17 ***thermophilus* cultivated in microfiltered pasteurized milk**

18

19 **ABSTRACT**

20 A set of 191 strains of *Streptococcus thermophilus* were preliminarily screened for the presence
21 of the genes codifying for cell envelope-associated proteinase (*prtS*), and for glutamate
22 decarboxylase (*gadB*) responsible for γ -aminobutyric acid (GABA) production. Growth and
23 proteolytic activity of the *gadB* positive strains (nine presenting the *prtS* gene and 11 lacking it)
24 were studied in microfiltered pasteurized milk. Degradation of both caseins (capillary
25 electrophoresis) and soluble nitrogen fractions (HPLC), and changes in the profile of free
26 amino acids (FAA, ion-exchange chromatography) were evaluated at inoculation and after 6
27 and 24 hours incubation at 41°C. None of the strains was capable of hydrolyzing caseins and β -
28 lactoglobulin and only two hydrolyzed part of α -lactalbumin, these proteins being present in
29 their native states in pasteurized milk. Contrariwise, most strains were able to hydrolyze
30 peptones and peptides. For initial growth, most strains relied on the FAA present in milk,
31 whereas, after 6 hours, *prtS*⁺ strains released variable amounts of FAA. One *prtS*⁺ strain
32 expressed a *PrtS*⁻ phenotype and two *prtS*⁻ strains showed a rather intense proteolytic activity.
33 Only five strains (all *prtS*⁺) produced GABA, in variable quantities (up to 100 mg/L) and at
34 different rates, depending on the acidification strength. Addition of glutamate did not induce
35 production of GABA in non-producing strains that, however, unexpectedly showed to adopt the
36 degradation of arginine into citrulline and ornithine as an alternative acid resistance system and
37 likely as a source of ATP.

38

39 KEYWORDS: *Streptococcus thermophilus*, microfiltered milk, proteolysis, free amino acids,
40 GABA, arginine, citrulline, ornithine.

41

42

43 INTRODUCTION

44 Among lactic acid bacteria, *Streptococcus thermophilus* represents the second most important
45 species of lactic acid bacteria (LAB) of industrial interest, after *Lactococcus lactis* and it is the
46 only species of this genus recognized as “Generally Regarded As Safe” by the FDA¹. *S.*
47 *thermophilus* is widely present in raw milk and is a major dairy starter used in the
48 manufacturing of both artisanal and protected designation of origin (PDO) cheeses²⁻³, in
49 traditional yoghurt preparation, in combination with *Lactobacillus delbrueckii* subsp.
50 *bulgaricus*, and more generally in fermented milk products.

51 It was highlighted that *S. thermophilus* in milk satisfies its amino acid requirement by efficient
52 biosynthetic capacities and by cooperation with other species of the dairy environment, being
53 the most studied the proto-cooperation with *Lb. delbrueckii* subsp. *bulgaricus*. The proteolytic
54 system of *S. thermophilus* consists of (i) an extracellular cell envelope protease, called PrtS and
55 belonging to the subtilisin-like serine protease family⁴⁻⁶, (ii) an efficient transport system for
56 import of amino acids and oligopeptides, and (iii) a pool of intracellular peptidases for further
57 degradation. PrtS is reported to be present only in a minority of the strains studied to date. Non-
58 expression of *prtS* gene is reported as well¹. Letort et al.⁷ evidenced that growth of *S.*
59 *thermophilus* in liquid milk shows two different exponential phases and that expression of PrtS

60 takes place in the second one. In general, the proteolytic activity allows the PrtS⁺ strains in
61 pure culture to grow and produce acid in milk more rapidly than the PrtS⁻ strains.⁸ More
62 recently, the existence of a range of cell-associated extracellular peptidase activities was
63 reported for a strain with PrtS⁻ phenotype, including aminopeptidase, carboxypeptidase,
64 peptidyl dipeptidase and X-prolyl dipeptidyl peptidase.⁹ The ability of *S. thermophilus* to
65 hydrolyze undenatured (native) β -lactoglobulin (b-Lg) and α -lactalbumin (a-La) whey proteins
66 in milk has not been elucidated yet, as most of the studies have been conducted on heat
67 denatured whey proteins. A single strain of *S. thermophilus* inoculated in heat-sterilized
68 reconstituted whey powder promoted the hydrolysis of up to 10% b-Lg and 2-3 fold more a-
69 La.¹⁰

