Abstract: Background: *Vitis vinifera* L. (grape seed extract) is a natural source of proanthocyanidins with antioxidant and free radical-scavenging activities.

Hypothesis: Grape seed extract supplementation may prevent vascular endothelium impairment associated with diabetes mellitus in rat pulmonary artery.

Study design: We evaluated endothelial function of rat pulmonary artery ex-vivo at the intermediate stage (4 weeks) of streptozotocin (STZ)-induced diabetes mellitus. We also evaluated the protective effect of grape seed extract administered daily, beginning the day after diabetes induction, or 15 days after diabetes induction, until the day of sacrifice. In addition, we compared the effect of grape seed extract supplementation with that of vitamin C.

Methods: Rats were made diabetic with streptozotocin (STZ, 65 mg/kg i.v.). Thirty days later rats were sacrificed and pulmonary vessels reactivity and endothelial function compared to that of age-matched healthy animals.

Results: Concentration-response curves to ACh, NE, sodium nitroprusside (NO donor), but not to histamine and iloprost (prostacyclin analog), were significantly altered 4 weeks after STZ-injection. Antioxidant supplementation (3 mg/kg/day) with either vitamin C or grape seed extract, starting the day after diabetes induction, significantly improved vasodilation to ACh and SNP. Norepinephrine-induced contractions were preserved by grape seed extract, but not vitamin C supplementation. Conversely, vitamin C but not grape seed extract showed beneficial effects contrasting the loss of body weight in diabetic animals. Abnormal vascular function was not reversed when antioxidant supplementations were postponed 15 days after the induction of diabetes.

Conclusions: This study provides scientific support for the therapeutic potential of an antioxidant therapy in endothelial impairment associated with diabetes. A daily supplementation of grape seed proanthocyanidins and/or vitamin C given at the earlier stage of disease may have a

complementary role in the pharmacological therapy of diabetes and pulmonary vascular dysfunction.

1 **Abstract**

2 Background: *Vitis vinifera L.* (grape seed extract) is a natural source of proanthocyanidins
3 with antioxidant and free radical-scavenging activities.

4 Hypothesis: Grape seed extract supplementation may prevent vascular endothelium
5 impairment associated with diabetes mellitus in rat pulmonary artery.

6 Study design: We evaluated endothelial function of rat pulmonary artery *ex-vivo* at the
7 intermediate stage (4 weeks) of streptozotocin (STZ)-induced diabetes mellitus. We also
8 evaluated the protective effect of grape seed extract administered daily, beginning the day
9 after diabetes induction, or 15 days after diabetes induction, until the day of sacrifice. In
10 addition, we compared the effect of grape seed extract supplementation with that of vitamin
11 C.

12 Methods: Rats were made diabetic with streptozotocin (STZ, 65 mg/kg i.v.). Thirty days
13 later rats were sacrificed and pulmonary vessels reactivity and endothelial function
14 compared to that of age-matched healthy animals.

15 Results: Concentration-response curves to ACh, NE, sodium nitroprusside (NO donor), but
16 not to histamine and iloprost (prostacyclin analog), were significantly altered 4 weeks after
17 STZ-injection. Antioxidant supplementation (3 mg/kg/day) with either vitamin C or grape
18 seed extract, starting the day after diabetes induction, significantly improved vasodilation to
19 ACh and SNP. Norepinephrine-induced contractions were preserved by grape seed extract,
20 but not vitamin C supplementation. Conversely, vitamin C but not grape seed extract
21 showed beneficial effects contrasting the loss of body weight in diabetic animals. Abnormal
22 vascular function was not reversed when antioxidant supplementations were postponed 15
23 days after the induction of diabetes.

1 Conclusions: This study provides scientific support for the therapeutic potential of an
2 antioxidant therapy in endothelial impairment associated with diabetes. A daily
3 supplementation of grape seed proanthocyanidins and/or vitamin C given at the earlier
4 stage of disease may have a complementary role in the pharmacological therapy of diabetes
5 and pulmonary vascular dysfunction.

