Abstract—Heart disease is known to be one of the main cause of death worldwide. In the United States, the disease is the leading cause of death for people of most ethnicity. In Indonesia, the disease contributes 17% of the total mortality. It is also well-known that a regular or continuous monitoring the heart rate is important to minimize the fatality. At the current technological state, the monitoring method is expensive and often requires wearable sensor, which is inconvenient. This study intends to establish a relationship between the heart rate and speech signals empirically by using a regression and correlation analysis. The speech signals are analyzed through a frequency analysis using fast Fourier transformation. The results suggest that vowel ‘e’ speech signal has a strong correlation to the heart rate.

Keywords—Heart Rate, Vowel Speech Signals, Fast Fourier Transform

I. INTRODUCTION

Around seventy million people worldwide suffer from heart disease [1]. Most of them died because they did not receive appropriate medical treatment in timely manner. According to the WHO report, more than 200 000 Indonesian people died because of heart attack, which contributes 17% of the total deaths [2]. Early detection is believed to be a solution to reduce the mortality rate of heart-disease patients. Early detection is highly needed [3].

A common diagnostic tool to assess human heart rate condition is electrocardiogram (EKG or ECG) [4]. ECG is a non-invasive contact tool to check the electrical activity of the heart based on the bio-potential signals acquired from human skin surface [5]. It requires patients to wear adhesive gel patches or chest straps that may cause skin irritation and discomfort [6].

Lately, along with the increasing number of heart disease patients who require long-term and continuous heart rate monitoring, the demand of contact-less and convenient heart rate measurement increased significantly. Some previous researchers have shown that heart rate can be identified from a distance. For example, Ref. [7] found that English vowel speech signals can be related to the human heart rate. The previous research about heart rate extraction using English vowel speech signal showed that heart activity can be accurately estimated by applying Fourier analysis, including short-time Fourier transform (STFT) and discrete Fourier transform (DFT) to detect the formant maximum peaks from the English vowel-speech signals [7]. Reference [8] has proposed a novel non-contact-less technique for heart-rate extraction. The human speech signals contain heart-beat modulation in which the relevant ECG information can be extracted.

Although the number of works in this area is limited, the conjecture that speech signal is show-how related to the heart rate has rather sound ground. The model of source-filter theory of speech production suggests that the speech production is a result of air molecules movement across the human vocal tract. The produced speech is controlled by the vocal tract volume, shape, and length. The larynx and vocal cord, important components of the vocal tract, contain muscles covered by many blood vessels connected to the circulatory system. Thus, the heart rate is dynamically related to the variations of vocal cord parameters and is directly related to the acoustic properties of human speech [7], [9].

The objectives of this work are of the following. The first is to explore pattern that may relate the heart rate to the speech signals, particularly, vowels in Indonesia language. The second is to establish a mathematical model of the relation and to evaluate the level of conformity of the model.

The manuscript contains the following sections. Section II Research Methods presents the research procedure, data collection methods, and data analysis methods. Section III Results and Discussion presents the obtained patterns relating heart rate to speech signal. In addition, the patterns are also mathematically quantified, and the model validity is statistically examined. Section IV Conclusions briefly presents the current research focus and related findings.

II. RESEARCH METHODS

The research was performed the flowchart depicted in Fig. 1 [10]–[12]. The statements of the research problems have been given in Section I. Shortly, we would explain the data acquisition procedure and data analysis techniques.

Fig. 1. The research procedure.

Two essential types of data to support this study are the heart-rate data and the associated speech signal. The heart-rate data and vowel speech signals were collected from 20 adults, 10 males and 10 females. They were asked to speech the vowels: 'a' 'i' 'u' 'e' and 'o' for a duration about 6 s, and their voices were recorded using a smart-phone. The example of the speech signal for vowel 'e' in Indonesia language is shown in Fig. 2.

The collected speech signal was transformed to the frequency domain by applying the Fourier transform:

$$X(f) = \int_{-\infty}^{+\infty} x(t) \exp(-2j\pi ft) dt, \quad (1)$$

where $x(t)$ is the speech signal data in the time domain and $X(f)$ the data in the frequency domain. An example of computed speech signal spectra is shown in Fig. 3.

Prior the transformation, the signal was smoothed out by applying the fifth order of the Butterworth filter with the cutoff frequency of 1 kHz and 6 dB roll-off. Mathematically, the gain of an n -order Butterworth low-pass filter is

$$G^2(\omega) = \frac{G_0^2}{1 + \left(\frac{\omega}{\omega_c}\right)^{2n}}, \quad (2)$$

where ω is the angular frequency, ω_c is the cutoff frequency, and G_0 is the DC gain.

In addition to the filtering, the signal was also passed through a Hamming window. The window formulas is

$$w(n) = \alpha - \beta \cos\left(\frac{2\pi n}{N-1}\right), \quad (3)$$

where $\alpha = 0.54$, $\beta = 0.46$, and the index $n \in [0, N-1]$.

From the signal spectra $X(f)$, we identified the frequencies related to the five most dominant spectra. Subsequently, we determined the differences between those frequencies, and the average of these frequency differences was considered to be the most relevant feature for heart rate prediction. The definition of the frequency difference is graphically shown in Fig. 3.

The heart-rate data were collected by means of Pulse Oximeter. To obtain the data for the condition of high heart

Fig. 2. The example of the speech signal for vowel 'e' in Indonesia language.

rate, the participants were asked to perform some light exercises, jogging or jumping, prior the data acquisition. In total, 100 speech signals were collected.

