## Abstract

In skilled migration research, the role of the study location in graduates' residential behaviour remains unclear. This paper addresses this lacuna by examining the attractiveness and retention of higher education cities for local attendants in the period after study, using Belgium as an empirical case study. Drawing on a unique linkage of census and register data for 1991-2010, logistic and Cox regressions illustrate the relative success of smaller cities once individual, familial and contextual factors are considered. Location-specific characteristics beyond the economic are found to shape skilled migration towards the higher education localities, particularly in the short term.

**Keywords:** internal migration, location-specific capital, graduates, higher education cities, Belgium

**JEL Codes:** I21 - Analysis of Education < I2 - Education and Research Institutions < I - Health, Education, and Welfare; J24 - Human Capital|Skills|Occupational Choice|Labor Productivity < J2 - Demand and Supply of Labor < J - Labor and Demographic Economics; R11 - Regional Economic Activity: Growth, Development, Environmental Issues, and Changes < R1 - General Regional Economics < R - Urban, Rural, Regional, Real Estate, and Transportation Economics; R23 - Regional Migration; Regional Labor Markets; Population; Neighborhood Characteristics < R2 - Household Analysis < R - Urban, Rural, Regional, Real Estate, and Transportation Economics

## Introduction

Over recent decades, theoretical models and empirical analyses within human capital mobility research numerously studied the drivers and consequences of skilled migration, internationally and regionally (Fratesi, 2014). Concentrating on drivers at the regional level, research has identified important individual and contextual determinants of the residential behaviour of the highly skilled, mainly from an economic perspective. One strand of literature focusses on the role that Higher Educational Institutions (HEIs) hold in producing and mobilizing human capital (e.g. Baryla & Dotterweich, 2001; Venhorst, Van Dijk & Van Wissen, 2010). However, skilled migration in relation to HEIs is mostly considered as driven by labour market opportunities (and wages). In this paper, we argue that other non-tradable non-economic factors, particularly location-specific capital, need to be accounted for. This can provide a useful perspective for those concerned with spatial fragmentation and decreasing quality of life in urban centres (Poelmans & Van Rompaey, 2009).

Cities benefit from the presence of skilled people. As skilled people have acquired high levels of human capital, tend to have above average incomes and, therefore, pay higher taxes. In this respect, cities of Higher Education (HE) are of great interest. University graduates remain in their study region when it is a central region of a metropolitan city - generally with a strong labour market offering ample job opportunities - but have higher propensities to leave when the place of study is peripheral (Baryla & Dotterweich, 2001; Dotti, Fratesi, Lenzi & Percoco, 2013; Haapanen & Tervo, 2012; Hoare & Corver, 2010; Krabel & Flöther, 2014; Venhorst et al., 2010). It is doubtful, however, that locally produced knowledge will remain in the city merely because of a strong local economy. The relative importance of local amenities as a pull factor - as suggested by Biagi, Faggian & McCann (2011) - might be underestimated, especially in the case of Belgium, where long-distance migration is rather uncommon due to the small scale and the highly urbanised and dense landscape. Knowledge of the mediating role of the HE location beyond the local labour market structure in the residential behaviour of young graduates remains insufficient. This paper argues that non-economic characteristics of the study region too often are left aside, yet potentially shape the residential mobility of the highly educated more than is generally acknowledged. Hence, it aims partially to fill this gap by building on the concept of "location-specific capital" (Davanzo, 1983, p.553),

using Belgium as a case study. It is hypothesized that the acquaintance and familiarity with the local environment of the HEI, rather than merely the job opportunities, facilitates a future move of recent HE attendants towards HE cities.

This hypothesis is tested by analysing the residential behaviour of young adults in the decade after their HE study using information from individual longitudinal census data from 1991 and 2001 linked to register data on geographical mobility between 2001 and 2010. Analyses illustrate the attractiveness of smaller cities for former attendants of the local HEI; individual characteristics and the acquaintance with the local area seem important determinants in the settlement of young skilled individuals, irrespective of the broader labour or housing market conditions.

### **Human capital on the move: some determinants**

Increased levels of education and intensified residential mobility among the highly educated has expanded the importance of human capital mobility in contemporary societies (Butler & Hamnett, 2007). The high residential mobility of young university and college graduates has been shown to be crucial for the process of human and financial capital redistribution (e.g. Faggian & McCann, 2009).