11 **Abbreviations:** GSE, grape seed extract; His, histamine; L-NAME, nitro-L-arginine-
12 methyl ester; NADPH-oxidase, nicotinamide adenine dinucleotide phosphate-oxidase; NE,
13 norepinephrine; NO, nitric oxide; ROS, reactive oxygen species; SNP, sodium
14 nitroprusside; STZ, streptozotocin.

15

16 **Introduction**

17 The endothelium is a dynamic organ, which regulate vascular tone in response to various
18 hormones and neurotransmitters via several vasoactive mediators and primarily nitric oxide
19 (NO) (Sandoo *et al.*, 2010). Hyperglycaemia and an excess of reactive oxygen species
20 (ROS) adversely affect endothelial function (Tousoulis *et al.*, 2013) and are typical
21 consequences of diabetes mellitus. As a result of endothelial impairment and a reduction of
22 endothelial nitric oxide (eNOS) activity, an increased risk of microangiopathy, peripheral
23 artery diseases (McGill *et al.*, 2008), cardiovascular and also respiratory dysfunctions
24 (Rosenecker *et al.*, 2001) are observed in diabetic patients.

1 The relationship of diabetes with pulmonary vascular disease had been almost disregarded
2 until recent epidemiological and *in vitro* studies revealed that ROS and diabetes are risk
3 factors for pulmonary arterial hypertension (Moral-Sanz *et al.*, 2014; Wong, 2013). Even
4 with the maintenance of near-normal glycaemic values, endothelial dysfunction persists in
5 diabetic patients (Ceriello *et al.*, 2007; Dogra *et al.*, 2001). Although balancing
6 carbohydrate and insulin is the most important task in managing diabetes, epidemiological
7 studies suggest that regular consumption of foods rich in polyphenols and beverages rich in
8 vitamin C plays a vital role for **maintaining** weight, **and keeping** blood low-saturated fats
9 and blood pressure under control, thus reducing the risk of cardiovascular complications
10 (Mccall *et al.*, 2009).

11 Evidence suggests an important role for dietary factors in modulating endothelial function,
12 in particular antioxidant compounds (Bondonno *et al.*, 2012), and it has been observed that
13 poor vitamin C blood levels correlate with impaired endothelial function in type-1 diabetic
14 patients (Odermarsky *et al.*, 2009).

15 Flavonoids and proanthocyanidins are the most common antioxidant compounds present in
16 many fruits, vegetables and seeds of Mediterranean diet, and several studies have suggested
17 that grape seed extract confers vascular protection due to the direct effects of its **polyphenol**
18 content on endothelial cells (Blanch *et al.*, 2015; Cui *et al.*, 2012; Edirisinghe *et al.*, 2008;
19 Feng *et al.*, 2010).

20 A short-term (30 days) **administration of** streptozotocin, **used to induce** pancreatic injury, **is**
21 **also used to represent** type-1 diabetes, **since** alterations such as cardiovascular dysfunction
22 **are common problems associated with diabetes**. Even so, the progression of the disease
23 becomes evident in tissues and organs already after 15 days from diabetes induction (**James**
24 ***et al.*, 1994; Toleikis and Godin, 1995; Tong and Cheng, 2002**). This study therefore aimed

1 to evaluate the protective effect of 15 and 30 days of a grape seed extract supplementation,
2 on pulmonary artery responsiveness in diabetic rats treated for 4 weeks with streptozotocin.
3 Results have been compared with those of vitamin C, a physiological non-enzymatic
4 antioxidant present in the blood, which was shown to improve endothelium-dependent
5 responses under certain conditions such as diabetes mellitus or hypertension (Ting, 1996;
6 Taddei et al., 1998).

7

8 **Materials and methods**

9 *Animals and Surgical Procedure:*

10 A total number of 64 male Sprague-Dawley rats weighing 200 - 225 g were used. Animals
11 were assigned at random into four groups of 8 animals each, as follows: (a) age-matched
12 healthy control rats, diabetic rats daily treated with: (b) vehicle, (c) ascorbic acid and (d)
13 grape seed extract, starting on the sixteenth day after the STZ injection and continued daily
14 for the last 15 days. A separate set of animals were also divided into the same groups as
15 mentioned above, but treatment started the same day of diabetes induction.

