identical in appearance	HRQoL: HIGH	HIGH ITT analysis Overall dropout over 18 months (20%); however; imbalanced dropouts – 30% from control group, 10% from intervention No comparison of characteristics of dropouts vs. trial completers	UNCLEAR No protocol	UNCLEAR Baseline reported for all participants Only a limited range of characteristics reported, but well-matched baseline with exception of mental health diagnosis (40 vs. 50%, intervention vs. control)
Janaudis-Ferreira 2011[197]	UNCLEAR 'Patients were randomly (in blocks of four) assigned to an intervention or control group. Randomisation was stratified according to the presence or absence of the use of supplemental oxygen at rest' No further details	LOW 'The sequence was kept in opaque envelopes by an investigator who was not involved in the recruitment process These envelopes were drawn by the trainer after the subjects had completed their preassessment session, allowing for concealed allocation'	HRQoL: LOW Control group underwent sham exercises The outcome assessor and the patients remained unaware of the group allocation Each patient exercised individually at different times and locations	HIGH No data on characteristics of dropouts 16% lost to follow-up – 2× as many in treatment arm than control arm, but loss to follow-up unrelated to intervention ITT analysis used	UNCLEAR No protocol available	UNCLEAR Baseline characteristics reported for all patients recruited but smoking status not reported
Jang 2006[267]	Tossed coins	UNCLEAR	HIGH			
Jarab 2012[266]	LOW 'Participants were randomly assigned to intervention and control groups via a minimisation technique using MINIM software'	UNCLEAR No details given	HRQoL: HIGH Health-care utilisation: LOW	3/66 intervention and 3/67 control group patients withdrew by 6 months; no details given about reasons	UNCLEAR	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Karapolat 2007[237]	UNCLEAR No detail	UNCLEAR 'Sealed envelopes'	HRQoL: UNCLEAR	LOW Loss to follow-up 1/27 intervention, 3/22 control; no reasons given	UNCLEAR	HIGH Five participants excluded from control group post randomisation 'because they did not satisfy inclusion criteria'
Katiyar 2006[240]	LOW Computer-generated randomisation	UNCLEAR NR	HRQoL: HIGH Supervised self-administered. Intervention vs. UC	HIGH Low dropout 3/24 but not ITT analysis	UNCLEAR No protocol	HIGH Baseline reported for only the completers
Kayahan 2006[238]	UNCLEAR 'Randomised', no details	UNCLEAR	HIGH	UNCLEAR Reported but no reasons given or information on management of data	LOW All outcomes reported	UNCLEAR Small sample
Khdour 2009[251]	LOW Computer-generated minimisation	UNCLEAR	HRQoL: HIGH Self-reported UC vs. intervention Admissions: LOW Patient questionnaires confirmed by hospital records	HIGH No ITT analysis – as per-protocol analysis reported Dropouts, lost to follow-up and death balanced across groups No comparison of characteristics of dropouts vs. completers	UNCLEAR No protocol	LOW Baseline data reported for all participants Good range of variables reported and well balanced across all variables

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Khdour 2011[279]	LOW Minimisation	UNCLEAR	HRQoL: HIGH Self-completed questionnaires (intervention vs. UC) Admissions: LOW Patient records verified from hospital record	HIGH No ITT analysis 27% dropout Balanced numbers and similar reasons for dropout between groups	UNCLEAR No protocol	HIGH No comparison of baseline characteristics of dropouts vs. completers Baseline balanced with the exception of 10% more 'never smokers' in control group
Kim 1993[119]	UNCLEAR	UNCLEAR	'Double-blind' control group received sham intervention HRQoL: LOW	HIGH 129 patients enrolled, 67 'provided 6 months of usable data'; detail provided on loss to follow-up but not by study arm; 17 patients dropped out before randomisation, in 4-week control period before randomisation Follow-up: 41/66 intervention; 26/46 control	UNCLEAR All data on measures in methods were reported in results	HIGH No detail on baseline characteristics of those lost to follow-up

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Ko 2011[213]	LOW 'Subjects were randomised, by random number generator, to receive either PR or UC (UC). A computer programme (allocation by minimisation) was used to assist the randomisation of subjects equally into each group taking into account five factors'	UNCLEAR Not discussed	HRQoL: HIGH Readmission/ exacerbation: LOW From records 'Owing to the nature of the intervention, this was an open study for patients and therapists but the technicians . . . were not involved in the delivery of the PRP and were not aware of the randomisation status'	HIGH ITT analysis At 6 months – loss to follow-up in both arms > 10% 20% and 17% in control and intervention arms, respectively Reasons for non-completion similar across groups No reporting of baseline characteristics of dropouts	LOW Protocol available at www.clinicaltrials.gov NCT00287625 Verified with published protocol all reported	HIGH Includes patients with comorbidities and there are significant differences between the control and the intervention arms (cardiac-related comorbidity 17% in intervention vs. 30% in control group), likely significant given low numbers of participants and only 10% reported improvement in HRQoL at 6 months and nil at 12 months
Koff 2009[120]	Envelopes – not stated shuffled but presumably	UNCLEAR Envelopes – not stated sealed or numbered	HRQoL: HIGH Self-reported but intervention vs. UC control and unblinded	UNCLEAR No ITT analysis Very low drop outs (5% 1 participant from each branch with $n = 40$)	UNCLEAR No protocol	UNCLEAR Baseline reported for all patients and well balanced with the exception of % flu vaccinated (100% vs. 85%) and living alone 15% vs. 30%, both of which may impact on HRQoL
Koppers 2006[184]	UNCLEAR Stated randomised but no details	UNCLEAR NR	HRQoL: LOW Self-completed – blinded assessor control is sham training	HIGH Very low dropout rate – 8%; three participants, same reason (severe exacerbation) Characteristics – NR ITT analysis – NR	UNCLEAR No protocol One of the three study arms was dropped owing to financial reasons	UNCLEAR Baseline – reported for all participants but smoking status not reported

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Kunik 2008[121]	LOW Used 'Statistical Analysis Systems plan procedure to create randomisation list, with blocks of size 2 to provide approximate equal number per class. The statistician provided randomised numbers and treatment codes to the study co-ordinator . . .'	LOW	HRQoL: HIGH	HIGH High loss to follow-up 8 weeks: 63/120 and 60/118 1 year: 56/120 and 52/118 Reasons for dropout not given by arm	UNCLEAR	LOW
Kwok 2004[70]	LOW Random number table	LOW Remote telephone allocation	Readmissions: LOW Verified from electronic hospital records	UNCLEAR Not ITT analysis 11% dropout rate, half due to death No comparison of characteristics of dropouts vs. trial completers	UNCLEAR No protocol	HIGH Baseline reported for all participants Appears well balanced except PEFR (misprint) However, patients with asthma and bronchiectasis included, but their distribution between groups not documented