Graduation and entry into the labour market are decisive moments when it comes to migration of young adults (Feijten & Mulder, 2002; Kley & Mulder, 2010). Spatial mobility among the highly skilled is particularly directed towards urban regions functioning as economic and social attraction pools and offering affordable rental housing (Florida, 2002; Venhorst, Van Dijk & Van Wissen, 2011; Whisler, Waldorf, Mulligan & Plane, 2008). As job opportunities are often the primary driving force of migration during the first years after graduation, the poorer opportunities in peripheral regions of origin theoretically impose a large motivation for migration to central (urban) opportunity-rich areas with well-paid jobs (Borjas, Bronars & Trejo, 1992; Haapanen & Tervo, 2012). A highly urbanised and dense environment, such as Belgium, however, creates a context in which people do not feel obliged to migrate towards or live in the urban environment in order to work there. Graduates either are attracted initially but leave the city towards the suburbs as they start having a family or higher earnings, or immediately settle in the suburbs where urban employees commute to work on a daily basis (Kulu & Milewski, 2007; Verhetsel, Thomas & Beelen, 2010). The loss of the most skilled, whether

immediate or postponed, is detrimental: losing above-average skills and incomes weakens economic growth and raises the tax burden for the remaining city-dwellers (Böckerman & Haapanen, 2013)<sup>1</sup>. Their employment in the city or their contribution to the local economy through intensive use of urban amenities, do not safeguard major cities from reduced fiscal incomes as non-residents do not contribute directly to local (city) taxes (Verhetsel et al., 2010). Although many services are administered and funded by central and regional governments, the generation of revenue via local taxes determines cities' abilities to provide services such as road maintenance, social security, housing and education.

HEIs can play a valuable role in determining the attractiveness and affluence of cities. Location-specific amenities offered in these urban contexts include natural amenities (Graves, 1980), manmade amenities (Blomquist, Berger & Hoehn, 1988) and social, cultural and skill-dependent amenities (Florida, 2002). Conditional on the extent to which different amenities are satisfactory, people are more or less likely to prefer a particular destination (Whisler et al., 2008). Given that psychological costs of migration are reduced through knowledge of local facilities, proximity of relatives and availability of information (Coniglio & Prota, 2008; Delisle & Shearmur, 2010), the regional familiarity with the former location of the HEI could matter significantly to graduates' propensity to settle in the city of HE after getting a degree. Hence, 'location-specific capital' (Davanzo, 1983, p.553) - built up as social networks and knowledge of local facilities and amenities through residential experience during HE study - eases the move (Venhorst, 2013). In this paper, it is argued that residence close to the HE city or residence in student accommodation provides better opportunities to acquire this location-specific capital, linked to environmental, social and cultural characteristics (e.g. Delisle & Shearmur, 2010; Whisler et al., 2008). Consequently, settlement in the former HE area allows recent graduates to recoup and reuse a part of the location-specific advantages acquired, thereby preventing the loss of value of their investment in close friends and knowledge of local circumstances (DaVanzo, 1983).

To disentangle the variable role of study location and local acquaintance, this paper accounts for determinants described in earlier studies on skilled migration. These have

---

<sup>1</sup> Cities' surcharges – based on one's fiscal income and immovable property – raised in an attempt to reduce fiscal shortages, thereby substantially adding to the fiscal burden for stayers (Devogelaer, 2004).

illustrated how a graduate's decision to migrate is subject to individual characteristics such as gender (Faggian, McCann & Sheppard, 2007), ethnicity (Faggian, McCann & Sheppard, 2006) and discipline or type of HE (Faggian, Comunian, Jewell & Kelly, 2013; Venhorst et al., 2010), as well as to pull factors that relate to economic aspects of the destination area, such as the unemployment rate, the existence of a knowledge-economy or interregional wage differentials (Buch, Hamann, Niebuhr & Rossen, 2013; Dotti et al., 2013).

There is a dearth of research focusing specifically on the role of location-specific capital in relation to graduate migration. The purpose of this study is partially to address this gap by assessing the impact of the study region on graduates' residential mobility, accounting for individual and parental characteristics, and for contextual features.

## **Data and methods**

This study uses inter-linked Belgian 1991 (1 March 1991) and 2001 (1 October 2001) census data, and register data on residential changes and deaths between 1 January 2001 and 1 January 2010 for the entire de jure population. The selected population consists of students in full-time HE on 1/10/2001, providing information on the HEI location and student accommodation. In the absence of a direct measurement of graduation, we aim to maximize the completion rate within the sample by restricting analyses to students in the final stages of their HE programme, i.e. students aged 20-24 years in a (professional) bachelor/undergraduate programme or aged 21-25 years in other types of HE. The age criterion excludes a small proportion of students who are older and whose socio-economic and demographic characteristics differ considerably from those of the younger students (1.6%). Students who are not officially domiciled with their parents at the time of their studies (6.0%) and doctoral students are excluded for similar reasons. Students enrolled in more than one HE type (0.1%) are excluded to avoid double counting. The final selection comprises 82,549 students (subsequently also referred to as 'graduates') with a valid HEI location in Belgium.