16 After a period of not less than 5 days following arrival, rats were made diabetic by a single
17 injection of STZ (60 mg/kg i.v.). Control animals received an equivalent volume of STZ
18 vehicle (0.1 N citrate buffer, pH 4.5). Same day as diabetes induction, 5% glucose was
19 added to the drinking water to prevent hypoglycaemia.

20 Diabetes induction was considered successful when the blood glucose level was equal or
21 higher than 300 mg/dl (Glucotrend, Roche Diagnostic, Monza, Italy). This was generally
22 the case within 48-72 hours after STZ injection, as described before (Pinna *et al.*, 2001).
23 All *in vitro* experiments were carried out the day after last treatment.

1 Ascorbic acid and grape seed extract were dissolved in distilled water every day at a
2 concentration of 3 mg/kg/day as tested in a study by Pinna *et al.* (2001), and both
3 administered by oral gavage.

4 *Characteristics of plant material:*

5 The standardized extract from *Vitis vinifera* L. grape seed (a brownish-orange powder) was
6 a kind gift of Indena S.p.A. (Milan, Italy). The starting herbal material has been identified
7 against a crude drug standard and authoritative literature source by a botanical analyst. The
8 seeds harvested in September-October from cultivated plants in the European Community
9 were artificially dried and ground to a fine powder. The extraction solvent was water at the
10 temperature of 70-90 °C. Drug extract ratio (DER) was 10-15:1 (native extract). The water
11 content in the dry extract was 5% or less. No excipient or other components
12 (antioxidants/preservatives) for adjustment were added to the powder. The extract was
13 standardized to provide $\geq 95.0\%$ (accuracy: $\pm 15\%$) of proanthocyanidins by Folin-Ciocalteu
14 method coupled to UV-visible spectrophotometry, which is a classical method used to
15 determine polyphenol content in plant extracts, as described in the European
16 Pharmacopoeia (Council of Europe, 2007).

17 The analysis specifically revealed a relatively low amount (8.6%) (by HPLC) of flavane
18 monomers (catechin, epicatechin and epicatechin gallate), and about 91% oligomeric
19 proanthocyanidins (OPC) of which 9% (by HPLC) were of the dimeric type. Pentamers,
20 hexamers, heptamers and their gallates accounted for less than 5% (w/w). HPLC
21 quantitative analysis was carried out as described by Gabetta *et al.* (2000). Briefly,
22 monomers and dimers were quantitated by HPLC-UV at room temp on a SupelcoSil LC-18
23 column (250×4.6 mm i.d.), particle size 5 μm (Supelco). The solvent system was a linear
24 gradient using MeCN (solvent A) and 0.3% phosphoric acid (solvent B) from 10% A to

1 20% A in 45 min, then to 60% A in 20 min. The flow-rate was 0.7 ml/min, the UV detector
2 was set at 278 nm and the injection volume was 10 μ l.

3 All experimental procedures involving animals and their care were conducted in
4 accordance with institutional guidelines that are in compliance with national (Decreto
5 Legislativo N° 26, March 4, 2014, G.U. N° 61 March 14, 2014) and international laws and
6 policies (86/609 EEC Council Directive 2010/63, September 22, 2010: Guide for the Care
7 and Use of Laboratory Animals, United States National Research Council, 2011).