70 Amino acid biosynthesis pathways were identified by in silico studies⁶ and the number and
71 nature of amino acids essential for growth were found to be strain dependent with some strains
72 exhibiting no absolute amino acid requirement.^{4,11,12} It is worthy to note that most of these
73 studies were conducted on a limited number of strains and this fact might explain some
74 contradictory results. Very little information is available on the changes in free amino acid
75 content of milk during growth of *S. thermophilus*. At this regard, it has to be considered that
76 milk contains few free amino acids and peptides. However, milk native proteases, such as
77 plasmin and cathepsins, contribute to initiate casein degradation^{13,14} and thus provide more easy
78 access to the microbial proteases.

79 Presence of bioactive substances in foods is receiving increasing attention within the scientific
80 community. Among these, γ -aminobutyric acid (GABA), a non-protein amino acid that is
81 widely distributed in nature¹⁵, possesses a variety of beneficial effects and physiological

82 functions, such as neurotransmission, induction of hypotension and secretion of insulin and
83 plasma growth hormone ^{16,17} as well as stimulation of immune cells.^{18,19} Ability to produce
84 GABA was evidenced in *S. thermophilus* and related to the presence of the *gadB* gene.²⁰
85 LAB strains producing GABA were observed among *Lactococcus lactis* (22), *Lactobacillus*
86 *brevis* (23), *Lb. buchneri* (24), *Lb. helveticus* (25), *Lb. paracasei* (26), *Lb. plantarum* (27) and
87 *Lb. sakei* (28) species.

88 Other LAB species able to produce GABA are *Lactococcus lactis*²¹, *Lactobacillus brevis*²², *Lb.*
89 *buchneri*²³, *Lb. helveticus*²⁴, *Lb. paracasei*²⁵, *Lb. plantarum*²⁶, and *Lb. sakei*.²⁷ In microbes,
90 production of GABA has been reported to increase acid tolerance.²⁸ During cell growth, the
91 intracellular pH decreases as a consequence of the accumulation of organic acids. The glutamic
92 acid decarboxylase (GAD) system converts one molecule of glutamate into one molecule of
93 GABA consuming an intracellular proton, thus shifting the cytosole pH towards neutrality.
94 GABA is then released into the extracellular environment, thereby contributing to
95 alkalinisation.²⁹

96 The capability of producing GABA is expected to be dependent on both the degree of GAD
97 activation and availability of free glutamate²⁸. High levels of glutamate may be released by
98 proteolytic enzymes in dairy products, since milk proteins are rich in this amino acid.³⁰ To our
99 knowledge, few studies have considered fermented milks and cheeses as potential vehicles for
100 GABA.³¹⁻³⁴ In this context, the biodiversity of the microbiota in raw milk cheeses represents an
101 unmatched source of strains to investigate for GABA production ability.

102 The aim of this work was to investigate the proteolytic activity of *S. thermophilus* strains in
103 mildly heated (pasteurized) milk and to shed light on their behaviour with respect to available

104 free amino acids and production of GABA. To conduct this study, 165 wild strains isolated
105 from both artisanal and PDO raw milk cheeses as well as 26 strains from commercial starter
106 cultures were preliminarily screened for the presence of the *prtS* and *gadB* genes; on this basis,
107 20 strains were selected for this study.

108

109 **MATERIALS AND METHODS**

110 **Bacterial strains.** A set of 191 *S. thermophilus* strains, including 165 wild strains from the
111 bacterial collection of the Institute of Sciences of Food Production of the National Research
112 Council of Italy (CNR-ISPA, Milan, Italy), previously isolated from Italian raw milk cheeses,
113 and 26 strains from the Sacco S.r.l. (Cadorago, Italy) culture collection, was used in this study
114 (**Table 1**). The strains were previously identified by partial 16S ribosomal DNA sequence
115 analysis as described by Morandi et al.³⁵ and analysed by RAPD-PCR analysis with primers
116 M13, D11344 and D8635 to exclude clonal relatedness.² Twenty strains harbouring the
117 ORF*gadB* gene were selected for the study of proteolytic activity and GABA production in
118 milk.