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Lamers 2010[185]	LOW Randomisation was performed by an external agency using a computerised random number generator In order to avoid an imbalance of chronic illness and general practice (care level) over the two groups, stratification for general practice and chronic illness (diabetes mellitus or COPD) was performed. Furthermore, to obtain equal numbers in both arms, a blocked design with a block size of two was applied	LOW Randomisation was performed by an external agency using a computerised random number generator The researchers entered patients into a computer connected to an external agency, which performed the randomisation using a computerised random number generator	HIGH	HIGH ITT analysis Very high dropout rate from both the intervention and control groups Intervention group only 74% received the intervention Only 67% and 75% reached even the first follow-up in intervention and control group	LOW Protocol available This paper seems to report only a subset of the outcome measure	UNCLEAR Education level mismatched between baseline groups – up to 9% variation between percentage of highly educated in intervention and control groups
Larson 1988[122]	UNCLEAR Randomisation stated but not described	UNCLEAR NR	HRQoL: LOW Comparison of interventions Double-blind trial	HIGH *n* = NR Only *n* is number who completed study	UNCLEAR No protocol	HIGH Baseline characteristics table is for only the completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Larson 1999[123]	UNCLEAR Randomisation stated but method not reported	UNCLEAR Concealment – NR	HRQoL: UNCLEAR Study was comparison of interventions; however, blinding of assessors not reported; participants blinded to baseline and previous responses	HIGH ITT analysis – NR Poor completion rate – 41% 'There were no significant differences between those who completed the study and those who dropped out of the study in terms of demographics, pulmonary function tests, and arterial blood gases' but no detail of this	UNCLEAR No protocol	HIGH Baseline data reported for only the completers of study
Lee 2002[66]	UNCLEAR Nursing home was randomised, not patient; no method given but homes were randomised based on number of admissions	UNCLEAR	HRQoL: HIGH UC vs. intervention Hospital admission: LOW	HIGH No reporting of the distribution of dropouts between groups No ITT analysis	UNCLEAR No protocol	HIGH Limited range of baseline characteristics reported: reported for only the study completers
Leung 2010[165]	LOW Computerised telephone dial-up system – stratified randomisation	LOW Remote allocation by telephone dial-up	HRQoL: LOW Questionnaires were interviewer administered – and is comparison of interventions States blinded outcome assessment 'An assessor blinded to allocation performed outcome assessment'	LOW ITT analysis Only 12% dropout rate Similar dropout rate between branches and has comparison of characteristics of those lost to follow-up/ dropouts, different by age and FEV_1/FVC ratio	UNCLEAR No protocol	LOW Baseline well matched data for all participants included Training intensity well standardised

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Li 2002[200]	Randomly	NR	HRQoL: UNCLEAR	NR		
Liddell 2010[145]	UNCLEAR 'Separate but identical randomisation processes were carried out at each outpatient department' No comments on method of randomisation	LOW 'Equal numbers of once-weekly and twice-weekly allocations were created, and then stored in sealed envelopes. These envelopes were only opened after the initial assessment and patient consent' Not sequentially numbered	HRQoL: UNCLEAR Self-completed SGRQ but is an equivalence trial on intervention 'Follow-up assessments were completed within 2 weeks of the end of the programme. At follow-up, blinding was not possible as staff and patients were aware which programme the patients had attended'	HIGH 33% dropout rate – all accounted for and similar rates/reasons in each group ITT analysis Baseline variables used for missing data from dropouts No comparison of completers to follow-up	No protocol	HIGH Three participants did not have COPD on spirometry (no comment on which group they were randomised to) = 10% of participants Baseline reported for all participants Some variation in baseline characteristics > 10% in mean FEV_1 Smoking not reported as a variable
Lindsay 2005[214]	UNCLEAR 'Randomly allocated'	UNCLEAR	HIGH	LOW Withdrawals reported, and ITT performed	LOW All outcomes reported	UNCLEAR Underpowered
Linneberg 2012[224]	UNCLEAR 'Patients were randomised (in blocks of 20) for the intervention group or control group'	UNCLEAR No information given	HRQoL: HIGH	Reasons for dropouts were reported, but not by arm Follow-up at 1 year: 49/59 for intervention, 47/59 for control	UNCLEAR	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Littlejohns 1991[146]	LOW Random number table	LOW Sealed numbered envelopes kept centrally	HRQoL: HIGH Self-reported intervention vs. UC control Admissions: LOW	HIGH No ITT analysis 88% trial completion rate Balanced loss to follow-up Characteristics of dropouts and trial completers compared; however, characteristics reported of only those who died	UNCLEAR No protocol	HIGH Baseline characteristics of all patients reported for a wide range of characteristics Average HRQoL appears significantly different (9.4 vs. 7.2 – intervention vs. control) in both physical and psychosocial domains
Liu 2008[260]	LOW '. . . assigned to the cell phone group according to a table of random numbers'	UNCLEAR	Blinding not reported in whole study HRQoL: UNCLEAR Admissions: LOW Exacerbations: HIGH Appear to be self-defined	HIGH No ITT analysis Dropouts evenly matched between groups but no comparison of characteristics Unclear at what point data removed from analysis for dropouts	UNCLEAR No protocol	UNCLEAR Baseline appears very well matched but smoking history not reported and only reported for study completers

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Livermore 2010[166]	LOW 'We used the Excel Bernoulli function to generate a random sequence of numbers, with a 50% chance of each of the two groups occurring. Randomisation was linked to subject numbers'	UNCLEAR 'Randomisation . . . was concealed until after the baseline assessment was completed' No details about how this was achieved	HRQoL: HIGH Self-completed but intervention vs. control Admissions: LOW Record review	UNCLEAR Graded unclear as low drop out at 6 months but higher later Dropout rate at first assessment (post intervention) = 0% Dropout rate at 6 months = 2.5% Dropout rate at 12 months = 17% Dropout rate at 18 months = 22% Similar dropout rates for each branch but no reasons given Low at 6 months, high at 12 and 18 months ITT analysis done	UNCLEAR No protocol	HIGH No significant baseline differences – but no report on characteristics of dropouts Blind outcome assessor for a 20% sample good correlation between assessments of non-blinded and blinded assessors

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Lord 2010[147]	UNCLEAR 'Using block randomisation through consecutive sealed envelopes' Not enough details to decide	UNCLEAR Sealed but not numbered envelopes	HRQoL: LOW Self-completed questionnaires but comparison of interventions 'At seven weeks follow-up, study participants were again assessed by the same respiratory physiotherapists, who were blinded to treatment allocation. All subjects were instructed not to tell the physiotherapist which group they had been allocated to'	HIGH ITT analysis 22% drop out rate Similar dropout rate and reasons in each group Block allocation resulted in control group 20% smaller than intervention group No comparison of characteristics of dropouts	UNCLEAR No protocol	HIGH Baseline characteristics reported only for those completing study Although they did not reached significance (because of small numbers of participants) there were clinically significant baseline differences in recovery after ISWT and in the ISWT distance itself
Madariaga 2007[174]	UNCLEAR No details	UNCLEAR No details	UNCLEAR No details	LOW No loss to follow-up	UNCLEAR	HIGH States 34 randomised in methods, 33 in abstract and baseline imbalances in dyspnoea score High for HRQoL
Mador 2004[126]	UNCLEAR No description of how randomised	LOW Used 'opaque sealed envelope' (p. 2037)	LOW	LOW Dropout accounted for, and similar in two groups; no imputation for dropouts	LOW All outcomes reported	LOW Multiple measures and tests; no adjustment for multiple testing
Mador 2005[125]	UNCLEAR 'Randomly assigned'	UNCLEAR	HIGH	UNCLEAR Withdrawals briefly reported, but no ITT	LOW All outcomes reported	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Mador 2009[124]	UNCLEAR Stated randomised but no detail	UNCLEAR Stated concealed but no detail	HRQoL: LOW Self-reported comparison of interventions	HIGH 12.5% dropouts balanced between groups No comparison of characteristics between dropouts and completers No ITT analysis	UNCLEAR No protocol	HIGH Baseline reported for only the completers
Magadle 2007[254]	LOW 'Using a random number table'	UNCLEAR Not stated	Patients blinded by 'sham IMT' control; outcome assessment HRQoL: LOW	LOW Loss to follow-up: intervention 2/10, control 2/15	LOW	LOW
Maltais 2008[198]	LOW 'We used a centrally administered, computer-generated permuted block randomisation scheme using blocks of two, stratified according to sex and participating site'	LOW 'We communicated assignments by e-mail to research staff who were not otherwise involved in the trial. The case manager subsequently informed patients of their group allocation. Study personnel were unaware of the permuted block size'	HRQoL: LOW Comparison of interventions Home vs. hospital-based rehabilitation	LOW 'The primary analysis took a modified intention-to-treat approach using all patients who provided data at the specified follow-up time regardless of adherence' 'The withdrawal rate was similar in both treatment groups' Although reasons for withdrawal reported, they were not reported by group 'The baseline characteristics of the patients who withdrew were similar to those of patients who completed the trial'	LOW Protocol available ClinicalTrials.gov registration number: NCT00169897	UNCLEAR Baseline reported for all patients Baseline: home rehabilitation group 8% GOLD stage IV vs. 18% in hospital Although groups matched to dyspnoea Pack-years reported but not current smoking status