8 *Ex-vivo experiments on isolated pulmonary artery rings:*

9 Animals were sacrificed with an *i.p.* injection of thiopental sodium (20 mg/kg). Lung and
10 heart were rapidly excised and larger intrapulmonary artery segments were removed and
11 cleaned of adherent parenchymal tissue. Two pulmonary arterial rings (2 mm) from each
12 lung were mounted under 0.8 g of resting tension, in a 5 ml organ bath and perfused with
13 Krebs solution (118 mM NaCl, 4.7 mM KCl, 1.2 mM KH_2PO_4 , 1.1 mM MgSO_4 , 2.5 mM
14 CaCl_2 , 25 mM NaHCO_3 , 5.5 mM glucose, pH 7.4) at 37 °C, continuously bubbled with
15 95% O_2 and 5% CO_2 . Artery rings were connected to isometric force transducers for
16 tension recording (PowerLab, ADInstruments, UK). Following equilibration for 1 h,
17 preparations were precontracted with a submaximal concentration of norepinephrine (NE,
18 10 μ M) to check the vitality of preparations. Norepinephrine was then removed with
19 several washes with Krebs' solution and rings were allowed to rest a further 30 min, until
20 basal tone was restored. Thereafter, cumulative concentration-response curves to the
21 agonists were performed. In between two cumulative concentration-response curves, tissues
22 were washed several times with Krebs' solution and they were allowed to rest for at least
23 30 min. With the exception of norepinephrine itself, concentration-response curves were
24 done in EC_{60} -norepinephrine-precontracted tissues. The EC_{60} value for norepinephrine used

1 to evoke precontracted tone, was estimated to be 60 nM for pulmonary artery rings from
2 control rats and 150 nM for diabetic rats, in preliminary experiments.

3 A different set of diabetic and healthy pulmonary arterial preparations were used to study
4 the effect of **grape seed extract** itself.

5 Contractile responses to norepinephrine were measured as increase in tone above baseline
6 (mN/mg tissue), whereas relaxant responses were expressed as percentage of relaxation on
7 EC₆₀-norepinephrine precontracted tissues.

8 *Drugs and Chemicals:*

9 Norepinephrine hydrochloride, Nitro-L-arginine methyl ester hydrochloride, acetylcholine,
10 SNP, indomethacin, ascorbic acid and STZ were purchased from Sigma-Aldrich. Iloprost
11 (SHL 401) was purchased from Shering (Berlin, Germany). All compounds were freshly
12 dissolved in distilled H₂O, except Iloprost, which was purchased as a concentrated water
13 solution.

14 *Statistical Analysis:*

15 All data were expressed as mean±S.E.M. of eight experiments and represent unpaired data.
16 Concentration-response curves were fitted and compared by analysis of variance (ANOVA)
17 using GraphPad Prism3.0. If *P* values were less than 0.05 the treatment affected the
18 response over the tested range of concentration (Ludbrook, 1994). Maximal responses and
19 *pD*₂ values (-log EC₅₀) for each agonist were compared by one-way ANOVA followed by
20 Tukey's *post hoc* test using GraphPad InStat.

21

22 **Results**

23 *Serum glucose levels and body weight:*

1 A fivefold increase in glycaemia value was observed in untreated STZ-diabetic rats ($491 \pm$
2 12 mg/dl), compared to control animals (112 ± 9 mg/dl), ($P < 0.001$). After 30 days of
3 treatment with either **grape seed extract** or ascorbic acid, glycaemia in treated diabetic rats
4 was still unchanged compared with untreated diabetic rats (Figure 1).

5 Although there was no difference in body weight prior to diabetes treatment, after 4 weeks
6 of diabetes induction, the body weight of the untreated diabetic group was significantly
7 lower (213 ± 9 g) than that of the healthy group (354 ± 22 g), ($P < 0.001$). Nevertheless, body
8 weight of diabetic rats treated for 30 days with ascorbic acid was significantly higher
9 (266 ± 20 g), ($P < 0.05$) than that of the untreated diabetic rats (Figure 2).

10 *Relaxation to acetylcholine and histamine:*

11 Pulmonary arteries precontracted with (EC_{60})-NE responded to ACh (1 nM – 30 μ M) with
12 concentration-dependent vasodilations. The response to ACh, which are endothelium-
13 dependent and mediated by the release of NO, showed a reduced efficacy in diabetic
14 pulmonary arteries. Concentration-response curves to ACh in **the** control and **in the** diabetic
15 groups were significantly different ($P < 0.005$), (Figure 3).