119

120 **Detection of *prtS* and ORF*gadB* genes.** DNA was extracted according to Cremonesi et al.³⁶
121 from 1 mL of overnight grown bacterial culture, incubated in M17 broth (Biolife, Milan, Italy)
122 at 37 °C by the DNA Isolation System Kit (M-Medical, Genova, Italy), according to the
123 manufacturer's recommendations. Genomic DNA was used in the PCR reactions to detect the
124 presence of the *prtS* (531 bp) according to Galia et al.³⁷ using the primer Prt/For (5'-TAC GGT
125 GAA TGG TTT AACG-3') and Prt/Rev (5'-AAT TAC TTT ACT ACC AAC CG-3'). In

126 addition, the presence of ORF*gadB* (1.380 bp) gene was tested with primers P3/For (5'-ATG
127 AAT GAG AAG CTA TTC AGA GAG AT-3') and P4/Rev (5'-TTA ATG ATG GAA GCC
128 ACT GCG GATG-3')²⁰. Amplification conditions were: initial denaturation at 94 °C for 5 min
129 followed by 30 cycles of 94 °C for 1 min, 55 °C for 1 min and 72 °C for 1 min. Final extension
130 was carried out at 72 °C for 5 min. All the PCR reactions were carried out in a Mastercycler
131 (Eppendorf, Hamburg, Germany). Each DNA amplification was performed in 200- μ L
132 microtubes using 25 μ L of reaction mixture containing 50-100 ng DNA template, PCR Master
133 Mix 2X (Thermo Fisher Scientific Inc., Waltham, MA, USA), 10 μ M of the primer pair and
134 double-distilled water to achieve the final volume. Amplification products were separated on a
135 1.5% agarose gel GellyPhor (Euroclone, Pero, MI, Italy) stained with GelRedTM (Biotium,
136 Hayward, CA, USA). Molecular size markers (TrackItTM 1 Kb Plus DNA Ladder, Life
137 Technologies, Carlsbad, CA, USA) were included in each agarose gel.

138

139 **Milk incubation trials.** Before incubation trials, strains were inoculated twice in succession in
140 reconstituted skim milk (10% w/v) and incubated at 37 °C overnight. To avoid presence of
141 contaminating bacteria, somatic cells and spores, microfiltered pasteurized (75° C for 15 s)
142 milk (MPM) was used for incubation trials. Freshly produced MPM was taken at an industrial
143 plant (Tetrapack, Arhus, Denmark), immediately frozen and kept at -18 °C until inoculation.
144 Stationary-phase-grown cells from overnight cultures of each *S. thermophilus* strain were
145 inoculated in six sterile tubes containing 50 mL MPM at a final cell density of 7.01 ± 0.37 log
146 CFU mL⁻¹ and incubated at 41 °C for 24 h. The optimal conditions (41 °C) for *S. thermophilus*

147 growth in milk were also applicable to the production of GABA, since Yang et al.⁴⁵
148 demonstrated that 40 °C, pH 4.5 were the optimal conditions for GAD activity.

149 A negative control (non-inoculated MPM) was included in each incubation trial. In selected
150 experiments, MPM was supplemented with glutamic acid (Sigma-Aldrich, Milan, Italy) to
151 increase the concentration by 1 mMol L⁻¹. At each sampling time, the content of three tubes
152 was mixed and pH (Metrohm, Origgio, CO, Italy) and viable cell count enumeration of *S.*
153 *thermophilus* were determined and aliquots taken for proteolysis analyses.

154

155 ***S. thermophilus* viable cell count.** During the incubation trials, 1 mL of the cultured MPM
156 samples was taken after 0, 6 and 24 h, serially diluted on the decimal scale in one-quarter-
157 strength Ringer's solution and plated on M17 agar (Biolife) in duplicate for viable counts. The
158 plates were incubated under aerobic conditions at 37 °C for 48 h.