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Man 2004[148]	LOW A random number generator to assign an intervention to the first patient entering the study Minimisation method taking into account age, sex, length of hospital admission, ISWT distance and FEV_1	LOW	It was not possible to blind patients or the assessors HRQoL: HIGH Admissions: LOW	LOW Follow-up: 16/21 control, 18/21 intervention Details of dropouts by study arm	UNCLEAR	LOW
Martin 2004[228]	UNCLEAR Stated randomised but no detail given	UNCLEAR	HRQoL: HIGH Intervention vs. control Hospital admission: LOW Method of data collection – NR	HIGH Deaths between intervention and control were not balanced (9 vs. 4); low dropout rate (13.5%) Unclear if ITT analysis – based on missing data from baseline seems likely that it is not	UNCLEAR No protocol	UNCLEAR Baseline reported for all participants for some variables but not others – limited number of variables reported and gender imbalance between groups
McGeoch 2006[229]	UNCLEAR 'Randomly selected' and use of 'random numbers table' 'Cluster randomisation of surgeries'	UNCLEAR	HIGH 'No blinding'	UNCLEAR Withdrawals reported, but no detail on management of data	LOW All outcomes reported	UNCLEAR Baseline differences for primary outcome SGRQ, 'not clinically significant'
Monninkhof 2003[186]	UNCLEAR	UNCLEAR Using sealed envelopes	HIGH No blinding	LOW Withdrawals and dropouts reported No difference between groups	LOW All outcomes reported	LOW

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Moore 2009[285]	LOW Minimisation method	UNCLEAR States concealed but no details on method	HRQoL: UNCLEAR Intervention vs. control – control group did receive some educational material/ consultation	HIGH No ITT analysis $N = 27$, dropouts and lost to follow-up balanced between groups Dropout = 27%	UNCLEAR No protocol	HIGH Baseline reported for only the participants completing study Small sample size ($n = 20$) Baseline well balanced
Mota 2007[175]	UNCLEAR No details	UNCLEAR No details	Participants in control given sham training Outcome assessments blinded – 'blind regarding the assigned training or sham groups' HRQoL: LOW	LOW HRQoL: LOW Loss to follow-up 2/8 in control due to exacerbation Intervention 10/10 completed	UNCLEAR	HIGH Baseline characteristics for completers only SGRQ values for baseline not given – only % change at follow-up
Mularski 2009[127]	LOW Computer-generated random number table	UNCLEAR Sealed, un-numbered envelopes	HRQoL: LOW Comparison of interventions	HIGH ITT analysis Imbalanced dropouts 52% vs. 30% (intervention vs. control)	UNCLEAR No protocol	HIGH Baseline reported for all participants Significant differences in average age (71 years vs. 64 years), BMI (26 kg/m^2 vs. 31 kg/m^2) and current smoking 17% vs. 34%) in intervention vs. control
Murphy 2005[252]	UNCLEAR 'Randomly assigned 1 : 1 ratio'	UNCLEAR 'Blinded sealed envelopes'	HRQoL: HIGH Exacerbations: LOW	UNCLEAR Withdrawals reported, but no ITT	LOW All outcomes reported	UNCLEAR Baseline differences for smoking history, hospitalisations

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Nakamura 2008[261]	UNCLEAR Stated as randomised but method not described	UNCLEAR Allocation concealment – NR	HRQoL: UNCLEAR Two interventions and one UC control However, tool was administered by a trained interviewer – blinding not reported	HIGH Follow-up was reasonable – 22% dropout – but not balanced between groups; reasons for dropout were not reported and there was no comparison of characteristics	UNCLEAR No protocol	HIGH Baseline reported for only the completers No reporting of smoking status or baseline HRQoL
Ng 2011[215]	LOW Computer-generated random number list with 'permutated blocks'	LOW 'It was then sealed in a database file with a security password'. . .' The occupational therapist who was blind to the list opened the file and assigned the subject to treatment or control group . . .'	HRQoL: LOW Control group did dummy breathing exercises	HIGH 24% lost to follow-up and discontinuation Unbalanced loss, greater in control group	UNCLEAR No protocol available	HIGH Baseline characteristics: more female in control (93 vs. 85%) and general health subscale (intervention vs. control 42.5% vs. 49.5%)
Nguyen 2008[128]	LOW An investigator who was not involved in the day-to-day study operations generated the randomised sequence using random sequence generator feature [SPSS version 14 (SPSS Inc., Chicago, IL, USA)] Stratified by two clinical sites in blocks of six	UNCLEAR 'separated sealed opaque envelopes'	'Study staff not involved in the intervention' HRQoL: UNCLEAR Exacerbations – LOW	HIGH $n = 11$ (36%) dropped out – similar in characteristics to those who remained, except more likely to be female, current smokers, reported no musculoskeletal problems, rated themselves as having advanced computer skills and less likely to have participated in face-to-face support groups or PR	LOW NCT00102401	HIGH Not clear whether some baseline measures may have been completed once nurse (not patient) knew their allocation Study stopped only because of technical problems

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Nguyen 2009[129]	UNCLEAR Stated randomised but no methods detailed	UNCLEAR	HRQoL: UNCLEAR Self-completed questionnaires, comparison of interventions, but one intervention arm had more contact with the research teams	LOW ITT analysis Low dropout	LOW Trial registration: ClinicalTrials.gov (NCT00373932)	HIGH Data reported for all participants but significant differences in characteristics between groups (age and disease severity) $n = 17$
Nield 2007[130]	UNCLEAR Stated as randomised but not described	UNCLEAR	HRQoL: UNCLEAR Administration of questionnaire is not reported; however, a comparison on two interventions against a UC/minimum intervention control	HIGH Dropouts and reasons not reported by group 'Loss of subjects did not impair group equivalency at either week 4 or week 12' but no details	UNCLEAR Not protocol	HIGH Baseline mismatched – one intervention group had higher-than-average BMI Smoking not reported except 'Most subjects were white men, with an average age of 65 years, with a FEV_1% pred = 39; they were former smokers Were all former smokers? Also mismatch in baseline HRQoL between PLB intervention group and control (21 vs. 29)

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Ninot 2011[250]	LOW Computer-generated sequence, block randomisation	UNCLEAR Remote allocation by fax machine	HRQoL: HIGH Neither participants or researchers were blinded Hospital admissions: LOW From records Exacerbations: HIGH From patient interview	HIGH No ITT analysis 16% dropout balanced in number between groups and reasons given differ between groups	UNCLEAR No protocol	UNCLEAR Demographics of dropouts similar to those who completed study Baseline imbalances in 6-MWD and mean age
Normandin 2002[131]	UNCLEAR	UNCLEAR	HRQoL: HIGH Reported as an unblinded study	HIGH 7/27 proportion lost from both groups. Reason similar between groups, except more withdrew consent in the high-intensity arm (dropout due to exacerbations, equal between groups)	UNCLEAR HRQoL in methods and results	HIGH Baseline data for only the completers Data available, balanced for gender and age Some potential imbalance in some biological/physical measures but not consistent in favour of one group or another
Norweg 2005[132]	LOW Randomised using biased coin design plus probability table	UNCLEAR No mention of allocation concealment Unclear whether baseline measures taken prior to randomisation	HRQoL: HIGH Administered by first author who delivered intervention	UNCLEAR Withdrawals accounted for but higher withdrawal/dropout in the exercise training-plus-activity training group at 6/52 Also, a priori, not including those who did not follow through with treatment recommendation	LOW Outcomes stated a priori and reported; however, stated that results would be assessed according to age and depression; no results by depression are presented but probably insufficient power to do this; did adjust for depression	HIGH No other adjustment needed Exclusion of non-compliant patients from analysis