16 Sensitivity to ACh, expressed as the pD_2 , also appeared reduced in arterial pulmonary rings
17 from diabetic rats (6.64 ± 0.08) compared to that observed in pulmonary artery from healthy
18 animals (6.86 ± 0.09), but the difference was not statistically significant. Maximal
19 vasodilation was significantly reduced in pulmonary artery from diabetic rats ($75.4 \pm 2.5\%$)
20 when compared to that of vessels from healthy animals ($98 \pm 2.6\%$), ($P < 0.001$). Pulmonary
21 preparations from diabetic rats supplemented with either **grape seed extract** or ascorbic acid
22 (3 mg/kg/day) for 30 days, showed a restored response to ACh, and their vasodilatory
23 response to ACh was not different from control tissues. Antioxidant supplementation from
24 day 16 to 30 resulted ineffective.

1 The relaxation induced by histamine was concentration-dependent (0.1–30 μ M), however
2 no significant difference was observed between any of the respective groups (Figure 4).

3 *Relaxation to sodium nitroprusside:*

4 Sodium nitroprusside added cumulatively (0.3 nM – 1 μ M) produced on its own complete
5 relaxation of the NE-constricted pulmonary artery rings. Sensitivity to SNP, expressed as
6 the pD_2 , was significantly higher ($P<0.01$) in pulmonary artery from untreated diabetic rats
7 (7.94 \pm 0.03) than that from healthy animals (7.49 \pm 0.04), and the SNP concentration-
8 response curve in diabetic rings was shifted to the left ($P<0.01$), compared to the curve in
9 the controls (Figure 5). Antioxidant supplementation from day 16 to 30 resulted ineffective
10 and did not modify tissue sensitivity to SNP. The pD_2 values in grape seed extract-
11 (7.97 \pm 0.04) and in vitamin C-treated group (7.99 \pm 0.07) did not differ significantly from
12 that of untreated diabetic group. Antioxidant supplementation from day 1 to 30 restored
13 tissue sensitivity. Significant difference ($P<0.01$) was found between pD_2 values in diabetic
14 rings and those of grape seed extract- (7.57 \pm 0.06) or vitamin C-treated animals
15 (7.35 \pm 0.05).

16 *Relaxation to iloprost:*

17 The stable prostacyclin analogue iloprost, added cumulatively (0.3 nM – 0.3 μ M) to the
18 NE-constricted rings evoked concentration-dependent vasodilations in pulmonary vessel
19 tissues. Tissue sensitivity to iloprost, expressed as the pD_2 were comparable in the diabetic
20 (7.88 \pm 0.33) and in the control group (7.80 \pm 0.14), as well as maximal responses (E_{max})
21 being (46.2 \pm 3.3%) and (44.1 \pm 1.5%) in the diabetic and in the control animals, respectively.
22 Hence, concentration-response curves performed in the untreated diabetic and in the control
23 rings were not significantly different. Ascorbic acid or grape seed extract supplementation
24 for 30 days did not alter iloprost-induced vasodilation in the diabetic group (Figure 6).

1 *Norepinephrine-mediated vascular contraction:*

2 Norepinephrine (1 nM – 10 μ M) induced impaired concentration-related contractions in
3 pulmonary artery rings from untreated diabetic rats, compared to controls (Figure 7).
4 Sensitivity to NE, expressed as the pD_2 was significantly reduced ($P<0.05$) in **the** diabetic
5 (7.15 ± 0.03) compared to control tissues (7.45 ± 0.03). Maximal response was **also**
6 significantly attenuated ($P<0.01$) in pulmonary artery from diabetic rats (0.98 ± 0.07
7 mN/mg), compared to that observed in **the** healthy animals (1.21 ± 0.03 mN/mg) and the two
8 concentration-response curves performed in **the** untreated diabetic tissues and in **the**
9 controls were significantly different ($P<0.001$). **grape seed extract** supplementation
10 administered daily for 30 days protected vascular function from diabetic damage and
11 concentration-response curves performed in **the grape seed extract**-treated and in **the**
12 untreated diabetic tissues were significantly different ($P<0.01$). On the contrary, **grape seed**
13 **extract** for 15 days or vitamin C supplementation for either 15 or 30 days administered to
14 diabetic animals had no effect on NE-induced responses.