Logistic regression and Cox modelling are used to estimate the attractiveness and retention capacity of HE cities as a residential destination for recent local students. Our main explanatory variable - *HE City* - is based on the reported location of HE attendance in 2001. Analyses focus on the largest and most important HE cities, defined

by LAU-2 units or municipalities (Eurostat's system of Local Administrative Units is illustrated in Appendix A); smaller cities are grouped together. This results in the following classification: Brussels-Capital Region (BCR), Antwerp, Ghent, Liège, Charleroi, Leuven, Hasselt, Mons, Namur, Louvain-la-Neuve, other regional cities and other smaller cities. To allow representative comparisons, all 19 Brussels municipalities<sup>2</sup> are grouped into a single geographical unit.

Location-specific capital refers to the acquired familiarity with the area through residential experience or having studied in the city, leading to knowledge of local circumstances and to networks of close friends (DaVanzo, 1983; Venhorst, 2013). The concept is approximated by measures of residential proximity to the HEI location. Student accommodation - *StudAcc* - in Belgium chiefly comprises rooms in private properties, rented from landlords or from the educational institution on an individual basis. Despite living in student accommodation, it is a national habit that students generally remain officially registered at the address of the parents during their HE. The comparison of the HEI location, the official residence and the location of daily departure allows the distinction between being in student accommodation or not. Residence in 2001 - *Res01* - is based on the official address of the parents at the LAU-2 level on 1/10/2001 and separates students living in the HE city from those officially domiciled elsewhere. Furthermore, the degree of urbanisation - *Urban01* - of the 2001 residence is considered, distinguishing the central city, agglomeration, banlieue, commuterzone and other municipalities (LAU-2) (Van Hecke, Halleux, Decroly & Mérenne-Schoumaker, 2009).

In line with the abovementioned determinants in skilled migration literature, a number of socio-economic and demographic characteristics have been included as control factors. *EduPar* considers the educational level of the most educated parent<sup>3</sup> (only one in cases of a single parent household) and differentiates between low (no formal, primary, lower secondary), intermediate (higher secondary), high (tertiary) and unknown education. The occupational status of the father (or mother in the case of a single mother household) - *OccupStat* - recodes 14 response categories into five groups: blue-collar, white-collar, self-

<sup>3</sup> Parents are distinguished on the basis of the young adult's household composition in 1991 and 2001. Educational information for parents is derived from the 2001 census or the 1991 censuses in case of incomplete or missing educational information.

employed/managerial, unemployed and unknown occupational status. The type of tertiary training - *HE Type* - distinguishes professional bachelors, academic bachelors, academic masters and postgraduate masters (i.e. additional degree to tertiary qualification).

Demographic measures are origin, age and sex. The nationality of origin - *NatOrig* - is defined based on the nationality at birth and the current nationality of both parents, thereby identifying first as well as second generation migrants. *NatOrig* distinguishes Belgian, Turkish/Moroccan (including North-African and Middle-Eastern), South-European, Western and non-Western (including former Communist countries) respondents. This classification relates to the Belgian migration history and the presence of large groups from these origins in urban areas. *Age* (including age squared to control for non-linear effects) and *Sex* are added too.

In a first step, the model comprises all students (N=82,549), comparing movers from the domicile of the parental home with non-movers. Persons who died before the first move-out (N=19) are excluded. The dichotomous dependent captures whether or not an individual has moved out of the parental home, i.e. changed LAU-2 unit (i.e. municipality) to live in an independent household during the period 2001-2010.

In a second step, the analysis is limited to actual movers, comparing those who are attracted to the HE city and those who moved elsewhere. Young adults who moved abroad (N=2,382) are excluded. To isolate processes of attraction, this migrant population is further reduced to those who were *not* officially domiciled in the HE city on 1/10/2001 (N=56,578). Attraction towards the HE location is thus conceptualised as a residential move to the city of HE (versus not moved to HE city) since 2001, among mobile students who did not live in this city. This second series of models include all covariates from the first logistic models and are extended with indicators related to distance and context.