159

160 **Estimation of proteolysis and GABA production in incubated milk samples.** Individual
161 casein fractions were evaluated by capillary zone electrophoresis (CZE). One mL of incubated
162 MPM sample was clarified by centrifugation (3000g for 10 min), added with 10 mL of 10 M
163 urea sample buffer and, after 4 hours, filtered on 0.22 µm disposable filter and analysed by
164 CZE. Buffers and separation conditions for CZE were as described by Masotti et al.³⁹ Analyses
165 were carried out using a P/ACE System MDQ unit (Beckman Instruments Inc., Fullerton, CA,
166 USA), equipped with a diode array detector operating at 214 nm and a coated capillary column
167 (DB-WAX 126-7012; Agilent Technologies Inc., Santa Clara, CA, USA), 500 mm x 50 µm i.d.,
168 with slit opening of 100 x 800 µm.

169 The soluble nitrogen components were analysed by high-performance liquid chromatography
170 (HPLC). Ten mL of incubated MPM samples were adjusted to pH 4.6 using 1 M HCl,
171 centrifuged (Du Pont Instruments Sorvall RC-5B, 12000g for 20 minutes at 10 °C) and filtered
172 through a sterile 0.22- μ m filter. The filtrate was analysed by HPLC according to the conditions
173 described by De Noni et al.⁴⁰ An Alliance workstation (Waters, Milford, MA, USA) was used,
174 coupled with a 996 DAD detector (Waters) operating at 205 nm. The concentration of α -
175 lactalbumin (a-La), β -lactoglobulin (b-Lg), proteose-peptone (PP) and small peptides (SP) were
176 calculated using the external standard calibration curves as described by Pellegrino et al.⁴¹
177 Free amino acids were analysed by ion-exchange chromatography as described by D’Incecco et
178 al..⁴² The same filtrate as for HPLC was adjusted to pH 2.2 using 1 M HCl and filtered on 0.2
179 μ m RC filter prior to injection into the chromatograph. A Biochrom 30+ (Biochrom Ltd,
180 Cambridge, UK) automatic amino acid analyzer was used operating under the conditions
181 provided by the manufacturer. Briefly, a 10-step elution program with six lithium citrate
182 buffers of increasing pH and ionic strength was adopted, post-column derivatization with
183 ninhydrin and detection at 440 and 570 nm. Injection volume was 100 μ L, and quantification
184 was performed using 4-level calibration lines for 21 amino acids in the range 0.75-22.5 mg L⁻¹.

185

186 ***Statistical analysis.*** Statistical treatment of data was performed by means of the SPSS Win
187 12.0 program (SPSS Inc., Chicago, IL, USA). Data were submitted to Student's t-test. P<0.05
188 was assumed as significance limit.

189

190 **RESULTS AND DISCUSSION**

191

192 ***Presence of prtS and ORFgadB genes and growth behaviour of strains.*** The presence of *prtS*
193 and *ORFgadB* genes were firstly investigated in 191 *S. thermophilus* strains of different origins.
194 The screening of a spectrum of strains was necessary since cell envelope-associated proteinase
195 is rather exceptional in *S. thermophilus* and GABA-production varies widely.^{1,22} In fact, a total
196 of 72 strains (38%) harboured the *PrtS* gene but only 20 (10%) were *ORFgadB* positive (Table
197 1, Fig. 1). These last were considered as the putative producers of GAD and chosen for this
198 study.