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Oh 2003[284]	UNCLEAR 'Patients were randomly assigned to the experimental group in order of referral . . .'	UNCLEAR No mention	UNCLEAR It is not clear, but likely, that measures are not done by same person as whom delivering intervention	LOW 11 withdrawals – accounted for High dropout – 11/34 but greater in control	LOW All outcomes assessed	LOW Also no difference at baseline between dropouts and those who continued
O'Neill 2007[150]	LOW Patients were randomised in sets of 12; in each set, half were randomised to group 1 and half to group 2; random numbers were generated by an independent researcher	LOW 'Stored in sealed envelopes . . . opened after recruitment and assessment, before which none of the coordinator, research team and patient was aware of group allocation	HRQoL: HIGH	HIGH	LOW	HIGH Baseline characteristics were in only the completers of the PR programmes ($n = 34$ and 32)
Ortega 2002[176]	UNCLEAR	UNCLEAR	HRQoL: HIGH	HIGH Only mentioned with relation to dropouts 7/54 randomised patients dropped out and were not included in demographics or study data Numbers given by group: 1/18, 2/18, 4/18, reasons given	UNCLEAR HRQoL mentioned in methods and results	UNCLEAR Small numbers but some small imbalances in patient characteristics HRQoL appears somewhat imbalanced at baseline across domains but appears to be within chance variability

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
O'Shea 2007[167]	LOW 'Group allocation was generated by a member of the research team not involved in participant recruitment' 'Block randomisation'	UNCLEAR 'Created in envelopes until after completion of baseline measurement'	'All measurement sessions were conducted by an independent trained assessor, blinded to group allocation' Exacerbations: LOW	LOW Follow-up at 24 weeks: control 22/27, intervention 19/27; reasons given for withdrawal Those who withdrew more likely to have reduced 6-MWT distance and to have never completed PR HRQoL: LOW	UNCLEAR	LOW
Ozdemir 2010[239]	LOW 'Randomised . . . according to tables of random numbers'	UNCLEAR No details given	HRQoL: HIGH	LOW No loss to follow-up – last follow-up at 1 month	UNCLEAR	LOW
Paz-Diaz 2007[269]	UNCLEAR No detail	UNCLEAR No detail	No detail	HRQoL: LOW	LOW	UNCLEAR
Petersen 2008[225]	UNCLEAR Reported as randomised but no details	UNCLEAR Allocation concealment not considered	HRQoL: HIGH Self-completed but intervention vs. UC	LOW ITT analysis with 100% follow-up of all 19 participants	UNCLEAR No protocol	HIGH $n = 19$ for intervention vs. control study 'There were no difference in any of the baseline characteristics between the "COPD training" and "COPD control" groups', but no detail given

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Petty 2006[133]	UNCLEAR 'Block randomisation'	UNCLEAR	HIGH Self-administered, 'no blinding'	HIGH '82% retention rate' No other information provided Disproportionate dropout in one group	UNCLEAR '9-month follow-up data not provided because of poor response'	LOW
Pomidori 2012[243]	UNCLEAR 'Random assignment' to one of two exercise regimes; no other details	UNCLEAR No details given	HRQoL: LOW Comparison of two exercise regimes	36/47 (77%) follow-up at 1 year; A1 5/23 and A2 6/24 Reasons not given for dropouts, nor characteristics of dropouts	UNCLEAR	HIGH Baseline characteristics presented for only those followed up at 1 year No data provided on SGRQ – only that from baseline to 12 months: 'values significantly improved'
Prince 1989[151]	UNCLEAR Stated as randomised but method not described	UNCLEAR NR	HRQoL: LOW	HIGH Dropouts 2 vs. 4 on control vs. intervention No ITT analysis; no comparison of characteristics	UNCLEAR No protocol	HIGH Reported baseline characteristics for completers only. 6-MWD 371 vs. 412
Probst 2011[234]	UNCLEAR Reported randomised but no methods given	UNCLEAR	HRQoL: LOW Comparison of interventions	HIGH No ITT analysis 37% dropout, balanced in numbers between groups, reasons not broken down by intervention Comparison of baseline characteristics of participants who dropped out vs. trial completers	UNCLEAR No protocol	HIGH Baseline data reported for only the participants completing trial Good range of variables reported and groups well matched

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Puente-Maestu 2000[177]	UNCLEAR 'Blocks of four patients established before the first patient was included	LOW 'The physicians who sent the patients for rehabilitation were unaware of the randomisation sequence'	HRQoL: UNCLEAR Not mentioned 'HRQoL – unclear . . . measured . . . by . . . nurse' Study almost certainly unblinded for patients and most staff	HIGH 8/49: five patients withdrew from one group and three from another Reasons were non-medical (scheduling/no adherence/ personal affairs); no mention of how these compared with completers or if reasons balanced across groups	UNCLEAR HRQoL in results and methods	HIGH Baseline data given for only the completers does not include gender Mostly respiratory markers Seem fairly balanced including HRQoL
Puente-Maestu 2003[275]	UNCLEAR Patients randomly assigned but no description	UNCLEAR No mention of allocation concealment	No mention of blinding; outcome unlikely to be influenced on lack of blinding	LOW 10 patients dropped out, five from each group; all accounted for	LOW All outcomes reported	LOW
Puhan 2006[257]	LOW 'Online central randomisation'	LOW 'Central randomisation using a computerised minimisation procedure'	Not reported for participants. Self-report questionnaires. Health-care staff supervising ex and those doing post intervention testing were blinded	LOW ITT performed and attrition/withdrawals reported	LOW Protocol available but not checked All specified outcomes evident in results	UNCLEAR Baseline differences for antibiotic use, 6-MWT
Rea 2004[230]	LOW Practices randomised – computer-generated random number table	UNCLEAR	HRQoL: HIGH Self-reported intervention vs. UC control Hospital admission: LOW Data collected from records	Balanced per cent dropout (14 vs. 12%) Similar reasons for dropout between groups ITT analysis of hospital admissions LOW Not ITT analysis – for HRQoL HIGH	UNCLEAR No protocol	HIGH Baseline characteristics only reported for completers Intervention vs. control groups very unbalanced numbers (83 vs. 52) Randomisation based on GP practices but no data present on practice demographics/location

Singh 2003[241]	UNCLEAR Patients divided randomly no descriptions	UNCLEAR No mention	UNCLEAR No mention	LOW All patients completed	LOW All outcomes reported	LOW Groups balanced at baseline
Sívori 1998[263]	LOW Randomised using random number tables	NR	Not reported for any outcomes Patient notes were used to determine days of hospitalisation (days/patients/year calculation)	28 patients completed Details of attrition provided. No details to suggest ITT performed	LOW	Intervention differed with respect to training, although upper and lower limb training group had double the intervention with respect to time from what it appears to suggest from the papers; group similar at baseline; high attrition
Smith 1999[168]	LOW Random computer-generated numbers	UNCLEAR	HRQoL: HIGH Unblinded study, self-completed questionnaires, intervention vs. control Hospital admissions: LOW Case note review	LOW ITT analysis Similar numbers of dropouts and deaths) 10% overall dropout Reported similar characteristics between dropouts/deaths and trial completers (not presented)	UNCLEAR No protocol	LOW Baseline reported for all patients – well balanced
Soler 2006[180]	UNCLEAR	UNCLEAR	HRQoL: HIGH Self-report questionnaires Hospital admissions: LOW	UNCLEAR Withdrawals reported but no detail on management of data	LOW All outcomes reported	UNCLEAR Baseline differences for ISWT, endurance shuttle walk test. Planned intervention of rehabilitation not done Small sample