Assuming the proximity of the HEI is associated with the likelihood of settling there, the distance between the 2001 residence and the HEI location - *DistHEI* - is considered (below 15km, 15-30km, 30-50km and above 50km). All distances are calculated based on the centroids of the LAU-2 units. Although the Belgian geographical context makes long-distance moves uncommon, if they occur, they tend to concern metropolitan destinations, particularly Brussels. Consequently, the distance moved - *DistMoved* - is added to the model. It distinguishes similar categories as the previous indicator.

To account for the structural variability between destination areas, three types of contextual indicators are considered. Based on the related literature, the models include the availability of affordable rental properties (e.g. Helderma, Mulder & van Ham, 2004; Plantinga, Détang-Dessendre, Hunt & Piguet, 2013), population density (e.g. Buch et al., 2013; Garasky, 2002) and job availability (Krabel & Flöther, 2014; Venhorst et al., 2011). All covariates concern cross-sectional information and are based on LAU-2 units (except Brussels, which is considered as the compound region of 19 municipalities). The proportion of affordable rental properties - *Rental* - is calculated as the share of private rental properties with monthly charges below €750 in the housing market in 2001. Population density - *Density* - accounts for the number of inhabitants/km<sup>2</sup> in 2001. To allow a meaningful interpretation, it considers an increase per 1000 persons. Job availability - *Job* - in the destination area is calculated as the number of available jobs per 100 inhabitants between 15 and 64 years of age in 2006<sup>4</sup>. Quadratic terms are included for all structural covariates to control for non-linearity.

The third step of the modelling estimates the extent to which cities retain the attracted graduates in the long run using Cox Proportional Hazards modelling (Cox, 1972; Box-Steffensmeier & Zorn, 2001). The event ('failure') is described as the move out of the municipality of first settlement. The exposure time equals the number of days between leaving the parental home (and thus arrival at the new destination) and the moment the respondent left the first destination (HE city) or 1/1/2010 for those who did not leave the first destination (censored individuals). For clarity reasons and statistical power, analyses are restricted to young adults who settled in their former HE city, extracted from the second series of logistic models (N=13,442; 54 censored cases before the earliest event in a stratum are excluded). The baseline model accounts for HEI location, controlled for age. Extended models include all the above-mentioned indicators controlling for socio-economic and demographic background and for residential and structural variability.

## Results

### *Stayers versus movers*

In 2001, Belgium had 55 municipalities (LAU-2) with an HEI. The 10 most important HE cities (illustrated in Appendix A) together comprise 81.3% of the 82,530 HE students. About one-third of the students lived in student accommodation, with highest propensities in Leuven, Ghent and Louvain-la-Neuve. A detailed overview of all covariates is provided in Appendix B.

The first series of logistic modelling in table 1 exemplifies the differences between graduates who left the parental home (85.2%) during the observation period and those who did not. Model 1 demonstrates that former students from Antwerp, Ghent, Liège and Louvain-la-Neuve are more likely to have moved than the reference group, i.e. Brussels' students. Students from Charleroi, Hasselt and smaller cities conversely, show lower odds of moving. Accounting for the familiarity with the HEI location or the urban environment (model 2), does not result in drastic shifts of the estimated odds ratios (ORs). Characteristics of the parental residence hardly have an influence, contrary to the positive impact of student accommodation. Additional control for socio-economic and sociodemographic characteristics in model 3 results in ORs below unity for Leuven and Hasselt and increased odds of moving for graduates from Louvain-la-Neuve, again compared with Brussels' graduates. A higher socio-economic parental background, being female and having a Belgian origin enhance the odds of leaving the parental home. Logit-models proved robust when excluding the young adults with unknown parental socio-economic characteristics.

### *Modelling cities' attractiveness for movers*

To look closer at these residential moves in relation to the HEI location, subsequent analyses apply to home leavers within national boundaries between 2001 and 2010, who had their residence outside the HE city at the start of the observation period (1/10/2001) (N=56,678). With 23.9% of these highly educated being attracted to the HE city (table 2), the urban environment of the former place of study is clearly an attractive place to settle. Attractiveness, however, varies markedly between cities. The capital city attracted 36.2%

of its non-resident graduate home leavers. Ghent and Antwerp both appear able to keep up, followed by Liège and Leuven. Namur, Charleroi and Mons take intermediate positions, whereas Hasselt and Louvain-la-Neuve have the smallest proportions of graduate in-migrants (11.7% and 11.2%), together with other regional and smaller cities.

**Table 2.** Mobile graduates with an official residence outside the study region in 2001 (*N*), separating those who are attracted to the study region with this first residential move in the period 2001-10 (*N* and %), stratified by the higher education (HE) city attended in 2001.