We assumed that the heart rate is linearly related to the average frequency or

$$\text{bpm} = \beta_0 + \beta_1 \cdot \Delta f, \quad (4)$$

where β_0 and β_1 are the model coefficients, bpm is the heart rate in bpm and Δf is the average frequency difference in Hz.

The validity of the proposed linear model (4) would be checked by using the two statistics: t -statistic to measure the significance of β_1 and the coefficient of determination R^2 . The t -statistic has the following hypotheses:

$$\begin{aligned} H_0: & \quad \beta_1 = 0, \text{ and} \\ H_a: & \quad \beta_1 \neq 0. \end{aligned}$$

Thus, we expect that the empirical data to support the case where $\beta_1 \neq 0$. The coefficient of determination would measure to which extent the assumed linear model fits to the empirical data. The relevant formulas are

$$R^2 = 1 - \frac{SS_{\text{res}}}{SS_{\text{tot}}}, \quad (5)$$

$$SS_{\text{tot}} = \sum_i (\text{bpm}_i - \overline{\text{bpm}})^2, \quad \text{and} \quad (6)$$

$$SS_{\text{res}} = \sum_i (\text{bpm}_i - \widehat{\text{bpm}}_i)^2, \quad (7)$$

where bpm_i is the i th data of bpm, $\overline{\text{bpm}}$ is the average bpm, and $\widehat{\text{bpm}}_i$ is the predicted bpm.

Eighty-five percents of the data were used in the training phase where the coefficients β_0 and β_1 were estimated by using the least-squares method. The remain data were used to evaluate the accuracy of the developed linear model.

III. RESULTS AND DISCUSSION

A. Linear Model Development

The main result of this work is the relation between the heart rate and the frequency difference. These relations are

Fig. 3. The spectra of the speech signal shown in Fig. 2 and the definition of frequency difference Δf .

Fig. 4. The averaged frequency differences in Hz versus the heart rate in bpm for the Indonesian speech signal for the character 'a'.

Fig. 7. The averaged frequency differences in Hz versus the heart rate in bpm for the Indonesian speech signal for the character 'e'.

Fig. 5. The averaged frequency differences in Hz versus the heart rate in bpm for the Indonesian speech signal for the character 'i'.

Fig. 8. The averaged frequency differences in Hz versus the heart rate in bpm for the Indonesian speech signal for the character 'o'.

Fig. 6. The averaged frequency differences in Hz versus the heart rate in bpm for the Indonesian speech signal for the character 'u'.

TABLE I. SOME STATISTICS DESCRIBING THE RELATIONS BETWEEN THE FREQUENCY DIFFERENCE Δf IN HZ AND THE HEART RATE IN BPM. THE VALUES OF $\hat{\beta}_0$ AND $\hat{\beta}_1$ ARE THE ESTIMATES OF β_0 AND β_1 IN EQ. (4). THE STATISTIC p -VALUE MEASURES THE SIGNIFICANCE OF $\hat{\beta}_1$; p -VALUE SMALLER THAN 5% IS CONSIDERED SIGNIFICANT.

Speech Signal	$\hat{\beta}_0$	$\hat{\beta}_1$	R^2	adj- R^2	p -value
'a'	58.358	0.113	0.801	0.789	0.000
'i'	56.206	0.145	0.716	0.699	0.000
'u'	45.653	0.174	0.813	0.803	0.000
'e'	45.057	0.233	0.876	0.869	0.000
'o'	51.449	0.166	0.422	0.385	0.004

graphically shown in Figs. 4–8 and are numerically evaluated in Table I.

From these results, we conclude the following. The hypothesis that the heart rate is linearly related to the frequency difference is strongly supported the empirical data. This strong supports can be seen from the values of the computed coefficient determinations, which are in the range of 0.700–0.869,

except for the case of 'o' speech signal. The t -statistic also supports the hypothesis that can be seen from the p -statistics, whose values are extremely, except for the case of 'o' speech signal.

B. Testing of the Regression Model

The best model established in the previous section is the case of 'e' speech signal. This case provides the model of $\text{bpm} = 45.06 + 0.233 \cdot \Delta f$. In this section, we test the accuracy of this model. We use the testing data set, which are collected separately from the data set utilized in the model training. The results are tabulated in Table II and graphically are shown in Fig. 9. With the coefficient determination of 0.85, these results are rather satisfactory.

TABLE II. THE RESULTS OF THE TESTING OF THE MODEL $\text{bpm} = 45.06 + 0.233 \cdot \Delta f$, WHICH IS OBTAINED FOR THE VOWEL 'E'.

No.	Age	Gender	Heart Rate (bpm)		
			Measurement	Estimation	Error (%)
1	23	M	69	77	8

15	23	M	78	78	0

Fig. 9. A comparison of the measured heart rate and the predicted heart rate using a linear model. The coefficient of determination R^2 of these data are 0.85.

IV. CONCLUSIONS

Capability to continuously monitor the heart rate is of interest from the medical perspective. The continuously monitoring of the heart rate are arguably crucial to prevent the sudden death due to heart attack. The existing techniques are rather impractical. This work intends to establish the relation between

the speech signal frequency and the heart rate. This particular relation would facilitate the continuous heart rate monitoring. The results suggest that the heart rate may be somehow related to the speech signal frequency by a linear model. This model is rather accurate for vowel speech signals of 'a', 'i', 'u', and 'e', but is less accurate for the vowel speech signal of 'o'.