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Solomon 1998[136]	LOW Random number table	UNCLEAR NR	Admissions: LOW	HIGH Total recruitment/follow-up – NR No ITT analysis	UNCLEAR No protocol	HIGH Baseline reported for only participants who completed the trial Gender imbalance 43% vs. 55% male in intervention vs. control)
Spencer 2010[169]	LOW 'Randomisation (performed using computerised number generation)'	UNCLEAR 'Randomisation (performed using computerised number generation) was concealed in opaque envelopes and prepared by an investigator not directly involved in the study' Numbering and sealing of envelopes not reported	HRQoL: HIGH Self-completed questionnaire – intervention vs. control trial Hospital admission: LOW Exacerbations: HIGH Self-reported and defined as worsening symptoms 'The assessor and subjects were not blind to group allocation'	ITT analysis used 18% lost to follow up Reasons listed Identical numbers dropped out due to death/illness Approximately 2× as many dropouts from intervention arm Reported characteristics of those who withdrew appear to have a lower FEV_1 and be more likely to be smokers	LOW Protocol available at Australia and New Zealand Clinical Trials registry	LOW Baseline characteristics similar – presented for all participants

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Spruit 2002[247]	UNCLEAR	UNCLEAR Limited reporting 'concealed envelopes'	HRQoL: HIGH	UNCLEAR 18/48 dropped out of the study: three in each group dropped out owing to lack of motivation (6/48), and seven in resistance training group, plus five in endurance training group (12/48) owing to hospitalisation/exacerbation (two and one of these died, respectively) Comparison in some baseline characteristics between dropouts and completers is given; no details given by outcome	UNCLEAR HRQoL mentioned in methods and results	HIGH Baseline data given appears balanced (only 1/8 factor statistically significant difference (diffusion capacity for CO_2) but baseline data given for only the completers
Sridhar 2008[155]	LOW 'By the use of random numbers'	UNCLEAR	HRQoL: high Readmissions: LOW 'Corroboration of self-report with hospital admissions was undertaken by respiratory research nurses against local hospital records'	LOW Follow-up: 55/61 Intervention: 49/61 control. All loss to follow-up due to death HRQoL: only data at 2 years follow-up reported	UNCLEAR	HIGH Imbalance in SM activities at baseline; more control participants had reserve antibiotics or steroids

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Stulbarg 2002[137]	UNCLEAR	UNCLEAR	HRQoL: HIGH	UNCLEAR	UNCLEAR	HIGH
	Stratified randomisation using four strata related to oxygen saturation and anaerobic threshold		Self-reported via SF-36 and CRQ, with feedback given about previous scoring by the patient	103/115 completed the study; four dropouts from each of three groups ($n = 40/37/38$); reasons are given but not numbers for each reason, nor by group; those who dropped out 'were not significantly different in baseline characteristics from those who remained in the study except for high $PaCO_2$ and lower age'	HRQoL tools mentioned in methods, also given in results	Baseline characteristics given in detail for only the completers. Fairly well balanced – some small differences between the three groups but not extensive
Davis 2006[395]	UNCLEAR	UNCLEAR	HRQoL: HIGH	UNCLEAR	LOW	UNCLEAR
	'Randomised' no details			Overall dropout reported, but no reasons given or information on management of data	All outcomes reported	High dropout rate
Carrieri-Kohlman 2005[394]	UNCLEAR	UNCLEAR	HIGH	UNCLEAR	LOW	LOW
	'Methods and 2-month outcomes reported elsewhere'		'Blinded assessor'	Withdrawals reported, but no ITT	All outcomes reported	
Subin 2010[242]	UNCLEAR	UNCLEAR	HRQoL: LOW	No loss to follow-up	UNCLEAR	LOW
	'Randomly assigned to one of three groups through block randomisation'	No detail given	Three active interventions compared			

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Theander 2009[220]	LOW The randomisation procedures were performed by an independent person from the research group, who took a random envelope from the prepared box with sealed envelopes	UNCLEAR Opaque envelopes but not sequentially numbered	HRQoL: HIGH Self-completed, intervention vs. UC control	HIGH ITT analysis: NR Reasonable completion rate but three dropouts due to ill health and death in intervention group; only one dropout from control group (burden of assessment)	UNCLEAR No protocol	HIGH $n = 26$ Recruitment was terminated at 30 patients – power calculation suggested that 40 patients more appropriate – reasons for stopping recruitment not detailed Baseline reported for only the completers Gender and employment status imbalance between groups
Toshima 1990[138]	LOW 'Computer-generated list of the words "rehabilitation" and "education" in random order'	LOW 'The recruiter reported the name to an independent person who made assignments according to the random order lists'	HRQoL: LOW (both groups had an intervention)	LOW Balanced losses between arms 89% follow-up at 6 months Reasons for loss to follow-up given by arm	HIGH 'In this article, some preliminary results are presented'	HIGH 10 participants dropped out between recruitment and starting the intervention. No baseline data are provided for these participants, nor allocation group
Ries 1995[276]	LOW 'The randomisation scheme was fixed before the trial with a block size of 8; assignment was determined by a table of random numbers . . .'	LOW Clinical personnel were unaware of the randomisation scheme	HRQoL: HIGH Hospital and ED visits: HIGH Self-reported	Nine people (six intervention; three control) dropped out prior to treatment 'Patients who dropped out and those who remained in the study did not differ'	UNCLEAR	HIGH Baseline criteria for only the 119/128 randomised

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Trappenburg 2011[188]	LOW 'To conceal the assignment sequence, a central web-based service was used. Randomisation was carried out using the minimisation technique to balance the control and intervention groups for centre and gender'	LOW	HRQoL: HIGH Patient-completed questionnaire Exacerbations: HIGH Self-reported, but well defined and adjudicated by three assessors Length of exacerbation time: HIGH Self-reported Health-care utilisation: LOW Telephone call verified by record	UNCLEAR No ITT analysis Reasonably balanced reasons for loss to follow-up with 16% and 19% from control and intervention group respectively, but more comorbidity in control group (5 vs. 2) Subjects lost to follow-up had more severe airflow limitation and were more frequently recruited from an outpatient clinic ($p < 0.05$)	UNCLEAR No protocol	UNCLEAR Baseline data for all patients given Baseline: control group had a lower percentage educated to college standard (12% vs. 7%) and more with secondary education (62% vs. 68%) – potentially relevant as intervention was action plan and recording was diaries and self-reporting No details on timing of recruitment/follow-up period. i.e. more exacerbations/more severe exacerbations/longer recovery over winter months
Troosters 2000[248]	UNCLEAR Prepared before study	UNCLEAR Sealed envelopes	HRQoL: HIGH	UNCLEAR 13/50 intervention 17/50 control dropped out; these appeared fairly balanced; the patients who dropped out were not dissimilar to those who were followed up (except age $p < 0.004$)	UNCLEAR HRQoL mentioned in methods and results	HIGH Baseline data given for only the completers (see above also) Groups seem balanced
Van Gestel 2012[208]	UNCLEAR 'RCT' – no further details	UNCLEAR No details given	HRQoL: HIGH	2/22 withdrew from intervention group; 1/21 from control group owing to exacerbation	UNCLEAR	HIGH Baseline data for only the 40 participants with follow-up data