199 In view of characterizing their proteolytic activity, strains were grown in MPM where proteins
200 are present in their native status, i.e. caseins are aggregated into large micelles and whey
201 proteins are soluble globular monomers. On the contrary, in reconstituted skim milk, usually
202 adopted as growth medium, proteins are extensively glycosylated by the Maillard reaction⁴³
203 and the additional sterilization treatment (e.g. 110 °C for 10 min) induces whey protein
204 denaturation and binding to the casein micelle surface⁴⁴, so impairing access to proteases. Of
205 relevance here, the temperature (41 °C) for *S. thermophilus* growth in milk was shown to be
206 suitable for the production of GABA, and the acidic pH due to lactic acid fermentation proved
207 to maximize the GAD activity and specificity.⁴⁵

208 Although the initial concentration of viable cells was comparable among strains (7.01 ± 0.37
209 $\log \text{CFU mL}^{-1}$), important differences in growth and acidifying activity were evidenced (Table
210 2). The commercial starters showed the highest acidification rate and a rapid growth after 6 to
211 24 h, reaching final loads nearly one log higher than wild strains. Vice versa, the TR strains
212 isolated from Trentingrana were characterized by the lowest growth and acidification rates,

213 with final pH values often remaining above 6 (Table 2). *S. thermophilus* strains isolated from
214 raw milk cheeses showed an intermediate behaviour. Only nine out of the 20 studied strains
215 harboured the *prtS* gene (Table 2). Overall, *prtS*⁺ strains showed highest counts and lowest pH
216 values after 24 hours. Previous studies evidenced that high milk-acidifying capacity in *S.*
217 *thermophilus* is associated with high cell wall proteinase activities.^{6, 46}

218

219 ***Proteolytic activity.*** The proteolytic activity of the 20 strains was firstly assessed through the
220 evaluation of changes in the free amino acid (FAA) content (Fig. 2). The initial content of FAA
221 in the uncultured MPM (negative control) (n=4) ranged from 83 to 93 mg L⁻¹, in agreement
222 with the figures recently reported by Pellegrino et al.⁴¹ for raw milk, and remained constant
223 throughout the 24-hour observation period (not shown). On the contrary, a decrease of FAA
224 content was observed for most of the strains during the initial 6 h of incubation, with a
225 subsequent increase (Fig. 2). This finding is consistent with the fact that *S. thermophilus*
226 growth in milk is diauxic and that the first growth phase relies on the utilization of free amino
227 acids and peptides while PrtS proteinase synthesis in pure culture only begins in the
228 intermediate non-exponential growth phase.⁷ There were, however, a few exceptions. Three
229 *prtS*⁺ strains, namely SC1, VS429 and SE95, proved to release FAA also during the first 6 h,
230 roughly corresponding to the first exponential growth phase, whilst *prtS*⁺ BT232 kept uptaking
231 FAA from MPM over the whole incubation period (Fig. 2). Between 6 and 24 h, the FAA
232 content remained steady or slightly decreased for most of the *prtS*⁻ strains (Fig. 2), whereas
233 VAL40 and VS436 released FAA at a rate comparable to that of *prtS*⁺ strains.

234 With the aim of identifying the preferred protein substrates for the proteolytic activity of
235 different strains, the casein and the pH 4.6-soluble nitrogen fractions in the MPM samples
236 taken after 6 and 24 h were analysed by CZE and HPLC respectively. Three *prtS*⁺ (SE95, SC2
237 and BT232) and three *prtS*⁻ (VS436, VAL40 and TR12) strains were selected for this
238 assessment on the basis of their characteristic behaviour in releasing and uptaking FAA as
239 previously observed (Fig. 2). The small decrease of α s1-casein (2%) and β -casein (5-10%)
240 observed in all of the samples after 24 h of incubation, being comparable to that of the control
241 sample, was attributed to the residual activity of plasmin (data not shown). In fact, although
242 microfiltration allowed to lower plasmin activity in MPM by removing the somatic cells, which
243 carry part of the enzyme activation system,¹³ our incubation temperature was close to the
244 optimum temperature for plasmin activity in milk, i.e. 37 °C.⁴⁷ Our results are not in contrast
245 with those of Miclo et al.⁴⁸ who demonstrated that *prtS*⁺ strains of *S. thermophilus* were able to
246 hydrolyze purified casein fractions individually dissolved in sodium phosphate buffer at pH 7.5.
247 In fact, it is known that, until strong acidification occurs, casein fractions in milk are
248 aggregated into large micelles and thus less susceptible to proteolysis.⁴⁹