HE city <sup>a</sup>	<i>N</i> mobile graduates <sup>b</sup>	<i>N</i> attracted mobile graduates to the HE city	% attracted mobile graduates to the HE city
Brussels-Capital Region	9,281	3,361	36.2
Antwerp	4,784	1,536	32.1
Ghent	9,579	3,116	32.5
Charleroi	697	131	18.8
Liège	5,520	1,456	26.4
Namur	1,622	339	20.9
Leuven	6,972	1,768	25.4
Mons	2,172	379	17.4
Hasselt	1,852	217	11.7
Louvain-la-Neuve	3,183	356	11.2
Other regional cities	5,069	551	10.9
Smaller cities	5,847	286	4.9
Total	56,578	13,496 <sup>c</sup>	23.9

Notes: <sup>a</sup>HE cities are ranked according to ascending population size.

<sup>b</sup>Graduates are defined as mobile when at least one residential move is observed (i.e. leaving the parental home). Here, only non-resident students in the HE city on 1 October 2001 are considered.

<sup>c</sup>The attracted former attendant students considered in the subsequent Cox survival analysis. A total of 54 cases are dropped from the analyses as these are censored prior to the first event time, thus making no contribution to the models' estimates.

Sources: Census 2001 and National Register 2001-10, authors' calculations

To assess and explain cities' attractiveness, logistic regressions are conducted among these mobile young highly educated individuals, predicting the odds of moving to the city in which he/she studied versus moving elsewhere. ORs are presented in table 3.

Model 1 presents the crude effect of the HEI location, with BCR as the reference group. All ORs are lower than unity, indicating that Brussels' graduates are most likely to be attracted towards their HE city. The effect of the HEI location remains fairly similar after including indicators that account for the ability to build up location-specific capital (model 2). Characteristics of previous residence and affiliation with urban settings prove to be important factors for understanding migration towards the HE locality. A stay in student accommodation and living close to the HEI or the urban environment in general, greatly enhance the likelihood of graduates being attracted to the HE city. Controlling for socio-economic and demographic characteristics (model 3) results in highly similar odds

for HE city and residential characteristics. Results indicate an educational differential; those with academic degrees show higher odds of being attracted to live in the city in which they studied than their counterparts with a bachelor degree. Socio-economic parental characteristics behave similarly: graduates having a parent with a tertiary degree or being employed in white-collar jobs exhibit higher ORs than those having low educated parents and those having blue-collar or self-employed fathers (or mothers in the case of a single-mother household). All minority ethnic groups show evidence of intensified likelihood of attraction towards the HE city compared with their Belgian-origin counterparts. Particularly, being of Turkish or Moroccan origin has a favourable effect on the HEI location's attractiveness. Age was found irrelevant, whereas female graduates are less likely than males to settle in the HE city during this first move out of the parental home.

Including an additional control for the distance moved (model 4) does not generate notable shifts in the ORs, except for Ghent. An inverse 'U'-shaped relation is observed between the tendency of being attracted towards the HEI location and the distance over which one has moved.

Incorporation of three contextual variables (affordable rental properties, population density and job availability) has a considerable impact on the HE location's attractiveness (model 5). Relatively small cities, such as Namur and Mons, become more attractive than the BCR, the ORs being half to twice as high as in the capital. The attractiveness of Ghent and Charleroi no longer differs from that of Brussels. The ORs of Antwerp and Leuven drop, those of Liège and Hasselt ameliorate slightly relative to BCR. Accounting for inter-urban divergence considerably affects the importance of some background characteristics. Overall, socio-economic and demographic indicators as well as the distance moved lose significance or magnitude. Importantly, however, ties with the HEI location or urban environment remain of great importance once inter-city differences are considered. Concerning the structural variability, an inverse U-shape is observed for population density, indicating how the relation with urban attractiveness turns negative once a certain density threshold (i.e. 5,640 inhabitants/km<sup>2</sup>) is exceeded. Both the availability of affordable rental dwellings and of jobs appears to trace a fairly weak negative relationship with the odds of graduate attraction to the city of HE.

Sources: Census 1991 and 2001 and National Register 2001-10, authors' calculations

In sum, these regressions show that the position of Brussels as the capital of Belgium does not necessarily imply a higher attractiveness among its recent graduates when cities' structural characteristics are held comparable. The results are in line with an economic narrative. The opportunity to acquire familiarity with the study region together with individual characteristics, however, remains important in graduates' residential behaviour toward the HE locality. The subsequent part of this paper considers this further by investigating differences between cities of HE in the retention of graduates.