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Van Wetering 2010[273]	LOW 'Patients were randomised to the INTERCOM programme or to UC using a computerised procedure with concealed patient allocation'	UNCLEAR 'Patients were randomised to the INTERCOM programme or to UC using a computerised procedure with concealed patient allocation' No comment on method of concealed allocation	HRQoL: HIGH Self-completed and comparison of intervention vs. control Exacerbations: UNCLEAR Patient defined reason for attendance at GP/ED Hospital admissions: UNCLEAR Linked paper[182] reports hospital record review during economic analysis of a subset of patients – this paper on whole cohort does not	LOW ITT analysis At 4 months, 94% completion At 12 months, 90% completion At 2 years, 85% completion Low risk of bias at 4 and 12 months Reported differences in dropouts – age in both groups (older vs. younger)	LOW Protocol available NCT00840892	HIGH Baseline characteristics similar and reported on whole cohort, but 9% more current smokers in intervention group
Vogiatzis 2002[265]	UNCLEAR NR Described as stratified randomisation; no specific details of strata mentioned	UNCLEAR	HRQoL: HIGH	UNCLEAR HRQoL: no specific mention other than for the whole study; for the whole study, 9/45 patients did not complete the programme – four in one group, five in the other Reasons were not given by group but overall; the reasons were pulmonary infection and non-compliance 'Characteristics were not significantly different from those of the completing patients'	UNCLEAR HRQoL mentioned in methods and results	HIGH Details given for only the completers (36/45) Baseline data seem balanced Baseline HRQoL data not shown, only change

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Vonbank 2012[246]	UNCLEAR 'Randomly assigned'	UNCLEAR No details given	HRQoL: LOW All participants received active intervention	HIGH 7/43 lost to follow-up; no details provided on dropouts	UNCLEAR	HIGH Data provided at baseline for only the participants who completed the trial
Wadell 2004[221]	UNCLEAR Semi-randomised Stratified by sex, FEV_1 and work capacity	UNCLEAR No mention of allocation concealment	UNCLEAR Not mentioned	LOW Two dropouts – discussed and from different groups	LOW All outcomes reported	LOW
Wakabayashi 2011[262]	LOW 'A case manager independent of the study randomly assigned patients to either group I or group U using a computer-generated list'	LOW 'Patient allocations were sealed in numbered envelopes by an independent evaluator, not involved in the interventions . . .'	Hospital admissions: LOW	HIGH Does not report, as ITT analysis not done for the reported outcome of emergency attendance and admission	UNCLEAR No mention in methods that ER attendance and admissions would be reported – only secondary outcome measures were mentioned; however, all outcome measures mentioned in methods were reported No protocol available	HIGH Under-recruited (100 needed, 102 recruited but 17 dropped out) Baseline difference in emergency visits and hospital admissions
Wang 2004[203]	Randomly	NR	UNCLEAR		LOW Lung function, QoL, 12-MWD reported	

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Warlies 2006[209]	External randomisation Method not completely clear: patients were allocated a code number, chosen by randomly opening shuffled, securely closed envelopes	Allocation number in securely closed envelopes	HRQoL: HIGH Study described as open label Patients were not given assistance with completing the SGRQ to avoid results being biased	4/28 in intervention group and 4/32 in control group discontinued Six found participation too onerous/were not motivated, including all four in the control group; one in the intervention group withdrew without giving a reason and one developed lung cancer; including these eight, there was a total of 12 patients with missing data Variable number of patients included for different outcomes depending on completeness of assessments	No obvious selective reporting All outcomes mentioned in methods also reported in results section	No further comments
Waterhouse 2010[277]	LOW 'Random allocation sequence using the RALLOC procedure in Stata 8 . . .'	UNCLEAR	'All were blinded to the telephone intervention arm until 1 month post rehabilitation, when only the assessment team and research participants were unblinded' HRQoL: HIGH Interviewer-led completion – unblinded participants and assessors	HIGH No ITT analysis Only 50% and 57% follow-up for community and hospital rehabilitation, respectively, for acute outcome and 57% long-term outcomes Reported comparison of dropouts vs. completers – well matched on reported features	LOW Trial registration: Current Controlled Trials ISRCTN86821773	HIGH Does not show baseline for all recruited participants, only for those who started the trial Smoking not reported as a variable

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Watson 1997[231]	UNCLEAR 'With random assignment of subjects to either UC or enhanced care'	UNCLEAR No details given	HRQoL: HIGH No details about blinding of assignments	13/69 lost to follow-up, details not given by study group	UNCLEAR	HIGH Some large baseline imbalances, for example influenza immunisation, access to a nebuliser and marital status
Wedzicha 1998[157]	UNCLEAR Stratified randomisation based on MRC dyspnoea score; blocks of eight No details on generation of sequence	UNCLEAR 'Codes held in sealed envelopes'	HRQoL: HIGH	UNCLEAR Eight dropouts out of 63 in exercise group; eight dropouts out of 63 in control group; reasons given More withdrawal as reason in exercise group (7 vs. 3) and more details in the control group (0 vs. 2)	UNCLEAR SGRQ, CRQ, Extended Activities of Daily Living assessment (EADL) mentioned in methods and results given; HADS mentioned in methods and baseline data but following data appear not to be presented	UNCLEAR Baseline data given for only the followed up patients; groups are fairly well balanced at baseline for demographics; no details of how dropouts differed from completers Possible baseline difference for shuttle walk test
Weekes 2009[158]	UNCLEAR 'Randomisation occurred in a standard way using sealed opaque envelopes containing randomised codes' Not clear how the randomised codes were generated	UNCLEAR 'Using sealed opaque envelopes' Not sequentially numbered	HRQoL: HIGH Not clear if self-reported or with unblinded outcome assessor; controls given leaflet – is this different from UC? 'A randomised controlled unblinded trial was performed'	LOW 'All patients who completed at least two assessments (baseline and one other) were included in an ITT analysis to provide an unbiased assessment of the treatment effect' Dropout reasons available online Dropout rates broadly similar between intervention and control groups	UNCLEAR No protocol	LOW Baseline characteristics included for all randomised patients who reached baseline assessment Difference of 8% and 10% in ex/current smokers between intervention and control groups – fewer smokers in intervention group High death rate/comorbidity diagnosis rate, but similar between groups

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
				6-month 33% dropout 12-month 37% dropout and baseline characteristics of dropouts compared		Deaths 7/59 but this probably reflects this patient group and rates that are broadly similar between groups
White 2002[159]	UNCLEAR	UNCLEAR	LOW	LOW	LOW	LOW
	No description of sequence generation but groups unequal, suggesting computerised	Opaque sealed envelopes		Nine dropouts in intervention arm, six in brief advice; all accounted for	All outcomes reported	Groups balanced at baseline
Wijkstra 1994[189]	UNCLEAR	UNCLEAR	HRQoL: HIGH	LOW	UNCLEAR	HIGH
	After stratification by FEV_1% pred, their limiting factor in exercise capacity and maximal workload, the patients were randomly allocated	No details given		Dropouts: intervention 2/30; control 0/15 Reasons for dropouts provided		Baseline imbalance in inspiratory vital capacity
Wijkstra 1995[190]	UNCLEAR	UNCLEAR	HRQoL: HIGH	LOW		LOW
	Stratified by FEV_1, maximum workload and limiting factor to exercise Randomly allocated to one of three groups	No details given		Clear details given by study arm for reasons loss to follow-up • group A: 5/15 • group B: 4/15 • group C: 3/15		