249 The main soluble whey proteins, namely a-La and b-Lg, as well as proteose-peptones (PP) and
250 small peptides (SP) were all evaluated from HPLC chromatograms.⁴¹ Values and relative
251 changes of these fractions in MPM at the different sampling times are shown in Table 3.
252 Identifying single peptides and studying their production and subsequent degradation was of
253 limited interest in the context of this study. The negative control proved to be stable throughout
254 the incubation time except for the PP which increased as an expected result of plasmin activity
255 on β -casein. Among the tested strains, none was able to hydrolyze b-Lg and only two (SE95

256 and VAL40) operated a limited hydrolysis of a-La (Table 3). This finding confirmed the strong
257 resistance of native whey proteins to proteolysis,^{41, 50} due to their globular structure stabilized
258 by disulphide bonds and, more relevantly, explained the unavailability of free cysteine. This
259 amino acid is only present in whey proteins and is reported to be essential for growth of some
260 strains of *S. thermophilus* and stimulating for others¹¹. Strain SE95 confirmed to have a strong
261 proteolytic activity which begins quite early, as already observed. In fact, besides the reduction
262 of a-La, the net content of PP was lower than in the control at 6 h and then levelled off,
263 indicating that additional PP formed by plasmin were progressively hydrolyzed to SP and these
264 last, in turn, to FAA. Compared to SE95, strain SC2 showed a lower proteolytic activity in the
265 first step of growth (Table 3), when the consumption of FAA was fast (Fig. 2), and thereafter a
266 more extensive degradation of SP to which corresponded a high rate in FAA accumulation. In
267 contrast, the lack of degradation of SP and the progressive consumption of FAA observed for
268 *prtS*⁺ BT232 strain concurred to evidence that this strain expressed a *PrtS*⁻ phenotype,
269 highlighting the non-expression of *prtS* gene. Interestingly, strains VS436 and VAL40,
270 although *prtS*⁻, were able to hydrolyze PP (Table 3). These two strains initially consumed part
271 of the content of FAA available in milk but successively both were able to increase it, albeit to
272 a limited extent (Fig. 2). This finding might be explained by the presence of a broad range of
273 extracellular peptidases on the cell wall of *prtS*⁻ strains, as recently reported by Hafeez et al.⁵¹
274 The inability of TR12 to hydrolyze whey proteins and peptides were evident from data in Table
275 3, confirming that growth of this strain in MPM mostly relied on available FAA as a source of
276 nitrogen. The low proteolytic capacity of TR strains of this study, all isolated from natural
277 whey starters, i.e. mixed cultures containing *Lactobacillus* spp., is consistent with the results

278 of Courtin et al.⁵² showing that PrtB of *L. bulgaricus* largely contributes to the optimal growth
279 of *S. thermophilus*.

280

281 **Free amino acid profile.** Changes in average molar concentration of individual FAA are shown
282 in Table 4 whereas the whole data set is presented in S1. Only in few cases, differences
283 between *prtS*⁺ and *prtS*⁻ strains were statistically significant after 6 h of incubation, since
284 standard deviation was very high. Literature on amino acid requirements of *S. thermophilus* is
285 scarce and sometimes contradictory because of the different conditions of the assessment.^{4, 6, 11}
286 Nevertheless, there is wide agreement on the fact that type and number of amino acids essential
287 for growth of *S. thermophilus* are strain-dependent.⁶ Although PrtS allows *S. thermophilus*
288 better to grow alone in milk, the efficiency of transport systems as well as the intracellular
289 peptidases and *de novo* synthesis of amino acids are also responsible for such a high
290 variability.⁷ This fact can be argued from the evidence that, while several FAA (glutamate,
291 aspartate, methionine, proline) evolved similarly between *prtS*⁺ and *prtS*⁻ strains, although with
292 different rates, others (lysine, leucine, tyrosine, glycine) showed an opposite behaviour.
293 Interestingly, proline content increased 6 times in MPM incubated with *prtS*⁺ strains and
294 represented up to 20-28% of total FAA after 24 h incubation. This relevant increase may be
295 related to the presence of an extracellular X-prolyl dipeptidyl aminopeptidase (PepXP)
296 observed in *S. thermophilus*.^{9, 10, 48} Interestingly, Derzelle et al.⁵³ reported that PepXP is
297 specifically upregulated in *S. thermophilus* when grown in milk with respect to a synthetic
298 medium (M17). Glycine was the only amino acid to reach a significantly higher concentration
299 in *prtS*⁻ than in *prtS*⁺ strains (Table 4). Concerning the behaviour of the branched chain amino

