Drexel University  
Philadelphia, PA, USA

## Outline

### Introduction

### Risks from Pathogens in Biosolids

Routes

Pathogens

### Current US Biosolids Regulatory Outline—For Pathogens

### Risk Assessment Framework

### Exposure tools & gaps

Air

Groundwater

Land/Food Chain

Surface Water

### Dose-Response Gaps

### Simplified Risk Approach

### End Matter

# Biosolids

## Definition:

*“Biosolids are the nutrient-rich organic materials resulting from the treatment of sewage sludge (the name for the solid, semisolid or liquid untreated residue generated during the treatment of domestic sewage in a treatment facility). When treated and processed, sewage sludge becomes biosolids. . .”*

Source: USEPA

## Route of Accumulation into Biosolids

Pathogens in wastewater may be reduced in several ways

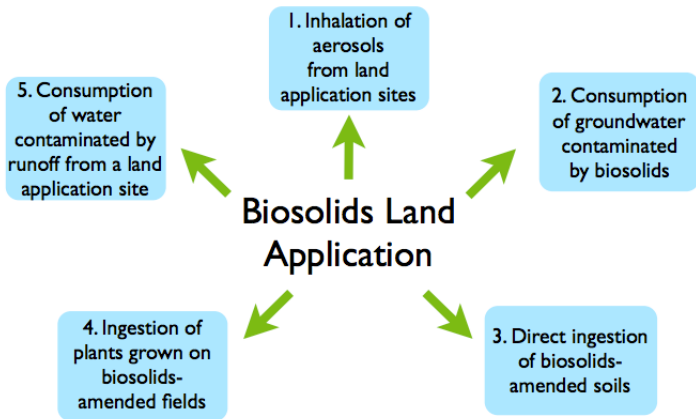

1. Inactivation during treatment
  2. *Physical removal into solids then separated*
- 

If the pathogens then survive sludge treatment, they will remain in the biosolids for disposal.

## Physical Application Methods

## Pathways

source: Teng *et al.* The Open Environmental Engineering Journal, 2013

## Biosolids Classification

Many other (non-pathogen requirements) must also be met

- ▶ **Class B Biosolids** Require waiting time between application and public access, restriction on types of agriculture, and buffer zones
    - ▶ Requires a process for significant reduction of pathogens (PSRP)
  - ▶ **Class A Biosolids** Can be applied to land without restriction
    - ▶ requires a process for *further* reduction of pathogens (PFRP)
-

## Synopsis of Requirements

	PSRP (B)	PFRP (A)
fecal coliforms	$< 2 \times 10^6/gm$	$< 1000/gm$
<i>Salmonella</i>	1 log reduction	$< 3/4gm$
enteric viruses	1 log reduction	$< 1/4gm$
viable helminths	—	$< 1/4gm$

Certain processes can be designated specifically as PSRP's or PFRP's if they can be shown to consistently meet these requirements

---

Note that none of this is explicitly risk based

## Unique Aspects of Microorganisms

- ▶ Adverse effects may result from single or short term exposure
- ▶ Low concentrations lead to stochastic variability (Poisson and extra-Poisson)
- ▶ Therefore models must be capable of describing short term fluctuations in space and time
  - ▶ Most environmental fate & transport models have at least time averaging
  - ▶ Models of treatment processes have not been well developed to describe pathogen removal and its *variability*

## Data Needs—1

- ▶ Emission rates (size distributed) — varying climate, weather, application methods
- ▶ Near site air dispersion models with short averaging times
- ▶ Air decay rates of microorganisms —  $f(RH, insolation)$

## Data Needs—2

- ▶ Complexities of unsaturated flow transport
- ▶ Decay rates in saturated and unsaturated flow
- ▶ Filtration efficiencies, attachment, detachment
- ▶ Because microorganisms (or particle laden microorganisms) are low concentration, need stochastic models

## Data Needs—3

- ▶ Survival of pathogens on soil (surface)
- ▶ Effect of different application practices
- ▶ Soil-hand transference
- ▶ Eating (pica)

## Data Needs—4

- ▶ Decay in soil, migration into subsurface
- ▶ Incorporation of pathogens into edible plant tissue
- ▶ (Multiplication), survival and decay in plant tissue
- ▶ Impact of post- harvest handling (field to table)

## Data Needs—5

- ▶ Runoff and subsurface flow
- ▶ Decay and filtration removal processes
- ▶ Treatment of water supply (possible route might be shallow wells)

## Dose Response Data Gaps-1

We know that microbial dose response to bolus doses can be well described by:

$$p = 1 - \exp(-kd) \text{ (exponential)}$$

or

$$p = 1 - \left[ 1 + \frac{d(2^{1/\alpha} - 1)}{N_{50}} \right]^{-\alpha} \text{ (beta-Poisson)}$$

But describing multiple/repeated exposures remains a challenge

## Dose Response Data Gaps—2

- ▶ Missing data for some key pathogens
  - ▶ Helminths
  - ▶ Inhalation exposure to most agents (bacteria, viral, protozoal)
  - ▶ Dermal pathogens
- ▶ Sensitive and susceptible subpopulations — impact on infectivity

## **A Spreadsheet-Based Site Specific Risk Assessment Tool for Land-Applied Biosolids**

Jingjie Teng<sup>1,\*</sup>, Arun Kumar<sup>2</sup>, Patrick L. Gurian<sup>1</sup> and Mira S. Olson<sup>1</sup>

- ▶ Steady state performance and transport
- ▶ Assume infectivity in air, water, dermal identical
- ▶ incorporation uncertainty & variability
- ▶ Calculations in a spreadsheet environment with visual basic macros

# Simplified Approach — Example Results

Cumulative risk from single land application.

## Research Needs

While we have the tools to do a “rough” screening level risk assessment, to do a more thorough job, there are many areas of research that need to be done (some not unique to biosolids):

- ▶ Dose-response data on pathogens of concern via routes of interest
- ▶ Integration of multiple doses and doses via multiple routes (PBDRMs)
- ▶ Process performance models for pathogen removal — incorporating variability in an explicit fashion. Need underlying basic data on process parameters impact on pathogens.
- ▶ Environmental fate and transport models predicting short term variability in exposure.