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Wittmann 2007[210]	UNCLEAR External randomisation: no further details	UNCLEAR No detail: the fact that randomisation occurred externally may contribute to concealment of allocation	LOW	13/107 dropouts in intervention group and 15/105 dropouts in control group during rehabilitation; reasons for both given Follow-up 1 year later was 98% (180/184) No details on differences between patients dropping out or remaining in study	UNCLEAR No obvious selective reporting All outcomes mentioned in methods also reported in results section	91/303 eligible patients refused to participate; 32 of these specifically requested, and received, the intervention (not as part of the study); the authors state that this means that the most motivated patients were excluded
Wong 2005[74]	LOW Computer-generated randomisation (p. 2123)	UNCLEAR	LOW Outcomes measured by nurse blind to group assignment	LOW Two dropouts but analysed with imputed values	LOW All outcomes reported	LOW
Wood-Baker 2006[170]	LOW 'Cluster randomisation' 'Computer-generated randomisation package'	UNCLEAR	HIGH Self-administered, 'no blinding'	UNCLEAR Withdrawals reported, but no detail on management of data	LOW All outcomes reported	HIGH Imbalance at baseline for gender, smokers, activity levels 'Underpowered'
Wright 2003[211]	UNCLEAR Reported randomised but no details given	UNCLEAR NR	HRQoL: HIGH Intervention vs. UC control	HIGH Large imbalance in dropouts between control and intervention groups – total recruitment not reported but completers $n = 21$ in intervention group and $n = 5$ in control	UNCLEAR No protocol	HIGH Not clear if baseline reported for all participants and small number of variables reported (weight not BMI) No smoking status Very heterogeneous age and symptomology within treatment group

Author year	Sequence generation	Allocation concealment	Blinding	Incomplete outcome reporting	Selective outcome reporting	Other
Xu 2010[204]	Random number	NR	UNCLEAR Use of QoL questionnaire		6-MWD, Borg score	
Yamaguti 2012[235]	UNCLEAR Randomisation was stratified according to gender, using random block sizes of 2 and 4	UNCLEAR No information given	HRQoL: HIGH	HIGH Follow-up: intervention 15/15, control 12/15 Information given on reasons for loss to follow-up ITT analysis done using baseline observation carried forward for missing data	UNCLEAR Outcomes in methods all reported in results	LOW
Yeh 2010[139]	UNCLEAR Stated randomised but no detail	UNCLEAR NR	HRQoL: HIGH	LOW ITT analysis	UNCLEAR No protocol	HIGH Very small trial $n = 10$ Feasibility study Baseline reported for all participants Smoking status – NR
Zhang 2008[205]	UNCLEAR Randomly	UNCLEAR	HRQoL: HIGH Self-administered questionnaire	HIGH Three losses to follow-up in group A; no reasons given	LOW	

6-MWD, 6-Minute Walk Distance; 6-MWT, 6-Minute Walk Test; 12-MWD, 12-Minute Walk Distance; AECOPD, acute exacerbation of chronic obstructive pulmonary disease; BMI, body mass index; ER, emergency room; ISWT, incremental shuttle walk test; ITT, intention to treat; NR, not reported; PEFR, peak expiratory flow rate; PI, principal investigator; PLB, pursed lip breathing; SCL-90-R, Symptom Checklist-90-Revised; VAS, visual analogue scale.

Appendix 28 Funnel plot of studies for multicomponent self-management interventions vs. usual care: St George's Respiratory Questionnaire outcomes at 13 weeks' follow-up – review 4

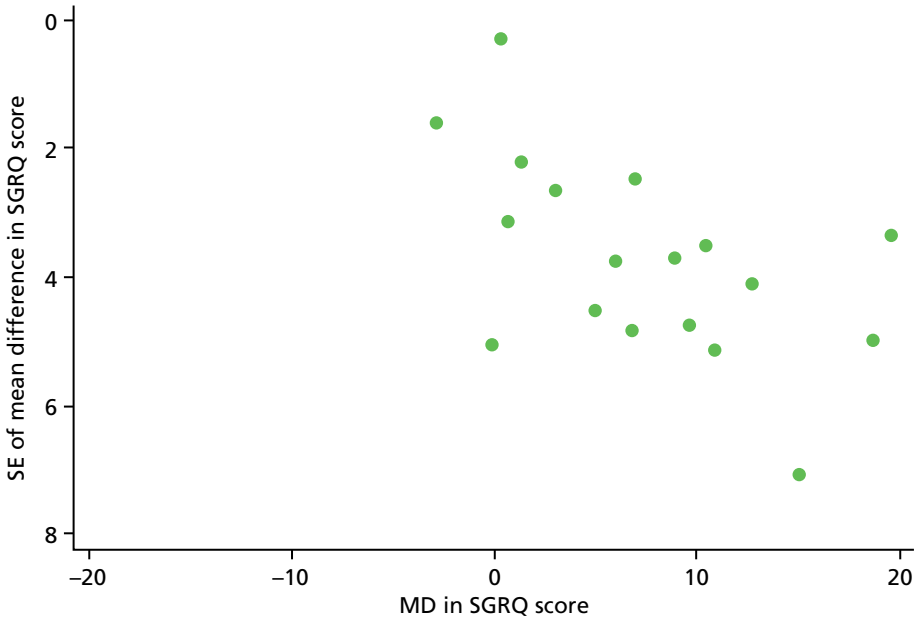

FIGURE 80 Egger's test: coefficient of bias 1.98, *p*-value 0.001.

Appendix 29 Funnel plot of studies for multicomponent self-management interventions vs. usual care: St George's Respiratory Questionnaire outcomes at between 3 and 6 months' follow-up – review 4

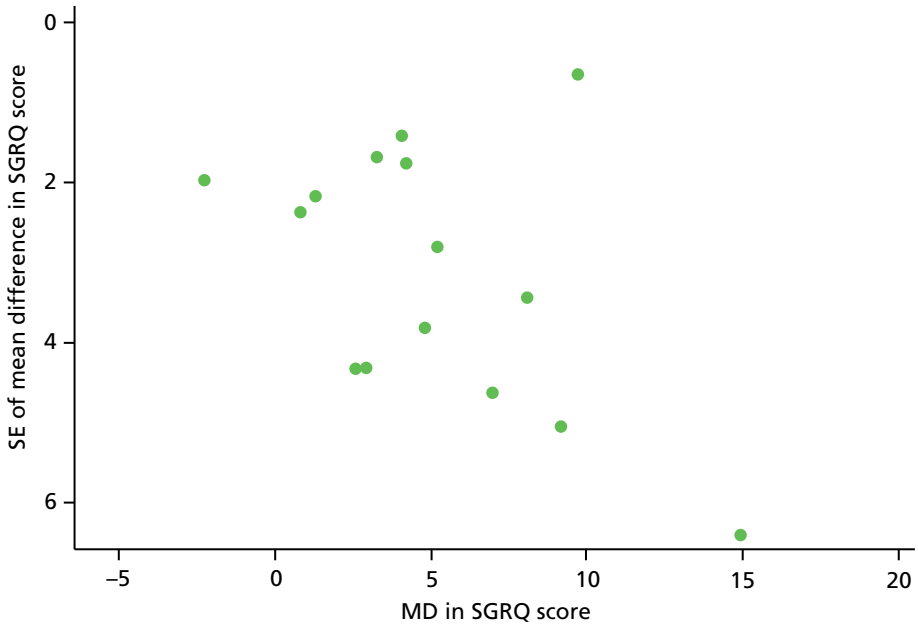

FIGURE 81 Egger's test: coefficient of bias –1.80, *p*-value 0.054.