### *Who Stays?*

The analyses in this section are restricted to the 13,442 highly educated who actually moved to their HEI location between 2001 and 2010. During the observation period, which starts when leaving the parental home and ends on 1/1/2010, 6,992 graduates left the city again and 6,450 were right-censored. The cumulative survival for graduates is calculated as the percentage of graduates still in the city of HE at the end of each interval in the observation period.

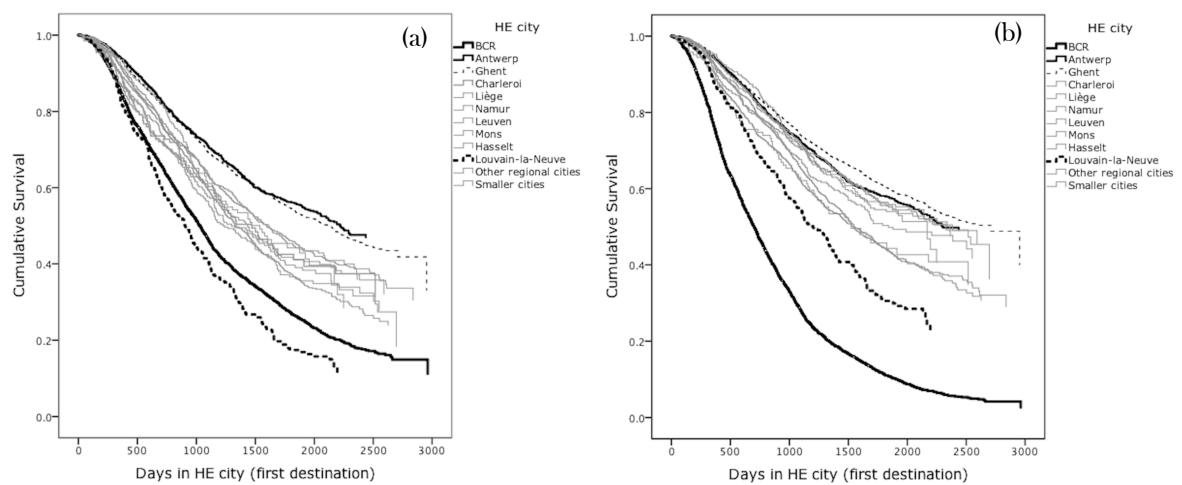

Plotting the HE cities' survival curves for the basic model sheds light on the retention capacity of HE localities (figure 1(a), model 1). For clarity, graphs only highlight the most distinct curves. Survival curves in colour are provided in in Figures C1 and C2 in Appendix C. In the Brussels capital and Louvain-la-Neuve, the latter characterised by a large student population, cumulative survival rates after first settlement quickly drop below 50% (respectively solid and dashed bold lines at the bottom). Antwerp and Ghent on the contrary are able to retain a larger share of their graduates over time (respectively solid and dashed black lines at the top). All other cities take intermediate positions in terms of remaining attractive for the settled former students (grey).

Overall, the explanatory power of individual, residential and structural indicators in relation to differential graduate retention of HE cities is rather modest: the characteristics that proved important for the attractiveness of HE locations appear to lose their significance for predicting retention over time. The cumulative survival for the different HE locations after statistical control for socio-demographic and residential features (model 2, not shown) reveals a highly similar pattern. The additional control for inter-urban divergence (figure 1(b), final model) illustrates that, once structural variability is accounted for, cumulative survival rates for BCR drop considerably. This diminution is not observed

for the other HE cities. As the second largest city, Antwerp, performs quite well in retaining its students for a long period of time. Ghent remains in its leading position, yet less pronounced. In line with the particularity of a typical ‘student city’, Louvain-la-Neuve does not manage to retain its graduates in the long term.

**Figure 1.** Cumulative survival function for attracted graduate migrants (N=13,442), by city of higher education (HE) in 2001: (a) model 1 includes HE institution (HEI) location and controls for age; and (b) the final model includes HEI location and controls for demographic, socio-economic, residential and contextual characteristics.

Sources: Census 1991 and 2001 and National Register 2001-10, authors’ calculations

In sum, these findings reveal that cities differ in their ability to attract and retain their locally produced graduates. During the observation period 2001-2010, Ghent, and, to a somewhat lesser extent, Antwerp, retain the highest share of their graduates who made a residential move into the city.

### Discussion and conclusions

Human capital research has increasingly devoted attention to individual and contextual drivers of skilled young adults’ residential behaviour enhancing our comprehension of economic determinants of graduate migration. However, extant studies too often overlook the potential importance of non-economic characteristics of places. One study that attempts to broaden the economic approach to skilled migration is Ciriaci’s (2014) paper on the relevance of universities’ research and teaching quality for the residential behaviour of the

student population in their early professional career. However, rather than only institutional characteristics, this study argues that location-specific capital related to the study region in general determines migration patterns of graduates in the short and long term after their graduation.