15 *Effect of grape seed extract on pulmonary arterial rings:*

16 **Grape seed extract** added cumulatively (0.1 - 30 μ M) produced a slow and sustained
17 relaxation of the NE-constricted pulmonary arterial rings. The relaxation induced by **grape**
18 **seed extract** was concentration-dependent and it was not significantly altered by diabetes
19 (Figure 8). Nitro-L-arginine-methyl ester (L-NAME, 10 μ M) pretreatment significantly
20 inhibited **grape seed extract**-mediated vasodilation ($P < 0.01$). Pretreatment with
21 indomethacin (1 μ M) plus L-NAME (10 μ M) completely blocked vasodilation. On the
22 contrary, ascorbic acid (0.1 - 30 μ M) did not induce on its own any response.

23

24 **Discussion**

1 The present study showed that pulmonary arterial rings from 4-weeks STZ-diabetic rats
2 displayed altered reactivity, resulting in altered vasodilation to ACh, SNP and reduced
3 vasoconstriction to NE. Grape seed extract and vitamin C prevented the observed
4 alterations of vascular responsiveness, when supplemented at the earlier stages of diabetes.
5 An intact vascular endothelium was shown to play an important role in the control of
6 vascular tone (Sandoo *et al.*, 2010). Conversely, endothelial dysfunction was associated to
7 the pathogenesis of a large spectrum of human diseases (Su, 2015; Prieto *et al.*, 2014)
8 including diabetes (Hamilton and Watts, 2013) and vascular impairment (Tousoulis *et al.*,
9 2013). Substantial evidence also indicated that diabetes mellitus impairs eNOS activity as
10 well as enhances ROS production, thus resulting in diminished NO bioavailability (Su,
11 2015), increased NO degradation and peroxynitrite formation (Zou, 2007).

12 Endothelium-dependent vasodilation to ACh was significantly impaired in pulmonary
13 artery from 4-weeks STZ-diabetic rats. Our result was congruent with that of Lopez-Lopez
14 *et al.* (2008) and suggested an altered synthesis or release of NO from vascular
15 endothelium. On the other hand, impaired vascular endothelium and altered vascular
16 reactivity in response to ACh was observed in aortic rings from STZ-diabetic rats after 8-
17 weeks of disease, but not after 2-weeks (Pieper, 1999). Our study showed that either grape
18 seed proanthocyanidins or vitamin C supplementation for 30 days, starting the day of
19 diabetes induction to the day of sacrifice, had a protective effect on pulmonary artery
20 vasodilation to ACh.

21 On the contrary, both supplementations failed to restore vascular function when postponed
22 15 days after diabetes induction.

23 SNP showed increased tissue sensitivity in the untreated-diabetic pulmonary vessels,
24 suggesting the presence of a compensatory mechanism to counteract a reduced endothelial

1 NO synthesis and release. Lopez-Lopez *et al.* (2008) observed unaltered relaxation to SNP
2 in 6-weeks untreated-diabetic and control pulmonary vessels, however, the discrepancy
3 may be related to fluctuating changes during the course of the disease. Our data also
4 indicated that a daily supplementation of vitamin C or grape seed proanthocyanidins
5 administered immediately after diabetes induction preserved vascular response to SNP.
6 Prostanoids such as PGI₂, PGF_{2α} and TXA₂ were also involved in the regulation of vascular
7 function. In particular, PGI₂ played a compensatory role in vasodilation when endothelial
8 NO release was impaired (Beverelli *et al.*, 1997) and its synthesis increased in rat aorta 8
9 weeks after diabetes induction (Csanyi *et al.*, 2007). Our result showed that the stable PGI₂
10 analogue iloprost evoked comparable vasodilations in the control and in the diabetic
11 preparations. However, as in the case of ACh, vascular responses to iloprost might change
12 with the progression of disease.
13 Contractile response to NE decreased significantly in 4-week untreated diabetic rats. On the
14 contrary, Lopez-Lopez *et al.* (2008) found increased contractile responses to phenylephrine
15 in pulmonary arterial rings from 6-week diabetic rats. The discrepancy may be explained by
16 differences in experimental conditions (longer period of diabetes, different adrenergic
17 agonist used) and in particular by the fact that the response to phenylephrine was expressed
18 as % of KCl response, as in this case an overall impaired contractile capacity would go
19 unaccounted.
20 NE-induced contractions in the diabetic and in the control preparations were comparable if
21 rats received a daily supplementation of grape seed proanthocyanidins, but not vitamin C,
22 starting at the earlier stages of diabetes.
23 Several *in vitro* and epidemiological studies suggested an important role of dietary factors
24 with antioxidant properties in preserving endothelial function in a dose dependent manner