Appendix 30 Funnel plot of studies for multicomponent self-management interventions vs. usual care: St George's Respiratory Questionnaire outcomes at ≥ 6 months' follow-up – review 4

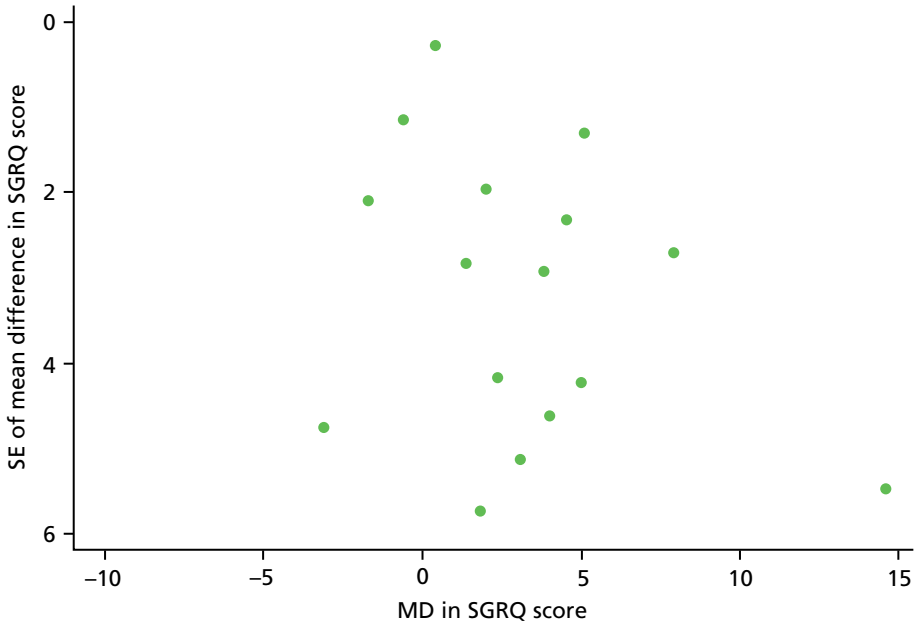

FIGURE 82 Egger's test: coefficient of bias 0.99, *p*-value 0.031.

Appendix 31 Funnel plot of studies for multicomponent self-management interventions including supervised exercise: St George's Respiratory Questionnaire outcomes at ≤ 13 weeks' follow-up – review 4

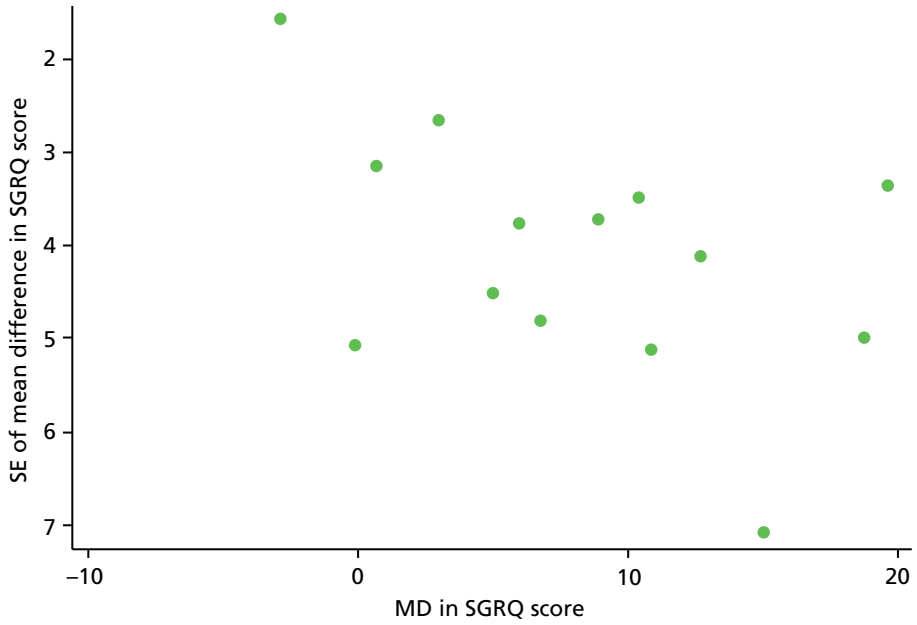

FIGURE 83 Egger's test: coefficient of bias 3.91, *p*-value 0.006.

Appendix 32 Funnel plot of studies for enhanced care interventions: hospital admissions at ≥ 6 months' follow-up – review 4

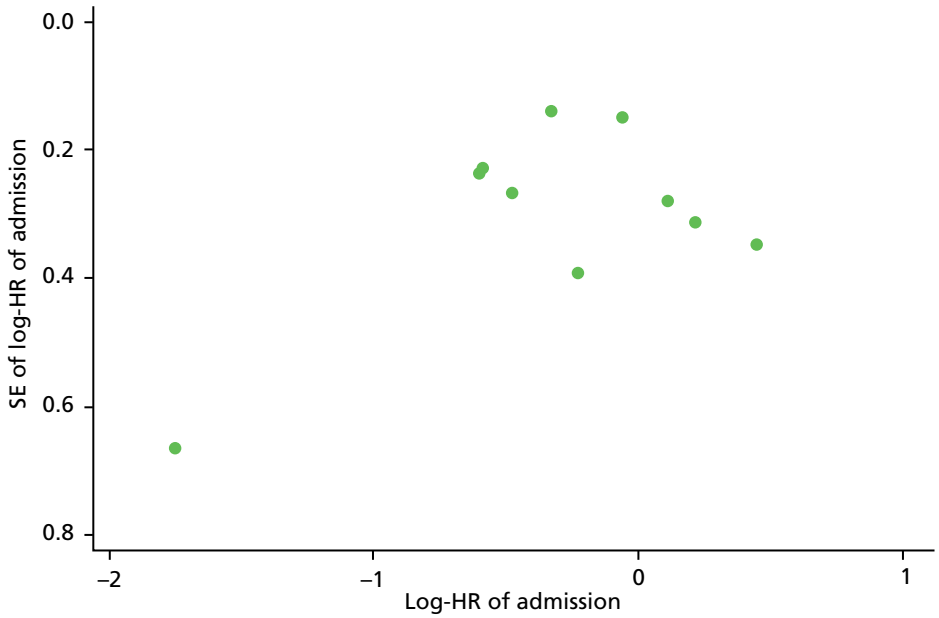

FIGURE 84 Egger's test: coefficient of bias –0.43, *p*-value 0.749.

Appendix 33 Funnel plot of studies for combined strength and aerobic interventions: St George's Respiratory Questionnaire outcomes at ≤ 13 weeks' follow-up – review 4

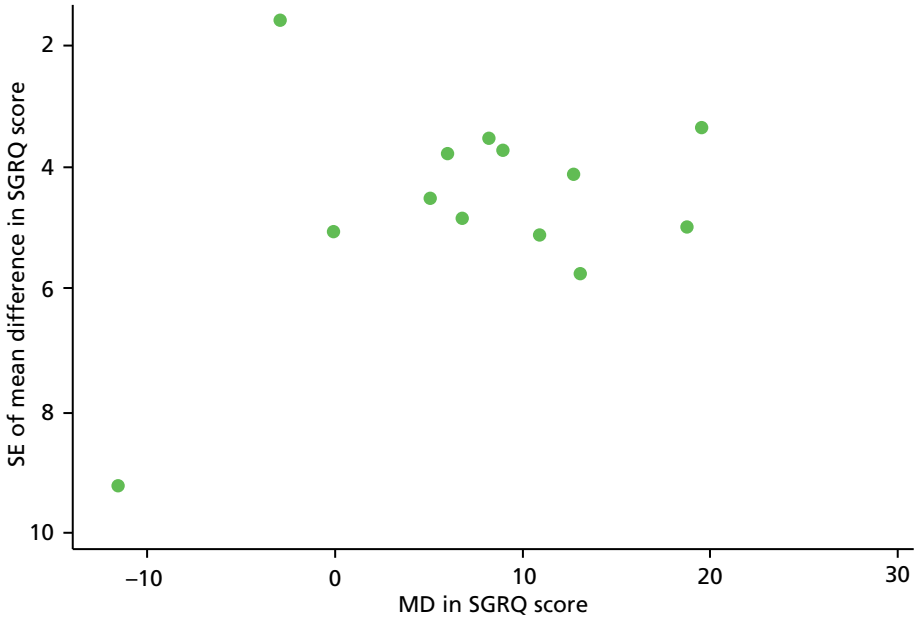

FIGURE 85 Egger's test: coefficient of bias 2.79, *p*-value 0.061.