The present study reveals some noteworthy results. First, analyses demonstrated high levels of residential mobility among the skilled (85.2%) who tend to settle either within the close environment of their parental home or in larger urban areas. For about one-third of the graduate home leavers, the urban locality was related to the location and process of HE knowledge acquisition, suggesting the role of regional familiarity in their residential behaviour. At first sight, the BCR appeared the most attractive destination compared with any other HE city in Belgium. Assuming that graduates make a comparative assessment of costs and benefits related to a move in order to obtain a suitable job, its attractiveness to high-skilled people is rather self-evident as expected income is higher (Borjas et al., 1992; Statistics Belgium, 2011). Long-distance moves being observed only in the case of Brussels supports this argument. Of course, only the BCR has both French and Flemish universities and colleges on its territory and thus a larger catchment for its in-migrants than other cities; Regional boundaries, cultural differences and language barriers seem powerful incentives for young adults (not) to migrate in the Belgian case.

Second, the BCR's attractiveness seems at least partly indebted to its capital function and international character rather than being the former HE city. Once structural between-city variability is accounted for (affordable rental housing, population density and job availability), smaller cities such as Namur and Mons exhibited higher rates of in-migration of their graduates than the BCR. Cox modelling demonstrated how these smaller cities better manage to retain their graduates in the decade after migration than BCR. The idea that a large city, *ceteris paribus*, is most attractive (Buch et al., 2013) does not hold. Of course, the availability of facilities, services, amenities, transportation and a vibrant social life are plausible explanations for a city's appeal (Howley, 2009). Yet, cities' sustainability could be at odds with cities' liveability, as the latter requires functions and populations to be dispersed at lower densities (Neuman, 2005). The inverse 'U'-shaped effect of population density in our logit models suggests that once a certain threshold has been crossed, the attraction of a city, i.e. Brussels and, to a lesser extent, Antwerp, could be reduced owing to an inferior (perceived) liveability compared with smaller cities, such as Namur, Mons,

Liège or Ghent. The high price of living space and dwellings within the capital, negatively adds up to its (perceived) attractiveness. So despite the job opportunities in the labour market that demand increasingly high requirements in terms of skills (Van Hamme, Wertz & Biot, 2011), the BCR seemingly is unable to overcome sensed differences in quality of life compared with suburban or other areas.

Third, parental capital can facilitate a move, parental resources off-setting a potential lack of financial means, especially at the very beginning of one's professional career. The higher attraction of ethnic minority origin groups to cities of HE study could indicate how the lack of economic parental resources (especially among Turks and Moroccans) is counterbalanced by the acquired location-specific capital that is built up through residence-based experiences.

Overall, this paper's findings support the idea that 'location-specific insider advantages' (Fischer & Malmberg, 2001) or 'location-specific human capital' (Haapanen & Tervo, 2012) acquired during HE can enhance the appeal of a city after graduation. However, location-specific advantages appear likely to become less useful once graduates have built up economic capital through the expansion of a professional career and an increasing wage. This phenomenon was most pronounced in Brussels, which, as discussed above, was relatively less successful at retaining graduates over the long term. Of course, the replenishment of graduates who leave the cities with more recent graduates could secure cities' sustainability in terms of highly skilled population, especially in the Brussels' case where absolute numbers of HE graduates are highest. Importantly, however, the earnings of graduates at the start of their professional career are lower than later on and so are their tax contributions. Furthermore, the replenishment with non-local graduates, i.e. the exchange of graduates between HEI locations in Belgium, is negligible. In line with the importance of regional familiarity for graduate residential choices (Venhorst, 2013), non-locally produced graduates tend to settle in the close environment of their former HEI or their family but rarely in another HE city.

The apparent relative success of smaller cities in attracting and retaining graduates may be due to the fact of graduates having found jobs that match their profile. Our data do not provide information on job status or location after graduation, and this is one of the limitations of the study. As such, models cannot account for the type of job, income or other individual labour market-related characteristics that affect graduate migration. Given

the considerable divergence between conditions and opportunities offered by labour markets in each of the HE cities, the incompatibility of HE degrees and low-skilled jobs plausibly hinders residential attractiveness. Commuters were not traceable in the graduate population as a consequence of the selection criteria used. All things considered, the interpretation of our findings in light of the recently observed urban fiscal shortages and social polarisation is rather conservative, particularly in the case of Brussels where absolute numbers of commuters are very high. Thus, we may well underestimate the financial burden non-resident workers place on the city's infrastructure, and the relative advantage of smaller cities in terms of attraction and retention of graduates.