300 acids, it is noteworthy that isoleucine did not accumulate and showed the same final
301 concentration in both groups, whilst for leucine and valine the final concentrations were
302 remarkably higher in *prtS*⁺ strains. This different behaviour is consistent with the presence of
303 two different biosynthetic pathways in *S. thermophilus*, one leading to formation of isoleucine
304 and the other to leucine and valine.⁵⁴ It should be mentioned that, consistently with their lowest
305 proteolytic activity among *prtS*⁻ strains, the six TR strains were unable to release methionine
306 (not shown). For most FAA, the behaviour here described for *prtS*⁺ strains agrees with that
307 found by Stulova et al.,⁵⁵ who however investigated a single strain grown in reconstituted skim
308 milk. Major differences with our data regarded the content of aspartate and glutamate that,
309 according to these authors, continuously increased.

310 **GABA production.** Production of GABA was examined in relation to free glutamate and
311 glutamine behaviour because both these amino acids may be involved in the metabolic
312 pathway.⁸ As mentioned above, only five out of the 20 strains harboring the *gadB* gene were
313 capable of producing GABA in MPM (Fig. 3). This observation suggests that a silent GAD
314 gene might be present in the non-producing strains as a consequence of a frameshift mutation,
315 resulting in inactive forms of GAD, as also evidenced by Somkuti et al..²⁰ All of the GABA-
316 producing strains were *prtS*⁺, and the highest levels were found for the strong proteolytic
317 VS429, SE95 and SC1 strains. Interestingly, while comparable residual quantities of glutamate
318 were found in MPM samples incubated with GABA-producing strains, the levels of glutamine
319 varied greatly. In particular, free glutamine increased during incubation in the high proteolytic
320 strains, as expected, while the trend was opposite in the less proteolytic ones (SC2 and BT122)
321 and was comparable to that of non-producing strains, regardless whether *prtS*⁺ or *prtS*⁻ (not

322 shown). Remarkably, no free glutamine was detected in TR strains, although synthesis of this
323 amino acid was reported by Monnet et al.¹² to be essential for growth of *S. thermophilus* in milk.
324 Variable amounts of glutamate were found in MPM incubated with no-GABA producing
325 strains (Fig. 3). These strains likely consumed glutamate to a different extent for synthesizing
326 other amino acids they need for growth through the glutamate dehydrogenase/ α -ketoglutarate
327 pathway⁶. According to Stulova et al.,⁵⁵ glutamate could supply ammonia for up to 25% of the
328 amino acids in the biomass. Among *prtS*⁻ strains, VAL40 and VS436 actually produced a very
329 limited amount of GABA. Both these strains evidenced a peculiar proteolytic activity towards
330 PP (Table 3) which are rich in glutamate³⁰. An early production of GABA was observed for
331 strains BT122 and VS429, while for strains SC1, SC2 and SE95 the production initiated at a
332 later stage (Fig. 4). This different behaviour might be related to the different acidification rate
333 of the strains, as can be argued from the pH values recorded at 6 h (Table 2). In fact, BT122
334 and VS429 reached the lowest pH among wild strains.