1 (Ghosh and Scheepens, 2009; Mccall *et al.*, 2009). While proanthocyanidins received
2 widespread acclaim for their health benefits, several studies indicated limited
3 bioavailability, and no conclusive results **have been** obtained in clinical studies (Blanch *et*
4 *al.*, 2015). These results may not necessarily indicate that polyphenol-rich foods are not
5 useful. Instead, it should be taken into account that the bio-absorption of polyphenols is
6 very low, and, furthermore, they are rapidly metabolised. Maximum proanthocyanidins
7 plasma level in humans **are** about 0.15 μM , 1-3 h after polyphenol-rich foods intake (Ghosh
8 and Scheepens, 2009). This concentration is probably too low to have a direct antioxidant
9 protective effect at **a** vascular level *in vivo*, as suggested by Cohen and Tong (2010), and
10 also to evoke vasodilation *in vitro*. In our experimental conditions, the lower concentration
11 at which grape seed proanthocyanidins evoked vasodilation **was** 1 μM , in agreement with
12 that observed by Lorenz *et al.* (2004) in rat aortic rings. Furthermore, vasodilation **was**
13 partially blocked by L-NAME or indomethacin, suggesting that grape seed
14 proanthocyanidins may activate endothelial NO and prostaglandin synthesis.

15 Our data also showed that grape seed proanthocyanidins extract was as active as vitamin C
16 in restoring ACh and SNP responses, but more active than vitamin C in restoring NE
17 altered contractility, perhaps as a consequence of **the** synergistic effects among
18 proanthocyanidins contained in the grape seed extract, or among their active metabolites.

19 Both antioxidants **resulted** ineffective on glycaemia, but vitamin C supplementation
20 **contrasted** the loss of body weight in diabetic animals.

21 The timing of antioxidant supplementation also **appeared** to be as an important parameter
22 while looking at **vasoprotection**. **In our** experimental conditions, grape seed
23 proanthocyanidins and vitamin C **resulted** active in preventing vascular dysfunction only
24 when administered at the very early stages of diabetes.

1 Not much is known about the mechanisms of action of proanthocyanidins: it was suggested
2 that dietary polyphenols or their metabolites activate, at low concentration, intracellular
3 signalling pathways leading to vascular protection, rather than having a direct antioxidant
4 effect on vascular endothelium. Alternatively, they may interfere or inhibit pro-oxidant
5 enzymatic processes (Ghosh and Scheepens, 2009), and also synergistic effects among
6 polyphenols present in the food or among their active metabolites might increase their
7 efficacy.

8 Vascular response of pulmonary arteries was altered in the 4-week diabetic rats and grape
9 seeds proanthocyanidins and vitamin C supplementations were useful to preserve
10 endothelial function. Natural antioxidant intake is essential for humans, but dietary vitamin
11 C or the intake of other antioxidant natural compounds may be sub-optimal in oxidant
12 stress exposed, diabetic patients. Although the mechanism by which polyphenols protect
13 endothelial function is still not clear, a daily supplementation of both grape seed
14 proanthocyanidins and vitamin C seems to be a good strategy to prevent or delay diabetes-
15 associated endothelial dysfunction, along with the conventional pharmacological approach.