Ideally, multivariate models would include a wide array of location-specific factors. While it is almost impossible to integrate an exhaustive list of all kinds of amenities, a database with such extensive covariates is not (yet) available but would be a useful development for further research. Indeed, to grasp fully the potential ability of (HE) cities to attract and retain the most skilled, further study of the location-specific incentives shaping graduate migration is needed. Acquaintance with or knowledge about the available housing stock, availability of childcare and primary schools, cultural amenities, language or regional boundaries, social networks and perceived environmental quality constitute location-specific factors of future research interest. In probing the role that HE locations hold in graduate migration, future studies should particularly aim at better disentangling (1) the location-specific factors bound to a place, to local communities or to the life course, that attract people; and (2) social, cultural and ethnic variability, especially within the context of increasing diversity and social polarization in many Western urban areas.

Local authorities need to invest further in enhancing central cities' attractiveness and should implement policies to meet the residential preferences of young adults in the long run, as they accumulate financial resources and move through the life course. Only in safeguarding the value of location-specific capital in all stages of life, will a higher proportion of people who studied in the city contribute to local tax revenue and to the long-term sustainability and liveability of cities.

## Appendix A. Regions and higher education cities in Belgium

**Figure A1.** Administrative regions and largest higher education cities in Belgium

Spatial boundaries are according to the NUTS classification of the Local Administrative Units system as defined by the Commission Regulation No. 1059/2003, set up by Eurostat.

(1) Regions are NUTS-1 units. There are three regions in Belgium, i.e. Flanders, Wallonia, Brussels-Capital Region.

(2) Provinces are NUTS-2 units. Belgium constitutes 11 provinces, i.e. Antwerpen, Limburg, Oost-Vlaanderen, Vlaams-Brabant, West-Vlaanderen, Hainaut, Liège, Luxembourg, Namur, Brabant wallon, Brussels-Capital Region.

(3) *Metropolitan* cities are Brussels-Capital Region, Antwerp, Ghent, Charleroi and Liège. *Regional* cities are Aalst, Arlon, Brugge, Doornik, Genk, Hasselt, Kortrijk, La Louvière, Leuven, Mechelen, Mons, Namur, Oostende, Roeselare, Sint-Niklaas, Turnhout,

Verviers. This distinction is based on the urban facilities/provisions and the extent to which these are used by local residents and/or non-local residents (Van Hecke et al., 2009). The spatial units are defined based on the municipalities, i.e. LAU-2 units, formerly NUTS-5. There are 589 Belgian municipalities. Populations range from 56 (Honnelles) to 445,570 (Antwerp), densities from 1 inh./sq.km (Honnelles) to 19,442 inh./sq.km (Saint-Josse-ten-Node, part of the Brussels-Capital Region). Table A1 provides some general characteristics of the largest higher education cities.

**Table A1.** Main characteristics of the largest higher education cities.

HE cities	Population (1/10/2001) <sup>a</sup>	Density (1/10/2001) <sup>a</sup>	Job ratio (1/1/2006) <sup>b</sup>	Wealth Index (average 2004- 2006) <sup>c</sup>
Brussels-Capital Region <sup>d</sup>	964,405	5,975 with municipal values ranging from 1,903 to 19,442	86 with municipal values ranging from 38 to 232	88 with municipal values ranging from 52 to 114
Antwerp	445,570	2,179	93	95
Ghent	224,685	1,439	106	106
Charleroi	200,233	1,962	68	79
Liège	184,550	2,660	85	86
Namur	105,248	599	87	101
Leuven	88,581	1,564	113	119
Mons	91,123	622	77	89
Hasselt	68,373	669	109	113
Louvain-la-Neuve	27,703	840	86	105

Notes: <sup>a</sup> Derived from the 2001 census, authors' calculations.

<sup>b</sup> Source: Vlaamse Arbeidsrekening, Job ratio as the annual average of 2006

<sup>c</sup> Source: Statistics Belgium; The Wealth Index is a summary index that compares the mean fiscal income per inhabitant of an administrative unit (here LAU-2) with the mean fiscal income of a Belgian citizen. The Wealth Index of Belgium is set equal to 100. An index value below 100 indicates that the mean income per resident within a specific municipality is below the national mean income. The opposite is true for index values of more than 100.

<sup>d</sup> In this study, the Brussels-Capital Region constitutes of its 19 municipalities.