335 In parallel incubation trials, MPM was supplemented with 1 mmol L⁻¹ glutamate. All *prtS*⁺ and
336 a selection of *prtS*⁻ strains were tested. As shown in Fig. 5, almost all the available glutamate
337 was converted into GABA by the five producing strains, although the relative differences in the
338 yield changed for some of them. In particular, for SC1 the yield was close to that of VS429,
339 whereas in not supplemented MPM it was a half (Fig. 3). For both these strains the amount of
340 glutamine increased with the addition of glutamate. Previous studies^{45, 56} evidenced the amount
341 of produced GABA to be strictly dependent on glutamate availability, although experimental
342 conditions were not always comparable to ours. In order to evaluate GABA production by
343 *Lactococcus lactis* subsp. *lactis* in milk, Gardner-Fortier et al.²¹ added 10 mmol L⁻¹ of

344 glutamate (10 times more than in this study) and, after 5 days of incubation, found amounts of
345 GABA (50-80 mg L⁻¹) close to those here obtained (83-108 mg L⁻¹) (Figure 5). Total
346 conversion of GLU into GABA occurred reaching levels found to promote significant decrease
347 of blood pressure,^{31, 57} and it can rationally be expected that higher GABA conversion yield
348 could be obtained in presence of higher GLU content. Wu et al.⁵⁸ recently observed that
349 selected strains of *L. brevis* increased production of GABA when co-cultured with *S.*
350 *thermophilus*. GABA production was not induced in the non-producing strains, with the
351 exception of BT232 that, however, converted into GABA less than 5% of the added glutamate.
352 Consumption of glutamate by strains unable to perform decarboxylation was confirmed to be
353 strain-dependent (Fig. 5). VAL40 used approximately 35% of the whole amount of available
354 glutamate without increasing the production of GABA.

355 As already mentioned, decarboxylation of glutamate to GABA represents an acid resistance
356 mechanism for several bacterial species to survive in the acidic environment. Similarly, an
357 arginine-mediated pathway, involving the arginine deiminase (ADI) system, is adopted by a
358 variety of lactic acid bacteria^{42,59,60} as an alternative acid resistance system. Arginine is
359 stoichiometrically converted to citrulline and this last to ornithine producing two mol of
360 ammonia per mol of degraded arginine. Although, to our knowledge, this mechanism has not
361 been described for *S. thermophilus* in milk, we evidenced that strains unable to produce GABA
362 generally operated a more extensive degradation of arginine (Fig. 6). In fact, in MPM samples
363 incubated with these strains, with the exception of SC3 and SC5, at least half of free arginine
364 was converted into citrulline and ornithine, irrespective of the absolute amounts. Furthermore,

365 this pathway gave a bioenergetic benefit to these strains because of the ATP generated by
366 degradation of arginine.

367 This study provides new evidence on proteolytic pathways of *S. thermophilus* in milk. A range
368 of *S. thermophilus* strains, all sharing the *gadB* positive character, was examined by evaluating
369 the ability to hydrolyze individual protein fractions and to accumulate or use single FAA in a
370 minimally heat-treated milk. Interesting systematic differences were observed between PrtS⁺
371 and PrtS⁻ strains, although several strains displayed an intermediate behavior. A strain-
372 dependent adoption of specific proteolytic pathways has been found in *S. thermophilus* grown
373 in minimally treated milk, where proteins are present in the native form and overall availability
374 of FAA is restricted. Some wild strains from raw milk cheeses were almost unable to release
375 FAA, indicating their habit of growing in mixed population. Our data showed the capacity of
376 synthesizing GABA to be infrequent in *S. thermophilus* and the yield to be dependent on the
377 available amount of glutamate. Since *S. thermophilus* is largely used in a variety of fermented
378 foods, strain screening based on this trait may be of interest in the manufacturing of functional
379 foods. The five strains able to fully convert the glutamate into GABA could represent microbial
380 factories for industrial GABA production. Notably, new evidence was given that strains unable
381 to produce GABA may adopt the degradation of arginine into citrulline and ornithine as an
382 alternative pathway helping to raise intracellular pH and as a source of energy. Our findings
383 demonstrated that the characterization of single strains with respect to their actual proteolytic
384 activity and ability of using peptides and specific FAA in milk provides strategic information to
385 identify those having the most suitable behaviour for manufacturing of targeted fermented
386 dairy products.

387

388

389 **ACKNOWLEDGMENTS**

390 We thank Dr Fabio Dal Bello from Sacco S.r.l. (Cadorago, CO, Italy) for providing SC strains
391 and for critical discussion of the results.