16

17 **Acknowledgements**

18 We are grateful to Indena S.p.A. for generously providing a free sample of grape seed
19 extract. The authors thank Dr. Manuela Magnani for the assistance in manuscript
20 preparation.

21

22 **Conflict of Interest**

23 Angelo Sala and Christian Pinna have no conflicts of interest associated with this
24 publication. Paolo Morazzoni is an employee of Indena S.p.A., a pharmaceutical company

1 that produces and commercializes the standardized grape seed extract that was used for this
2 research study. This research was completely funded by institutional funds from the
3 Department of Pharmacological and Biomolecular Sciences, University of Milan.

1 **Figure Legends**

2 **Figure 1.** Glycaemia (mg/dl) in control, untreated diabetic, grape seed extract- (GSE) and
3 vitamin C-treated for 30 days. * $P<0.001$: control vs. diabetic.

4 **Figure 2.** Body weight (g) in control, untreated diabetic, grape seed extract- (GSE) and
5 vitamin C-treated for 30 days. * $P<0.001$: control vs. diabetic; ⁺ $P<0.05$: vitamin C vs.
6 diabetic.

7 **Figure 3.** Cumulative concentration-response curves for acetylcholine in pulmonary arterial
8 rings from control, untreated diabetic, grape seed extract- (GSE) and vitamin C-treated for
9 15 days (starting on day 16 after diabetes induction) and for 30 days. Data represent the
10 mean % of vasodilation of NE-precontracted rings \pm S.E.M. (n=8 in each group). Statistical
11 significance for curves: * $P<0.001$: control vs diabetic; ⁺ $P<0.01$: vitamin C (30 days) vs.
12 diabetic; and GSE (30 days) vs. diabetic.

13 **Figure 4.** Cumulative concentration-response curves for histamine in pulmonary arterial
14 rings from control, diabetic untreated, grape seed extract- (GSE) and vitamin C-treated for
15 30 days. Data represent the mean % of vasodilation of NE-precontracted rings \pm S.E.M. (n=8
16 in each group).

17 **Figure 5.** Cumulative concentration–response curves for SNP in pulmonary arterial rings
18 from control, diabetic untreated, grape seed extract- (GSE) and vitamin C-treated for 15
19 days (starting on day 16 after diabetes induction) and for 30 days. Data represent the mean
20 % of vasodilation of NE-precontracted rings \pm S.E.M. (n=8 in each group). Statistical
21 significance for curves: * $P<0.01$: control vs diabetic; vitamin C (30 days) vs. diabetic; GSE
22 (30 days) vs. diabetic.

1 **Figure 6.** Cumulative concentration–response curves for iloprost in pulmonary arterial
2 rings from control, diabetic untreated, grape seed extract- (GSE) and vitamin C-treated for
3 30 days. Data represent the mean % of vasodilation of NE-precontracted rings±S.E.M. (n=8
4 in each group).

5 **Figure 7.** Cumulative concentration–response curves for norepinephrine in pulmonary
6 arterial rings from control, diabetic untreated, grape seed extract- (GSE) and vitamin C-
7 treated for 15 days (starting on day 16 after diabetes induction) and for 30 days. Contractile
8 tension is expressed as mN/mg weight tissue, and data are shown as the means±S.E.M.
9 (n=8 in each group). Statistical significance for curves: * $P<0.001$: control vs untreated
10 diabetic; ⁺ $P<0.01$: GSE (30 days) vs. diabetic.

11

12 **Figure 8.** Cumulative concentration–response curves to grape seed extract (GSE) in
13 pulmonary arterial rings from control, untreated diabetic, control+L-NAME, control+L-
14 NAME+indomethacin. Data represent the mean % of vasodilation of NE-precontracted
15 rings±S.E.M. (n=8 in each group). Statistical significance for curves: * $P<0.01$: control vs
16 control+L-NAME. Lower panel: an original tracing showing GSE-induced relaxation in
17 control tissue.
